From the ethical point of view, the motivations which encourage the companies to get involved in the development and innovation in green IS are the problems of our planet reflected in *global warming, scarce non-renewable resources and pollution.* Nevertheless, in reality, in most situations, they are constrained by *legal regulations*. According to Porter's conclusion, *the regulations which aim getting results and not processes will force the companies to redesign their technology, so that they could increase the efficiency of their activity by cutting costs and increasing the product quality and produce less polluting goods* (Porter, 1991 in Ashford, Hall, 2011). Being open to the legal changes regarding the environment protection as well as anticipating them might offer an advantage of the *temporary monopolies* to the companies and this is similar to any technological innovation, in the ICT field even more, being considered extremely dynamic.

THE CHANGES REQUESTED BY GREEN IS

The motivations which determine the companies to adopt changes in IS are varied. They can be internal as well as external and they are closely related to the objectives and priorities of the organization. Complying IS with the organizational objectives and strategies have been an important concern of the management teams during the last decades, once the important role they play has been identified. On the other hand, any possible failure in this process might lead to the loss of certain opportunities, wasting resources and not meeting the proposed goals (Bush et al., 2009).

In case of most organizations the objectives are of a financial side or are related to the finances. Green IS often requires partial or total replacement of the infrastructure, which means making a significant investment while the profit will be obtained on the long term: green practices can affect system requirements related to hardware, software, and business processes (Beal, 2010). The characteristics which

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

should be included in IS in order to become green can be identified starting from the IS components mentioned by Löser (2015): IT (physical servers, personal and office computers and network devices), shared services (database or storage), business applications (ERP systems), IT human resources (skill and knowledge) and managerial capabilities for organizational process and business transformation related to IS. The first component involves mainly the technical part and it actually represents green IT (Figure 1).

In what follows, starting from the agile life-cycle model, considered the most efficient nowadays, we present the way in which the green concept might be integrated in all stages of the life-cycle of the IS. The model we mention has four main stages (Figure 2)

The interest in green IS might appear from the *project selection and approval stage*. In this stage, a *team of managers, developers and clients agree on the goals, objectives and requirements of the product, they evaluate the alternatives and estimate the risks*. Introducing a new IS, replacing the current one or updating it can have the issue of the influence on the environment as the starting point. Such a decision can be made either by introducing some new regulations or by adopting a protection strategy for the environment or even both. The most visible influences on the environment, from the point of view of the end user, are CO_2 emissions, in direct proportion to the consumption of energy and also the waste generated at the end of the product life. The negative influences are not always visible. For example, a significant quantity from the resources used in the production process (energy, material and chemical substances) will not appear in the final product. Sarkis et al. (2013) considers that an average desktop computer and monitor requires ten times its weight in fossil fuels, water and chemicals as material and

Figure 1. Green IS components

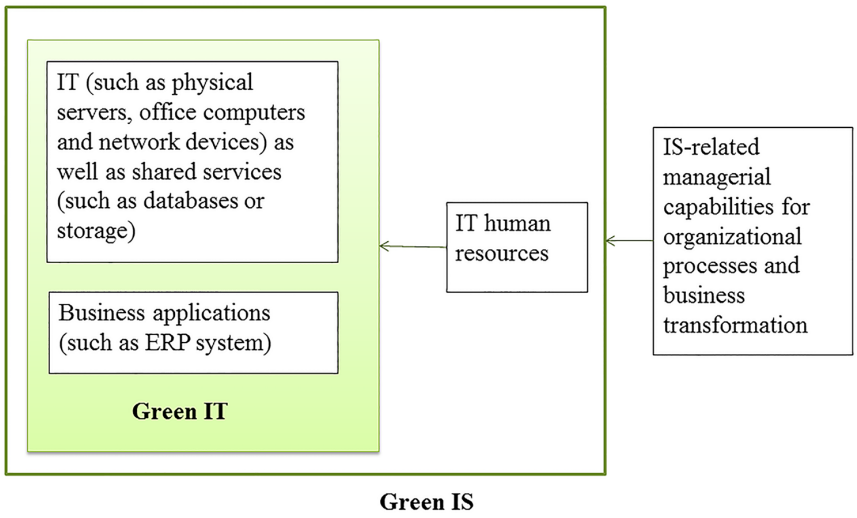

Figure 2. Agile development life-cycle

resources inputs. In case the environment considerations are different than the approach, the protection principles could be integrated into the requirements of the new system. In this stage there is established the purpose of the new system, there are estimated the necessary resources, there are made feasibility studies and there are described the expected benefits. Regardless of the vastness of the system which will be implemented and of the changes it might bring, the objectives of the new system should be in agreement with the organizational goals. The concern for the environment during the selection and approval stage can be clearly seen in the following:

- Analysis of the opinions and directions adopted by partners and the business environment generally speaking, as regards the world trends on ecology but also the trends specific to the field in which the organization operates.
- Clear definition of the organizational goals considering the environment and the strategies that should be adopted in order to accomplish them.
- Formulation of a set of environmental requirements to be included in the non-functional requirements of the new system.
- Analysis of the regulations on the environment in force in the country in which the company activates or, if it is the case, international regulations for the multinational companies. It would also prove useful to make an analysis of the trends on the long run in this field considering there are a larger and larger number of constraints regarding the use of natural resources, pollution and waste.
- Elaborate a viable proposal for green IS which could highlight the financial benefits as well, not only those specific to the environment protection. The analysis of the cost-benefit proportion should be based on detailed measurements regarding the influence on the environment. From the financial point of view, the main advantage is currently given by saving energy.

During this stage there are also made the feasibility studies. There are analyzed the following types of feasibility: economic, operational, technical, schedule and legal. There is made a list of potential criteria and risks which should be considered when making a decision regarding the continuity of the project depending on the obtained results expressed in key milestones. In the context of an increased importance awarded to the environment, there could be introduced a new analysis of *environmental feasibility* as a distinct component. It will undertake components from other types of studies in order to develop them, for example, the influence of technologies used nowadays or those which are necessary to implement a new system on the environment, identify the most environmental-friendly equipment, the volume of waste as a consequence of replacing the current equipment with a new one required by the functioning of the new system, organize the network so as to generate minimum negative effects, reducing the costs by less energy consumption.

The feasibility study on the environment will bring new elements, such as the analysis of a potential development of *green and sustainable software*. This concept was defined by Naumann et al. (2011) as *software with minimum negative on the environment and on the society effects in all stages of cycle-life (design, development and usage) or software with positive effects on sustainable development*. The above-mentioned authors consider that the direct impact refers to the consumption of resources and energy during the design and production and then use of the software. The indirect impact refers to the effects from the use of the applications in order to accomplish the processes within the organizations and to the systematic effects on the environment on the long run.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In case the protection of the environment plays a leading role in the development of the new system, the *environmental feasibility* should clearly show the consequences on the environment as well as the benefits the project implementation might bring. This analysis will be continued during the design and development of the system in order to estimate the consumption of non-renewable resources and the level of pollution entailed by the new system. Environmental feasibility has to answer to the following questions (Lopez-Lopez, 2011):

- **Carbon Footprint:** How much CO_2 a software development, management or maintenance phase will emit?
- **Energy:** How much energy is consumed in the development phase?
- **Travel:** How much traveling time is required in the development phase?
- **Waste:** How much resources are consumed in activities that create no visible value to software end users?

Similar to the other types of feasibility, the one specific to the environment will bring the following benefits to the project: it strengthens the general frame as well as the motivation behind accomplishing the proposed system, it contributes to the increase of the success chances due to the detailed analysis of the elements which influence the success of each project, it allows the identification of the business alternatives, it helps in making a decision when choosing one particular project out of several proposals, it offers a detailed documentation on the situation of the company, according to each feasibility category. It will also allow the identification of the internal and external restrictions in the accomplishment of the project, as well as an objective estimation of the success chances.

During the second stage of *project initiation,* there is established the team which will take part in it and contribute to its accomplishment, there are identified the available funds and financial sources, there is designed the initial architecture of the system, there is configured the environment in which the project will be developed, there are purchased the necessary tools and there is estimated a life span of the project based on the abilities displayed by the team, the demands and the initial architecture. The issue of the environment protection could be introduced in this stage, as part of the activity of purchase of the necessary equipment and establish the initial architecture of the system. It can shape in the following:

- Correct evaluation of the equipment and applications used in the company as regards the effects on the environment, estimate the need to replace them or a re-design of the current processes would be enough, hence energy could be saved, CO_2 emissions reduced without increasing the volume of waste. Another important aspect, in this case, is the evaluation of the consequences of the changes required by green IS and to what extent they comply with the organizational goals and could be included in the adopted strategies regarding the environment.
- Identify the changes imposed by the purchase, use and discharge of the current IT resources, including establishing the criteria which should be met by the equipment which is planned to be bought and also be eco-friendly. Very useful in this situation is the eco-labeling of the IT products introduced by the International Organization for Standardization in 1992, at the United Nations Conference on Environment and Development, at Rio de Janeiro, shaped in the standards from the ISO 14000 family.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The third stage, *construction iterations*, actually designates the accomplishment of the project in successive stages. Each of them includes the planning, construction as well as adaptation to the changes required by the interested parties. The efficient communication is essential in the agile model since the final success of the project depends on it. At each iteration the users can formulate requirements on the influence they expect the future system to have on the environment and the developers should consider and include in the project. They can also demand an estimation of the impact on the environment made by specialized companies or require that the created system should comply with the regulations on the environment adopted by the organization.

During this stage, the green and sustainable software concept that was presented earlier can be applied. The problems referring to the environment, presented by Naumann et al. (2011) are specific to fixing errors (bugs) and, in the Greensoft Model, are referring to electrical energy and other resources used by: employees' workstation, IT infrastructure (as networking devices, servers and storages), heating and air conditioning, office lighting, transportation in case of business trip for meetings with customers and even the employees' daily way to work. Also, they propose three categories of sustainability criteria and metrics for software products: *Common Quality Criteria and Metrics, Directly Related Criteria and Metrics, and Indirectly Criteria and Metric* (Naumann et al., 2011) each of them referring to first, second and third-order impacts identified by Berkhout and Hertin. The latter refer to: indirect effects of ICT production and usage over the environment (first order impacts), indirect effects that result from economy structural changes, production processes, the products themselves and the distribution (second order impact) and the indirect effects resulted from stimulating consumption, economic growth as a result of ICT usage („rebound effect") and the impact on the way of life and the value systems (third level impact). According to the mentioned model, each iteration is followed by a review of the impact over the environment. After each application component is created, it becomes quite easy to measure and monitor the energy consumption. The results obtained can then be used to optimize the energy consumption in the next iterations. But the Greensoft Model is not the only software development model that takes into consideration the impact upon the existing environment. Shenoy and Earatta (2011) have proposed another model in which they suggest measures that can be adopted in order to reduce carbon emissions during the software lifetime circles.

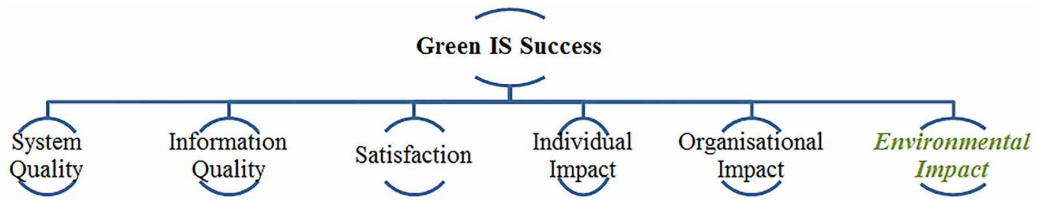
Mahmoud and Ahmad (2013) are proposing a green model for sustainable software engineering that offer a full picture over the way software affects the environment, in two stages: how the life-cycle of a software product effects the environment through ICT and how software itself can aid in keeping the environment green or not by monitoring and utilizing resources efficiently, thus contributing to creating a green ICT. They mention the following set of general operational or low-level software goals for satisfying environmental sustainability: use of environmentally approved products for development, reduce transportation means and instead use the Internet for communication, use of cloud computing in terms of IaaS (Infrastructure as a Service), use of service oriented software, sacrificing performance above a limit for energy efficiency, running the system on computers with power profiles, reduce the number unnecessary activities in the system and use of a reusable system (Mahmoud and Ahmad, 2013). As can be observed the essential element in all approaches is to improve energy efficiency. It can be estimated as the ratio of useful work done and used energy (Johann, 2012):

$$Energy\,Efficience = \frac{Useful\,Work\,Done}{Used\,Energy}$$

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Other important aspects that need to be considered during this stage refer to reducing the volume of data to a reasonable and relevant level for the organization, as well as developing and implementing some techniques of organizing the data in a manner that favors the diminishing of negative influence over the environment. Another aspect that can be considered is the possibility of migrating towards cloud computing. The benefits brought by this process are: less energy consumption and CO_2 emission, less equipment needed to run the IS and less e-waste (Kumar & Buyya, 2012; Beloglazov el al., 2012; Elgelany & Nada, 2013).

Finally, the last stage of the agile life-cycle is the *product release*. This stage encompasses two components: final testing of the entire system, as well as any necessary final reworks and documentations and the product is provided to the users in order to maximize operational integration (Isaias & Issa, 2015). During this stage, users can verify if the final product is in agreement with the chosen environmental standards. They can ask for a final report regarding the IS influence over the environment and can request changes. The direct effects of this stage over the ecosystem are similar to those during the iteration construction phase.



INTEGRATING GREEN IS WITH THE ORGANIZATION'S OBJECTIVES

To have a favorable impact over the organization's activity, IS must be designed to answer the five dimensions proposed through Delone and McLean IS success model (2004), analyzed and developed by Gable et al. (2008) and furthermore by Isaia and Issa (2015). Including environment protection as a priority of IS involves adding it to the mentioned model (Figure 3).

Even the "green IS" name itself makes it impossible to exclude this component from the requirements that the IS, if it is to be successfully implemented and used by organizations. Beyond the particular company traits, it must answer specific general requirements regarding the environment, previously presented in both the agile life-cycle model analysis, and it must also be integrated in the organization's financial and strategic objectives.

Green IS has a key role in both the tactical short-term and in transforming businesses in the longer-term (Sherringham and Unhelkar, 2010). As a result, adopting a green IS must be designed in agreement to the organization's objectives in order for it to be successful. References can be made to both financial objectives (turnover, profit, dividends, stock exchange listing, and cash flow) and to strategic ones (market share, product quality, position at the top, reputation, consumer satisfaction, extending the product diversity).

Figure 3. The conceptual basis for the IS-impact measurement model
Source: adapted from Gable et al., 2008; Isaia and Issa, 2015

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Financially, a green IS can contribute to accomplishing the company objectives by reducing cost through energy economy, recycling equipment, reducing or eliminating environmental taxation by implementing appropriate regulations, resource economy. From a strategic point of view, green IS contribution to accomplishing the company objectives is noted by attracting new customers, increased competitiveness, diversifying the portfolio of products that take the environment into account and increasing the overall company image.

Another essential element is maintaining the company's ability to face technology changes. Due to keeping ICT as an essential element, full or partial IS changes will trigger technology changes. From an environmental perspective, these changes are bi-directional. It was proven that changing hardware generations to newer ones will trigger an increased beneficial environmental relationship, but the same changes trigger an increase in the amount of waste. Another important characteristic is that management-level employees should sustain environmental protection. By their attributions, they can help or hinder the adoption of a green IS.

SOLUTIONS AND RECOMMENDATIONS

Starting from the organization's objectives, the potential of shifting from an IS to a green IS can be appreciated by evaluating the activity and company features on three lanes: the speed of adopting new green IS findings; the interest for direct and indirect effects of these findings to environmental changes and the financial implications. The next table presents the way in which enterprise sustainability can be appreciated in the context of green IS adoption (Table 3).

Table 3. The enterprise sustainability in the context of green IS adoption

Indicators	The Speed in Adopting New Green IS Findings	The Interest for Direct and Indirect Effects of Green IS Findings	Financial Implications of Green IS Findings
Application of environmental standards within the organization	-	Promoting environmental protection and reducing the negative effects on the environment.	The costs of the application of standards and certification.
Participation in trainings regarding the environment and IS potential in this area, organized inside the company	Increased training of employees on green IS; Stimulate involvement in activities with creative potential.	Environmental awareness; Framing environmental protection as a priority in ICT product characteristics	Reducing the time to create own products; Labor productivity growth; Staff training expenses (if committed outside the firm).
Participation in trainings regarding the environment and IS potential in this area, organized by other organizations			Costs of the courses; Growth in labor productivity.
Organization's participation in pro-environmental actions.	Identifying creative ideas for new products development.	Dissemination of environmental values of the company employees; Improving the company's image.	Costs of time allocation; Expenditure on the financing of such actions; Income from improved company image.
Individual participation of employees in pro-environmental actions		Dissemination of environmental values of employees at the firm; Reducing environmental impacts through access to information on measures to protect it.	Expenses related to the financing of participation (if applicable).

Table 3. Continued

Indicators			The Speed in Adopting New Green IS Findings	The Interest for Direct and Indirect Effects of Green IS Findings	Financial Implications of Green IS Findings
The existence and use of a system for monitoring energy consumption			-	Minimize negative effect of energy consumption on the environment; Reducing emissions of greenhouse gasses.	Savings from reduced energy consumption.
The diversity of areas of activity of the organization			Increases the innovative potential; Reduce the risks of failure innovations.	Balancing environmental impact through various activities.	Diversified allocation of costs; Balancing profitability between activities.
The novelty of ICT use in firm (generation of hardware / software)			Familiarity with the latest generation of equipment and applications that support innovation and the emergence of new ideas; Better information on the ICT area.	New equipment are less polluting and consume less energy; New applications demand more resources.	Increased acquisition costs; Updating applications trigger, in many cases, the replacement of equipment; Increase work efficiency.
The volume of investments in equipment and applications			-	-	Expenses generated through investment in infrastructure. Additional investments for introducing environmental features of products.
Dissemination of information on green benefits of IS in the company (innovation / adoption)			Familiarity with features that allow employment in green ICT and knowledge of their potential; Expansion of product characteristics by incorporating environmentally friendly characteristics.	Reducing emissions of greenhouse gasses; Lower power consumption; Lower volume due to the trend of waste minimization; Reducing the amount of toxic substances on board.	-
Characteristics of human resources	Employee diversity training areas		-	Increase / decrease of environmental concerns relative to employee culture.	-
	Affiliation	Foreign	Collection of products for which the company acquires ownership.	Increase / decrease of environmental concerns relative to the culture of the employees in other countries.	Differences in relation to local salaries
		Native	Degree of readiness influences the quality of products made; Collection of products for which the company acquires ownership.	-	Bonuses allocated to reward creative ideas
	The degree of training and experience		It positively influences the creative potential in innovation and value realization chances for a higher level of training and / or experience in the field.	Usually supports favorable environmental concerns through a level of culture and civilization in proportion to preparation; Favorably / Unfavorably influences according to the rules of the organizations where they were formed.	Employment costs, usually proportionate to the level of training and experience
The number of abandoned projects in the Green IS on the first failure			Lack of stimulating creativity; Reduces the chances of potential innovative ideas materializing.	Limiting the negative effects in the use of traditional ICT.	Financial security by not assuming additional risks.
The number of green projects in the area continued despite more one or more failures			It stimulates creativity.	Increased negative effects of using traditional IS.	The increase in expenditures for each assumed failure / product.

Evaluating the organization's activity and features on these three lanes can be a trigger of IS change. The result of this evaluation can offer an estimation of the organization's ability to assimilate a new system and to capitalize its benefits over the environment. It must secure a growth of efficiency, calculated as the ratio between effort and effect, but the expected value of this indicator remains an option of the management of each organization.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

FUTURE DIRECTIONS AND CONCLUSION

This chapter explored the necessity and applicability of green IS. Organizations are interested in adopting green technologies regardless if they refer to production processes, parts design or other activities that just secure the proper organization's functioning, as it results from recent studies. Considering these results, it is demanded that the green concept is assimilated in both the development and usage phase. Literature has made it clear that this leads to environmental benefits, but it cannot guarantee that these initiatives will also benefit the organizations that implement green concepts. A long-term return of investment can only be estimated. Even so, green IS should be a social priority.

The criteria proposed for early evaluation of the conditions needed to for green IS implementation can be used in the selection and approval phase of the agile life-cycle project model, in order to identify the organization's ability to adapt to these changes. It would be essential to create a model that allows evaluation of green IS implementation consequences and the way in which it can be aligned to long-term organization strategy.

Green enterprise is a necessity, not a choice, and changing IS in order to comply with environmental protection requests must be a priority due to their important role. They hold a huge potential due to their ability to contribute to entire industry changes (transportation, energy, production). To ensure the environment is protected, green IS must adhere to this tendency in the development phase and also in the lifetime and until its end.

KEY TERMS AND DEFINITIONS

Agile Development Life Cycle: It is a set of principles that promotes adaptive planning, evolutionary development, early delivery, and continuous improvement for software development.

Energy Efficiency: Is the goal to reduce the energy consumption of products, services and processes related to ICT field. It has favorable effects on the environment mainly by reducing carbon footprint.

Environment Protection: All actions, regulations and policies that aim the conservation of the natural environment, preserving his current state or, if it is possible, reversing its degradation.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Technology: A green technology does not negatively affect the environment (through pollution, energy consumption, increasing the volume of e-waste, etc.) or diminish the negative effects of the similar technologies.

Green: A green company tries to minimize the negative influences of its products, services and business processes on the environment by implementing strict rules and regulations at all levels and across its entire value chain.

Rebound Effect: It is the reduction of the estimated effects of the green ICT or green IS because of consumer behavior or other systemic reactions.

Sustainable: It is a company's ability to remain in business a long time. This concept has three dimensions in present: economic viability, environmental responsibility and social equitability.

ABSTRACT

This chapter presents the overview of concurrent design process of green composite products with special focus on conceptual design stage of natural fiber composites product development. Design of green composites product especially during the early product development stage requires three main aspects in product design which are materials, design and manufacturing process to satisfy lower cost, high quality and fast development time requirements in order to ensure successful product launch into the market. In this chapter, the concurrent design process of green composite products are discussed involving several main stages in product development such as green composite materials selection for both natural fiber and matrix constituents, conceptual design development and concept design selection of green composite products, and green composites manufacturing process selection. In addition, discussion on life cycle assessment of green composites is also included in order to provide further insight of the sustainability design requirements to the overall product development process.

INTRODUCTION

Concurrent design is part of the activities in the concurrent engineering (CE) approach for product development whereby it involved integration of various aspects of the product development process. Unlike traditional product development process which implemented sequential work activities, the CE approach utilized parallel process activities especially during the early design stage of the product. Also termed as Simultaneous Engineering, the CE approach removed the existing gap between design and production process in product development which has created issues regarding cost and quality due to miscommunication especially with respect to different goals and requirements between the two sequential activities (Sohlenius, 1992). Through the implementation of the CE approach, both aspects are considered in parallel as early as in the conceptual design stage which helps to produce products which able to satisfy both requirements, thus providing higher end product quality without jeopardizing the design intent, and subsequently reduced the overall product development cost due to eliminating the cost of error and repair due to the mismatch between design and production activities (Sapuan, 2005). The CE approach also helps to secure higher product development competitiveness to the market by bringing down the product development time. For green composites product developments, the CE approach is a very suitable method to be implemented considering the nature of the development process whereby green composite product designers need to consider various aspects of the product requirement such as design, materials and manufacturing process altogether during the early stage of the product development activities (Sapuan & Mansor, 2014).

Green composites products have made notable presence as substitutional materials for synthetic composites in many product applications. One of the most aggressive player using green composites is the automotive manufacturers. Driven by stringent legislations towards environmental performance for new generation of vehicles, the automotive manufacturers have applied green composites in the construction of various components such as dashboard, door trim panels, headliners and seat backs (Bismark et al., 2006). The use of green composites contributed significantly towards gaining high weight reduction, product cost and improved biodegradability of the components at the end of the life cycle (Ashori, 2008). Research in applying green composites for structural automotive components are also increasing due to similar advantages as aforementioned such as towards the development of structural frontal bonnet for buggy vehicle (Alves et al., 2010) and bumper beam (Davoodi et al., 2010).

Based on the impact and advantages of CE approach towards successful product design and development, in this chapter the concurrent design process of green composite products are discussed. Special attention is given towards the conceptual design stage of the green composites product development which involved several main activities such as green composite materials selection for both natural fiber and matrix constituents, conceptual design development and concept design selection of green composite products, and green composites manufacturing process selection. In addition, discussion on life cycle assessment of green composites products is also included in order to provide further insight of the sustainability design requirements to the overall product development process. Finally, to demonstrate the application of concurrent design for green composite products, a case study on the conceptual design development of bicycle frame using green composites is also explained in the end of this chapter.

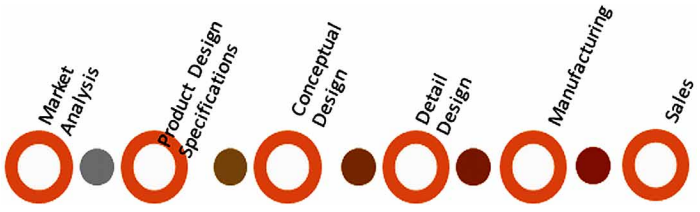
CONCURRENT DESIGN PROCESS OF GREEN COMPOSITE PRODUCTS



Concurrent design is part of the major activities within the overall product development process. In general, systematic product development process follows Pugh product development model, termed as Total Design, which comprises of market analysis, product design specifications, conceptual design, detail design, manufacturing, and sales (Pugh, 1991). In addition, other product development models also proposed embodiment design stage to be conducted in between the conceptual design and detail design stage such as proposed by Dieter (2000) and Pahl et al. (2007). Figure 1 shows the major activities in product development process.

The product development process starts with market analysis whereby the needs of all stakeholders for the intended product are identified through several systematic methods. The stakeholders involved may comprise of end users or customers, authorities such as government, management within the company as well as internal department groups such as manufacturing, sales and procurements. Careful consideration of their needs is important towards successful development and product introduction to the market. In CE approach, several systematic market analysis tools are available such as the Kano model and Quality Function Deployment (QFD) to determine the voice of the customer in order to tailor the desired product in fulfilling the customer preferences (Lin et al, 2011; Min et al., 2011; Yeh et al., 2011).

Based on the gathered information, the relevant attributes or factors towards successful product launch are analyze and compiled into a design guideline termed as Product Design Specifications (PDS) document. The PDS document served as the main reference which consists of all the necessary attributes that need to be considered by the new product during the whole development process. In Pugh Total Design model, the specific PDS requirements can be further group into specific elements such as cost, performance, weight and as well as standards and regulations. Similar case is applied in green composites product development whereby based from market analysis, specific PDS document are developed for the product which may includes similar elements such as cost, weight and technical performance as well as end of life requirements (recyclable and safe for disposal) and aesthetic appearance.

In the next stage of the product development process, conceptual design of the new product is developed based on the specific PDS requirements. Several tools are available within the CE approach to assist product designers in both idea brainstorming and idea generation such as the Ishikawa method or fishbone diagram method (Chandrasegaran et al., 2013), Ten Golden Rules for Ecodesign(Luttropp & Lagerstedt, 2006), Ecodesign Strategies Wheel (Brezet & Van Hemel, 1997) and Design for Assembly (DFA) (Chiu & Okudan, 2014). The design concept developed in this stage served as the founding model for the end product prior to detailed optimization process in the later stage. Information obtained at the end of the conceptual design stage are such as the overall geometry of the product, list of potential candidate materials for the embodiment of the product, the principles of operation and product work-

Figure 1. Major activities in product development process

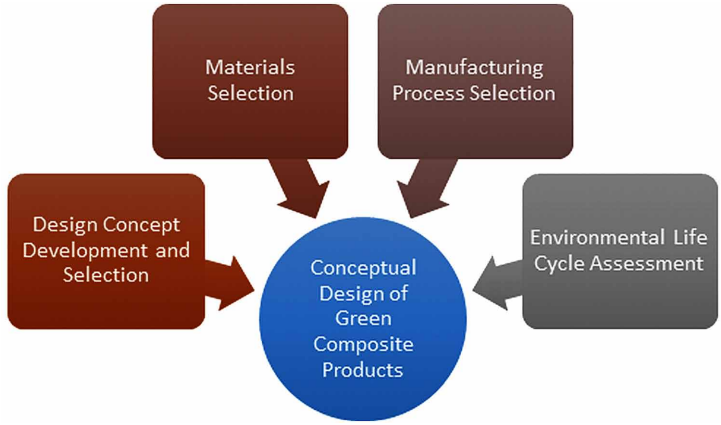
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ing mechanism. Incorporation of decision support system are the essence of modern conceptual design activities towards getting the correct design and decision as early as possible in the overall product development process (Ghazilla et al., 2013).

In the subsequent stage termed as detail design, the rough idea and solution for the particular product is further refined towards optimizing the end product in achieving the PDS requirements more specifically such as detail product drawing with specific dimensions and tolerance, target operational performance (maximum allowable stress and deformation), safety, cost, assembly method, packaging method and end product weight. In this stage, more CE tools are applied especially with the assistance of computerized modeling and simulation applications such as Computer Aided Design (CAD), Computer Aided Analysis (CAE) and rapid prototyping method. Extensive testing and modifications of the new product are conducted to determine the prototype performance and durability in meeting the design specifications.

After the product detail design stage, the optimized product is then brought to the manufacturing stage whereby the product is produced in high volume. Similarly with the previous stage, there are many CE tools applied to ensure highest quality, lower production cost and quick time to market are achieved for the product such as through the implementation of Lean Manufacturing method, Six Sigma (Wang & Chen, 2010) as well as Failure Mode and Effect Analysis (FMEA) (Yen & Chen, 2005). Finally, the end product produced is introduced to the market which comprise of activities such as sales, marketing and after-sales. The successful launch of the product to the market is the ultimate goal for any product to achieve highest customer acceptance and subsequently contribute to higher profits and larger market share compared to other product competitors.

CONCURRENT CONCEPTUAL DESIGN OF GREEN COMPOSITE PRODUCTS



As noted in the earlier section, this chapter is focused on describing the conceptual design stage of green composite product development using the CE approach. Ulrich & Eppinger (2004) stated that, despite only 5% of total product development cost and 15% of total development time is inflicted during the conceptual design stage, the same conceptual design activities contributed to almost 70% of the total manufacturing cost of the end product. Thus, the conceptual design stage has a very significant effect to the success of the product, especially to achieve the aim of CE approach which is lower cost and faster time to market with high product quality. Decisions made during the conceptual design stage will greatly influence the subsequent product development process, and using systematic concurrent conceptual design approach, optimized and justified decisions can be made to ensure that all the PDS requirements are fulfill and the final product is able to launch successfully into the market.

Concurrent conceptual design of green composite products involved several major activities which are design concept development and selection, materials selection, and manufacturing process selection. Due to the recent environmental awareness towards product sustainability, environmental life cycle assessment is also incorporated into the conceptual design stage of the product. Figure 2 shows the major activities associated with the concurrent conceptual design of green composite products.

Under the CE approach, there are many available tools to support the implementation of all the activities in the concurrent conceptual design stage. However, for green composites product application, available literature reviews in the conceptual design stage is still limited. This is due to several factors such as the green composites itself is fairly a new explored field with respect to product development compared to synthetics composites in particular and conventional engineering materials (metals, ceram-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Major activities in the concurrent conceptual design of green composite products

ics, plastics) in general. Apart from that, due to the inherent limitation of green composites properties especially structural properties (such as strength, elastic modulus, dimensional stability and thermal resistance) compared to synthetic composites, current product application of green composites are limited to non-structural products with low load bearing capability. However, by using systematic concurrent conceptual design process, it is highly possible to break the design barrier and apply green composites to products with higher load bearing requirements. In return, more environmentally sustainable product can be developed for new markets such as automotive, aerospace, building and construction using green composites to reduce the current consumption of less environmentally favorable synthetic composites. The following sections will discuss the activities related to concurrent conceptual design process of green composite products.

DESIGN CONCEPT DEVELOPMENT AND SELECTION OF GREEN COMPOSITE PRODUCTS

Design concept development and selection is conducted to obtain potential solutions in term of geometry for the green composite products. As we are aware of, green composites is inherently weak in term of structural strength and stiffness compared to synthetic composites which is made from synthetic fibers such as glass, carbon and aramid. Therefore, in order to directly substitute the use of synthetic composites with green composites, the original product geometry needs to be altered to cater for the materials property limitation. Among the possible solution is by enlarging the initial product geometry such as thickness and surface area, adding stiffeners such as ribs and wedges to the main structure, or reducing the stress concentration areas by using larger value of fillet radius and chamfer size to product sharp corners. However, these alternatives to enhancing the original green composites product structural performance is applicable at the detail designs stage of the product, while the original issue still lies in the conceptual design stage as to create the initial form of the product. In addition, the geometrical design of green composite products are more challenging due to their unidirectional force tolerance of the fibers as compared to homogenous materials such as metals which has almost equal load absorption capacity at all force direction.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In general, there are two main activities under the concurrent conceptual design approach which relates to the design concept development and selection. First is the design concept development whereby initial form of the green composites product is produced and then followed by selection of the possible design concept developed to obtain the best of final design concept for the green composites product. The following sections described both major activities related to the design concept development and selection stage.

Design Concept Development of Green Composite Products

In the design concept development process, possible solution in term of geometry for the intended product is developed. The development process normally covers idea generation and idea development. In the idea generation, based on problem statement or design requirements, possible solutions is generated which is able to address all the design intents. There are many methods available for design concept development for green composites products such as Theory of Inventive Problem Solving (TRIZ), Morphology Chart and biomimetic. One of the most important advantages of the aforementioned methods is that they provide a systematic idea generation process for users in generating ideas for the intended green composites products, which is a valuable alternative to the inherent creative thinking and experiences of the designer themselves. All the methods served as a guideline for users in producing solutions for the green composites products.

One of the available design concept development method under the concurrent design approach is the Theory of Inventive Problem Solving method (or originally term as Teoriya Resheniya Izobretatelskikh Zadach in Russian language) which is a systematic problem solving method based on study of patents. Developed in 1940s by Russian patent officer name GenrichAltshuller, the TRIZ method proposed several algorithms to identify the problem and create the final solutions based on the available solution model. The TRIZ method is reported to excel in solving problem with contradictions, which is defined as the problem which has both improving and worsening characteristics for the selected solution. The TRIZ method is able to address the worsening effect while still able to keep the improving effect both simultaneously by solving the contradiction. Among the solution model in TRIZ is the trimming tool, 40 Inventive Principles, and 76 Standard Inventive Solutions (San et al., 2009).

Among the initiative in applying TRIZ for green composites product design was the integration of TRIZ-Morphological Chart-AHP method for the development of hybrid natural fiber composites automotive parking brake lever design (Mansor et al., 2014b). The new integrated method has provided an all-round tool for composite product designers to execute many aspects of product design such performing problem identification, idea generation, concept design development and concept design selection using a single integrated and systematic approach. Apart from that, conceptual design of automotive rear spoiler component was also developed using TRIZ method which encompassed the use of kenaf fiber composites as the construction material (Mansor et al., 2015). For other product developments areas, the TRIZ method was also reported to be applied for conceptual design of notebook casing product (Yeh et al., 2011), eco-friendly bottle casing (Chen et al., 2012), vacuum cleaner (Yen & Chen, 2005) and washing machine (Yamashina et al., 2002) by integrating the TRIZ method with other CE tools such as QFD, FMEA, Eco-design and axiomatic design.

Another design concept development method under the concurrent design approach is the Morphology Chart which is a systematic idea generation method based on the function of the product. Products are in general comprised of multiple components whereby all the components are design to perform different

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

functions. By analyzing the product functions, alternatives method to serve the functions are brainstorm and arranged into a simple matrix. Finally, the potential solutions or the potential design concepts for the product are developed by combining the individual function alternatives listed in the matrix. The advantage of this method is that it provided visual solution to aid users in developing the potential ideas for their products as well as expanding the richness of potential solutions created (Silvester et al., 2013). Despite the usefulness of the method, very limited report on the application of the morphology chart for composite product development purpose was available. One notable application was for the development of polymer composites automotive pedals (Sapuan, 2006). The morphological chart was employed to generate ideas based on the sub-functions of the component. Among the sub-functions included are pedal movement control method, cylinder or cable actuation method, geometry of the pedal pad, pedal profile, rib reinforcement pattern and location of the pivoting shaft of the component. Apart from that, the Morphological Chart was also employed by integrating it with the TRIZ method for hybrid natural fiber composites automotive parking brake lever design (Mansor et al., 2014b).The combination of TRIZ and Morphological Chart method utilized in the report was also found able to effectively produce many innovative conceptual designs using green composites as the construction material to develop the product, which can be further applied in other green composites related product for various applications

Alternatively, the biomimetic or biomimicry concept is also part of the available concept development method in concurrent design. The biomimetic concept is an idea generation model which is inspired by nature. The term was introduced by Otto Schmitt in the 1950s. Despite the recent introduction of the method, the informal application of the model for product design purpose was documented since long ago such as by Leonardo da Vinci in his idea of a mechanical flying contraption which is based on bat physical characteristics (Yurtkuran et al., 2013). The biomimetic model was revitalized by Benyus (1997) through her publication on the concept of harnessing natures inherent patterns and strategies into solution for modern products.

In general, there are two approaches in implementing biomimetic for idea generation and development in product design. First approach is termed as problem-based approach or top-down approach whereas the second approach is termed as solution-based approach or bottom-top approach (Versos & Coelho, 2011). In the problem based approach, designers seek solution for the nature characteristics, and apply relevant traits from the nature to achieve the intended product goal and design requirements. There are six (6) recommended steps associated with the implementation of the biomimetic problem-based approach which are:

1. Problem definition,
2. Reframing the problem,
3. Searching for biological solution,
4. Defining the biological solution obtained,
5. Extracting the principles or method from the biological solution and finally
6. Applying the principles to the intended design.

On the other hand, application of the biomimetic method using the solution-based approach is started the other way around whereby the designers first identify the principles of solution from nature and later apply the principles to address the design problem. The second approach is solution driven and offered the advantages of obtaining new possible applications for the nature's principle identified aside from the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

intended initial design requirement. In the solution-based approach, there are seven (7) implementation steps involved which started from:

1. Identification of the biological solution,
2. Defining the biological solution,
3. Extracting the principles from the biological solution,
4. Reframing the solution to explore the possible application for the biological solution principles,
5. Searching for suitable design problems relevant to the biological solution principles,
6. Defining the design problem and finally
7. Applying the biological solution principles to solve the design problem (El-Zeiny, 2012).

There are several reported case studies on the implementation of the biomimetic model for idea generation of composite products. By mimicking the cross-section of a lily plant leaf using scanning electron microscopy, designers obtained design ideas for composite sandwich panels for improved structural performance (Easterling, 1990). Furthermore, the initial compressive strength for composite laminates was also reported able to be improved by adopting nature's bamboo bast fiber structure which incorporate double helical configuration to the new composite laminates design. Similar report also found that the interlaminar shear strength of composite laminates may also be enhanced by mimicking the bamboo's inherent interlaminar transition zone model to the new composite laminates design (Li et al., 1995). In addition, another report also identified that by using biomimetic concept, the composite joining strength was able to be increased by implementing similar T-joint configuration principles occurred during growth of tree brunch (Burns et al., 2012b). The bio-inspired T-joint principle was also reported able to improve the ductility and damage tolerance of structural joint performance for aerospace composites (Burns et al., 2012a).

Design Concept Selection of Green Composite Products

After the design concept development process, normally more than one (1) possible design solutions are able to be created for the intended product. The next stage involved is to determine which solution that is most suitable to carry out the product function and selected as the final design concept. The final design concept will be the reference for the final product when it is launch into the market after enduring the optimization process later on during the detail design stage. The final design concept evaluation is conducted based on the previously determined PDS. There are many concurrent design tools for design concept selection applicable for this purpose. Among them are the Pugh concept selection method (Pugh, 1991) and the weighted objective method (Cross, 1994). For design concept selection process which involved more advanced decision making capability, the use of multi criteria decision making (MCDM) methods such as Analytic Hierarchy Process (AHP) and Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) may also be employed to obtain the final decision. Mansor et al. (2014b) reported the application of the AHP method for design concept selection process of automotive parking brake lever made from hybrid green composites. Furthermore, Davoodi et al. (2011) also reported on the application of the TOPSIS method for the design concept selection process of automotive bumper beam component using hybrid green composites. In addition, the design concept selection of similar automotive bumper beam component using synthetic composites was also carried out using the AHP method as reported by Hambali et al. (2009a).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

MATERIALS SELECTION OF GREEN COMPOSITE PRODUCTS

Materials selection is another important activity in the concurrent design of green composite products. Green composite materials are comprised of two main constituents, which are the reinforcing natural fibers (such as kenaf, oil palm empty fruit bunch, jute, sisal, hemp and pineapple leaf fibers) and the matrix or resin which acts as to hold all the fibers together giving the final shape to the composite materials as well as distributing the load evenly to the whole composite structure. Thus, major concern within the materials selection activity of green composite product development is to decide on the best type of natural fibers and type of matrix material to be selected to produce the green composite material (Shah, 2013). Materials selection for green composites are often challenging considering the vast amount of option available for both fiber material and matrix material, and also by the introduction of newer class of fiber and matrix materials into the market due the recent advancement in research on green composites worldwide. For instance, the green composites matrix can be choosen from two categories of polymers, which are thermosetting matrix and thermoplastic matrix. Both categories can be further diversified into matrix derived from petroleum resource and matrix material derived from natural resources such as thermoplastic starch (Hamma et al., 2014) and poly-lactic acid (PLA) (Fiore et al., 2014).

The complexity of deciding on the best fiber and matrix material are also inflicted due to the multiple stakeholder requirements that need to be satisfied simultaneously during the product development process. Among the stakeholders which have direct requirements for decision makers to fulfill in the materials selection process are the customer, product designer and product manufacturing engineer, and in most cases, their preference for the materials to be selected are conflicting between each other (Sapuan, 2010). Thus, to address this complexity, the multi criteria decision making (MCDM) method is employed during the concurrent design process to aid decision makers in getting the optimized decision for materials selection. The use of MCDM method enabled all the selection criteria from various stakeholders and pool of potential materials with varying attributes between them to be analyzed simultaneously in a systematic and quantitative ways (Behzadian et al., 2012).

On the other hand, aspects that are considered in materials selection for green composite product can be group into three (3) main categories namely functional, sensorial and intangible properties. The functional aspect is related to the functionality and technical performance of the material to suit the intended application such as mechanical properties, thermal properties and acoustic properties. Secondly is the sensorial aspect of the material which involved consideration such as visual (i.e. colour intensity and colorfulness), tactual (i.e softness-hardness), weight (heavy–light), olfactory (i.e. odorless–fragrant) and auditory (i.e. loudness-quietness) (Baxter et al., 2015). The third aspect involved is the intangible properties such as perceived values and cultural meanings, emotions, trends of the material (Karana et al., 2008). The consideration of all the mentioned aspects is crucial towards successful green composite product development whereby the material selected will also provide meaningful experience of the end product itself to the customers and acts as a linked between the user with the end product as highlighted in the Meaning of Material (MoM) model for materials selection process proposed by Karana et al. (2010).

In general, the materials selection process for green composites product can be divided into two (2) main stages, which are the screening and ranking stage (Jahan et al., 2010). The screening stage is performed to narrow down possible alternative materials to a manageable quantity based on the product design general requirements. Among the screening methods applied in materials selection are the Ashby chart (Shah, 2014), ternary diagram using three bi-dimensional factors (specific strength, specific stiff-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ness and cost per weight) (Koronis et al., 2013) and knowledge-based system (using IF-THEN rule based technique) (Sapuan & Abdalla, 1998).

The ranking process is later performed to analyze in detail the list of potential candidate materials and select the best alternative material which is able to successfully meet all the selection criteria. In green composites materials selection, the selection criteria is extracted from the PDS developed for the intended product. In most cases, the ranking process by the majority of the available MCDM ranking methods is started by determining the weight of the selection criteria or the magnitude of preference between the selection criteria involved using method such as Digital Logic (DL) method and Analytic Hierarchy Process (AHP). However, Attri & Grover (2013) reported that there are MCDM methods which do not need the information of the weight for the selection criteria such as Preference selection index (PSI) method (Maniya & Bhatt, 2010), VlsekriterijumskaOptimizacija I KOmpromisnoResenje(VIKOR) method (Girubha & Vinodh, 2012) and Grey Relational Analysis (GRA) method (Chan & Tong, 2007). The weight ratings are quantified based on individual preference or from group preference involving the product stakeholders. For group decision making, the average value for their preferences is calculated using either arithmetic mean or geometric mean method and applied for the respective selection criteria (Wu et al., 1998).

The next process involved during the ranking stage is analyzing the score of every candidate materials based on the respective attributes with respect to the selection criteria and weight of the criteria as defined in the previous process. Finally, the rank for every candidate materials are determined based on the individual total score value obtained whereby highest score value represents the best candidate material to fulfill the intended design requirement. In overall, selection of the MCDM method to be applied also depends on the user's preference with consideration of computational time, amount of mathematical calculation required and level of complexity of the algorithm involved (Attri & Grover, 2013). Among the ranking methods which are available for materials selection process including for green composites are Analytic Hierarchy Process (AHP) method (Akadiri et al., 2013; Mansor et al., 2013), Preferences by Similarity to the Ideal Solution (TOPSIS) method (Anupam et al., 2014; Mansor et al., 2014a), Preference Ranking Organization Method for Enrichment Evaluation (PROMETHEE) method (Çalişkan et al., 2013; Peng & Xiao, 2013), ELimination Et Choix Traduisant la REalité (ELECTRE) method (Shanian & Savadogo, 2006) and weighted property index method (Findik & Turan, 2012).

MANUFACTURING PROCESS SELECTION OF GREEN COMPOSITE PRODUCTS

Another important aspect involved in concurrent conceptual design stage is the green composite product manufacturing process selection. Similarly with the previous section, MCDM methods are normally employed to perform the selection process due to the presence of multiple selection criteria and multiple manufacturing process alternatives which needs to be analyzed concurrently. In general, the manufacturing process selection criteria for green composites product is determined based on the final composites product architecture which are the volumetric composition of the green composites in term of intended fiber volume fraction and porosity), reinforcement geometry in term of fiber length and fiber orientation, and the type of matrix chosen, whether it is thermoset or thermoplastic matrix (Shah, 2013). In addition, the criteria for the manufacturing process selection also includes end product quality and low labor cost (Singh et al., 2011). Furthermore, the manufacturing process flexibility, good precision to reach the required dimensional tolerance, low cost, low scrap and rapid production capability are also desirable

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

traits for selection of green composites manufacturing process (Jahazi & Hossein-Nejad, 2004). Hambali et al. (2009b) demonstrated the application of MCDM method for automotive bumper composites manufacturing process selection using AHP method. In their report, among the selection criteria applied were cost (tooling, labor and equipment), production characteristics (production quantity, rate of production and processing time), geometry of the final composite product design (such as shape, wall thickness and weight), type of materials used, ease of maintenance and availability of the equipment and labor.

LIFE CYCLE ASSESSMENT OF GREEN COMPOSITE PRODUCTS

Due to the increase of awareness from consumers on the product they consumed especially on its effect to the environment, product designers are now incorporating design for sustainability tools for new product being developed. The growing trend isalso now applied for products which used green composites as the raw material. In the concurrent conceptual design stage, one of the tool applied is the life cycle assessment (LCA) method which served as to determine the potential environmental impact of the product throughout its entire life cycle (Finkbeiner & Hoffmann, 2006). The implementation of the LCA method in the conceptual design stage helps product designers especially the one dealing with green composites to quantify the resulting potential environmental burden throughout the whole product life cycle starting from raw materials extraction, production and up to the its end of life of stage. Apart from that, the LCA method will also yield quantitative measures to assess "how green" is the green composites product itself as targeted during the initial product development process. Furthermore, the information obtained through LCA method also help designers to identify key product life cycle stages which contributes to the highest environmental burden so that correction action can be undertaken as early as possible such as during the conceptual design stage of the product (Joshi et al., 2004).

There are many reported studies on the implementation of LCA method for green composites product development. Wötzel et al. (1999) applied LCA method using Eco-indicator 99 impact assessment method to assess the environmental impact of automotive side panel component developed using hemp/epoxy green composites. Schmehl et al. (2008) also reported the application of LCA method to measure the potential environmental impact of hemp/PTP thermoset green composites for passenger bus body component casing product design. Moreover, Luz et al. (2010) utilized the LCA method to assess the potential environmental burden of sugarcane bagasse/polypropylene green composites for interior component of passenger vehicle. They also analyzed the environmental performance of the similar component constructed using talc/polypropylene composites and later compared both materials in term of the environmental performance throughout the component life cycles.

CONCEPTUAL DESIGN OF GREEN COMPOSITES PRODUCT: CASE STUDY ON GREEN COMPOSITES BICYCLE FRAME DESIGN

Bicycle is among the earliest form of road transportation created by men. Among the main component of a bicycle is the frame which acts as the main load bearing structure of the vehicle which holds all the other components together to make it functional. Currently, steel is the most used material to construct the frame component due to its high strength and stiffness properties required for safe and reliable operation to the user. Synthetic composites were also used to construct the frame component especially

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

carbon fiber composites to gain better lightweight properties compared to steel for higher cycling performance while maintaining the structural requirements for safe and functional operation. However, despite the lightweight gain by using carbon fiber composites, trade-offs were made in term of higher material cost, which limits the carbon fiber composites bicycle frame to high-end users such as competitive racing cyclists, maintaining the domination of steel for bicycle frame design. On the other hand, green composites, made from natural fiber such as kenaf, sugar palm and pineapple leaf reinforced in either thermoplastic or thermoset matrices is gaining wider attentions nowadays especially as the most potential candidate materials to replace the use of synthetic composites such as carbon fiber composites and steel for various structural applications. Green composites offer the cost and lightweight solution to synthetic composites and steel, respectively. Furthermore, green composites which used fibers made from natural resources also provide better sustainability performance such as renewable and recyclable compared to synthetic fiber made from petroleum resource. However, green composites still lag behind synthetic composites and steel especially in term of structural performance, henceforth seeing the application of green composites material to be concentrated to non-structural products. In order to gain the potential of green composites as substitution material to construct the bicycle frame, other solution to address its inherent low structural performance must be worked out, and among the solution is through applying CE approach of the product during its development process. In this case study, the integrated TRIZ-Morphological Chart method is selected to assist in developing innovative design solutions during the concurrent conceptual design stage for the new bicycle frame using green composites material. The development process of the new bicycle frame conceptual design using green composites material is divided into three stages and the explanation are described as below.

Stage 1: Problem Identification

In the first conceptual design stage, problem identification of the project was first determined using the TRIZ method. The aim of the case study was to utilize green composites for bicycle frame construction to improve the product cost, sustainability and lightweight performance compared to the current frame material, which is steel. However, applying green composites also reduced the structural performance, which is crucial to guarantee functional and safe operation of the product. Thus, a contradiction occurred in which by improving one parameter of product, another parameter worsened in the same time. According to the TRIZ method, the contradiction occurred is classified as engineering contradiction due to the type of the parameter involved. Next, the specific problem statement is matched with TRIZ 39 engineering parameters to convert it to general problem statement. TRIZ engineering parameter number 2 (weight of stationary object) was selected to represent weight of the green composites bicycle frame as the improving parameter in the design while engineering parameter number 11 (stress) was selected to represent the reduce of structural performance due to lower stress that can be absorbed by the green composites bicycle frame.

Stage 2: Solution Generation

In the second stage of the conceptual design process, solutions to solve the known contradiction were generated. Again by applying TRIZ method, general solutions were obtained using the TRIZ contradiction matrix based on the identified improving and worsening parameters as shown in Table 1. In this particular case, four potential inventive solution principles were suggested based on the contradiction

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Contradiction matrix for the green composites bicycle frame based on the TRIZ 39 Engineering Parameters

Improving Parameter	Worsening Parameter	TRIZ 40 Inventive Solution Principles
#2. Weight of stationary object	#11. Stress	#10. Preliminary action (prior action – "do it in advance") #13. The other way around #18. Mechanical vibration/oscillation #29. Pneumatics and hydraulics

(San et al., 2009)

matrix which are number 10 (preliminary action or prior action – "do it in advance"), number 13 (the other way around), number 18 (mechanical vibration/oscillation) and number 29 (pneumatics and hydraulics). The proposed solution principles served as guidelines in brainstorming the potential idea to solve the problem.

The next step taken was to analyze each of the general solution principles obtained from the contradiction matrix to determine relevant general solution associated with the product. Based on the conducted analysis, the principle number 10 and number 13 were found to provide the most suitable solutions to solve the problem faced in the design. Thus, specific solution strategies relevant to the green composites bicycle frame were later devised based on the general solution selected. Table 2 summarizes the overall specific solution strategies based on the TRIZ general solution principles identified to be applied to the new green composites bicycle frame.

Stage 3: Conceptual Design Development

In the final stage, the classical Morphological Chart method was applied to refine the previously identified TRIZ specific solutions strategies into appropriate alternative system elements. The integration of Morphological Chart with TRIZ method enabled further identification of possible specific design features related to the recommended TRIZ principles, which in return also enhanced the effectiveness of the TRIZ method. Furthermore, the integrated TRIZ-Morphological Chart method also provided a

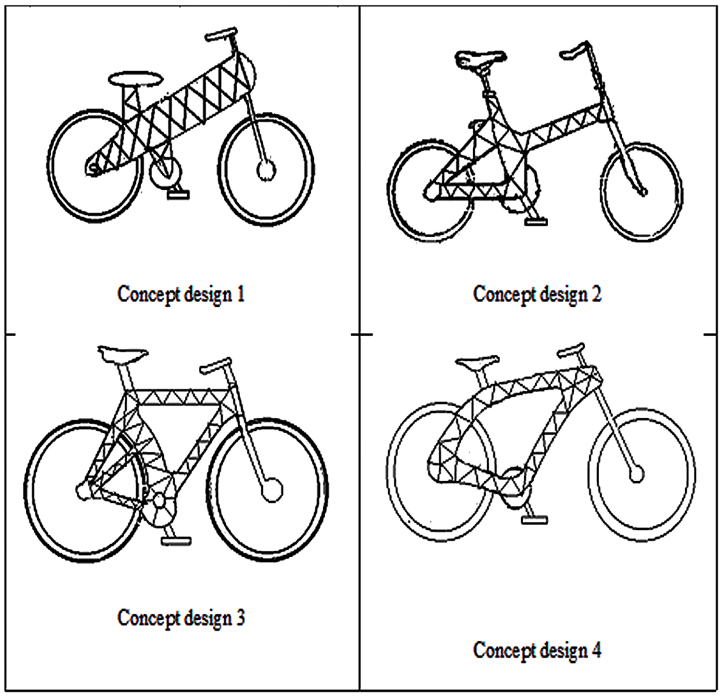
Table 2. Specific solution strategy for the green composites bicycle frame based on the TRIZ solution principles

TRIZ General Solution Principles	Solution Descriptions	Specific Solution Strategy
#10. Preliminary action (prior action – "Do it in advanced")	1. Perform the required change of an object (either fully or partially) before it is needed 2. Pre-arrange objects such as that they can come into action from the most convenient place without losing time for their delivery	• Add ribbing pattern as reinforcements on the bicycle frame to increase structural strength and stiffness (Imihezri et al., 2005) • Change from multiple section frame to single piece frame to increase strength and stiffness by eliminating concentrated stress using joints as well as ease of frame manufacture using green composites material)
#13. The other way around	1. Invert the action used to solve the problem 2. Make movable parts fixed, and fixed parts movable 3. Turn the object 'upside down'	• Change from straight shape frame to arch shape frame to increase static vertical load bearing capability • Change from tubular-shape frame cross-section to beam-shape frame cross-section such as I-beam shape design to increase stiffness as well as ease of frame manufacture using green composites material (Imihezri et al., 2006)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

quick way for designers to systematically translate the general TRIZ solutions into specific design idea and generate more solution ideas for the desired conceptual design. In addition, the designer may also visualize the solution idea more clearly prior to combining them together to generate new conceptual design of the product. Figure 3 shows the developed Morphological Chart for the green composites bicycle frame design.

Note: Example for development of concept design 1= Rib pattern (X) + single frame + frame shape (flat) + frame cross-section (I-shape).



Using the Morphological Chart developed in Figure 3 as guideline, four (4) new conceptual designs of the green composites bicycle frame were developed as shown in Figure 4. Each of the new conceptual designs combined individual elements related to the design feature listed in the chart. For example, concept design 1 was developed using the combination of X-type ribbing pattern as the frame reinforcements and was based according to single frame construction as opposed to the multiple frame for the current steel bicycle frame. The single frame construction design was permitted due to the capability of producing single piece component using polymer composites manufacturing technology such as injection molding and resin transfer molding process. Moreover, concept design 1 also retained the straight shape frame design for design simplification and an I-shape frame cross-section to replace the tubular steel frame cross-section applied in current bicycle frame design. The I-shape frame cross-section also helped to enhance the structural rigidity of the green composites structure while in the same time reduced the volume of material used for lightweight purpose. Utilization of the solution strategies identified using the TRIZ method for the development of new green composites bicycle frame conceptual designs have allowed innovative and practical design solutions for structural purpose to be achieved despite the initial limitation on mechanical properties of the green composite material.

Figure 3. Morphological chart for green composites bicycle frame design

TRIZ solution principles and specific solution strategy	Design feature	Conceptual Design Solution			
		1	2	3	4
#10. Preliminary action (prior action – "Do it in advanced") i) Add ribbing pattern as reinforcements on the bicycle frame ii) Change from multiple section frame to single piece frame	Rib pattern	I	V	X	
	Single frame	Yes	No		
#13. The other way around i) Change from straight shape frame to arch shape frame ii) Change from tubular-shape frame cross-section to beam-shape frame cross-section	Frame shape	Flat	Arch	Mixed	
	Frame cross section	I-shape	T-shape	Rectangle

CONCLUSION

The know-how of materializing green composites into workable and acceptable products both for non-structural and structural applications as substitution to conventional engineering materials and synthetic composites is an important feature required to product designers. Despite the challenging task faced due to the limitation on the structural properties of green composites, the inherent inadequacy can be addressed successfully through implementation of systematic CE approach especially during concurrent conceptual design process. Without compromising the functional requirements such as structural strength and safety, innovative solutions and optimized decision can be developed for the green composite products which also able to provide better sustainable advantages to consumers throughout the product entire life cycle especially when compared to synthetic composite products. Many CE tools are applicable to handle the product development process involving idea generation and development as well as MCDM for materials, process and design selection for green composites. The potential of success was made available for reference to designers and practitioners in the green composites field through the case study shown in the previous section using systematic CE approach during the conceptual design stage of the product.

ACKNOWLEDGMENT

The authors wish to express sincere gratitude to Universiti Teknikal Malaysia Melaka for the warm support provided throughout the preparation of this publication.

KEY TERMS AND DEFINITIONS

Composites: Made of different parts or materials.

Conceptual Design: Outline of solutions to a design problem.

Concurrent Design: Design activities which exist, happen, or done at the same time.

Life Cycle Assessment: A tool for the systematic evaluation of the environmental aspects of a product or service system through all stages of its life cycle.

Morphological Chart: A graphical representation based on the function analysis for idea generation purpose.

Natural Fiber: Textile fibre made from natural resources as opposed to synthetic materials.

TRIZ: A structured problem solving method. It is a Russion acronym for "Teoriya Resheniya Izobretatelskikh Zadatch" which means 'Theory of Inventive Problem Solving'.

This research was previously published in Green Approaches to Biocomposite Materials Science and Engineering edited by Deepak Verma, Siddharth Jain, Xiaolei Zhang, and Prakash Chandra Gope, pages 48-75, copyright year 2016 by Engineering Science Reference (an imprint of IGI Global).

Chapter 33
Cloud Computing Technology for Green Enterprises

Prachi Chaturvedi
Madhav Institute of Technology and Science, India

ABSTRACT

Computing technology acting a very vital role in our day to day activities. Later the associated high volume of energy consumption has become a major concern every economically and environmentally. Green computing is associate rising application in computing effectively that leads to very important greenhouse gas reduction. In toughened computing has become an important half that has got to be thought of seriously by ordered generation data and communication technology designers. Green computing is to use computer and connected resources in atmosphere, friendly ways in which. Such practices embrace the implementation of energy-efficient central method unit (CPU), servers and peripheral any as finding innovative ways in which of reducing resource consumption and proper disposal of electronic waste. Many IT manufacturers and vendors endlessly invest in designing energy economical computing devices, reducing the use of dangerous material, and galvanizing the recyclability of digital devices and printing papers.

INTRODUCTION

The field of "green technology" encompasses a broad range of subjects — from new energy-generation techniques to the study of advanced materials to be used in our daily life. Green technology focuses on reducing the environmental impact of industrial processes and innovative technologies caused by the Earth's growing population. It has taken upon itself the goal to provide society's needs in ways that do not damage the natural resources. This means creating fully recyclable products, reducing pollution, proposing different technologies in numerous fields, and making a middle of economic activity around technologies that profit the atmosphere. The massive quantity of computing factory-made worldwide contains a direct impact on atmosphere problems, and scientist's area unit conducting varied studies so as to scale back the negative impact of computing technology on our natural resources. A central purpose of analysis is testing and applying different non-hazardous materials within the products producing method.

HISTORY OF GREEN COMPUTING

In 1992, the U.S. Environmental Protection Agency launched Energy Star, a voluntary labeling program that is meant to push and acknowledge energy potency in monitors, climate management instrumentation, and different technologies. This resulted within the widespread adoption of sleep mode among shopper physics. The term "green computing" was in all probability coined shortly when the Energy Star program began; For a computer disposal, it's necessary to grasp everything there's to grasp so as to be concerned inexperienced computing. Basically, the full Green side took place quite an few years back once the news that the atmosphere wasn't a natural resources extremely move and other people started realizing that that they had to try and do their half to guard the atmosphere. Basically, the economical use of com putters and computing is what Green computing all is concerning. The triple bottom line is what's necessary once it involves something Green and therefore the same goes for Green Computing. This considers social responsibility, economic viability and therefore the impact on the atmosphere. Several businesses imply target a bottom line, instead of an Green triple bottom line, of economic viability once it involves computers. The thought is to create the full method encompassing computers friendlier to the atmosphere, economy, and society. This suggests makers produce computers in an exceedingly manner that reflects the triple bottom line completely. Once computers area unit sold-out businesses or individuals use them in an exceedingly Green manner by reducing power usage and doing away with them properly or utilization them. The thought is to create computers from getting down finishing a Green product.

BACKGROUND

Governments Go Green

Many governments worldwide have initiated energy-management programs, like Energy Star, a global commonplace for energy economical equipment that was created by thus Environmental Protection Agency in 1992 and has currently been adopted by many different countries. Energy Star reduces the number of energy consumed by a product by mechanically change it into ——sleep mode once not in use or reducing the number of power employed by a product once in ——standby mode. Amazing, standby——leaking, the electricity consumed by appliances once they area unit changed, will represent the maximum amount as 12% of a typical household's electricity consumption. In Australia, standby power may be a primary issue for the country's increased greenhouse emission emissions — quite five megatons (CO2 equivalent) annually.

Green Computing

Green computing is that the study and follow of exploitation computing resources expeditiously. The goals area unit like green chemistry; that's cut back the utilization of unsafe materials, maximizes energy potency throughout the product's period, and promotes recyclability or bio-degradability of defunct merchandise and manufacturing plant waste. Taking into thought the popular use of knowledge technology business, it's to guide a revolution of types by turning Green during a manner no business has ever done before. Its price action that this Green technology should not be on the subject of sound bites to impress activists however concrete action and structure policy. Opportunities belongs Green technology

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

like never before in history and organizations area unit seeing it as the simplest way to form new profit centers whereas making an attempt to assist the environmental cause.

In the arrange towards Green IT ought to embody new electronic merchandise and services with optimum potency and every one attainable choices towards energy savings. Modern IT systems rely on an advanced mixture of folks, networks and hardware; in and of it, a green computing initiative should be general in nature, and address progressively subtle issues. Components of like answer might comprise things like user satisfaction, management restructuring, restrictive compliance, disposal of electronic waste, work, virtualization of server resources, energy use, skinny shopper solutions, and come on investment (ROI). As twenty first century belongs to computers, gizmos and electronic things, energy problems can get a significant ring within the returning days, because the oral presentation on carbon emission, heating and temperature change gets hotter.

Taking into thought the popular use of knowledge technology business, it's to guide a revolution of types by turning green during a manner no business has ever done before (Info-tech, 2009; (Depavath Harinath, 2008). Green Computing is that the term accustomed denote economical use of resources in computing. This term typically relates to the utilization of computing resources in conjunction with minimizing environmental impact, maximizing economic viability and making certain social duties. Green Computing is extremely a lot of associated with different similar movements like reducing the utilization of environmentally unsafe materials like CFCs, promoting the utilization of utile materials, minimizing use of non-biodegradable elements, and inspiring use of property resources. One among the spin-offs of Green Computing is EPEAT or Electronic merchandise Environmental Assessment Tool. EPEAT merchandise serves to extend the potency and lifetime of computing merchandise. Moreover, these merchandise area unit designed to reduce energy expenditures, minimize maintenance activities throughout the lifetime of the merchandise and permit the re-use or usage of some materials.

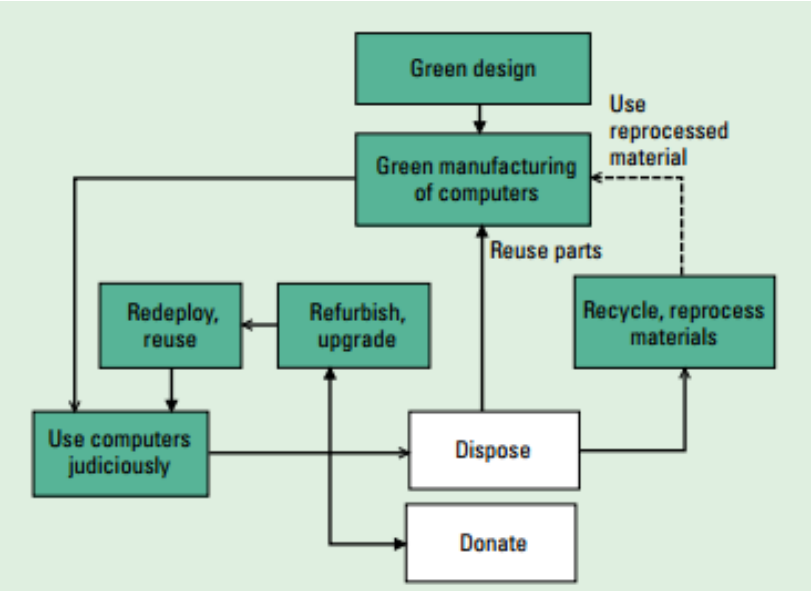
The first manifestation of the Green Computing movement was the launch of the ENERGY STAR program back in 1992 and ENERGY STAR served as a sort of voluntary label awarded to computing merchandise that succeeded in minimizing use of energy whereas maximizing potency, so ENERGY STAR has been applied to products like monitors, TV sets and temperature management devices like refrigerators, air conditioners, and similar things. One of the primary results of Green Computing is that the Sleep mode perform of PC monitors that place a consumer's equipment on standby mode once a pre-set amount of your time passes once user activity isn't detected because the idea activity isn't detected because the idea developed, Green Computing began to cover skinny shopper solutions, energy accounting, virtualization practices, and E-Waste.

Green Computing Practices

Some common Green Computing practices embody turning off the monitor once it's not in use or exploitation a lot of energy economical monitors like LCDs rather than ancient CRT monitors, volunteer computing or file sharing practices, virtualization of servers, exploitation a lot of energy economical and fewer droning cooling systems (like exploitation liquid cooling systems rather than the traditional heat sinks and fans), temperature maintenance and regulation to scale back thermal shock wear and tear to pc components, and increased on-line security measures through the utilization of firewalls, anti-spyware and anti-virus programs to scale back the increasing quantity of E-Waste on the web and on different networks.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

WHY GREEN COMPUTING?



In a world wherever business is transacted 24/7 across each potential channel obtainable, corporations ought to collect, store, track and analyze huge volumes of knowledge—everything from click stream data and event logs to mobile decision records and a lot of however this all comes with a price to each businesses and also the surroundings. Knowledge warehouses and also the sprawling knowledge centers that house them dissipate an enormous quantity of power, each to run legions of servers and to cool down them simply however much? A large sixty one billion kilowatt-hours of electricity, at associate degree calculable value of $4.5B annually (Info-tech, 2009). The IT business has begun to deal with energy consumption within the knowledge center through a range of approaches as well as the employment of a lot of economical cooling systems, virtualization, blade servers and cargo area networks (SANs). However a elementary challenge remains. As knowledge volumes explode, ancient, appliance central knowledge reposting approaches will solely still throw a lot of hardware at the matter. This can quickly negate any inexperienced gains seen through higher cooling or a lot of tightly packed servers. (Info-tech, 2009) to reduce their hardware footprint, organizations conjointly ought to shrink their "data footprint" by addressing what quantity server area and resources their info analysis needs within the initial place.

A mix of latest info technologies expressly designed for analysis of huge quantities of knowledge and reasonable, resource-efficient, open-source software system will facilitate organizations economize and become greener (Info-tech, 2009).

Organizations (Figure 1) will do therefore within the following 3 key areas: reduced knowledge footprint, reduced reading resources, and reduced in progress management and maintenance (Info-tech, 2009). This technology is useful as it:

- Scale back energy consumption of computing resources throughout peak operation Save energy.
- Throughout idle operation Use eco-friendly sources of energy.

Figure 1. Green computing design

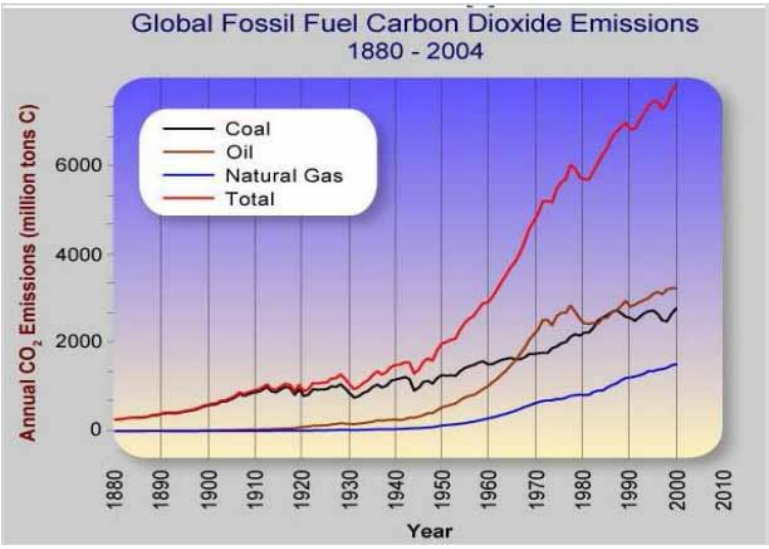
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Scale back harmful effects of computing resources.
- Scale back computing wastes

Global warming and also the drawback of minimizing environmental impact from fossil-fuel emissions have raised to the highest of worldwide public policy agenda. As a result, businesses and customers alike have begun to embrace environmentally property merchandise that provide low-carbon solutions that may not solely scale back their international gas (GHG) emissions, however will do therefore by a lot of economical energy consumption and lower prices. Sensible readying of a lot of economical computing resources, beginning with Green PCs, has become a key focus for several businesses and customers trying to scale back their own energy consumption and carbon footprint. this is often fueled by a rise publicly awareness of the consequences of global climate change, recognition by businesses and customers that reducing energy usage will save prices and by government regulation covering everything from energy potency to power management and reduction of dangerous materials to e-waste disposal.

EXISTING WORKS IN GREEN COMPUTING

Today all manufactures corporations try to determine such knowledge center that area unit low cost and use low energy/power. In America in 1992 introduced an energy star program. Its main aim was given awarded to those computing merchandise that use minimum energy and provides most potency in its operating. In Energy star program were enclosed such product as laptop monitor, TV sets, white goods, Air conditioning and other physical science devices of these merchandise could also be friendly Green computing (Depavath Harinath, 2008).



EPEAT (Electronic merchandise Environmental Assessment Tool) check the product's normal. All products that area unit registered area unit higher to guard human health and these items will be simply upgraded and recycled. This merchandise has reduced the proportion of lead, mercury and metallic element. These merchandise area unit a lot of efficient in energy and scale back the environmental impact.

IBM additionally has additionally contributed these problems. IBM has helped the purchasers to buy the merchandise consistent with green computing. Consistent with the analysis of the IBM in 1990, He saved 4.6 billion KWh of electricity and additionally prevented 3 million metric tons of greenhouse gas emission.

Google is making an attempt to determine its knowledge Centre building on Oregon's river to faucet electricity power. Microsoft Company is additionally making an attempt to determine its knowledge Centre building close to Washington for electricity power money services company (HSBC) is making ready its building of information Centre close to Niagara Falls for cooling and low energy consumption. In knowledge centre the servers evolve an outsized quantity of warmth therefore for his or her cooling company establishes totally air-con equipment's. The lot of powerful instrumentation of servers and so a lot of cooling needed from warming and secure operating accurately. Consistent with the report of employee scientists Jonathan Koomey of Lawrence Berkeley National Laboratory and AMD that was free in 2005 to chill and power the servers one.2% of total USA electricity is needed. In 2010 consistent with Gartner the 2000 world companies can pay a lot of energy on knowledge centers on servers than hardware's of the computers. Kumar says that energy prices is currently 100% of the common IT budget of the planet can increase five hundredth in next few years. The percentage of greenhouse gas is increasing terribly quickly. The annual rise of the greenhouse gas in air is given in Figure 2.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Annual rise of greenhouse gas in air
(Taruna, 2014)

**For a more accurate representation see the electronic version.*

The graph shows that annual emission of greenhouse gas in past years, the black, blue and brown lines show the rise of greenhouse gas owing to cool, fossil fuel and oil severally and therefore the line shows the whole emission of greenhouse gas including all such factors that additionally includes physical science.

If we tend to see the energy consumption throughout the particular use of the merchandise and through the standby mode, we tend to observe that in the standby mode the energy consumption quantitative relation is a lot of. e.g. Ink jet printer use twelve watts during use whereas printing and take five watts throughout idle state. Table 1 shows the facts and figure clearly.

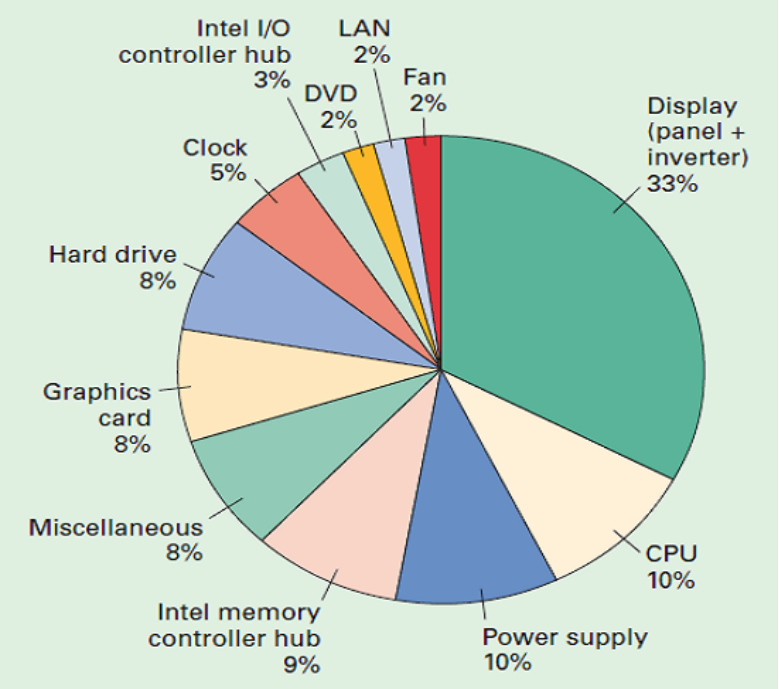
Different physical science merchandise use completely different energy consumption. during this table it's seen that if we tend to switch off the merchandise once victimization, we will save an outsized quantity of energy which might be utilized different functions. By this way, we will decrease our budget annually and supply higher setting to the planet. Intel printed a report regarding green computing within which they showed that elements of laptop use energy especially monitor or show consumes an outsized quantity of energy.

Table 1. The annual power wastage and price

Appliance	Hours per Day	Watt When on	Annual Cost of Use	Watt on Stand by	Annual Cost on Standby	% Wasted
TV	2	75	$ 7.12	14	$ 14.61	67%
VCR	1	15	$0.07	8	$9.07	99%
Computer	2	60	$5.69	13	$13.57	70%
Micro wave	25	1700	$20.17	24	$27.05	57%
Battery Charger	6	12	$ 3.41	10	$3.79	53%
Total cost			$ 49.36		$ 104.50	

(Priya Rana (2010))

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



If we tend to turn off of the portable computer once it's idle state. we will save energy and cash. The PC architecture try to line up such style within which show unit consume less energy/power. within the figure two it has been seen that in portable computer all elements consume energy however show unit consume abundant energy that is one third (1/3) of the whole energy consumed by a portable computer. Most a part of the energy is wasted throughout process within the kind of heat that is the loss of energy and sources.

In Figure 3 it's clear that show unit of the portable computer is intense abundant energy that's thirty third of the total energy consumed by a portable computer. It's been that the portable computer is incredibly stunning however its battery charging efficiency isn't smart. The performance of the CPU depends upon the battery of the portable computer.

PRESENT SCENARIO

These days with fast increase in technology, electronic merchandise square measure used for brief span and older merchandise square measure drop often. One reason is replacement is way cheaper than repairing of electronic gadgets. in keeping with North American nation environmental protection agency several electronic products that don't seem to be in used i.e. regarding 3/4th in quantity were thrown away either drop in waste, unused, aggressive land i.e. Landfills or destroy by burning or exported to completely different countries like Asian countries.

Figure 3. Power Consumption of average lap top
(Willium & Curtis, 2008)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

If drop in unused lands, then the virulent chemicals made by this electronic product either unleash within the atmosphere or get combine into soil and water. In European countries measures are taken to forestall such style of electronic waste disposing. By burning chemicals like lead, mercury, cadmium-ashes square measure combining in air that is such a lot harmful that it unwell impact organic phenomenon. As, whereas burning PVC plastic that is gift in creating laptop and in several physical science elements produces dioxins and frame that once more is dangerous.

Another methodology followed by developing countries currently is to export their e-waste to developing countries usage that is happening over this electronic waste may be a smart factor, however a lot of that the unsatisfactory purpose is that the method the raw materials from this merchandise square measure processed and handled, which might hurt the employees World Health Organization square measure handling this merchandise whereas usage moreover as is harmful to surroundings.

The distinction between the usage method in developed and developing countries is that, in developed countries like Europeans elements, a number of the e-waste like plastics don't seem to be reprocessed to evade brominates furans and dioxins being discharged, whereas in developing countries there's no such steps condemned usage. During a survey of 2005, eighteen Europeans seaports were inspected and it's found that regarding 475 of e-waste was tried to export lawlessly. this is often conjointly a serious concern that violation of law of nations are happening to urge eliminate e-waste to such associate degree extent that in UK alone a minimum of twenty 3,000 metric tons was lawlessly shipped to Republic of India, continent and China (Taruna, 2014). In this method, in North American nation conjointly it's found that 50-80% of the waste ought to be used for usage in their country.

It is lawlessly exported, China tried to solved this major drawback by prohibition the import of e-waste, however these laws don't seems to be operating as still tones of e-waste is foreign lawlessly (Figure 4). A best example is GUIYA of GWANGDONG province, Republic of India conjointly facing this e-waste trade drawback. Several scrap yards may be seen in metropolis, Mumbai, Bangalore, Firozabad, Meerut, were thousands of employees square measure leading perished life as a result of they're thinking to earn for these days discarding the thought that what is going to happen to them tomorrow.

If they still board between dangerous chemicals. Now, why developed countries square measuring selling, exportation their e-waste in developing countries, answer is that the low value of usage. To

Figure 4. Landfills due improper disposal of computers

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

recycle a glass of monitor in North American nation it'll value ten times a lot of then in any developing countries, and why developing countries square measure mercantilism these e-waste answer is –recycling of this e-waste will extract substance like copper, nickel, iron, gold, silicon-by mercantilism these metals scraps recyclers will create cash.

It is cheaper to own the arduous labor of pull apart and melting down items done place aspect the country although which means the useless scraps and alternative dangerous materials can litter that space (Wikibooks, 2002). And in developing countries in contrast to developed countries laws, are in abdicate. individuals square measure taking job in their scrap yards as a result of it offers them tight wages to measure and infrequently kids square measure seizing their jobs, that square measure terribly dangerous for his or her health. Surroundings in developed countries is paying a lot of specialize in priority over the profit drawing specially in business and economy, and innovation in own hometown than social control of laws. It's not higher to ship developed countries electronic waste to alternative countries for disposal rather than- proper strategies ought to be created to recycle most element utilized in producing and usage of minimum dangerous chemicals and last although to dispose their e-waste, disposal should be complete 100% eco-friendly method.

It will be higher to use completely different chemical composition for brand new discovery in order that single chemical won't reside in atmosphere in abundance, as a result of the abundance presence of specific component will cause major dangerous effects.

One way that EU has adopted, that is kind of spectacular conjointly is- once producing associate degree instrumentality, manufacturer is accountable financially or physically for his or her instrumentality, until their survivability- that arises a competitive encouragement for corporations to set up greener merchandise (Wikibooks, 2002).

The strategies, operations that China, Republic of India and Islamic Republic of Pakistan has adopted- that's the e-waste usage and discarding square measure extraordinarily polluting and is extremely unhealthy for humans. Examples as well as open burning of plastic waste, exposure of virulent solders, stream selling of acids, and widespread general selling.

In developing countries stakeholders customers square measure probing for smart facility however cheaper product. In keeping with Basel Action Network administrator Jim Pockett- once associate degree electronic waste is taken for recycler, eightieth of that material is loaded in instrumentality ship, aiming to countries like Republic of India, China, Pakistan, wherever the worst happens to that (Wikibooks, 2002).

In developing countries stakeholders /customers square measure probing for heaper smart facility profitable product, once a budget word comes means that comprising with the weather utilized in the manufacture of product, as star merchandise square measure very little expensive however a lot of surroundings friendly ;this a good drawback as in developing countries versus developed countries price of currencies encompasses a large distinction that also plays a key role in selecting the merchandise, moreover as makes a good gap within the non-public sector businesses.

POLICIES IN DEVELOPED COUNTRIES

Many government programs round the world nowadays centered on environmental property, are exploring technology initiatives for reducing greenhouse gases. As an example, the ministry of science, technology and innovation, of Denmark's efforts for Green IT institution and another example is from

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the ministry of economy, trade and business of Japan- that established Green IT initiative, which give a robust model of Green innovation policy.

The two organizations people example USA Department of Energy (DOE) and therefore USA Environmental Protection Agency (EPA) has also initiated within the field of Green ICT. Technology is also necessary to in also necessary to Green innovation however strategic public policy is crucial. To encourage clean energy projects, the USA administrations has dedicated $71 billion US to scrub energy funding with a supplementary people $20 billion for loan assurance and tax input (Araya, 2010).

The temperature change at (2008) sets a wrongfully binding objective for diminish kingdom greenhouse gas emission by eightieth from 1990 levels by 2050 (Porritt, 2010).

In Australian Government's ICT property set up 2010-15 Tony Chan pointed plans and actions for the agencies to reduce their unharnessed (Chan, 2010).

The ROHS (Restriction of the utilization of bound venturesome Substances in Electrical and Electronic equipment) laws (directive 2004/95/EC), operative since thirteen February 2003, is marked because the initial law within the world that limits the utilization (2004/95/EC), operative since thirteen February 2003, is marked because the initial law within the world that limits the utilization of venturesome substances in electrical and equipment.

Six nephrotoxic substances are constricted: lead, mercury, cadmium, hexavalent atomic number 24, poly brominates biphenyls (PVV) and poly brominates diphenyl ethers (PEDS). For metallic elements, the most worth that is been set is 0.01%, that is Associate in Nursing exception case and for others it's been thought about the worth shouldn't exceed 0.1%.

The WEEE (Waste Electrical and electronic equipment) legislation (directive 2002/96/EC) has conjointly are available in force on thirteen February 2003.This regulation is regarding assortment, utilization and return of electronic merchandise. It's supported take back system wherever the used product will be came back by the shoppers that are freed from price and also the authority is given to the assembly team for managing e-waste properly (Hanne, 2011). Green grid pool may be a tremendous initiative. It is a world association of corporations devoted to developing and endorses standards, measuring methodology, processes and new technologies that lead to energy potency in information centers (The Green Grid, 2010).

POLICIES IN DEVELOPING COUNTRIES

In Kobenhavn summit, Republic of India has committed to reduce IT emission by 20-25% as compared to the 2005 emission levels. For Green Republic of India, Government of Republic of India, ministry of environment and forest (2011) has conjointly initiated few steps beneath National Action set up on Climate Change (NAPCC). They need projected tentative action set up for implementation of Green Republic of India mission throughout 2011 to 2012 (Kavita Suryawanshi, 2012).

To control Associate in nursing increasing downside in Africa, Safaricom has initiated Associate in nursing e-waste theme in African nation, in conjunction with African nation. In Africa, most of the utilization is finished on a straightforward go, casual, free basis typically in wild ungoverned dumpsites or landfills. The problem is that the majority African countries don't however have policies in situ to support the established of e-waste plants. Republic of Zambia alone has regarding ten million mobile users, the estimation is given by the Republic of Zambia info and Communication Technology Authority (ZICTA) that is that the regulator of states medium sector. Most of the countries are counterfeit devices

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

from China that simply last many months and are disposal of carelessly. AS compared to different regions the usage of electrical Associate in nursing equipment isn't to it extent high however still it's increasing in an unpleasant part (Malakata, 2014).

MAIN PROBLEM AND ISSUES

As we all know that these days the most issue is that the manufactures are making ready such devices that are however additional economical and correct however they use additional energy and evolve terribly toxics, dangerous gases and chemicals. Several physical science firms particularly in pc use lead, mercury, metal and different toxics chemicals. It's been calculated that in producing of computers will four to eight pounds of lead alone.

According to a replacement analysis it's calculable that computers and different physical science devices form up two-fifth of all lead in land-fills on the planet. Thanks to this reason pollution is increasing terribly quickly. Information center servers use fifty times additional the energy per sq. ft. as in workplace. Information centers are the most energy consumption sources. In a survey in America energy consumed by information center in USA and every one over the globe are going to be doubled in next few years.

DISTINCTIVE FEATURES OF A GREEN COMPUTER

Green pc options facilitate in crucial whether or not the pc users obtain is actually green or not. Most computer makers have introduced a series of green PCs, however don't investigate the subsequent options to establish however green their computers are.

- **Low Use of Risky Elements:** Plenty of risky substances are utilized in the assembly of a pc starting from the additional deadly ones like metal, lead, chromium, and mercury to the comparatively less risky ones like flame retardants, pesticides, and chlorinated plastics. A Green PC parts ought to ideally be fully freed from these deadly substances; so IEEE environmental performance criteria needs the makers of green computers to expressly declare the share composition of those substances on the merchandise. As for the less risky substances, the main focus is on reduction of their use, since their elimination might not be fully doable.
- Energy potency is one among the options of Green Computers that pleases not solely the environmental enthusiasts however conjointly the budget-conscious purchaser. Each Green PC can have associate energy star rating on that, and therefore the additional the celebrities the additional energy economical the pare going to be. Some Green computers are accessible with the choice of running them on renewable energy like solar power that the makers can provide with all the desired accessories.
    - **Recycled Materials Used for Manufacturing:** A really Green PC can have most of its parts, particularly the plastic ones, made from recycled materials. So, the makers are needed to declare of recycled material utilized in the assembly of the PC and it ought to be with minimum thresholds at 10 percent. However, it's additional environmentally friendly to decide on a PC designed with quite twenty-five % of recycled material. Ideally, computer circuit boards are the sole things which will not contain recycled material.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Finish of Life Recovery:** The Green computers are designed in such how that at the tip of their life their parts is simply reused, disassembled, or recycled. A minimum of sixty fifth of the components of the pc ought to be useful or reusable. Apparently, a number of the higher brands of Green computers guarantee a minimum of ninetieth reusable or useful components. Also, the components that are risky ought to be marked consequently for straight forward identification and skilled handling.
- **Use of Renewable and Bio-Based Materials:** Another of the necessary inexperienced pc feature is that the accumulated use of renewable or bio-based materials. once more a minimum of 10% of such materials ought to be utilized in the production of the Green PC parts, and therefore the same should be declared.
- **Longer Life:** Green computers are available standard and upgradeable styles with the thought of extending their life cycle. The makers are needed to produce a minimum of three years warrant or guarantee, and that they should conjointly ensure that the replacement components are going to be created accessible to all or any patron's up to a minimum of 5 years and this is often definitely an honest reason to shop for a Green PC.
- **Finish of Life Take-Back Facility:** Each Green PC comes with a take back policy, whereby the manufacturer provisions to require back the pc at the tip of its life and provide the customer a replacement purchase at a competitive worth. Hence, it's obligatory to verify the complete of Green PC in shopping for or taking back.
- **Manufacturer's Certification:** Before decide on a selected complete of inexperienced computers, should make sure that its manufacturer has ISO-14001 certification, that is that the clean minimum for a manufacturer to qualify as environmental policy compliant.
- **Packaging Material:** More the question of the fabric utilized in useful packages too necessary. Therefore, checking the packaging material details is essential to check that the fabric used is totally non-toxic and a minimum of ninetieth of it's useful. It'll be even higher if the packaging is formed of recycled material.
- **EPEAT Ratings:** Before creating the ultimate call of the acquisition slightly of analysis on WWW.epeat.net, wherever all Green computers and laptops are allotted a rating and. Clearly tell however green the pc is and with this the buyer can notice careful reports on however every of those computers score on the various environmental criteria.

WORK IN GREEN COMPUTING

Today computers play important role in our lives. Computers are the wealth of data of internet. It's in no time in communication and to share alternative peoples. These are its smart qualities however it takes plenty of energy to form, package, and store and move knowledge from one place to alternative once technology changes then the computer are drop during lowland. It's a significant downside and it produces pollution. Once Manufacturer Company prepares computers, then these use lead, cadmium, mercury and alternative cytotoxic materials. It's been calculable that four to 8 pound of lead alone is employed during a single pc. Computers and alternative physics create (2/5) of all lead in lowland, because of this reason it's realizing that Green PC ought to introduce. Within the starting in computers it had been given attention their speed, worth and price. However currently it's tried that these devices use less and less energy. Currently such material is developed that is a lot of green and cytotoxic material is exchange by

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

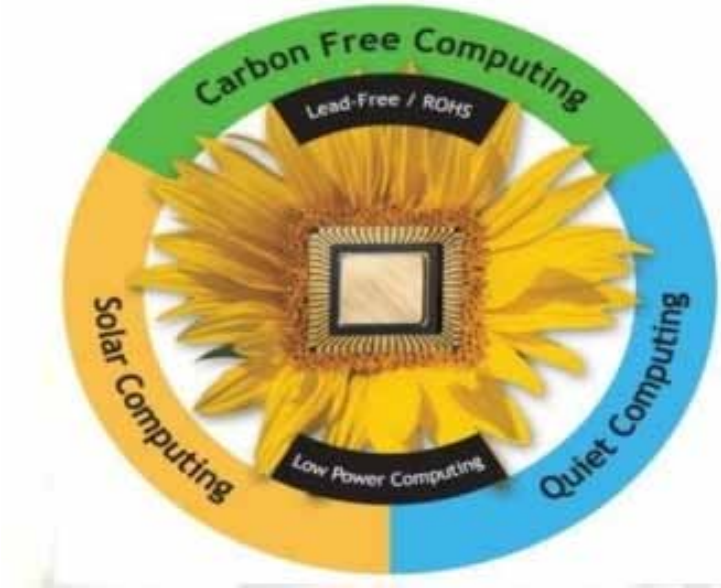
them. It has been guessed that carbonic acid gas emission, heating and climate changes are becoming hotter to hotter. It is calculable that out $250 billion power per annum is spent within which V-day of that power is spent on computing. Faster processor use a lot of energy and slower or inefficient processor may additionally use double power that is that the wastage of energy in style of heat that produce pollution in the environment. The waste heat conjointly causes reliability issues in central processing unit because it might crash because of abundant temperature. Equally he facility offer that are used in PC are inefficient. It has been calculable that these are forty seventh of total offers. However currently power offer technology has been changed, as a result of it's accepted that each one components of pc rely upon power offer. That the economical and low energy consumption is introduced. Currently eightieth offer are a lot of economical. Software package that manage power are also facilitate the PC to sleep or log of or hibernate once computer isn't in use.

GREEN COMPUTING, PROBLEMS AND ADVANTAGES

1. In engineering virtualization is an incredibly vital effective tool. It's value effective, Green energy and efficient computing. During this tool the most servers is split into multiple virtual machines that facilitate the server to run completely different applications. By exploitation this system corporations will enhance their server utilization rates.
2. The businesses ought to manufacture such processors that use low energy. Intel, Sun and Advance small Devices (AMD) are currently attempting to manufacture such processor. Sun has designed multicore processors that are terribly economical regarding fuel.
3. In computers power choice setting is additionally useful, within which sleep mode is active, once the system isn't working. It's an honest follow. These features are often set through PC's control board. It takes PC's in standby mode and switch off the monitor, once laptop is in idle mode.
4. It's conjointly determined that flat monitor use less energy than electron beam tube (CRT) monitor. Liquid display (LCD) uses terribly low energy than typical monitor.
5. Disk drives take less power than alternative physical components of PC. Currently solid state drives as flash memory or DRAM is accustomed store knowledge. They take less energy as a result of they need no moving half, so the energy consumption could also be reduced as compared to the disk.
6. We must always use print paper only if we'd like. We will browse soft copy. If we wish textual matter (print copy), we ought to use such variety of printers that have the capability to print the paper each aspect. It reduces paper consumption and energy consumption. Recycled used ink in powder type and toner of the printer are often used again.
7. Screen savers are active once system is in idle state, if we have a tendency to permit the monitor to travel to standby mode throughout idle state of the PC. It'll conjointly decrease energy consumption.
8. PC manufacturer ought to design such a variety of pcs which might be battery-powered from non-typical sources of energy like Sun energy, air energy, pedaling a motorbike, turning a hand crank etc.
9. In pc some devices also are vital. Video card, graphic card, 3D performance software package take a really great amount of energy. If we have a tendency to use older video card, these cards use very little power. In these cards, there is not a heat sink or fan. Green Computing will facilitate United States of America to secure and safe place for United States of America within the world. If every

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

person attempts to save the atmosphere, then our mother earth can healthy and happy for survival. Here are given some advantages of Green computing, it helps United States of America to scale back the quantity of pollution in air or close. It saves the facility consumption and reduces the quantity of warmth that evolved the merchandise. It conjointly reduces the pressure on paper trade that could be a main issue. Renewable resources are inspired to use once more Green Computing facilitate to market the effective utilization of natural resources. It conjointly promotes United States of America to avoid such merchandise that destroys green computing.



AN EXAMPLE OF VIA TECHNOLOGIES GREEN COMPUTING

VIA Technologies, a Taiwanese company that manufactures motherboard chipsets, CPUs, and alternative element, introduced its initiative for "green computing" in 2001. With this green vision, the corporate has been that specialize in power potency throughout the look and producing process of its merchandise. Its environmentally friendly merchandise area unit factory-made employing a vary of fresh computing ways, and also the company is endeavor to coach markets on the advantages of green computing for the sake of the setting, additionally as productivity and overall user expertise.

Carbon-Free Computing

One of the VIA Technologies' concepts is to scale back the "carbon footprint" of users — the number of greenhouse gases created, measured in units of dioxide (CO_2). Greenhouse gases naturally blanket the planet and area unit answerable for its additional or less stable temperature. A rise within the concentration of the most greenhouse gases – dioxide, methane, inhalation general anesthetic, concentration of

Figure 5. Green computing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the most greenhouse gases — dioxide, methane, inhalation general anesthetic, and fluorocarbons — is believed to be answerable for Earth's increasing temperature, that could lead on to severe floods and droughts, rising ocean levels, and alternative environmental effects, touching each life and the world's economy. When the 1997 city Protocol for the international organization Framework Convention on Climate amendment, the globe has finally taken the primary step in reducing emissions. The emissions area unit mainly a results of fossil-fuel-burning power plants. (In the us, such electricity generation is answerable for thirty-eight PC of the country's dioxide emissions.) VIA aims to supply the world's 1st laptop merchandise certified carbon free, taking responsibility for the amounts of greenhouse gas they emit. The corporate works with environmental consultants to calculate the electricity used by the device over its life, typically 3 years. From this information, one will conclude what quantity carbon dioxide the device can emit into the atmosphere throughout its operation. This estimate can serve as associate degree indicator, and also the company can pay regional organizations for the – sequestering, or offsetting, of the emissions. Counteractive dioxide are often achieved in numerous ways in which, one way is to plant trees that absorb greenhouse gas as they grow, within the region within which the processors were purchased. The necessary quantity of trees per processor is described by VIA's Tree Mark scoring system. VIA promotes the employment of such energy sources as solar energy, thus power plants would not go to bum the maximum amount fossil fuels, reducing the number of energy used. Wetlands conjointly offer a good service in sequestering a number of the dioxide emitted into the atmosphere through they create up solely four to PC of the Earth's terra firma, wetlands area unit capable of interesting twenty-five PC of the atmospheric dioxide. VIA is functioning closely with organizations answerable for protective wetlands and alternative natural habitats, et al United Nations agency support intensive use programs for ICT equipment. The numbers paid to those organizations are described by a proportion of the carbon free product's worth. Carbon-emissions management has been key issues for several corporations United Nations agency have expressed a firm commitment to property. Dingle could be a ideal of an organization with an inexperienced image, known for its free worldwide product-recycling program. Dell's Plant a Tree on behalf of me project permits customers to offset their carbon emission by paying an additional $2 to $4, counting on the merchandise purchased. AMD, a world chip manufacturer, is additionally operating toward reducing energy consumption in its merchandise, reducing on unsafe waste and reducing its eco-impact. The company's use of silicon-on-insulator (SOI) technology in its producing, and strained semiconductor capping films on transistors (known as dual stress liner technology), have contributed to reduced power consumption in its merchandise.

Solar Computing

Amid the international race toward alternative-energy sources, VIA is setting its eyes on the sun, and also the company's star Computing initiative could be a vital a part of its green-computing comes. For that purpose, VIA partnered with Motech Industries, one among the most important producers of star cells worldwide. Solar cells match VIA's power economical semiconductor, platform, and system technologies and alter the corporate to develop totally solar powered devices that area unit nonpolluting silent, and extremely reliable. star cells need little or no maintenance throughout their life, and once initial installation price area unit lined, they supply energy at just about no price. Worldwide production of solar cells has raised chop-chop over the previous couple of years; and as additional governments begin to acknowledge the advantages of solar energy, and also the development of electrical phenomenon technologies goes on, costs are expected to still decline. As a part expected to still decline. As a part

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of VIA's ——pc-1 initiative, the corporate established the first-ever solar-powered cyber civic center within the Pacific, powered entirely by star technology.

Quiet Computing

A central goal of VIA's green-computing initiative is that the development of energy-efficient platforms for low-power, small-form issue (SFF) computing devices. In 2005, the corporate introduced the VIA C7-M and VIA C7 processors that have a most power consumption of a pair of0W at 2.0GHz and a median power consumption of 1W. These energy-efficient processors turn out over fourfold less carbon throughout their operation and may be expeditiously embedded in solar- powered devices. VIA isn't the sole company to handle environmental concerns: Intel, the world's largest semiconductor maker, disclosed eco-friendly merchandise at a recent conference in London. The company uses virtualization computer code, a method that allows Intel to mix many physical systems into a virtual machine that runs on one, powerful base system, so considerably reducing power consumption. Earlier this year, Intel joined Google, Microsoft, and alternative corporations within the launch of the Climate Savers Computing Initiative that commits businesses to fulfill the Environmental Protection Agency's Energy Star tips for energy-efficient devices. Kevin Fisher, Intel's EU standards director, says that whereas the corporate is devoted to its green-computing plans, it's vital to not blame the IT business alone for carbon emissions worldwide. He argues that the business conjointly helps in saving vast amounts of power thanks to the web, enabling, as an example, on-line looking and asking. Worldwide, standby power is calculable to account for the maximum amount as one PC of worldwide greenhouse emissions. Most of the energy utilized by merchandise on standby doesn't result any helpful perform. A small amount are often required for maintaining memory or an enclosed clock, remote-control activation, or alternative features; however most standby power is wasted energy. Energy Star–enabled merchandise minimizes this waste.

STEPS TO GREEN COMPUTING

1. Develop a property inexperienced computing set up. See the business leaders the weather that ought to be factored into such a concept, as well as structure policies and checklists. Such a concept ought to embrace utilization policies, recommendations for disposal of used instrumentation, government pointers and proposals for buying proposals for buying green PC instrumentation. Green Computing best practices and policies ought to cowl power usage, reduction of paper Consumption, in addition as recommendations for brand spanking new instrumentation and utilization recent machines. Organizational policies ought to embrace communication and implementation.
2. Recycle Discard used or unwanted equipment in a very convenient and environmentally accountable manner. Computers have poison metals and pollutants that may emit harmful emissions into the setting. ne'er discard computers in a very lowland. Recycle them instead through manufacturer programs like HP's Planet Partners utilization service or utilization facilities in your community. Or give still-working computers to a non-profit agency.
3. Create environmentally sound purchase choices. Purchase Electronic Product Environmental Assessment Tool registered product. EPEAT could be a procurance tool promoted by the non-profit-making in experienced physical science Council to:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

a. Facilitate institutional purchaser's measure, compare and choose desktop computers, notebooks and monitors supported environmental attributes.
b. Give a transparent, consistent set of performance criteria for the planning of product.
c. Acknowledge manufacturer efforts to scale back the environmental impact of product by reducing or eliminating environmentally sensitive materials, planning for longevity and reducing packaging materials.

4. Scale back Paper Consumption. There square measure several simple, obvious ways that to scale back paper consumption: email, electronic archiving, and use the ——track changes feature in electronic documents, instead of separate corrections on paper. after you do print out documents, make certain to use either side of the paper, recycle frequently, use smaller fonts and margins, and by selection print needed pages.
5. Conserve energy close up your pc after you understand you won't use it for associate degree extended amount of your time. Activate power management options throughout shorter periods of inactivity. Power management permits monitors and computers to enter low-power states once sitting idle. By merely striking the keyboard or moving the mouse, the pc or monitors awakens from its low power sleep mode in seconds. Power management techniques will save energy and facilitate shield the setting.

SUSTAINING THE LONGER TERM

- The greatest challenges for businesses making an attempt to be eco-responsible square measure very understanding what that basically means that, and then creating changes that square measure property over time, whereas adding business worth.
- Another challenge is leveling the requirements of assorted stakeholders United Nations agency every have completely differently ideas of what changes ought to be created. Some environment non- governmental organizations would really like sure flame retardants far from electronic product, whereas the fireplace safety community thinks. About removing or dynamical flame retardants in physical science. One drawback is that the substitute replacements square measure fairly new, they need not been essentially assessed with identical rigor applied to the first materials.

SOLUTIONS TO BE ADOPTED

As E-waste square measure originating day by day in developed countries and even turning into issues for everybody, thus currently it's time to scale back the impact of e-waste and to require a necessary steps towards Green Computing to create our surroundings clean and free from all this sort of nephrotoxic chemicals. One amongst the solutions concerning this be in and of itself the countries particularly focusing towards the developing countries should ought to undergo the policies strictly or to adopt this policy seriously that the govt. are secure.

The developing countries should conjointly avoid into take a waste from the developed countries at low cost. Victimization them for producing of another product that price them low cost as doing so. Another resolution may be with the contribution of voters in addition because the manufacturers/producers. The voters or customers may contribute towards this by creating their desirable option to buy

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

those electronic products which might be recycled or it may be use and conjointly those that contains a less nephrotoxic chemicals.

In academic institutes create Green IT subject a required one instead of associate degree nonobligatory one, in order that new ideas may be developed by students, supported green IT and there upon on innovation during this field that would create product a lot of cheaper and fewer venturesome and may have the skills to draw in a lot of customers than traditional product. By introducing in academic establishments is that the solely thanks to invite a lot of project and ideas. Awards, scholarships ought to be created to extend a lot of and a lot of contribution during this field. Awareness among public is needed however what if cheaper healthy product square measure launched in market positively individuals can get drawn to get them. Like on each health venturesome product warning is come back same approach on electronic gadgets it ought to be written weather it's green product or not. Government ought to charge further tax on those corporation that aren't following Green ICT rules as well as not manufacturing green ICT product.

CONCLUSION

Green computing represents an accountable thanks to address the problem of worldwide warming. By adopting green computing practices, business leaders will contribute completely to setting stewardship—and shield the environment whereas conjointly reducing energy and paper prices.

Chapter 34
Green Specifications:
A Concrete Example

Thomas Schulze
University of Mannheim, Germany

Colin Atkinson
University of Mannheim, Germany

ABSTRACT

Green specifications provide a foundation for reducing the environmental impact of computing applications and improving the consumption behavior of users by providing a clear and precise specification of the environmental impact of specific services. They can either be used to specify the actual behavior and environmental impact of existing services or to define the requirements that a to-be-built service must fulfill. Green specifications describe the properties of a service from distinct viewpoints such as a structural viewpoint which describes the data types and external components that the service uses, a functional viewpoint which describes the effects of the service's operations using pre- and post- conditions and a behavioral viewpoint which describes the externally visible states and transitions exhibited by the service. These are augmented with non-functional information describing the environmental properties of, or constraints on, the service. In this chapter we provide an introduction to green specifications and give a concrete example of their use to specify a Video on Demand (VoD) service.

INTRODUCTION

With the growing impact of computing on global warming, it is imperative that the environmental cost of IT services be reduced and that the consumption behavior of users be moderated. Green specifications (Atkinson & Schulze, 2013; Atkinson, Schulze & Klingert, 2014) provide the foundation for these improvements by providing clear and widely-understandable descriptions of the environmental cost of computing services in relation to what they do. They can either be used to describe the as-is properties of an existing service, or the required properties of a yet-to-be-built service. Only when both of these elements are unified (i.e. provided functionality and environmental impact) is it possible for service providers to arrive at optimal tradeoffs and for users to make the most informed consumption choice.

The goal of this chapter is to provide a concrete example of green specifications applied to the specification of a realistic service, and to show how they can be used to reduce the impact of consumption of the service on the environment. The chosen example, a Video on Demand (VoD) service is a highly relevant one because a recent study by Sandvine stated that the two video streaming services Netflix and YouTube account for about 50% of all North American downstream traffic. In this chapter we therefore use green specifications to describe the required properties of an exemplary, yet-to-be-built VoD system which we call SoftFlix. Although exemplary, we have strived to make the functionality and environmental costs of the service as realistic as possible.

The concept of green specifications is a general one, and in principle any existing specification technique can be enhanced to make it "green". However, to have maximum impact green specifications need to be understandable by the largest possible range of stakeholders in IT services, not just the service providers and system implementers. The green specification approach we apply in this chapter is therefore based on a simple yet comprehensive specification technique specifically developed to support widely-understandable specifications – the KobrA method (Atkinson., Bayer & Muthig, 2000). This makes extensive use of graphical UML diagrams and tables to describe the required properties of services from various different viewpoints.

In the next section we provide the necessary background needed to understand the green specifications described in this chapter. In particular we describe the relevant features of the KobrA development method, the concept of GreenSLAs, which provide a stepping stone to the notion of green specifications, and other existing optimization techniques which are used today to improve the efficiency of IT service. In section 3 that follows, we then introduce the SoftFlix VoD example and show how it can be specified using the standard KobrA approach. Section 4 continues by showing how the standard KobrA models from section 3 can be enhanced into green specifications by adding appropriate environmental impact constrains. In section 5 we then present some scenarios in which the information in the green specifications is used to enhance the eco-efficiency of the SoftFlix VoD service. In section 6 and 7 we provide an outlook on future work and conclude with some closing remarks.

BACKGROUND

In the past decade many optimization methods have been developed and applied to reduce the energy consumption and environmental impact of computing services. Green specifications make it possible to maximize the effect of some of them. In the following we will therefore provide the necessary background to understand why certain measures of green specifications lead to a reduction of the environmental impact. Furthermore, we will describe the KobrA approach in short, which is used in our example to specify the SoftFlix VoD service.

Existing Optimization Techniques

Recently developed optimization techniques operate at different levels of abstraction. The first, and most straight forward approach is to optimize the infrastructure. In data centers this includes the optimization of ESFs (Energy Storage Facilities) and HVAC (heating, ventilation, and air conditioning) systems as well as the actual servers. Especially since the invention of the PUE (power usage effectiveness) metric, the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

focus has narrowed towards the reduction of the energy consumption of the first. Free Air Cooling and other energy efficient HVAC systems make it possible to save large amounts of energy. The separation of cold and hot air in different isles enables further reductions. Furthermore, the development of new more energy efficient yet more robust server hardware allows higher room temperatures. In addition ice storage facilities can be installed in data centers to support HVAC systems during times where less renewable energy is available. By introducing these measures huge amounts of energy (i.e. 50 per cent and more) can be saved.

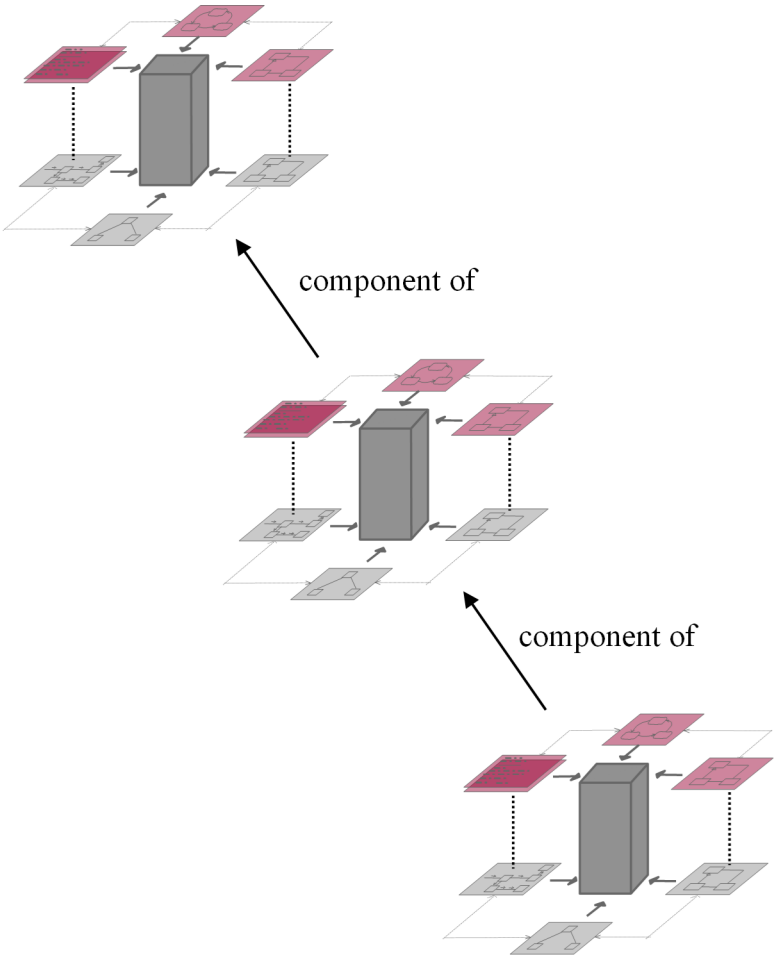
However, all of these approaches have one thing in common: They require large investments in new infrastructure equipment. Therefore, other approaches have been developed which focus on optimizing the utilization of the already existing infrastructure. The most prominent example is the technique of virtualization. By arranging for multiple user instances to share the same hardware infrastructure fewer servers are needed. In the European Union project FIT4Green (Basmadjian et al., 2010) for instance the framework plug4green was developed which consolidates virtual machines to fewer servers and dynamically switches off unneeded ones. On average these techniques led to savings of more than 20 per cent in a cloud data center. As well as maximizing resource utilization, virtualization allows computing tasks to be shifted in time or space to better fit the availability of renewable energy. As renewable energy sources like solar or wind are not always available, shifting utilization times can have a dramatic effect on CO_2 emissions. The two European Union Projects All4Green (Basmadjian et al., 2013) and DC4Cities (DC4Cities, 2014) are developing approaches to maximize the ability to use these techniques. However, virtualization is just one way to optimize utilization. Frequency scaling is another way to reduce the energy consumption in times of low utilization. Here, the frequency of the CPU or GPU is lowered. In addition, stand by modes have been developed that significantly reduce the time needed to startup servers. This means that they can be switched to standby mode in situations where they would normally have been kept switched on and kept operating in idle mode.

Even in data centers where all of the above mentioned optimization techniques are applied, it is possible to further reduce the energy consumption or environmental impact. Service Level Agreements (SLAs) are contracts between the data center provider and the customers specifying the rights and duties of both sides. One example is the guarantee term of an availability of 99.99 per cent which means that the service must be running 99.99 per cent of the time. While SLAs grant the customer a certain quality of service at the same time they restricts the data center in their range of possible optimization techniques. GreenSLAs have been proposed as a way to make SLAs more environmental friendly, by introducing more flexibility and environmental constraints. By using GreenSLAs, a customer can for instance define a lower availability during weekend and night times, which leads to reduced energy consumption. This frees the provider from having to guarantee continuous higher availability which would mean that more redundant infrastructure needs to be available therefore consuming more energy. The monetary gains derived by the data center can be partially forwarded as a reward to the customer as an incentive to provide the data center with these flexibilities in the first place. This leads to a win-win situation. GreenSLAs operate on the same service independent level as traditional SLAs. They do not normally focus on application dependent aspects. Green specifications build on the idea of GreenSLAs but apply them on an application dependent level thereby further extending the benefits of this technique.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

KobrA

The KobrA method (Atkinson., Bayer & Muthig, 2000) was defined in 2001 at a time when component-based development and model driven development were emerging as promising new technologies to provide developers with a means for describing the former (components) using the latter (UML models). Its solution was to adopt an inherently view-based approach to component specifications by strictly prescribing how different UML diagrams and tabular operation specifications should be used to model the properties of components from distinct perspectives. KobrA's basic strategy for doing this is illustrated schematically in Figure 1 which shows a system (i.e. service) containing three components, the second of which is contained within the first and the third of which is contained in the second. The system and the components are represented by the three cubes and the views of them by the artifacts surrounding them.



KobrA defines four basic principles by which UML diagrams and operation specifications should be used to describe the properties of a system or component:

- **Uniformity.** The principle of uniformity states that all stable, behavior-rich objects (i.e. architectural components) in a system should be modeled in the same basic way. This is the principle that dictates that a complete system (which in a sense is just a large component) be modeled in the same way as a simple data structure (e.g. a Hashtable). This is shown in Figure 1 by the fact that the top cube (representing the system) has the same constellation of views surrounding it as the other cubes (representing nested subcomponents).
- **Encapsulation.** The principle of encapsulation requires that all components be modeled from two perspectives – an external, black-box perspective from the viewpoint of clients of the component, and an internal, white-box perspective from the viewpoint of implementers of the component. The former viewpoint is called the specification of the component and the latter is called the realization of the component. In Figure 1 the upper set of views of a component (i.e. a cube), represent the specification views and the lower set of views represent the realization views. For the purposes of system or component specification, only the upper, purple views are relevant.
- **Locality.** The principle of locality, which is perhaps the most unusual and idiosyncratic principle of KobrA, requires that every view must be of a component or operation comprising the system (the subject of the view) and if it is explicitly represented in the view as a model element, that element must be specially labelled as being the "subject" of the view. Other components and operations may be modeled in the view, but only one component or operation can be the subject. Note that in Figure 1, every view points to a particular component (i.e. cube), which is the subject of the view.
- **Parsimony.** The principle of parsimony requires every view to contain exactly the right amount of information (i.e. model elements) needed to describe the properties of the subject from the perspective of that viewpoint – no more and no less. KobrA provides an extensive list of guidelines prescribing what type of UML elements, or textual elements should be used in each kind of view, and what information should be shown using them.

As mentioned previously, the views that are of relevance for specifying the externally visible properties of a component or system are the upper (purpose) specification views. As can be seen from Figure 1, KobrA specifications are made up of three kinds of specification views –

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

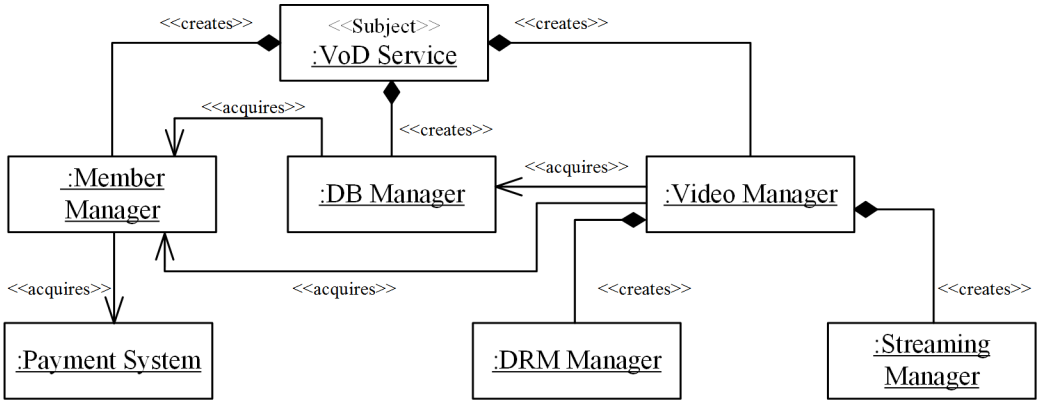
Figure 1. KobrA component hierarchy

- **Structural View.** The structural view describes the externally visible types and external components (e.g. services) which the system uses to deliver its own functionality, and takes the form of a UML class diagram. These external components are often called required services in other component models. Because of the principle of parsimony, model elements are only included in the view if they are needed for an understanding of the subject of the component. Moreover, that component/system is included in the view with a special label (i.e. stereotype) "subject" to indicate that it is the focus of the view. The other services/components that are acquired by the subject (i.e. so that it can use their services) are only shown from the perspective of the subject. In other words, only the attributes and methods of the acquired components that are used by the subject are included.
- **Operational View.** The operational view describes the functionality of the component. It is actually composed of a set of tabular operation specifications, each describing the effects of one operation of the component in terms of pre and post conditions. The original KobrA notation used a semi-formal style where the pre-and post-conditions were described in natural language, but with strict references to the information in the structural and behavioral views. A more formal form of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

operation specifications is also available which uses OCL expressions to define the pre and post conditions. In addition to the precondition (called "assumes") and post condition (called "result"), other possible rows in operation specification tables include a receives clause (the input parameters), a read clause (the referenced global data) and a changes clause (the referenced global data).

- **Behavioral View.** The behavioral view describes the externally visible states and state transitions visible to external users of the component/system and takes the form of a UML state diagram. The transitions in the state diagram correspond to invocations of the operations offered by the service, while the states correspond to situations where different sets of operations can be invoked.



As expressed by the principle of parsimony each of these views should contain only the minimum information necessary to characterize the properties of the components/system from the corresponding viewpoint. In addition KobrA defines a strict set of consistency rules which ensure that the information conveyed in the different views is consistent.

A KOBRA SPECIFICATION OF THE SOFTFLIX VOD SYSTEM

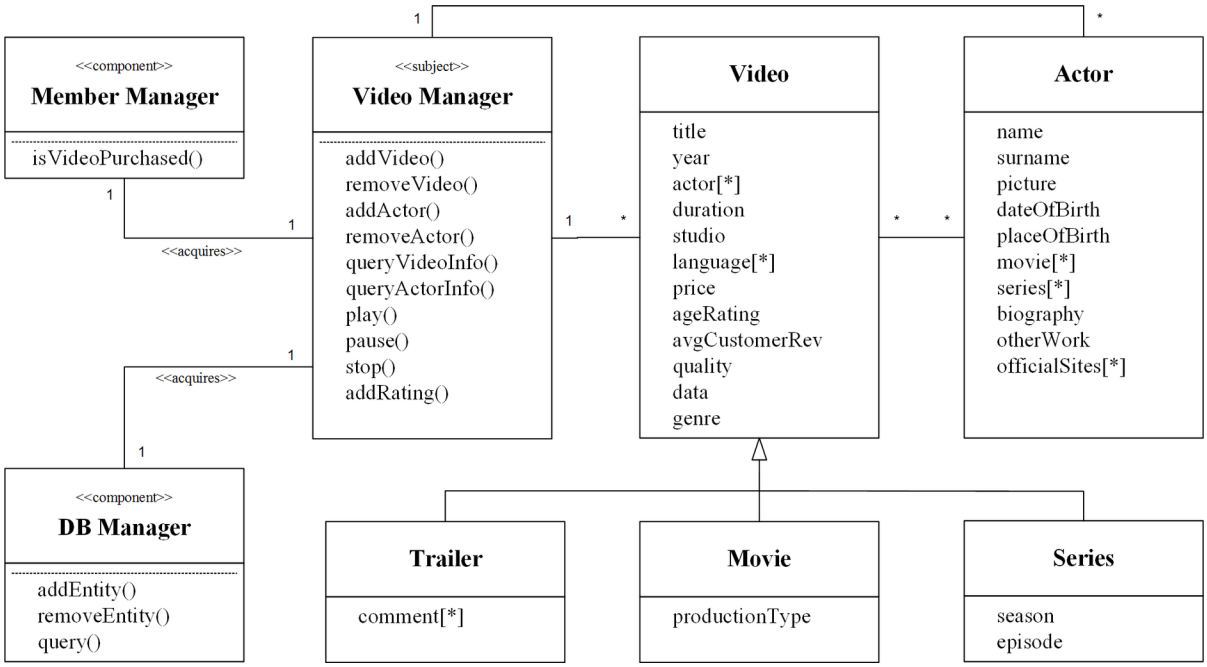
As mentioned previously, the example we will use to illustrate green specifications is a VoD service which we refer to as SoftFlix. More specifically, we focus on specifying the backend of the VoD service. In this section we show the normal KobrA specification for the component. The enhancement of these specification models to create a green specification is then demonstrated in the following section.

Figure 2 shows a high-level component model of the service. It is composed of three high-level components – The Member Manager, the DB Manager and the Video Manager. The Member Manager is responsible for all actions related to the user account like logging in and out, buying videos, as well as creating, modifying or removing information. It acquires the Payment System to handle the purchase of videos and the DB Manager to have access to the database. The DB Manager handles all read, write and query requests, and hides the details of the underlying implementation of the database. The Video Manager manages all actions related to the video itself like adding, removing or querying videos, but also playing or stopping videos. For the latter actions, the subcomponents DRM Manager and Streaming

Figure 2. High-level component model of a VoD service

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Manager are used. The first is responsible for enacting all digital right management actions, whereas the latter handles the streaming of the video to the user. In general, it is not essential to use a component diagram in KobrA. However, we have decided to include it here, as it helps to clarify the context for the diagrams provided in the next sections.



The Structural View

When specifying a software service it is important to characterize the information that is conveyed to the user in a specific context (i.e. the data types passed over its interface). As explained earlier KobrA uses UML class diagrams for this purpose.

Figure 3 shows the structural view specifying the Video Manager component. The Video Manager class is tagged with the stereotype <<subject>> explicitly marking the component for which the structure is described. It therefore sets the context and focus on the video manager. As indicated before, the principle of parsimony in KobrA requires that as little information as necessary is included in the structural specification. This means that nothing is contained in the diagram that does not directly belong to context of the Video Manager and is not visible from the outside. A method, for instance, which converts the video data into the correct format to be stored in the database is not externally visible and therefore not of relevance in the specification. The Video Manager offers ten externally visible methods to add, remove and query videos as well as actors, and provides the possibility to play, pause, stop and rate a video. The exact specification of each method is contained in the operational view described below.

All externally visible information relevant in the context of the video manager is provided and structured into the five classes, Video, Actor, Trailer, Movie and Series, where the latter three are subtypes

Figure 3. Structural view of a KobrA specification on the video manager

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of Video. The information concerning an actor therefore comprises the name, a picture, the date and place of birth, a biography, other work like theatre plays for instance, a list of official websites as well as a list of movies and a list of series they appeared in.

Furthermore, the two components Member Manager and DB Manager are acquired by the video manager. Again, due to the principle of parsimony only methods that are used in the context of the video manager are represented within this view. Thus, only the method isVideoPurchased() is shown here, even though, as we will show later, the member manager provides much more functionality.

The Operational View

As well as describing the data structures and services used by a service it is important to specify the exact functionality the service provides. In KobrA this is done in a tabular format through so called operation specifications. The most important attributes that are specified are the following:

- **Name:** The name of the operation
- **Description:** A short textual description of what the operation does
- **Receives:** The input parameters
- **Returns:** The output parameters
- **Assumes:** The pre-condition that must be met in order to guarantee the post-condition
- **Result:** The post-condition
- **Constraints:** Restrictions that limit the realization/implementation

For each operation specified in the structural view a functional description should be provided. Operation specifications only contain information that is visible to the outside, i.e. only describe what the operation does and not how it is done.

Table 1 shows the operation specification of the play operation located in the video manager. As explained in the description compartment, it retrieves the video from the database, then enacts DRM methods, namely watermarking and encryption, then encodes it to make it more fault tolerant and finally streams it. Note that even though the play operation actually consists of many steps (i.e. check,

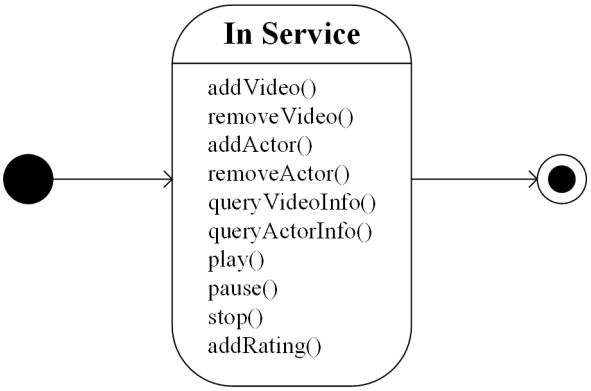
Table 1. A KobrA operation specification for the play operation of the video manager

Name	**play**
Description	The operation checks if the video was purchased, retrieves the video from the database, enacts DRM methods, encodes the video and streams it to the client
Receives	**name**: the name of the video which is supposed to be played **sessionID**: the session ID of the member who wants to watch the video
Returns	A protected and encoded video stream
Assumes	The VoD service has been started and a member has logged in
Result	• It was checked that the video was purchased by the member and was located in the database, • if the video was purchased and was located in the database, it has been retrieved from the database, • the watermark has been included into every frame of the video, • the video has been encrypted, • encoded, and • has been streamed

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

query, apply watermark, encrypt, encode and stream), it is perceived as one operation from the outside. It is, however, plausible to additionally have operation specifications for each of the different steps. For example the operation isVideoPurchased is part of the member manager which is acquired by the video manager (cf. Figure 7). For this method a separate operation specification should be defined. However, it is also used in the first step of the play operation. In terms of implementation, this will therefore be a simple method call in the play method.

The inputs specified in the receives row (Table 1), i.e. sessionID and the name of the video, are used on the one hand to check if the video was purchased and on the other hand to retrieve the video from the database. In case of a successful execution of the operation a protected and encoded video stream is returned as indicated by the return statement. However, in order to be able to execute the operation in the first place, two pre-conditions must be met: (1) the VoD service must have been started and (2) the member must be logged in. This is specified in the assumes row. Finally, the post-conditions are specified, i.e. what happened or has become true on completion of the operation that was not true before.



The Behavioral View

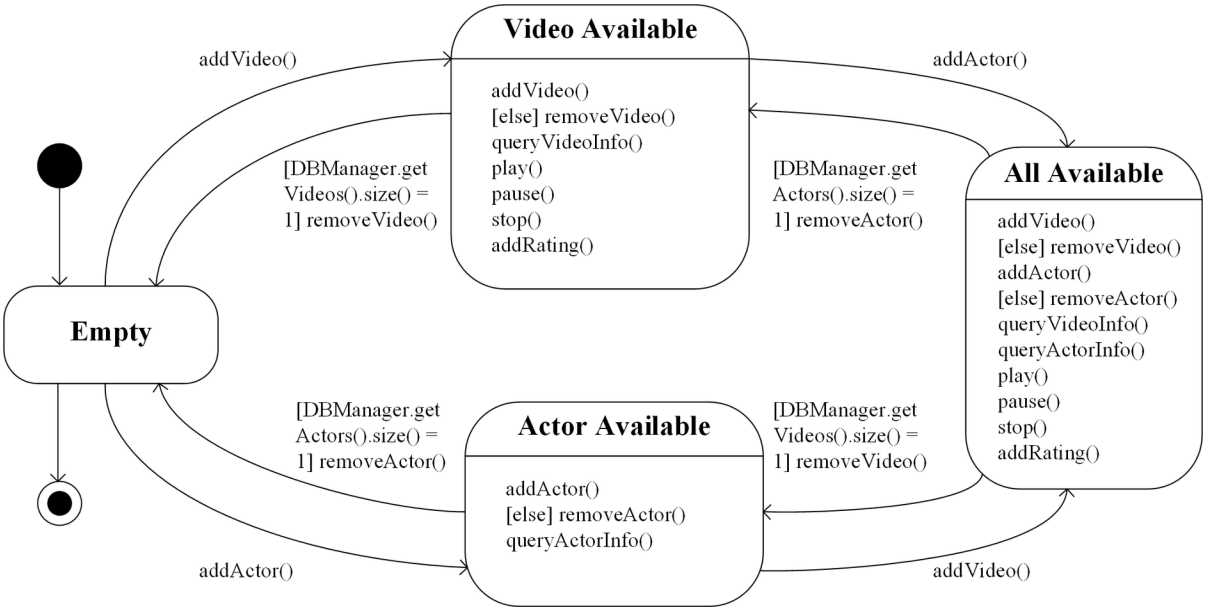
The third important topic to address during the specification of the software service is how the system behaves to certain events. The result of each event must be externally visible. In KobrA this is done using UML state chart diagrams.

Figure 4 shows the behavioral specification of the video manager. The state chart consists of only one state: In Service. When the service is in this state each of the ten operations contained within it can be executed. It is possible to add and remove videos and actors, query both video and actor information, play, pause and stop a video and furthermore add a rating to each video. After the execution of each operation, the video manager is again in the In Service state. Note, that every operation specified within the state chart must also be included in the structural specification (Figure 3) and should be specified in an operation specification (see e.g. Table 1).

Noticeably the state chart in Figure 4 is kept very simple. KobrA does not directly specify how detailed the specification should be. In general the rule of thumb is to include as little detail as possible but as much detail as necessary. In the example of the video manager, one could for instance introduce three other states called Video Available, Actor Available and All Available (cf. Figure 5). The intention

Figure 4. Behavioral specification of the video manager

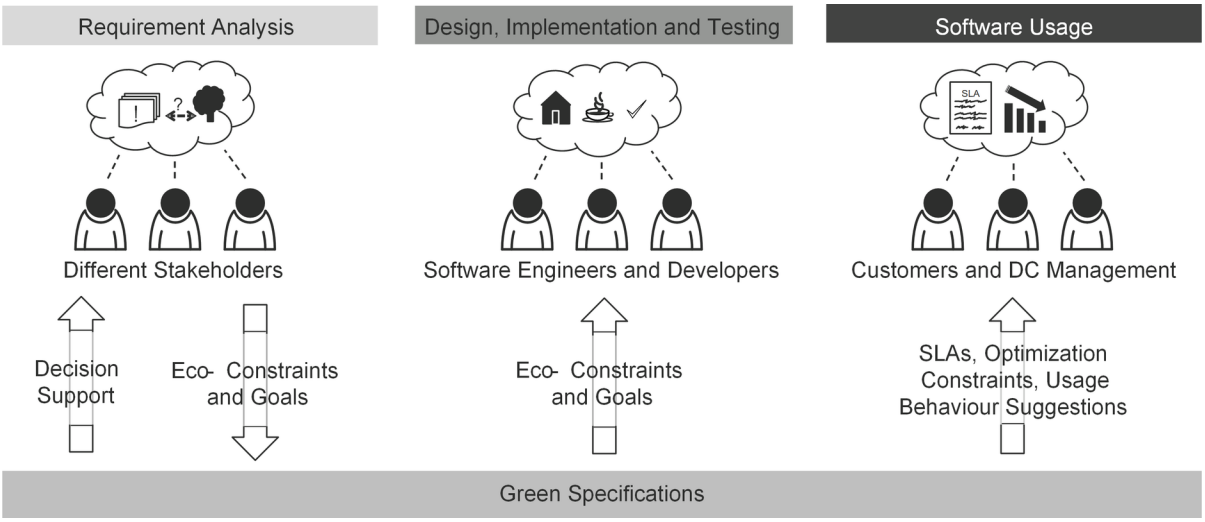
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



behind this is to explicitly specify that there are states during the first initialization of the VoD service in which not all operations are available due to missing entries in the data base. If there is no video or actor stored (state: Empty), the only possible operations are adding a video or an actor. If a video was added the video manager changes its state to Video Available. In this state it is possible to add another video, query video information, play, pause and stop the video, add a rating and also remove the video. If only one video is available in the data base at the point in time when the operation removeVideo is executed, the state changes to Empty again. In addition it is possible to add an actor. When adding an actor while in the Video Available state, the state changes to All Available, while if the current state is Empty, the state changes to Actor Available. In the latter state, it is only possible to execute operations related to an actor, namely add, remove and query actor information, or to add a video. If a video was added the state again changes to All Available.

It is difficult to give a general answer to the question whether the specification in Figure 5 is better than the one in Figure 4. This depends on the personal assessment of the involved stakeholders concerning the importance of the topic of an empty database. However, normally such a situation should only occur once during the initial setup phase and is therefore typically not of high relevance. The behavioral specification in Figure 4 should therefore meet the needs of a typical situation.

THE GREEN SPECIFICATION OF THE SOFTFLIX VOD SYSTEM



In the following, we will use the KobrA specification described in the previous section as a basis for our green specification of our SoftFlix VoD System. As explained previously, green specifications can be used for two basic purposes. They can be used to describe the as-is properties of an already implemented

Figure 5. More detailed behavioral specification of the video manager

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Impact of green specifications on the different service live-cycle phases

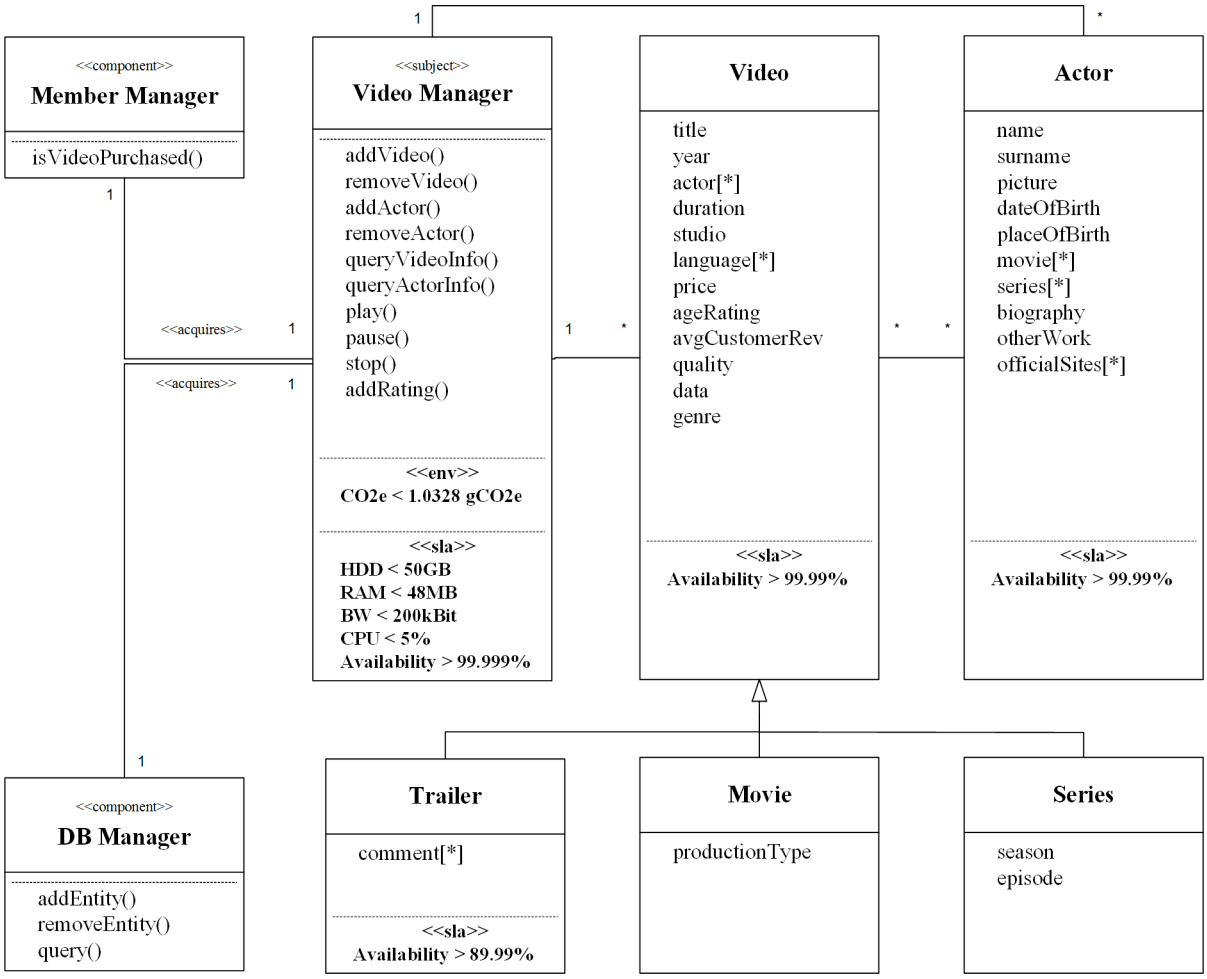
service and they can be used to described the requirements of a yet-to-be built services. In this section we focus on the latter.

Figure 6 shows the impact of green specifications on the different live cycle phases of the service. First green specifications can act as decision support during the requirement analysis. As we will illustrate later in this section, green specifications make it possible to anticipate the effects of the service on the environment based on the consumer's consumption choices. That means on the one hand that the awareness of green concerns is raised and on the other hand that the consumer's ability to balance the benefits of service consumption with the likely effects on the environment is raised. Second, green specifications are used to define constraints and SLA guarantee terms within the requirement process to which the developers and data center personnel have to adhere later in the design, implementation, testing and usage phase. It is for instance possible to limit the amount of energy used by a certain component by inserting the corresponding constraint in the green specification. The developers then have to adhere to this constraint by developing the component in a way that ensures its compliance. Furthermore, it is for example possible to define availability constraints for certain operations or components, i.e. SLA constraints and guarantee terms which have to be taken into consideration by the responsible data center personnel while the service is in use. Even though they are similar to regular GreenSLAs, the inclusion of such SLA terms within a green specification allows a significantly finer level of detail which as we will show shortly increases opportunities to reduce the environmental impact of services.

The Green Structural View

The structural view of the KobrA specification of the video manager (cf. Figure 3) is used as a basis for the structural view of the green specification. In order to be useful for developing green software the model is enriched with eco-efficiency constraints. Hence, the model is annotated with the stereotype <<env>> (cf. Figure 7) which specifies an environmental constraint the developer has to adhere to when implementing the service. Green specifications do not prescribe how this information is represented. It

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



is for instance possible to use the CO2 emissions or the power consumption if the focus is on optimizing these values. We have used the unit CO2 equivalents (CO2e) in our model, which is both dependent on the energy consumption and the energy source mix. CO2e is more generic than CO2 emissions. It expresses the amount of CO2 emissions that would have the equivalent global warming effect. Therefore, it also includes other greenhouse gases like methane for instance. In general, the constraint is provided as an upper bound, i.e. execution of the service should never cause more than x amount of CO2e units of emission. Nevertheless, it is also possible to provide an average value. In this case, the execution should on average cause no more than x amount of CO2e units. The latter is, however, much more difficult to grasp for the developer and more difficult to monitor later on. This is mainly because the energy consumption of the software service is dependent on the energy consumption of the underlying hardware infrastructure. As the relationship between utilization and energy consumption is typically not linear and the assumption of exclusive usage rights for the component is normally not valid, it is much harder to know the average value during the implementation phase in comparison to an absolute maximum value.

The intention of adding the ecological constraints is to add a restriction on the CO2e units of the overall component. This is expressed by the constraint within the class labeled with <<subject>>. For the given example the overall maximum CO2e units of the video manager is therefore 1.0328gCO2e per month and user. This number must always be greater or equal to the sum of the CO2e units caused by all operations (green operational view) weighted with the probability of execution (green behavioral view) multiplied by the average number of times the user accesses the service.

As mentioned before it is also possible to additionally provide guarantee terms for a corresponding service level agreement (SLA). Like the ecological constraints, this information is added using a stereotype, i.e. <<sla>>. These terms guarantee the user of the service a certain quality of service (QoS) or quality of experience (QoE), respectively. Therefore, as shown in Figure 7, the availability of a video for instance must be greater or equal to 99.99%. Availability constraints put on data types refer to their existence. Only one of the three subtypes trailer, movie and series has been enriched with an additional SLA constraint. However, this does not mean that they are not subject to any kinds of SLA constraints. As is familiar from object-oriented programming, all attributes of a parent are passed on to its children. Therefore, the SLA constraint defined for a video is inherited by trailer, movie and series as well. However, the attribute availability is then overwritten for the class trailer to be only 89.99%. The SLA terms within the video manager itself again refers to the whole video manager service. As with the ecological constraints the SLA constraints specified in the structural view restricts the developer's implementation choices. It also restricts the service provider to a certain extent. The more fine grained these restrictions are specified the more freedom is given to the service provider. Consider the availability constraint of a trailer for instance. For a customer it may not be important to have continuously access to a trailer. The reduced availability level of 89.99% does not require a complete, redundant infrastructure and as a result, fewer resources are needed, which again results in fewer CO2e units of emission. Therefore, the overall CO2e constraint for the video manager is lower than it would be otherwise. Of course the actual impact depends on the estimated number of trailers. In traditional SLAs as commonly used today, only the availability of the whole service is defined. As the user is, however, not willing to sacrifice any availability objective when it comes to movies or series, the availability of the whole service would be defined as 99.99% and a great deal of optimization potential would be lost. Thus, in comparison to the traditional approaches of defining SLAs, green specifications provide much more scope for exploiting optimization techniques, since they provide much more detail about possible flexibility.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

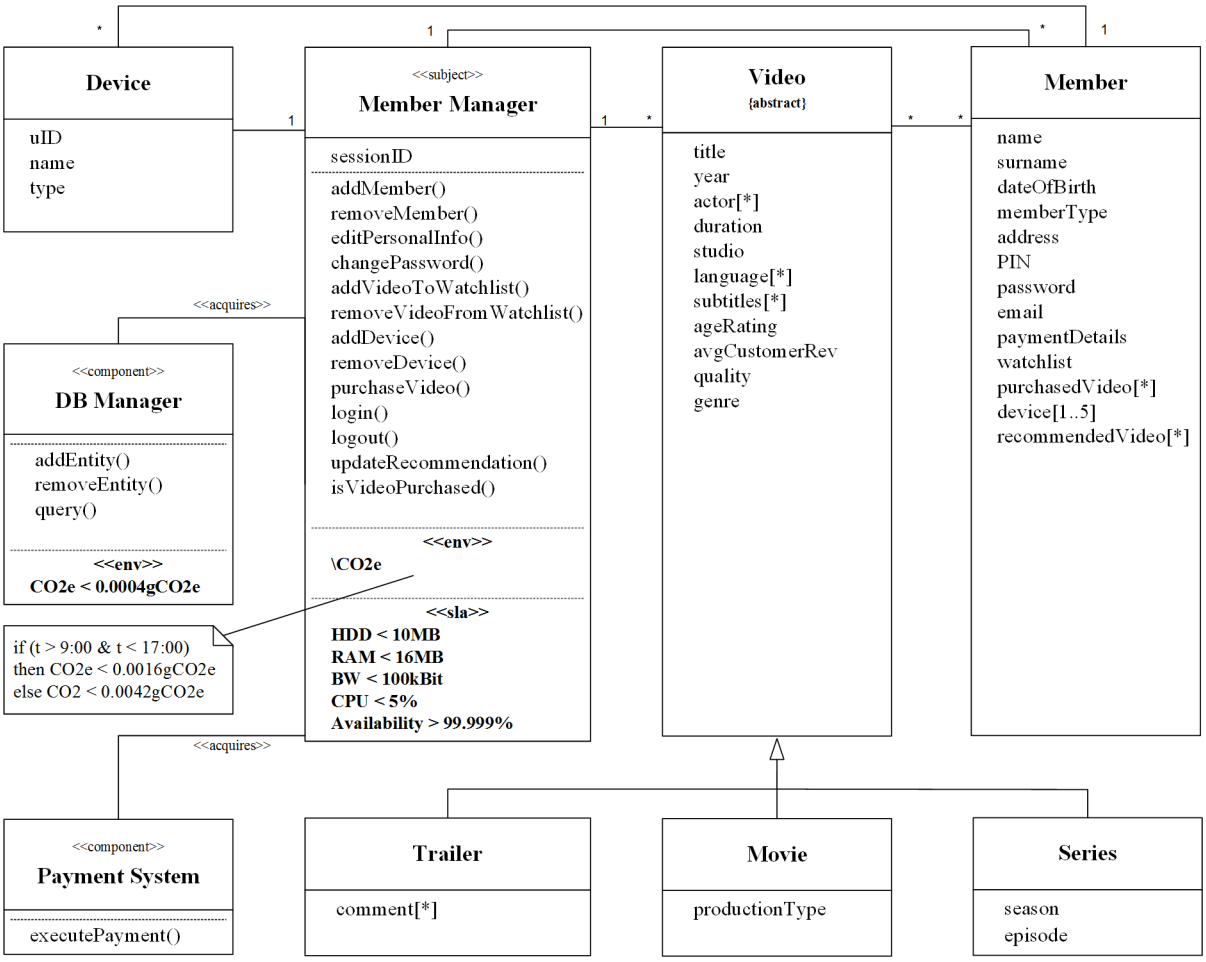


Figure 7. Structural view of a green specification for the video manager

Similar to the video manager, the member manager is specified using KobrA. Figure 8 shows an already enhance version of a structural KobrA specification, i.e. a green specification of the member manager. Like the video manager, the classes have been annotated with ecological and SLA constraints. The member manager consists of six classes describing the data structure, where four of them ((Trailer, Movie, Series, and Video) are already known from the video manager specification. Note, however, that the attribute data is missing in the Video description. This is a consequence of the, by now well know, principle of parsimony. As the actual data of the video (i.e. the actual content) is not of importance in the context of the member manager, it is not specified here. In addition, a Member and a Device is defined. A member consist of personal information (e.g. name, age, address, email), the PIN, the password, the member type (e.g. prime member), payment details, his/her watchlist containing all videos he/she marked as interesting to watch in the near future, a list of purchased videos, a list of devices he/she owns and a list of recommended videos which have been automatically generated by the VoD service based on previously watched videos and videos on the watchlist. A device is identified by the uID, has a name and is of a certain type (e.g. PC, Smartphone, TV). The devices are used as a kind of copyright

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Structural view of a green specification for the member manager

protection. Each member is allowed to register only up to five devices, which makes it more difficult to illegally share videos with a large group of people. Furthermore, the member manager acquires the DB Manager and an external Payment System.

For the data types Video, Member, Trailer, Movie, Series and Device no environmental and SLA constraints are provided. However, they are indirectly limited by the constraints limiting the overall component. Therefore, the availability constraint used for the overall component (Availability > 99.999%) constrains the availability of these two classes as well. The same holds true for the DB Manager. However, in addition it is annotated with an environmental constraint and indirectly restricted by the overall SLA constraints of the Member Manager. The environmental constraint is bound to the context of the Member Manager. This means that whenever the Member Manager uses the DB Manager, the emission must be lower than 0.4 mg CO2e. However, this limitation does not restrict the CO2e unit of emission caused by any action not involving the Member Manager. Furthermore, Figure 8 shows a so called derived attribute within the Member Manager which can be used for describing more complex constraints. The environmental constraint is dependent on the time of day. During daytime, when people are normally working, the CO2e constraint is set to 0.0016 gCo2e, whereas during the evening this value is allowed

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to be higher, i.e. 0.0042 gCO2e. The reason for this is twofold. On the one hand the assumption is being made that during daytime more solar energy is available which leads to fewer emissions. On the other hand the assumption is being made that during daytime less people are watching videos because they are at work. Therefore, QoS constraints like response time can be lowered. Once again, how the constraints in the specification are met is the responsibility of developers and data center personnel and is not part of the specification. Finally, it can be noted that the Payment System has not been annotated with any constraints. This is the usual case for any external component. However, it might also be possible in special situations to define constraints for external components as well. In these cases an external service must be selected which adheres to these constraints.

The Green Operational View

Green operation specifications are built on operation specifications of the kind described previously (cf. Table 1). Table 2 shows the operational view of the green specification for the play operation. Similar to the structural view enhancements, both environment and SLA constraints are added. The constraints limit the CO2e units the operation may emit to 0.1mg per minute of video, restricts the use of resources such as the hard disk (<7.76MB multiplied by the duration of the video), memory (<16MB), bandwidth (<195kBit) and CPU (<5%), and furthermore sets a guaranteed availability of the operation to 99.999%. Like the green structural views, these are constraints that the developer and responsible data center personnel have to take into consideration during the implementation and execution of the service.

In general KobrA does not define the level of formality the descriptions need to adhere to. In principle it is a tradeoff between universal, understandability and precision. Mission critical services will probably we described in a more mathematical, formal way. A compromise commonly used in KobrA

Table 2. A green operation specification for the play operation of the video manager

Name	**play**
Description	The operation retrieves the video from the database, enacts DRM methods, encodes the video and streams it to the client
Receives	**name**: the name of the video which is supposed to be played **sessionID**: the session ID of the member who wants to watch the video
Returns	A protected and encoded video stream
Assumes	The VoD service has been started and a member has logged in
Result	• It was checked that the video was purchased by the member and was located in the database, • if the video was purchased and was located in the database, it has been retrieved from the database, • the watermark has been included into every frame of the video, • the video has been encrypted, • encoded, and • has been streamed
Constraint: Environment	CO2e < 0.1mg * video.duration
SLA: Resources	HDD < 7.76MB * video.duration RAM < 16MB BW < 195kBit CPU < 5%
SLA: Availability	Availability > 99.999%

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

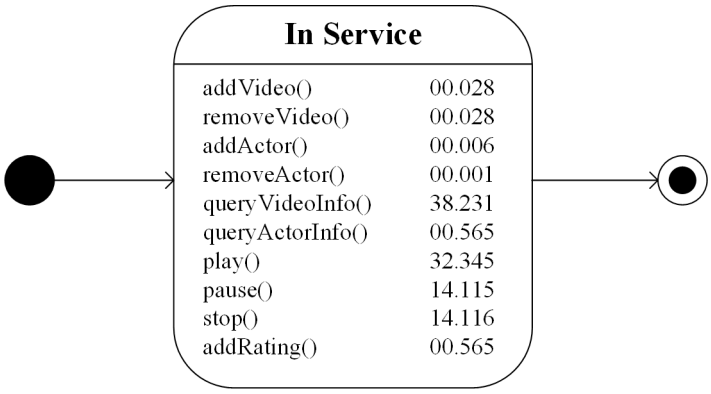
Table 3. Green operation specification of the enactWatermark operation

Name	**enactWatermark**
Description	Adds a watermark to every frame of the video
Receives	**video**: the video to which a watermark is supposed to be added **watermark**: the content of the watermark, consisting of the member ID and the current date and time.
Returns	The video with embedded watermark
Assumes	pre: VoD.OclIsInState(Running) and MemberManager.OclIsInState(LoggedIn)
Result	post: VideoFrames->notEmpty() implies (WatermarkedFrames->size() = VideoFrames->size())
Constraint: Environment	CO2e < 0.038mg * video.duration
SLA: Resources	RAM < 16MB CPU < 5%

is the Object Constraint Language (OCL). Table 3 shows the green operation specification for the enactWatermark operation using OCL in the pre and post condition. The operation is located in the DRM Manager, which is a subcomponent of the Video Manager (see Figure 3).

Digital watermarking is the process of adding hidden information to a digital source. In the case of videos this information is added to the frames of the video, preferably without any visible disturbance for the viewer. The benefit of digital watermarking in contrast to traditional DRM methods lies in the fact that even when copying the video by filming it with another camera, the watermark is still intact. In Germany this technique is already in use in most cinemas and has already lead to successful arrests.

The green operation specification in Table 3 specifies that the watermark should be embedded into every frame of the video. For this purpose it needs the video and the watermark as input. In order to uniquely identify the video in the case of a copyright violation it uses the member ID and the time and date in the watermark. The pre-condition is equivalent to that of the play method, but is described using OCL. The VoD system must both be running and the member must be logged in. The post condition, which is also specified in OCL, requires the operation to have inserted the watermark into every frame, i.e. the number of watermarked frames is equivalent to the number of video frames.



In addition, the specification contains environmental as well as resource constraints. Note, that only the RAM and CPU is restricted by the green specification, as these are the only resources used by the operation. Furthermore no constraint on the availability is provided. In this case, however, the overall availability constraint provided in the green structural specification of the component is used.

The Green Behavioral View

In the context of a green specification a behavioral view of the kind described in Figure 9 is used to on the one hand describe usage profiles and on the other hand to place constraints on certain behavior. This means that in contrast to the green structural and green operation views not only additional constraints, but also additional information related to the constraints located in the structural specification are provided.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Green behavioral specification of the video manager

In Figure 9 the behavioral view of the green specification of the Video Manager is shown. Each operation is annotated with a probability of execution while in this state. The probability of playing a video when being in the state In Service is therefore 32.345 per cent, of adding a video is 0.028 per cent and so on. This reflects the typical usage profile of the Video Manager. Adding such probabilities to the state chart diagram transforms it into a Markov Chain. This technique is commonly used, for example, in the area of reliability predictions in software engineering (Reussner, Schmidt, & Poernomo, 2003). A Markov Chain within a green specification enables the overall probability of executing the different operations to be calculated. In combination with the constraints contained in the green operation specifications it is then possible to calculate the minimum restrictions the overall constraints need to specify and, vice versa, check if the constraints specified for the individual operations are consistent to the overall restrictions.

Retrieving the probability of executing an operation is a two-step process. First, the probability of being in a state needs to be identified. If the Markov Chain is time-homogeneous, a simple steady state analysis can be used for this purpose. Also in certain other cases it is possible to use this approach. At this point, however, we refer the interested reader to other literature concerning the topic of Markov Chains. Once the probability of being in a state is known, it can be multiplied by the probability of executing the operation. Next, it is possible to calculate the lower boundaries for the overall constraints by multiplying the overall probability of an operation with the corresponding constraints specified in the operation specifications and calculating the sum over all operations.

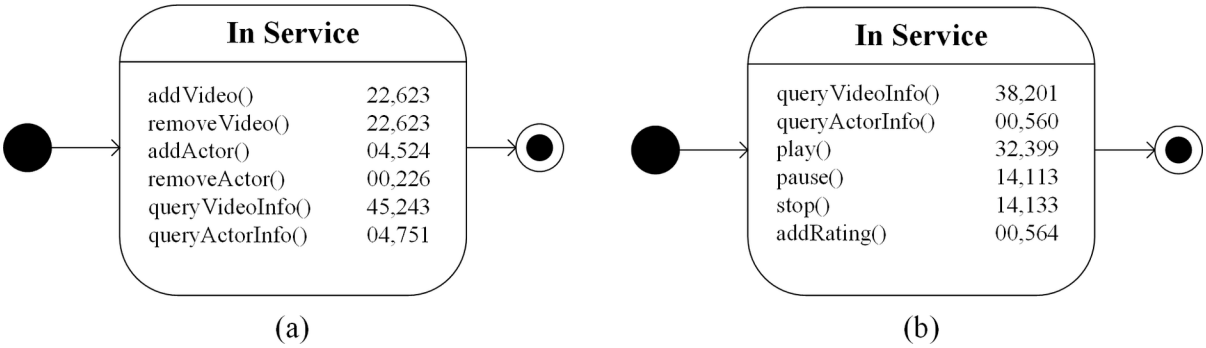
Taking the green behavioral specification from Figure 9 as an example, the minimal overall constraint restraining the CO2e emissions can be calculated as follows: The steady state probability of the state In Service is 1 since it is the only state available. Thus the overall probability of executing an operation is 1 times the probability specified for each operation in the state In Service. For the play operation it is therefore 1 x 32.345 = 32.345 per cent.

Table 4. CO2e emission constraints of all operations in the video manager

$CO2e_{addV...}$	$CO2e_{removeV...}$	$CO2e_{addA...}$	$CO2e_{removeA...}$	$CO2e_{queryV...}$	$CO2e_{queryA...}$	$CO2e_{play}$	$CO2e_{pause}$	$CO2e_{stop}$	$CO2e_{addR...}$
0.00714	0.00714	0.00011	0.00011	0.00143	0.00071	9.10000	0.02499	0.02499	0.00004

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

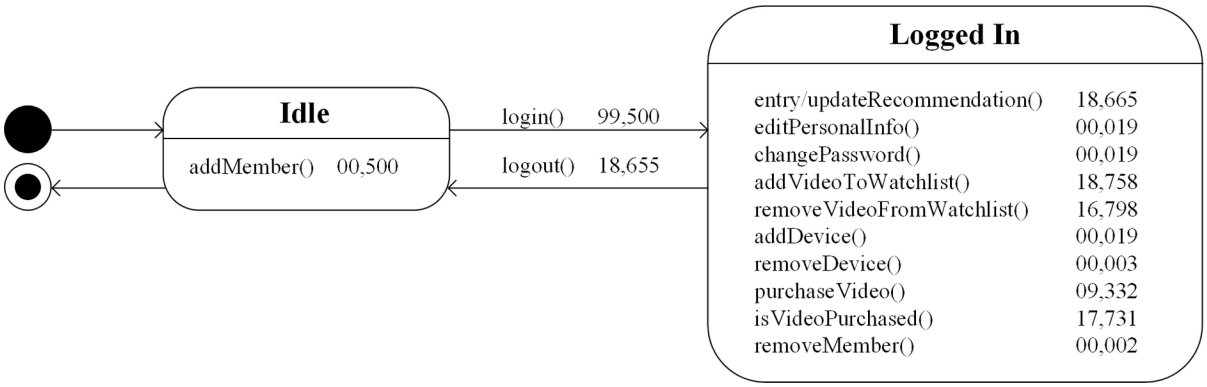
Now, assuming the CO2e emission constraints provided in Table 4, the minimal overall CO2e constraint for the Video Manager is 2.951 mgCO2e. However, as the specification of a CO2e constraint is not mandatory in the operation specification, there is a good chance that the calculated minimal value of the overall constraint is too low. Picture for instance the scenario that the CO2e constraints for the operations pause and stop are not provided in the operation specification. This would result in a minimal overall CO2e constraint of about 1.030. If this value would be set as the overall constraint it would result in the fact that neither of the operations can be executed or the CO2e constraints of one or multiple operations must be undercut. However, as the predicted use of both operations is more than 28% it is unlikely that they will ever be executed and by knowing this the specification of the other constraints becomes obsolete. Therefore, in any cases were the specification of the constraints in the operation specification is incomplete the overall constraint should be specified with caution and never be set to the minimum calculated value.



It is also possible to create multiple green behavioral specifications of the same component. This is useful for specifying typical usage profiles for different user types or usage scenarios. Figure 10 shows the behavioral view of the green specifications for the two user types administrator (a) and VoD-user (b).

Note that both specifications differ fundamentally from each other. While the admin mainly queries, adds and removes videos a user mainly queries, plays, pauses and stops videos. Following the principle of parsimony only operations utilized by the corresponding user are included in each specification.

The calculation of the minimal overall constraints is similar to the one with only one user. The first step is to calculate the minimal overall constraints for each user separately. Then these individual constraints are multiplied by a weighting factor and finally summed up. These weighting factors express the estimated distribution of usage of the different users. For the example in Figure 10 it is assumed that the number of accesses of admins in comparison to users is about 1:100000 (i.e. that while only one administrator is accessing the system one hundred thousand users will access the system within a certain timespan). Thus, the weighting factor for the user is 0.999991 and for the administrator is 0.000009.



In Figure 11 the behavioral view of the green specification of the Member Manager is shown. As in the previous specification all internal and external state transitions are annotated by probabilities. The Member Manager can be in two states: Idle and Logged In. The steady state probability of being in the Idle state is 1.2 and the steady state probability of being in state Logged In is 98.8. At a first glance it

Figure 10. User type specific green behavioral specification of the video manager

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. Green behavioral specification of the member manager

appears that the login operation is the most important operation of the Member Manager with a probability of 99.5 per cent. However, due to the relatively low steady state probability of the Idle state from which the login operation is executed the overall probability of the login operation is only 1.194. This means that at any given time the probability of executing the login operation as the next step is 1.194 per cent. Therefore, it is important to differentiate between the probabilities provided in the diagram and the overall probabilities.

REDUCING THE ENVIRONMENTAL IMPACT

Previously we have provided some examples on how green specifications can help to reduce the environmental impact by inserting constraints. For instance, by inserting a lower availability constraint for a trailer in the structural view it is possible to reduce the number of redundant servers, or by specifying resource constraints in the operational view of the enactWatermark operation it is possible to restrict the resource utilization and with that in the best case the number of necessary servers. In the following we will provide a few more examples showing how green specifications can further help to reduce the environmental impact of the SoftFlix VoD service and allude to some not so obvious implications originating from the previously described green specifications.

In principle, when trying to further reduce the environmental impact of a software service one should start by identifying the aspects of the service which are expected to have the highest environmental impact. First the component with the highest impact can be identified by looking at the constraints limiting the whole component within the structural view. In the example of the SoftFlix VoD service this is the Video Manager which has an overall CO2e constraint of 1.0328g. Next, the operation with the highest impact within this component can be located by identifying the highest CO2e constraint related to the probability of execution. This information can be extracted from the green operational and green behavioral view. For the Video Manager this is the play operation with an overall impact of 3.479 (assuming an average duration of 90 minutes). When looking at the corresponding operation specification one can identify multiple tasks, namely checking if the video was purchased, retrieving the video, including the Watermark, encrypting, encoding and streaming the video. Now, depending on the flexibilities of the

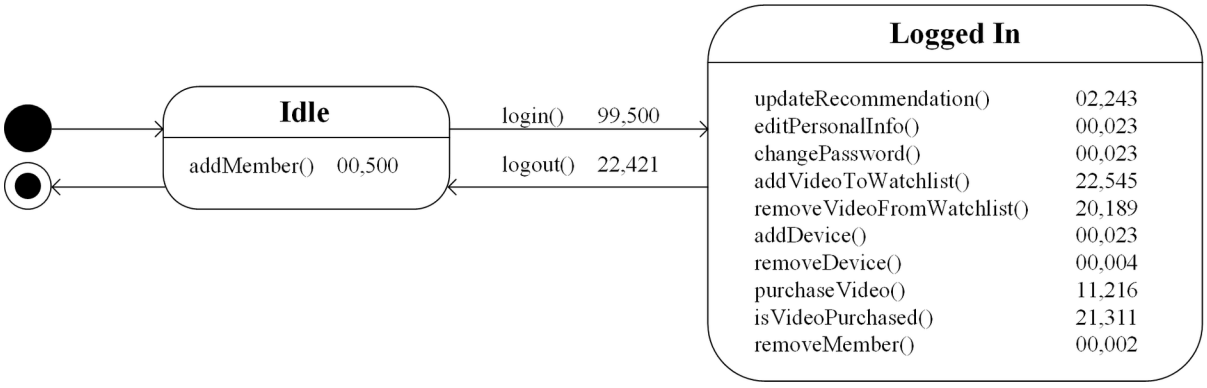
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

stakeholder different actions can be taken to modify the requirements and with that foster a more eco-friendly play operation. In the current form of the specification a check is being performed to ensure the video was purchased every time the operation is called. By changing the structure to ensure that only videos can be played that are on a list this check becomes obsolete. Next, the specification states that the watermarking process includes the watermark into every frame of the video. On second thoughts this might not be necessary. A normal video contains 24 to 48 frames per second. If the watermark would only be embedded in for instance ten per cent of the frames the whole process would use less resources and become more energy efficient. Of course, it is not possible to simply put the watermark into every 10th frame, as these could easily be eliminated and exchanged by interpolated frames. Instead the watermark should be included in larger groups at random distances, which results in an unacceptable user experience when removed (cf. Table 5).

Besides enhancing the energy efficiency of the subtask "include watermark" it is also possible to enhance the eco-efficiency directly by providing more flexibility on the time of execution. As renewable energy sources like solar and wind energy are not always available this flexibility can significantly reduce the environmental impact. In the current specification the watermarking task is done on the fly every time the video is played. However, many people use the watchlist feature giving the service provider the chance of knowing what the member is likely to watch in the near future. This information can be used to include the watermark into the videos on the watchlist at times where renewable energy is available. In order to support this approach customers can be encouraged to add and remove videos to the watchlist by granting them a discount for every video which has been added at least 24 hours before watching and has not been on the watchlist longer than one week for instance.

Table 5. An optimized green operation specification of the play operation

Name	**play**
Description	The operation retrieves the video from the database, enacts DRM methods, encodes the video and streams it to the client
Receives	**name**: the name of the video which is supposed to be played **memberID**: the ID of the member who wants to watch the video
Returns	A protected and encoded video stream
Assumes	The VoD service has been started and a member has logged in
Result	• If the video was located in the database, it has been retrieved, • If the video did not contain a watermark before, it has been included into ten percent of the frames. These frames are larger groups, distributed randomly, • The video has been encoded, and • has been streamed
Constraint: Environment	CO2e < 0.0473mg * video.duration
Constraint: Resources	HDD < 7.76MB * video.duration RAM < 16MB BW < 195kBit CPU < 5%
SLA: Availability	Availability > 99.99%
SLA: Cost	If the video was added to the playlist between 24 and 168 hours ago cost = 0.09€ * video.duration / 100 else cost = 0.21€ * video.duration / 100



EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The next subtask in the operation specification is to encrypt the video. This is another commonly used security feature to assure copyright protection. However, in theory this step becomes obsolete when using a good watermarking technique. Therefore, dependent on the position of the stakeholder it is possible to eliminate this subtask completely and by that reduce the environmental impact even further. Table 5 shows the operational view of an optimized green specification for the play operation. Due to the change enabling the watermarking task to be executed independently of the play operation, the member ID is used within the watermark instead of the season ID (cf. receives compartment). In addition, the cost specification is refined to promote the desired user behavior. Note that the cost is not the cost of developing the operation but the cost to execute the operation which is to be paid by the user and therefore specified as part of the SLA. Within the result compartment, both the check of whether the video was purchased and the task of encryption has been removed. In addition, the description of the result of the watermarking task has been modified according to the enhancements presented above. In addition both the environmental and resource constraints except the one from the hard disk could be lowered. Obviously, the measures taken to reduce the environmental impact have a large effect on the overall environmental friendliness of the SoftFlix VoD service given that they can reduce it by up to 47.25%. Note, however, that although green specifications allow inefficiencies to be removed, most of the proposed optimizations depend on the cooperation of the customers.

The change to the operation specification of the play method also impacts other parts of the green specification, like the corresponding constraints in the structural view and even the probabilities in the behavioral view, due to the new cost model entailed. In addition, a new independent operation is needed in order to control the execution of the watermarking process to ensure that it is synchronized with the generation of renewable energy.

The aspect with the second largest impact on the environment is the updateRecommendation operation which is executed whenever a member logs in. Similar to what have been proposed for the task of including the watermark, this operation can be optimized by introducing more time flexibility. More specifically, by eliminating the entry keyword and instead executing the operation mainly at times where renewable energy is available, significant CO2 emissions can be saved (cf. Figure 12). A secondary effect is that the operation is on average executed less frequently (i.e. the probability of execution and by that the overall environmental impact of the operation is lower). Note, that this change in probabilities means also the importance of the other operations that are executable in the log in state increase in the

Figure 12. An optimized green behavioral specification of the member manager

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

context of the Member Manager. This change towards a more environmental friendly service again is expected to have a low to no impact on the quality of the user experience.

Even though it should always be used with care, it is also possible to optimize the service further by modifying aspects that have an impact on the quality of experience. Often such restrictions are bound to a specific group of members and combined with monetary gains. SoftFlix has two types of paying members: Premium Members and Standard Members. In contrast to the latter, the premium membership is more expensive and contains special features like for example earlier access to new movies. From an environmental point of view it is possible to further differentiate between these two member types by lowering the quality of experience of standard members.

Table 6 shows the green operation specification of the streaming operation. Here, an SLA parameter has been inserted indicating the maximum time a member has to wait for the video to start. This time span is longer for standard members compared to premium members. The technical implication behind this is that more servers can be kept in cold standby. Servers kept in this mode need more time to startup but consume less energy than servers in hot standby mode. However, such measures to reduce the environmental impact always need to be carefully evaluated to be compliant with the needs of the members.

While there are many more ways to optimize the SoftFlix service and make it more environmentally friendly we would now like to draw your attention to an implication of an already described optimization step that is not visible at first sight. The principle of parsimony that is used in all green specifications leads to models including the minimal set of elements needed in the different contexts. As seen earlier a video specified in the structural view of the Video Manager contains among other attributes an attribute with the name data, which is the raw data, i.e. the video itself. In contrast, a video in the Member Manager does not contain this attribute, as the video itself is not of importance in that context but only its metadata.

In practice the developer would normally have developed one method to retrieve a video from the data base. However, the two specifications differ and indicate that two different implementations of the operations involved should be developed. Therefore, the query operation should be implemented twice, one retrieving only the metadata for the Member Manager and one also including the video itself. Thus,

Table 6. An optimized green operation specification of the stream operation

Name	**stream**
Description	The operation streams the video to the client
Receives	**video**: the video which is supposed to be streamed
Returns	A video stream
Assumes	The VoD service has been started and a member has logged in
Result	The video has been streamed
Constraint: Environment	CO2e < 0.031mg
Constraint: Resources	BW < 195kBits/s
Constraint: Availability	Availability > 99.99%

SLA: MaxTimeToStart	If (memberType = Premium) then
	maxTime = 3 seconds
	else
	maxTime = 15 seconds

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

at least two green operation specifications of the query operation should be specified. The result is a more environmentally friendly SoftFlix VoD service.

As we have indicated, although they reduce the environmental impact of services, optimizations also tend to limit the freedom of certain stakeholders. Green specifications provide the possibility to let all stakeholders make well informed choices and decide to what degree certain optimizations are acceptable.

FUTURE RESEARCH DIRECTIONS

As we have shown in this chapter green specifications provide an important foundation for developing more environmental friendly software services. In our example of specifying a VoD service we have used the metric CO2e to express the eco-friendliness. However, as mentioned earlier, green specifications do not limit the stakeholders to the use of this specific metric. Therefore, one research direction focuses on analyzing the practicability and usefulness of existing metrics and if applicable defining new ones.

Furthermore, green specifications do not specify where the values for the constraints originate from. In our example we have used the knowledge of domain experts. However, such an approach might not always be applicable due to the absence of such experts. Furthermore, these estimations might not always be very accurate which might lead to complications during development and later execution. For example, if a constraint is set to a value which is simply impossible for a developer or service provider to adhere to, a conflict could arise. Therefore, the second research direction focuses on finding ways to more easily and more accurately estimate these values.

CONCLUSION

Green specifications enable more environmental friendly software services to be developed by describing the relationship between different consumption choices (at different QoS levels) and environmental impact in a way that is understandable to the widest possible range of stakeholders. Evidently, green specifications can have a significant impact on the eco-efficiency and can even in already optimized environments lead to significant savings.

KEY TERMS AND DEFINITIONS

Behavioral View: The behavioral view describes the externally visible states and state transitions visible to external users of the component/system and takes the form of a UML state diagram.

CO2e: CO2 equivalents (CO2e) express the amount of CO2 emissions that would have the equivalent global warming effect to a mixture of gases emitted in an industrial process such as methane or nitrous oxide.

Functional View: The functional (a.k.a. operational) view describes the functionality of a component. It is actually composed of a set of tabular operation specifications, each describing the effects of one operation of the component in terms of pre and post conditions.

Green Specifications: Green specifications describe the properties of a service from distinct viewpoints which describes the data structure, its externally visible states and transitions exhibited by the service, and the effects of the service's operations. These are augmented with non-functional information describing the environmental properties of, or constraints on, the service.

KobrA: The KobrA method is a view-based approach to component specifications that strictly prescribes how different UML diagrams and tabular operation specifications should be used to model the properties of components from distinct perspectives - the behavioural, structural and functional viewpoint.

Structural View: The structural view describes the externally visible types and external components (e.g. services) which the system uses to deliver its own functionality, and takes the form of a UML class diagram.

Video on Demand: A Video on demand (VOD) service provides users with the ability to watch video content on demand over the internet. Popular examples today are Netflix, or Amazon Instant Video.

Watermarking: Digital watermarking is the process of adding hidden information to a digital source for security purposes. In the case of videos this information is added to the frames of the video, preferably without any visible disturbance for the viewer.

Chapter 35
Introducing Eco Friendly Urban Traffic Control Room: A Green Approach

Somasree Bhadra
University of Calcutta, India

Anirban Kundu
Netaji Subhash Engineering College, India

Sunirmal Khatua
University of Calcutta, India

ABSTRACT

In this article, new services in Green Computing environment is introduced. Energy and power is saved in an efficient manner using proposed services. These services are still undefined to the researchers in most of the cases. A typical framework of hierarchical structure for typical software managed central urban traffic control room is considered as case study. Each type of services is shown with an example which is interrelated with central traffic control room scenario. The authors' aim is to produce an energy efficient and power savings method in computing environment. Urban Traffic Control Room is considered as a case study. This is because in today's world urban traffic management is one of the most burning issues of any smart city management. Use of complex yet efficient software in the urban traffic control room may aid in proper management of road traffic. Keeping in mind growing environmental concerns, efficient green system architecture needs to be in place to ensure high performance, reliability and security of such an important public service sector.

INTRODUCTION

Modern IT systems rely upon a complicated mixture of people, networks and hardware. Green computing shows an initiative with systemic nature, and addresses increasingly sophisticated problems. Elements of such a solution may comprise items such as end user satisfaction, management restructuring, regulatory compliance, disposal of electronic waste, telecommuting, and virtualization of server resources, energy

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

use, thin client solutions, and return on investment (ROI). As 21st century belongs to computers, gizmos and electronic items, and as the public debate on carbon emissions, global warming and climate change gets warmer, energy issues will get a serious ring in the coming days. Taking into consideration its popularity, the industry of Information Technology has to lead a revolution of sorts by turning GREEN in a manner no industry has ever done before.

Green computing is the study and practice of using computing resources efficiently. The primary objective of such a program is to account for the triple bottom line, an expanded spectrum of values and criteria for measuring organizational (and societal) success. The goals are similar to green chemistry; reduce the use of hazardous materials, maximize energy efficiency during the product's lifetime, and promote recyclability or biodegradability of defunct products and factory waste.

Effective power utilization, maximizing efficiency, proficient utilization, correct disposal of electronic gadgets, reliable and cost effectiveness, etc. are addressed in green computing research. Power consumption is minimized by implementing green concept in different functional components of personal computer (Mala et al., 2013).

Energy consumption rates based on services have been analyzed for different systems for facilitating green cloud computing (Anwar et al., 2013). Power consumption of resources and amount of electronic waste are reduced by implementing different eco-friendly hardware. Power consumption and heat have been reduced by proposed technique in (Schmidtet al., 2008). Different techniques such as unplugging a computer, use of LCD, use of flash drives have been discussed for minimizing power and energy wastage (Anwar et al., 2013).

In present day scenario, green computing concept is implemented everywhere due to increasing energy cost and growing environmental concerns. Efficient system architecture is required for analyzing performance, reliability, maintainability and security of the system. Energy and power consumption of a system depend on the particular system architecture. Energy usage of the system architecture is monitored and analyzed in (Zhong et al., 2010.).

Green computing concept is implemented in cloud computing. Large amount of energy is consumed by the data centers hosting cloud computing applications contributing high operational costs and carbon footprints to the environment. Hence, green solution is implemented to save energy and reduce operational costs (Ponnusamy & Sasikumar, 2012).

Rest of the paper is organized as follows: related work is mentioned in next section; proposed services in green computing are implemented in an urban traffic control room within proposed work section; layer based protocols in Green environment and Green index are discussed further; experimental results are depicted for better clarifications; conclusion is drawn in last section.

RELATED WORK

Green computing, the study of efficient and eco-friendly computing resource is under the attention of environmental organizations, and businesses from other industries. In recent years, companies in the computer industry have come to realize that going green is in their best interest, both in terms of public relations and reduced costs (Lakshmi et al., 2012). In (Mittal& Kaur, 2013), harmful impacts of computers over environment are discussed. In today's era computer is the basic need of everyone. Computer is required for different purposes by different sectors. Most of the CO_2 emission is produced through the heat generated by computer and its devices. The energy consumption by various computing devices also

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

plays a main role towards harming our environment. This research paper analyzes the factors related to awareness of green computing among common man. It also includes a survey questionnaire which takes all the factors into account and before starting actual survey a pilot study for this questionnaire was done which confirm its acceptance (Mittal et al., 2013). In (Aggarwal et al., 2012) power saving concept in cloud environment is discussed. As cloud-based services become more dynamic, resource provisioning becomes more challenging. The Quality of Service (QoS) constrained resource allocation problem is considered in this paper, in which customers are willing to host their applications on the provider's cloud with a given Service Level Agreement (SLA) requirements for performance such as throughput and response time. Since, the data centres hosting the applications consume huge amounts of energy and cause huge operational costs, solutions that reduce energy consumption as well as operational costs are gaining importance. In this work, we propose an energy efficient mechanism that allocates the cloud resources to the applications without violating the given SLA using Ant colony framework (Aggarwal et al., 2012). Energy efficient approach is adopted in cloud computing to achieve eco-friendly application. Cloud computing data centres are emerging as new candidates for replacing traditional data centres. Cloud data centres are growing rapidly in both number and capacity to meet the increasing demands for highly-responsive computing and massive storage. Making the data centre more energy efficient is a necessary task. In this paper, the focus is on organisation's internal Infrastructure as a Service (IaaS) data centre type. An internal IaaS cloud data centre has many distinguished features with heterogeneous hardware, single application, stable load distribution, lived load migration and highly automated administration (Quan et al., 2011). An energy aware resource allocation method for clouds is proposed in (Mazzucco et al., 2010). However, it is developed mainly for scheduling theservers for completing the customers jobs and not applicable for scheduling different applications that need critical performance requirements. Some other techniques also have been proposed for predicting the workloads of the servers by applying statistical methods (Gong& Wilkes, 2001). General energy saving approaches has been studied in (Berl et al., 2010). Saving energy in ICT divides into two main fields, saving energy for network (Sheikh, 2010; Gelenbe & Mahmoodi, 2011) and saving energy for computing nodes (Heath et al.,2005; Xian & Lu, 2006). Energy saving approach for Platform as a Service (PaaS) cloud data center is discussed in (Shinde et al., 2013). Integration of NAND flash memory into DB-based architecture and support by adjusted DBMS algorithms governing IO process is discussed in(Schmidt et al., 2008). Different green initiatives in different sectors are discussed in (Chakraborty et al., 2009). Authors have discussed efficient and minimum power utilization using green concept in (Jadhwani et al., 2012).

A scheduling algorithm called DSSTS is proposed to minimize the overall energy consumption for sporadic tasks with shared resources. This algorithm schedules the job in dynamic low speed and switches to high speed if another low priority task blocks it (Zhang et al., 2017). Relationship between energy consumption and microprocessor frequency for application purpose is establishes by theoretical and experimental evidences by (Vogeleer et al., 2017).

PROPOSED SERVICES IN GREEN COMPUTING

It is discussed by different researchers that ecological equilibrium is affected heavily by the large amount of power and energy emissions due to ever increasing usage of technology. Different services are proposed in this work for minimizing power and energy consumptions from electronic devices.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

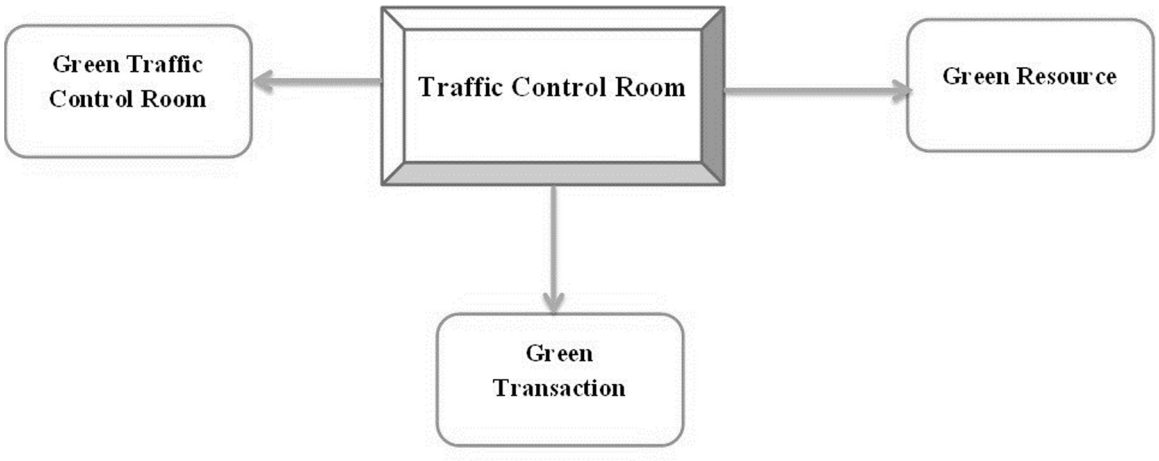
A typical urban traffic control room scenario is considered in our paper as a platform for implementing services. The proposed system framework is shown in Figure 1.

In our proposed approach different required services in a central traffic control room hierarchy are redesigned to produce a power saving system. In typical central traffic control room environment different types of traffic conditions are handled based on city traffic congestion along with management of general and emergency road traffic situation. It is considered that city traffic control room should function in such a manner that minimum power and energy would be used. Transaction, Resource management and security are the mandatory tasks to be performed by any city traffic control room. Different types of resource and repository are also playing a major role to run the office successfully. Different proposed services are explained in following sub sections:

Green Traffic Control Room

Maximum utilization of energy and manpower is ensured at the Central Traffic Control Room by introducing Green Traffic Room measures without compromising on efficiency. In this paper power savings and maximum resource utilization are achieved by introducing following approaches.

Reduce Power Consumption



Allocate optimal number of terminals in the control room based on needs without compromising on safety. Also, allocate maximum project members in a single room without affecting the efficiency. Minimum amount of power and energy is used.

Let, energy consumption by terminals and electronics devices per room is E_T and E_R respectively and total number of terminals and rooms used are N_T and N_R respectively.

Then,

$$E_T \propto N_T \tag{1}$$

Figure 1. Typical System Framework

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$E_R \propto N_R \tag{2}$$

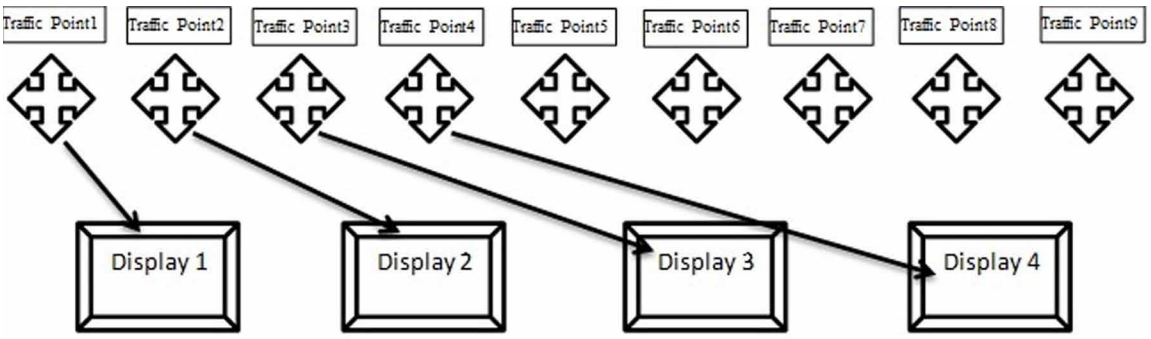
It is clear from Equation (1) and (2) that N_T and N_R must be minimized to obtain minimize energy consumption.

Total number of terminals could be minimized by implementing 'Minimal Terminal Display (MTD)' approach. In this approach we proposed that only concerned traffic point would be displayed in a terminal and whenever the particular terminal is attained or solved it will be replaced by next concerned terminal. In other words, there will not be displays for each and every traffic terminals. There will be minimal number of displays and selected problematic terminals would be displayed there and they will be replaced whenever required as depicted in Figure 2 and Figure 3.

Figure 2 presents situations of traffic points 1, 2, 3 and 4 are displayed in display 1, 2, 3 and 4 respectively. After these situations are handled they are replaced by next problematic terminals as displayed in Figure 3.

Traffic terminals are leveled based on some parameters. We consider Average Waiting Time (AWT) and Car Density (CD) at a certain time interval as the decisive parameters. We implement fuzzy set theory to identify the status of a particular terminal. Crisp input ranges for the parameters are shown in Table 1.

Figure 2. Minimal Terminal Display (MTD) instance 1



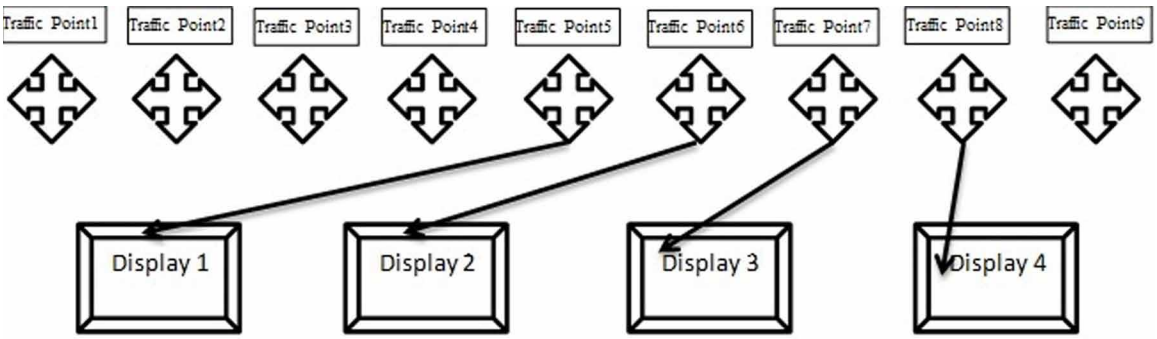


Figure 3. Minimal Terminal Display (MTD) Instance 2

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Crisp Input range for Parameters

Parameters	Crisp Input Range	State
Average Waiting Time (AWT)	0-0.4	Minimum
	0.3-0.7	Medium
	0.6-1.0	Maximum
Car Density (CD)	0-0.4	Low
	0.3-0.7	Moderate
	0.6-1.0	High

Lane status will be determined as a combination of parameters value. Combination of different parameters and corresponding lane status is shown in Table 2.

Level 4 lane status is considered as the most congested lane.

Total number of rooms could be minimized by placing maximum human resource in a single room without affecting comfort level and efficiency.

Parallel Processing

City traffic is always managed from traffic control room which is equipped with numerous video terminals. These terminals may receive live video footage from any traffic terminals (TP) spread all over the city. However during real time traffic management feeds from pre decided traffic points are considered.

We propose a green handling of traffic terminals at the control room. Nowadays, the roads are overloaded due to ever increasing traffic. It is observed that typical traffic signal management (release and Hold) is always predefined or manual. Accordingly the decisive terminals are predefined as well. However, it may happen that traffic situation may vary within a short while. Thus the decisive terminals may change thereafter. In this paper, we would devise a green mechanism to select proper decisive terminals.

Let, total number of traffic terminals (TP) is 'T', the number of Decisive Terminals is 'D' and the total traffic volume is 'v'.

$$T \propto v \tag{3}$$

$$D \propto T \tag{4}$$

and, T>>D

Table 2. Different Lane Status based on input parameters

	Minimum AVT	Medium AVT	Maximum AVT
Low CD	Level 1	Level 1	Level 2
Moderate CD	Level 1	Level 2	Level 3
High CD	Level 2	Level 3	Level 4

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

By combining Equations (3) and (4)

$$D \propto v \tag{5}$$

Thus,

$$D = cv\,.$$

where, c is a constant and is named as the Traffic Decisive Index

$$c = D \,/\, v$$

Let Single Terminal Energy Usage be ‘e’.

Energy required for Context Switch from current executing Terminal to new Terminal be ‘E’.

Here we assume that only decisive traffic terminal would be displayed in the display board in traffic control room instead of displaying all terminals. Energy usage would be ‘De’ instead of ‘Te’.

Energy saving would be (T-D)e.

Energy usage due to context switching would be (T-D)E.

It is obvious that e>>E, hence our proposed approach will save certain amount of energy without effecting system performance.

Green Transaction

Two types of transaction are typically involved in traffic management system, namely financial transaction and project-related transaction.

Financial Transaction

Usage of paper money is avoided by implementing electronic financial transaction. It is evident from different research work that online financial transaction is more eco-friendly than conventional transaction procedure (Lakshmi, Sarwani and Tuveera, 2012). Carbon emissions are reduced as the transaction is executed without being travelled. Usage of paper is minimized by this approach as the entire transaction is performed electronically.

Project-Related Transaction

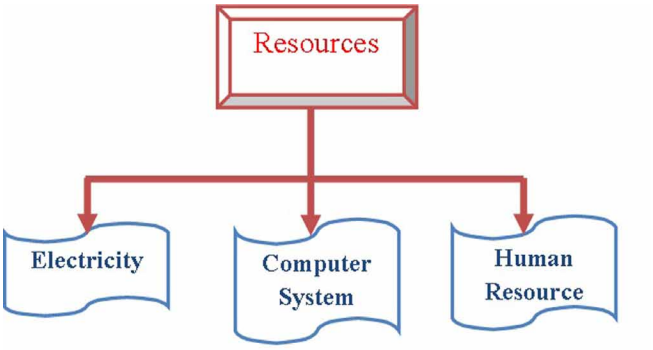
It is considered that different types of transactions including acceptance of new hardware or software components from vendors to successfully upgrade the system. It is proposed in this paper to execute these project-related transactions electronically to minimize the energy consumption and cost.

In present day scenario electronic transaction is most feasible and convenient way in every aspect. Hence more eco-friendly system is achieved by implementing electronic transaction system as shown in Table 3.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Comparison between Typical approach and proposed Green approach

Typical Paper Based Approach			Electronic Green Approach		
Transaction Medium	**Transaction Mode**	**Advantage/Disadvantage**	**Transaction Medium**	**Transaction Mode**	**Advantage/Disadvantage**
Paper	Physical	1. Wastage of Paper 2. Wastage of Trees 3. Wastage of Time 4. Wastage of Energy 5. High Carbon Emissions	Electronic	Electronic	1. Time Saving 2. No Paper wastage 3. Eco friendly



Green Resource

Different resources are required for a traffic control room to run the system smoothly. The resources used in typical traffic control environment are categorized as shown in the Figure 4.

Electricity usage is controlled by implementing an automated controller, namely Electricity Controller (EC). Operational activity of EC is explained in Algorithm 1 and in Algorithm 2.

Maximum utilization of natural resources is ensured by this algorithm. Lighting devices are controlled automatically by EC based on the actual requirement of artificial light. Lighting devices are powered on by the EC in case of insufficient natural light and sufficient light is required for that particular place.

Figure 4. Resource Categories

Algorithm 1. Light_Devices_Control

Input: Environmental Conditions
Output: Controlling light devices
Step 1: Start
Step 2: If there is no day light, go to Step 5.
Step 3: If there is sufficient day light, go to Step 6.
Step 4: If there is insufficient day light, go to Step 5.
Step 5: If there is a person sitting next to the light, then SWITCH ON LIGHT and go to Step 7.
Step 6: Then SWITCH OFF LIGHT, and go to Step7.
Step 7: Goto the NEXT LIGHT, if no LIGHT is left, then go to Step 8.
Step 8: End

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Algorithm 2. Cooling_Devices_Control

Input: Environmental Conditions
Output: Controlling cooling devices
Step 1: Start
Step 2: If the temperature is Hot, then DECREASE THE TEMPERATURE and go to Step 6.
Step 3: If the temperature is Cold, then INCREASE THE TEMPERATURE and go to Step 6.
Step 4: If the temperature is Optimum, then go to Step 6.
Step 5: If there is no person in the zone, then go to Step 6.
Step 6: Goto the NEXT DEVICE, if no DEVICE is left, then go to Step 7.
Step 7: End

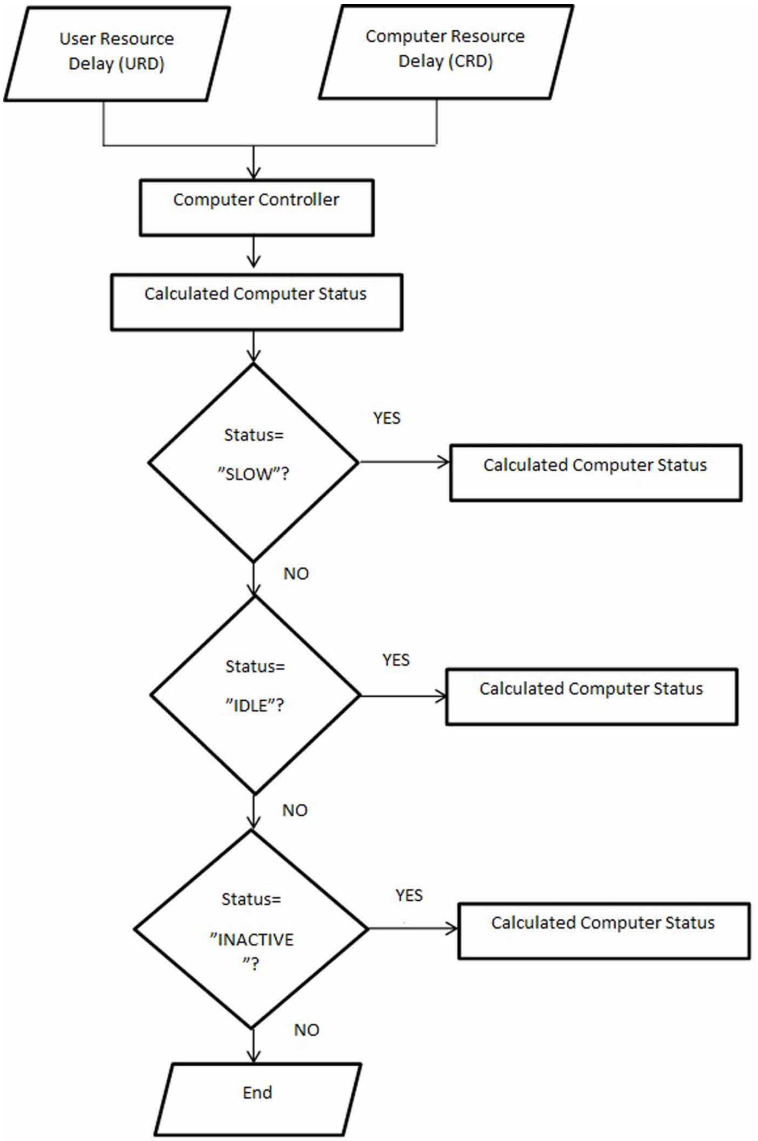
It is evident that maximum power and energy is consumed by the cooling devices. Hence maximum energy and power is conserved by minimizing the usage of these devices. This usage would be minimized by maximum utilization of natural resources. Operational activities of cooling devices are controlled by EC. Unnecessary power and energy wastage are minimized by implementing this automated approach. Power and energy wastage due to human error or negligence is avoided by this automated approach.

Large amount of time and energy wastage is caused by human resource wastage. It is avoided by implementing following approaches:

- Each Team is consisted optimum number of resources.
- A common transport is provided to avoid late arrival or early departure; hence the working hours will be maximized.

Most widely used resource by a modern corporate sector is computer. Hence energy usage of computer is considered as major resource of wastage. Hence operational activity of these computers are controlled and handled automatically as shown in Figure 5. Operational activity of the proposed automatic system is shown in Algorithm 3.

User Response Delay (URD) is the response delay from computer user side and Computer Response Delay (CRD) is the response delay from computer side. In this paper these two delays are considered as the decisive factor. Status of a computer is either ‘SLOW’ or ‘IDLE’ or ‘INACTIVE’ according to the degree of non-responsiveness. The status of the computer is measured by computer controller and the operational activity of computer controller is shown in Figure 6.



URD and CRD at any time instance is categorized as Minimum, Moderate and Maximum. Computer status is measured as the combination of two inputs as described in Table 4.

Algorithm 3. Computer_Control

Input: User Response Delay (URD) and Computer Response Delay (CRD)
Output: Status of Computer
Step 1: Start
Step 2: Collect URD and CRD.
Step 3: Compute the input through Computer Controller.
Step 4: If the computer status is ‘SLOW’, then LOG OUT and go to Step 7.
Step 5: Otherwise, if the computer status is ‘IDLE’, then SLEEP and go to Step 7.
Step 6: Otherwise, If the computer status is ‘INACTIVE’, then SWITCH OFF and go to Step 7.
Step 7: End

Figure 5. Operational flowchart of automatic computer controlling system

Computers are powered on or off automatically based on URD and CRD. Hence, wastage of power is minimized.

Human resource wastage is controlled by implementing following:

- Fixing the strength of each Team to an appropriate number so that Resources are not wasted due to paucity of work.
- By providing a common commutation to every employee, we can eliminate the wastage of time due to a late arrival.
- Set Short-term goals along with Long-term ones, while working on a project to minimise, project delays.

PROPOSED LAYER BASED PROTOCOLS IN GREEN ENVIRONMENT

In our paper we propose Layer based protocols to implement the Green concept. It is obvious that power and energy usage must be minimized to achieve an echo friendly system. Maximum utilization of resources and proper authorization and authentication of resources would reduce the power consumption.

A four level service layer abstraction in Green environment is introduced in this section. This is a logical and modularized separation that helps in describing of each service layer during the design process. It is the integrated and co-related modules as shown in Figure 7. This framework is basically an abstract representation of the proposed services.

Proposed Green Computing multi-layered service suites are discussed in following sub-sections:

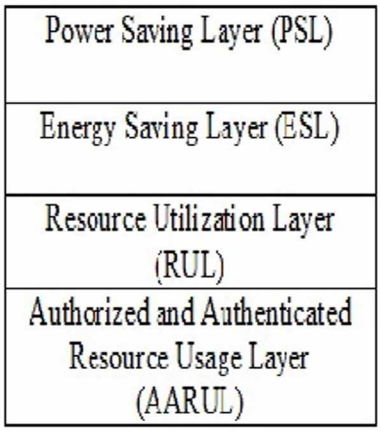
Power Savings Layer (PSL)

In this layer power usage of the system is controlled. Operational activity of PSL is shown in Figure 8.

In PSL unused devices are terminated to reduce the power consumption.

It is observed that power consumption in a system is directly proportional to the number of running device components in the system. Mathematical representation is as follows:

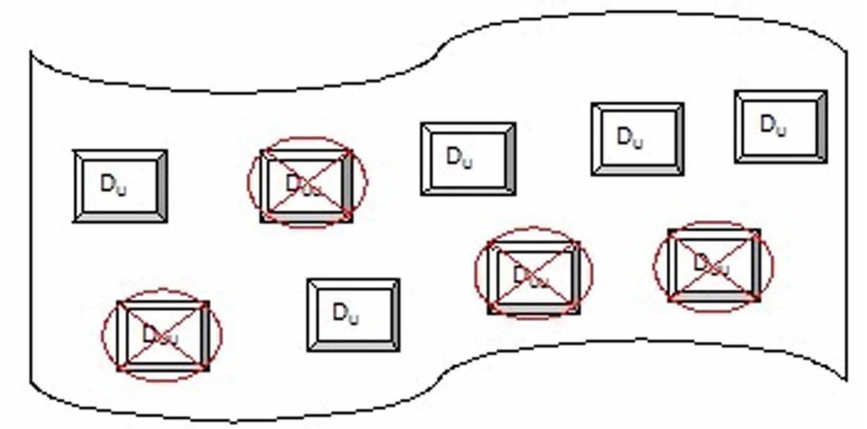
$$D_R \propto P \tag{6}$$



where, D_R = Number of running devices in the system;

P= Total power consumption in the system;

Similarly,



$$D_U \propto P_S \tag{7}$$

Figure 7. Proposed Service Layers in Green Computing Environment

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Operational activity of PSL

where, D_U = Number of used devices in the system;

P_S= System Performance;

$$\therefore D_U \propto D_R$$

$$\therefore D_{UU} = D_R - D_U$$

where, D_{UU}= Number of Unused devices in the system;

Let, power consumed by D_{UU} devices is ΔP.

As per Equation (1),

$$D_R \propto P$$

$$\therefore \left(D_R - D_{UU}\right) \propto \left(P - \Delta P\right)$$

Therefore, power consumption is reduced by terminating the unused devices without affecting system performance as P_S is related with D_U. Green Project is contained in this layer.

Energy Savings Layer (ESL)

In this layer energy usage of the system is controlled. Operational activity of ESL is shown in Figure 9.

In ESL energy wastage is minimized by terminating energy resources that are not occupied as shown in Figure 9.

Let there are ‘n’ number of devices in a system and corresponding energy usage is ‘m’ unit. Hence, total energy usage is “m x n”’ unit. It is obvious that,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$m \propto \left(m \times n\right) \tag{8}$$

and,

$$n \propto \left(m \times n\right) \tag{9}$$

If, 'p' number of devices are unoccupied then 'p x m' unit energy is wasted. Hence, 'p x m' unit energy is saved by terminating 'p' number of devices without affecting the productivity.

Green Projects and Green Transactions are the member of this layer.

Resource Utilization Layer (RUL)

In this layer available resources are fully utilized. This layer contains Green Resources. Maximum outcome is attained against minimum energy and power wastage. Maximum utilization of available resources is implemented in this layer as shown in Figure 10.

It is presumed that power and energy are wasted in case of inefficient resource usage. It is observed that resource idle time in sequential operation flow is larger than that of parallel operation flow. Hence energy and power are saved by minimizing resource idle time. This layer contains Green Resources.

Authorized and Authenticated Resource Usage Layer (AARUL)

It is observed that power and energy usage are reduced by using authorized and authenticated product. Usage of pirated product cause high power consumption and less efficient operation. Hence, more power and energy are required to accomplish the task.

Comparative analysis of energy, power and cost based on real time data is depicted in Figure 11. This layer contains Green Maintenance services.

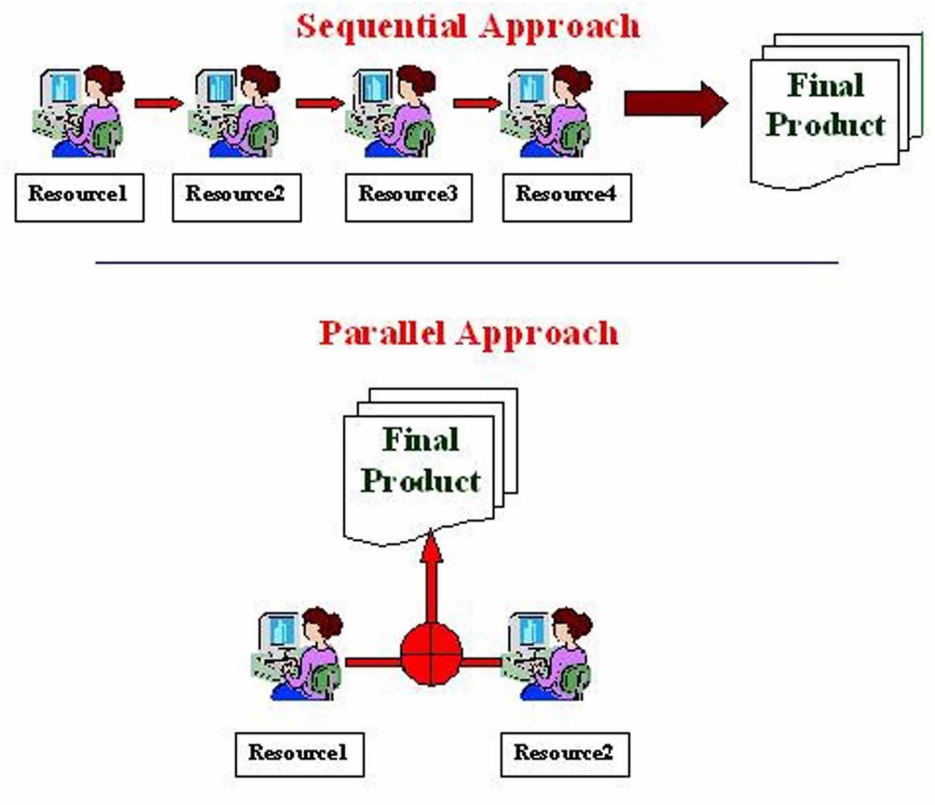
Figure 9. Operational activity of ESL

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Introducing Green Index

As per Green Project concept,

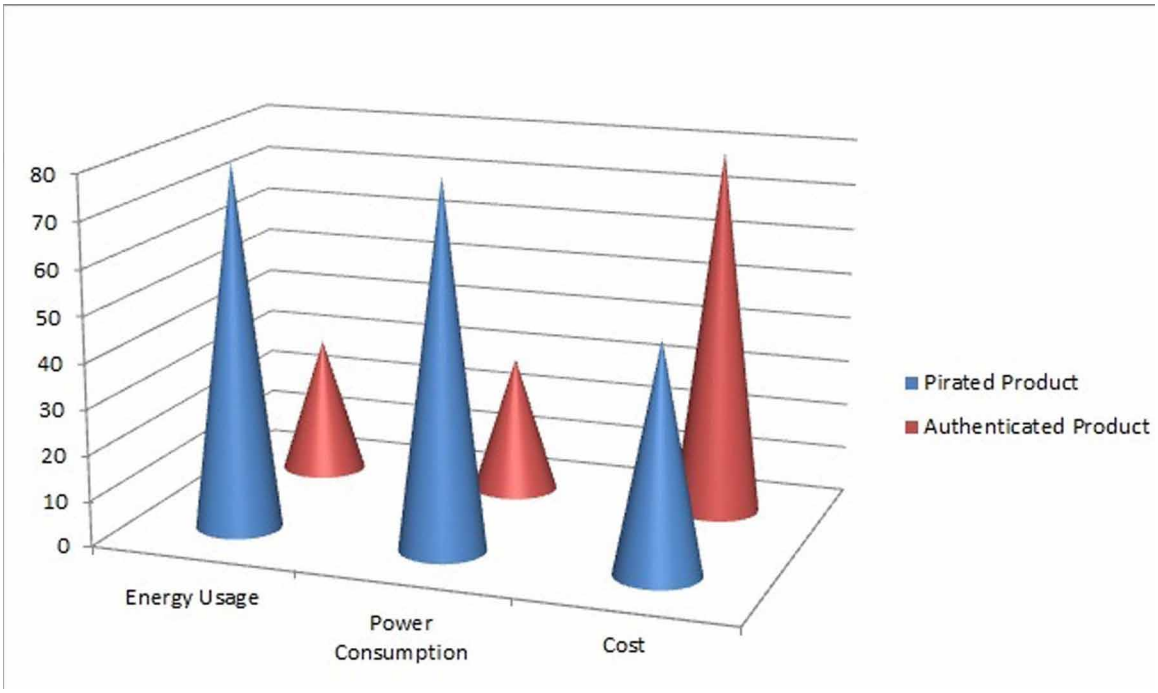
$$M_W \propto E_f \text{ or, } E_f \propto M_W \tag{10}$$



and

$$M_W \propto \frac{1}{P_M} \text{ or, } P_M \propto \frac{1}{M_W} \tag{11}$$

where, M_W = Working Men;



E_f = Efficiency;
P_M = Man Power Wastage;
As per PSL concept,

Figure 10. Operational activity of RUL

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. Comparative study of Energy Consumption, Power Consumption and Product Cost

$$E_f \propto \frac{1}{P} \tag{12}$$

and

$$D_R \propto P$$

where, P = Power Wastage;

D_R = Number of Running Devices;
∵Unused Devices = D_R- D_U
It is obvious that,

$$\therefore D_U \propto P \tag{13}$$

As, D_R value is presumed to be constant as efficiency of the system is not compromised.

$$\therefore Unused\ Devices \propto \frac{1}{P} \tag{14}$$

As per Green Project, Green Maintenance, and PSLconcept,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$P \propto R_N \tag{16}$$

$$P \propto \frac{1}{D_A} \tag{17}$$

$$D_U \propto E_f \tag{18}$$

where, R_N = Number of Room used;

D_A = Number of Authenticated Devices;
D_U = Number of Used Devices;

As per Equation (10) and Equation (18),

$$E_f \propto \left(M_W \times D_U\right) \tag{19}$$

As per Equation (11), Equation (13), Equation (16), Equation (17),

$$Power \propto \frac{\left(R_N \times D_U\right)}{\left(M_W \times D_A\right)} \tag{20}$$

where, Power = P_M X P;

It is presumed from Equation (19) and Equation (20) that minimum power wastage without affecting the efficiency is achieved, if and only if, right hand side value of Equation (20) is minimal. This value is designated as "Green Index" and the mathematical representation is as follows:

$$Green\ Index = \frac{\left(R_N \times D_U\right)}{\left(M_W \times D_A\right)} \tag{21}$$

Theorem 1. Performance and efficiency of an automated system is increased if amount of unused human resource and device is minimized

Proof:

As per Equation (10) and Equation (11),

$$E_f \propto \frac{1}{P_M} \quad (15)$$

As per Equation (14) and Equation (15),

Performance and efficiency of an automated system is inversely proportional with man power wastage and number of unused devices.

(Proved)

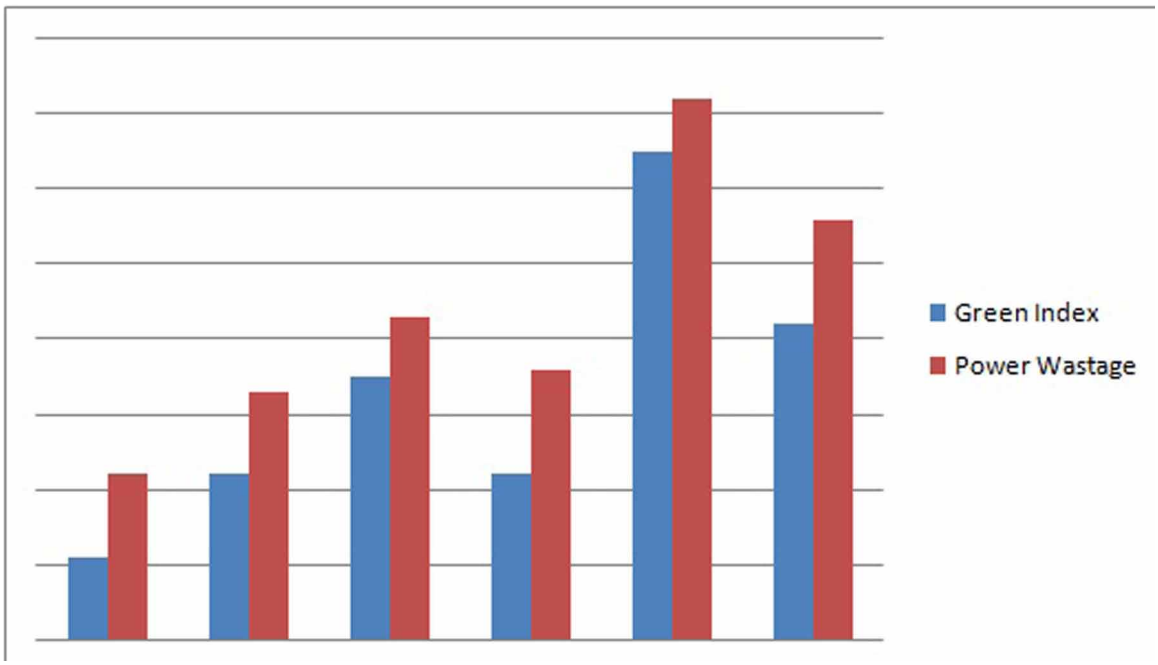
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

A real time case study having a varying Green Index value and corresponding power wastage is shown in Figure 12.

It is depicted from Figure 12 that minimum power wastage is achieved from minimum Green Index value.

EXPERIMENTAL RESULTS

Our proposed approach is implemented on an urban traffic control room having 30 computers, 8 ceiling fans, 8 tube lights and two air conditioners. Experimental details and result is shown in Table 5.



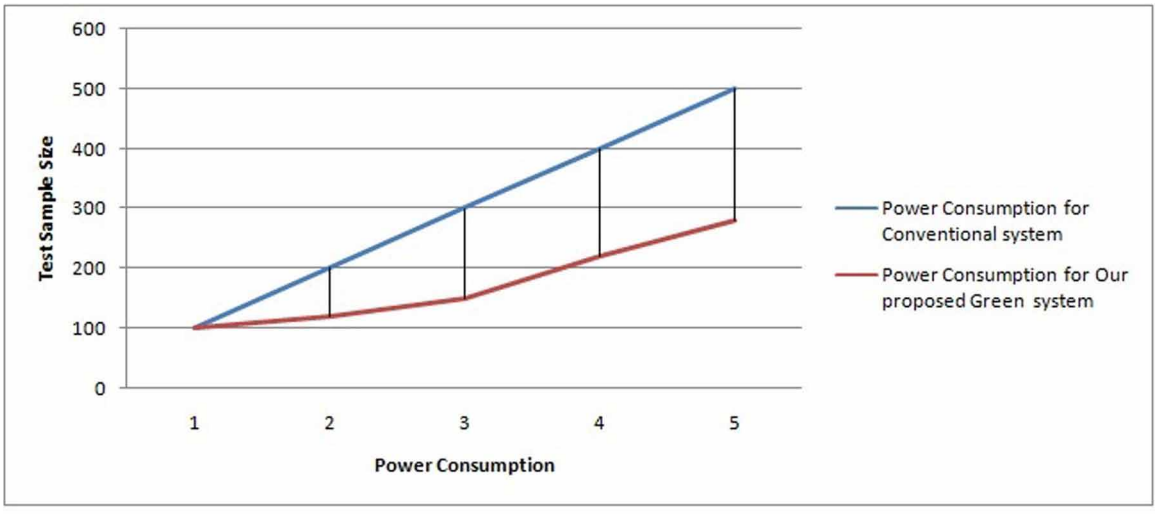
It is evident from Table 3 that power saving concept is successfully achieved by implementing our proposed approach without compromising with the service quality. Faster and efficient task completion is accomplished. Comparative performance analysis is shown in Figure 13.

It is evident from Figure 13 that maximum power consumption is achieved by our proposed green approach when test sample size is large. Hence, the proposed approach is more useful and efficient for large scale production.

Implementation of new devices or new architecture is suggested in various research works to reduce power consumption. Initial investment is required to employ new devices. Implementation of new architecture causes initial discomfort to workers. Hence production efficiency is reduced initially. Implementation of these proposals causes energy savings as well as initial efficiency loss as depicted in Figure 14.

It is evident from a real time case that, implementing typical existing approaches cause initial efficiency loss as shown in the Figure 13. It is evident that high efficiency and low power saving is achieved later by those approaches. Hence initial compromise in terms of efficiency may not be feasible in many sectors.

Figure 12. Green Index vs. Power Wastage



EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

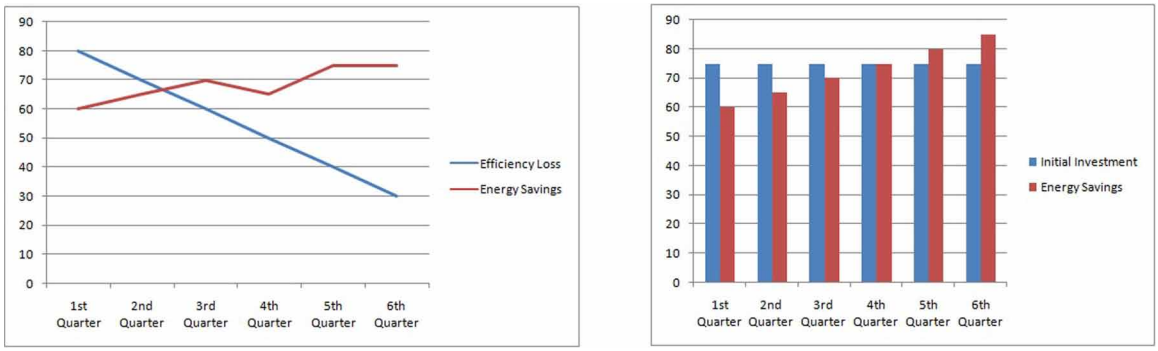
Table 5. Experimental Observations

Green Approaches	Task	Execution by Conventional Approach		Execution by Our Proposed Green Approach		Advantages
Green Project	Same projects are given to Two teams having 20 students each.	Test	Result	Task	Result	1. Time savings 2. Power savings
		Project is executed in sequential approach by another team and team is allowed to work in different places	Project is completed in 10 days and more power consumption	For one team project is executed in parallel approach and entire team works in a single room	Project is completed in 3 days and as single room is used minimum power consumption	
Green Transaction	Two same projects are given to Two teams.	Test	Result	Test	Result	1. Trees are saved as paper is not used. 2. Communication cost is minimum. 3. Fast communication 4. Fast processing
		Project requirement is given in a paper and only physical communication is allowed for another team	Physical communication makes the entire process time consuming	Project requirement is given through e-mail and e-communication is maintained for one team	Project is completed quickly due to fast communications.	
		One team is operating on a computer having old version software and no authorization/ authentication is checked	Project completion is delayed due to unexplainable behaviour of computer, such as sudden shut down, slow processing, malfunctioning due to unauthorized access.	Another team is operating on a computer having updated software.	Project is completed smoothly	
Green Resource	Two teams are given same resources to complete same project	Test	Result	Test	Result	1. Projects are completed in same time but minimum power is used.
		One team do not follow any automated system to operate the resources	Unlimited power usage	Another teams use the resources by implementing our proposed approach	Minimum power is used	

Figure 13. Comparative Power Consumption between Conventional System and Our proposed Green approach

**For a more accurate representation see the electronic version.*

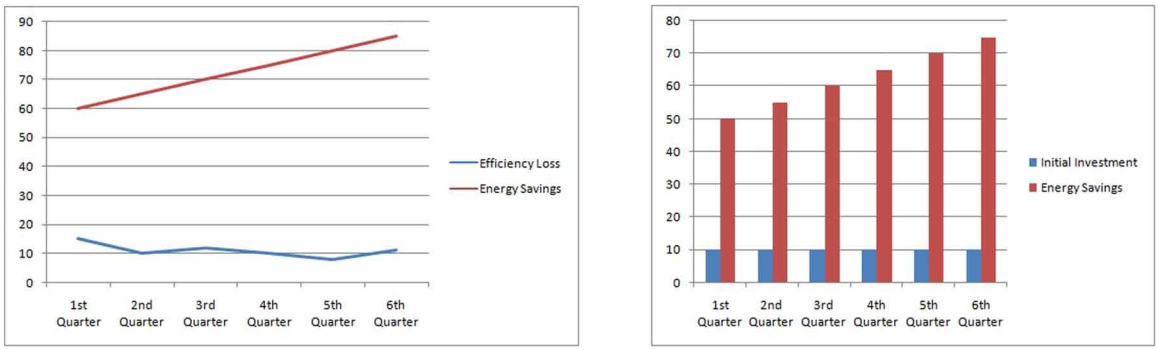
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



Initial investment is required for implementation of new architecture. Hence, expected outcome in terms of business as well as environmental point is achieved later as shown in Figure 14.

In our paper existing infrastructures of the system is tuned to achieve maximum energy savings. Highest degree of energy savings may not be achieved but maximum energy savings without compromising efficiency or initial investment. Energy savings with respect to the efficiency loss and initial investment is shown in Figure 15.

CONCLUSION



In this paper we propose different green services. We implement our proposed services in an urban traffic control room. It is evident from our framework and experimental results that proposed green approach is eco-friendly and efficient. Maximum power and energy are saved without affecting the accuracy of the system. We primarily focus on minimum energy usage without affecting the efficiency of the system. Different layer-based protocols are proposed to implement the Green concept in an automated system.

Figure 14. Efficiency Loss and Initial Investment for typical Green approaches

Figure 15. Efficiency Loss and Initial Investment with respect to Energy Consumption

**For a more accurate representation see the electronic version.*

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In layer-based protocol we concentrate on power savings, energy savings, and maximum utilization of resources, proper authorization and authentication of resources to minimize the energy wastage and maximize efficiency. Faster and efficient system is formed reducing the consumption of power and energy. System productivity is also increased as time and energy is preserved. Implementation of automated system in different sectors would be increased as the chance of environmental pollution is reduced by implementing this approach.

Chapter 36
Green Practices Implementation as Prerequisite to Sustain Firm Competitive Advantages:
The Empirical Study from Indonesia Large Scale Enterprises (LSEs)

Kardison Lumbanbatu
University of Diponegoro, Indonesia

Vincent Didiek Wiet Aryanto
Dian Nuswantoro University, Indonesia

ABSTRACT

Encompassing firms to apply green policy in a holistic management practices are strongly required in order to maintain competitive advantages and experience long-term marketing performance. This current empirical research is aimed to fill the lack of empirical findings and empirical studies on firm's innovative concept. Green-based product innovation, green management practices and green corporate image are presented as the antecedents and postulated as the sources of sustaining firm competitive advantages. A questionnaire-based survey was deployed to collect data from Large Scale Enterprises in Indonesia with Top Management, Operational and Marketing Managers served as respondents. 500 questionnaires were mailed and 388 were valid for further analysis. Data was analyzed by using Confirmatory Factor Analysis (CFA) and Structural Equation Modeling (SEM) via AMOS statistical software. Statistical findings demonstrated that green-based product innovation, green management practices and green corporate image significantly has a positive affect to sustain firm competitive advantages which is led to enhance long term marketing performance. However, green-based product innovation plays insignificant direct relationship on long term marketing performance. This study discusses some managerial implications for enterprises and recommendations on a basis of green implementation.

1. INTRODUCTION

Many reseach had been conducted regarding on green concept to find out the green operation of firms world-wide. The topic and the strategy applied were varies such as studies which assessed the greenness of environmental advertising conducted by Leonidou, Leonidou, Hadjimarcou, and Lytovchenko (2014); the finding claimed that the green advertisements played a significant role such as situation points, the profile of advertiser, targeting features, message factors and the nature. Other research showed the effects of consumers on environmental impact in product labelling (Borin, Cerf, and Krishnan, 2011), meanwhile the Consumer responses to Eco-labelling showed by Thøgersen, Haugaard, and Olesen (2010). Moreover, customer social responsibility attached to product, also trigger the green firm performance as shown by the strong impact of CSR-labelled products in retailers' assortment (Carrero and Valor, 2012); sustainability labels in the consumer perception (Binnekamp and Ingenbleek, 2008); Effect of green labelling on residential property price (Jayantha and Man, 2013); Exploring green consumers' product demands and consumption processes (Luzio and Lemke, 2013); Green care governance (Vik and Farstad, 2009); Label design (Henley, Fowler, Yuan, Stout, and Goh, 2011); competitive advantage has a strong relationship with CSR to increase higher and profitable corporate image (Bansal and Kumar, 2011), competitive advantage has a strong relationship with CSR to increase higher and profitable corporate image (Pop, Vaduva, Dabija, and Fotea, 2010), sustainable development as a set of transformation that align human relationship with nature (McLane, 2015), customers attitude on online grocery shopping It stated that the green image of firm will sustain customers trust

(Al Nawayseh and Balachandran, 2012), holistic sustainability of tourism attractions (Ottenbacher, Schwebler, Metzler, and Harrington, 2015), green new deal to seek for knowledge, Sustainability, and green development (Barth, 2011).

The green side of materialism in emerging BRIC and developed markets (Strizhakova and Coulter, 2013); The effect of green messages on brand purchase and brand rejection (Wheeler, Sharp, and Nenycz-Thiel, 2013); The influence of private labels on retailer cooperation (Zippel, Wilkinson, and Vogler, 2013); The nature and incidence of private label rejection (Nenycz-Thiel and Romaniuk, 2012); Understanding efficiencies behind logistics service providers' green offerings (Isaksson and Huge-Brodin, 2013).

Besides focusing on green product labelling, the most recently trending topic in green is green environmental. green management and environmental (Teixeira, Jabbour, and Jabbour, 2012); From shadow to green (Markandya, González-Eguino, and Escapa, 2013); environmental technology sector green (Guziana, 2011); Green teams: understanding their roles in the environmental management (Jabbour, Santos, Fonseca, and Nagano, 2013); environmental management capability (Wong, Lai, Shang, Lu, and Leung, 2012); Environmental innovations and profitability (Ghisetti and Rennings, 2014); environmental innovation embedded within high-performance (Antonioli, Mancinelli, and Mazzanti, 2013); effects of environmental policies (Saltari and Travaglini, 2011); How green is Environmental gardening identity (Kiesling and Manning, 2010); green and profitable sustainable (Figge and Hahn, 2012); Embedding "substrate" in environmental assessment of green (Peri, Traverso, Finkbeiner, and Rizzo, 2012); Going green or going away (Zhu, He, and Liu, 2014).

Studies which propose standards to apply green business strategies such as (Nulkar, 2014); how firm should have environmental consciousness and green (Huang, Lin, Lai, and Lin, 2014); available information on environmental issues (Mitomo and Otsuka, 2012); green product innovation on firm performance (Ar, 2012); Does international experience help firms to be green (Aguilera-Caracuel, Hurtado-Torres, and Arago´ n-Correa, 2012); Urban green space, public health, and environmental justice (Wolch, By-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

rne, and Newell, 2014); Influence of green spaces on environmental (Qin, Zhou, Sun, Leng, and Lian, 2013); Environmental performance (Rincón et al., 2014); pro-environmental self-identity (Whitmarsh and O'Neill, 2010); How green are environmental technologies (Papa, Pedrazzani, and Bertanza, 2013); business environment on environmental purchasing (Björklund, 2011); Pro-environmental behaviours (Kalamas, Cleveland, and Laroche, 2014).

The natural resources, renewable as well as un-renewable affected the firm policy implementation. Some previous studies related, such as the Energy, economic and environmental discourses and their policy impact by Winfield and Dolter (2014); impact of environmental proactively on multiple performance outcomes (Sambasivan, Bah, and Jo-Ann, 2013); green energy brands (Hartmann and Apaolaza-Ibáñez (2012); Does it really pay to be green (Clarkson, Li, Richardson, and Vasvari, 2011); renewable energy, environmental degradation and economic growth (Zeb, Salar, Awan, Zaman, and Shahbaz, 2014); Environmental orientation and corporate performance (Chan, He, Chan, and Wang, 2012); green information systems adoption and environmental performance (Gholami, Sulaiman, Ramayah, and Molla, 2013); strategy selection for environmental risk (Zhao, Neighbour, Han, McGuire, and Deutz, 2012); environmental competitiveness and innovation (Fankhauser et al., 2013); Effective environmental marketing of green cars (Siriwardena, Hunt, Teisl, and Noblet, 2012); How much green for the buck (Chabé-Ferret and Subervie, 2013); environmental management system for green (Hsiao, Chuang, Kuo, and Yu, 2014); Geo-Environmental Challenges (Ismail, Don, Diman, and Wijeyesekera, 2013); green innovation on environmental performance (Tzu-Yun Chiou, Hing Kai Chan, Fiona Lettice, and Sai Ho Chung, 2011); Going Green of Mission (Yozgat and Karataş, 2011); Prioritizing Drivers for Green Manufacturing: Environmental (Mittal and Sangwan, 2014); To be or not to be green (Cho, Thyroff, Rapert, Park, and Lee, 2013); Moving towards an ecologically sound society .

Concurrent encountered problems are vary, as Juan (2011) claimed that the most challenging problem concerns on the environmental is unwise energy consumption. Meanwhile Huber (2004) highlighted that the most difficult factors in achieving the living standard is the ecological sustainability. This finding aligned with Frenken and Faber (2009) demonstrated that recognized environmental innovation offer benefit to sustainability. These finding to conclude that there is a significant relationship between environmental issue and business. Furthermore, Yang and Chen (2011) reported some studies have been implemented to reduce the negative impact of industry on environmental. The effort of top management support on environmental management plays crucial role to increase firm performance (Y-S. Chen, 2008).

Some benefits impact of the improved innovation such as energy saving, reduction of CO2 emissions, savings water consumption, increased recycling, increased biodiversity, environmental pollution decreased. Carrion-Flores and Innes (2010) added some positive impact of innovation such as growth and competitive capability, higher productivity and economic wealth, waste reduction and environmental damage (Carrion-Flores and Innes, 2010). T-Y. Chiou, H.K. Chan, F. Lettice, and S.H. Chung (2011) stated that stresses on green innovation with lower environmental impact during life cycle will effect on higher green sales as the percentage of total sales. Furthermore, green innovation is considered as key factor to achieve sustainable development (M.-J. J. Lin and Chang, 2009), as well as the contribution on sustainable society (Carrillo-Hermosilla and del Rio, 2009).

There are two huge parts known in green innovation or environmental innovation. Firstly, green product design process (GPDP) or eco-innovative design (EiD) (Chang and Chen, 2004; K. Rennings, Ziegler, Ankele, and Hoffmann, 2006; Ziegler and Nogareda, 2009). Secondly, the relationship between environmental innovation and science or environmental innovation and science or government policy (K. Rennings, 2000; Kemp and Arundel, 2008; Janicke M., 2008; Carrion-Flores and Innes, 2010; Demirel

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

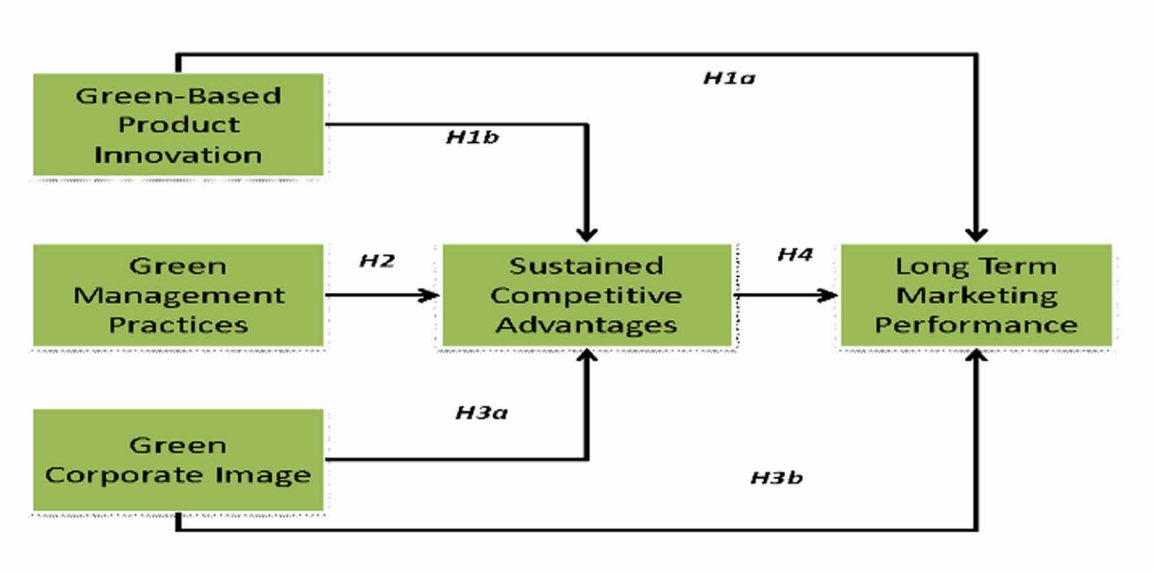
and Kesidou, 2011). Yang and Chen (2011) contended that there was the significant impact of innovation on new products. The lack of findings and scientific studies are considered as the most problems encountered to identify the green innovation concept. The improvement in innovation and economic development somehow lead to environmental damage.

Current study will investigate the impact of green based product innovation, assessing the relationship between green innovation, green management practices, green corporate image on sustained competitive advantage, and the impact of sustained competitive advantage on long term marketing performance. The study has the sequences as follows. The next step is presenting the theoretical framework and develops the research hypotheses. Section 3 discusses the methodology, data collection and analysis. Section 4 reveals the findings, section 5 demonstrates results, sump up, managerial implications and further research.

2. THEORETICAL FRAMEWORK AND HYPOTHESIS DEVELOPMENT

2.1. Green Innovation

Carrillo-Hermosilla and del Rio (2009) stated that it hardly to define green innovation even though many attempts have been made. Krammerer (2009) defined environmental innovation as a part of innovation which leads to the improvement on equality of ecological. Y-S. Chen, Lai, and Wen (2006) described the definition of green innovation relates with the engagement in energy saving, pollution prevention, waste recycling, green product design, furthermore, Halila and Rundquist (2011) said that the term of Eco-Innovation (environmental innovation, green innovation or continuously innovation) are mostly deployed to identify the innovation which contributes on environmental through ecology. Eco-Innovation also defined as the application which contains new product, technical, practical, system and product to avoid and reduce the negative impact on environmental. Current study focuses on green product innovation and analyzes the relationships between green-based product innovation, green management practices, green corporate image, sustainable competitive advantage and long term marketing performance as can be seen in Figure 1.



In this study, the green innovation defined as the whole actions taken by the stakeholder which is relevant to development and application, process, products, technical and management that offers contribution to reduce negative impact on ecology (Kemp and Arundel, 2008). According to Yu-Shan Chen (2011) green innovation could be classified in to three categories as green product innovation, green process innovation and green managerial innovation. This conventional category enhance to increase in creating the focus on eco-innovation concept. This study focuses on green based product innovation, green management practices, green corporate image, sustainable competitive advantage and marketing performance as seen at Figure 1.

2.1. Green-Based Product Innovation on Sustainable Competitive Advantage and Long Term Marketing Performance

There are some consideration to propose green product innovation and marketing performance as the antecedents and consequences for current study. Some factors in green product innovation which is believed as the key drivers for the efficiency of material usage, low cost will lead the way for firm to find out new method to change the waste to additional value. Besides, growth the cash flow, increased

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The proposed theoretical model

performance and corporate reputation (Eiadat, Kelly, Roche, and Eyadat, 2008). Krammerer (2009) noted that green product as public benefit instead of private benefit for customers to obtainand increase strong consumer demands.

One of research and development purposes is to design and to discover green technology for manufacturing green products. Hence, research and development required good cash flow performances. Kahloul and Zouari. (2013) stated that firm's immediate growth was triggered by research and development to sustain corporate growth.

Y-S. Chen et al. (2006) claimed that firms could leverage the resources' productivity through green innovation whilst Carrion-Flores and Innes (2010) demonstrated that there is a strong relationship environmental innovation and environmental performance based study on 127 manufacturers. Furthermore, the innovation could minimize the cost, determinant factor to a higher environmental performance. Gluch and Thuvander (2009) described that organization could push it capability to absorb the green innovation and business performance, a study conducted in Sweden.

Moreover, Edgeman., Bøllingtoft., Eskildsen., Kallehave., and Kjærgaard. (2013) Rick Edgeman also declared that to sustain excellence firm performance and firm going concern, Innovation is definitely needed to be accentuated.

Pujari (2006) conducted a survey concerned on projects of new product development in North America reported that Eco-Innovation has a positive impact on competitive advantage. The current research proposed hypotheses as follows:

Hypothesis 1a (H1a): The higher the degree of green-based product innovation, the higher the rate of sustainable competitive advantage.

Hypothesis 1b (H1b): The higher the degree of green-based product innovation, the higher the rate of long term marketing performance.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.2. Green Management Practices on Sustained Competitive Advantage and Long Term Marketing Performance

It is a crucial factor that top management support could achieve the innovative application. This innovative application is generally considered as a green management practices. Besides, (Ho, Lin, & Chiang, 2009) highlighted that the higher green management practices, the higher rate of firm's willingness to implement green innovation. Buyukkeklik, Toksari, and Bulbul (2010) emphasized that the environmental managerial cases is considered as a determinant factor to effect green managerial practices. This, at the finally could trigger the green innovation implementation, as in return, it could lead the firms to sustain competitive and high performance.

C.-Y. Lin and Ho (2008) declared that by support and motivation of firm will affect the willingness to adopt green practices. Furthermore, Jansson, Marell, and Nordlund (2010) claimed that values, trust, and norms that determine the willingness to adopt the Eco-innovation. Buyukkeklik et al. (2010), also claimed that even managers had just begun to care the environmental, so far it was not reflected green practices on his or her business.

M.-J. J. Lin and Chang (2009) conducted a study in Taiwan by exploring the effect of firm's etiquette on green learning and innovation performance. Furthermore, managerial focus is considered as the most crucial driver to adopt and apply the green practices as the empirical finding gained from industry in China. The green practices will finally lead to higher sustainable competitive advantage. Therefore, the current study proposed the hypotheses as follows.

Hypothesis 2 (H2): The higher the degree of green management practices and, the higher the rate of sustainable competitive advantage.

2.3. Green Corporate Image on Sustained Competitive Advantage and Long Term Marketing Performance

Many previous research which concerned on green corporate image demonstrated the similar findings that claims positive relationship between green corporate image and purchase behavior or loyalty (David, Kline, and Dai, 2005; Keh and Xie, 2009; Lee, Hsu, Han, & Kim, 2010). Furthermore, as consumer find more satisfaction, the more intense investigating conducted related with the new product, this defines the important of green corporate image in buying behavior.

Corporate Social Responsibility sometimes considered as firm green image. Kakabadse., Kakabadse., and Lee-Davies (2014) described that in order to sustain corporate image, CSR should be embedded within firm environment. Green corporate image which obtained from CSR will lead to green customer behavior and long term marketing performance.

Hsieh, Pan, and Setiono (2004) declared the important of consumers' attitude on green corporate image had a significant impact on brand purchase behavior. Corporate image and corporate reputation are believed to be the factors that affect consumer behavior, such as customer loyalty and word of mouth behavior. Furthermore, corporate reputation was also considered as the most influenced on word of mouth behavior. Besides, Ha (1999) product-related factor of green corporate image is the key predictor factor which is crucial in purchase intention, where those factors are believed could reduce the hardest in purchase decisions. Obviously, green corporate image could increase the competitive advantage. Therefore, the current study proposed the hypotheses as follows:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis 3 (H3a): There is a positive relationship between Green Corporate Image and sustained competitive advantage.

Hypothesis 3 (H3b): There is a positive relationship between Green Corporate Image and Long Term Marketing Performance.

2.4. Sustained Competitive Advantage and Marketing Performance

Higher marketing performance could be gained and leveraged through customer orientation with adequate understanding on aimed consumers. Firstly, Competitor orientation is also believed as other factor to increase marketing performance. The producers not only have to recognize and understand the strength, weakness, capability, long-term strategy but also potential competitors. Thirdly, inter-functional coordination utilization of coordinated resources in firms to create superior value for targeted customers (Narver, Slater, and MacLachlan, 2004).

Hadjimanolis (2000) claimed that the most important marketing performance measurement is sales growth, workforce growth, profits growth and market share growth. The argumentation on growth is the precisely indicators and convenience compared with accounting measurement. Financial performance and growth are the different aspects from marketing performance, which is having important information and uniqueness. Simultaneously, the growth and financial performance provide broaden description on actual performance from an industry compared with using self-measurement. Others findings found three criterion of marketing performance measurement, effectivity, efficiency and adaptability.

Mavondo (2008) summarized that human resources practicals has strong relationship with marketing effectiveness, operational effectiveness and marketing performance. Further in study conducted showed that human resources mediated the relationship of market orientation and performance, this could emphasize that human resources should take a part in market orientation (Hult, Ketchen, and Nichols, 2002).

Madu, Kuei, and Lin (1995) measure the market performance with some dimensions such as productivity, cost performance, profitability, competitiveness, sales growth, earning growth and market share. Moreover, market performance is organization ability to self-transformation encounter the challenges from the environment with long-term perspective. To sum up, the following hypothesis is related works of previous study:

Hypothesis 4 (H4): There is a positive relationship between sustain competitive advantage and Marketing Performance.

3. RESEARCH METHOD

3.1. Measurement

A self-administered questionnaire was constructed in accordance with robust literatures traced. The questionnaires focus on green firm's concept. Investigating the conceptual model, present study adopts a 19-item-questionnaire which contains of green-based product innovation (five items), long term marketing performance (three items), Green Corporate Image (four items), sustained competitive advantages (five items items) and Green management Practices (four items). A ten-point rating scale was used to measure the items which anchored by strongly disagree," (1) and "strongly agree,"(10).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.2. Sampling and Data Collection

The large scale enterprises in Indonesia are chosen for current research. There are some criteria considered to be fulfilled before selected as the sample. Firstly the length of firms operation is five years minimum, secondly, the number of workforces is also taken into consideration.

The data were collected from Indonesia during the late of 2013 and early 2014. Data collection was conducted via mailing and E-mail, face to face. A total of 500 questionnaires were sent, 400 were received and 388 were valid for further used. To increase the questionnaires rate of return, author resent questionnaires and called back. The sample size meets the requirement for the casual model with 19 indicator refers to Bentler and Chou (1987)'s claimed that about 5 to 10 observations per indicator variable.

3.3. Analysis

Testing six main hypotheses, present study deployed Structural Equation Modeling (SEM) via AMOS 4.0 and SPSS 16 software packages. Byrne (2001) suggested that the assessment of hypotheses' relationship among constructs to find out latent variables and identify the direction and the relationship, SEM software was used. Firstly, the measurement scale assessment, the EFA was conducted, then for test validation, CFA was done.

4. ANALYSIS AND RESULTS

4.1. Descriptive Statistics

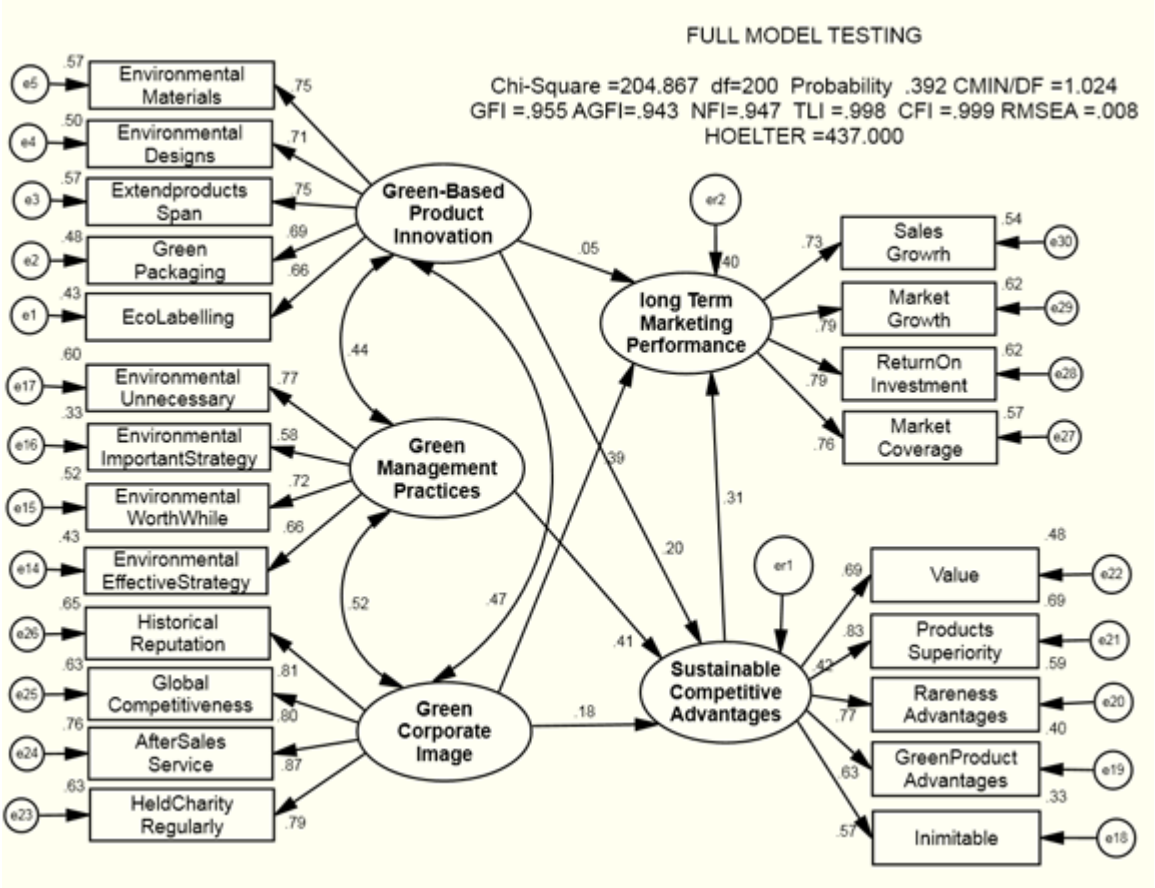
In terms of the number of workforces, all selected firms have been run the firms more than five years and have more than one hundred employees. The employees are distributed working in the field of Mining, Furniture & Industry Processing, Rubber industry, Lodging, Vehicles, Paper and Pulp, Chemistry, Leather, Electrical, Food and Beverages, Machine and Supplies, Machine and Office Utensil, Garment, Publishing and Printing, Gas, Radio, TV and Electronic, Textilee, Steel and Tobacco.

The very beginning and the latest responses were investigated to avoid response test bias as advised by J.S. and T. (1977) regarding on the nature, operational time and the total of employees. T-tests result demonstrated that the mean differences for each measure was not significant at a significance leve, 0.05, therefore, there is no "non-response bias"

4.2. Measurement and Structural Models

4.2.1. Measurement Model Results

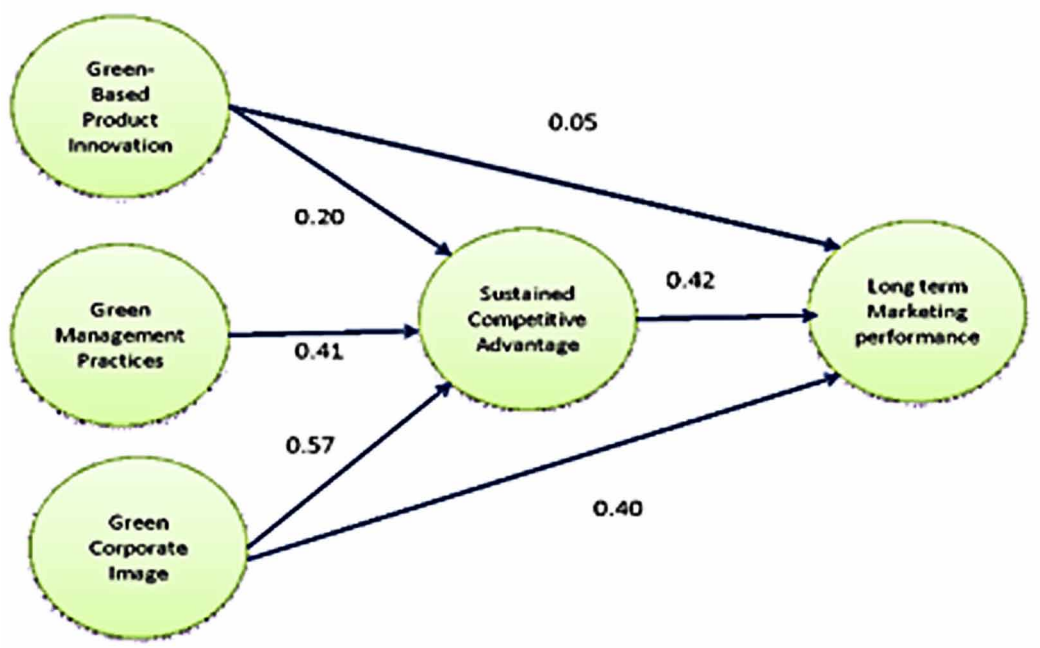
The usage of CFA to measure the reliability and validity, noticing that all observed indicators were considered free by standardizing the exogenous as well as endogenous latent variables. The statistical results described that the measurement model includes all of the indicator items of the constructs shown in Table 1. The global fit Indices of this model (2/df=2.00, GFI =0.955, AGFI= 0,943, NFI=0.947, CFI=0.999, TLI = 998 and the RMSEA=0.08, and Hoelter = 437) this output indicated that the hypothesized model fits the data. However, further validity should be examined the critical psychometric properties such as



EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

unidimensionality, reliability, and validity. Composite reliability Pop et al. (2010) were tested by computing the composite reliability estimation, whilst discriminant and convergent validity were measured by means of Average Variance Extracted (Peri et al., 2012).

The whole of items should be referred to confirmatory factor analysis (CFA) to verify unidimensionality, discriminant and convergent validity. Based on to the output of CFA, described at Table 1, the range of factor loading of CFA started from 0.70 to 0.90, and all loadings are significant ($p<0.001$), by means supports the unidimensionality and all composite reliability more than then considered that all construct meet the requirements.



Testing reliabilities of the constructs was conducted to compute cronbach's Alpha. Nunnally and Berstein (1999) claimed that a Conbach's Alpha of >,07 met the requirements on reliability. Having the all constructs are satisfactory and acceptance of convergent validity, the research can be proceeded. As suggested that AVE values for each construct should be more than the threshold (0,60). Finally, the statistical output demonstrated that the square root of the AVE value for each construct is bigger than the correlation coefficients which is becoming the evident for convergent validity as seen in Table 2.

Figure 2. Full model testing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Full structural model

The coefficient of determination of all proposed variables green-based product innovation (mediated by sustained competitive advantage), green management practices, Green corporate image < sustained competitive advantages) are high, this indicates that, the used variables (antecedents) are truly necessary and key determinant factor to increase marketing performance.

4.3. Structural Equation Modeling

Having met the requirement obtained from measurement issues, the structural model in Figure 1 was subsequently tested. According to the results are presented in Table 3, the measurement model includes all of the indicator items of the constructs shown in Table 1. The global fit Indices of this model (2/df=2.00, GFI =0.955, AGFI= 0,943, NFI=0.947, CFI=0.999, TLI = 998 and the RMSEA=0.08) respectively. These results indicate a good fit of the model.

4.4. Hypotheses Testing

The structural model illustrated in Figure 2 highlighted the insignificant and significant standardized path coefficients. Green-based product innovation is significantly related to sustained competitive advantage but it is insignificant on long term marketing performance directly. Green management practices as well as green corporate image are strongly as the key antecedents of sustained competitive advantages. Green corporate image is also significant on long term marketing performance directly. As predicted before, sustained competitive advantages are a determinant factor for long term marketing performance.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Results of the measurement model (confirmatory factor analysis

Constructs and Measurement Items	Standardized Loadings	*α*	*CR*	*EVA*
Green –Based Product Innovation (GBPI)		.90	.87	.76
• *Using less or non-polluting/toxic materials (Using environmentally friendly material*	.75			
• *Improving and designing environmentally friendly*	.71			
• *Recovery of company's end life product and recycling*	.75			
• *packaging (e.g.: less paper and plastic material used) for existing and new products*	.69			
• *Using eco-labeling*	.66			
Long Term Marketing Performance (MP)		.78	.75	.72
• *Sales growth*	.73			
• *Market share*	.79			
• *Return on investment*	.79			
• *Market Coverage*	.76			
Green Corporate Image (GPI)		.82	.84	.64
• *Historical and traditional reputation is strongly seen*	.83			
• *Achieving global competitiveness*	.81			
• *Providing after sales services*	.83			
• *Held regularly charity*	.79			
Sustained Competitive Advantage		.78	.92	.67
• *Value*	.57			
• *Product Superiority*	.63			
• *Inimitability*	.77			
• *Rareness Advantages*	.83			
• *Green Product Advantages*	.69			
Green Management Practices (GMP)		.73	.88	.74
• *Environmental innovation is not necessary to achieve high levels*	.77			
• *Environmental innovation is an important components of strategy*	.68			
• *Most environmental innovations are worthwhile*	.63			
• *Environmental innovation is an effective strategy*	.79			

Note: All items is measured with Ten-point scale, anchored by "Strongly Disagree" and "Strongly Agree. All factor loadings are standardized and significant at 5%, CR: Composite Reliability, AVE: Average Variance Extracted.

Table 2. Correlations and the square root of the AVE

Research Construct	Green–Based Product Innovation	Green Management Practices	Green Corporate Image	Sustained Competitive Advantage	Long Term Marketing Performance
Green –Based Product Innovation	0.90	0.56	0.68	0.47	0.43
Green Management Practices		0.94	0.78	0.56	0.27
Green Corporate Image			0.88	0.48	0.34
Sustained Competitive Advantage				0.85	0.24
Long Term Marketing Performance					0.92

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.4.1. Direct and Indirect Effects

H1a proposes that green-based product innovation affect sustained competitive advantages play significant role on sustaining the competitive advantages, whilst H1b green-based product innovation on long term marketing performance is insignificant, As Figure 3 showed that green-based product innovation has a positive effect on sustaining competitive advantages (0.20), meanwhile the insignificant green-based product innovation on long term marketing performance (0.05). Thus, H1a is rejected and H1b is supported. This suggested that long term marketing performance is more likely achieved through sustained competitive advantage rather than a direct relationship with green-based product innovation.

H2 proposes the effect of green management practice on sustained competitive advantages is supported (0.41).

H3a which proposes the effect of green corporate image on sustained competitive advantage and H3b the effect of green corporate image on long term marketing performance are supported (0,39) and (0.18) respectively. This could be meant that when corporate image is considered green, firm will sustain its competitive advantages and also will experience its long term marketing performance.

Once firms sustained its competitive advantages, firm will perform long term marketing performance as H4 proposes the effect of sustained competitive advantage on long term marketing performance is supported (0.31).

5. DISCUSSION AND CONCLUSION

Winning tough competition, green concept and green implementation is viewed crucial factors and part of firm's policy. Providing some insights for policy makers and top management into mapping the green concept as well as green image as aligned with previous study (Ellen, Webb, and Mohr, 2006; Melewar, Karasmanoglu, and Paterson, 2005).

Based on the acceptance of proposed hypotheses to sustain long-term marketing performance, firms should strongly emphasize on green-based product innovation by friendly material, design environmental

Table 3. The results of path analysis (base model)

Hypothesized Variables			Estimate	SE	CR	Hypotheses	Support
Long Term Marketing Performance	**<--**	**Green-Based Product Innovation**	.058	.078	.742	H1a	No
Sustained Competitive Advantages	**<--**	**Green-Based Product Innovation**	.219	.071	3.099	H1b	Yes
Sustained Competitive Advantages	**<--**	**Green Management Practices**	.528	.098	5.403	H2	Yes
Sustained Competitive Advantages	**<--**	**Green Corporate Image**	.163	.060	2.695	H3a	Yes
long Term Marketing Performance	**<--**	**Green Corporate Image**	.406	.069	5.896	H3b	Yes
long Term Marketing Performance	**<--**	**Sustained Competitive Advantages**	.352	.075	4.673	H4	Yes

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

friendly, green packaging as well as eco-labelling. Meanwhile, green management practices should be attained through green innovation to achieve high levels and green innovation as components of strategy. To increase the green firm image, there are some options to consider such as firm should depict their historical and traditional reputation are strongly shown, reaching global competitiveness, the availability of after sales service and social charity.

The existence of green based- product innovation is positively related with sustained competitive advantages, as well as green management practices, and green corporate imagee, further sustained competitive advantages has a significant impact on marketing performance. The purposes of this study is to offer added views and perception within the relationship between green-based product innovation, green management practices and green corporate image.

The evidences presented in this present study elaborated the relationship between between green-based product innovation, green management practices and green product image, market position and marketing performance. This showed that green-based product innovation in general have positive impact on market position and marketing performance. This could be shown that the strong significant and impact of all green innovation practices at the end will lead to higher rate of marketing performance, (Pujari, 2006; Y-S. Chen et al., 2006; T-Y. Chiou et al., 2011).

Some implications that can be taken such as the promotion made by firms to introduce, develop green-based practices, green innovation should be coordinated with any related fields and implemented as well to integrate the environmental and green innovation to increase marketing performance. For all stakeholders should more focus on environmental issue for green performance.

Like other studies, current study has some limitations that are recommended for future study to conduct such as manufacturing sectors, future research might use a sample from market in a different countries. Firstly, the data were collected from large scale enterprises in Indonesia with general manager, operational and marketing managers served as respondents. Having them as respondents for somehow have different perceptions on completing the questionnaires.

Secondly, based on the statistical output highlighted that the coefficient of determination is relatively low for the target variables such as green corporate image (0.163), and green based product innovation (0.058) that indicates the other green practices are compulsory considered.

Third, one of current study a hypothesis is rejected, that is the impact of green-based product innovation on long term marketing performance. Generally, green product innovation in a long term could not be sustained as a new innovation will be emerging.

Further research also could consider some options. Firstly, single respondent is enough to representative one firm, suggest avoiding multi-sources respondent that represent a firm since this could lead to bias respond. Secondly, a moderator variable such as environmental regulation is worth trying. Furthermore, to be more specific, and to make more specific, to mention a product line innovation is better than just generalizing products in common.

ACKNOWLEDGMENT

Herewith, we would like to thank the reviewers for constructive suggestions and valuable comments, also for the respondents participated in this study.

ABSTRACT

The global shift in ecological movement has significant impacts on business operation of manufacturing firms that are located in developing countries. The intense pressure of being environmentally sustainable has caused Green Supply Chain Management (Green SCM) concept to emerge as an important corporate environmental strategy for manufacturing companies. Information technologies and systems have permeated in most business activities, in which, they extend important opportunities to resolve environmental issues. However, many researchers, including manufacturers and government bodies often disregard the green concept of information technologies and systems in minimizing environmental issues. A comprehensive review on Green SCM, Green IT and Green IS for sustainable environmental performance in manufacturing companies is presented using Input-Process-Output (IPO) Theory and Technological-Organizational-Environmental (TOE) theory. In bridging the research gap, a model is constructed to link the aforementioned constructs. Next, the paper reports on the development of survey questionnaire using cognitive interviewing strategies, followed up with semi-structured interview to investigate and obtain preliminary findings on the influential factors, green activities and performance

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

outcomes from implementing Green SCM. Lastly, the finalized survey questionnaire was distributed to 60 ISO14001 certified manufacturing companies located in the region of Perak and Kulim. Out of 60 manufacturing companies, only 32 responses received as the dataset in analyzing for improvements in reliability, measurement error, and validity of measured items. The findings from this pilot study explain that internal and external factors have stronger influence over the implementation of green initiatives in supply chain with substantial outcome on environmental performance. The information technologies and systems being the physical resource, capability and backbone to run a business seamlessly are significantly recognized. But, the green component of IT and IS were poorly attended and disregarded to an extent in the process of greening the processes, operations or entire business. Therefore, further investigations are required in the main study to validate the findings obtained here and other possible association between the factors, practices and outcomes in realizing ecological improvements in the supply chain and firm itself.

INTRODUCTION

Manufacturing sector plays a key role in the modernization of a country, and is capable to extensively differentiate the developed countries from the developing ones (El-Khasawneh, 2012). The developing countries are the main contributors of increasing environmental issues, in which have negatively affecting the ecological sustainability as compared to the developed countries (Markandya & Halsnaes, 2004; Mithas, Jiban, & Roy, 2010). The increased levels of production of CO^2 and Greenhouse Gas (GHG) emissions are significantly causes adverse change to the global climate. This phenomena is in responds to the intensified growth of economic and urban populations of a nation (Gholami, Sulaiman, Ramayah, & Molla, 2013).

Being a nation that has emerged in a multi-sector economy, Malaysia offers a cost-competitive location for investors to capitalize in manufacturing advanced technological products for both national and international markets. Hence, manufacturing sector still remains as a significant contributor to the growth of Malaysia's economy (MIDA, 2012). Furthermore, Malaysia is making marginal, yet positive progression towards environmental management for the past few years (MGCC, 2012). Despite that, Malaysia is facing ecological challenges in terms of increased usage of energy (electricity), inadequate management of household and industrial wastes as well as poor treated gases emitted to the air (Abidin & Jelani, 2011; MGCC, 2012).

Industrialization, urbanization and boundless transactions are stimulating the production and widespread use of computers, printers, office equipment, servers, air conditioning devices and related IT infrastructures. These machines, hardware and infrastructures are consuming substantial amounts of energy to produce and operate (San Murugesan, 2008). Furthermore, ill-treated and irresponsible acts of manufacturing, managing and disposing of those tools are detrimental to the quality of air, water and soil that severely influence the environmental degradation (San Murugesan, 2008). In addition, the increase in information technologies and systems usage along with continuous high edge innovation has caused the shortening of IT product's life span, while mounting on the amount of e-waste being disposed. This scenario is obvious in developing countries like Malaysia, whereby the large scale adoption of PC, facilities equipment and proliferation of data centers are growing steadily in contributing to carbon emission, energy consumption and e-waste production.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The term green, eco-sustainable and environmental friendly are often used interchangeably. This concept describe an entity as a company, its products or production processes that consume less energy, minimize use of harmful materials, use of recycled materials, reduce of waste produce, minimize emission and pollution, as well as preserving natural resources (Molla, Cooper, & Pittayachawan, 2011). Both the Environmental Management (EM) and Supply Chain Management (SCM) have their own root that complement each other and must not be disregarded (Zhu, Sarkis, & Lai, 2008b). The implementation of Information Technology (IT) and Information System (IS) in SCM is becoming apparently important in a progressively globalized and competitive economy. The development of IT and IS in supply chain has rapidly changed the ways business are carry out seamlessly around the world. The uses of IT and IS are considered as prerequisite for an effective control of today's complex supply chain (Fasanghari, Roudsari, & Chaharsooghi, 2008). This highlighted that IT is a spring of essential resources for competitive necessity in achieving an edge in business (Li, Yang, Sun, & Sohal, 2009).

Although broader literature suggests that other internal and external factors have much stronger influence on the organization's behavior towards sustainability, yet the roles of Information Technologies and Systems (IT&S) are often ignored by organizations in the assessment of their environmental footprints (Jenkin, Webster, & McShane, 2011). The design, development and implementation of IT&S represent the backbone of ecological friendly efforts that support a firm's environmental management systems (Cai, Chen, & Bose, 2013).

The positive and negative impacts that IT&S might have on the organizations' environmental and sustainable movement still remain unexplored. Therefore, an in-depth research is required to determine the extent to which IT&S may improve sustainability in the realm of supply chains and logistics as suggested in (Melville, 2010). The same concern is displayed in the work of Zhu, Sarkis, & Lai (2008a) that emphasized the study on Green SCM is timely and necessary to better aid the organization and have yet to be fully investigated.

The business research on Green SCM, Green IT and Green IS have produced extensive review for last few years while the academia has now started to fill the research gaps and linkage of these three fields. Nevertheless, this topic is current and still lacking in research especially in the context of Malaysia. In responds to the research gaps identified, this study aims to identify and investigate the associating factors of Green IT&S, internal and external elements in influencing the implementation of Green SCM. Next, is to examine green practices within SCM that highly adopted and implemented within the manufacturing firms. Lastly, to investigate the outcomes from implementing the Green SCM on environmental and technological performance.

In this paper, proposed hypotheses are presented, along with method of study carried out for questionnaire development, pre-test with expert and pilot test of survey questionnaire. In the designing the questionnaire, cognitive interview method is adopted with selected ISO 14001 companies. The semi-structured interview during the pre-test allow the researchers to grasp initial understanding on the factors, practices and outcomes that related to Green SCM implementation. Whilst, the pilot test of the survey questionnaire is to determine the validity and reliability of the items measured.

The International Organization for Standardization (ISO) for 14001:2004 maps out a framework that an organization can follow to set up an effective environmental management system, as well as it provide an assurance that environmental impact is being measured and improved (http://www.iso.org/iso/iso14000). In this research, the respondents that are participating in the pre/pilot study and main study are Environmental Management System (EMS) ISO14001 certified manufacturing firms that are

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

located in Malaysia. The ISO 14001 manufacturing firms are choose as the population sample since those firms are expected to have embarked in environmental friendly activities in greening their business processes and operations.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Input-Process-Output (IPO) Theory

The current study attempts to conceptualize a successful implementation of Green Supply Chain Management from IPO conceptual model. The term of IPO is defined as "inputs that lead to processes that in turn lead to outcomes" (Ilgen, Hollenbeck, Johnson, & Jundt, 2005). The IPO Model explains Green SCM in terms of having "input", "process" and "output" which represent the building blocks of the integrated research framework of this study. IPO Model is used as the basis of the research framework which postulate input that represent the antecedents from TOE theory, follows by process that explains green practices carry out throughout the supply chain, and lastly output that portrays the performance outcomes resulted from employing the soundly antecedents and green practices.

Technological-Organizational-Environmental (TOE) Theory: Input Perspective

The TOE theory was developed in 1990 by Tornatzky & Fleischer. It identifies three aspects of an enterprise's context that influence the process by which it adopts and implements a technological innovation: that are, the technological context, organizational context, and environmental context (Tornatzky & Fleischer, 1990). The TOE framework as originally presented, and later adapted in IT adoption studies, provides a useful analytical framework that can be used for studying the adoption and assimilation of different types of IT innovation. The TOE framework has a solid theoretical basis, consistent empirical support and the potential for application to IT and IS innovation domains, however, specific factors identified within the three contexts may vary across different studies (Oliveira & Martins, 2011).

In this perspective, inputs, which refer to the antecedents that influence the Green SCM implementation. The factors are categorized into the three contexts of TOE framework, whereby Green IT and Green IS are represent technological context, follows with Internal Commitment in organizational context and Regulatory Pressure in environmental context. The four constructs identified represent the three contexts which explain technological and non-technological factors that drive the implementation of Green SCM.

Technological Context: Input Perspective

The implementation of Information System (IS) and Information Technology (IT) in Supply Chain Management (SCM) is becoming apparently important in an increasingly globalized and competitive economy. The advancement in the technology with high degree of automation in business processes is offering more opportunities than previously. IT as an infrastructure and a solution plays a critical factor in the improvement of SCM in within, downstream and upstream of the organization (Li, Yang, Sun, & Sohal, 2009). IT has leads to better performance in the supply chain with its power to provide timely, accurate, and reliable information, in which enabled real-time integration of SCM activities (Li et al., 2009). IT facilitates SCM by improving integration and coordination of physical flow as wells as

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the various information flow in the supply chain (Omar, Ramayah, May-Chuin, Sang, & Siron, 2010). Furthermore, data capture technologies such as barcode, global positioning, and radio frequency identification, ICT can significantly reduce labor, errors, and response time across the entire supply chain whilst decrease total supply chain costs and increase responsiveness in customer service (Lau & Huang, 2012). The use of IT is considered as a prerequisite for an effective control of today's complex supply chain (Fasanghari, Roudsari, & Chaharsooghi, 2008).

The green elements of IT and IS are often ignored by organizations in the assessment of their green movement and environmental footprints (Jenkin et al., 2011). Although technology components are critical, much are still lacking in the urgency to measure the impacts of IT and IS have on processes and business operations (Faucheux & Nicolaï, 2011). IT sector has begun to deploy on Green IT and Green IS, however, inadequate study exist on the actual practices in other sectors such as manufacturing, logistic and services (Faucheux & Nicolaï, 2011; Jenkin et al., 2011; Melville, 2010). Furthermore, most of the studies have concentrated on direct, first-order impacts of Green IT. Lately, researchers have initiated the investigation on the second-order effects of IT, or known as Green IS or IT for Green (Dedrick, 2010; Melville, 2010). The concept of "Green" is actively emerging in Malaysia with introduction of the strategic policies, programs and plans as part of government initiatives (PIKOM, 2012). Nevertheless, the importance of role of IT and IS for environmental sustainability in manufacturing sector is still under research.

Information Technologies and Systems (IT&S) have been contributing to environmental problems for the past few decades, which many have not realized till recently. The environmental issues are mainly caused by inefficient technologies, poorly designed systems and short life spans of IT products that take up the organizations' electricity costs (F Loeser, Grimm, Erek, & Zarnekow, 2012). But, IT&S are capable of reversing their impacts on the environment by going green. Green IT and Green IS are conceptualized in various ways depending on its context and scope. Green IT is referred as environmentally sound IT that focuses on practice of designing, manufacturing, usage and disposal of computers, servers and its associated subsystems with minimal or no impact on the environment, energy efficiency and total cost of ownership (Elliot & Binney, 2008; San Murugesan, 2008). In contrast, Green IS refers to the design and implementation of information systems that contribute to sustainable business processes (Dedrick, 2010; Faucheux & Nicolaï, 2011; Jenkin et al., 2011). Although, Green IT and IS are interrelated, but each has a different focus and purpose (Molla, 2013).

The adoption of eco-friendly technologies, systems and practices increase the ability to address IT&S environmental related concerns. These technologies, systems and practices are vital to be diffused and institutionalized rightly (A. J. W. Chen, Boudreau, & Watson, 2008). Hence, corporate greening can be construed as a first step towards the superior goal of environmental sustainability (Molla, 2009). Organizations are facing increasing pressure to look at every aspect of their operations and business with intention of greening, in preventing environmental degradation and negative financial credentials (Brooks, Wang, & Sarker, 2012). The increase in electricity costs has driven the rising demand for solutions that are able to reduce the need of high consumed technologies, and simultaneously use existing IS resources efficiently to operate the processes in an integrated and sustainable manner (Dedrick, 2010).

Therefore, with assimilation of IT&S solutions into supply chain daily activities, organization are capable of making sound and effective environmental decisions at each stage of SCM. Hence, Green IT is considered as one of the significant components that transforms supply chain management function towards environmentally conscious strategic movement (Cai et al., 2013; Gholami et al., 2013; Rao & Holt, 2005). The replacement of traditional technologies with Green IT has the capability to minimize

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the consumption of energy, carbon emission, equipment utilization and waste produced in manufacturing sector (Faucheux & Nicolaï, 2011; Molla, 2013). We therefore propose to contribute to the body of knowledge, in determining the extent to which technological factor coined as Green IT influence the implementation of Green SCM. The following hypotheses are therefore proposed:

Hypotheses 1 (H1): Green IT positively influences the implementation of Green SCM within ISO 14001 manufacturing firms in Malaysia.

In the recent years, IS literature began to realize the importance of sustainability, and its potential relationships in minimizing ecological footprints. The concept of Green IS is proposed with the focus to reduce the impact of IT but also used to help firms reduce their carbon footprint through automating the systems and application in order to transforms products, processes, and practices to an eco-friendly state (Melville, 2010; R. Watson, Boudreau, Chen, & Huber, 2008). Since, environmental sustainability is a supply chain commitment, therefore, Green IS is essential for creation, maintenance, and survival of environmental conscious practices in supply chain (Kenneth, Zelbst, Meacham, & Bhadauria, 2012). The Green IS have the ability to enable interconnectedness, realign and reinvent business processes in support of productivity and efficiency towards ecological improvements (Dwyer & Hasan, 2012).

The design and development of information systems represent the backbone of environmental management efforts that supports the firm's environmental management systems (Cai et al., 2013). Green IS encourages the application of information systems thinking and skills to initiatives across all functions of the organization (Adela J Chen, Watson, Boudreau, & Karahanna, 2010). Green IS is viewed as an enabler in inducing changes within and among business processes that decreases the environmental impacts through proper integration and coordination throughout the SCM (Boudreau, Watson, & Chen, 2008; Kenneth et al., 2012). Organizations are increasingly integrating their business processes without realizing that Green IS initiatives are not limited within companies, but extended to the externalities that need collaboration from the suppliers, customers and shareholders (Brooks et al., 2012). As emphasized in (Melville, 2010), a much in-depth research is required to determine the extent to which IS might improve sustainability in the realm of supply chains and logistics. Hence, the proposed hypothesis is:

Hypothesis 2 (H2): Green IS (IT for Green) positively influences the implementation of Green SCM within ISO 14001 manufacturing firms in Malaysia.

Organizational and Environmental Context: Input

Many researchers have placed a greater importance on firm's internal capabilities in order to overcome internal obstacles towards achieving sustainable competitive edge (Hart, 1995; Vachon & Klassen, 2006; Zhu & Sarkis, 2006). The internal factors encompass internal drivers (top/ middle management support, pressure from employees, leadership from influential individuals and environmentally committed organizational culture), environmental attitude, and internal obstacles (Holt & Ghobadian, 2009). The implementation eco-friendly within an organization rely on the associated internal and external factors. Some of external factors identified are legislation, competition and society (Holt & Ghobadian, 2009).

Companies that focus on development and deployment of firm's internal resources more than external factors are likely to implement successful Green SCM practices (Guang, Lenny, Baldwin, & Cucchiella, 2012). The top management environmental commitment, cross-departmental cooperation and employee

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

dedication, internal EMS with regular auditing as well as reliable financial resources are essential as the company organizational capabilities to efficacious implement environmentally friendly practices in the supply chain (Guang et al., 2012; G.-C. Wu, Ding, & Chen, 2012).

Many of these previous studies have concluded that regulation is a foremost external factor to drive an organization towards environmental management (Weng & Lin, 2011). Therefore, being compliance to the laws, regulations, directives and standard increase the organizations' capability to go green and be environmental friendly in the processes and business operations (A.J. Chen, Watson, & Boudreau, M.-C., Karahanna, 2009). Hence, regulation pressure plays an important role in shaping a firm's sustainability effort (Haanaes et al., 2011).

As highlighted in (Holt & Ghobadian, 2009), internal drivers and legislation are the most influential factors of Green SCM. Similarly, in (Zhu, Geng, Fujita, & Hashimoto, 2010), internal environmental management and regulations were the influential drivers in large Japanese organizations as well as among UK manufacturers (Kenneth et al., 2012). In (Diabat & Govindan, 2011), Interpretative Structural Modeling method was used to summarize the 11 drivers that affect Green SCM implementation, in which, the most influential driver is the government regulation and legislation. In addition to it, green movement is driven largely by stricter regulations as well as intense pressure from stakeholders and community (Srivastava, 2007; Zhu et al., 2008a). The previous research findings are supplement further with the recent articles that emphasize Government Regulation, Internal Readiness, and Corporate Social Responsibility as the motivators for an organization to make decisions pertaining to green initiatives within supply chain practices (Kohli & Hawkins, 2015).

Of the 30 research papers reviewed, the factors that scored the highest are regulations, expected business benefits, customer pressures and social responsibility, in which, comparable outcomes were discovered among EMS ISO 140001 manufacturing firms in Malaysia (Eltayeb, Zailani, & Filho, 2010). Many of the previous studies in Malaysia concluded that support from top management, legislation requirements, customer/supplier pressure and existence of Environmental Management System (EMS) are the most important factors that influence Green SCM within the manufacturing sector (Eltayeb et al., 2010; Eltayeb & Zailani, 2009; Ishak & Ahmad, 2010; Rusli, Rahman, & Ho, 2012). These findings are very much consistent with the results from other studies conducted outside Malaysia as well. The broader literature suggests that internal and external forces have strong influence on the organization's behavior towards sustainability (Jenkin et al., 2011).

Therefore, addressing own internal environmental management with continuous commitment is the first step towards Green SCM implementation, before extending the efforts to suppliers and customers (Zhu et al., 2010). Thus, the proposed hypothesis is:

Hypothesis 3 (H3): Internal commitment positively influences the implementation of Green SCM within ISO 14001 manufacturing firms in Malaysia.

In Malaysia, however, obtaining environmental protection certification of ISO 14001 is not compulsory. Most of the companies adhere to environmental requirements and legislations imposed in Europe, Japan, or USA (Zailani, Eltayeb, Hsu, & Tan, 2012) and environmental standards such as REACH, WEEE or RoHS (Eltayeb et al., 2010). Therefore, further investigation is required to identify the relationship of regulatory pressure in influencing company to integrate environmental thinking at each stage of product life cycle. Hence, the following hypothesis are proposed:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis 4 (H4): Regulatory Pressure positively influences the implementation of Green SCM within ISO 14001 manufacturing firms in Malaysia.

Green SCM Performance Outcomes: Environmental and Technological Performance

Performance measurement defines company's parameter to monitor, control and achieve specific objectives and outcome (Gunasekaran, Patel, & McGaughey, 2004). It provides a directive for the company to implement the desired practices, evaluate their execution, reveal the effects of the implementation and determine future actions or corrective plans (Ramayah, Siew, Ahmad, Halim, & May-Chiun, 2013). The improvement of the environmental performance is highly correlated to the factors that drive the emergence of Green SCM in an organization (Hsu & Hu, 2008). The implementation of GSCM practices in manufacturing sector shows favorable to significant achievement in environmental performance (Chien & Shih, 2007; Kenneth et al., 2012; Rao & Holt, 2005; Testa & Iraldo, 2010; Yan Li, 2011; Zhu et al., 2010; Zhu, Sarkis, & Lai, 2007b).

With reference to Malaysian context, companies that implement Green SCM attained significant positive outcome on the environmental performance in terms of enhancement in environmental compliance, reduction of emissions, harmful materials and wastes (Eltayeb et al., 2010; Eltayeb, Zailani, & Ramayah, 2011; Wan Hasrulnizzam Wan Mahmood et al., 2013). Hence, internal proactive environmental strategy and external institutional drivers will greatly influence the firm's environmental performance (Zailani et al., 2012). Despite that, Green SCM contributes to an insignificant outcome on environmental performance within the green practices of waste reduction (Azevedo, Carvalho, & Cruz Machado, 2011), reverse logistics and green purchasing (Eltayeb et al., 2011).

The relationship between GSCM and performance outcomes has been subject to numerous studies but the results are not conclusive since it varies according to the internal and external factors, firm characteristics, and geographical locations. The inconclusive result raises the question of what are the actual environmental outcomes that can be realized from implementing green practices in supply chains. As such, it highlights the need for in-depth studies of the relationship between GSCM and performance (Zhu, Sarkis, & Lai, 2007a). Besides that, a more rigorous research on environmental management is needed by researchers who are geographically located in Asian regions, as well as research with specific focus on Asian regions itself. (Seuring, Sarkis, Müller, & Rao, 2008). Hence, there is still a need to provide more empirical evidence on environmental performance within manufacturing sector in Malaysia The following hypotheses are therefore proposed:

Hypothesis 5 (H5): The implementation of Green SCM has positive influence on the environmental performance within ISO 14001 manufacturing firms in Malaysia.

The IT industry seems to have acknowledged and reacted to the role of IT in pursuing environmental sustainability. There are limited literatures and findings reported for industrial sectors as compared to IT sector (Faucheux & Nicolaï, 2011; Jenkin et al., 2011; F Loeser et al., 2012; Melville, 2010). In operations and manufacturing functions, environmental benefits from incorporating green information technologies and systems have begun to surface (A. J. W. Chen et al., 2008; R. T. Watson, Boudreau, & Chen, 2010). The use of Information Technologies and Systems (IT&S) are considered as prerequisite for an effective control of a complex and interconnected supply chains. IT&S are used as a decoupling

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

point to improve the performance of supply chain (Mason-Jones & Towill, 1999; Sundarakani, Tan, & Over, 2012). IT&S are regarded as organization resource (F. Wu, Yeniyurt, Kim, & Cavusgil, 2006) and organization capability (Molla et al., 2011) that required strategically for an organization to succeed in green movement. Information technologies and systems are the essential tools that enable automation, simulation, coordination, integration and optimization of functions throughout the supply chain (Auramo et al., 2005; I. J. Chen & Paulraj, 2004).

Greening of IT will assist in minimization of the environmental impacts with reduced power or energy consumption, carbon emissions and electronic wastes that will improve considerably power usage of office equipment, infrastructures, data center and facilities (Faucheux & Nicolaï, 2011; Molla, Deng, & Corbitt, 2010). Whilst, greening of IS will improve systems performance and usage, reporting capabilities, increases remote collaboration and interactions that reduce the impacts from logistics, track environmental information (such as toxicity, energy and water usage and wastes production) as well as monitoring and reporting environment baselines inputs (energy, water, materials) and outputs (waste, Greenhouse Gas (GHG) emissions) (Melville, 2010; R. Watson et al., 2008).

Green IT&S comprise a vast number of methods, metrics and perspectives, however, the scope and underlying measures still stayed vague and not well described (Erek, 2011). Organization are still using uncoordinated and improper environmental metrics to measure environmental impacts of IT in data centers, office environment as well as in industrial operations (Erek, 2011). Therefore, consumption of energy by IT equipment and hardware are poorly or roughly estimated, since mechanism used to measure it remains unclear. The lack of standardized procedures have caused difficulties for the organizations and government in monitoring, evaluating and controlling the environmental impacts from information technologies and systems. Recently, Green Grid presented a set of metrics and indices that can be formally adopted by organizations to measure on improvements of energy consumption resource efficiency of information technology in business processes, offices and data centers.

Organization were expected to switch to Green IT trend by year 2010, since the potentials of Green IT are very much appealing (Mines, 2008). Nevertheless, the assimilation of green IT&S as one of the environmental-friendly components within the organization's environmental initiatives are still poorly managed and integrated (Erek, 2011; Fabian Loeser & Erek, 2011). Hence, the extent of Green IT adoption and actual realization of the benefits are unknown to the organization, vendors, government and researchers. (Jamaludin, Hartini Ahmad, & Ramayah, 2012). Thus, further investigation with empirical evidence is essential in determining the effects of green information technologies and systems have on Green SCM, and its associated outcome coined as Technological performance. The following hypotheses are therefore proposed:

Hypothesis 6 (H6): The implementation of Green SCM has positive influence on the technological performance within ISO 14001 manufacturing firms in Malaysia.

METHODOLOGY

The important aspect in the data collection process is pilot study, which is defined as a small-scale trial run of all the procedures planned for use in the main study (Monette, Sullivan, & DeJong, 2002). The pilot study adopted the four-stage pre-testing as recommended (Dillman, 2000). The four stage methods comprises of: (1) item generation for questionnaires which are adapted from literatures, (2) cognitive

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

interview to obtain expert review on the questionnaire design; (3) semi-structured interview with representative of ISO14001 manufacturing firms to obtain preliminary understanding on factors, outcomes and green practices currently adopted within the organization; and (4) pilot survey questionnaire distributed to measure items validity and reliability.

Firstly, previous literatures were reviewed to identify the pertinent as well as relevant constructs and measures to be used in designing the questionnaire. The first draft of the questionnaire was developed with each item measured on a seven-point Likert scale. The questionnaire was reviewed by academician from similar areas. The interview sessions unstructured in nature, and were carried out at their office. The content of the questionnaires were satisfactory as it included the constructs and items to be investigated. The expert took almost 30-40 minutes to complete the questionnaire.

The recorded time indicates the need to shorten the questionnaire. This will allow the participants to take reasonable time of 10-15 minutes to respond to the questionnaire. The other comments recorded were on length, layout and measurement scale of seven Likert points. A lengthy questionnaire with unorganized layout have demotivating effect to the respondents from participating or completing the questionnaire. Moreover, seven point Likert scale with the given label might be confusing to some participants. The expert raises the concerns based on industrial practitioners' work nature and busy schedule. Hence, the changes suggested are required to improve the quality, and to ensure good participations in the main study.

The respondents for cognitive interview, semi-structured interview and distribution of final draft of the survey questionnaire are selected based on purposive sampling. The sample population are ISO 14001 manufacturing firms. These participants are expected to have embarked on green practices in their operations. Therefore, ISO 14001 manufacturing firms are in the best position to provide the required information (Kumar, Salim, & Ramayah, 2013). The information on the manufacturing firms has been obtained from Federation of Malaysia Manufacturers Perak Directory of year 2012. The ISO 14001 certification details were cross checked from SIRIM QAS website and companies' websites to ensure that they are practicing green activities.

The firms were approached using telephone calls and emails, but poor responses were received. Many of the manufacturing firms responded with various reasons such as the person in charge being on leave, on business trip and busy. While, some refused to participate due to confidentiality of the information disclosed. Furthermore, an official approval from Human Resources Department or Public and Trade Affair Department was required before the manufacturing firms could participate in the study. The tedious and time consuming approval process hindered the respondents from participating.

Nevertheless, upon further persuasions, follow up and assurance of the confidentiality of the information provided, three of ISO 14001 manufacturing firms from Ipoh gave their consensus to participate in the interview process. Whilst, survey questionnaire was distributed to ISO 14001 manufacturers located in Perak and Kulim regions. The survey questionnaire was collected with assistance of two enumerators for each region.

The improved version of survey questionnaire, also known as 2nd draft was re-tested during cognitive interviewing process. The cognitive interviewing method is considered as one of the imperative methods in the pilot study. Cognitive interviewing allows researchers to identify sources of response errors and accuracy of questions answered (Willis, 2005) as well as respondents' comprehension on the questions as intended (Dillman, 2000).

The two techniques that were used during cognitive interviewing process are think-aloud and probing questions. Each session took approximately one and half hour. The representatives were encouraged

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to express their thoughts as they were answering the questionnaire. Moreover, they are encouraged to paraphrase the questions by repeating the question in their own words. This is to ensure that wordings of the questions are being understood in the way intended and possible suggestions on the alternative wordings are encouraged. The body language portrayed was recorded too. The representatives are being probed with relevant questions to their earlier reactions, problems faced and comments provided.

This probing actions are to (1) identify the interpretation and assumptions made on the questions, (2) terms/concepts that were misunderstood, (3) questions that were inappropriate or had insufficient information, and (5) language used that caused misapprehension of the questions. In addition, the participants were also required to categorize each item according to their groups in order to reduce any item ambiguity and simultaneously improve the validity of the measures. It is a procedural remedy to control common method variance as recommended in (Podsakoff, P.M., MacKenzie, Lee, & Podsakoff, 2003).

The survey questionnaire was amended and corrected as suggested. The improved questionnaire is drafted as the 3rd version, and once again undergoes final check to ensure that the content, layout, grammar, spelling and arrangement of questions are all in the right order with three representatives. Since, the questionnaire achieved good remarks and was completed within reasonable time, all the items for the constructs are kept for a full scale pilot study with 60 ISO 14001 manufacturing firms that are located in Perak and Kulim states.

RESULTS AND DISCUSSION

Pre-Test Interview Analysis

During the pilot study, researcher conducted semi-structured interview with three ISO 14001 representatives in order to conduct preliminary investigation and obtain initial understanding on, (1) factors that influence ISO 14001 manufacturing firms to embark on green movement in supply chains, (2) role of information technologies and systems in supply chain as well as in improving environmental footprint in a manufacturing firm, (3) to identify environmental-friendly practices in supply chains, and (4) subsequent impacts on the company's performance from implementing those eco-friendly activities. Each session was recorded with the consent of the participant. Each interview session took about an hour for each company. This section reports on the preliminary findings from semi-structured interviews conducted during pilot study.

Green Supply Chain Management

The first interview session was with Managing Director (MD) of Company A, which is a European-based company that produces energy-efficient air filters for commercial and industrial use. The MD explained that the company is continuously researching and working towards producing green products. Apart from that, the company practice environment conscious activities at every stage of the product life cycle, which includes activities from downstream, in production and upstream.

Company A: "As stated in the sustainability report, our products are green because, firstly we build the products using environmental friendly and biodegradable materials. Secondly, resources used

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to produce the products are economically save. Thirdly, the life-time of the products is stretched to a longer time. These three steps have allowed us to minimize wastes that reduce the impact to the environment."

Company B is an American-based company that produces household gloves, industrial rubber gloves and high-risk gloves. The Production Director (PD) describe the compliance to the green movement are directly influence with green policies from parent company and internal efforts to reduce ecological impacts to the community and surroundings:

Company B: "With the assistance from in-house R & D, we are looking at ways to make our processes and products more environmental-friendly. We provide clear guidelines to our suppliers on the green requirements and compliance needed. However, only few of our suppliers are certified. We sell the waste to other companies that build tires and toys' parts, which reduces amount of wastes to landfill. Our newly invented packages use less resources, are easier to be produced, disposed and biodegradable."

The third interview session was with Operation Manager of Company C. Company C produces foil and hot stamping for decorative and security industries. The manager highlighted that the raw materials used in the production are according to the environmental standard, as well as directives from sisters companies and customers:

Company C: "The raw materials used must be according to requirements and chemical safety of REACH standard. Those wastes that can be reused will be inputted to distillation machines to check on the chemical composition, before being reused in other processes. These have saved us on cost incurred for scheduled wastes. However, those that are not recyclable will be safely disposed using third party services."

The brief transcribed interviews included reveal preliminary anticipation of ISO 14001 manufacturing firms in in implementing green practices in supply chain. Looking each stage of supply chain, the three representative enlighten in terms of, (1) opt for materials or components that are less hazardous with minimal impacts on environment, (2) design of products with reduced consumption of energy, extended product life time, use of biodegradable materials and minimization on the amount of resources used, (3) optimize in the packaging with minimal resources used, safe disposal and biodegradability of components in the packages/boxes, (4) improvements in products distribution and transportation through eco-logistics with mode that reduces air pollution and energy emission, (5) End-Of-Life (EOL) products undergo safe disposal as well as incineration of product remains and wastes via third party services. It is discovered that the firms are still far off from using recyclable and recycled materials in the development and production of the product.

Technological Drivers – IT and IS in SCM

As explained in previous section, internal factors which are top management support and internal commitment, whilst, external factors of regulatory and stakeholders pressure are the important drivers that motivate a firm to implement Green SCM. Nonetheless, technological components, particularly eco-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

friendly information technologies and systems are poorly consider in greening the activities, processes and operations throughout the supply chain. The three representatives interviewed highlighted on the importance of information technologies and systems as an enabler for seamless relationships at each stage of the product life cycle:

Company A: "Information technology and systems are part and parcel of our daily tools which are the catalysts to run processes efficiently, to communicate effectively, and to operate the whole business smoothly."
Company B: "IT is a necessity since different processes in supply chains need various different technology components, hardware, software, application and network to communicate to each other."
Company C: "In our company, ICT are utilized in streamlining essential activities in our business."

The above quotes clearly indicated the role of information technologies and systems as the enablers that drive businesses operations smoothly and soundly. Companies are obliged to reengineer supply chain, and deploy right information technologies and systems. This give the company the capability to facilitate seamless interaction with suppliers, accommodating customer requirements, and reacting proficiently to intensified race with competitors (Sundarakani et al., 2012).

Technological Context – Green IT and Green IS in SCM

Next, the companies' representatives were enquired on the extent of eco-friendly information technologies and systems are adopted in the firm:

Company A: "I believe that environmental friendly information technology and systems play an important role in today's supply chain management. IT can be a tool to get an organization moving towards environmental sustainability, but is difficult for us to quantify the ecological and financial gained. Some internal metrics are used to calculate. But, we have not completely measured the efficiency on the energy consumed, waste or emissions produced from IT infrastructure, hardware or system applications. This is neither a routine for us nor is a KPI."
Company B: "Moving towards sustainable IT and IS are long journey ahead. Investment in applications and software is easily justifiable as compared to IT hardware. The cost of greening IT is high. It is difficult for us to show the values it will bring to the business. We are still an infant in this context as compared to sustainable manufacturing practices."
Company C: "The process of greening of IT and IS are costly with vague impacts to the environment, operation and monetary benefit. It may takes extensive period of time for positive return."

Therefore, with incorporation of Green IT and Green IS solutions into everyday supply chain activities, organization's ability to make sound environmental decisions is greatly advanced. Green IT and Green IS must be one of the core elements of any organization's green strategy. On the other hand, most companies still fail to explicitly recognize and integrate Green IT and Green IS components into their sustainability plans (Hodges & White, 2009; F Loeser et al., 2012). This situation is mainly due to lack of environmental awareness, technological know-how and sense of urgency in minimizing ecological footprints from facilities, office equipment, data center as well as system application. Apart from human

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and financial resources, physical resources such as information technologies and systems are crucial for companies to successfully implement green practices in supply chain (Lee, 2008).

Organizational and Environmental Context - Internal and External Factors

The most significant driver that motivates EMS ISO 140001 certified manufacturing firms in Malaysia are regulations, expected business benefits, customer pressures and corporate social responsibility (Eltayeb et al., 2010). In this section, the interview with the companies revealed the influential factors that motivate the adoption of green practices in their operations and supply chain processes.

As quoted by Managing Director of Company A, the influential factors are top management support, employee commitment and external stakeholders:

Company A: "Firstly, continuous support from top management and parent company. The continuous improvement is a must as long as you have the right people, right system in place. It must be done through targets, review meetings, audits, corrective actions with sufficient resources, R&D, money. The constant dialogues with our stakeholders and good relationship with our customers and suppliers have profile us as green enterprise."

In company B, the act of greening is voluntary, and meets international environmental directives. The Production Director emphasized that strong commitment from management and employees are the vital factors that motivate an innovation, such as green movement in an organization:

Company B: "I very much believe that our green practice is voluntary since there is no push from local laws. Our management is very supportive and our employees are committed. We do it systematically with proper records of internal and external audits. It is not a requirement for our suppliers to be certified, but we comply with our customer's requirements. We do encourage our suppliers towards environmentally friendly practice and to be certified."

The Operation Manager of Company C gave emphasis on compliance legislation and internal commitment. These are main factors that contribute to the company certification on ISO 14001:

Company C: "We sell lots of our products to our sister companies and our subsidiaries. We do comply with environmental law and some other international body's directives. It is not compulsory by Malaysian law to be ISO14001 certified. We have do get good support from our parent company. However, cost and budget are always management's biggest concern."

Green practices in SCM are view as an initial strategy for firms to comply with environmental requirements and legislation imposed in most industrialized nations (Hu & Hsu, 2010). The most essential factor for an organization are availability of organizational internal resources, management commitment, cross-departmental support, strong employee involvement, internal knowledge sharing, relevant environmental trainings offered and qualified personnel assigned in handling environmental issues and green initiatives (Lee, 2008; Sarkis, Gonzalez-Torre, & Adenso-Diaz, 2010; Zhu et al., 2008a) as well as eco-friendly proactive culture (Walker, Sisto, & McBain, 2008). Furthermore, the implementation of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

green practices in supply chain requires long term investments which are costly with unforeseen return (Sarkis et al., 2010).

The necessity of a transparent regulation will induce organization to review their supply chain in order to ensure compliance to laws and environmental directives (G.-C. Wu et al., 2012). Policy makers and government agencies must play a proactive role in formulating relevant environmental standards and legislations) that has a profound impact (Zailani et al., 2012). This action will influence organizations toward green movement along with close monitoring of the progress in achieving environmental sustainability. Therefore, a company must be able to minimize the risks and uncertainty from internal resources, while closely respond to the government regulations, international environmental protection, and industry standards (G.-C. Wu et al., 2012).

Performance Outcomes: Environmental Performance

In many of the previous study reported that organizations that adopts green practices achieves good to significant improvement in their environmental performance. Those companies have successfully accomplish one or more benefits in terms of reduction on air emission produce, energy and water consume, toxic materials consume, amount of materials used as well as waste disposal volume (Zhu & Geng, 2010). The performance outcomes attained will varies between organization depending on the nature of business and size of the firm:

Company A: "Our current green movement throughout the supply chain has resulted in (1) significant increase in energy efficiency and reduced of carbon emission, (2) reduced consumption of hazardous materials and components, (3) reduced waste production and (4) increase process efficiency and product quality that leads to introduction new green product line.. The current water usage throughout the production is very minimal. We are still working towards environmental conscious packaging, waste management and logistics. Every year we carry out activities that promote green practices as well as programs to assist the ones in need and within our local community."

Company B: "We have (1) minimized the consumption of landfill waste and packaging, (2) used environmental friendly materials according to international standards, (3) Considerable amount of energy saving and (4) new green product line is introduced. We used lots of water throughout the production. The water wastes undergo treatments before being disposed. We are looking at ways to reuse the water. Our biggest achievement is on the packaging. The new packaging reduces the overall packaging material waste, as much as 81.9%.

Company C: "The materials used are according to REACH guidelines, therefore it is environmentally acceptable. This also increases our product quality. We managed to reduce to an extent the production of emissions and wastes. We have reasonably improved the environmental situation of our plant."

Green SCM concept is increasingly and widely diffused among companies that are seeking to improve their environmental performance (Testa, 2010). Most companies in developing countries adopted green solutions within the business operations with the intention to reduce the negative environmental effects rather than adopting a proactive approach to reduce the sources of environmental problems (Anbumozhi & Kanda, 2005). Therefore, manufacturing firms in different nations (e.g. Western vs. Asian countries) may face different pressures that have resulted in different environmental outcomes. Therefore, with the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

right internal support and proper regulation, firms are able to preemptively implement green practices in SCM for significant environmental performance without relying on end-of-the-pipe solutions.

Performance Outcomes: Technological Performance

As concluded from the pilot test with the three representatives, the impacts of IT and IS on reducing environmental issues within the supply chain or other processes still equivocal and insignificant to the management of the firm:

Company A: "The different parts of SCM processes have different requirements of hardware, software and applications. Some of these applications improve decision making, allow flexibility and enhance overall performance of SCM. Greening of IT and IS are highly dependent on the trade-off between benefit gained and cost incurred. We need to identify the company's critical areas for ecological improvement. With paperless, energy-efficient hardware/components, energy-efficient lighting and facilities equipment, virtualization, we are able to capture and contribute to environmental gains. We comply with directives such as Energy Stars, WEEE and safe e-waste disposal. Currently, we are still lacking in quantify the efficiency on energy consumed, waste or emissions produced from the IT infrastructure, equipment and applications installed. It is not part of our job routine too. We are not aware of any specific metrics to measure it. The ones developed in-house are not comprehensive. It will be great if parent company or internal management see the importance to quantify them as soon as they are implemented. It is possible as long as is taken into consideration within the internal audit process and firm's KPI."

Company B: "IT and IS are required to streamline the processes in SCM, that will result in better productivity, quality and visibility. Moving towards sustainable IT and IS will be a journey for us. We are still new to it, and it is not as significant as compared to sustainable manufacturing practices. We are taking little steps to install environmental friendly infrastructures, equipment, hardware, and system applications. We are very much dependent on software and applications. Those investments are much obvious to justify as compared to IT infrastructure and equipment. For us, virtualization technology is an obvious step for a company to implement green technologies. We often measure environmental indicators from supply chains as compared to IT infrastructure, equipment and facilities. We observe certain standards such Energy Star and EPEAT. We dispose e-waste in an environmentally friendly manner, whereby some are recycle and reuse, and others are managed by 3rd party vendor. Hopefully, with the budget and resources allocated, we will focus on installing, monitoring, measuring, and reporting systematically our green initiatives.

Company C: "The uses of IT and IS are critical and a prerequisite for seamless relationships throughout SCM processes, from the downstream till upstream. Without them, we will be in mess. We are working towards paperless office, use less electricity power and safe disposal of electronic waste. The entire greening processes are costly, and difficult to rationalize to the top management. We need to balance out between environmental and financial concerns. There are no specific metric used to measure eco-friendly activities related to IT and IS. But, we are trying to comply with certain standard like Energy Star."

The study observed that information technologies and systems are the foundation for the companies to run the business operations and processes smoothly. The technology improves the availability, vis-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ibility and timely distribution of information to customers, and simultaneously increase the production efficiency at each stage of the supply chain. The participants have successfully implemented methods to safely dispose their e-waste whereby consumable items are recycled, and others are disposed for safe landfilling and incineration at the disposal reserve areas by third party companies. The firms gain revenue from selling of the waste products that are recyclable. The realization on green information technologies and systems within an organization will simultaneously lower the energy and utility costs, waste disposal costs and consumable items, in which leads to a more tangible saving in costs and resources (Mithas et al., 2010; R. T. Watson et al., 2010).

Therefore, with a strong support from management and availability of financial resources, the companies are able to purchase energy efficient computer systems, as well as replacing current systems with energy efficient systems. Whilst, some look at implementing latest technology such as virtualization and cloud computing to reduce the power consumption. The companies place more importance on use of software and applications such as collaboration tools, telecommuting, telepresence and video conferencing tools to reduce travelling, as well as maximize the efficiency of supply chain processes in reducing total energy consumption.

The three companies interviewed are lacking in adopting metrics, standards or framework to measure their IT functions, its positive and negative impacts to the environment. Although, there are numbers internationally agreed standards for Green IT&S measurement, but, it must be supplemented with internal framework that includes clear targets and measurement items related to IT&S. (United Nations Conference on Trade and Development UNCTAD, 2011). Companies that invest highly in green information technologies and systems are able to enjoy financial and environmental gains through systematic implementation measurement (Mithas et al., 2010).

The measurement of the relationship between Information Technologies and Systems with the environment is a relatively new topic (United Nations Conference on Trade and Development UNCTAD, 2011). The direct impacts can easily be demonstrated and measured by use of scientific knowledge such as metrics with mathematical calculation. However, in some context, the impact is harder to captured and assessed. Despite the importance of the field, empirical evidence on the impact of information technologies and systems on environmental outcomes is lacking, where many gaps still remain uninvestigated with regard to developing countries (United Nations Conference on Trade and Development UNCTAD, 2011). The evidence from developing countries is limited as compared to developed countries, since there is a greater barrier in obtaining the required data. Moreover, the evidence from developed countries cannot be generalized to the developing countries.

Pre-Test Questionnaire Analysis

The aim of pilot testing the questionnaire is to determine and subsequently improve the validity and reliability of the questionnaire. Pilot test give advance sign on possible instruments, methods or sampling issues to be resolved before proceeding to the main study (Teijlingen van, Rennie, Hundley, & Graham, 2001). The important of pilot testing is highlighted in De Vaus (pg. 54) "Do not take the risk (De Vaus, 1993). Pilot test first." The sample size for pilot test, is explained in (Sudman, 1983), that "20 to 50 cases is usually sufficient to discover the major flaws in a questionnaire before they damage the main study" (pg. 181), which also highlighted in Sekaran & Bougie (2009). For this study, a total of 37 responses were received out of 60 manufacturing firms. There are five incomplete questionnaire, therefore are discarded in total calculation. For the pilot study, a total of 32 questionnaires were used as the dataset

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to increase reliability, decrease measurement error, and improve the validity of each construct a well as item measurement, as suggested in (Dillman, 2000).

Table 1 presented respondents' profile that were involved in the pilot study. The majority of respondents hold an executive position (16 respondents or 50.0%) as compared to other positions which comprised of 13 respondents (40.6%) for managerial positions and 3 respondents for the director positions (9.4%). This combination of positions makes a total of 32 respondents that participated in this study. It can be concluded that majority of the respondents in this study (20 respondents or 62.5% from the total sample size) worked at the information technology department. The remaining 12 respondents (37.5%) were employed at the operation department.

In terms of industry sectors, electronics industry has an equal number of respondents as rubber and plastic products industry, which are seven. The respondent's distribution between chemicals and chemical products industry was the same number with machinery equipment industry. These both industries consisted of 3 respondents (9.4%) from the total respondents. One of the respondent belong to the metal products industry and the remaining 11 respondents represented other industries such as automotive parts, stationery, paper & packaging, food & beverages industries. The majority of the respondents are from Multi-National Company (MNC) which represent the total 71.9%. From the total of 32 respondents, 9 firms were categorized as Small and Medium Sized Enterprises (SME).

The reliability of the measurement items is measured in ensuring the quality of the research instrument used in this study. The analysis of Cronbach's Alpha-Coefficient was performed in order to access the reliability of the measurement. The widely accepted social science cut-off of alpha value is 0.70 or higher for a set of items to be considered as a reliable scale, however, some use 0.75 or 0.80 while others are as lenient as 0.60. (Nunnally & Bernstein, 1994).

Table 1. Summary results of respondent profiles

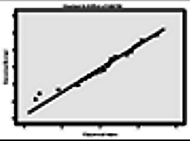
Respondents Profile	n	%
Position		
Director	3	9.4
Manager	13	40.6
Executive	16	50.0
Department		
Operation Department	12	37.5
Information Technology	20	62.5
Industry		
Electrical and Electronics Products	7	21.9
Chemicals and Chemical Products	3	9.4
Rubber and Plastics Products	7	21.9
Metal Products	1	3.1
Machinery Equipment	3	9.4
Others	11	34.4
Firm Size		
SME (0 – 150 employees)	9	28.1
MNC (151 employees and above)	23	71.9

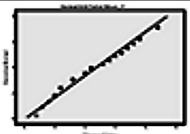
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

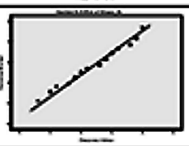
The Cronbach's Alpha values are quite sensitive to the number of items in the scale, in which will caused the Cronbach's Alpha values to fall below 0.60. For the pilot study, it is much appropriate to report mean inter-item correlation for the items. The optimal range for the inter-item correlation is 0.20 to 0.40 (Briggs & Cheek, 1986). Table 2 presented on reliability analysis of the measurement items used in this study.

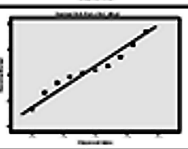
There were substantial variations in Cronbach's Alpha values for all variables, ranging from 0.611 to 0.878. Given that alpha values greater than 0.60 are generally considered to indicate a reliable set of items. It is indicated that Regulatory Pressure has the lowest value of reliability value, which is 0.611. However, this variable is still considered acceptable and reliable since the value is above 0.60 and the mean inter-item correlation was above 0.20 (mean inter-item correlation of 0.269). In addition, the variables for Internal Commitment and Technological Performance were also indicated as the reliable grouped items (0.744 and 0.769 respectively). Furthermore, Green Supply Chain Management (GSCM), Green IT, Green IS, and Environmental Performance has a reliable set of items grouped to measure the variables accordingly (0.861, 0.850, 0.845, and 0.878 respectively). Since all the measurement items met the threshold value of the reliability analysis (Cronbach's Alpha > 0.60 and mean inter-item correlation range of 0.20 to 0.40), it is concluded that, all the measurements items are acceptable, valid and reliable to be used in full scale main study.

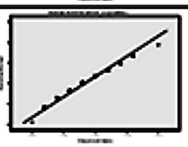
The normality test was also performed in order to test the assumption of distribution. The variables are normally distributed as long as the value of Skewness and Kurtosis statistics are within the range of ±2.0 (Pallant, 2010). Normal Q-Q plots is also one of the methods used to measure the normality of the variable. If majority of the observed values (smaller dots) lie on a straight line in the plot, then, that variable is consider as approximately normally distributed (Pallant, 2010; Sheridan, Steed, & Ong, 2010). Table 3 illustrated on Skewness and Kurtosis statistics. As presented, all the interested variables in this study were in the range of ± 2.00, in which indicate normal distributed items. In addition, majority of the observed values lie on the straight line in the Q-Q plot, in which explained on the nature of normally distributed items. Most of the criteria used to measure the normality distribution are successfully met, therefore it concludes that the items and data collected for the pilot study are normally distributed.

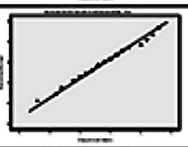


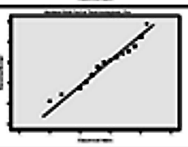












Next, Pearson's correlation was used to investigate the relationship between the variables of interest, and research hypotheses since normality assumption of the variable are met (Field, 2009). This correlation analysis takes a value between ranges of -1.00 to +1.00. The sign at the front of the value indicates the direction of the correlation as either positive or negative (Bluman, 2012; Field, 2009). The coefficient

Table 2. Summary of reliability analysis

Variable	Cronbach's Alpha	Number of Items	Mean Inter-Item Correlation
Green Supply Chain Management (GSCM)	0.861	14	-
Green IT	0.850	8	-
Green IS	0.845	8	-
Internal Commitment	0.744	5	-
Regulatory Pressure	0.611	5	0.269
Environmental Performance	0.878	8	-
Technological Performance	0.769	8	-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Summary of normality distribution

Variable	Skewness Statistic	Kurtosis Statistic	Q-Q plot	Decision
Green Supply Chain Management (GSCM)	-0.529	0.485		Normally Distributed
Green IT	0.151	-1.027		Normally Distributed
Green IS	-0.257	-0.727		Normally Distributed
Internal Commitment	0.162	-1.529		Normally Distributed
Regulatory Pressure	0.374	-0.567		Normally Distributed
Environmental Performance	-0.031	-0.646		Normally Distributed
Technological Performance	-0.259	-0.477		Normally Distributed

correlation of 0.2 or above is consider satisfactory. The strength of the correlation is measure based on its coefficient. The coefficient correlation more than 0.81 to 1.0 indicates excellent strength, coefficient between 0.61 to 0.80 indicates very good strength, coefficient between 0.41 to 0.60 indicates a good correlation strength, the coefficient between 0.21 to 0.40 measures a fair strength, and correlation coefficient less than 0.20 shows a poor correlation (Bluman, 2012).

As shown in Table 4, bivariate correlation between all independent variables, which are Green IT ($r(32) = 0.858$, $p < .001$), Green IS ($r(32) = 0.766$, $p < .001$), Internal Commitment ($r(32) = 0.720$, $p < .001$), and Regulatory Pressure ($r(32) = 0.607$, $p < 0.001$), show a significant positive bivariate correlation to Green SCM. Therefore, an increase in Green IT, Green IS, Internal Commitment, or Regulatory Pressure, then Green SCM implementation within the organization will increases correspondingly since they are bivariate correlated.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Summary of Pearson correlation

Variables	1	2	3	4	5	6	7
1	1.00						
2	.804**	1.00					
3	.826**	.882**	1.00				
4	.650**	.699**	.588**	1.00			
5	.858**	.766**	.720**	.607**	1.00		
6	.897**	.812**	.847**	.635**	.856**	1.00	
7	.842**	.712**	.680**	.699**	.853**	.816**	1.00

Note: 1) Green IT; 2) Green IS; 3) Internal Commitment; 4) Regulatory Pressure; 5) Green Supply Chain Management (Green SCM); 6) Environmental Performance; 7) Technological Performance, **$p < 0.001$, $n = 32$

On other hand, it is also indicated that Green IT ($r(32) = 0.897$, $p < 0.001$), Green IS ($r(32) = 0.812$, $p < 0.001$), Internal Commitment ($r(32) = 0.847$, $p < 0.001$), Regulatory Pressure ($r(32) = 0.635$, $p < 0.001$), and Green SCM ($r(32) = 0.856$, $p < 0.001$) portray a significant positive bivariate correlation to Environmental Performance. This analysis indicates that positive effect in Green IT, Green IS, Internal Commitment or External Pressure increases with Green GSCM, then it will positively increase the influence on the outcome of environmental performance as they are bivariate associated.

The same scenario is observed for technological performance. Hence, Green IT ($r(32) = 0.842$, $p < 0.001$), Green IS ($r(32) = 0.712$, $p < 0.001$), Internal Commitment ($r(32) = 0.680$, $p < 0.001$), Regulatory Pressure ($r(32) = 0.699$, $p < 0.001$), and Green SCM ($r(32) = 0.853$, $p < 0.001$) are statistically bivariate positive correlated to technological performance. This is understood if any of the independent variable listed above has a positive influence on Green SCM implementation, then, it increases the technological performance of the firm.

Moreover, environmental and technological performance are bivariate correlated since these two variables achieved ($r(32) = 0.816$, $p < 0.001$) value between the two. Consequently, if the level of the environmental performance increases, then the technological performance will orderly increases. As a conclusion, the results obtained deduced that all variables are found to have a positive bivariate correlation to each other ($p < 0.001$). The strength of bivariate correlation was categorized from good to excellent correlation (Correlation range: 0.588 to 0.897), as presented in Table 4.

CONCLUSION AND FUTURE WORK

The systematic review of the literatures demonstrates that many of the studies on GSCM explain that top management support, employees involvement, regulations, government support and customer/supplier pressures are influential factors that motivate the adoption of green practices. The act of greening IT and IS have huge potential in addressing broader environmental issues in organizations, including supply chains and logistics. Although, information technologies and systems were embedded in supply chain processes for decades, but, the effects of greening and environmental sustainability from IT&S still remain vague and lacking in research. The existing research on Green IT and Green IS are very much fragmented with inadequate focus on evaluation of Green IT and Green IS potential as the enablers for business and environmental sustainability.

The findings obtained from pilot test demonstrated few important findings: (1) Validity and reliability of the measurement items in the survey questionnaires are achieved; (2) The companies opt for materials that are less hazardous, development of products with reduced consumption of energy, minimization on the amount of materials and resources, use of biodegradable materials for the products and packaging, longer life time of the product and safe disposal/incineration of product remains and wastes; (3) The companies are still far off from using recyclable and recycled materials in the development of the product or, packaging, or even recovering products that reach End-Of-Life (EOL); (4) The companies clearly indicated the role of information technologies and systems as the enablers that drive businesses, operations and processes seamlessly, smoothly and soundly; (5) Information technologies and systems components are mostly ignored in the process of greening or assessing environmental problems since it is not part of the company's environmental strategy, or performance indicators; (6) Those companies that are currently implementing eco-friendly information technologies and systems fail to report their findings and figures in the company websites or sustainability report; (7) The companies with influential internal management and strong dedication from all levels, as well as transparent and supportive environmental legislations are the motivating ingredients in moving towards green manufacturing or green enterprise; (8) Companies that are proactively implement green practices in SCM will achieve significant environmental performance as compared to those companies who still rely on end-of-the-pipe solutions; (9) Most of the companies have successfully implemented methods to safely dispose their e-waste whereby consumable items are recycled, and others are disposed for safe land filling and incineration at the disposal reserve areas by government and third party companies; (10) Companies gain earning from selling wastes and simultaneously improve the environmental situation of the firm; (11) Availability of financial resources will allow the companies to purchase energy efficient computer systems, and replacing current systems with energy efficient systems; (12) The companies enlisted importance on use of information systems and applications such as collaboration tools, telecommuting, telepresence and video conferencing tools to reduce travelling, as well as to maximize the efficiency of supply chain processes in reducing total energy consume; (13) Companies are still lacking in term of measuring the performance from technological aspects; (14) Unstandardized metrics and calculation used to measure the IT functions has led to inability for companies to quantify the negative and positive outcomes.

This study attempts to contribute in the following. First, green practices among manufacturing companies in Malaysia is rising yet the previous findings presented mainly focused on organizational and environmental factors in influencing Green SCM implementation. Many of the organizations disregard the incorporation of information technologies and systems components in addressing environmental issues within the supply chain and business operations. Secondly, to our best knowledge, this is the first attempt to explain Green IT and Green IS as the technological components of TOE framework in rationalizing the drivers that influence Green SCM implementation. This is an enlightening study in bridging multi-field of green areas of research. Thirdly, the newly introduced component known as Technological performance aims to address the specific performance resulted in the implementation of Green IT and IS in the supply chain itself, which in actuality are often neglected in the environmental assessment.

The next step of the research is to improve the theoretical foundation of the research model and test this model empirically through a large scale survey among ISO 14001 manufacturing companies in a developing country known as Malaysia. The findings will provide guidance to new manufacturers that choose to venture in green movement, to existing manufactures who face impediments to improve company's environmental performance, and to government in assisting, monitoring and regulating companies towards environmental sustainability.

Chapter 38
Green Investments and Returns:
A Developing Country Perspective

Nabila Nisha
North South University, Bangladesh

ABSTRACT

A vital issue that must be considered by all functional areas in recent times is green safety and sustainable ecological balance. To be part of this environment-friendly investment, even the banking sectors of the most environmentally affected countries in the world invest voluntarily in social and environmental activities that targets socially-responsive business and ethics in the form of green banking. Green banking mainly involves the environmental and social responsibility of banks in terms of the contribution they make towards ensuring sustainability of the environment and ecological system, through the wide range of financial products and services that they offer. This chapter will primarily focus on the present status of the banks in complying with the green banking policy to save the environment as well as to increase financial sustainability from the perspective of a developing country like Bangladesh.

INTRODUCTION

Global warming or the 'Green House Effect' has made many organizations environmentally conscious. As a result, green investments today are at the forefront of a significant number of business operations across the world. Green investments generally call for companies to finance green technology and pollution reducing projects that can lessen the impact of their operations on the environment, thereby leading towards an overall sustainability. In line with this global development and as a response to environmental degradation, financial sectors of many developed and developing countries have adopted green banking policies to address this issue of sustainable business practices. Green banking involves the environmental and social responsibility of banks in terms of the contribution they make towards ensuring sustainability of the environment and ecological system, through their in-house operations and the wide range of financial products and services that they offer. This chapter sheds some light into the present status of the banks in complying with the green banking policy to save the environment as well as to increase financial sustainability from the perspective of a developing country. To pursue this purpose,

conceptual research models and a survey questionnaire based on the models were developed to study the general perception of bankers regarding environmental safety and the concept of green banking, along with the current range of green products and services being offered in Bangladesh. Responses from the survey were also used to examine bankers' attitude towards the adoption of green banking initiatives in a developing country like Bangladesh. Findings of this chapter will provide further insights into understanding the environmental responsibility and the environmental performance through the perception and attitude of bankers. Moreover, this study can assist various commercial banks to take into account varied perspectives of bankers while considering the idea of investing in green banking or other forms of green investments in order to aid the sustainable development of all financial products and services in Bangladesh.

BACKGROUND

In recent years, the eminent problem of global warming has finally shifted the attention of business practices of all functional areas to climate change, resource efficiency and environmentally conscious issues. As such, initiatives related to green safety and sustainable ecological balance is growing in support. To be part of this environment-friendly investment, most of the companies today focus more upon socially-responsible approaches rather than the traditional profit maximization (The Financial Express, 15 July, 2015). In other words, business practices has moved away from the 'profit, profit and profit' motive to the objective of 'planet, people and profit'. A recent report by OECD claimed such socially-responsible approaches as green investments or investments that are broadly related to the sustainability of the environment (Inderst, Kaminker & Stewart, 2012).

Green investments can be made by companies to their underlying technology, projects or ventures as well as their financial products and services (Croce, Kaminker & Stewart, 2011). For instance, any investments in renewable energy, recycling and waste management, water management, energy efficiency or environmental technologies are various ways of appearing 'green' in the market (The Daily Observer, May 26, 2015). Besides, going paperless to save the environment is another approach to define 'greenness' for specific goods and services.

Although green investments are a global initiative, these eco-friendly policies play a special role particularly for those developing countries which are more vulnerable to climate changes and where natural calamities are a common phenomenon (The Financial Express, 29 July, 2013). One such example is that of Bangladesh, which is a low carbon emitting country and has historically suffered huge losses due to changes in climate patterns. As a result of these adverse effects and to initiate a progressive step worldwide, the central bank of the country, Bangladesh Bank, has shown a profound commitment towards the vision of green investments and has opted towards congenial business operations that are sustainable towards the environment (Ahmad, Zayed & Harun, 2013). Prominent examples of green investments in Bangladesh include the use of natural non-toxic materials and recycled wastes in the ceramics sector; environment-friendly buildings and land projects using the highest standards of green technology, effective wastage management and efficient energy systems, organic compounds for building materials, and eco-friendly paints by the real estate sector; tree planting initiatives, the use of renewable energy and installation of eco-friendly solar panels, introduction of environment-friendly public transports, etc (The Financial Express, 1 August, 2015). Moreover, Bangladesh Bank is also going to commence a

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

new Export Development Fund worth about US$ 500 million to support environment-friendly industrial and development projects in the country, as a global response to save the environment (The Financial Express, 15 February, 2015).

Environmental degradation has become such a pressing issue today that even the financial sectors need to address this universal issue. This is because financial institutions, particularly banks, play a vital role in the economic system of a country and generally affects all types of business practices through their financing activities. Thus, banks should contribute to the saving of the environment by considering environmental aspects as part of their lending and investing principles, which would then divert industries to invest in environmental management and the use of appropriate green technologies (Masukujjaman & Aktar, 2013). In fact, banks these days are quite pro-active in terms of green investments on the global front. Adoption of eco-friendly banking practices and in-house operations, broadly known as green banking, is a prime example of green investments by the banking sector (The Daily Observer, May 26, 2015).

Green banking mainly focuses on two aspects: green revolution of internal operations through the consumption of renewable energy, digitalization and other measures that can reduce the emission of carbon mark from the banking activities and the use of environment-friendly financing like sustainable banking, ethical banking, green mortgages, green loans, green credit cards, mobile banking, online banking, etc. (Inderst et al., 2012). Adoption of such green banking initiatives can be found in many developed economies across the world. For example, HSBC has developed cheaper air and road travel incentives as a green choice for environmentalists and this has been aimed at saving paper by receiving no paper statements and doing no paper marketing. The UK Green Investment Bank, on the other hand, finances green projects on commercial terms and helps fund the creation of new energy and waste infrastructure across the country, thereby reducing a substantial amount of greenhouse gas emissions (Hossain, Ahmed & Nisha, 2015). Hang Seng Bank from Hong Kong introduced an integrated system that reduces the use of papers to save the environment and provides a comprehensive range of banking and general insurance products and services that can be availed either through mobiles or internet. Additionally, banks worldwide use energy-wise Green Machines, which source power from clean, emission-free methods such as wind power and invests hugely for local environment and wildlife projects in their community (Hossain et al., 2015). Even the introduction of green channel counters and green finance portfolios by the State Bank of India and Bank of Indonesia are different forms of green banking initiatives that can be observed from the global front.

The banking sector of Bangladesh is also equally contributing to green investments and has successfully adopted various forms of green banking policies that is being applied by the central bank as well as the leading commercial banks of the country. It thus becomes important to gain insights into the green banking activities that is being adopted in Bangladesh both for in-house operations and financing activities of the banks. In particular, outlooks of bankers with regard to such initiatives of green investments by the financial sector need to be examined in order to understand and assess their social responsiveness in the context of Bangladesh.

ISSUES, CONTROVERSIES AND PROBLEMS

The banking industry is an integral component of the financial system of Bangladesh and plays a crucial role in the economic development of the country. Over the last 30 years, there has been a steady growth

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

in this sector, as several private and foreign banks entered the country and led to the development of the country's financial architecture. Currently, this industry consists of four state-owned banks, four specialized banks, thirty-one private commercial banks, eight Islami Shariah based private commercial banks, and nine foreign commercial banks (Hossain et al., 2015). All these scheduled banks are solely monitored and regulated by the central bank of the country - Bangladesh Bank, which formulates and implements policies and guidelines related to various financing and banking issues.

One such guideline issued by Bangladesh Bank during 2011 is related to environmental risk management and green banking. The guidelines of this Green Banking Policy aimed to ensure environment-friendly business practices by banks and financial institutions by incorporating environmental risks into Core Risk Management (CRM), thereby promoting sustainable financial and economic growth across the entire country. This step by Bangladesh Bank is a profound commitment towards the vision of green world through green initiatives in Bangladesh. In fact, it is probably the only central bank which has issued such an indicative guideline for green banking in the South-Asian continent.

Under this Green Banking Policy, Bangladesh Bank initially selected ten commercial banks in Bangladesh for implementing green banking practices on the basis of their CAMELS rating and Risk Based Capital Adequacy (RBCA) measurement (The Daily Observer, May 26, 2015). The central bank authority then instructed these banks to consider the following major activities under green banking: Green Banking Unit, Green Banking Policy, Green Banking Budget, Online banking, Mobile and Internet banking, Allotment of funds in green financing and Environment risk rating. Over time, all the scheduled banks of Bangladesh initiated their own Green Banking Policy Guidelines approved by their respective Board of Directors as well as have Green Banking Unit (GBU) for pursuing Green Banking activities. They even have their own Green Office Guide for conducting various in-house green activities today. For instance, a glance at the current major green house activities of banks in Bangladesh reveal the use of

e-statement for customers instead of paper statement, making online communications, using more daylight instead of electric lights or using energy saving bulbs such as LED lights, video/audio conferencing instead of physical travel, sharing electronic files, voice mail, and e-mail instead of paper memos, using papers on both sides, common use of table stationeries instead of individual use and efficient use of printer cartridges, photocopy toner, office stationary, etc. Additionally, Bangladesh Bank introduced a number of refinance lending for renewable energy generation, effluent treatment plants and energy efficient kilns for manufacturing bricks. A revolving refinancing fund has also been placed in the areas of solar irrigation pumps, solar home systems, biogas plants, effluent treatment plants, brick kiln and solar photo voltaic module assembling plants, etc – with the sole aim of promoting green investments in Bangladesh.

However, amidst all these green investments and green banking developments in the country, banks have been facing major challenges in the implementation of this Green Banking Policy. The foremost challenge has essentially been the 'mandated' implementation of green banking initiatives by the banks. Since it has been made mandatory by the central bank, despite having inhibitions about it, all scheduled banks of Bangladesh had to implement various methods of green banking within their operational structures for both their banking transactions and in-house activities. The lack of the option of voluntariness in this regard has met with certain resistance from the top management as well as the operational staff of the banks. Change in the working environment and the alternate provision of banking services under green banking resulted in problems like coordination among all concerned authorities for green banking, proper awareness and effective implementation, immediate concentration on lending policies and procedures of the banking sector, high costs of implementation, conflict among management and bank-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ers, etc. As such, it becomes imperative to examine the thought process of bankers towards the concept and implementation of the Green Banking Policy, since they are the ones who are at the forefront of execution of the green banking initiatives in the banking sector.

With regard to green banking, a limited number of studies have been conducted in the context of Bangladesh. For instance, Masukujjaman and Aktar (2013) highlighted the green banking road map in Bangladesh, the status of its implementation and also explored the activities of commercial banks in comparison with global green banking initiatives. The study concluded that Bangladesh is far behind their counterparts from the developed countries, but as of now, most of the banks are in a transition to green banking in the country. Ullah (2013) then conducted a comparative analysis among different types of banks operating in Bangladesh and tried to conclude whether the banks have properly adopted the Green Banking Policy guided by the Bangladesh Bank. Findings by Ullah (2013) claimed that only public and foreign commercial banks have invested in green banking projects whereas the initiatives of state-owned commercial banks or state-owned specialized development banks are nothing remarkable to be reported. Next, Ahmad et al. (2013) explored the green banking activities of all commercial banks in Bangladesh and attempted to determine the reasons behind adopting green banking from the perspective of bank employees. Six factors namely economic factor, policy guideline, loan demand, stakeholder pressure, environmental interest and legal factor were found to be the major influencers regarding the adoption of green banking by the commercial banks. Shakil, Azam and Raju (2014) also did an evaluation of green banking practices among the scheduled banks of Bangladesh and found that while some banks has taken certain green banking initiatives, there are still a good number of banks which are in the first phase of the Green Banking policy guideline set by Bangladesh Bank. Findings by Shakil et al. (2014) further stated that it is due to large initial cost and lack of governmental and technical support, that green banking practices is not implemented on a large scale in Bangladesh.

Furthermore, there are a number of local studies which were conducted related to various aspects of green banking practices in Bangladesh. While Masum (2015) highlighted the need for green banking in Bangladesh, Hossain and Ahmed (2015) outlined the phases of implementation under the Green Banking Policy guidelines set by the Bangladesh Bank. Next, Hossain et al. (2015) explored consumer attitudes and perceptions towards green banking in Bangladesh and Hossain, Rahim & Hussain (2015) analyzed the future of green banking for the country. With respect to promoting a greener economy, studies by Nisha, Idrish & Hossain (2015) did an empirical analysis to understand the factors behind consumer acceptance and use of mobile banking services in Bangladesh. In addition, Hossain, Jilani & Haque (2015) evaluated the option of Islamic finance as a greener alternative for the banking sector of Bangladesh. Overall, if a conclusion is drawn from these past studies, it can be observed that only one significant research of Ahmad et al. (2013) considered the perspective of bank employees towards the concept of green banking. In view of everything, this is a crucial aspect that needs to be further studied.

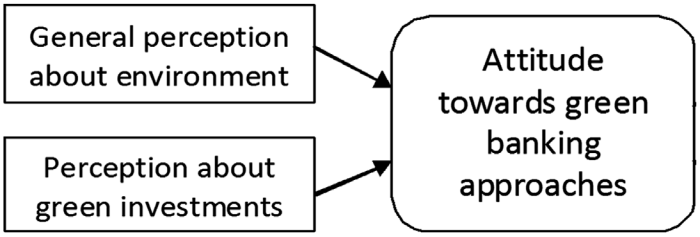
As such, this study focuses on the examination of the perception of bankers towards environmental issues and green investments, thereby highlighting their attitude for green banking initiatives, its products and services and the future potential of such practices in the context of Bangladesh. The method of Structural Equation Modeling (SEM) was mainly applied to investigate the underlying relationships related to the perceptions and attitudes of bankers towards green banking practices in the country. SEM has the ability to isolate observational error from measurement of latent variables like the proposed constructs in this study. Thus, the use of SEM for evaluating the perceptions and attitudes of bank employees is the unique contribution of this chapter, since to the best of the author's knowledge SEM has not been used for any green banking research in the context of the bankers in Bangladesh.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

RESEARCH MODEL AND HYPOTHESES

This chapter seeks to explore the extent to which bankers' perceptions about the environment, particularly the environment of Bangladesh, as well as their general perception about green investments influence their attitudes towards green banking approaches. Moreover, this research claims that the attitude of bankers will ultimately shape their reasons for using green banking and its related products and services and will also determine the future potential of such green banking initiatives from the bankers' perspectives.

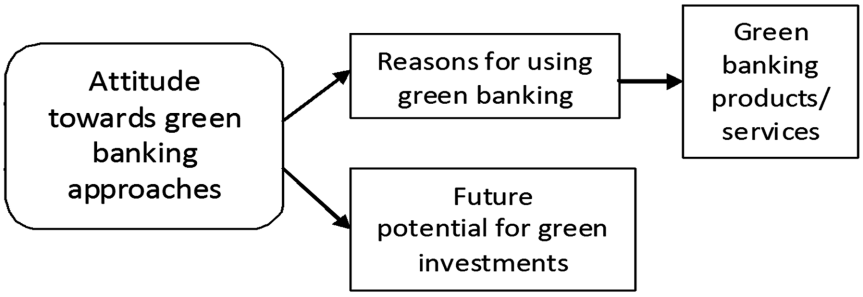
In order to quantify these relationships, two research models were developed. The first model explored the relationship of factors such as bankers' general perceptions of environment and green investments with their attitude towards various forms of green banking initiatives currently being undertaken in Bangladesh. The second proposed model, on the other hand, investigated the extent to which the bankers' attitude towards green banking influenced their reasons for using green banking, its related products and services as well as their perceptions about the future potential of green banking approaches in Bangladesh.



Next, a three-part methodology was utilized to understand these relationships conceptualized in the two research models. This methodology consisted of a survey instrument development, an Exploratory Factor Analysis (EFA), a Confirmatory Factor Analysis (CFA) and Structural Equation Modeling (SEM) to further confirm correlations and inferred causal relationships among the factors of the two models. Surveys were conducted using focus groups and walk-through assessments of selected commercial banks from where the bankers' perspectives were obtained. Once the survey instruments were created, industry experts like bank officials and managers were requested to review the questionnaire before the survey data were collected in person.

The responses from the questionnaires were then analyzed using SPSS Statistics Base and through their descriptive statistics, outliers were identified that might have resulted from possible data entry errors. The survey data was split into two parts following the outlier identification and an exploratory factor analysis was run on one dataset to determine the underlying factor structures. Finally, using the results of the exploratory factor analysis, the user-friendly interface of SPSS Amos was used to run a confirmatory factor analysis, using the second dataset to examine the reliability and validity of the measurement models without identifying the directional relationship among the factors. The two hypothesized models were then drawn to examine the underlying directional relationships among bankers' perception and attitude towards the green banking activities of the Bangladesh banking sector. See Figure 1 and Figure 2.

The hypothesized models and the proposed hypotheses are given below:



H1: General perception about the environment significantly affects the attitude of bankers towards green banking.

Figure 1. Proposed research structure 1

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Proposed research structure 2

H2: Perception about green investments significantly affects the attitude of bankers towards green banking.
H3: Attitude of bankers towards green banking approaches significantly affects their reasons for using green banking.
H4: Attitude of bankers towards green banking approaches significantly affects the future potential of green banking initiatives.
H5: Reasons by bankers for using green banking significantly affect the concept of green banking products and services.

RESEARCH METHOD

To investigate the two research models, methods and techniques employed for data collection involved a primary research. The primary research involved gathering of data by conducting survey of a representative convenience sample of 800 bankers from selected commercial banks operating in the capital city of Bangladesh - Dhaka. The bank representatives were particularly surveyed and interviewed regarding the green banking initiatives employed by their banks. The survey required developing and circulating questionnaires for the bankers by presenting the information in quantifiable terms, in order to gauge the impact of their perception of environment and green investments upon their attitudes towards green banking initiatives and how this attitude was influencing their reasons for using, offerings and future potential of green banking products and services.

As such, the questionnaire was designed to enable the respondents to rate, on a Likert scale of 1 to 5, the extent to which they are aware of and care about environmental changes, the extent to which they think that the environment of Bangladesh is adversely affected due to climatic changes and whether they believe that Bangladesh needs to take precautionary measures regarding environmental issues in the form of green investments. This questionnaire also sought to find out the respondents' attitude towards green banking initiatives, in terms of their interest and support for such practices, their reasons for using green banking, their perception of future potential of green banking in Bangladesh as well as their perception about the different types of green banking products and services that commercial banks currently operating in Bangladesh offer. After a three-week survey, 733 completed and usable responses were finally obtained from the survey.

The two conceptual research models were then tested using the structural equation modeling (SEM) facilitates of SmartPLS (version 2.0). Through partial least squares (PLS) method, first the measurement

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

models were examined to assess the reliability and validity of all variables and then, the structural models were analyzed to examine the relationships hypothesized in the two research models.

MEASUREMENT MODEL ANALYSIS

Results from the measurement models are presented in Table 1 and Table 2 and it includes information about the reliability, validity, correlations and factor loadings. The composite reliabilities of the constructs ranged between 0.700 and 1.000, which exceeds the 0.7 recommended cut-off values (Nunnally & Bernstein, 1994). The average variance extracted (AVE) was greater than 0.5 in all cases and greater than each square correlations, which indicates that all the three models have both convergent validity and discriminant validity (Fornell & Larcker, 1981). Moreover, the internal consistency reliabilities (ICRs) of multi-item scales modeled with reflective indicators was 0.75 or greater, suggesting adequate reliability. The pattern of loadings and cross-loadings also supported internal consistency and discriminant validity, with some exceptions: two items from each construct of general perception about environment and perception about green investments from research model 1; and, one item from each construct of reasons for using green banking and future potential of green banking and two items from green banking products and services under research model 2 were deleted, due to their low loadings and high cross-loadings.

STRUCTURAL MODEL ANALYSIS

The path coefficients and significance levels in the structural models are presented in Figure 3 and Figure 4. The construct of general perception about environment (0.192, $p<0.05$) from research model 1 displayed a significant path towards the attitude of bankers for green banking approaches while the perception of green investments (0.122, $p>0.05$) showed an insignificant path in shaping the attitude of bankers.

On the other hand, the construct of attitude of bankers for green banking approaches in research model 2 reported a significant and positive path towards reasons for using green banking initiatives (0.407, $p<0.05$) and future potential for green banking (0.380, $p<0.05$). However, the same behavioral path was not seen regarding green banking products and services (0.296, $p>0.05$), which were found to be insignificant in the model.

Therefore, all hypotheses with the exception of H2 from research model 1 and H5 from research model 2, are supported. As such, it can be stated that the hypothesized relationships between environment and the attitude of bankers towards green banking, along with the reasons for using green banking and its future potential being shaped by the bankers' attitude have been rightly proved.

SOLUTIONS AND RECOMMENDATIONS

This study has revealed quite a few understandings towards the perception and attitude of bankers regarding the concept of green banking, its related products and services and its future potential in Bangladesh. Findings of the study show that bankers are quite well-informed about the general conditions of the world environment and they have clear ideas about global warming and the impact that climate changes

can have upon the environment. Moreover, a good number of bankers displayed interest and agreement regarding the care and sustainability of the environment that is being promoted today worldwide. Most of the bankers were even found to be aware of the vulnerability of environmental conditions in Bangladesh and how this degradation was inviting natural calamities to the country. As such, it can be deduced from the survey results that bankers in Bangladesh are clearly in favor of saving the environment.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

However, most of the bankers did not know that a broad term used to refer to methods of environmental sustainability is actually the green investments. Some of them could identify ways to care for the environment or sustain resources like saving power, gas or water, reduced use of papers or controlling pollution, but a majority of the bankers did not have vivid ideas as to what can be varied ways of green technologies or green investments. As such, the central bank of Bangladesh in association with the government can fund documentaries wherein facts about global warming and different types of green investments can be displayed to create awareness and to educate the bankers as well as the general people of the country. This will help to change the perception of people towards green investments and bankers can get more ideas regarding the use of green financing like green bonds or green asset classes in their institutions. Survey results at this point give an impression that bankers actually opted for the use of green banking as part of their in-house activities and external functions only because the central bank of Bangladesh mandated the use and application of the Green Banking Policy. This implies that although bankers did care for the environment and were interested to sustain resources, they did not have adequate knowledge regarding the overall concept of green investments.

To further analyze the situation and attitude of bankers, the survey then probed onto the reasons as to why bankers accepted the use of green banking in their institutions. Results indicated that a majority of the bankers agreed that green banking techniques were being applied into their institutions to comply with the mandated policy of the central bank. To add more, some bankers feel that rather than being socially responsible or caring for the environment, employment of green banking in some selected banks of Bangladesh is just an act of image resurrection and a result of stakeholder pressure. For instance, some bankers claimed that using green banking helps to attract international customers to the bank to a large extent since being socially responsible is a concern for many of the clients today. Nonetheless, at least green banking techniques are being used and that is a major takeaway for a developing country like Bangladesh. Bankers, however, claimed that the reasons why green banking are being used in their banks did not have anything to do with the products and services that are currently being offered under green banking in the country. For example, survey results reported that electronic communication and office automation have been willingly accepted by bankers as part of

in-house green banking approaches. This is because bankers feel such techniques made work life easier and convenient for them and if in the process, it helps to save the environment as well then it is an added advantage for the banking sector. On the other hand, most of the bankers stated that electronic banking, mobile banking or the use of ATMs and credit/debit cards might be methods of green banking but it has been mostly accepted by both customers and the bankers because banking transactions become a lot easier with such services. At this point, it can be deduced that the attitude of bankers towards green banking products and services is quite positive and the reasons for using green banking in their institutions did not define their attitude towards the use of its related products and services.

Moreover, bankers evidently came up with various ideas regarding the future potential of green banking in the banking sector as well as other industries of Bangladesh. For instance, some bankers feel that the commercial banks should provide more loans at lower interest rates to eco-friendly industries or pro-environmental projects undertaken by any industry. This will help to spread the concept of green banking to other sectors of the country. Banks can also encourage borrowing facilities to those industries which plan to fund the implementation of solar energy programmes, green plantations, micro and macro level hydro projects, bio-mass electricity or bio-gas projects for the country. A majority of the bankers further stated that both the central bank and commercial bank authorities can impose restrictions on establishment of any industry or projects without using the green banking methodologies. Survey results

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

thus indicated that the attitude of bankers in Bangladesh mostly is in favor of creating awareness and spreading green banking approaches, not only in the financial sector but to other major industry settings of the country as well.

Findings of this chapter are mostly in line with the results reported by Ahmad et al. (2013) and Ullah (2013). Ahmad et al. (2013) claimed that policy guidelines by the central bank and stakeholder pressure are two major influencing factors for the commercial banks of Bangladesh to adopt green banking; while, Ullah (2013) stated through a comparative analysis of the country's commercial banks that brand image is a prime reason why the financial sector opts for green banking approaches in Bangladesh. Overall, it can be concluded that acceptance of green banking in both internal and external activities of banks in Bangladesh may have been acts of image improvement, pressure from central bank and stakeholders or just another progressive step to match with the developed economies. However, since every step counts, green banking approaches in Bangladesh can be treated as another small contribution to green investments, environmental care and sustainability and a better global environment from this side of the world.

All these recent developments in green banking initiatives by the banking sector of Bangladesh like online services, internet or mobile banking, office automation or electronic communications, conveys much significance. Already through various in-house green banking methods, banks are attempting to reduce the use of paper inside their offices and in their transactional activities, but since the present era is that of computers, more automation can be achieved by the banks. For instance, all communications regarding loan applications, credit proposals and their approvals can be conveniently done through electronic means which not only eliminates the use of paper but also saves time. Even the issuance of circulars from the central bank or from other commercial or foreign banks can be easily converted into electronic circulars, which can be reproduced and circulated through emails to all other urban and rural branches of the banks. Communications between different departments, branches and head office of the bank can also be efficiently done through this electronic means of circulation which will clearly eliminate the use of papers and save the environment. It is therefore imperative that the government of Bangladesh mandates the use of electronic means for all intra-bank, inter-bank and central bank communications. Such a step by the government will further their vision of a 'Digital Bangladesh' in the country as well (Islam & Khair, 2012).

Banks nowadays widely encourage the use of internet banking, mobile banking and the use of electronic bank statements in Bangladesh. However, papers like deposit slips or cheque books are still in use. Introduction of bank cards with secured chip and pin numbers can replace the use of such documents for banking transactions. A major challenge in such an initiative might be the unavailability of proper technological infrastructure and resources, but government support in the form of financial assistance to improve the facilitating conditions of the country can aid the banking sector to introduce such socially responsive business practices. Additionally, banks can establish an online resource center to eliminate the use of any hard copy for bank manuals, reference books, client circulars, etc.

Implementation of all green banking initiatives is a long-term project and like everywhere in the world, any such environmental-friendly measures are expensive (The Financial Express, 29 July, 2013). However, to safeguard the environment from the impacts of global warming and climatic changes, it is necessary to implement various forms of green investments and green technologies to mitigate any environmental hazards. In the context of Bangladesh, a positive perception for the environment and an equally positive attitude of bankers towards the use and future potential of green banking approaches for in-house and external activities of the banking sector, clearly paves the way of implementing other

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

forms of green investments in the country. The government and the central bank of Bangladesh should thus be more forthcoming in this regard by making budgetary allocations to promote green industries and by providing more financing facility for extensively implementing green investments in the financial sector, ultimately encouraging other industries of the country to participate as well.

FUTURE RESEARCH DIRECTIONS

The present study is solely based upon the green banking initiatives of some selected commercial banks of Bangladesh. Future research can examine the forms of green banking activities adopted by the central bank or the nationalized banks of the country. A similar research can also be conducted for a different developing country to do a more in-depth analysis of green investment approaches. Moreover, this study has mainly emphasized on the assessment of the perceptions and attitudes of bankers towards green banking. A longitudinal study can be adopted in future works to examine a different research model in order to examine the factors that can influence the adoption of green banking from the perspective of customers. This will provide a better insight into the perceptions of users and can help to enhance the understanding of individual users' intention to adopt green banking services in the context of Bangladesh.

CONCLUSION

The primary objective of this chapter is to provide a conceptual model that determines the perception of bankers towards environment, green investments and their attitude towards green banking that defines the reasons for using its related products/services and the future potential of such initiatives. Lack of studies in the area of bankers' perceptions and attitudes towards environmental safety and the concept of green banking is a major reason why such study is required to obtain a clear picture of the present status of commercial banks and their role in the adoption of green banking practices, particularly in developing countries. Thus, the findings of the current study are expected to make a significant contribution to the emerging literature on green banking studies by going beyond comparative analysis of banks and employing variables to assess the perception and attitude of bankers, who are mainly the people involved in the implementation and execution of green baking approaches. Results reveal that the perception of bankers towards environmental protection, care and sustainability was quite positive, but despite their agreement about environmental safety the bankers displayed limited knowledge about the concept and related methods of green investments. A more deterministic role that defines the attitude of bankers towards green banking has been mainly identified as image improvement and/or pressure from the central bank and stakeholders of the banking sector. In contrast, since green banking initiatives has made banking transactions easier to avail and working conditions more convenient for the bankers, no matter whatever the reason is for the individual banks to adopt green banking practices, bankers mostly are in favor of such initiatives and its related products/services. A significant number of bankers also gave a lot of insights regarding the future potential of green banking practices for the commercial banks of Bangladesh. Since the findings of this research are perceptual in nature, the attitude of bankers can be further influenced by appropriate documentaries to create awareness regarding global warming,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

environmental safety issues and green investments. Moreover, the intervention of government through budgetary allocations for green banking and increased involvement of the central bank to promote financing facilities for green initiatives can enable a more positive, supportive and encouraging attitude of bankers towards green banking practices in Bangladesh.

KEY TERMS AND DEFINITIONS

Commercial Bank: A financial institution that accepts deposits and provides loans to the general public. It also provides basic banking services to industries and can fund industry-specific projects as well.

Environmental-Friendly: Any practice that reduces any harmful impact on the environment.

Global Warming: Rapid change in the eco-system that brings about a change in the climate and which can have a direct impact on biodiversity, agriculture, forestry, dry land, water resources and human health.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Banking Unit: An operational unit in an organization which consists of employees from various departments and the main function of this unit is to design, evaluate and administer activities related to green banking initiatives of that organization.

Green Banking: An approach that promotes environmental-friendly practices and reduces carbon footprint from banking practices. This can be achieved in many ways such as reduced use of paper through the use of online banking instead of branch banking.

Green Finance: Any financial instruments, investments or projects that are climate change specific and primarily related to renewable energy, environmental technology or sustainability related markets.

Green Investments: Investments that focus their attention to climate change, resource efficiency and the safeguarding of the environment as a whole.

Social Responsibility: Any act or practice that works for the overall benefit of the society and focuses more on the improvement of the economy and eco-system rather than just the maximization of profits.

Sustainable Development: Any practice that has a sole aim to preserve natural resources for the betterment of the environment and eco-system.

Chapter 39
Why Do Companies Engage in Green Marketing?
Alternative Green Marketing Strategies and the Motivations for the Green Marketing Approach

Özge Kirezli
Istanbul Bilgi University, Turkey

Melis Kaytaz Yiğit
University of Marmara, Turkey

ABSTRACT

In recent years, consumers and the business world have deemed environmental issues to be more important, and green marketing has become a competitive advantage involved in corporate strategies. This chapter aims to study the concept of green marketing in the business world. First, according to literature, evolving green marketing definitions are described in detail, and the importance of green marketing approach it assessed. Then, since green marketing approach must be integrated with corporate strategies, four green marketing strategic models are presented and discussed. The chapter concludes with a discussion of the implications for green marketing of motivating factors such as pressure from consumers, NGOs and environmental organizations, legislative authorities, cost and profit considerations and competition between companies.

INTRODUCTION

The business world is experiencing a paradigm shift that requires new strategies and approaches to deal with competition and the changing needs of consumers who are becoming more conscious all the time. Companies have acknowledged that the only way to retain a positive position in consumers' minds is to enhance their image in areas that they appreciate. This is the basic explanation of modern business's

focus on sustainability, social responsibility and green practices. The market system made it necessary for businesses to involve nature in their business plans due to society's perception of the potential threat of its depletion.

Western societies began to perceive the harmful and devastating effects of industrialization and development in the early 1960s (Ghoshal, 2005). As Apel (1980) noted industrial revolution, our scientific and technological civilization, has presented all nations, races, and cultures, regardless of their group-specific, culturally relative moral traditions, with a common ethical problem, the sustainability of nature. For the first time in the history of the mankind, human beings are faced with the task of accepting collective responsibility for the consequences of their actions on a world-wide scale. This is made more specific in the Potsdam Institute for Climate Change's study of irreversible processes in the world caused by pollution, unplanned and unsustainable production and consumption systems. On the other hand, the amount of greenhouse gasses rose by 70% between 1970 and 2004, and global temperatures have risen by 0.76°C (1.36°F) since the 1850s (Vorholz, 2009). Environmental consciousness, therefore, arose first as a response to these problems respectively in industrial and developed societies. The idea of sustainability, which lies at the core of green marketing, dates back more than forty years, to the new mandate adopted by the International Union for Conservation of Nature and Natural Resources (IUCN) in 1969. Sustainability was also a key theme of the 1972 United Nations Conference on the Human Environment in Stockholm (IUCN Report, 2006). The concept was intended to suggest that it was possible to achieve economic growth and industrialization without environmental damage. Since then, this idea has been accepted and appreciated by industry, consumers and NGOs. However, translating this concern into action to protect the environment and integrating it with the principles of marketing were ideas that emerged in the 1970s (Peattie, 2001).

The term green marketing describes a business's efforts to design, promote, price and distribute products that will not harm the environment (Pride and Ferrell, 1993). Clearly, there are a wide variety of considerations to be addressed by companies that choose to embrace a green marketing agenda. Among them are concerns such as: developing offerings that conserve energy and other natural resources in their production process (Porter, 1991), creating advertisements and other promotional messages that accurately reflect the company's concern for the environment (Kangun et al., 1991), setting prices for green products that balance consumers' sensitivity to cost against their willingness to pay more for environmental safety (Chase, 1991; Jay 1990), reducing pollutants and conserving resources in the transportation of products to market (Bohlen et al., 1993) and a host of other marketing decisions.

Thus, the question to be asked is how businesses should act when motivated by these concepts. Chamorro and Banegil (2006) emphasize that the goals of the philosophy behind green marketing cannot be achieved by simply setting up a marketing department to apply the techniques of green marketing. Respect for the environment needs to be reflected in all of the business's behavior, not only in commercial aspects (Chamorro & Banegil, 2006; Ottman, 1993, 1998; Coddington, 1993; McDonagh & Prothero, 1993; Peattie & Charter, 1994; Sheth & Parvatiyar, 1995; Wasik, 1996; Polonsky et al., 1997). Moreover, to get the entire business to be concerned about the environmental impact of their activities, the environment should become one of the determining values of its organizational culture. There are two concepts that justify this claim (Chamorro and Banegil, 2006). First, the environmental impact of a product can rarely be eliminated if environmental aspects are not taken into account by other functional areas of the business that affect the end product's ecological quality, such as design, supplies and production. Second, the majority of green purchasers do not just buy a green product, they

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

are also buying the producer's green image. As Peattie (1999) says, the business itself becomes part of the product consumed; product and business form the total product. For this reason, the manufacturer of a green product should ensure that all its other business activities are also green (Pujari and Wright, 1999). If a business markets its products as green while simultaneously ignoring other dimensions of its ecological impact, it will have little credibility with consumers and will risk being endlessly criticized by pressure groups (Peattie & Charter, 1994).

The currency of the issue and the fact that it binds a variety of parties, such as industries, marketing, governments and consumers, motivate the authors to provide a coherent picture of green marketing approach in modern organizations in the contemporary business world. After a brief introduction in the second part, this chapter offers a detailed review of the literature on green marketing, the concept of sustainability in the business world and the perspectives of consumers and environmental organizations. Then, businesses' motivations for green marketing are presented in terms of pressure by consumers, NGOs and environmental organizations, legislation, cost and profit considerations, corporate environmental responsibility and competition. The conclusion is a general discussion about the topic and its implications for both the academic and marketing worlds.

GREEN MARKETING: THEORETICAL BACKGROUND

The past decade has seen a growing awareness of the widespread environmental degradation that faces current and future generations. This awareness has increased to the extent that environmentalism has been identified as potentially, "the biggest business issue of the 1990s" (Kirkpatrick, 1990). According to another view, the concepts of sustainability and green marketing have been known for a long time, but not necessarily by their current names. For example, in the early 1970s, Kotler and Zaltman (1971) proposed the idea of social marketing, which encompassed environmentalism. While their idea was originally developed as a response to a natural disaster, it is not news that green marketing has gained ground recently and it is closely linked to environmentalism (Chamorro et al., 2007; Peattie, 2001) and the green consumer (McDonald and Oates, 2006; McEachern & McClean, 2002; Cope & Winward, 1991; MacKenzie, 1991). When the aim of satisfying human needs and desires is paired with technological advances, the result is two-fold. Humanity has enjoyed technological advances' improvements in living conditions, but on the other hand, over hundreds of years production and trade have polluted and depleted natural resources. Especially in the last thirty years, both industry and society have begun to worry about the potential outcomes of underestimating the importance of the scarcity of natural environments (Straughan & Roberts, 1999). This section analyzes the concept of green marketing, starting with basic definitions and background and continuing with the significance and usefulness of the concept in the business and consumer world.

Henion (1976) was first to define green marketing as: "the implementation of marketing programs directed at the environmentally conscious market segment" (Banerjee, 1999, 18). This definition has three key components:

1. It is a subset of the overall marketing activity,
2. It examines both positive and negative activities, and
3. A narrow range of environmental issues are examined.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

While this definition is a useful starting point, to be comprehensive green marketing needs to be more broadly defined (Polonsky, 1995, 2). Fuller (1999, 4) defines green marketing as: "the process of planning, implementing and controlling development, pricing, promotion, and distribution in a manner that satisfies the following three criteria:

1. Customer needs are met,
2. Organizational goals are attained, and
3. The process is compatible with ecosystems."

Peattie's even broader definition sees green marketing as: "the holistic management process responsible for identifying, anticipating and satisfying the needs of consumers and society in a profitable and sustainable way" (Peattie, 1995, 563). Two key issues are emphasized by this definition: environmental sustainability and holistic thinking. Holistic thinking is used to describe a strategy that looks at marketing efforts as a whole to develop a holistic marketing plan by coordinating all marketing efforts. Environmental sustainability has been defined as meeting the needs of the present without compromising the ability of future generations to do so.

Mintu et al. (1993, 17) define green marketing as: "the application of marketing tools to facilitate exchanges that satisfy organizational and individual goals in such a way that the preservation, protection, and conservation of the physical environment is upheld." Green marketing imparts an ecologically proactive role to marketing organizations. It fosters not only sensitivity to the effects that marketing activities may have on the natural environment, but also encourages practices that reduce or minimize any detrimental effects.

According to Polonsky (1994) green or environmental marketing consists of all activities, designed to generate and facilitate any exchange intended to satisfy human needs and desires, such that their satisfaction occurs with minimum detrimental impact on the natural environment. This definition also includes the protection of natural environment by attempting to minimize the detrimental impact that exchange has on the environment. This second point is very important since human consumption is by its very nature destructive to the natural environment. To be more accurate, products that are marketed with green claims should be called "less environmentally harmful," rather than "environmental friendly." Thus, green marketing should try to minimize environmental harm, not necessarily to eliminate it.

Stanton et al. (1994, 636) claim that green marketing is: "any marketing activity of a firm that is intended to create a positive impact or lessen the negative impact of a product on the environment in order to capitalize on consumers' concerns about environmental issues." Pride and Ferrell (2010, 23) define green marketing as: "a strategic process involving stakeholder assessment to create meaningful long-term relationship with customers while maintaining, supporting, and enhancing the natural environment." Briefly, green marketing refers to activities that satisfy customer needs and desires in such a way that when their fulfillment occurs, negative environmental impact is minimized throughout the entire process, from product development to consumption and disposal. A general comparison between traditional green marketing approach and green marketing is presented by Figure 1.

World population is projected to double in the next 40 years, and when environmental pollution and scarce natural resources are considered in conjunction with this estimate, it can be seen that humanity is approaching an extinction threat (Polonsky, 1995). Thus, the united efforts of both society and industry engender the concept of green marketing. Until the twenty-first century, concern for the physical environment as a strategic marketing issue has evolved through several distinct stages. Tracing the evolution

Reaach of Marketing Decisions	From manufacture to product use	Entire product value chain from otaining raw materials to post consumption
Ecological Demands	Legal requirements	Beyon law: design for environment
Green Pressure Groups	Confrontation or passive attitude	Open relationship and collaboration

of green marketing, Peattie (2001) identified three phases: ecological green marketing (1970s), environmental green marketing (1980s) and sustainable green marketing (1990s), which are shown in Figure 2.

Ecological and environmental green marketing were the initial forms of green marketing; however, the bond between sustainability and green marketing is the fundamental characteristic of the latest stage in its development. The term "sustainability" was first used in 1972 by the World Commission on Environment and Development" (also known as the Brundtland Commission). It was defined as economic development that meets the needs of the present generation without compromising the ability of future generations to do so (UNGA Report, 2001). At first, the definition was not clear enough, but it cleverly

Figure 2. Stages of green marketing
Source: Data driven from Peattie, 2001

Stages of Green Marketing	Time Frame	Characteristics	Consequences
Ecological Green Marketing	1960s and 1970s	· Emphasis on pollution and resource depletion · Identifying problematic sectors: automobiles, oil and agro-chemicals · Concerning a minority	· Increased environmental regulation and law · Need for legal and technical staff
Environmental Green Marketing	1980s	· Publication of the Brundtland Report · Reduce environmental damage by green consumers · Using green marketing opportunities as a competitive advantage	· The rise of the green consumer · Innovation in clean production systems · New terms of eco-performance, environmental quality
Sustainable Green Marketing	1990s	· Meet the full environmental costs of production and consumption to create a sustainable economy. · Radical changes in the way people live, produce and consume	· Intense social concern for industry and consumers · New terms of quality of life, sustainable models · Integrated efforts to seek solutions involving suppliers, consumers and even competitors

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

captured two fundamental issues, the problem of the environmental degradation that so commonly accompanies economic growth and the enduring need for such growth to alleviate poverty. While there is no standard definition of corporate sustainability, some authors have made attempts to define it, rather vaguely, as: "demonstrating the inclusion of social and environmental concerns in business operations and in interactions with stakeholders" (van Marrewijk & Were, 2003, 107). So more than just taking ecological degradation into account, the interest was shifted to the potential harm caused by humanity to humanity. The core of sustainability thinking has become the idea of its three dimensions, environmental, social and economic sustainability.

Van dam and Apeldoorn (1996) perceive sustainable marketing as a way to determine feasible tradeoffs between business and environmental concerns. Undoubtedly, the concept of sustainability is significant from multiple angles, and unlike green marketing, sustainable marketing is a macro marketing concept (Fisk,1998). Although this chapter only considers the business side, it would be quite beneficial to discuss the ramifications of the concept for a variety of parties, including the world economic system as a whole, marketers, consumers and legal authorities. Peattie (2001, 140) perceives its significance by its natural ability to join the concepts of physical environment, society and the economy and to recognized their interdependence. Morrison (2003) also indicates that for corporations sustainability involves: "an integration of social, environmental, and economic accountability for the purpose of forging a new framework within which leaders make decisions and assume the accompanying responsibilities." Previously, these were seen as separate issues for interests to be traded off (in particular, environmental protection and economic growth were presented as a choice).

Belz (2006, 21–22) identifies some dimensions of sustainability marketing:

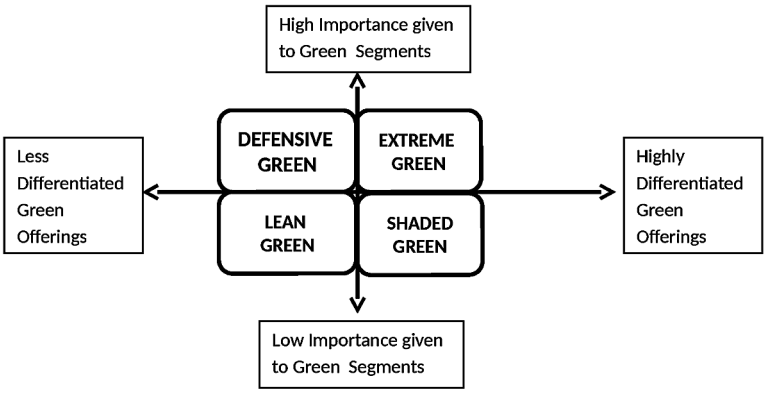
- **Socio-Ecological Problems:** The analysis and identification of ecological and social problems are points of departure in sustainability marketing. Social and ecological concerns are core concepts at the heart of sustainable marketing.
- **Intersection of Social and Individual Benefits:** Sustainability marketing aims to create no harm to the environment, while at the same time ensuring customer satisfaction.
- **Transformational Facets:** By dealing with public and political issues and changing business practices in favor of sustainability, companies build the conditions for the successful marketing of sustainable products.

VISUALIZING DIVERSE GREEN MARKETING STRATEGIES

Integrating sustainability with green marketing will undoubtedly require more effort than developing less harmful products and cleaner production processes. A single action or set of discrete actions are insufficient to embrace the entire philosophy of green marketing. Although these activities are tactically essential to the overall success of the greening program, green marketing is a holistic and integrated approach that continually reevaluates how firms can achieve corporate objectives and meet consumer needs while minimizing long-term ecological harm, as Peattie (1995, 563) emphasizes. This section analyzes green marketing strategically.

The growing global importance of environmental issues forces companies to consider their overall corporate strategy and establish converging objectives among different functions. It involves an enriched way of looking at marketing, its objectives, and its strategies that even goes beyond social marketing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



(Kilbourne, 1998; Prothero, 1998; Peattie, 1995). Current practices also support the undeclared consensus that the transformation from industrial era marketing to sustainable green marketing is necessary to ensure the sustainability of the entire economic system.

Appraisals of green marketing strategies involve distinct views, so this section presents four models of its strategical implications: Shrivastava's (1995) "The Implications of Porter's Forces in Green Marketing," Prakash's (2002) "Greening Strategies," Ginsberg and Bloom's (2004) "The Green Marketing Strategy," and Kotler's (2005) four levels of environmentally sustainable strategies.

1. **Shrivastava's Implications of Porter's Forces in Green Marketing:** According to Shrivastava (1995, 949) it is possible to derive modified strategies from Porter's generic competitive forces: least-cost leadership, focus and differentiation. By applying these sustainability principles, ecologically sustainable generic strategies were presented as a new paradigm.
    a. **Ecologically Sustainable Least-Cost Strategy:** Products and processes are designed to assure improved environmental quality. Large scale operations are appreciated due to the savings they entail. Basic training on safety and environmental issues should also be given to employees. Building green partnerships or alliances are another way to improve ecological efficiency.
    b. **Ecologically Sustainable Differentiation Strategy:** Product attributes such as ingredients are packaging are modified to create differentiation. Environmentally safe packaging serves as a critical issue. Manufacturing facilities are of moderate size, and special training is given to employees in this strategy. Companies tend to work with many vendors to deal with waste management, transportation costs and reduce packaging. Technology transfer of environmentally safe production systems is desirable; however, this is an expensive strategy.
    c. **Ecologically Sustainable Niche Strategy:** Apart from including environmental considerations in technology development and use, new product development and process improvements, firms can also serve niche markets of environmentally conscious consumers. If a company works with limited vendors, it is assumed to improve the environmental quality of the products due to customized offerings. Extensive technological possibilities are important in terms of competitive advantage, but are relatively expensive and may not be environmentally safe.
2. **Prakash's Greening Strategies:** Prakash (2002) suggests that companies are likely to engage in green marketing strategies in three ways: value-adding processes; management systems and products. Value adding modifies or reengineers current systems to reduce negative environmental impact. Management systems set environmental objectives to measure environmental performance. However, if these objectives are not quantifiable and easy to measure, it is quite difficult to monitor progress. The first two strategies are companywide, but the third one adopts a micro perspective and deals with specific products as green products. Focusing on the performance of products is thought to be important in several ways (Prakash, 2002, 286; Charter, 1992): by reusing products and developing products for reuse; by repairing and extending product life cycles, by recycling and converting products into raw materials, and by reducing or generating less waste.
3. **Ginsberg and Bloom's "The Green Marketing Strategy":** According to Ginsberg and Bloom (2004, 80), there is no single green marketing strategy that is right for all corporations, and strategies should be derived from the likely size of an industry's green market and companies' ability to differentiate their products as green. Hence, they offer four strategies that range from the relatively passive lean green strategy to the more active and aggressive extreme green approach (Figure 3).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Ginsberg and Bloom's green marketing strategy matrix
Source: Ginsberg & Bloom, 2004

a. **Lean Green:** Companies that adopt this strategy do not consider publicizing or communicating their green initiatives, their interest is reducing costs and improving efficiencies by activities designed to reduce negative environmental impact. In other words, attaining the competitive advantage of lower costs is the key issue for lean greens. The main drive is compliance with regulations and finding preventive solutions for the long term. Last but not least, lean greens are reluctant to advertise their green identity and do not promote green activities or products.
b. **Defensive Green:** This strategy uses green marketing as a response to competition, to a crisis or as a precaution. Defensive greens have identified green niche segments as important customers who cannot be lost. Since they do not have the competitive advantage of differentiated green products, extensive promotion is likely to be a waste of resources. Sponsoring small environmentally-friendly events and programs or PR activities are good for them, if they are attacked by regulatory authorities, NGOs or competitors.
c. **Shaded Green:** Shaded greens make substantial financial and non-financial commitments by investing in long-term, system wide and environmentally-friendly products and processes. These companies have achieved the competitive advantage of being able to differentiate their products as green, but choose not to do so, and in order to make money, they stress other functional attributes. Shaded greens promote their products' tangible benefits to the customer, and their green benefits are perceived as secondary.
d. **Extreme Green:** Extreme greens have ethical values and are highly interested in integrating environmental issues into business. Achieving green strategies is often the initial driving force for these companies. They use life-cycle pricing approaches, total quality management and manufacturing standards that are safe for the environment. Extreme greens' products and services usually serve niche markets.

4. **Kotler's Environmental Sustainability Strategies:** The first three green strategies have been presented in sequential order, and Kotler's (2005) perspective unifies them all in the most interpretative approach. He suggested four approaches to environmental sustainability, which are:
   a. **Pollution Control and Prevention:** Cleaning up waste after it has been created or minimizing waste through green marketing programs or by developing safer biodegradable or recyclable products and/or packaging.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

b. **Product Stewardship:** Minimizing environmental impacts throughout the full product life cycle by designing products that are easier to recover, reuse or recycle.
c. **New Environmental Technologies:** Investing in research and development to pre-empt fully sustainable strategies, for example developing environmentally biodegradable cleaning products that also work at low temperatures and thus save energy.
d. **Sustainability Vision:** Developing a framework to show how the company's products, service, processes and policies comply with pollution control and prevention, product stewardship and new environmental technologies.

5. **Green Marketing Strategies Proposed by the Authors:** As literature suggest, there exist various forms of greening strategies. In a broader concept it is possible to classify strategic approaches in 3 views, which are Authentic Green Marketing, Relational Green Marketing and Egoistic Green Marketing. The details of each type are discussed below.
   a. **Authentic Green Marketing:** Companies adopting that strategy have tight ethical values and consider environment as a necessary factor of production. This strategy requires a holistic approach, with all actions of the firm coordinated to integrate environmental issues across all functional areas. The vision is not just complying with the regulations or promoting the company as "socially responsible", but to make a contribution by developing sustainable creative solutions to current ecological and social problems. The company shows tendency to integrate green views in company's mission and vision, moreover in operations, that is to be reflected by elements in marketing mix; product, price, promotion and place.
   b. **Relational Green Marketing:** Financial or non-financial investments to green marketing are undoubtedly, important for companies, when opportunistic costs of these are to be thought. So sometimes, companies may not be satisfied by doing ethical actions for the world, for the humanity, they desire to achieve extra benefits. In that perspective, they use green marketing as a promotional tool to enhance company's image. Green wash threat occur within that strategy. The company may choose to mention green objectives in mission and vision, but the operational reflection is weaker than "Authentic Green Marketing". A limited perspective in green marketing mix adaptation is to be seen in that type, beside product approach, promotion or place adaptation could be seen.
   c. **Egoistic Green Marketing:** Like Ginsberg and Bloom's "Lean Green" Strategy, companies aim to consider green marketing only method to ensure lower-costs. Low cost issue may be handled internally, through revise of operations to enhance efficiency, new process designs, product modifications (re-fillable, re-useable, recyclable) or externally, to comply legal obligation avoid negative consequences like penalties, extra taxes, or even consumer boycotts. In other words, realization of that strategy depends only on marketing mix's "product" element.

MOTIVATIONS FOR GREEN MARKETING APPROACH

Society also has critical impact on companies, and as Vale (2005) arguers, nowadays companies cannot succeed without taking a variety of stakeholders into account in their strategical and tactical approaches. Esty and Winston (2006) point out that not only are the relations between consumer, organization and natural environment being redefined, but the effects of each party on the others are being interpreted as pressure by a variety of stakeholders, including producers, legal authorities, pressure groups (environ-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

mentalists), NGOs, consumers, competitors and suppliers. Considering market actors in the development environmental marketing strategy will help industrial marketers to achieve their strategic objectives. Polonsky (1995) argues that that if firms are being forced by legislation to modify their behavior, they would benefit from understanding why changes in public policy occur and how legislators are motivated. As the most powerful stakeholders, as decision makers, consumers determine the fate of companies by holding the power to buy or not buy, and green marketing offers a proactive strategy that can enable companies to cater the market by selling nature-friendly products and services that reduce or minimize any detrimental impact on environment. Polonsky adds that (1995) for companies' desire for the competitive advantages of green marketing is based on the assumption that the consumers prefer environmental products and options. Therefore, consumers and the competition are both relevant stakeholders that need to be considered when firms develop their environmental marketing strategies. Lantos (2001) underlines the need for a balance and cooperation between the diverse groups that affect greening strategy; however, uncertainty remains about how to achieve this balance.

Companies accept their responsibility to minimize harm to the environment and improve their processes and products to become green (Hart & Ahura, 1997, 67). Undoubtedly, their practices are an important question for analysis; however, the forces that drive companies to go green can be more attractive to the parties involved in green marketing. The literature suggests several reasons for businesses' increased use of green marketing (Polonsky, 1995, 31):

- Companies see green marketing as an opportunity to fulfill their objectives and achieve competitive advantage (Polonsky, 1995,Keller 1987, Shearer, 1990).
- Companies feel social responsibility and obliged to behave ethically (Polonsky, 1995).
- Legislative authorities are forcing firms to be more responsible (Polonsky, 1995).
- Competitors' green activities pressure firms to change their own activities (Polonsky, 1995).
- Cost and profit opportunities associated with recycling, waste disposal, reductions in material usage and the elimination of packaging force companies to change their attitudes and hence behavior (Polonsky, 1995, Azzone & Manzini, 1994).

Other factors can be added to this list, such as pressure by consumers, NGOs and environmental organizations. Each of these motives will be discussed in more detail as part of companies' perceptions of green marketing philosophies.

Non-Governmental Organizations (NGO's): Associations Pressure

NGOs are institutions that work for the benefit of the society regardless of their interest. Environmental problems are getting worse day by day, creating the need for voluntary organizations and international NGOs. In the realm of international development, NGOs have been characterized as the new "favored child" of official development agencies and proclaimed a "magic bullet" for targeting and fixing the problems that have befallen the development process (Edwards & Hulme, 1996).

Arts (2002) interprets the relationships between business and non-governmental organizations, especially environmental organizations (NGOs), as antagonistic in nature since they have competing objectives. In other words, the conflict between the two parties is caused the negative effects of industry on the environment, which are harshly criticized by NGOs. Hence, clashes on environmental issues occur between NGOs and companies, and the tension is not just between industry and NGOs, but also between

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

legal authorities and NGOs. Governments are criticized by NGOs for their slow, bureaucratic negotiations, which lead to the postponement of measures, vague compromises and a lack of implementation (Bendell & Murphey, 2000).

Already in the late 1980s and early 1990s, green alliances, collaborative partnerships between environmental NGOs and businesses that pursue mutually beneficial ecological goals, became popular phenomena, both in practice and in American academic literature (Stafford et al., 2000).

It is important to know whether or not these alliances successfully contribute to the existing legislative authorities for policy making and regulation. Arts (2002, 28) found two potential answers to this question:

- An optimistic view is that they function well to provide solutions to problematic issues, like emissions control, or enhancing recycling by establishing more flexible and cost-effective green alliances with businesses.
- A pessimistic view would consider them temporary solutions rather than sustainable long-term operations.

Green alliances are strategic tools for the environment, society and business. Mendleson and Polonsky (1995, 9) described the benefits for businesses of green alliances between NGOs and companies, and claim that they:

- Increase consumer belief in green products and their claims,
- Provide businesses with access to environmental information,
- Give marketers access to new markets,
- Provide positive publicity and reduce public criticism, and
- Educate consumers about key environmental issues relating to businesses and their products (Coddington, 1993; Mendleson, 1994).

Since the 1970s, when environmental concern emerged as an issue, numerous NGOs have been founded for the purposes of environmental protection and improvement. Figure 4 shows examples that are either well known for their activities or have been at work for a long time, along with their objectives and practices, and foundation date.

Legislative Authorities

Governments want to protect consumers and society from the threat of resource depletion, and according to Polonsky (1994) this occurs in several ways:

1. Curtailing the production of harmful goods and by-products,
2. Modifying consumer and industry use and consumption of harmful goods, and
3. Ensuring that all types of consumers have the ability to evaluate the environmental consequences of the production, consumption and disposal of goods.

Governments impose new laws, regulations and proposals on businesses in response to increasing environmental concern, and may enact even more restrictive controls if businesses fail to modify their behavior (Mathur & Marhur, 2000). Researchers believe that sustainable development can be achieved only

Adapted from http://library.duke.edu/research/subject/guides/ngo_guide/ngo_links/environment.html

NAME OF NGO	SINCE	OBJECTIVES	ACTIVITIES
Greenpeace	1971	ensure the ability of the earth to nurture life in all its diversity	campaigns, regional/global projects, activating publics against harmful operations
UNEP (United Nations Environment Programme)	1972	to assess in environmental issues at the global and regional level	global reports, regional/global projects, supporting new technologies
Center for International Climate and Environmental Research	1990	to conduct research and provide reports, information and expert advice about issues related to global climate change and international climate policy	research, reports on environment, regional/global projects
European Environment Agency (EEA)	1994	to establish a network for the monitoring of the European environment.	European Topic Centre on Air and Climate Change ;Renewable energy
Center for Environmental Research and Conservation	1994	to proliferate a deeper understanding of ecology in order to inform political, social and economic decision making	seminars, research and regional/global projects
Intergovernmental Panel on Climate Change (IPCC)	1998	to assess information; human-induced climate change, the impacts of human-induced climate change and options for adaptation and mitigation.	publishings of special reports on topics relevant to the implementation of environmental laws

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

by proactive corporate marketing and active government intervention. They suggest a two-dimensional shift in the approach to ecological problems: from consumption marketing to sustainable marketing and from the invisible hand to the more visible hand of government (Karna et al., 2003; Sheth & Parvatiyar, 1995). As a consequence, there may be a greater role for government to play in establishing sustainable behavior. Brennan and Binney (2008) advocate a tripartite approach to green marketing practices composed of legislation, education and enforcement.

In short, the role of government is to regulate businesses at the most concrete level. Porter and van der Linde (1995, 128) describe the need for regulations comprehensively;

- To create pressure for green innovations and to increase the likelihood that product innovations and process innovations in general will be environmentally friendly.
- To improve environmental quality in cases in which innovation and the resulting improvements in resource productivity do not meet the cost of compliance.
- To alert and inform companies about likely resource inefficiencies and potential areas for technological improvement.
- To establish demand for environmental improvement until companies and consumers are better able to perceive and measure the resource inefficiencies of pollution.

When environmental problems emerged globally, governments were perceived as saviors due their legislative capabilities. Hence government's role as the protector of consumers and society has significant implications for green marketing. According to Polonsky (1994), regulations imposed by legal authorities assist consumers by reducing the production of products that are hazardous to environment, modifying or eliminating consumer use of harmful products and ensuring that all consumers have sufficient information to evaluate products' environmental score cards.

Porter and van der Linde (1995) evaluate the current situation as a transitional phase of industrial history in which companies are still inexperienced in handling environmental problems creatively. Consumers, too, are unaware that resource inefficiency means that they must pay for the cost of pollution. So regulation, as a strategic tool of governments, is essential for shaping the economy. Alternatively, the right to pollute might be turned into a tradable commodity the supply of which governments can control by imposing taxes for excesses (Sinding, 2000; Tietenberg, 1985). However, producers in pollution-intensive industries generally have difficulty passing the costs of compliance on to consumers due to the elasticity of demand (Dean & Brown, 1995).

According to a study by Lau and Srinivasan (1997), the driving force for better environmental performance is largely the fear of penalties that can be imposed by governments when environmental laws are violated. Hence, legislative authorities serve as a threat that ensures compliance to the law by industry.

Government and legal authorities are undoubtedly significant actors in terms of creating and improving green standards and hence green strategies. The typical instruments that are imposed by them are: taxes (emission taxes), fees, subsidies, regulations and standards (Kotler, 2005, 126). As an initial solution, governments can levy taxes to correct externalities or offer subsidies to reduce pollution (Sinding, 2000, 80). The logic of these taxes is to impose some kind of cost for taking advantage of the environment.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Customer Pressure

The role of legislative authorities has a considerable effect on industry, but the results may be limited if environmental concern is not shared by the public. Consumers, as decision makers in the market place, can no longer be separated from environmental issues. The shift in consumer's interest or at least awareness of social and ethical issues can be explained by a few developments in the global economy. The most comprehensive explanation is the rise of environmental problems, such as pollution and mass extinctions and climate change. Negative attitudes towards industrialists portray them as the cause of these problems. In other words, global environmental problems are triggered by globalization, unbalanced power and insensitive practices, and consumers criticize multinational corporations' abuse of nature (Zinkhan & Carlson, 1995). Auger et al. (2003) put forward the interesting opinion that the availability of higher quality products had given consumers the power to evaluate products based on non-traditional attributes such as a product's ethical identity, environmental friendliness or additional benefits.

Mintel (1994) reports a significant willingness among consumers to let their buying patterns be affected by a wide range of ethical issues. These issues include human rights, labor relations, land rights, the environment, irresponsible marketing, fair trade, nuclear power and animal testing. However, Rex and Baumann (2006) criticize the consistency of consumers' attitudes toward ethical purchasing since it varies by the type of product or brand. Ethical consumption is a general term that symbolizes the tendency to consume socially acceptable products. Green generally refers to consumers' who have specifically environmental concerns (Bohlen et al., 2003) that are distinct from a broader range of social concerns. Similarly, Peattie (2001, 132) defined green consumers as those who tend to avoid products that:

- Endanger the health of consumers or others,
- Significantly damage the environment in production, use or disposal,
- Consume disproportionately large amounts of resources,
- Cause unnecessary waste through over-packaging, excess features or unduly short lifespan,
- Use materials derived from endangered species or habitats,
- Involve cruelty to animals,
- Adversely affect other countries.

Cost and Profit Consideration

Green marketing was always seen as a concern for or an approach to the environment that stressed the efficient use of resources, but companies may not always be motivated by the concept of social responsibility and choose to prioritize internal issues such as cost savings or extra profits as motivational factors (Polonsky, 1994).

According to Yurman, innovative approaches can help new industries in two ways:

1. A firm develops a technology for reducing waste and sells it to other firms, or
2. A waste recycling or removal industry develops (Polonsky, 1995; Yurman, 1994).

Polonsky (1994) claims that companies could choose creative solutions, instead of merely reducing waste, for instance when businesses try to find markets or uses for their waste materials, and one

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

business's waste becomes another's manufacturing input. On the other hand, managers have recognized that it is necessary to better understand the drivers of both costs and profits and the actions that they can take to affect them. Popular management frameworks such as balanced scorecard and value-based management rely on a better understanding of the drivers of value to aid managers in making decisions to improve corporate value creation (Epstein & Roy, 2001; Kaplan & Norton, 2000).

Recent work by Epstein and Westbrook has developed the action-profit linkage model that investigated the causal relationships and linkages within organizations and the levers that managers can pull to improve both customer and corporate profitability and improve corporate performance (Epstein & Westbrook, 2001). All of these models depend on a careful identification and measurement of the drivers of performance. However, the identification and measurement of social and environmental strategies is particularly difficult since they are usually linked to long time horizons, a high level of uncertainty and impacts that are often difficult to quantify (Epstein & Roy, 2001).

Corporate Environmental Responsibility: Social Pressure

Environmental regulations and policies mitigate many problems related to natural resources; however, Shrivastava (1995, 937) drew attention to the necessity of voluntary efforts to address industrially induced ecological problems. Companies must realize that they are part of the wider community and behave in an environmentally responsible way. They set themselves environmental objectives as well as corporate and profit objectives. In some cases, concern for environmental issues has been integrated into company's organizational cultures. Companies who manufacture products can make a further contribution to environmental improvements by encouraging their suppliers to be more environmentally responsible. Growing concern for the environment has changed the perspective of the stakeholders. Managers are increasingly asking how to improve sustainability performance, and, more specifically, how they can identify, manage and measure the drivers of improved sustainability performance and how social performance affects overall long-term corporate goals (Epstein & Roy, 2001, 586).

Corporate responsibility is often divided into economic, social, and environmental categories like the categories proposed for the popular concept of sustainable development (Karna et al., 2003; Peattie, 1995). Nevertheless, there is no single accepted definition of corporate social responsibility. It is related to business decision making linked to ethical values, compliance with law, and respect for people, communities and the environment (Karna et al., 2003). The environmental dimension is the core issue of green marketing and over time, companies are becoming committed to being socially responsible in the environmental dimension, too. Today we can find social responsibility reports on the websites of corporations (Ginsberg & Bloom, 2004). In other words, businesses have realized that they must be prepared to provide their customers with information about the environmental impact of their products and operations (Ottman & Terry, 1998).

The literature on corporate social performance, responsibility and responsiveness also shows that businesses have social responsibilities that may or may not reinforce the profit objective (Prakash, 2002; Wood & Jones, 1995). Business green their products and policies because they wish to be socially responsible—"it's the right thing to do." This may or may not generate quantifiable profits in the short run. However, in the long run, socially responsible policies have economic payoffs (Hart & Ahuja, 1997).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Competitive Pressure

Global competition and continuous improvements have eliminated the differences between products and brands so that majority of the offerings can be accepted as identical. (Christensen, 1995). Competitors serve as important market actors that stimulate companies to establish or maintain a competitive position. In many cases, businesses compete with companies that promote environmental behavior. For example Xerox's launch of "Revive 100% Recycled Paper" was intended to address the introduction of recycled photocopier paper by other manufacturers (Polonsky, 1994). Likewise, Esty and Winston (2006) claim that even if no industry organization is driving change, one company's leadership and brave action can change the competitive market in a variety of ways. For example, in 1990, Heinz launched a project intended to stop dolphin deaths, which stimulated other actors to engage in similar activities.

With consumers, business customers and governments demonstrating increasing concern about environmental issues, companies recognize the importance—and potential benefits—of dealing with these concerns. Companies that market goods with environmentally responsible characteristics are likely to have a competitive advantage over companies without green credentials. In the 1990s, the view that green strategies can give a competitive advantage was promulgated by authors such as Elkington (1994), Azzone and Bertele (1994) and Porter and van der Linde (1995) (Peattie, 2008). Porter and van der Linde perceived that search for environmentally superior solutions may lead to innovation and the creation of more efficient and effective technologies. Even though environmental legislation creates new challenges for companies, which stimulated them to innovate and achieve improvements in competitive, as well as environmental, performance. This is what Varadarajan (1992) termed "enviropreneurial marketing" (Peattie, 2008). In enviropreneurial marketing challenges in the environment, such as resource depletion or pollution, are seen as an opportunity instead of a threat, and according to this philosophy, negative external factors drive companies to explore and innovate in ways that give them a competitive advantage and also benefit consumers and the environment.

Polonsky (1994) argued that companies can use two green marketing strategies, can take two perspectives:

1. They can use the fact that they are environmentally responsible as a marketing tool, or
2. They can become responsible without promoting this fact.

There are examples of businesses that use both strategies. Coca-Cola exemplifies the second strategy by investing large sums of money in various recycling activities and modifying their packaging to minimize its environmental impact. While being concerned about the environment, Coca-Cola has not used this concern as a marketing tool. Many consumers may not realize that Coca-Cola is a very environmentally committed organization. Another business that is very environmentally responsible, but does not promote this fact, at least outside the organization, is Walt Disney World, which has an extensive waste management program and infrastructure in place. Yet these facilities are not highlighted in their general tourist promotional activities (Polonsky & Rosenberger, 2001; Murphy, 1985). As an example of the first strategy, Body Shop heavily promotes the fact that they are environmentally responsible, and the company offers consumers environmentally responsible alternatives to conventional cosmetic products. This philosophy is directly tied to its overall corporate culture, rather than simply being a competitive tool. However, this leads to the threat of greenwashing.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Greenpeace coined the term, greenwashing in 1991 to "describe corporate deceptions, exaggerations and cosmetic changes undertaken purely as public relations ploys" (Muldoon, 2006). The public is worried about green washing, which was practiced in the 1980s and early 1990s, so new standards and certifications had been put in place to facilitate the recognition of green products by consumers (Ginsberg & Bloom, 2004). Greenwashing is a deceptive use of green PR or green marketing. The term, green sheen, has similarly been used to describe organizations that attempt to show that they are adopting practices beneficial to the environment. For example, Procter & Gamble and Wal-Mart were severely criticized for putting a green label on a brand of paper towels made of non-recycled paper and packaged in plastic, simply because the inner tube for the towel was made of recycled paper (Laroche et al., 2001).

CONCLUSION

Industrialization stimulated increased the well-being of societies and improved conditions in the eighteenth century, leading countries to exploit resources for production and consumption without considering the potential social outcomes. Since the 1950s, industrialization had resulted in exponential increases in the human consumption of resources and health, wealth and population. That is to say, the post-war baby-boom led to an excessive need for energy resources, goods and services in many societies. The scarcity of resources under the pressure of rapid consumption became obvious. The research and development focused-progress of countries and societies engendered the inevitable dilemma of benefiting from the environment or exploiting it.

However, benefiting from nature was seen as a one-way approach, and humanity ignored the issue of renewing resources that were being consumed. The primary principle of economics, resource scarcity, was neglected until nature called for aid. According to Bahro (1996), ecological problems signify the dead end of capitalism. Thus, consumption without attempts to renew natural resources is unfortunately threatening the well-being of future generations. In a reactive manner, societies tried to identify environmental problems and offer solutions to maintain the ongoing relationship between humanity and nature.

In the 1990s, academics and researchers started to seriously discuss the implications of neglecting the sustainability of the entire system (Peattie, 2001; Van Dam and Apeldoorn, 1996). However, rather than criticizing the issue from limited viewpoints, in a broader sense the term, sustainability, binds consumers, NGO's and enterprises, since the solution is to engender a synergistic power that involves all these parties. Synergistic power means that, consumers, corporations, institutions and governments work together to minimize detrimental effects on the environment, and to foster the sustainability of common resources (air, water supplies and land), raw materials and product availability. Since then, consumers question the consequences of their purchasing patterns, in other words, the potential harms caused by their decisions, whereas companies have reorganized their business structures and operations to satisfy changing consumer demands.

During the last thirty years, this concern has intensified, our understanding of the interaction between the economy and the environment has developed, and our ideas about what might constitute green marketing have evolved. The business world has been dramatically changed, altered by business enterprises, consumers and environmental organizations, which interrogated public actions that affect the environment (Edward & Wilmot, 2008). Thus, niche areas emerged: environment ally friendly products (products that can be reused, refilled or recycled), tighter emissions controls and energy efficient operations that emphasize the integrating role of the environment in all production or trade processes (Kotler, 1999, 58).

Previous studies worldwide have either focused on the consumer's world—attitudes, values, purchasing habits —or on enterprises reorganizing themselves with greening strategies intended to minimize environmental pollution, the manufacture and use of energy efficient products and investments in the well-being of nature and society. This ends up with the problem of creating a common and well known definition of green business (Peattie, 2008, 563). What is considered green by one organization may not be by others. Furthermore, the definition of green business is undermined by the proliferation of green labeling and standards, which lead consumers to consider green labels simply a marketing tool with little substance behind them.

Acknowledging the crucial role enterprises have in the economic system, a comprehensive look at green marketing for business in terms of alternative strategies and motivations for green practices is sorely needed. Visualizing their motivations and questioning the actors involved in their green marketing efforts would help to define the notion of sustainability from an organizational perspective and contribute to uniting the stakeholders' efforts in green marketing and sustainability. This is the perspective that led this chapter to conceptualize the influences on modern companies' adoption of green strategies as six separate entities:

1. NGOs,
2. Legislative authorities,
3. Consumers,
4. Cost-profit considerations,
5. Corporate environmental responsibility and
6. Competition.

For business, green alliances can reveal new business opportunities, improve (environmental) performance and enhance reputations, while NGOs may achieve more environmental gains by cooperating with businesses rather than governments (Glasbergen & Groenenberg, 2001). In fact, both parties are disappointed in governmental policy making. For NGOs, governments are generally not effective enough in combating environmental problems. Governments are, according to NGOs, too involved in slow, bureaucratic, (inter-)national negotiation processes, which leads to the postponement of measures, vague compromises and a lack of implementation. Another motivating factor is the fact that legislations and regulations already exist for companies. Governments—as the sole law-making authorities—may assist consumers in some areas, by reducing the production of products that are hazardous to the environment, curtailing the use of harmful products and ensuring that all consumers have sufficient information to evaluate products' environmental score cards (Polonsky,1994). In addition, governments can also insist that suppliers address environmental issues. Thus, in many industries, technologies and production systems have been improved to create less pollution and conserve resources (Peattie, 2001).

Consumers' heightened attention to environmental issues is a challenge to businesses. Auger et al. (2003) hold the interesting opinion that the availability of higher quality products has given consumers ultimate power to evaluate products based on non-traditional attributes such as products' ethical identities, environmental friendliness or additional benefits. This means that, companies' strategies need to take these ethical consumers into consideration.

On the other hand, as another motivation as chance for cost reduction, Epstein and Roy (2001) claim that green marketing practices may lead to cost reductions in terms of less packaging, material substitu-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

tions, low energy consumption during production and reduced water disposal. The positive social effect of these activities is also a favorable outcome for companies.

Last but not the least, cooperation with competitors, purchasers or environmental groups has been identified as a potentially important means of developing and accessing green marketing resources and competences not otherwise readily available to individual businesses (Crane, 2000). Competitive pressure or cooperation can be another trigger for engaging in green marketing strategies.

In conclusion, sustainable green marketing establishes the environmental pillar of the concept of sustainability. A sustainable approach to consumption and production involves enjoying the environment as well as granting the same standard to future generations (Peattie, 2008). Belz (2006) regard the current paradigm shift as an evolution of marketing towards "transformational sustainability marketing" in which social, physical and environmental problems are as important as customer needs in marketing theory. The basic difference in this approach is the urgent need to integrate social and environmental issues into marketing strategies. Similarly, Hart (1995) mentioned the threat of understanding sustainability merely as pollution control. He claimed that even if companies were to achieve zero emissions by the year 2000, the world would remain stressed by carrying capacity and the potential destruction of farmlands, fisheries and forests. Thus, sustainability acquired a global perspective and began to promote the synergistic effect that companies, governments and environmental groups could produce even if some stakeholders were more concerned about sustaining the economy, while others were more concerned about sustaining the natural environment. This provided new opportunities for partnerships and collaborations.

Chapter 40
Educated Young Consumer Purchase Behavior Towards Green Products:
An Empirical Study in India

Gyaneshwar Singh Kushwaha
Maulana Azad National Institute of Technology, India

Nagendra Kumar Sharma
Maulana Azad National Institute of Technology, India

ABSTRACT

Green marketing is one of the emerging fields in India. Educated young consumers are very advantageous segment for green marketing. This paper aims to evaluate the purchase behavior and reactions of educated young consumers towards 'green products' which is an essential element of the green marketing. Various variables have been found on the basis of the literature review. The survey questionnaire was designed with the help of literature and expert's inputs and got 343 actual respondents. An exploratory factor analysis and linear regression analysis has been used to bring the findings of the study. The result of the study shows that EYCs (Educated young consumers) purchase behavior towards green product is positive. Green product awareness, Eco-labels and satisfaction and all these found significantly associated with the purchase behavior or intention, but premium price and consumer (those who are highly concern towards environment) has insignificant relationship with the purchase behavior. The concept of green marketing in India is emerging and the study can be a meaningful guide.

1. INTRODUCTION

India will soon have the largest, youngest workforce ever, nearly half of the population is under 24 years of age while about 64% of Indians are of working age (Tulloch, 2014). Majority of the population in India are young and hence we can say India is a young country. Young consumer those who have attained the age of adult i.e. eighteen years in India, play important role in buying decision process in the family and they individually purchase a good amount of products annually (Ghodeswar). Seven hundred degree

granting institution and thirty five thousand and five hundred affiliated colleges and about enrolling more than twenty million students. Indian higher education system is very large (Choudaha, 2013). The higher education system is continuously involved in producing young graduates each year. It is also a matter of pride that our youth is educated. But still in our country there are lots of problems related to the social issues such as environment, even there is separate mandate syllabus for environmental education in higher education system (Chhokar, 2010). India ranks on 155 out of 178 countries in the Environmental Performance Index (EPI, 2014). This is very poor in the world. There are so many causes for environmental problems but the industries are the main cause (Lin Ru-Jen et.al.2011). India and China are rapidly developing their economy and in both the countries industrial development is recorded well (Siraj, 2011). In order to reduce the blames most of the industries started adopting green practices in production and marketing of goods and services but are not found sufficient to provide a better safe guard to the environment (Lin & Sheu, 2012). On the other hand, it is also seen that people give more priorities to their comfort and life style rather than environment and hence the essentials of environment are ignored many times (Christensen, 1997). Educated and young consumer (EYC) can change the scenario because they are much more aware about the environment, they can raise the green issues and also change their consumer buying decision in a greener way and it is also one of the fact that they have to live more on this planet in comparison to others (World youth report,2003). Consumption of green products and services by these consumers may give a positive impact on the environment which will lead to the sustainable development (Singh, 2011). Higher consumption pattern among youths can also motivate to the marketer and manufacturer in order to bring new and innovative green products which will not be harmful for the environment. Many studies also find that adoption of green practices will also give positive impact on competitive advantage of the firm, customer satisfaction and creation of public image (Ar. Ilker, 2012). There are various types of green practices such as green marketing which consists of number of activities as development & design of green products, green pricing strategies, green promotions, eco-labeling and Green Supply Chain Management (GSCM) (Polonsky & Rosenberger, 2001). This paper is one of its kinds of exploratory study in Indian context as there is rarely any study found so far in this regard. The primary objective is to analyze the green purchase behavior of EYCs in India. Recently most of the companies have started green marketing approach in various categories like FMCG, Automobile etc. Adoption of green practices by companies may be the demand of today's era which is full of environmental problems, but few of the companies are adopting as defensive strategy just because of government pressure and threat of carbon emission tax. (Chan, 2013). The purpose of this paper is to highlight the young and well educated consumer's responses or reaction towards the eco-logical or green products as this market segment is very large and can be very advantageous to the green marketer and obviously for the environment.

At the end of the introduction part the paper is followed by the literature review which focuses on the green marketing and green product in detail, further it helps in identifying variables of the study. Rest of the body consists of theoretical model and development of hypotheses, research methodology, results and discussion, managerial implications, conclusions and at the end limitations and suggestions for future research.

2. LITERATURE REVIEW

In recent scenario it has been observed that consumers are more conscious about their purchase decisions, as they are giving preference to green products over non-green products (Lee, et al 2013). The significant cause for behavioral change towards green products is increasing consumer awareness about the environment (Saxena & Khandelwal, 2008). People are aware about the harmful impact of the product, especially young consumers those who are educated enough to understand the consequences of the environment (Straughan & Roberts, 1999). Knowledgeable consumer those who understand environment make greener purchase (Peattie, 2001). A study suggested that knowledge of consumer and his belief about the environment is a strong weapon for market segmentation (Awan & Raza). Consumers those who are young play very important role in buying decision in the family. (Kaur & Singh, 2006). It is also true that majority of the population in India are young, with more than seventy percent population below the age of forty and almost fifty percent below the age of twenty and these consumers are well aware about the brand and quality (Dutta et al, 2008). Young consumers have good spending capacity in any market (Moses, 2000). Therefore, young population is an important market segment (Yu & Zhou, 2009). Younger individuals are sensitive towards environment (Straughan & Roberts, 1999) and young consumers are much more inclined towards adopting environment friendly products (Getzner & Grabner-Krauter, 2004). Consumers who are young and also educated can give more attention towards green product. Studies shows that, income and environmental education both are positively related to the green behavior of the consumer and have very strong impact on green purchase behavior (Kreidler & Joseph, 2009). The consumers with higher ecological conscious consumer behavior have shown higher green purchase behavior (GPI) (Akehurst et al. 2012) Because education and environmental knowledge are associated parallel (Pac & Raposo, 2009). A study also shows that environmental knowledge and level of knowledge are positively correlated (Zimmer, et al, 1994). Some studies found that consumer attitude is not only affected by the education, but there are certain other demographic factors like age and income (Pickett, 2008). Consumption of green product can assure for long term sustainable development and competitive advantage. Companies can create competitive advantage if they use innovativeness which is related to environmental sustainability (Karna et al. 2003). There is a need of change in life style and adoptation of green products in the household consumption pattern for the long term sustainability (Christensen, 1997). Often green products are defined as the products which are safe for the environment or there is no or very less effect of it on the environment and also safe for the health. (Polonsky & Rosenberger, 2001). Many companies are involved in green marketing and focusing on green products and other green practices in the business operations. The consumption of green product is significant as it leads to triple bottom approach i.e. people, planet and profit (Cronin et al, 2011). But environmental performance of the product indicates the high price, as less polluting products are expensive to produce (Mahenc, 2008). But studies say that green products are often priced higher than traditional products but it doesn't mean they cost more specifically when we consider all the associated costs, often green products have higher front cost but lower term costs as they are more durables and save money at times for example traditional bulb and fluorescent lights (Polonsky & Rosenberger, 2001). Findings of the study show that young consumers are willing to pay for premium products and services (Dutta et al, 2008). The environmental consciousness drives consumer behavior towards the green products (Singh, 2011). Consumers who are conscious about the environment are willing to pay high price premium for green products even if the green product is less effective in its performance. (Lee et al 2013). It has also been observed that more

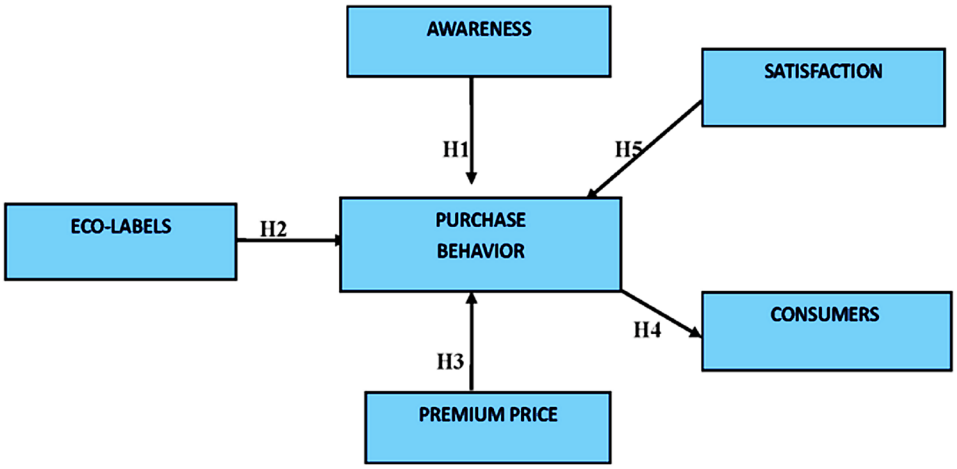
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

cost for green products generally create problem in willingness to pay by the consumers as they want to pay small premium while expecting equal performance of the product (Polonsky & Rosenberger, 2001). Indian consumers are more willing to engage in green practices than Americans, but majority of them are not willing to pay higher for green practices but they expect businesses to take full responsibility for green practices (Dutta et al., 2008). Green buying behavior attitude contains consumer willingness to pay more for green products and his concern for pollution and recycling (Gupta, et al, 2009). The demand for green products may also increase more as it is an innovative product segment and young consumer much more interested in seeking innovative and novelty products in the web market (Khare, et al., 2010). Consumers are interested to buy the product which is environment friendly but its purpose and knowledge must be clear and they must be aware about it (Pickett, 2008). Previous studies also show that many of the consumers do not trust on green product due to misleading information on the product. (Leire & Thidell, 2005). On the other hand, there are various eco-labels which insure that the product is eco-friendly in nature (D'Souza et al., 2006). Eco-labels or environmental labels help consumer in identifying the green product in the market (Rashid, 2009). Eco-labels have emerged as one of the main tools of green marketing and there are various government and non-government organisation for eco-labelling (Rex & Baumann, 2007). Eco-labels are the important ingredient of the green products and it influences the purchase of the green products. Consumer perceived that green products are not able to fulfill their claims, low in quality and are costly also (Ginsberg & Bloom, 2004). In such a scenario companies are facing problem of green washing, where the companies are promising for ecological benefits but are failed in actual performance (Chen, et al., 2013). There is need to focus on elimination of consumer skepticism, so that green product can build their value in the market place (Polonsky & Rosenberger, 2001). Green product is a basic element of the green marketing concept; green product satisfies consumer if it is actually green. Green marketing concept evolves in way back in 1980's in European countries. Many Asian developing countries are now involved in the green marketing such as China, India, Hong Kong, etc. Successful green marketing will lead to the sustainable development. Green marketing can be viewed as adherence to ethical and social responsibility requirements in marketing. (Dheeraj & Vishal, 2012). Young consumers those who are involved in consumption of green products in India are profitable for green marketers as well as also fruitful in achieving long term sustainability goal. (Leire, & Thidell, 2005).

After the depth study of literature we have summarized this in the form of Table 1 which is significant in understanding the important parameters of the study. The table contains the authors who have contributed their studies, parameters and its short description to understand the elements which are relevant to this research paper.

2.1. Theoretical Model and Hypotheses Development

The study reveals various important factors which are essential in understanding the green purchase behavior of EYCs towards the green products. There are various variables has been decided to take in the study which revolves around the educated young consumers (EYCs). These variables are EYCs who are highly concern towards environment, awareness about the green products, eco-labels, premium price which leads to the green purchase behavior of EYCs. Figure 1 shows all these variables in form of a model. This model is tested further in the study.



On the basis of the proposed model of the study various hypotheses has been formulated as:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Relevant parameters and their descriptions

S. No.	Parameters	Authors	Descriptions
1	**Young Indian**	Tulloch,2014; Ghodeswar; Dutta et al,2008	Majority of the population in India is young. They are profitable and major marketing segment.
2	**Young consumers and education**	Ghodeswar; Choudaha, 2013; Chhokar,2010; Straughn & Roberts,1999; Moses,2000; Nittala,2014);Getzner & Grabner-Krauter, 2004; Kreidler & Joseph, 2009;Akehurst et al. 2012; Pac & Raposo, 2009; Zimmer, et al, 1994; Pickett, 2008; Agyeman,2014	Young consumers are conscious in making their purchase decisions education and knowledge play significant role in this process.
3	**Green products**	Lin Ru-Jen et al.2011; Lin&Sheu,2012; Christensen, 1997; Singh,2011; Ar. Ilker,2012; Polonsky & Rosenberger, 2001; Chan,2013; Lee et al.2013; Saxena & Khandelwal,2008; Akehurst et al.2012; Karna et al.,2003; Cronin et al,2011; Khare et al.2010; Pickett,2008	People are becoming more aware about the green products due to harmful effect of non-green product on environment. Consumption of green products saves money and environment.
4	**Eco-labels**	Ar.Ilker, 2012; Polonsky & Rosenberger,2001; Chan,2013; Rashid;2009; Rex & Baumann,2007; Ginsberg & Bloom,2007	Eco-labels are the logo or mark which helps in identifying the green products.
5	**Green purchase behavior/ Intentions**	Chan,2013; Lee et al.2013; Saxena & Khandelwal,2008; Straughan & Roberts,1999; Peattie,2001; Kaur & Singh,2006; Getzner & Grabner-Krauter,2004; Karna et al.2003; Kreidler & Joseph, 2009; Akehurst et al.2012; Pickett,2008; Singh, 2011	Green purchase behavior/intentions are influenced with consumer education, knowledge and environmental awareness. Price also affects the green purchase behavior.
6	**Green Price**	Mahenc,2008; Polonsky & Rosenberger, 2001; Dutta et al.2008; Lee et al,2013; Gupta et al., 2009	Consumers are willing to pay green price or premium price only when the product pays attentions towards green ingredients.

Figure 1. Proposed research model for green purchase behavior

Above model consists of various variables which are associated with the educated and young consumers (EYCs). Such as green product awareness, Eco-labeling used on green product packaging, willingness to pay premium price, consumer, those who are highly concern towards environment and satisfaction through green products.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

H1: EYCs awareness has positive and significant relationship with the green purchase behavior;
H2: There is a positive and significant relationship between eco-labels and purchase behavior;
H3: There is a positive and significant relationship between premium price and purchase behavior;
H4: There is a positive and significant relationship between consumers who are highly concern for environment and purchase behavior;
H5: EYCs, who are satisfied with green products, have positive relationship with the purchase behavior towards green product.

3. RESEARCH METHODOLOGY

In order to test the relationship shown in the proposed model (Figure 1), we have developed a study based on quantitative arrangements. A set of questionnaire has been made and verified with the help of experts in the field of marketing management and consumer behavior. Later the questionnaire was rearranged with the help of valuable comments of these experts, so that meaningful results can be drawn. Total 23 numbers of items were taken in the study which defines each variable as ecological concern, awareness about green product, eco-labels, green product satisfaction, green purchase behavior, premium price and last 5 items taken for descriptive study. The respondents were selected from the various departments of Maulana Azad National Institute of Technology (MANIT), Bhopal, MP, India. The respondents were including undergraduate (UG) i.e. B. Tech students and post graduate (PG) i.e. M.Tech, MBA and MCA students. A questionnaire was designed by keeping in mind about the young consumer and green products. The convenient sampling technique has been used while data collection. The variables used in the questionnaire were measured on a five point Likert type scale (1= stongly disagree; 5= strongly agree). The questions were arranged as assertive sentences even they were negative in nature to fit in the Likert type scale. Total 500 questionnaires were printed on used papers (one sided) to save environment and were distributed and collected from the hostels and classrooms. While collecting questionnaire some of the respondents has been interviewed also regarding green product and environment which was informal in nature but we have discussed it in the paper. Total turned 343 actual respondents which is 68.6% of the total questionnaire distributed. In which male undergraduate (UG) students were 105, male postgraduate

Table 2. Demographic profiles of the respondents

Characteristics	*Number of respondents*	*Percentage (%)*
Gender (total)		
Male	249	72.60
Female	94	27.40
Education		
Undergraduate (UG)		
Male	105	30.61
Female	13	3.79
Postgraduate (PG)		
Male	144	41.98
Female	81	23.61

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(PG) students 144, female (UG) 13 and female (PG) students were 81 which is 30.61%, 41.98, 3.79% and 23.61% of the total respondents respectively (see Table 2).

All the data were compiled in a systematic order and loaded in the SPSS 22. Simple percentage was used to analysis the demography of the respondent and Cronbach's Alpha reliability test was used to measure the reliability of the data on measured items. To bring the findings of the study exploratory factor analysis and linear regressions analysis has been done.

4. RESULTS AND DISCUSSION

4.1. Reliability and Validity

Total number of questions was 23 in the study to bring the meaningful results. The reliability measure, for 23 item had a validated reliability measure of 0.619 Cronbach's alpha which is more than 0.6 and hence it is satisfactory (Malhotra, 2010, p.279). The KMO (Kaiser-Meyer-Olkin measure of sampling adequacy) is 0.638 and Bartlett's test of sphericity is ($p<0.000$) which is significant at 0.05 level. Both indicated that the variable set was appropriate for factor analysis (Karna et al., 2001).

Table 3. Factors affecting purchase behavior of EYCs

Factor	Factor Labeling	% Variance Explained	Loadings	Variables Included in the Factor
F1	Consumer (Highly concern for environment)	16.951	0.502	You are highly concern towards your environment.
			0.679	When you get an opportunity for doing something for your environment, you do it with full energy.
F2	Green Product awareness	13.935	0.533	The product which emits less carbon can be called green product.
			0.621	A product which saves energy can be called green product.
F3	Eco-labels	11.755	0.688	Eco-labels helps you in identifying green products.
			0.605	You generally check eco-labels on the product packaging while purchasing green products.
			0.653	Eco-labels assure the product is safe for the environment.
F4	Satisfaction	8.996	0.526	The green product purchased by you is fulfilling its claims and is satisfactory.
F5	Purchase intention	6.436	0.567	You prefer to buy green product, because it helps in protecting environment.
			0.661	You buy green products because of its features.
			0.538	You help your family in making purchase decision related to green products.
F6	Premium price	5.991	0.501	Sometimes you do not purchase the green products just because of higher price.
			0.539	You will more prefer to buy eco-product, if it saves money.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.2. Factor Analysis

The results of principal component factor analysis using varimax rotation yielded 6 factors that explained 64.064% of the variance. The first three factors environmental concern, green product awareness and eco-labels altogether explain 42.64% of the variance. The fourth factor which is labeled as satisfaction (through green product) explained 8.996% of the variance. Then fifth factor which is labeled as purchase intentions explains 6.436% of the variance and finally the sixth factor explains 5.991% of the variance. Table 3 represents a brief summary of factor analysis.

4.3. Regression Analysis

To test the hypotheses, linear regression was used with the help of SPSS 22. In this method EYCs purchase behavior used as a dependent variables and other variables which affects purchase behavior as green product awareness, eco-labels, premium price, Consumer (highly concern towards environment) and satisfaction used as predictors. Here H1, which is EYCs awareness, has positive and significant relationship with the green purchase behavior. The result shows a significant statistic between the EYCs green product awareness and the purchase behavior, which shows that the green purchase behavior can be positively affected by the green product awareness among EYCs. The summary can be seen in the Table 4 which shows that the H1 is statistically significant and hence it is accepted.

The result of H1 shows that if the green product awareness can be increased among EYCs it will definitely raise the green purchase behavior among them. In the same manner to test the H2 which states

Table 4. EYCs awareness for green products and purchase behavior

Model	B	SE	T	Sig.	Collinearity Diagnostics (VIF)
Constant	2.946	0.121	24.332	0.000	
Awareness	0.145	0.033	2.703	0.007	1

Adjusted R^2 =0.018 for model; F value of ANOVA=7.308; p value of < 0.000

Table 5. Eco-labels on green products and purchase behavior

Model	B	SE	T	Sig.	Collinearity Diagnostics (VIF)
Constant	2.693	0.183	14.704	0.000	
Eco-labels	0.158	0.050	3.159	0.002	1

Adjusted R^2 =0.026 for model; F value of ANOVA=9.981; p value of < 0.000

Table 6. Premium price and purchase behavior

Model	B	SE	T	Sig.	Collinearity Diagnostics (VIF)
Constant	3.063	0.122	25.079	0.000	
Premium price	0.060	0.035	1.697	0.091	1

Adjusted R^2 =0.001 for model; F value of ANOVA=0.861; p value of > 0.000

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

that, there is a positive and significant relationship between eco-labels and purchase behavior, here we again applied the same method and purchase behavior remain the same as dependent variables and eco-labels as predictors and used linear regression method and found a significant relationship between these two and hence the H2 is also accepted. Table 5 shows the summary of results of regression analysis.

In the same way we further tested H3 which states that there is a positive and significant relationship between premium price and purchase behavior. The result of the linear regression shows the relationship between these two not reliable significant as the p value > 0.05. Table 6 shows the regression summary. The interpretation of this result is that, EYCs does not want to pay

Premium price for the green product or we can say that they are not that much interested in green product to pay more price. It simply means that the premium price discourages EYCs to purchase green product and also influences their green purchase behavior. Hence H3 is not accepted, whereas H4 which states that, there is a positive and significant relationship between consumers who are highly concern for environment and purchase behavior also not accepted. As the p value is > 0.05 and hence we can say that the H4 is not accepted in this case. The summary can be seen in Table 7 It supports previous studies that people who are merely concern towards the environment does not mean that they are also interested or highly inclined towards the purchase of green products (Straughan & Roberts, 1999; Nittala,2014). Whereas the results also contradict with some of the studies (Schuhwerk & Lefkokk-Hagius,1995; Vlosky et al,1999 ; Rios et al,2006;Akehurst et al,2012).

Table 7. Consumer those who are highly concern for environment and purchase behavior

Model	B	SE	T	Sig.	Collinearity Diagnostics (VIF)
Constant	3.093	0.188	16.468	0.000	
Highly concern consumer	0.043	0.046	0.928	0.354	1

Adjusted R^2 =0.005 for model; F value of ANOVA=2.881; p value of > 0.000

Table 8. Satisfaction and purchase behavior

Model	B	SE	T	Sig.	Collinearity Diagnostics (VIF)
Constant	3.132	0.155	27.239	0.000	
Satisfaction	0.039	0.032	1.199	0.003	1

Adjusted R^2 =0.002 for model; F value of ANOVA=1.437; p value of < 0.000

Table 9. Showing the results of all hypotheses

S. No.	Hypotheses	Results
1.	H1-EYCs awareness has positive and significant relationship with the green purchase behavior.	Accepted
2.	H2-There is a positive and significant relationship between eco-labels and purchase behavior.	Accepted
3.	H3-There is a positive and significant relationship between premium price and purchase behavior.	Not accepted
4.	H4-EYCs, who are highly concern for environment, have positive relationship with the purchase behavior	Not accepted
5	H5-EYCs, who are satisfied with green products, have positive relationship with the purchase behavior towards green product.	Accepted

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

There may be several reasons for this difference such as demographical differences among these studies. Like, here in this study we are focusing on EYCs in India.

In the succession of the testing of the next hypothesis which is H5 stating that EYCs, who are satisfied with green products, have positive relationship with the purchase behavior towards green product is accepted. EYCs who are satisfied with the green product performance are more inclined towards purchase of green product. Table 8 summaries the regression results for H5.

In all the results we can see that there is no collinearity found as the value of variance inflation factor (VIF) is less than 5 (Malhotra, 2010). Table 9 shows a glimpse of the results of the hypotheses.

4.4. Descriptive Analysis

The results of the descriptive analysis are on the basis of taking simple mean of the responses. When they (EYCs) have been asked that "you always try to avoid those activities which can harm our environment, majority of the respondent (69%) chose that they are agree that they avoid those activities such as excessive use of water or avoiding products which can cause problem to the environment. Many of the respondents are agree that they get the information about green product from advertisement. Somewhat these consumers are agreeing that the green product is better but still they are not strongly agreed on this issue. In a response to the question that, do they consider environment more than price and quality of the product, they gave moderate reply which can be interpreted that they consider price and quality more than environment. EYCs are also not interested to pay premium price for the green product though they are highly concern for environment. Reason behind these phenomena may be that they are mostly in their study phase and are unemployed so there is a lack of economic viability and they cannot pay more (see Table 10).

Generally they buy consumer durable products but it is very often, as there is nothing fixed buying pattern or criteria for it. According to EYCs opinion on automobile, it is the most harmful for the environment. EYCs are convinced that if people will start consuming green product it will definitely give a positive impact on the environment. It is a very good sign that our educated youth trust in green product and environment. Most of them are agree that transportation used in product delivery process is also one

Table 10. Descriptive statistics

Variable	Mean
You always try to avoid those activities which can harm our environment.	3.82
From advertisements you get the information about the green product.	3.56
Green products are better than non-green products in terms of performance.	3.33
When you go for purchase you mainly concern for environment over the price and quality.	3.12
You can pay extra for a green product even if the non-green product performance is better than it.	3.32
Generally, you buy consumer durables which saves energy.	2.94
Automobiles are considered most harmful for the environment.	3.88
When people will start consuming eco-products, it will definitely give a positive impact on our natural environment.	4.13
Transportation activities involve in product delivery is also one of the main sources of environmental degradation.	3.68
Company should adopt take back policy of used/waste/scrap products for recycling it, to save environment.	4.18

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the major sources of environmental problem in form of air and noise pollution. EYCs are very much support that there should be buy back or take back of used /waste/scrap policy which will enhance and encourage recycling and a safeguard can be provided to the environment.

4.5. Informal Interview Analysis

In order to understand more about the reaction of EYCs towards green product we have interviewed many respondents informally, like without showing them that we are asking something very formal. We asked questions before and after they fill their questionnaire. We asked them what you know about green product. Many of them are really not aware about terminology "green product" but they are smart enough to make the guesses as "the product which does not harm the environment." They told us that EYCs are day by day getting aware about the green product. We also try to buy it provided the price should not be very high. Majority of them told us that people buy consumer electronic product which is eco-labeled as 'Star ratings' (shows energy efficiency) because it saves electricity bills. Many of them are aware about the eco-labels but do not know about the technical description of it and they are also not sure about the authenticity of eco-labels. EYCs opinion about the green product is that the company should focus the green features of the product, highlighting eco-labels, give emphasis on advertisement, lowering price than ordinary product and Government should also make some more strict norms to be followed by the marketers.

5. MANAGERIAL IMPLICATIONS

The research indicates that EYCs are aware and supporting green or ecological products but when it comes to purchase of these products they are not highly motivated towards the green pricing so they take less interest in purchasing of such product. In recent scenario it can be seen that companies are taking much interest in greening business so that objective of sustainability and long term profitability can be maintained but the results which are shown here in the study is critical and the management have to work a lot in all the dimensions specially in the price reduction of green products, so that these consumers can participate in marketing process. There are few companies who are charging premium price for green products but here in case of EYCs in India, this practice is not advisable for the marketers. The study also motivates the investors or managers those who want to invest in the green market as the demand of the green product is favorable among these EYCs and on the other hand it will also give an opportunity to the organization in greening their operations which can be helpful in creating competitive advantage to the firm. Targeting EYCs would be profitable as it is a creamy marketing segment in India.

6. CONCLUSION

In order to make better policies and plan for the green marketing, concept it is very important to focus closely in each segment of the market especially EYS's, as we have already discussed that this segment is important. The analysis of the study shows that there is increasing consumer awareness towards the green market, which is a very good indicator for the success for the green market. There is a positive relationship found between green product awareness and green brand preference (Mourad & Ahmed,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2012). But due to various challenges or obstacles, such as premium price or green price, substitution of raw material and extra greening cost to the company etc. creates problem to the manufacturers and marketers. EYS's are very much aware about the green products and eco-labels which give a positive impact on purchase behavior. But it is also seen in the study those consumers who are highly concern for environment they are not willing to pay premium price. There may be several reasons such as they are student and their purchasing power does not allow for paying more for a green product or the marketer of the green products have not yet made a better promotional program for this segment. On the other hand, their green product satisfaction gives a significant impact on the purchase behavior. There are conservation donors those who want to save the environment are willing to pay the price premium over direct payment. (Ferraro, et al., 2005). There are environmental conscious people those who can give up to forty percent extra for the green product. (Laroche, et al., 2001). But all it depends upon the income level, consumption behavior pattern and lifestyle etc.

There is a very vast gap in the field of promotion of green products, which can be observed in Indian market scenario. Marketer must try to develop various sales promotions and premiums especially for the young consumers, but as the concept is getting old and may not be very workable in case of young consumers. Therefore, marketers must try to do it in more innovative and attractive style for these consumers in order to build purchase behavior towards green products. (Te'ni-Harari, 2009). There may be some educational programs for the consumers which can help them understanding about the importance of green products. Marketer's role is not just to throw the product in the market, but there is responsiveness towards better sales of that product, which is only possible, when they position the product in the green market. There are claims that marketing offers important ways of changing consumer behavior and influencing attitudes and beliefs. (Jones et al., 2008). The concept of green marketing is not only limited to the business only but it has the greater responsibility such as developing environmental sustainability. To achieve the ecosystem conservation objectives in low-income nations, international organizations and domestic governments have invested heavily in promotion of green product. (Ferraro, et al., 2005). In UK many of the prominent retailers are continuously involved in designing the product to reduce the water, energy and waste and they are also trying to reduce the price of the green product. (Jones, et al., 2008). These are the good indicators for the development and expansion of the green marketing. Finally, on the basis of this study it can be said merely education and being young is not the sufficient criteria for the purchase behavior towards green products. There may be some more reasons which leave a scope for further study in this area.

7. CONTRIBUTION OF THE STUDY

The study is significant in many ways as it gives an insight into the purchase behavior of young and educated consumers. This market segment is large and expanding day by day. Knowing their consumption pattern and reaction towards green products can be very fruitful for the sustainability and profitability. Few of the research papers are available relevant to this study such as Ghodeswar; Choudaha, 2013; Chhokar, 2010; Straughn & Roberts, 1999; Moses, 2000; Nittala, 2014; Getzner & Grabner-Krauter, 2004; Kreidler & Joseph, 2009; Akehurst et al.2012; Pac & Raposo, 2009;. Zimmer, et al, 1994; Pickett, 2008. The paper finds that there is a positive relationship between the consumer buying behavior and purchase of green products. (Agyeman, 2014). Young and educated consumers those who are in the universities and professionally they are teachers and results shows that the education have a negative

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

impact on the green purchase behavior. (Nittala, 2014). These few papers are based on the exploratory and empirical research work. These research papers are very good which gave base to bring this study. There are few research gaps found while studying these papers such as both the papers have not targeted the young segment who are students, although one paper have done its work in education arena (Nittala, 2014). Previous studies also, have not performed to test the relationship between eco-labels and consumer satisfaction in context to EYCs. This research paper has filled these research gaps with the help of empirical study on young and educated consumers who are willing to take good purchase decisions especially for featured products like green products.

8. LIMITATIONS OF THE STUDY

Like every study have some limitations and obstacles, in the same manner we have also face few challenges such as lack of relevant research studies in context to India, and while going for filling the questionnaire we found less number of students in the campus as final examinations were over and most of the students about to go to their homes. The study has one more limitations that the results of the study cannot be generalize in certain circumstances.

9. FUTURE RESEARCH SCOPE

This research can be extended more by taking few additional variables in the existing research paper such as green advertisement and green product promotions etc. The study can be done on broader parameters.

Chapter 41
Tourists Becoming Increasingly Aware of Green Tourism:
Tourist Intention to Choose Green Hotels in Bangalore, India

Nichola A. Ramchurjee
University of Mysore, India

Esther P. Ramchurjee
Independent Researcher, India

ABSTRACT

The continual development of the hospitality industry has led to negative impacts on the environment. However, the development of green hotels could be a solution to this problem. As more tourists are becoming gradually concerned about environmentally friendly products and services, it is crucial for the hotel industry to take an interest and participate in the green initiative. A questionnaire method was used to collect data from 209 participants using the intercept approach in several main tourist sites in Bangalore, India. The analysis showed that tourists staying in hotels in Bangalore give substantial influence on their intention to choose green hotels and thus environmentally friendly services and products. Therefore, it is of primary importance for green hotel operators/managers to continuously educate their guests about the importance of being environmentally friendly and the environmental impacts of their behaviors.

INTRODUCTION

Tourism is considered vital to the world's economy. According to the World Travel and Tourism Council (WTTC, 2016) the direct contribution of travel and tourism to GDP was US$2.23 trillion (3.0% of total GDP) in 2015 and is forecasted to rise by 3.3% in 2016, and to rise by 4.2% pa, from 2016-2026, to USD3.3 bn (3.4% of total GDP) in 2026. In 2015 Travel and Tourism directly supported 107,833,000 jobs (3.6% of total employment). This is expected to rise by 1.9% in 2016 and rise by 2.1% pa to 135,884,000

jobs (4.0% of total employment) in 2026. Tourism is an activity that has grown by around 25 per cent in the past 10 years. It now accounts for around 10 per cent of the world's economic activity and is one of the main generators of employment. Tourism, being a main source of income and employment in many countries highly depends on environmental resources that include pristine beaches, warm climate, clean air, landscape formation and others (Kasimu, Zaiton, & Hassan, 2012). Within the tourism sector, economic development and environmental protection should not be seen as opposing forces—they should be pursued hand in hand as aspirations that can and should be mutually reinforcing. Policies and actions must aim to strengthen the benefits and reduce the costs of tourism.

Making tourism more sustainable is not just about controlling and managing the negative impacts of the industry. Tourism is in a very special position to benefit local communities, economically and socially, and to raise awareness and support for conservation of the environment. In the last 20 years, the concept of sustainable development has become widely accepted as the way to a better future, even though its roots go back to the 1980s. According to the World Commission on Environmental Development (1987), sustainable development is defined as "meeting the needs of the present without compromising the ability of the future generations to meet their own needs." Sustainable development also leads to the integration of economic, social and environmental dimensions in decision making without sacrificing the needs of future generations. Harmonizing the development of the business with the natural environment is the key, as well as improving human well-being by lessening the damage to the Earth and its organisms.

Among the various industries in tourism, the hotel industry plays a major part. Traditionally, the operational activities of hotels constituted a threat to the environment due to the high consumption of energy, water (Kasim, 2009) and waste generation. Although, the hotel industry may not be the only one that creates substantial environmental pollution and consumes large amounts of global environmental resources, its primary purposes are providing services (such as food, drinks, hot/cold water, linens, towels, lightning, air conditioning, water and swimming pools) and these activities clearly consume huge amounts of energy, water, non-recyclable goods and natural resources, thus directly or indirectly harming the environment (Han, Hsu, and Sheu, 2010).

In general, the daily operations of hotels create substantial amount of pollution. Public concerns for issues affecting the environment have significantly increased over the past decade, thus, pressuring the hotel industry to become more environmentally sustainable. This saw the emergence of the green tourism concept and it is being introduced in urban facilities and lodges. Green tourism, a form of ecotourism, is low-impact tourism with an eye toward protecting the environment and culture of an area (Lee, Honda, Ren, & Lo, 2016). Therefore, hotels are adopting green practices because they are more aware of their environmental impact and carbon footprint.

However, in developing countries this has not been the case as some hotels have not yet adopted the basic green practices and hence they have never enjoyed the benefits of going green. One of the important aspects that should be understood about green practices was that the range of the term "green" is broad and varying based on perspective. Green was defined from an economic point of view by Gupta (2006) who defines "greening" as corporate environmental performance in meeting stockholders' expectations. Shrivastava (2000) views environmental management as a tool to fit into a social and ecological system. Further, Gupta and Sharma (2002) defined green practices as environmentally friendly management principles in which executive levels convert natural resources into better outputs or products. During the last few decades it has become a common phenomenon to focus on the environmental impact of the hotel

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

industry with each hotel striving to achieve environmental sensitivity even though there is no universally agreed upon definition of a green hotel (Harris & Crane, 2002). Academics, governmental agencies and nonprofit environmental organizations have introduced their own definitions of a green facility.

Some scholars defined green hotel as an environmentally sensitive hotel that operates its business in a manner that minimizes degradation of the environment (Iwanowski, 2003). The specific areas of focus are energy efficiency, recycling, water conversation, and clean air practices (Bohdanowicz, 2005). Similarly, Manaktola and Jauhari (2007) define a green hotel as a lodging facility committed to ecological practices such as saving of water, energy and waste. In the hotel industry, practices associated with green concerns are diverse; they may encompass a variety of activities from pollution prevention to stakeholders' awareness campaigns regarding these activities. However, for the purpose of the study this research views green practices as internal efforts or activities of a hotel to implement environmentally friendly practices towards the goal of reducing its operating costs. The term "green facility or hotel" can be used interchangeably or synonymously with "an environment friendly hotel," "an eco-friendly hotel," or "a sustainable hotel."

Hotel managers/operators recognized the 'green shift' in consumers' behaviors/desires to purchase and promote environmentally friendly services and products, proactive management and so they have taken the steps to implement environmentally conscious practices to improve their competitiveness (Lee and Moscardo, 2005) and image. These consumers' behaviors are composed of consumer commitments, responsibility, attitudes and willingness to pay more for green products (Farj and Martinez, 2007a).

The term 'green' refers to the actions that reduce the impacts on the environment (Han, Hsu, and Sheu, 2010), such as recycling (Ramchurjee and Suresha 2014), saving energy and water, purchasing eco-friendly products, and using transportation with lower CO_2 emissions such as using public transportation (ITP, 2013). The concept of 'green hotels' are environmentally friendly properties whose managers are eager to institute programs that save water/energy (Green Hotels Association, 2008) and reduces waste/emission by reducing operational costs, while saving money in order to protect "OUR EARTH."

From responsible business perspectives, green hotels must incorporate green strategies into their decision making. Hotels whether they have adopted green initiative program or not, must operate in a responsible manner towards the local community, local culture, and the surrounding ecology and to their employees (Kang, Stein, Heo and Lee, 2012).

But, some hotel managers/operators are resistant to adopting 'green initiatives' such as investing in environmental protection programs and introducing environmentally friendly activities. These businesses/companies believe that these initiative programs require considerably large capital investment, and they do not realize any significant financial benefits to the hotels (Oliver, Naar and Harris, 2015).

However, for those hotels that have introduce green initiative programs, they have found that this image reflects the set of beliefs, ideas (Manaktola, and Jauhari, 2007) and brands that promotes the public's environmental concerns and awareness to move away from more conventional processes that destroy the environment to more sustainable practices. Therefore, there's a growing number of consumers nowadays who are demanding green hotels, and so green management has become directly associated with customers demand and satisfaction (Enz and Siguaw, 1999), increased employees' morals (Laroche, Bergeron and Barbaro-Forleo, 2001), willingness to pay more for green products (Mensah, 2008) and corporate image (Butler, 2008). Nowadays, green management has consequently become an important part of both strategic and operational planning and it has now become standard, rather than being just a temporary side interest (Manaktola, and Jauhari, 2007).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green hotel establishments actively follow eco-friendly guidelines and practice environmental management; they commit themselves to carrying out environmental improvements, demonstrating such efforts through eco-labels or the green globe logo and acquiring techniques related to the best practices in environmental management with experts' help (Han, Hsu, & Sheu, 2010). It is generally agreed that turning a lodging property green not only fulfills environmentally cautious customers' green needs and assumes the responsibility of performing environmental duties, but also results in substantial cost saving through various environmental benefits (Manaktola, and Jauhari, 2007).

Environmental Attitudes

Environmental attitude is a complex mental state involving beliefs and values of individuals to behave environmentally. In other words, it taps the consumer's cognitive and affective judgment with respect to environmental protection and green living (Lee, 2008). Attitudes are evaluative judgments towards an object with respect to some degree of favor or disfavor (Eagly and Chaiken, 1993). It is the enduring, individually defined moral obligations to protect the environment. Supporting the view that these judgments play a major role in determining human social behaviour (e.g. Ajzen and Gilbert Cote, 2008; Fishbein and Ajzen, 2010), there is a plethora of empirical evidence linking attitudes to pro-environmental behaviour (for two recent meta-analyses, see Bamberg and Mo¨ser, 2007; Klo¨ckner, 2013). Both the supply and demand sides of the tourism industry of purchasing and consumption have been shown to be affected by environmental values (Holden, 2005). Zografos and Allcroft (2007) used environmental values in their study as a base to segment potential ecotourists in Scotland. Hedlund (2011) found positive relationships between environmental values and the willingness to accept economic sacrifices to protect the environment and the intentions to buy ecologically sustainable tourism alternatives.

With the increasing profile of environmental issues, more research is being conducted on consumer's environmental attitudes and behaviors. Most of this research is questionnaire-based, especially given Dunlap and Van Liere's introduction of growth limits, natural balance and anti-anthropocentrism in 1978 – a new environmental paradigm scale that is widely used by scholars (Stern, Dietz, & Guagnano, 1995). The complex environmental issues that characterized the 1990s – including the deterioration of the ozone layer, waste, biodiversity and global environmental changes – led Dunlap, Van Liere, Mertig, and Jones (2000) to develop a new ecological paradigm (NEP) scale based on the environmental paradigm scale, ecological crisis and other related issues. The new ecological paradigm scale consists of the following five dimensions: limited growth, anti-anthropocentrism, fragile natural balance, anti-exceptionalism and the possibility of ecological crisis. The scale was used to measure the cognitive and emotional tendencies of the respondents on environmental issues in this study.

Laroche, Bergeron, Barbaro-Forleo (2001) investigated the relationships between attitudes towards environmental issues and consumers' willingness to pay more for green products. Nine hundred and seven individuals from a large North American city participated in the study. The results indicated a strong relationship between attitudes towards environmental issues and consumers' willingness to pay more for green products. Mair's (2011) study on tourists participating in carbon-offset programs found travelers that purchased offsets had positive environmental values. Barber et al. identified the market of "the Millennial male with strong environmental attitudes" as a "substantial market for ecological products" (Barber, Taylor, & Strick, 2010, p. 64). Dolnicar (2010) found environmental values, or a moral obligation to protect the environment, was a strong predictor of environmentally-friendly tourist

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

behavior and environmental behavior at home. Ham and Han (2012) show that purchase-related loyalty, measured as intentions to visit, acceptance of price premiums, and providing recommendations, were amplified by consumers with positive environmental values.

Environmentally Friendly Activities (EFA)

People have become aware of the fragility of our environment and the need for preservation of natural resources. Thus, in recent years, increasing numbers of individuals with environmental concerns, identify themselves as an environmentalist engaging in environmentally friendly activities (EFA) (Han, Hsu, and Sheu, 2010 and Manaktola, and Jauhari, 2007). Individuals who perceive the importance of EFA concerning ecological issues actively engage in those types of behaviors (Kalafatis, Pollard, East, and Tsogas, 1999) and (Laroche, Bergeron, and Barbaro, 2001). These categories of consumers are willing to change their buying behavior in a more ecologically favorable way (avoidance of disposable products) and behave in an environmentally friendly fashion in their everyday lives (e.g. recycling activity), thus sacrificing friendly products and even paying extra for the products (Manaktola, and Jauhari, 2007). On the other hand, consumers who do not engage in EFA tend to feel environmental problems will resolve themselves, those who are engaged as eco-friendly customers frequently believe our ecological situation faces serious problems that need corrective action and strongly feel that they should do something for the protection of the environment (Han, Hsu, and Sheu, 2010). Given their perceptions about rigorousness of the environmental problem, such individuals' EFA affects their purchasing behavior (Laroche, Bergeron, and Barbaro, 2001).

Therefore, in the context of the tourism industry, we could expect that the formation of intentions to stay at green hotel can differ between tourists often engaging in EFA and tourists infrequently engaging in EFA. In particular, to gain a better understanding of the linkages, we posit that the higher the EFA of the tourists, the higher the intention to visit green hotel.

Eco-friendly attitudes refer to the individual value judgement of environmental protection (Lee, 2011). In other words, eco-friendly attitude taps the individuals' cognitive assessment of the value of environmental protection. In 2010, Han, Hsu and Sheu defined attitudes of environmental concern as rooted in a person's concept of self and it is the degree to which an individual perceives him or herself to be an integral part of the natural environment. Attitude represents what consumers like and dislike and consumer product purchasing decisions are often based on their environmental attitudes (Lyer, 1999). Eco-friendly attitude is commonly understood as a cognitive judgement towards the value of environmental protection (Lee, 2011). In his study, Balderjahn concluded that individuals who had a positive attitude towards the environment participated more in the buying and consumption of green products (Balderjahn, 1988).

Examining consumer eco-friendly attitudes toward hotel s' green practices and behaviour, researchers (Manaktola, and Jauhari, 2007) concluded that customers who are aware of a hotel's eco-friendly practices show preference to patronize a green lodging property. Further, Roberts indicated that consumer attitudes are significantly predictors of ecologically conscious consumer behavior (Robert, 1996). His findings revealed that environmentally conscious people are likely to engage in eco-friendly consumer behavior and individuals who believe their specific ecological activities can cause positive change are more likely to display green consumer behavior. Similarly, a recent study by Han and other researcher revealed that hotel customer's eco-friendly attitudes positively affect their expressed intention (Han, Hsu, and Sheu, 2010).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Therefore, tourists with positive environmental attitudes tend to choose green hotels. Therefore, it is of primary importance for green hotel operators to continuously educate the guests about the importance of being environmentally friendly and the environmental impacts of their behaviour.

Maximizing hotel guests' involvement in executing green practices can be the key strategy to improve the green image of the hotel, which in the long–run improves the guests' behavioral intention to the hotel. Thus, managers should establish green attributes to offer direct experience opportunities to the guests.

How a Hotel's Green Image Can Influence Tourists' Behavioral Intent

When green management was first introduced, the major reasons for a hotel to "go green" center on complying with government regulations and saving money by reducing waste and energy usage. However, since a growing number of customers are now demanding green hotels, green management has become directly associated with product quality, employee morale (Enz and Siguaw, 1999), customer satisfaction and demand (Manaktola and Jauhari, 2007), the willingness to pay a premium for green products (Laroche, Bergeron & Barbaro- Forleo, 2001) and corporate image (Mensah, 2004; Penny, 2007). According to a study by the International Hotels Environment Initiative and Accor, 90% of hotel guests would prefer to stay in a hotel that cares about the environment (Mensah, 2004). Penny (2007) also conducted a survey that examined the attitude of hotel managers in Macau towards green management. He found that 65% of respondents believe that good green management can contribute to a hotel's image and competitiveness. Green management has consequently become an important part of both strategic and operational planning. It has now become standard, rather than being just a temporary side interest, as it was in the 1970s (Butler, 2008).

Despite the significant effect of image on product/service value (MacInnis and Price, 1987), customer satisfaction and loyalty (Andreassen and Lindestad, 1998), to date, no research efforts have focused on examining the image of a green hotel from the perspective of hotel guests. But despite the increasing concern for the environment, green products were found to struggle with a low market share (Wong, Turner, & Stoneman, 1996). According to UK surveys, the number of green consumers has grown only slightly, and their willingness to purchase green products has also declined (Mintel, 1991, 1995).

Hotel Guests' Preferences and Awareness for Green Attributes and Environmentally Friendly Initiatives in Hotels

Watkins, 1994, indicated in a study conducted by Virginia Polytechnic Institute and State University (Virginia Tech) and Lodging Hospitality that frequent travelers would stay in hotels with environmental strategies, but they would not be willing to pay a premium for those rooms. The study reported that some environmentally friendly hotel attributes that travelers may consider when selecting a green hotel included, but were not limited to: recycling bins, energy-efficient lighting, using recycled paper for promotional materials, changing sheets only when requested, and turning of lights in unoccupied guest rooms. Despite the fact that travelers in the survey said they were likely to stay in hotels that provided such attributes, and despite the fact that a large portion of the travelers considered themselves environmentally conscious consumers, they did not necessarily consider themselves environmentally conscious travelers (Watkins, 1994). In other words, their beliefs were not necessarily followed up by their actions when traveling.

Kasim (2004) studied tourists to Penang Island, Malaysia and found that tourists were knowledgeable and cared about the environment but they did not consider a hotel's environmental strategy as a

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

foundation for their hotel choice. That is not to say that they would not approve of room attributes that were environmentally friendly. Tourists were willing to accept rooms with water saving features, recycling bins, fire-safety features, energy saving features, and information on local ecotourism attractions.

Green hotels follow strict green guidelines to ensure that the guests are staying in a safe, non-toxic and energy efficient accommodations. Here are some basic characteristics of a green hotel:

- Housekeeping uses non-toxic cleaning agents and laundry detergents
- 100% organic cotton sheets, towels and mattresses
- Non-smoking environment
- Renewable energy sources like solar or wind energy
- Bulk organic soap and amenities instead of individual packages to reduce waste
- Guest room and hotel lobby recycling bins
- Towel and sheet reuse
- Energy efficient lighting
- Serve Organic and local grown food
- Non-disposable dishes
- Offers a fresh air exchange system
- Newspaper Recycling
- Gray water recycling

Selecting the right decisions in developing a green hotel is very crucial. Selecting a location, the technology and other green equipment in plan of developing a green hotel are all interrelated. Getting a certification such as LEED or GRIHA has become very important nowadays, as the current generation of people trust in these certifications. Whereas building a green hotel used to cost a premium, current studies show that the cost of building to LEED standards is not greater than conventional approaches, while those buildings are healthier for occupants and less expensive to operate (Butler, 2008).

The hospitality industry in general has been feeling the pressure from society as well as governmental regulations related to the implementation of more environmentally friendly policies (Bohdanoqicz, 2006; Zurburg, Ruff & Ninemeier, 1995).

In order to monitor and improve energy savings, a hotel needs an energy management program that includes temperature controls, motion-sensitive lighting systems, and Energy Star rated devices and Appliances (Iwanowski & Rushmore, 1994). An energy program coordinator of the United Nations Environment Program suggested that consuming less energy and adopting energy-efficient technologies reduce the need for investment in energy infrastructures and increase the competitiveness of businesses (Accor, 2006). A solid waste management program is intended to reduce the volume and toxicity of the garbage being sent to the landfill (Iwanowski & Rushmore, 1994). Kirk (1995) suggested that waste can be recycled either by reusing products, or by recycling the materials, by minimizing waste in operations. For the efforts, hotels have installed soap and shampoo dispensers in guest bathrooms instead of individually packed toiletries (Bohdanowicz, 2006). With such waste management programs, the Willard InterContinental Hotel in D.C. reduced waste by 22%, from 1029 tons in 2005 to 807 tons in 2006 (Envirelation, 2007). Environmental management has been targeted at reducing wastage of water and improving water quality. Excessive water use can deplete or destroy local water resources, and threaten the availability of water for local needs (The Center for Environmental Leadership, 2003). Nearly all

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

hotels pay for the water they consume twice: first to obtain fresh water and then to dispose it (Dodds, 2005). Water consumption depends on the services and facilities offered, and on existing water conservation practices (Bohdanowicz, 2006).

Demographic Characteristics and Environmental Friendly Behavior

Generally, findings concerning demographic characteristics and environmentally friendly variables are controversial, with some researchers arriving at significant differences concerning demographic characteristics and environmentally friendly behavior (Han, Hsu, & Lee, 2009) and (Gronhoj & Olander, 2007), and others supporting the opposite (Straughan and Roberts, 1999). Previous research has yet to agree on the role of demographics in green purchasing (do Paço et al., 2009; Roberts, 1996). Zografos and Allcroft (2007) found significant differences in hotel choice based on gender, age, and education levels. Zografos and Allcroft, 2007 segmented audiences and found skeptical audiences were slightly younger and more likely to be female than male. People who were categorized as concerned were more educated and were older.

Previous studies highlighted differences between males and females regarding their environmental attitudes and actions. According to Gronhoj & Olander, 2007, women are more concerned with environmental issues and more likely to participate in environmental activities than men. (Han, Hsu, & Lee, 2009 aimed to investigate sex differences in environmentally conscious behaviors in a green hotel. The study sample was composed of 371 hotel customers from the USA (men – 46.6%, women – 53.4). The findings indicated that women are more willing than men to pay extra money for "green" hotels. Studies on differences in environmentally friendly behaviors among different age groups have not always produced similar findings.

Finisterra do Paco, Raposo, Leal Filho, 2009 investigated the demographic profile of the green consumer in a sample of 887 Spanish individuals, 18-year-old and above, and found

significant differences regarding different age groups and environmentally friendly behaviors. Different findings were revealed by (Laroche, Bergeron and Barbaro-Forleo, 2001), who found no statistically significant differences between consumers at different ages in their willingness to pay more for green products. (Han, Hsu, & Lee, 2009 supported that older individuals were more willing to pay more for 'green' hotels than younger ones. In contrast, (Lee, 2008) investigated green purchasing behaviour in a sample of 6.010 Hong Kong adolescents and argued that younger individuals were more likely to buy 'green products'.

The findings regarding different educational levels and environmentally friendly behaviors have been equivocal. Musa, Seng, Thirumoorthi (2011) explored the influence of the demographic profile of divers on underwater behavior. Data were collected using a sample of 302 divers from Malaysia. The results showed that divers were generally responsible underwater, with the ones with a higher education being more concerned about the environment, and behaving in a more environmentally friendly manner. However, (Laroche, Bergeron and Barbaro-Forleo, 2001), who investigated the demographic profile of consumers willing to pay more for environmentally friendly products found no significant differences in their willingness to pay more among individuals with different levels of education. Although, many studies have examined the impact of demographic characteristics on environmentally friendly behaviour, no definitive and conclusive findings have been established regarding the relationship between the two variables.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chia-Jung and Pei-Chun (2014) provide evidence that sex, income and age have significant influences on tourists' choice behaviors. In other studies, demographic variables like age and household income were not significant (Tierney et al., 2011; Berezan et al., 2014). Singh (2011) found that within a sample of 60-85-year-old, 85% believe in green marketing and 52% purchase green products. Additionally, Singh found older adults report the quality of green products (35%) and the convenience in buying (31%) were the most important reasons for purchasing green products; however, two-thirds of the sample of seniors (66%) noted the lack of information as a reason that would prohibit them from purchasing a green product. One-fifth (20%) of the respondents purchase green travel products.

MATERIALS AND METHODS

A study research questionnaire was best adopted to obtain personal and social facts, attitudes and behavior, values and beliefs data from tourists visiting the tourist sites in Bangalore, and so it was utilized for this study.

Data Collection

The present study adopted a questionnaire methodology, where a quantitative approach research was used to collect data from tourists. Two hundred and twenty (220) questionnaires were distributed and 209 questionnaires were returned, achieving a 95% response rate. The potential participants were contacted at tourist sites such as hotel lobbies and recreational areas (famous sites and scenic nature sites). Each participant (220) was approached and information about the study (i.e. topic, objectives, purpose, confidentiality and project leader contact information) were given and asked if the tourist was willing to participate in the study. Those tourists who were willing to participate were provided with a questionnaire (with both English Language and the native spoken language Kannada). The project assistant helped in translating the language so that the questions were easily understood by the participants. Questionnaires were collected and the participants and the project team discussed more about the questions and what they would like to see happen in the near future for India's "Silicon Valley".

Questionnaire Development

The instrument used for the study was designed independently. One area of inquiry explored the likelihood of what the participants would choose if sustainable/green conservational features were available at the hotels in which the participants stayed at and if these programs can influence consumer choices. Participants were asked to rate ten (10) specific features that hotels adopting the green initiative would have benefit from; of course, many hotels are now in the phrase of implementing their green initiative programs. Participants were asked if implementing these programs would decrease, increase or not change the likelihood of booking a reservation at green hotels. The ten (10) features were adopted from previous literature (Butler, 2008) and also by reviewing current industry policies and practices, these features include:

- Eco-certification
- Energy saving lights

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Renewable energy
- Recycling general wastes (plastic/paper)
- Recycling kitchen wastes
- Reusing items
- Reuse linen
- Environmentally friendly (EF) paper products
- Rain/grey water reuse
- Bio-chemicals

RESULTS

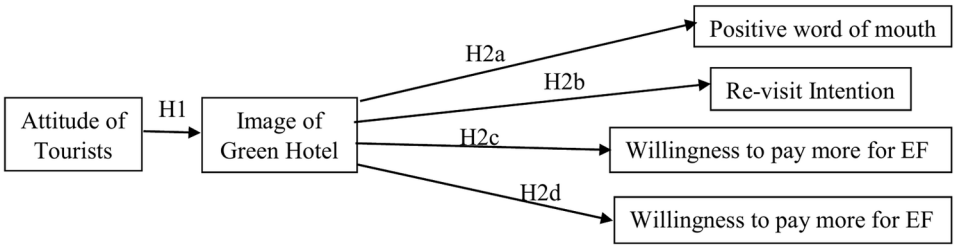
Profile of Participants

The profile of the participants is based on age, gender, education and occupation can be seen in Table 1.

DESCRIPTIVE STATISTICS OF THE HYPOTHESES

Nowadays, hotels that are becoming environmentally conscious in their functions fulfill their environmental responsibility and achieve substantial cost-saving through various environmental benefits (Han, Hsu, and Lee, 2009). This action increases and promotes environmentally friendly products and services to hotel guests who would prefer to stay in a hotel that implements green management.

H1: Investigating the attitude and behavior of tourists towards green practices in hotels.



Apart from the cost-efficiency of green practices in hotels, green management has now played a critical role in marketing, operational building (Ramchurjee and Suresha 2014) and the image of the hotel.

Table 1. Profile of Participants

Characteristics	Description	Values	Characteristics	Description	Values
Gender	Male	69%	Education	Pre-University	17%
	Female	31%		University	30%
Age	18-25	16%		Post-Graduate Degree	2%
	26-33	30%		Other	22%
	34-41	15%	Occupation	Student	0
	42-49	7.0%		Professional	46%
	50-57	21%		Self-Employed	3%
	58-65	7%		Homemaker	40%
	65-74	4%		Unemployed	11%
Education	Primary	11%			
	High School	18%

Figure 1. Displays the relationship among the variables of attitude of tourists towards green practices, image of green hotel, positive word of mouth; re-visit intention, willingness to pay more for EF services and willingness to pay more for EF products

Many studies have been conducted to show the connection between environmental responsible attitude and behavior, image, positive word of mouth, re-visit intentions and willingness to pay for environmentally friendly services and products (Han, Hsu, and Sheu, 2010).

H2: Investigating the extent to which the image of hotels will influence.
H2a: Positive word of mouth
H2b: Re-visit intention
H2c: Willingness to pay for environmentally friendly services
H2d: Willingness to pay for environmentally friendly products

In terms of descriptive statistics, the tourists reported relatively high scores for the 'attitude and behavior of tourists towards green practices in hotels' variable (M=3.76, SD=0.06). A large number of studies indicated that tourists are becoming more aware of the importance of protecting the environment and they are more involved in practicing environmentally friendly behavior on holidays (Kalafatis, Pollard, East, and Tsogas, 1999). In other words, people have become increasingly aware of the fragility of our environment and the need to perverse our natural resources (Enz and Siguaw, 1999) and (Laroche, Bergeron, and Barbaro, 2001). Thus, individuals who are environmentally responsible perceive the importance of engaging in such types of behaviors (Laroche, Bergeron, and Barbaro, 2001) and (Lita, Surya, Ma'ruf, and Syahrul, 2014) concerning ecological issues. These groups of consumers are willing to change their buying behavior towards more environmentally friendly activities (recycling, green purchasing) and behave in environmentally friendly ways in their everyday lives (Enz and Siguaw, 1999).

In terms of the extent to which the image of the hotels will influence 'positive word of mouth' variable (M=3.66, SD=0.07), 're-visit intention' variable (M=3.46, SD=0.07), 'willingness to pay more for environmentally friendly services' (M=4.00, SD=0.07) and 'willingness to pay more environmentally friendly products (M=4.06, SD=0.06). It was discovered that attitude toward green behavior of hotels had positive impact on the overall image, and the overall image had positive impact on the intention to visit, word-of-mouth, and willingness to pay more (Choi, G. et al., 2009). Many studies from North America and Europe have found that consumers demonstrate a strong willingness to pay for hotels committed to environmentally friendly practices, but cultural and social structures determine consumers' green orientation and willingness to pay (Han, H. et al., 2011). One study (Ramchurjee and Suresha 2014), examined the broader connection between hotel customers' eco-friendly decision-making and overall hotel image, re-visit intention, word-of-mouth and willingness to pay more in a green hotel context.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The results showed that the overall image is a positive function of attitude towards green behavior and that the overall image significantly affects visit intention, word-of-mouth intention and willingness to pay more. Figure 1 displays the relationship among the variables of attitude of tourists towards green practices, image of green hotel, positive word of mouth; re-visit intention, willingness to pay more for EF services and willingness to pay more for EF products. This study shows how the following variables are hypothesize.

Demographic Differences: Gender

An independent sample t-test was calculated aiming to seek the differences between males and females' participants. Statistically significant differences were found between 'gender' and 'willingness to pay more for EF products' (t_{208}=-5.341, p<0.05) and gender and positive word of mouth (t_{208}=-5.521, p<0.05). No statistical significant differences were found between the other three groups in 'green practices' (t_{208}=-3.605, p<0.05), 're-visit intention' (t_{208}=-2.558, p<0.05), and 'willingness to pay more for EF services' (t_{208}=-1.294, p<0.05). Studies have shown that gender differences were found with the intention to visit again which was affected by their previous experiences with green hotels (Han, Hsu, and Sheu, 2010). The male participants scored significantly higher than their female counterparts as seen in Table 2.

Demographic Differences: Age

An analysis of variance was conducted to test the differences between 'age' and the five subgroups. The analysis revealed that there are strong significant effects for 'green practices' ($F_{5,208}$=5.830, p<0.05), 'word of mouth' ($F_{5,208}$=2.912, p<0.005), 're-visit intention' ($F_{5,208}$=4.365, p<0.001), 'willingness to pay more for environmentally friendly services' ($F_{5,208}$=4.309, p<0.005) and 'willingness to pay more for environmentally friendly products ($F_{5,208}$=5.268, p<0.005).

Demographic Differences: Levels of Education

An analysis of variance was conducted to test the differences between levels of education and the five subgroups. The analysis showed there are significant effects for 're-visit intention' ($F_{3,208}$=0.319, p<0.005),'willingness to pay more for environmental friendly services' ($F_{3,208}$=0.314, p<0.005) and 'willingness to pay more for environmentally friendly products' ($F_{3,208}$=0.384, p<0.005). No significant effects were reported for 'green practices' ($F_{3,208}$=0.279, n. s) and 'positive word of mouth' ($F_{3,208}$=0.213, n. s).

Table 2. Results of t-Test for the study variables by Gender

	Green Practices	Word of Mouth	Re-visit Intention	Willingness to pay more for services	Willingness to pay more for products
	M (±SD)	M (±SD)	M (±SD)	M (±SD)	M (±SD)
Male	3.36(±0.31)	3.26(±0.33)	3.85(±0.35)	3.64(±0.37)	3.18(±0.29)
Female	3.77(±0.82)	3.65(±0.94)	4.05(±0.62)	4.00(±0.93)	3.46(±0.13)
t	-3.605	-5.521	-2.558	-1.294	-5.341
p	p<0.05	p<0.05	P<0.05	P<0.05	p<0.05

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Correlation Among the Five Subgroups

Correlation analysis was computed for the five subgroups and the 209 participants in this study. The results suggest that 9 out of 10 correlations were statistically significant and were greater or equal to (r_{209}= +0.60, p<0.01), two-tailed test. The 'attitude of tourists towards green practices' showed the highest correlation with 'willingness to pay more for EF products' (r_{209}=0.972, p<0.01). The second highest correlation is between 're-visit intention' and 'willingness to pay more for environmental friendly services' (r_{209}=0.916, p<0.01). The remaining variables indicated moderate correlation, with no significant effect reported for 'word of mouth' with 'willingness to pay more for EF products (r209=0.091, p<0.01). In general, the results suggest that the tourists who adopt green practices are willing to re-visit the same destinations and are willing to pay more for environmentally friendly services and products offered by hotels that are implementing and that are already following the green initiative. According to many studies, it has been shown that customers' green attitudes are significantly associated with their expressed intentions to visit green hotels when on vacation, spreading positive word-of-mouth when they are satisfied with the environmentally friendly products and services being offered by the green hotels, leading to visiting that destination/hotel again and again and they are of course willing to pay for it (Han, Hsu, and Sheu, 2010). Table 3 shows the correlation analysis between the five subgroups.

Current Practices at Hotels Which Affect the Environment

In order to measure the current practices in the daily operations of hotels the following characteristics were used (1) Eco-certification, (2) Energy saving lightings, (3) Renewable energy, (4) Recycling general products (plastics/paper), (5) Recycling kitchen products (cooking oils, unused vegetables/foods), (6) Reusing items, (7) Reuse linen, (8) Environmental friendly (EF) paper products, (9) Rain/grey water reuse, and (10) Bio-chemicals.

The results (beta weights for each variable and their significance, based on the t-values, as well as variance explained by each regression) are described in Table 4.

Mean Responses for Sustainable Practices

Table 5 shows relatively high ratings for increased tendency to choose a hotel based on sustainable practices. Particularly, consumers provided the lowest ratings for practices that might lessen from their

Table 3. Correlation analysis between the five subgroups

	Green Practices	Word of Mouth	Re-visit Intention	Willingness to pay more for services	Willingness to pay more for products
Green Practices

Table 5. Mean Responses for Sustainable Practices

Sustainable Practices	Mean	S.D.
Eco-certification	3.77	0.55
Energy Saving Lighting	3.54	0.50
Renewable Energy	3.64	0.50
Recycling General Wastes	3.50	0.50
Recycling Kitchen Wastes	3.63	0.50
Reusing Items	3.43	0.48
Reuse Linen	3.30	0.46
EF paper products	3.54	0.50
Rain/grey water reuse	3.65	0.48
Bio- cleaning chemicals	3.53	0.50

experiences, like reusing items and reuse of linen. The ratings are not significantly different from each other, but present a different view of customer perceptions, since previous researches suggested consumers are most likely to perceive value associated with the practices they directly observe (e.g. Millar & Baloglu, 2011). Earlier researches suggested consumers require a discount to give up amenities, like toiletries (Chia-Jung & Pei-Chun, 2014). The current samples placed higher value on eco-certification, rain/grey water reuse and renewable energy.

DISCUSSION

The average age of the participants was 29 years old and males dominated with 69%. 30% of the participants had a university degree and 46% were professional employed. Overall, the data showed that 44% of the male participants were in the age groups 26-33 having a university degree and being professionally employed.

The results of the hypotheses for the current study is supported by (Ramchurjee and Suresha 2014), study showing that attitude towards green behavior positively affects overall image, and that overall image positively affects positive word of mouth, re-visit intention and the willingness to pay more for environmentally friendly services and products. Many studies have shown that there are significant impacts on the overall image of hotels and the willingness of consumers to pay more for these activities. This can be corroborated by (Ramchurjee and Suresha 2014) that tourists are becoming more aware of the importance of protecting the environment and being more involved in practicing environmentally friendly behavior on holidays. This may start by tourists choosing green hotels to stay at, while engaging in nature-based activities (Ramchurjee, 2013).

As the concerns for the natural environment increases, individuals are adopting environmentally friendly attitudes and behavior. In the Demographic Differences – Gender, statistical significant differences were found for willingness to pay more for environmentally friendly products and female participants, scoring significantly higher than their male counterparts. This result corresponds with many other studies in that women are more willing to pay more to be sustainably friendly towards the environment. On the other hand, significant differences were found between positive word of mouth and male participants. Satisfied tourists, in this case, the male participants are more likely to become promoter via positive word of mouth (Ramchurjee, 2013).

The Demographic Differences – Age has shown significant statistically differences with all the subgroups. This may suggest that age plays a major role in the concerns of the tourists for the environment, where older-aged groups will show more appreciation for the smaller things in life (Hopkins, and Roche, 2009), thus saving the environment for younger generations, and the realization of the younger-aged groups that they have to save the environment for their future as well as for other generations.

Guests do not actually see what happens with the recycling systems adopted by any hotel, and so they are not overly concerned about the waste management system, only that their rooms are daily cleaned. In India, waste is a massive concern and is somewhat controlled to a certain extent by the private enterprises. Some hotels, take waste management to another level, where they recycle their excessive food and vegetable wastes to other useful products such as compost

Conservation of water is a relatively new concept in India. Traditionally, hotels felt that if water was available, guests would be happy; however, with environmental concerns on the rise, conservation is now needed as a measure to help to combat India's growing population.

This study found that age had a negative relationship with three (3) features such as eco-certification, recycling (food waste) and rain/grey water reuse. Few hotels in Bangalore are eco-certified and are willing to implement green initiative programs into their daily operations. Some hotels managers/operators think that by implementing these programs cost money, and that they will not receive any return on their investment.

This study did not find any significant relationship with gender and income and considers that it reflects the same results as previous studies concerning hotel guests regarding sustainability (Tierney,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hunt, and Latkova, 2011) and (Berezan, Millar, and Raab, 2014). When people are motivated to adopt green practices, gender – male or female does not show any differences as to as individual gender.

However, levels of education did record high relationships with recycling general wastes (such as plastic, paper and aluminum), reusing items and rain/grey water reuse (conservation of water). These three features would be expected to have high association because of their impacts on the environment. Thus, hotel guests with high level of education will take into consideration recycling, reuse and conservation of items to show their environmentally friendly attitudes and behaviors.

This study did find socio-demographic factors having moderate significance with selecting a hotel that had employed environmentally sustainable practices, and so we expected environmental values to have positive connection with selecting hotels that participated in green practices. Our results have shown positive relationship between environmental values and the selected green features. This can be related to other studies that show hotel guests have positive associations between environmental values with green hotels while there are on holiday (Cometa, 2012). This further shows that the value of green hotels may increase beyond the group of green consumers.

Our findings indicate positive relationship with environmental belief and all the selected practices that are being offered by green hotels in Bangalore. Belief, in relation to environmentally friendly practices is a value, customers perceived to be offered by green hotels and the willingness of consumers to participate in these activities and their willingness to pay more for these environmentally friendly services and products [36] offered by the hotels.

The overall results proposed that the participants in the survey were more likely to choose green practices (11%-16%) than the general population (5%) influenced by sustainable practices.

These results could provide guidance and opportunities to hotel managers/operators as a source to increase their green practices (Oliver, Naar, and Harris, 2015) and share these operations with their guests, who can enjoy the experience of being included in the decision of hotels to become 'sustainable.'

Consumer concerns about environmental practices, and sustainability issues on a broader scale, are not likely to dissipate. Therefore, each nuanced level of understanding about consumer preferences and decision-making can direct sustainability managers, product developers and marketers in a more enduring, responsible solution to tourism's sustainability challenges.

CONCLUSION

Today, the society we live in judge industries on their ethics, social accountability, socio-environ-economic awareness and their financial inputs and outputs. As the public understanding of global warming and environmental degradation growths, it is expected that businesses/firms that contribute to these harmful behaviors must now move in a 'green' direction.

As this study submitted, a green hotel image becomes a powerful operational tool in attracting and retaining more guests. From the analysis, environmentally friendly activities of tourists give significant influence to their intention to choose green hotels, being promoter via positive word of mouth. In practice, the findings of this study should contribute to encouraging green hotel operators/managers to consider their green initiative programs as part of the guest experience and recognize the investment towards 'becoming' green will be realized significantly.

Chapter 42
Improving the Supply Chain (SC) Stream With Green Product Design (GPD) Strategy:
Green Supply Chain Management (GSCM)

Rodrigo Villanueva
Universidad Autonoma de Ciudad Juarez, Mexico

Emilio Jimenez-Macias
Universidad de la Rioja, Spain

Julio Blanco-Fernandez
Universidad de la Rioja, Spain

ABSTRACT

The current Supply Chain (SC) is under change. The traditional way to generate a product contained the following stages: product design, raw material selection, material transportation, manufacturability, distribution and disposition at end of life. Product design for instance, is considered an extremely important stage of a product, being that, it directs the way the product can potentially be managed along the SC. It defines the raw material to be used, the possible supplier to select, the industrial processes involved in its fabrication, the packaging for its transportation and the newest stage where the product reaches its end of life and needs to be disposed. The Product design then becomes Green Product Design (GPD), where energy, time, resources become critical for a company. GPD takes into account the whole product life cycle. This chapter presents the importance of having a GPD process into the SC, the way to incorporate it, and the benefits of implementing it into the SC.

INTRODUCTION

With the development of economic and the progress the industry of products conflicts arise between these two main drivers. The company´s economic gain faces the challenge to reduce energy consumption and environmental resource care. Today consumers have become more aware of environmental care and seek for products that are manufactured following green practices. Therefore, companies are motivated

to invest in strategies that will help address these highly changing needs and establish a competitive advantage among competitors.

Supply chain (SC) is a methodology that aims to achieve organizational goals, some authors are considering it as the new strategy for proficiency in this globalized world (Elgazzar, Tipi, & Hubbard, 2012; Ngai, Chau, & Chan, 2011) and supply chain management (SCM) is the group of activities that aims to plan, integrate and control those activities as a strategy. Nevertheless, with the increasing worldwide awareness of environmental care, a green production has become an important metric for almost every manufacturer, so the SCM is turning into green supply chain management (Lee, 2009; Mark & Anton, 2014).

A more sustainable supply chain performance is indicated by a company's capacity to reduce the use of materials, energy or water and to find solutions that are more eco-efficient by improving the management of their supply chains (Ortas, Moneva &, Alvarez, 2014).

The general idea is that the use of green operational practices reduces energy consumption and waste, consequently producing higher revenues. Among these practices, Green product design (GPD) is one of the main themes in the literature on environmental management (Albino, Balice & Dangelico, 2009).

The introduction of GPD is undoubtedly one of the new trends in industry as significantly influences the cost of manufacturing a product throughout the SC. The main goal of GPD is the reduction of environmental impacts in each stage of any product's life cycle and in parallel will bring benefits for the company like: reduction of energy consumption, less waste disposal, less resources consumption, improved social and corporate image and therefore more revenue. Therefore, the purpose of chapter is to provide an input regarding the importance that GSCM via GPD brings to any company's SC.

The chapter is organized as follows: Section 1 Introduction, 2 incorporates a description of Supply Chain, Supply Chain Management and examples of application and success, Section 3 presents the description of Green Supply Chain Management and overview of the components, examples of applicability and success and the potential competencies, Section 4 describes Green Product Design, its practices, benefits, and process and a way to implement into a SC, closing with Section 5 Conclusions and remarks.

Supply Chain (SC)

The SC is the sequence of events that cover the entire lifecycle of a product or service from beginning (raw material distribution) to end (final customer use) according to Blanchard (2010). Therefore, SC includes all of the tasks involved directly or indirectly in fulfilling a customer´s need.

The SC can be extremely complex as it integrates independent organizations that work together to develop, control and manage a product (Wu, Chen & Hsieh, 2012). The integration of independent companies lead for SC to become an important element in current global economy, SC is the new strategy for competence (Ngai et al., 2011).

The supply chain is integrated by three main components (Villanueva-Ponce, Romero-González & Alor-Hernández, 2014)

- Supplier (raw material)
- Manufacturer (product)
- Distributor (to end user)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

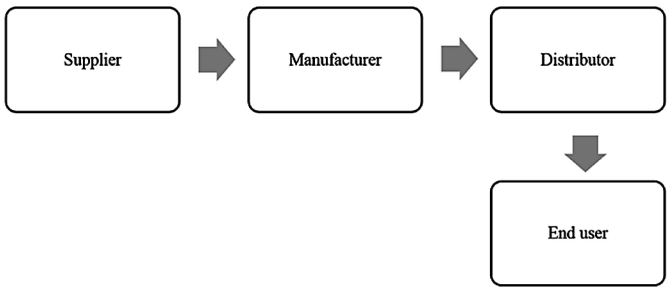
As seen in Figure 1, the point of start of a SC begins with the supplier of a determined raw material followed by the manufacturer and the distributor.

Supplier Selection

Suppliers have a direct influence on final product quality, final cost and delivery time. Therefore, represent a very important link in any GSCM system, and the selection of the right supplier is crucial for a successful SC. The supplier selection process (SSP) involves evaluation and selection task where the performance of a group of suppliers is measured. The evaluation will be defined by the product requirements, and generally a group of experts assess the set of attributes.

The criteria to be considered when selecting a supplier will be defined by the SC's needs and product requirements. Due to the multiple attributes, the common techniques used for supplier evaluation are classified as multi-attribute decision making because they permit to evaluate simultaneously those attributes (Shaw, Shankar & Yadar, 2012). However, during the last decades, traditional approaches for selecting suppliers have only considered the quality, cost and lead time, but nowadays, those attributes are no longer enough to choose the right supplier and companies need to incorporate more and newer attributes such as environmental characteristics into the common supplier selection criteria.

Table 1 illustrates a list of attributes used when evaluating a supplier with a multicriteria technique in a literature review from 2009 to 2015 including non-disclosed environmental attributes.



For a deeper discussion about the supplier selection process, the multicriteria techniques & tendencies, readers can review the reports from (Chai, Liu & Ngai, 2013) and for green supplier selection, the newest tendencies appear in (Govindan, Rajendran, Sarkis & Murugesan, 2013).

Manufacturing

One of the strategies used during this important step in the design flow is Design for Manufacturing (DFM) and Design for Assembly (DFA) which integrated form Design for Manufacturing and Assembly (DFMA) as one common activity. The objective is to design a product that is easily and economically manufactured. The importance of designing for manufacturing is given due to the fact that a great part of manufacturing costs of a product are caused by the design step.

For each assembly component, there is opportunity for an assembly challenge to reduce complexity. The importance of this is to eliminate waste, variation, complexity, and avoid using different sizes, shapes or colors so the operators and automated processes can easily complete the fabrication step.

Figure 1. Supply chain

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Main attributes evaluated in traditional supplier selection process

Attributes	Year							Total
	2009	2010	2011	2012	2013	2014	2015	
Price	15	13	22	16	22	5	18	**111**
Quality	12	14	19	15	17	4	19	**100**
Delivery	9	10	19	16	17	2	15	**88**
Aftermarket Service	3	5	10	5	8	2	3	**36**
Management	1	1	6	10	0	0	4	**22**
Relationship with supplier	5	2	7	3	0	0	7	**24**
Flexibility	1	4	2	7	0	0	4	**18**
Capacity	1	0	1	3	6	3	3	**17**
Risk	2	0	3	3	4	1	4	**17**
Environmental impact	0	1	1	2	3	3	13	**23**
Security	1	0	0	4	0	0	0	**5**
Performance	0	0	0	2	2	1	0	**5**
Finances	0	0	0	4	0	0	2	**6**
Warranty	0	0	0	0	2	0	0	**2**
Rate	0	0	0	0	2	0	0	**2**
Government facilities	1	0	0	0	0	0	0	**1**
Transport facilities	0	0	0	1	0	0	0	**1**
Experience	0	0	0	0	1	0	0	**1**
Technology	0	0	0	0	1	0	7	**8**
Geographical position	0	0	0	0	0	0	4	**4**

The following guidelines should be followed when designing for manufacturing:

1. Understand the product. The need to have a vast understanding of the product will lead to a better result on the design and in consequence to the steps to fabricate the product.
2. Minimize total number of components. The reduction of the number of parts in a product is potentially the best opportunity for reducing manufacturing costs. A final assembly formed out of less parts represents a reduction of materials, purchased components, processes to assemble, handling, process time, quality inspection, testing among others.
3. Develop a modular design. The use of modules in product design simplifies manufacturing activities like assembly, maintenance, inspection, service or rework. Modules add flexibility to product update in the redesign process.
4. Use of standard components. Standard components help reduce the cost as these can be reused instead of generating new custom-made items for every new assembly to launch reducing product lead time.
5. Design parts for multiple use. Focus on design a part that can be used in different applications, it is necessary to identify the parts that are suitable for multiple use. This step is aimed to define a set of standard part families from which multiple use parts are created.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

6. Minimize handling. When assembling a part it drives additional process time to position, orient, fixate or joint components. Therefore, the use of indexing features, guiding posts are needed to help on the orientation of a part.
7. Minimize the variations. The utilization of standard components whenever possible is a must. In a final assembly that needs certain types of fasteners, it should be avoided the similarity of components and keep a standard one for all the activities.
8. Minimize assembly directions. All parts should be assembled from one direction if possible. The desired way to add additional components if a top down operation, in this way, the effects of gravity help the assembly process, instead of having to compensate the other way around.
9. Packaging of product compliance. When designing the product, try to minimize the flow of material waste, parts, and so on, in the manufacturing operation; also, take packaging into account, select appropriate and safe packaging for the product.

Distribution

The distribution flow ensures that the level of quality determined by the manufacturer is maintained throughout the distribution network in the SC. As a result, all the products are distributed to retail stores, automotive industry, and others selling the product to the general public without any alteration of their properties. The distribution should be defined according to the properties of the product being transported. These requirements and properties should be kept intact from shipment to delivery to its final customer. The distribution should be implemented through a quality system operated by the distributor or wholesaler to ensure that:

- Products are in good care.
- Storage conditions are observed at all times.
- Contamination from or of other products is avoided.
- Products are stored in appropriately safe and secure areas.
- Packaging will withstand the transportation.
- Packaging can be designed in a way to eliminate waste.

In addition, the distribution quality system should ensure that the products are delivered to the final destination within a satisfactory time period.

Supply Chain Application

Due to the recent rapid growth of consumers demanding newer, improved, flexible, modern, and custom made products, industry must switch into a more innovative, faster and more flexible way of being that could offer a wide variety of products to satisfy modern demands. The way to achieve these demands requires a boost in technology and a division of manual labor.

The globalization is a tactic that most companies have implemented in their operational activities to strengthen inner capabilities and be competitive. Driving the companies to outsourcing the activities that are not handled internally to improve their competitive advantage, any part of the SC could be integrated by different independent organizations located far from each other and still bring the most effective way to acquire raw material, manufacture and distribute a product.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

A company must focus in its sustainability by utilizing resources to meet the needs without compromising the future. Business sustainability signifies the resiliency of organizations over time where they are closely connected to healthy environmental, economic and social systems so they are better positioned to respond to internal or external shocks (Ahi & Searcy, 2013).

Increasingly, researchers in different fields are taking into account the influence and implications of business sustainability on traditional assumptions and practices in their fields, (Gimenez & Tachizawa, 2012). Sustainability is important for businesses and supply chains, as stakeholders are increasingly concerned about society, the environment and economic development (Golicic & Smith, 2013).

Supply Chain Management is one of these research fields and an introduction is provided in the next subsection.

Supply Chain Management (SCM)

SCM is described as the management of a network of relationships within a firm and between interdependent organizations and business units consisting of material suppliers, purchasing, production facilities, logistics, marketing, and related systems that facilitate the forward and reverse flow of materials, services, finances and information from the original producer to final customer with the benefits of adding value, maximizing profitability through efficiencies, and achieving customer satisfaction (Stock & Boyer, 2009).

SCM is described as the management of the inputs of goods or services including arrange of activities not only within a single department in an organization but also from different departments and outside the organization, for final users from procurement of raw materials through to the end of the products' useful life (Eng, 2005). The systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole. (Mentzer, et al., 2001)

SCM encompasses the planning and management of all activities involved in sourcing and procurement, conversion, demand creation and fulfillment, and all logistic management activities (Gibson, Mentzer & Cook, 2005). Nonetheless, one of the most complete definitions of SCM is found in (Lummus, Krumwiede & Vokurka, 2001), they defined it as "all the activities involved in delivering a product from raw material through to the customer, including sourcing raw materials and parts, manufacturing and assembly, warehousing and inventory tracking, order entry and order management, distribution across all channels, delivery to the customer, and the information systems necessary to monitor all of these activities".

Based on all the previous authors described above, SCM in summary, is the management of an interconnected industry system involved in the provision of product and/or services required by an end consumer and comprehends all movement and storage of raw material, work-in-process inventory, and finished goods from point of origin to point of consumption.

As stated then SCM involves a wide number of activities and independent companies with the shared goal, and there is the need to minimize or eliminate the negative effects of the SC processes to the environment. The extension of the SC that includes activities that aim to reduce and eliminate the environmental impact of a product along its entire life cycle is defined as the Green Supply Chain Management and it is described in the next section.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Supply Chain Management (GSCM)

The current condition of the planet, the uncontrolled increment of population and the deterioration of the natural resources is diminishing the quality of life for all inhabitants to a dead end. One way of reducing the harm impact of this condition is by incorporating environmental care into supply chains. Green supply chain management (GSCM) practices are geared toward improving environmental performance (Mirhedayatian, Azadi & Farzipoor, 2014).

GSCM is a scheme by leading industrial companies, extending pressure on their suppliers to achieve certain levels of environmental performance, stimulating operational cooperation by all SC members. Nonetheless, all along the SC, the environmental impact must be evaluated, because only a collaborative work among SC partners leads to reduce environmental influence to a minimum and, at the same time, provide financial profits (Golicic et al., 2013). GSCM is a way for firms to achieve profit and market share objectives by lowering environmental impacts and increasing ecological efficiency (Buyukozkan & Cidci, 2012). GSCM tends to minimizing and preferably eliminating the negative effects of the SC on the environment (Andic, Yurt & Baltacioglu, 2012).

Thus, the general idea intended in GSCM is to reduce through the whole SC cycle: pollution, waste, energy consumption, and use of hazardous materials. In essence, GSCM is an important approach for organizations to manage their environmental and social responsibilities at the same time of fulfilling government regulations and public awareness of environmental protection.

Common procedures in GSCM begin applying a set of internal environmental policies conceived to obtain green purchasing practices with suppliers, good-practices in eco-design, cooperation and communication with customers, and investment recovery during production process and post-sale (Zhu, Sarkis, & Lai, 2008b), closing so the GSCM loop.

A lot of global enterprises have already adopted GSCM or are considering its adoption for such various factors as response to diverse environmental legislation and regulation, improvement of the image of their enterprise brand, work innovation, and cost reduction (Chun, Hwang & Byun, 2015).

GSCM Practices

There is a wide variety of application for GSCM in the industry. A lot of reports appear in literature informing about benefits obtained by a good GSCM philosophy with supplier participation, informing that green practices can result in immediate statistically significant gains in stock prices (Bose & Pal 2012).

A comprehensive approach to understand how the adoption of GSCM practices, including green sources, influences environmental and operational performance indicators is found in Lopes de Sousa, Cortegoso de Oliveira Frascareli, and Chiappetta Jabbour, (2015). They consider pertinent to study the relationship between the adoption of GSCM practices and the performance of companies, establishing that this relationship requires a more individualized perspective between each GSCM practice and performance indicators being studied.

Chinese car companies have experienced increasing environmental pressure while simultaneously recognizing various benefits and incentives to turn green SC (Zhu & Sarkis 2004, 2006).

UK organizations, that have a progressive attitude towards green SC, are also the most active operationally that is traduced in financial benefits (Yusuf, Gunasekaran, Musa, El-Berishy, Abubakar, & Ambursa, 2013).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Similarly when European Union's restriction on hazardous substances directive took effect in 2006, Hewlett-Packard anticipated this and invested money in finding alternatives, providing a competitive product and increasing profitability (Nidumolu, Prahalad, & Rangaswami, 2009).

A study reflecting the current developing country's automobile GSCM status is presented in Diabat and Khodaverdi, (2013). They show, the automobile industry has attempted to improve their economic, environmental, and sustainability performances simultaneously.

Yang, Lu, Haider and Marlow, (2013) present a study that provides an empirical assessment of internal green practices and external green collaboration in the container shipping. The study's main findings are that internal and external GSCM practices have a positive effect on all the environmental practices. On the other hand external practices have a greater influence on environmental practices than internal practices

Zhu, Sarkis and Lai, (2013), present a study of 396 Chinese manufacturers and the main drivers why these have adopted GSCM and they indirect way that these green practices improve the economic performance. The results also provide policy insights for professional organizations, regulators, and legislators to further promote GSCM.

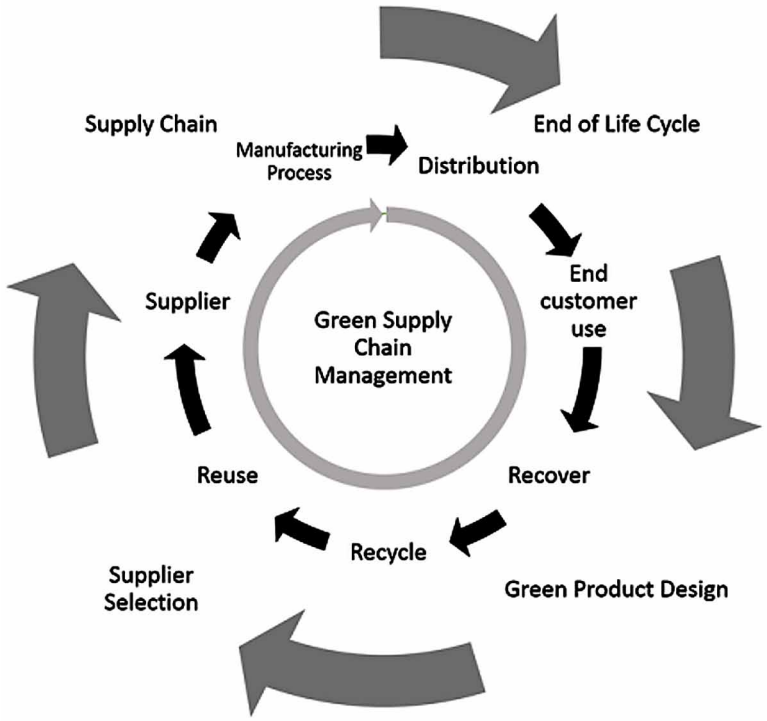
Laosirihongthong, Adebanjo and Tan, (2013), examine the deployment of practices in the implementation of GSCM and analyze their impact on environmental, economic, and intangible performance by considering business strategy as organizational focus, they found that legislation was a consideration that resulted in companies enhancing their environmental, economic and intangible performance.

These are some of the main studies discussing the relationship between GSCM practices and performance to show the main indicators of this relationship. The next subsection presents a general overview of the GSCM elements.

GSCM Overview

There is a variety of practices that can be performed within GSCM. The scope of GSCM ranges with the supplier selection process through to manufacturer, end customer closing the loop with the reverse logistics that will feed the green product design (Villanueva-Ponce et al., 2015).

In this particular illustration it can be seen the way the GSCM manages the broad activities of the typical SC strategy involved in a product generation that may comprehend activities that involve selection of materials or disposition of a former product component in order to recover, recycle or reuse it to feed the cycle back to raw material supplier selection.



A brief description of the GSCM cycle is presented in the next subsections.

1. Supplier Selection

As described in the SC section, setting the correct supplier will impact along the entire SC. The supplier in the GSCM manages the same responsibility and has the same importance. The collaboration now in the activities extends to improve environmental performance for developing green products and innovations. The supplier such address activities such as recyclability, reusability, waste reduction, environmental material exchange, and hazardous material reduction. Companies have pushed suppliers to boost their environmental performance to assure that the materials being purchased are environmentally friendly and meet the needs.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Green supply chain management

2. Supply Chain

A green SC can be defined as the extension of the traditional SC but including activities to reduce environmental impacts of a product all over its entire life cycle, such as green design, waste management, reuse, recycle, harmful material reduction among others. Green SC as the reduction of energy and virgin raw material usage and waste generation, and increasing product recovery options (El Saadany, Jaber &Bonney, 2011)

Therefore, green SC usually refers to the SC functions such as production, purchasing, materials management, warehousing and inventory control, distribution, shipping, and transport logistics now considering the impact to the environment.

3. End of Life Cycle

Refers to the operations like recycling, remanufacturing, and reuse adding complexity to the product design. Also the reverse logistics recovery process where products are collected from the end users and returned to the factory for a proper disposition, thus reducing manufacturing costs.

4. Green Product Design

Refers to activities whose intention is to decrease the negative environmental impacts of products during their entire life cycle. Green design is closely related to environmental risk management, product safety,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

pollution prevention, resource conservation, and waste management. It emphases mainly on the returned products and materials from the point of use to back to the beginning of the SC.

GSCM Competencies

The percentage of companies that have established a GSCM in order to incorporate the ecological care is increasing. These firms do acknowledge the huge impact to the environment that needs to be reduce and have implemented a plan to respond to legislation, regulations and social concern. In some cases the bigger the company, the greater the interest in integrating a GSCM. The GSCM Competencies represent a broad set of activities.

Table 2 illustrates a list of competencies that main authors are enforcing when applying GSCM into their SC systems. It is observed that there are two competencies that are leading the list; the first is related to Green Product Design with 25 quotes, followed by Environmental Management with 20 quotes.

Table 2. GSCM competencies and main actions implemented review

Competency	Quotes	Authors
Green product design	25	(Amindoust, Ahmed, & Saghafinia, 2012); (Awasthi Cauhan, & Goyal, 2010); (Chia-Wei & Hu 2007); (Ge 2009); (Haiying 2011); (Hsu & Hu 2009); (Jabbour & Jabbour 2009a); (Kannan, Govindan, & Rajendran, 2015); (Kuo, Wang, & Tien, 2010); (Lee 2009); (Lee, Kang, Hsu, & Hung, 2009); (Li-yun & Yu-zhong 2008); (Lin 2013); (Mafakheri, Breton, & Ghoniem, 2011); (Sun, Wong, & Lee, 2013); (Tseng & Chiu 2013); (Weiwei & Lei 2012); (Wen & Chi 2010); (Xiangguo & Tongjuan 2011); (Xiaopeng & Changxin, 2009); (Xu, Kumar, Shankar, Kannan, & Chen 2013); (Yang & Wu 2007); (Yeh & Chuang 2011); (Yu-zhong & Li-yun 2008)

Therefore, Green Product Design is acting as a one of the key competencies that needs to be explored in GSCM and will be described in the following sections of this chapter.

Green Product Design (GPD)

GPD can also be called design for the environment or eco design, refers to measures taken during product development resolve at minimizing a product's environmental effect during its whole life cycle. It is considered one of the GSCM activities as it integrates environmental aspects into the process of designing a part due to the fact that most of the environmental influences caused during manufacturing and disposal are direct effects of decisions taken at this early phase.

A green product is defined by the use of green design, green materials, green manufacturing processes, green packaging for distribution (Chan, 2011; Chu, Luh & Chen, 2009). Then GPD, is generally defined as the useful method to decrease the environmental impact of a product generation and it has become one of the most important practices for achieving sustainability (Johansson & Sundin, 2014; Khor & Udin, 2013; Luh, Chu, & Pan, 2010).

GPD is easy to say, but there are a number of restrictions because all the SC activities must be integrated (Baud-Lavigne, Agard, & Penz, 2014). There are many traditional ways to do things considering different scenarios or alternatives for the same product (Russo & Rizzi, 2014) and companies must be able to evaluate simultaneously many attributes in all these scenarios, focusing the efforts in saving energy through their SC, (Moon, Youn, Chang, & Yeung, 2013).

GPD takes into account the whole product life cycle considering the product's environment impact in the production, use, disposal and recycling process in addition to consideration of product features, performance, longevity, cost and other technical and economic attribute.

Companies that have adopted a green design process may have products that are easier to recover, recycle and reuse. For that reason unlike TPD flow only contains four steps as seen in the previous section, GPD contains three additional steps: recover, recycle, reuse. These are fed back into the concept design step directing the ongoing development of a new product based on the lessons learned of the last.

Green Product Design Practices

Wu and Ho, (2015), performed a study on green mobile phone design considering the environment, quality, cost and customer demand. Using fuzzy theory and quality planning. The case study found that customers' concerns focused on the toxicity of the phone material, the power consumption and the environmental impact of the battery.

Wang, Chan, and Li, (2015), performed a case study concerning a consumer electronic product performing a design evaluation. The approach presented in this research help companies decrease development lead time by screening out poor design options.

Zhu et al. (2013), present a study of 396 Chinese manufacturers and the main drivers why these have adopted GSCM and they indirect way that these green practices improve the economic performance. The study results show that designers and product developers are playing an important role in GSCM, where internal cross-functional cooperation and supply chain relationships should also be encouraged.

To reduce energy consumption, local governments have organized energy audits for those manufacturers consuming excessive energy, and forced these manufacturers to re-design their technologies and products (Zhu & Geng, 2013).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Diabat *et al.* (2013), applied a study to the automotive industry as they consider it has the strongest drivers and pressure to implement GSCM. It expresses that the developing country's automobile SC members have attempted to improve their economic, environmental, and sustainability performances simultaneously. Their study indicates that GPD, cooperation with customers, and reverse logistics are the top three main GSCM practices that can bring better GSCM performances.

Eltayeb, Zailani and Ramayahc, (2011), present a study of the relationship between GSCM practices and economic, intangible aspects, environmental and operational performance, they found that only GPD affects positively the correct environmental performance. GPD and reverse logistics positively affect cost reduction.

Yang *et al.* 2013, present a study that provides an empirical assessment of internal green practices and external green collaboration in the container shipping industry and how these variables influence their green performance and firm competitiveness. The study's main findings are that internal and external GSCM practices have a positive effect on all the environmental practices applied in this type of industry.

Green Product Design Benefits

Recently, many companies have acknowledged the concepts of green supply chain management and green product design, nevertheless, moderately little research attention has been devoted to the consideration of relations between greening the supply chain, environmental performance and competitive advantage. Due to this fact, this section provides information about companies improving their environmental performance enhancing their competitive advantage in the global market.

Villanueva-Ponce *et al.* (2015), present a structural equation model analysis of GSCM in the maquiladora sector based on the incorporation green attributes to the supplier selection. The study's main findings are that GPD has a direct and positive impact on corporate image and financial profit. This means that any product with a stronger internal GPD processes are more likely to have a greater extent of green performance and economic benefits. In addition GPD represents a key element in the increase GSCM activities within the organization.

Wu & Ho, (2015), performed a study on green mobile phone design considering the environment, quality, cost and customer demand, and determined the importance of product design in technical attributes. It is expected that limited corporate resources can be applied in the key technical factor, thus developing a product research and design model to balance economic development and environmental protection. Although the consideration of environmental factors in the product design stage may increase the development cost, the green products may be favored by customers, thus increasing market share and profits.

Chiapetta Jabbour, Jugend, Lopes de Sousa Jabbour, Gunasekaran, and Latan, (2015), developed a study to present and test a conceptual framework that describes the technical, human and organizational aspects of the adoption of GPD practices and the effect of these on firms' environmental, operational and market performance. It shows that the adoption of GPD impacts the environmental performance and is not exclusive to large companies, but for any company.

According to Montabon, Sroufe and Narasimhan, (2007), green strategy can be an incentive for companies to make continuous efforts on environmental improvements to their green performance beyond green regulations. Thereby, economic performance relates to the manufacturing plant's ability to reduce costs associated with purchased materials, energy consumption, waste treatment, waste discharge, and fines for environmental accidents (Wagner, 2008; Zhu et al., 2004; Zhu, Sarkis, & Lai, 2008a).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to Seman, Zakuan, Jusoh and Arif, (2012), greening is a new approach, idea, product, process or service that contributes to differentiation from competitors and reduces adverse environmental impacts. For a company to present growth in the future, green innovation is needed to create new markets because market forecasts indicate that these fields will experience above average growth in the next 10 years, thus providing potential and opportunities (Walz & Eichhammer, 2012).

Organizations need to adopt green practices to comply with the laws and regulations. However, these activities may take organizations above and beyond compliance, and help them develop competitive advantages and bring tremendous profit (Bose et al., 2012). For example, Clorox introduced the Green works line to address significant environmental concerns associated with the household cleaning products and by the end of the year, the line had grown the US natural cleaners market by 100% (Nidumolu, et al., 2009).

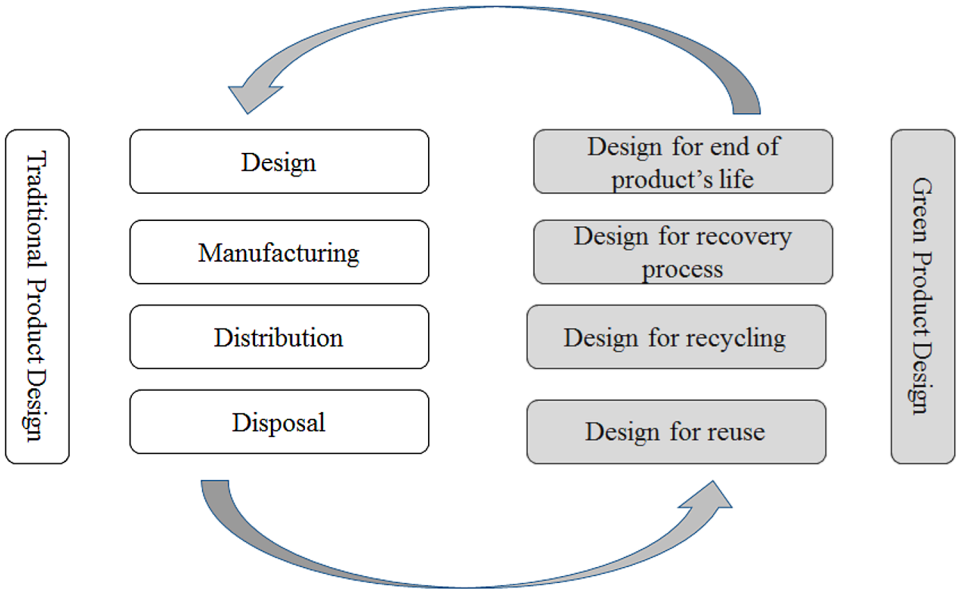
In addition social concern about environmental issues and global warming is causing consumers to demand the green products and companies need to improve their environmental performance improving its green image and thus, in higher sales and profits in the long term (De Giovanni & EspositoVinzi, 2012). Green operational activities in SC bring benefit for the members, and one of the most important is the corporate image (Hsu, Kuo, Chen, & Hu, 2013).

Green Product Design Implementation Process

Many buying firms are demanding that their suppliers implement GSCM practices and fulfill even additional environmental requirements. Supplier firms that have already implemented GPD are in a better position to win more business from large customer firms.

Green design can point the direction that each SC component will follow. Companies need to invest in the design core group and help develop an understanding of how design decisions impact the products' entire life cycle.

The GDP process is formed by four key items:



1. Design for end of product's life cycle.
    a. Aimed to reduce the environmentally hazardous materials at the end of life.
2. Design for recovery process.
    a. Intended to facilitate the return of the waste part back to the manufacturer for proper disposition.
3. Design for recycling.
    a. Pointed to facilitate the disassembly of the waste product and reprocessing of the material.
4. Design for reuse.
    a. Focused in the reuse of a product or component of it.

The GPD process and the Traditional Product Design (TPD) process are identical in their role of fulfilling basic needs. The goal is to conceptualize a design, manufacture it and deliver it to a final customer. There are notable differences between these two in terms of design process flow.

As seen in Figure 3, GPD process flow goes on each SC phase reducing the environmental impact of the product throughout all the entire life cycle.

Figure 3. Green product design flow

1. Design for End of Product's Life Cycle

Defines the product longevity to assure the economic indicators, such as the value and environmental requirements in the product life cycle. At the same time, seeking the necessary reliability, security, and the service that the product will provide, all this in order to reduce resource consumption. The end of life cycle reflects the essence and core of green product design.

There are some initiatives that can be incorporated when disposal is reached:

- **The Extended Manufacturer Responsibility:** This is an approach designed to encourage the integration of environmental costs associated with goods throughout their life cycles into the market price of the products.
- **Recycling Program:** Basically an initiative set an easy way to establish the reduction of waste discharges to the environment by recycling a product.
- **Reuse Program:** This is the program that provides extra utilization to a product or components to an assembly.
- **E-Waste Recycling:** Nothing more than the approach to dispose of all the electronic devices in proper ways to avoid contamination to the land field or water.

2. Design for Recovery Process

Also called, reverse logistic process ensures that products are returned from the end customer to the manufacturer for its proper disposition. This process involves a big range of activities; collection, sorting, processing and reconditioning.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Companies use reverse logistic in order to collect the product at end of the life cycle. This strategy requires an extra effort for companies including the capacity to adapt this process to different social conditions (Khor et al., 2013). However, this strategy lets to companies to recycle parts and components in the product, because finally, companies are focused in obtain financial benefits and this concern never is forgotten in a GPD (Chu et al., 2009).

The models of reverse SC in the developed countries include three types:

1. **Manufacturer Take-Back (MT):** Requires the manufacturer building the enormous recycle network with an excessive cost trying to find ways to enhance the sustainability for future operational success.
2. **Retailer Take-Back (RT):** Retailer Take-Back (RT). Can effectively utilize the stronger marketing network of retailer, but the manufacturer has to face some coordinating problems with retailer.
3. **Third Party Take-Back (TPT):** In the case of enterprises are unable to invest building themselves reverse logistic systems, the trend is to outsource this activity to the third party.

3. Design for Recycling

Recycling is strongly connected to GPD. A proper green design of the product will result in an easy way to establish the recycling phase of it, and the reduction of waste discharges to the environment.

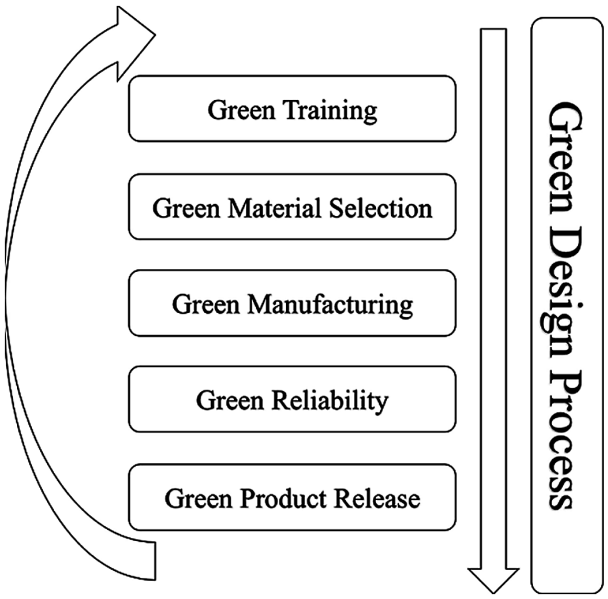
The recycle stage indicates the volume of used products that will be collected after the end of life cycle, and is continuously shorter.

4. Design for Reuse

Companies can achieve and be benefited by waste management, taking as an advantage the reuse of the initial product, reducing ecological risks, and improving process efficiency with the final result of creating products and processes that are environmental friendly throughout its life.

Incorporation of GPD into a SC

Converting the TPD process into a GPD process takes efforts. Going green is a term not well understood, and has many economic and technical implications from the materials being used to the type of energy, and the quantity being consumed.



A product can be regenerated into a green one for its coming generations and the cycle that is followed to create a GPD process is shown in Figure 4.

1. Green Training (GT)

The first step into transforming TPD development is the GT. The personnel involved into the development of the product from its conception to release and final distribution needs to be educated into the green way of doing things. The approach is to find the right recipe to develop a product that will meet the quality of a regular product, the expected life cycle, the lower use of energy, the easy disassemble and the potential recycle and reuse at the end of its life.

Figure 4. Green product design incorporation process

The technology, the method and tool research relating to a green product is important therefore there is imperative to conduct an environmental research. In the case of developing green material a publication needs to be issued in order to expand knowledge and establish investigation networks among the globe. GT should be strongly implemented in engineering and purchasing groups as these are in direct contact with suppliers.

a. Green Engineering Group

The Engineering group is formed by three areas that develop and manage the conception, process and finally control the manufacturing of any product.

- **Product Engineering Group:** The initiator of the concept, it has a close relationship with the rest of the departments within the company such as process, manufacturing and purchasing. This group needs to be trained to learn how its decisions impact the rest of the SC organisms. It is key to know what green materials can be used, reduce the number of components in one assembly to minimize the energy consumption and number or processes involved when manufacturing a product.
- **Process Engineering Group:** The importance of having a GT applied to this group relies on the need to teach the members of this group how to communize production processes or steps in order to eliminate redundant operations saving energy consumption and perhaps material waste.
- **Manufacturing Engineering Group:** This group is in charge of all the manufacturing of the product therefore the importance as to what materials can be reused with the existing manufacturing tools, what considerations need to be taken to avoid risks for the product being built, what disposal needs to be performed to the waste of the material and the recycling rate that some materials can offer.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

b. Green Purchasing

The purchasing department is extremely important due to the nowadays industrial globalization, where economic networks need to arise and manage the demanding market. Buyers are in the perfect position to identify an ecological hazard and generate requirements for suppliers to meet. Green standards in purchasing provide a basis for constructive negotiation with suppliers and should encourage the impulse of the activities with their own SC providers.

2. Green Material Selection (GMS)

The ISO 11496 specifies a system to uniform marking of products that have been fabricated from plastics materials; intended to help identify plastics products for subsequent decisions concerning handling, waste, recovery or disposal.

Material coding is also important when disposing the products that reached its end of life providing an immediate identification of hazardous from non-hazardous materials. For example, when applying a revision on material such as the automotive regulation of removing lead from all components and boards, a new part number should be assigned to distinguish them from lead-based ones.

Ever since the restriction on hazardous substances in regulations took effect, companies have put into a great number of resources and costs in respond to the management of hazardous substance after realizing that numerous certainties still exist in current management methods, the International Electro technical Commission (IEC) setup the Hazardous Substance Process Management (HSPM) standard, namely IECQ QC 080000 HSPM. Obtaining this certification can help companies mitigate risks associated with hazardous substances (Hsu & Hu 2009).

When switching to sustainable practices and greater use of organic natural materials, companies produce non-hazardous products, controls processes that can harm the environment diminishing the environmental impact. Therefore, GDP is a health concern and companies must no evade that responsibility (Smith & Yen, 2010).

3. Green Manufacturing (GM)

GM is a concept that is implementing the current industrial processes, its emphasis is on the use of green design of products reflected by reducing parts, rationalizing materials, using green raw materials, reusing components, using eco-friendly packaging among others. The main characteristic of GM is that minimizes waste and pollution throughout the complete manufacturing process.

It is vital for a company to enhance its ability of improving energy utilization efficiency through inner energy audit and energy management. All the current Lean Manufacturing methods which primary objective is to eliminate waste in a production process are associated with energy and resource consumption. In current GSC when selecting a supplier not only the well-known attributes are evaluated, also the green criteria is incorporated into the evaluation. In order to eliminate waste, there has to be a better use of the current industry resources when manufacturing the product.

GM is the only way of building products with sustainable development strategies using the modern technology and the lessons learned of previous processes and products.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. Green Reliability (GR)

Each aspect of going green has reliability implications due to the intrinsic reliability risks that arise when material properties, material substitutions or components replacement are incorporated. Companies have yet to understand the reliability aspects when going green. If a product fails prematurely, the guidelines call out how to dispose of the product, nevertheless reliability engineering offers solutions for preventing it from failing. Reliability engineering is going to play an important role in all the enterprises because they are trying to replace a current material used in a product that must be as good or better. Some of the emerging requirements are; higher reliability, warranty requirements, new materials properties.

To fulfilling the last requirements in GPD, some authors are focusing their research in determining the main tasks and activities for a successful GPD (Gmelin & Seuring, 2014). There is a consensus about the important role that human resources play, including the technician's knowledge and abilities the management commitment with resources supply (Wong, Lai, Shang, Lu, & Leung, 2012) and the supplier capacities, attributes and relationship (Khor et al. 2013).

CONCLUSION

The presented chapter brings initiatives and describes the current situation and potential growth of the GSCM and GPD in the industry. The GPD application studies presented in this work do present to have direct impact on firm's internal and external performance outcomes. Various studies found significant positive relationship between GPD and environmental outcomes. Designing green products, packaging and greening manufacturing processes, business organizations can generate benefits to the environment, in the form of reduced waste and better resource utilization, in parallel to economic benefits and cost reductions to the organizations. Inside the company, GPD practices have a significant effect in reducing consumption of hazardous materials and wastes that potentially may have negative effects internally. Outside the company, GPD practices have positive effect on the natural environment through reducing the use the amount of materials and energy that would be translated into emissions and wastes throughout product life cycle. This indicates that GPD practices can be of value to the organizations as well as to the external environment.

Therefore, GPD practices do play significant role in achieving economic, social and environmental requirements.

ABSTRACT

This study aims to examine how ethics and buyer-supplier relationship can contribute to enhanced innovative green procurement performance in the South African context. The hypotheses of this study were tested based on the data collected from manufacturing companies. Data collection involved convenience sampling and survey methodology in a research setting using procurement managers as subjects. The construct measures were based on existing measures and previous research studies. The reliability and validity of items were tested using exploratory factor analysis. Further the output of exploratory factor analysis was used as an input in the regression analysis using SPSS 20.0 version. The findings suggest that that supplier subtle practices; buyer-supplier bonding; continuous education and training and creativity and innovation are found to be strong determinants of innovative green procurement performance. The present study is unique in terms of scope and its contribution to both buyer-supplier relationship theory and practice.

INTRODUCTION

Procurement management is the management of external resources that are necessary for managing the primary and support processes of the organization (Van Weele, 2006). In today's dynamic business environment organizations mostly outsource business activities and therefore, procurement management has transformed into a functional domain of strategic relevance (Rajagopal and Bernard, 1993; Fernández and Kekale, 2007; Weele and Raaij, 2014). Gradually the concept of green procurement has evolved to meet the modern organizational requirements. Today, almost all world class organizations practice new and innovative eco-friendly methods of production (Bag, 2012). green procurement promotes sustainable production and consumption (Liu et al., 2012; Tanner and Kast, 2003). Recently, there has been increasing number of studies on Green procurement (Ehrgott et al., 2013; Kumar Sahu et al., 2014; Chekima et al., 2016; de Medeiros et al., 2016; Akhavan and Beckmann, 2017; Ateş et al., 2017; Bag and Gupta, 2017; Brewer and Arnette, 2017; Li and Huang, 2017; Yan et al., 2017).

Bag, (2016b) argued that collaboration, cooperation and coordination both with internal and external stakeholders enhance green procurement performance. It has been established that trust plays a critical role in the relationship between buyer-supplier relationship and innovative green procurement performance (Bag, in press). Also it is interesting to note that bringing the suppliers into confidence before taking any major decisions or initiating any new project strengthens the tie between buyers and suppliers by building a sense of confidence, pride and belongingness in the minds of the suppliers (Gupta and Narain, 2012). Therefore, it is evident that strong buyer-supplier relationships are necessary for improved innovative green procurement performance. However, every purchase decision has ethical, resource, waste and community impact implications (Young et al., 2010). So it is obvious that green procurement will also involve more ethical decision making at every stage of the procurement process.

Jonnes (1991) defined ethical decision as a decision that is both legal and morally acceptable to a bigger community. Interestingly, environmental or 'green' purchasing, and activities dealing with human rights such as purchasing from suppliers that use child labour and supplier deceitful and subtle practices are rarely mentioned in the ethics literature and is considered as a gap in the existing literature which further motivated the researchers to pursue the current study.

The purpose of the current study is to examine how ethics and buyer-supplier relationships can contribute to enhanced innovative green procurement performance in the South African steel and engineering industry.

This research has the following objectives, as follows:

- To identify various variables to Ethics from South African steel and engineering industry viewpoints;
- To identify various variables to Buyer-Supplier relationship from South African steel and engineering industry viewpoints;
- To understand relationships among identified variables to Innovative green procurement performance;
- To suggest a model for innovative green procurement performance from South African steel and engineering industry.

The chapter is organised as follows:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Variables have been identified through reviewing procedure of relevant literature which has been presented in the *Literature Review*. Research methodology used in the present research has been explained in *Research Methods*. The results and discussions of this research are presented in *Data Analysis and Findings*. Conclusions drawn from the study, social implications and future research directions are provided in the *Conclusion*.

LITERATURE REVIEW

In this section, the review of literature is conducted considering selected papers from reputed journals such as *IJLRA, IJPE, IJPR, IJLSM, IJPM and SCM.* Authors have made an effort to discuss Ethics, Buyer-Supplier relationship and Innovative green procurement performance in the sub-sections.

Ethics

Jonnes (1991) defined ethical decision as a decision that is both legal and morally acceptable to a bigger community. Environmental factors (work, personal, professional, governmental, legal, and social) join individual attributes to affect the ethical decision process.

Rest (1986) presented a theory of individual ethical decision making that can easily be generalized to organizational settings.

Ethics is an important dimension of purchasing and supply management and forms a part of course curriculum in purchasing and supply management (PSM) courses. Birou et al. (2016) has conducted an interseting survey on purchasing and supply management courses and their teaching approaches. It was found that basic understanding of ethical and professional standards among PSM professionals is part of the learning objectives for undergraduate purchasing courses and normally instructors utilise average 3.25% of class time covering the topic on ethics.

It is worth to understand what basically influences purchasing ethical decisions. We know that values are one of the important dimensions of culture. Certain values particularly professional responsibility and beneficence are driving actions of purchasing professionals. Other values such as truth and justice are also important. Landeros and Plank, (1996) has shown the linkage of values to behaviours and the potential to better understand ethical versus unethical behaviours in terms of values and value tradeoffs.

Now, let us look into the ethics literature for selecting relevant studies and further developing the building blocks of the study.

Several researchers used innovative tools to capture the data more accurately. Wood, (1995) instead of using traditional open ended questionnaire, used an interesting methodology to capture richer insights of the organizational factors which influence ethical practices. Respondents were asked to mention one or multiple situations they have experienced where ethics were a major concern. Further they were also asked to explain how they resolved that situation effectively.

Cooper et al. (1997) conducted a study to firstly identify the key ethical issues faced by procurement professionals and secondly to identify various organizational factors which are helpful or presenting challenges to their working environment for acting ethically.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Carter (2000a) found that unethical practices in buyer supplier relationships are related to two broad categories of antecedents i.e. internal organizational characteristics and external, inter-organizational characteristics.

Carter (2000b) argued that a buyer's deceitful practices produce a significant, negative effect on supplier satisfaction, while there is no relationship between subtle practices and supplier satisfaction.

Another study by Ellis and Higgins (2006) offers a critique of the strategic consequences of Codes of Practice, specifically codes that have apparently been developed to guide ethical practices in supply chain management.

Karjalainen et al. (2009) explored the area of non-compliant purchasing behaviour, also known as "maverick buying": employees, both purchasing and non-purchasing, who buy goods and services outside of established contracts or procedures.

Eltantawy et al. (2009) concluded that strategic supply management skills and perceived reputation have a positive direct impact on performance. Supply management ethical responsibility is not directly affected by skills and has an indirect impact on performance through its positive relationship with perceived reputation.

From the above studies a conclusion can be drawn that ethical decisions lead to promote greater transparency and can be of great importance from green procurement perspective.

Buyer-Supplier Relationship

In the early nineties buyer-supplier relationship management started gaining more attention from supply chain researchers. Buyers gradually started reducing the supplier base and focused specifically on developing a handful number of strategic suppliers. In that process buyers treated key suppliers as close partners and started sharing confidential information, discussed long term growth and developmental plans with them. This lead to enhanced mutual dependency and ultimately more satisfaction is derived from the relationship (Moeller et al., 2006; Yazici, 2013; Hooshangi et al., 2016).

Burki and Buvik (2010) found that relationship duration is a significant antecedent in overcoming firm's difficulties in business relationships and also enhancing relationship quality. Rutherford et al., (2008) argued that buyer's perception of both the salesman and selling firm's commitment have a significant positive relationship with buyer's propensity to stay. Steward et al., (2010) found that buyer intraprenuerial ability and skills positively influences the quality of internal and external supplier relationships. Bag, (2016c) found that soft skills of green procurement workforce are essential for managing the green practices effectively.

Buyer-supplier relationship management can influence firm's performance with regard to innovation and operational efficiency (Revilla et al., 2013). Therefore supplier selection and evaluation criteria's must be carefully considered before finalizing a supplier. Perez-Arostegui et al. (2012) recommended to use reliability and quality as key criteria's' while selecting suppliers.

Previous researchers have used Institutional theory (Hemmert et al., 2016); Relational exchange (Srivastava and Singh, 2013); Principal-agent theory (Steinle et al., 2014; Wandfluh et al., 2016); Resource-based theories (Gualandris & Kalchschmidt, 2016); Transaction cost theory (Cox, 2007; Abd. Rahman et al., 2009); Agency theory (Norrman, 2008) and Social network theory (Bag, 2016a) as theoretical lens to study links in buyer-supplier relationship management.

Innovative Green Procurement Performance

Venkatesh and Luthra (2016) suggested manufacturing firms must consider procurement function as a strategic enabler for business sustainability.

Green procurement promotes business sustainability in terms of better inventory management, sustainability in production (producing first time right product and less wastage), and sustainability in distribution (Bag, 2016d).

Thus green procurement practices is all about considering social, environmental and financial aspects in making procurement decisions (Walker et al., 2012). From the recent research work in the area of green procurement it was found that green procurement practices cannot achieve success without integrating the component of innovation. Innovation must be intertwined in the fabric of green procurement for firms to become creative and go green effectively (Bag, 2016b). Now, readers may wonder why firms focus on innovative green procurement practices. It is certain that there are some pressures in the surrounding business environment which drives green procurement in organisations. From the literature it is evident that both regulatory pressures and market pressures are the critical green procurement drivers which ultimately enhance customer satisfaction (Dubey et al., 2013 and Luthra et al., 2014).

However, the success stories are few and most firms fail because they do not measure the innovative green procurement performance. Firms must focus both on green purchasing effectiveness and green purchasing efficiency which will ultimately lead to the final outcome i.e. enhanced innovative green purchasing performance.

Every firm has certain business objectives which further funnels down to operations and purchasing sub-objectives. Therefore, every firm need to measure performance to evaluate how far it is from the set goals. Also they must identify the strengths and weakness to further initiate performance improvements programs (Van Weele, 2006).

Firms must note that other than financial measures, non-financial measures also add significantly in the procurement performance (Kakwezi and Nyeko, 2010).

Green procurement and efficient order processing report (2015) shows that organizations with green procurement policies have more efficient order processing and higher numbers of purchase order line items processed. Therefore efficiency of green procurement process may be considered the first parameter for performance measurement.

Bag (in press) argued that there is more openness and transparency in the green procurement process which ultimately helps in improving trust in the buyer-supplier relationship. It includes discussing green procurement policy; publication of the results of the green procurement tendering process and discussing the long term strategies with key suppliers. So we may consider openness and transparency in the green procurement process as the second parameter for performance measurement.

Green procurement contract management is very essential to further avoid any conflict at a later stage. Developing green supplier scorecard system and periodical measurement of performance will help to derive the potential environmental and ethical benefits. Green procurement contract management and green supplier performance may be considered as the third parameter for performance measurement and indicators will include on time delivery, environmental quality management, ethics, relationship management and green contract management.

The professionalism of the procurement workforce may be considered as the fourth parameter for performance measurement. In case the procurement personnel are not competent to handle the complex

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

procurement activities, they will not be able to add value. The indicators include capacities and training of green procurement workforce.

Green procurement cost is the fifth parameter for performance measurement. UN Procurement Practitioner's Handbook shows that firms' can save directly or indirectly by implementing green procurement. However, it involves long-term efficiency savings and more efficient and effective use of natural resources.

Creativity and innovation is the sixth parameter for performance measurement. Unlike traditional procurement all modern procurement process includes sourcing ideas. Today creativity and innovation is considered the core of procurement competencies.

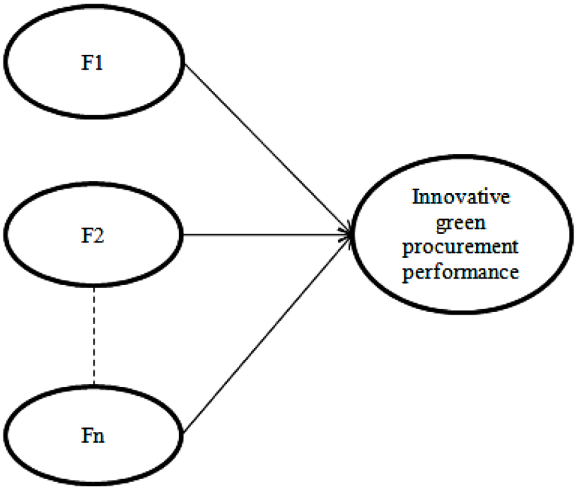
Theoretical Perspectives on Ethical Decision, Buyer-Supplier Relationship, and Innovative Green Procurement Performance

Supply management ethical responsibility antecedents include personal demographics of the buyer, top management support, presence of a company policy on ethics, periodic policy reviews, the amount of training that a buyer receives, sanctions against unethical behaviour, the length of time that the buying firm has had a relationship with a supplier, and the level of coordination that the buying firm has with a supplier (Eltantawy et al., 2009). Therefore, from the past studies it is established that ethical decision in procurement management is linked with buyer-supplier relationship management (i.e. length of relationship and level of coordination between buyer and supplier). Now, our next effort will be towards establishing a link with innovative green procurement performance. Organizations normally analyse carefully all possibilities associated with implementing a green procurement policy, such as potential environmental and ethical benefits.

Dubey et al. (2014) found that waste reduction through collaboration is a positive determinant of environmental performance. Innovative green procurement is used as a tool to enhance the economic, social and environmental development of recipient countries. Innovative green procurement seeks to follow a number of safeguards and checks in the procurement process to positively assist in the areas such as human rights, labour rights, environmental impacts, local entrepreneurship, empowerment women, poverty eradication and governance. In every step of innovative green procurement process ethical decision making is involved.

Dubey and Bag (2013) found that buyer-supplier relationship management is the positive determinant of environmental performance.

Therefore, on the basis of existing literature review it can be argued that ethical decision and buyer-supplier relationship influence innovative green procurement performance, here author propose the conceptual framework for the current study and further presented in Figure 1.



Research Hypotheses

The following hypothesis has been proposed based on the review of existing literature and further discussion with supply chain experts.

H1: Satisfaction with supplier relationship positively influences Innovative green procurement performance.
H2: Supplier subtle practices positively influence Innovative green procurement performance.
H3: Safety, health and environment positively influence Innovative green procurement performance.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Research framework

H4: Buyer-supplier bonding positively influences Innovative green procurement performance.
H5: Supplier deceitful practices positively influence Innovative green procurement performance.
H6: Customer focus positively influences Innovative green procurement performance.
H7: Continuous education and training positively influences Innovative green procurement performance.
H8: Creativity and innovation positively influences Innovative green procurement performance.

RESEARCH METHODS

This section comprises the strategy adopted for data collection, identifying measures and conducting non-response bias testing for the study.

Data Collection

The survey instrument included dimensions of Ethics, Buyer-supplier relationship as well as Innovative green procurement specific constructs. The procurement managers of steel and engineering sector were selected to seek responses. The target sample frame consisted of South African firms who have successfully implemented innovative green procurement practices. The samples were derived on the basis of convenience sampling technique. In this case email survey method was employed. The initial email consisted of cover letter and the questionnaire. Email list has been compiled from Steel and Engineering Industries Federation of Southern Africa (SEIFSA) database.

Before questionnaire was finalized for final survey, it was pretested with ten experts from the industry who are having work experience for over fifteen years and professional members of Mining Industry association of South Africa (MIASA) and CILT SA. Based on the pretesting the questionnaire was slightly modified for more clarity of few items. The final instrument for the final survey was measured basically using a five point likert scale. The first section of the questionnaire includes questions on dimensions of Ethics in terms of thirteen items. The second section includes questions on dimensions of buyer-supplier

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

relationship in terms of twelve items. The third section includes questions on dimensions of Innovative green procurement practices in terms of seven items.

Initially, the questionnaire was sent to a sample size of 150 companies. Two weeks after sending the initial email, a gentle reminder email was sent to all potential respondents. Those respondents who did not reply within another 4 weeks were further telephoned and second friendly reminder was sent. In response, researcher received total 100 usable questionnaires, an effective response rate of 66.6%. The overview of responses is presented in Table 1.

Measures

Extensive literature review was conducted to identify the theoretical constructs for current study. Therefore, the constructs has been adopted from previously tested scales. Ethics captures the success of relationship between buyer-supplier relationship and innovative green procurement performance using seven key indicators as outlined by Landeros and Plank, (1996). Buyer-supplier relationship management includes trust, power, commitment and involvement (Giannakis, 2012).

The demand of innovative green procurement has been rapidly changing and firms have adopted more innovativeness to achieve the desired results. Firms use different tools and techniques to measure green procurement performance which differ from the traditional procurement process. The indicators related to this construct have been considered from past studies such as (Dubey et al., 2013; Blome et al., 2014; Bag, 2016b). This construct intend to measure the degree of openness and transparency of the green procurement process, green contract management and supplier performance, level of professionalism of the procurement workforce, green procurement costs and lastly the degree of creativity and innovation achieved from green procurement practices.

DATA ANALYSIS AND FINDINGS

This section presents the data analysis conducted for the research and the related findings.

Exploratory Factor Analysis

Before conducting the EFA analysis data exploration was carried out. Further the data was coded and all necessary assumptions of parametric tests were checked before conducting the data analysis.

In the first step data cleaning was done. All statements are checked for presence of any missing value. However, no missing values were found in the SPSS output. Secondly, the standard deviation of all responses was checked and no values were found to be zero.

Table 1. Sample overview

Type of Companies	Annual Turnover	n	Percentage
Exempted Micro Enterprise (“EME”)	< R10 million	25	25
Qualifying Small Enterprise (“QSE”)	<R50 million	35	35
Generic (‘GEN”)	>R50 million	40	40

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Thereafter, principal component analysis was run to conduct the exploratory factor analysis. Further, the anti image correlation and its diagonal elements was checked. For this purpose the results were copied and pasted in excel and by using conditional formatting so that values greater than 0.60 were highlighted. All diagonal elements were above 0.60 and therefore found fit for further analysis.

Next, we checked the communalities to see if all values are above 0.50 i.e 50%. The values are presented in Table 2 (see appendix). All values were above 50% and therefore all statements were retained for further analysis. The total variance explained by factors is presented in Table 3 (see appendix). The first factor explains more than 18 percent variance; second factor explains over 14 percent variance and third factor explains more than 10 percent variance followed by other 8 factors. Eigen values greater than 1 were only retained. Here 11 factors were retained and cumulative variance explained is more than 84 percent. Also Varimax rotation was done to equally distribute the variance. While running factor analysis the following two options were selected: sorted by size and suppress small coefficients. The component matrix is presented in Table 4 (see appendix). The results of rotated component matrix obtained have been presented in Table 5 (see appendix). Also the component transformation matrix is calculated and presented in Table 6 (see appendix).

Only values above 0.50 were retained and cross loadings were removed. The final 9 factors are presented in Table 7 (see appendix). Here, the reliability of factors was also checked and SPSS output indicates that the instrument and items are reliable for study.

Regression Analysis

Multiple linear regression analysis is conducted to test the functional relationship between variables.

The regression model can be represented in the form of a linear regression equation as:

$$F8=\beta0+\beta1F1+\beta2F2+\beta3F3+\beta4F4+\beta5F5+\beta6F6+\beta7F7+\beta9F9+e \quad (1)$$

$\beta0$ is the Innovative green procurement performance intercept, $\beta1$, $\beta2$, $\beta3$, $\beta4$, $\beta5$, $\beta6$, $\beta7$, $\beta9$ the slopes of F1, F2, F3, F4, F5, F6, F7, F9 and e= error

Regression Model

$$\text{Innovative green procurement performance (F8)} = 2.01+0.118F2+0.005F4+0.067F7+0.048F8+e \quad (2)$$

Table 8 (see appendix) shows the summary of regression model. The VIF value of regression output as shown in Table 8 is less than 5 which shows that regression output is relatively free from multicollinearity effect. From the regression analysis output it is found that Supplier subtle practices; Buyer-Supplier bonding; Continuous education & training and Creativity and innovation are found to be strong determinants of Innovative green procurement performance.

CONCLUSION

Earlier studies in the field of green procurement have mostly focused in indentifying the drivers and barriers such as (Walker and Phillips, 2008; Eltayeb and Zailani, 2010; Datta et al., 2012; Tate et al., 2012; Dubey et al., 2013). The current study has put an effort to understand the critical factors influencing innovative green procurement performance. This study is unique in the sense that it has considered very important variables such as ethics and buyer-supplier relationship in the study. From the data analysis findings it is found that supplier subtle practice; buyer-supplier relationship; continuous education and training and creativity and innovation are strong determinants of innovative green procurement performance.

In the current study it has been found that supplier subtle practices improve innovative green procurement performance. Green suppliers asking buyer for information about their competitors may basically help suppliers to come up out with more competitive solutions at a competitive pricing. Secondly, if the green supplier approaches personnel in engineering, manufacturing, or other departments outside of purchasing may help them to gather more technical information which in most cases purchaser may not be able to provide. Again this may help the green suppliers in further developing a complete green package with the complete information gathered while interacting with several departments outside of purchase. Thirdly, green supplier need to increase the prices when there is a shortage of raw material or product in the market. This is necessary to sustain in the cut throat competition else the green supplier will lose money and will ultimately be out of the business. Fourthly, supplier offering gifts of nominal value to customers and buyers is basically seen as development of good relationships and is common in South African steel and engineering sector.

The second findings from the data analysis it that buyer-supplier bonding positively influences innovative green procurement performance. Trust and commitment plays a critical role in buyer-supplier relationship. Also compatibility between buyer and supplier is seen as an important variable for successful green procurement projects.

Another interesting point which came out of the analysis is that continuous education and training positively influences innovative green procurement performance. Green procurement workforce requires continuous education and training on a periodical basis to handle complex innovative green procurement process. Top management must provide full technological support and financial support for the success of green procurement project.

Final finding shows that creativity and innovation positively influences innovative green procurement performance. Increased sourcing ideas and analytical thinking is observed among South African buyers practicing innovative green procurement. Also creativity leads to new product development and which ultimately enhances customer satisfaction.

Social Implications

Innovation is considered as a basic mantra for survival in this highly competitive market. South African steel and engineering sector is spending millions of Rand (local currency) annually to innovate and come out with new product and service offerings. However, innovation cannot be sustainable until and unless it is in aligned with triple bottom line elements i.e. Economic, Social and Environmental dimensions. Previous studies have suggested that many companies are ignoring the social element which ultimately

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

influences the innovation performance in the long term. Innovative green procurement must consider the safety and health of workers and surrounding environment. It should also consider the wages, benefits of labours and factory staff. Finally, child labour practice which is prevalent in many African countries should be eliminated and children must get a healthy environment to study and become self dependent in life. South Africa is currently bleeding due to inflation and high rate of unemployment. Large corporations should develop more innovative green products and solutions and bring to local market at economic prices. This is only possible by developing a network of strategic suppliers and cooperation from final customers. Large corporations must contribute a percentage of profit for supporting the society. There are numerous small tool makers, engineering firms who must be supported by large corporations and these expenses can be covered under enterprise development and supplier development projects. This will ultimately enhance the Broad Based Black Economic Empowerment (BBBEE) score level of the large corporations which will benefit them in qualifying government tenders. Therefore, the country can only transform by joining hands together and helping each other.

Limitations and Future Research Directions

The current study suffers from certain limitations. The study was conducted among South African steel and engineering firms based in Gauteng district. Therefore, the results cannot be generalised. Secondly, convenience sampling technique was utilised for the purpose of data collection. Thirdly, cross sectional data was used for the study. To eliminate these limitations author proposes to use longitudinal data and considering different country and sector to validate the results.

KEY TERMS AND DEFINITIONS

Buyer-Supplier Relationship (BSR): BSR involves developing strong bonds to accomplish both short and long term organisational goals. Trust and commitment is the base of such a relationship. The customer need to disclose ethical policies, confidential information and long term growth plans with key suppliers to improve the quality of supplier relationships.

Ethical Decision: Ethical decision is a decision that is both legal and morally acceptable to a bigger community. Environmental factors (work, personal, professional, governmental, legal, and social) join individual attributes to affect the ethical decision process.

Exploratory Factor Analysis: A multivariate statistics method used to uncover the underlying structure of a relatively large set of variables. It is a technique within factor analysis whose overarching goal is to identify the underlying relationships between measured variables.

Innovative Green Procurement Performance: Innovative green procurement is the selection of products and services that minimize environmental impacts. It involves sourcing ideas and includes more efficient and effective use of natural resources. Innovative green procurement performance consists of measures such as Efficiency of green procurement process; Openness and transparency of the green procurement process; Green contract management and supplier performance; Professionalism of the procurement workforce; Green procurement costs and creativity and innovation.

This research was previously published in Ethics and Decision-Making for Sustainable Business Practices edited by Ionica Oncioiu, pages 1-23, copyright year 2018 by Business Science Reference (an imprint of IGI Global).

Table 7. Final set of factors

Factors	Variables	Items	Cronbach's Alpha
Factor 1 Satisfaction with Supplier Relationship (SRS)	23	Buyer feel fairly satisfied with the performance of key suppliers	0.82
	21	Innovative problem solving skills improves supplier performance	0.87
	25	Key supplier work efficiently	0.84
	24	Buyer find real enjoyment in dealing with key suppliers	0.87
Factor 2 Supplier Subtle Practices (SBP)	6	Supplier asks buyer for information about their competitors	0.73
	3	Supplier uses backdoor selling techniques such as approaching personnel in engineering, manufacturing, or other departments outside of purchasing	0.73
	4	Supplier increases prices when there is a shortage of raw material supply	0.79
	5	Supplier offers gifts to buyers	0.78
	7	Supplier knowingly over-commits resources or production schedules	0.80
Factor 3 Safety, Health & Environment (SHE)	8	Supplier do not indulge into child labour practices	0.38
	10	Supplier focus on occupational health and safety aspects	0.75
	9	Supplier never violated human rights	0.65
Factor 4 Buyer-Supplier Bonding (BSB)	14	Trust plays a critical role in buyer-supplier relationship	0.65
	16	Commitment plays a critical role in buyer-supplier relationships	0.69
	18	Compatibility between buyer and supplier is essential for building good business relationships	0.79
Factor 5 Supplier Deceitful Practices (SDP)	1	Supplier lies to or grossly misleads buyer in a negotiation	0.92
	2	Supplier uses less competitive prices or terms for buyers who purchase exclusively from the supplier	0.91
Factor 6 Customer Focus (CF)	12	Supplier focus on customer health and safety	0.45
	15	Power balance plays a critical role in customer-supplier relationships	0.77
	13	Complaint handling is effectively done by supplier firms	0.48
Factor 7 Continuous Education & Training (CET)	29	Green procurement workforce receives continuous education and/or training on a periodical basis depending upon the level of competency of individual buyers	0.48
	28	Green procurement workforce is capable to handle complex innovative green procurement process	0.47
	22	Technological support and financial support is extended to key suppliers	0.74
Factor 8 Innovative Green Procurement Performance (IGPP)	27	More openness and transparency is maintained in innovative green procurement process	0.51
	30	Innovative green procurement include more efficient and effective use of natural resources	0.50
Factor 9 Creativity & Innovation (CI)	32	Increased sourcing ideas and analytical thinking is observed among buyers practicing innovative green procurement	0.79
	33	Creativity leads to NPD which enhances customer satisfaction	0.75

Chapter 44
Increased Value Through Sharing in Multi-Sided Markets: Sustainability With Ridesharing

Nina Tura

ABSTRACT

The demand for more sustainable business models is increasing the need for current businesses to develop their business processes and value creation mechanisms. One way to improve sustainability is sharing resources and services in a new sharing economy paradigm. This chapter builds a conceptual model for taxi ridesharing to describe the value potential that is born by increasing the efficiency of taxi businesses. First, a framework for multisided markets is built to understand the different value elements of taxi ridesharing. Then, a conceptual mathematical model is introduced to understand the value symmetries including the cost saving potential and allocation from the perspectives of the customer and the supplier. The model shows that it is possible to have a system that creates value for both the taxi driver and the passenger, while simultaneously leading to significant reduction in CO2 emissions.

INTRODUCTION

The increasing awareness and interest in sustainable innovation (Boons et al., 2013) have led companies to start looking for opportunities beyond their traditional business areas. Global demand (see, e.g., United Nations, 2015), changing customer behavior and market conditions, together with the development of digital technologies have resulted in the birth of interesting new business models. One example is the

emergence of the sharing economy where people have started to look for options for the consumption and ownership of resources. Shared services and so called peer-to-peer (P2P) rental markets are growing fast –their value reached $26 billion already in 2013 (Botsman, 2013). Today, sharing business models include a wide range of examples of sharing goods (eBay), services, transportation (Uber), accommodation (AirBnB), and money (crowdfunding) (Owyang, Samuel, & Grenville, 2014; Cohen & Kietzmann, 2014).

This relatively new business field has recently attracted the attention of both academic and managerial audiences (Botsman, 2013; Schor & Fitzmaurice, 2015; Cohen & Kietzmann, 2014; Belk, 2014). Due to urbanization challenges, people have started to look for options for non-satisfactory public transport and technologies, and digitalization has enabled new sharing mobility services to expand (Firnkorn & Mueller, 2011). The main characteristics of the sharing economy include the ability to facilitate sharing between strangers and rely upon impersonal trust. Especially ridesharing has grown in popularity as people want to travel fast, efficiently and at low cost (Kriston, Szabo & Inzelt, 2010).

One interesting sharing application is taxi ridesharing. There are several empirical modeling examples of the potential benefits of taxi ridesharing that show significant cost efficiency potential and positive environmental outcomes. (Santi et al. 2014a; d'Orey, Fernandes & Ferreira, 2012). Santi et al. (2014a; 2014b) have shown that ride combining could result in a 40% cut in cumulative trip length in New York taxi service – a significant benefit in terms of traveled distance versus additional travel time. d'Orey, Fernandes and Ferreira (2012) have estimated a potential of a 48% increase in the average occupancy per traveled kilometer. If passengers accept on average a 5-minute delay, it could be possible to share over 70% of the taxi rides in New York (Shmueli et al. 2015). Despite these examples, so far no many commercially viable services exist for taxi ridesharing.

In this chapter the focus is on understanding the potential for wide market acceptation of taxi ridesharing. There are two sides on the market: taxi drivers and passengers who share rides. In order to build a successful marketplace for sharing taxi rides, both sides of these markets need to have a sufficient number of entities. The second necessary perspective is the perceived value. In order to succeed in significant market penetration, both the buyers and sellers need to accept the new system. The necessary requirement for acceptance is that both sides need to get value from the system - the system needs to create a situation where both the buyers and the sellers feel that they benefit from it.

The challenge is to understand how this system should be built and where the value for the users would be. Introducing a sharing option might increase the level of passengers' discomfort, but as there are other benefits, such as reductions in service costs, the overall utility may rise (Ma, Zheng & Wolfson, 2013). To ensure the implementation of new business in two- and multi-sided markets, the value needs to be addressed from the perspectives of all involved parties (Adner & Kapoor, 2010). The objective of this chapter is to contribute to the literature by offering an analytical framework for understanding the limits for value creation when implementing sharing into an existing taxi company business model. The analysis of this problem requires two significant perspectives: 1) multi-sided markets and 2) value creation for both sides and between the markets. Multi-sided markets describe a business context where value is based on interaction between different types of actors (Adner & Kapoor, 2010; Ethiraj & Posen, 2013). Value can be created by direct network effects where value is created by the interaction of similar actors operating in the same markets or by indirect network effects where value is created by interactions between actors in different markets (Eisenmann, Parker &Van Alstyne, 2006).

The research question in this chapter is *How to create a sustainable business model for a taxi sharing service?* To answer this question, a conceptual framework and a mathematical model are introduced. These combine the value perspectives of both the passengers and drivers and aim at increasing understanding

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the acceptance conditions for taxi pairing service. Individual taxi ridesharing is treated as a point-like transaction, and no indirect sustainability effects are taken into account. The model shows that both the driver and the passenger gain perceived benefits but also perceived losses in the pairing of taxi rides. The model also shows that the gained efficiency benefits can be turned into monetary gains, but the division of these gains is a matter of negotiation. Effectively, the division of benefits is a zero sum game between the driver and the passenger. In this chapter value is understood as additional benefits experienced by the implementation of the service, the difference between the evaluation of benefits and costs. Besides market value, value is understood to include intangible value (e.g. soft value elements such as customer satisfaction or societal value) that may not be directly measured in monetary terms. The outcome of the study is a detailed description of how value can be determined in a multi-sided market. Understanding this market is critical in order to get a new service successfully into the market. An important aspect of multi-sided markets is that all sides of the market need to accept the new product. If either side declines adaptation, the new product will not penetrate the market.

The chapter is organized as follows: first there is an overlook to existing literature on two-sided markets and value creation. The theoretical framework is followed by an in-depth description of a taxi-sharing case. After these, the final framework for calculating the value of using a taxi sharing service is introduced, which is followed by solutions, recommendations for future research, and conclusion.

BACKGROUND

Motivation Towards Sharing Business Models

Today, sustainability is strongly present in the development of new products and services. In addition to creating sustainable value by products, technologies and processes, recent literature has paid particular attention to the creation of sustainable business models (e.g. Abdelkafi & Täuscher, 2016; Gauthier & Gilomen, 2016). In these business models the focus is on adding value to the company and stakeholders, but also to the environment and the society (Boons & Lüdeke-Freund, 2013). The practical implication of this is that monetary measurements, such as revenue or profit, are no longer necessarily the main drivers for development (Schaltegger & Wagner, 2011; Porter & Kramer 2011). Instead, sustainability-oriented measurements, such as carbon performance (Hoffmann & Busch, 2008) and resource efficiency (Chee Tahir & Darton, 2010) have become part of business and innovation development (Nidumolu, Prahalad & Rangaswami, 2009; Seebode, Jeanrenaud & Bessant, 2012). In customer markets this can be seen in the emergence of multiple examples of services based on sharing. These examples, such as transportation (Uber) and accommodation (e.g. Airbnb) demonstrate new economic thinking in which otherwise private resources (car or home) are shared by other, often anonymous, users of the same system. Both these services have been widely adopted by users around the globe, which has led to major commercial success evident in the valuation of companies such as Uber (51B$) and AirBnB (21,5B$) (Austin, Canibe & Slobin, 2015). These business models are successful examples of a sharing economy (Hamari, Sjöklint & Ukkonen, 2013).

Sharing business models rely on the idea of sharing and collaborative consumption (Botsmann & Rogers, 2010b) and P2P activities where people give, obtain and share resources (both human and physical). Value is created in many forms, including financial value (monetary rewards) and so called soft value streams of ecological and social rewards. Different types of services are emerging (e.g. bike

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and car sharing services) and increasing in importance (for example in AirBnB there were 10 million overnight stays by 2012). The sharing economy has also strong reliance on digital technologies and it involves the participation of so called high cultural capital consumers, who, instead of sharing out of necessity, elect to share (Schor & Fitzmaurice, 2015). According to Schor and Fitzmaurice (ibid.), the main motivations for participation in the sharing economy include positive economic impacts, reduced ecological impacts, increase in social connections and building social networks, as well as ideological commitment to the concepts of sharing and collaborating. The value creation activities are usually co-ordinated through community-based online services (Albinsson & Perera, 2012; Belk, 2010; Botsman & Rogers, 2010a; Hamari et al., 2015) or platforms that aim at facilitating exchanges between groups of people, establishing so called circuits of commerce (Zelizer, 2010). Platforms give common rules and build mutual trust among relative strangers taking part in sharing activities (Zelizer 2010; Belk 2014).

The motivation towards the sharing economy can arise from social, economic or technological premises. A key social driver is the increased population density that necessitates new urban solutions (Kriston, Szabo & Inzelt, 2010). The economic drivers include financial flexibility, monetizing excess or idle inventory, valuating access over ownership, or reduced transaction costs (Chui et al. 2012; Henten & Windekilde, 2016). Technological drivers are the enabling techniques, such as the increase of mobile devices, platforms and enabling payment systems (Black & Lych, 2004). Some criticism has risen concerning the complexity related to the sustainability of the sharing economy, such as deterioration of workers' rights, the sustainability benefits becoming captured into existing non-sustainable business models, or an undesirable substitution effect, such as a rebound effect resulting from increased total consumption of resources (Martin, 2016; Lopez et al.2014; Schor & Fitzmaurice, 2015; Henten & Windekilde, 2016).

Paying attention to the value proposition is crucial in establishing a functioning business model (Osterwalder & Pigneur, 2010). The interest towards sharing options is increasing, which means that companies need to pay attention to the characteristics of sharing business models. These include creating understanding of the involved stakeholders and their impact on the overall value creation and the acceptance of the business. In the following, particular attention is payed to the features of value creation in multi-sided markets.

Value Creation in Multi-Sided Markets

Value creation is a complex concept which has been studied by multiple researchers. Due to its subjective nature and multiple levels of analysis, no ultimate definition exists (Lepak, Smith & Taylor, 2007). Many sharing economy business models rely on so called two- or multi-sided markets (Adner and Kapoor, 2010; Ethiraj & Posen, 2013). According to Eisenmann, Parker and Van Alstyne (2006), in traditional value chains value is understood as flow from costs to revenue (moving from left to right). In two- (or multi-) sided markets the costs and revenue are allocated for both sides instead. This is due to distinct groups of stakeholders (such as customers and suppliers) on each side.

The literature on two- or multi-sided markets pays attention to the use of platforms to connect different consumers or consumer groups in order to internalize indirect network externalities and share their value via a functioning pricing system (e.g. Evans 2003; Eisenmann et al. 2006; Ambrus & Argenziano 2009). Network externalities are born when the utility of a consumer depends on the purchase decision of another consumer (Ambrus & Argenziano 2009). Realized positive network externalities can be seen as value appropriation. In the case of sharing the extra capacity of taxi rides, multiple positive and negative externalities are born.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In order to establish successful business models for the sharing economy, we need to create more clear understanding of how value is created and divided among the participating groups (suppliers and customers). From the business perspective, the focus is more or less in earning profits. However, understanding value from the customer perspective is more complex. Generally, the marketing literature sees customer value as a trade-off between benefits and costs that result from an exchange (see e.g. Ulaga & Eggert, 2006). Furthermore, it can also be seen as a trade-off between quality and price (e.g., Bolton & Drew, 1991; Grewal et al, 1998). The consumer behavior literature goes beyond monetary costs to include understanding psychological, emotional and cognitive factors through benefits and sacrifices (e.g. Cronin et al., 2000; Graf & Maas, 2008). Besides monetary benefits and costs, in this chapter value is seen to include also intangible factors – the additional benefits and sacrifices (i.e. value reducing elements) experienced by the taxi ridesharing service implementation. These value elements are discussed below.

Customer Perspective on Value Creation in Sharing Economy

From the perspective of the customer (taxi passenger), sharing offers an opportunity for *immediate economic impacts,* i.e. *money savings* (Schor & Fitzmaurice, 2015), as customers may *split the fares* of the service (Santi et al. 2014b). Splitting fares aims at covering the possible drawbacks of the service (e.g. the loss of privacy and extra time), with the goal of achieving wider passenger acceptance for shared services (ibid.). Furthermore, the possible benefits include *higher flexibility*, *practicality* and *better access to services*. In the sharing economy, in addition to rational value elements (such as the usefulness and quality of a product or service), we need to consider also emotional elements (Elster, 1998). These elements include *enjoyment of the activity* (Hamari et al. 2015) and the so called *"feel-good factor",* as well as other *psychological benefits* (e.g. promoting sustainability, or in rideharing fulfilling a request for help) (Schor & Fitzmaurice, 2015), as ideological issues (e.g. lifestyle, generosity, feelings and cultural issues) are strongly related to the driving motivations of the sharing economy. According to Hamari and Ukkonen (2013) the emergence of the sharing economy may help people in learning the social norms of sharing and collaboration. Furthermore, the benefits include also longer-term rewards such as *community experience* and *gift-exchange systems* (Schor & Fitzmaurice, 2015).

Although benefits exist, we should not underestimate the possible drawbacks of shared services. These drawbacks include *requirements for extra time* and *loss of privacy* (Santi et al., 2014b; Teal, 1987). For example, in the case of taxi sharing this means *passenger discomfort* quantifiable in terms of a longer travel time (Santi et al. 2014b) or sharing the ride with a stranger. In addition to emotional benefits, there might exist emotional factors hindering the development of shared business models. These could be *cognitive costs,* as there may be *perceptions of possible discomfort, risk* and *embarrassment* (Schor & Fitzmaurice, 2015). Although sharing services are argued to provide economic benefits for the customer, they may also involve *unexpected costs,* as more time and effort is needed in searching and coordination (Hamari et al. 2015).

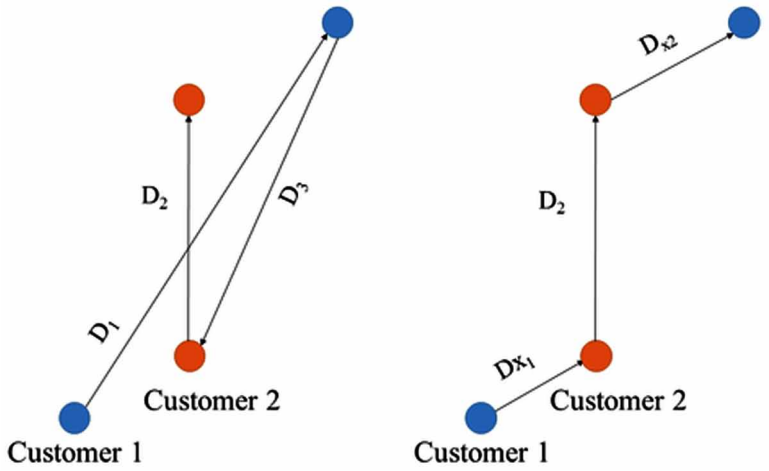
Supplier Perspective on Value Creation in Sharing Economy

From the supplier perspective, value creation is often understood via profit – monetary revenue earned from the customer minus costs. However, from the supplier perspective, the sharing business involves also other, intangible value elements, which are not always possible to measure in monetary terms.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

From the economic perspective, the sharing economy provides opportunities to deliver more value to the consumer, but also create new opportunities for the producers to *earn income*. According to Schor and Fitzmaurice (2015, pp. 12), this is because "these sites are peer-to-peer and able to re-distribute value across the supply chain, to producers and consumers, and away from middlemen." However, this can also have a negative impact on old business areas (e.g. the emergence of AirBnB has reduced the number of rented hotel rooms), and the development of internet-based platforms has created new markets that do not only complement but substitute existing markets (e.g. transportation) (Henten & Windekilde, 2016). The emergence of shared services can thus *decrease the need for the number of service providers* (e.g. reduce the need of taxi service providers / individual taxis) and *reduce the use of existing services.*

In theory, the sharing economy reduces ecological impacts (e.g. lowers greenhouse gas emissions) by circulating goods (e.g. Martin & Shaheen, 2010). For example, ridesharing is argued to help in solving traffic problems, lowering the environmental load and allowing more efficient use of all kinds of resources (Kriston, Szabo & Inzelt, 2010). From the supplier perspective, the increased efficiency can help in *reducing costs* such *as fuel and production costs* (Santi et al. 2014b). However, little research has been done on whether these benefits are actually realized or whether they are largely assumed (Schor & Fitzmaurice, 2015). *Economic rationalization* (including institutional dependencies and development realism) is seen as one of the most important barriers for companies implementing sustainability actions (Eckhardt, Belk & Devinney, 2010), which may also be relevant for the implementation of sharing models. As sharing services usually means splits in fares (Santi et al. 2014b), it is uncertain whether the incomes of executing P2P business will cover the additional costs (e.g. fuel and depreciation). Furthermore, little is known about possible *unexpected costs* (such as maintaining technologies, coordination) (Hamari et al. 2015).



The motivation for participating in sharing economy activities may also arise from the desire to increase social connections and build social networks. This may offer community experience for the customer but also allow the suppliers to *market their services, increase the awareness of the company and create new partnerships.* However, according to Schor and Fitzmaurice (2015, pp. 13): "number of platforms advertising this feature of business fail to deliver durable ties". Many shared models are highly *dependent on technologies and platforms* and require learning and adoption efforts, which may involve significant *investments* (time and monetary efforts). Also *technological risks* need to be taken into account.

Framework of the Value Impacts of Sharing Economy

In general, ridesharing business is based on sharing vehicles by passengers, including different transportation models such as carpooling and public transportation. Furthermore, dynamic (or real-time) ridesharing refers to services or systems that arranges matching rides in short notice (Agatz et al., 2012). This business of dynamic ridesharing has increased significantly over the past few years including hundreds of thousands of riders and millions of customers (Helling & Ajmal, 2017). This is an example of a new, growing industry within sharing economy (Kriston, Szabo & Inzelt, 2010) with the possibilities to provide multiple sustainability-related benefits such as reducing the number of vehicle trips and thus lowering emissions. One application of ridesharing is taxi ridesharing. This refers to model where passengers share their taxi-rides instead of taking individual rides. Figure 1 demonstrates two taxi rides that have synergies. The rides do not need to overlap fully to provide efficient pairing. The biggest benefit of pair-

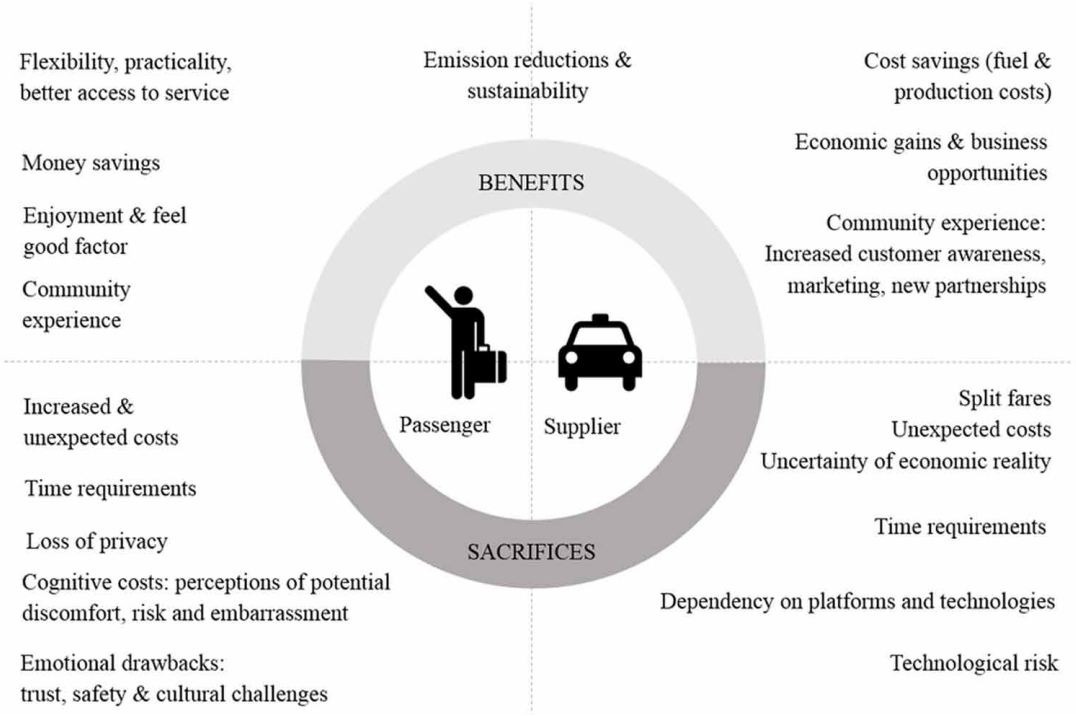
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Example of combining two rides

ing the rides is the decrease of the total driven distance. When combining the rides, the total distance is reduced significantly, which creates financial benefit potential and leads directly to CO_2 emission savings.

The sharing economy has been argued to bring multiple benefits by reducing the environmental load, increasing social well-being, and providing possibilities to gain profits (e.g. Schor & Fitzmaurice, 2015), and to work as a potential driver for radical sustainability improvements at local and global levels. As urbanization is increasing fast globally, the new forms of business are more than welcome to address the challenges of people accumulating to live in certain areas (Cohen & Kietzmann, 2014). Despite the rapid emergence of the sharing economy, little research has been done regarding value creation in the sharing economy and whether the benefits are actually realized or are just largely assumed (Schor & Fitzmaurice, 2015). In the sharing economy, the value creation of many business models is dependent on two or more independent stakeholder groups, being examples of two- or multi-sided markets (Evans, 2003). In order to take advantage on sustainability and the emerging sharing models of business we need to understand how value is created for the wide range of actors involved. Successful establishment of business in the two-sided market requires understanding of value creation and capturing activities for both stakeholder groups, as all sides of the market need to accept the new product or service.

The potential of taxi ridesharing is estimated to be huge with multiple monetary and non-monetary benefits (Santi et al. 2014a; d'Orey et al., 2012). Figure 2 summarizes the value elements of the taxi ridesharing in a two-sided market as a theoretical framework. Value is divided between the customer (passenger) and supplier, including both positive and negative value elements (i.e. benefits and sacrifices).



DESCRIPTION OF THE MODEL

In this part, a conceptual mathematical model describing the value creation in taxi sharing is presented. The model describes the allocation of different elements of value in a single sharing transaction. Value is presented as the net benefits of the monetary and non-monetary values described in the framework.

The core of understanding both driver and passenger acceptance is in understanding the logic of how value is created for both the taxi driver and the customer. The decision to adopt is a simple yes or no

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Framework of the value impacts of taxi ridesharing

situation. It is assumed that the customers and the driver will accept the pairing option when their net benefits exceed zero (1, 2), i.e. acceptance is likely if they both benefits from the pairing.

Acceptance functions (1)

$$a_c = \begin{cases} 1; NB_{c,n} > 0 \\ 0; NB_{c,n} \leq 0 \end{cases} \quad (1)$$

$$a_d = \begin{cases} 1; NB_d > 0 \\ 0; NB_d \leq 0 \end{cases} \quad (2)$$

The first part of the model is the calculation of an individual customer's net benefit (3). The two sources of value for the customer are created by monetary savings that are dependent on the price without pairing ($R_{n,a}$) and the price of a paired ride ($R_{n,s}$). In addition to monetary value, there are also various perceived non-monetary benefits (PB_n) and losses (i.e. sacrifices) (PL_n) that are created due to pairing. These components are described in the framework above. Evaluation of the size of these value components at the general level is challenging, because their relative value compared to the monetary

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

value is highly individual, as they are based on personal preferences. They can thus be argued to exists, but in our model we describe these components as compound variables.

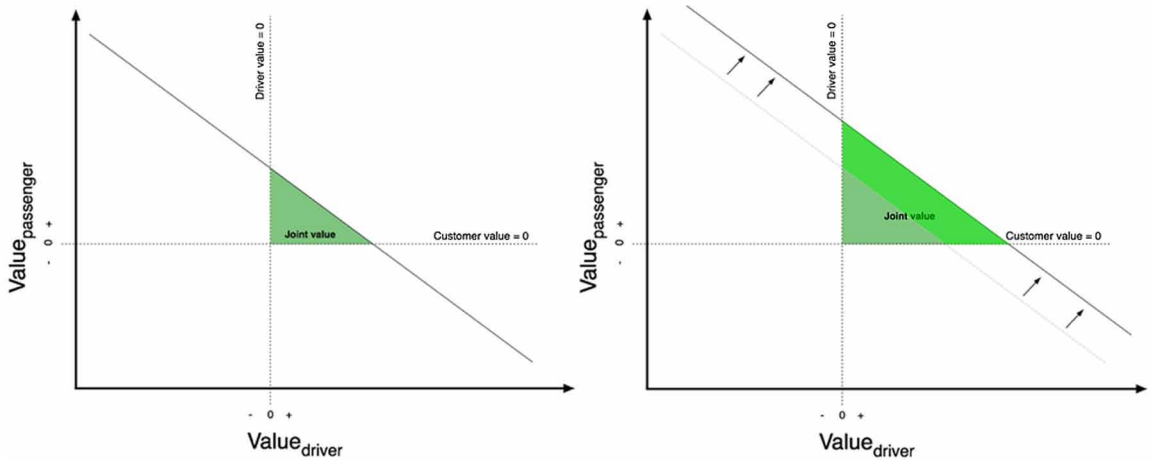
$$NB_{c,n} = R_{n,a} - R_{n,s} + PB_n - PL_n \tag{3}$$

For the drivers, the net benefits can be argued to be composed mostly from monetary value (4). From the revenue perspective, pairing the rides reduces the expected revenue, depending on the unpaired price ($S_{n,a}$) and paired prices ($S_{n,s}$). Pairing also leads to diminished driving costs, which are dependent on the total costs of unpaired rides (c_n) and the distance of paired rides (c_s). In addition to direct cost savings, drivers also get other, indirect benefits from pairing (PB_d). These benefits are created e.g. through good publicity due to green awareness and increased revenue enabled by opportunity revenues, as cars are available for additional rides.

$$NB_d = \sum_{1}^{n=c}\left(R_{n,s} - R_{n,a}\right) + \sum_{1}^{n=c} c_n - c_s + PB_d \tag{4}$$

The true value of the system can be evaluated by looking more closely at the value addition and reduction from combining value creation and perceived losses. (5,6,7). In the end, the added value of the system is created from driver's perceived benefits, cost savings from more efficient use of taxies, and each customer's perceived benefits from pairing. The only negative side at the system level is the customer's perceived loss.

$$NB_s = \sum_{1}^{n=c} NB_{c,n} + NB_d \tag{5}$$



$$NB_s = \sum_{1}^{n=c}\left(R_{n,a} - R_{n,s} + PB_n - PL_n\right) + \sum_{1}^{n=c}\left(R_{n,s} - R_{n,a}\right) + \sum_{1}^{n=c} c_n - c_s + PB_d \tag{6}$$

$$NB_s = PB_d + \sum_{1}^{n=c}\left(c_n + PB_n - PL_n\right) - c_s, \begin{matrix} \forall a_c = 1 \\ \forall a_d = 1 \end{matrix} \tag{7}$$

Pricing has a significant role when looking at the decision at the individual level. At the system level, pricing is not an issue as the total system benefit remains the same, independent of the prices. However, price is critical in defining the balance of benefits between customer and driver as these benefits from a zero-sum game (Figure 3). The more these pricing benefits are moved to the customer side (implies a low price for a combined ride), the higher levels of PLn are allowed, while the driver needs more benefits from PB_d. The opposite is true when pricing is moved to benefit the drivers more.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Perceived passenger and driver value

Non-monetary value components have a significant effect on the system level value creation. If the positive non-monetary variables are higher than the negative aspects, the overall value increases (Figure 3, right). The practical outcome of additional value creation is that it is easier to find a pricing combinations that will lead to joint value creation. The effect is reversed, if the negative non-monetary components are larger, making the creation of joint value combinations harder. This also implies that if the non-monetary benefits are extremely high, there is no opportunity for joint value creation. This may be the case when e.g. the customer finds significant discomfort from sharing a taxi and there is no monetary compensation that will negate this inconvenience.

SOLUTIONS AND RECOMMENDATIONS

This study has focused on understanding the value potential of taxi ridesharing. Taxi sharing has been found to create direct benefits for the society, such as reduced CO_2 emissions (d'Orey et al., 2012) and providing a pathway to sustainability (Heinrichs, 2013; Cohen & Kietzmann, 2014). Although the viability and benefits of taxi sharing have been identified empirically (Santi et al. 2014a; d'Orey et al. 2012; Shmueli et al., 2015), these models have not yet achieved a substantial place in the market. This raises the question of why these models have not yet become a common practice.

In order to answer the question presented above, the focus needs to be turned from system level analysis to understanding value creation for the customers and drivers. In this study, a model describing value creation for the driver and the passenger from sharing taxies has been created. The chapter presented a conceptual model for defining the conditions for the creation of a fair system for each participant. From the supplier perspective, the benefits can be defined relatively simply as the value created directly from increased revenue potential and more efficient use of resources. These value components have also been confirmed by previous studies on the topic (d'Orey et al. 2012). The customer perspective is more complex, as value from sharing is created as a combination of monetary and social value. The measurement

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of monetary value is relatively straightforward, but the measurement of the more abstract social value is challenging, as the comparison of these value components is hard and highly individual.

The goal for creating the model was to understand how a situation where all the participating actors would benefit could be constructed in taxi sharing. All combinations were found to be extremely good for the whole system, but they may not necessarily provide additional value for the participants involved. There is significant value potential in combining taxi rides, but how this value should be divided between the driver and the passenger is not self-evident. Although value is created from both monetary and social value components, value appropriation is done with the monetary component.

On the basis of the conceptual model, it is clear that an optimal value allocation scenario can be built for sharing taxies. In order to operationalize this kind of a concept for wide use, a platform is needed to facilitate ride pairing and value appropriation. As there are no current widely implemented solutions on the market, this means that a platform needs to be created for this purpose. As two-sided markets are highly dependent on a wide acceptance of the service, without sufficient density (number of necessary passengers and taxi drivers), the chance of finding a ride decreases and may also outweigh especially the financial benefits (Agatz et al., 2012). Therefore, any new system should be done initially on a large scale or the benefits from the system might be significantly decreased.

Practical examples of ridesharing are now starting to rise. Modern alternatives to traditional taxies, like Uber and Lyft have started their ride sharing services (Uber: uberPOOL and Lyft: Lyft line). Both services are still relatively new on market, but they have been steadily growing. E.g. uberPOOL service has grown from a single city pilot to cover 45 cities in the world (Uber, 2017). So far no extensive independent study on the performance level of these services and their potential social impact exist.

Another perspective to the future of ridesharing is the role of governments. Agatz et al. (2012) suggest an establishment of subsidized rideshare system (supported by the government and local businesses, such as taxis), to increase the capacity and efficiency of the urban transportation system relatively inexpensively. Some experiments on so called "hybrid" business models have also already been executed. For example, in 2012 the city of Helsinki adopted a pilot model of on-demand bus service, Kutsuplus, which combined characteristics of public transport and taxi. As an emerging service, Kutsuplus was argued to be one of the world's most highly developed trip-combining hardware using new technology and providing a solution to congestion problems (see e.g. Brustein, 2014), and it grew fast in popularity among consumers. Despite these factors, after two and half years of working, the test is now in hold, as the necessary economic and technical conditions to move the service to the hands of private actors do not exist (Sulopuisto, 2016).

The example above highlights the importance of the impact of public sector support. The society can have an effect on the birth of these models by supporting their development (for example by taxation) and encouraging the use of the systems. On the other hand, the decision makers have the power to slow down the development. Policy makers should thus provide support for the emergence of the types of platforms that make sense from economic, environmental and social perspectives. This is in line with the notion of Cohen and Kietzmann (2014) of the importance of economic and non-economic incentives by agencies in improving overall system performance and reducing conflicts between the private and the public sector. According to Demailly and Novel (2014), making the sharing economy into a sustainable economy is much dependent on public authorities and their support (i.e. ecological taxation and regulations, efficient public transportation) to reinforce the value and environmental benefits of sharing.

FUTURE RESEARCH DIRECTIONS

This chapter has presented a model that describes the value components for drivers and customers, but so far there is little to no information about the numerical sizes of these components or their priorities. First, this sets a clear need for future research to understand the different customer preferences in sharing taxi rides. One example of value asymmetry is that some customers might value the reduced CO_2 emissions as positive compared to a regular taxi ride, whereas other users would value the reduced personal space while traveling in a negative way. Even though there are several challenges in the incommensurability of different value types, the utilization of a numerical valuation method could offer interesting insights into how different customers perceive value in this context. Thus, the intangible cultural and behavioral factors that affect the value perceived by individuals could be further incorporated into the model. These could be e.g. the variables tested by Möhlman (2015), such as 'trust', that have an effect on the satisfaction experienced by the customer when choosing the sharing option.

Second, better understanding on the long-term effects of such a model to taxi markets is needed. Increasing the potential profit of a taxi car and potentially lower user prices can have a significant effect on both the supplier and customer markets. If sharing rides lowers prices significantly, it is likely that the total number of passengers will increase, thus increasing the need for more taxi services. On the driver side of the market, increasing the profit potential should also lead to an increasing interest in offering taxi services. However, for example if the increasing effect of lowering prices is not very significant, the effect from sharing might be negative to the supplier side of the market. These long-term effects need to be thoroughly analyzed in order to understand the long-term effects of taxi sharing service on the market. Understanding these dynamics may also be necessary to get drivers to accept this new service concept.

Thirdly, creating a platform for sharing taxi rides offers interesting possibilities for both drivers and passengers. This value creation ability will also create opportunities for new businesses. Finding a good way to organize such a business and the appropriate business model for the platform is a clear follow-up question for future research.

In order to create successful innovations within the sharing economy and ensure their diffusion, we need to create scenarios where all the parties involved accept the conditions and the value created. Although this chapter has shed some light on the perceptions of creating sustainable sharing business models, more knowledge is needed on how to manage public-private partnerships (Cohen & Kietzmann, 2014) and to ensure the value creation for both sides in two- (or multi-) sided markets.

CONCLUSION

Careful design and management of the business model is crucial in order to get wide acceptance for sharing models such as taxi sharing service. Although sharing business models have been identified to have an impact on promoting sustainability (Heinrichs, 2013), research on the implementation and approval conditions for these models remains insufficient. Therefore, the main contribution of this chapter is showing the potential for wide market acceptation of sharing business models. The study contributes to the literature by focusing on the case of taxi ridesharing, illustrating an example of value creation in two-sided markets. Second, authors have introduced a conceptual mathematical framework in which the value perspectives of passengers and taxi drivers are combined. Thus the study proposes boundary conditions for building the system and creating a sustainable business model for taxi ridesharing.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Taxi sharing models are an example of business in a two-sided market (e.g. Evans, 2002) in which the successful adoption of the model is dependent on the involvement of the society. Redesigning the transportation system means a structural change to the socioeconomic system, and to facilitate both firm-level and system-level sustainability, sustainable business models are needed (Stubbs & Cocklin, 2008). The emergence of the sharing economy has already enabled the birth of new types of business models and information-based systems (such as Uber). Relying purely on these often privately owned models can, however, fail in achieving the desired environmental and social goals (Cohen & Kietzmann, 2014). According to Schor (2014), the sharing economy includes a wide potential for the creation of economic value. However, this value needs to be equally shared among the different types of actors, which requires collaboration within the private and the public sector.

From the supplier perspective, the model presented in this chapter helps in understanding the possibilities to do business in a new way. As value is usually understood through money and the price of the ride, the models helps in seeing the actual business benefits of combining rides. The tighter the margins the driver gets (e.g. if the fuel prices rises), the more willing the supplier should be to combine taxi rides (as the margin of a single ride falls, the profitability of combining rides rises).

From the passenger perspective (rational decision making), combining taxi rides involves also many soft value elements (e.g. enjoyment of the activity, enhancing sustainability) which is why some passengers may be willing to share rides without higher (monetary) benefits. On the other hand, Hamari et al. (2015) argue that although people may have a positive attitude towards collaborative consumption, it does not necessary translate into actual participation. Economic benefits, such as saving money and time, have a significant effect on behavioral intentions.

In this chapter, authors have proposed a conceptual model of value sharing, which in turn raises interesting openings for further research, including better understanding of different customer preferences and long-term effects of taxi sharing (and related) models. Furthermore, to create a sustainable business model for sharing taxi rides requires the creation of a platform and management practices. An interesting aspect about the mathematical model is that it shows how pricing questions are irrelevant at the system level. However, price contributes to value allocation between individual agents and therefore plays a major role in the decision making of an individual, and the eventual acceptance of sharing. This finding underlines the importance of this study – in sustainability issues it is important to move beyond system level value towards the level of individual decision makers. This is a challenge for future research, as it should increase understanding of individual agents and the effect of their behavior on system level sustainable value creation.

KEY TERMS AND DEFINITIONS

Business Model: Description of an organization's value creation, capturing and delivering principles and related activities.

Market Penetration: A measure of the market volume of a service (or product) compared to the total sales volume of competing services. It includes activities aiming at increasing the market share of a new or an existing service.

Monetary Value: The value of a service (or product) that is received by selling. It is the sum of money that the customer is willing to pay for the service and what is consumed in providing the service.

Multi-Sided Markets: Economic platforms that have two or more distinct user groups participating in the value creation and capturing activities. These groups provide network benefits for each other.

Sharing Economy: Collaborative consumption and peer-to-peer activities based on sharing resources (goods, services), which are usually coordinated through online platforms.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Societal Value: A concept including benefits that are addressed by the society and promote the well-being of wider areas and groups of people. The benefits include for example value elements that promote the development of transportation, healthcare, education and the environment.

Sustainability: Continued economic development without reducing natural productive capacity.

Sustainable Development: Development that aims to fulfill the needs of the present without compromising the needs of future generations. Sustainability is understood through three dimensions: ecological, economic and social.

Value: The worth of all benefits and rights experienced by ownership or participation, including both hard benefits such as money and soft benefits like enjoyment of the activity.

Value Allocation: A strategy which aims at balancing the overall amount of value between the participating actors. For example in taxi ridesharing, this includes negotiations between the taxi driver and the passenger about the price of the ride. A related term is value appropriation, in which the stakeholders involved compete to capture the value created by the business action.

Chapter 45
The Italian Doctrine *Economia Aziendale* and the Primary Interest of the Organizations

Emiliano Di Carlo
University of Rome "Tor Vergata", Italy

ABSTRACT

The aim of this chapter is to enter into the debate on the objective of the firm and more in general of the organizations, in order to discuss the contribution that the Italian doctrine Economia Aziendale (EA) can give to this debate and to the sustainable economic development. To this end, it is pro-posed the concept of primary interest of the organizations, the aziende according to the EA (i.e., business entities, public administrations and non-profit organizations), which is to satisfy human needs through the production of useful goods and services (the objective of the azienda) ensuring a sustainable value creation in the short and long term (the condition for the survival and growth of the azienda). For business entities, the primary interest supports the so called 'integration thesis' according to which business and ethics can be achieved together, since the profit is considered as a condition that allows the survival and growth of the firm favouring all stakeholders and the community.

INTRODUCTION

In the aftermath of the global financial crisis, several scholars of the Italian discipline *Economia Aziendale* (*EA*) have been committed in recognizing its possible causes in the alienation of individuals involved in business from what are the right rules to well conduct the business itself, suggested by the *EA* (Cavalieri, 2009; Coda, 2010). In this line, the lecture by Prof. Massimo Saita, held at the University of Milan Bicocca in December 2014, entitled 'The foundations of *Economia Aziendale* forgotten before the crisis.'

The aim of this chapter is to enter into the debate on the objective of the firm and more in general of the organizations, the *aziende* according to the *EA* (i.e. business entities, public administrations and non-profit organizations), in order to discuss the contribution that the *EA* can provide to this debate and to the sustainable economic development.

The need to explore the suggestions of that doctrine comes from at least the following considerations:

1. The limits of some of the most popular theories on the objective of the firms, in particular shareholder theory and agency theory, that diffused the gloomy vision of human nature (Hirschman, 1970) in universities and business schools around the world (Agle, Donaldson, Freeman, Jensen, Mitchell, & Wood, 2008; Ghoshal, 2005; Giacalone & Wargo, 2009);
2. The alternatives to the shareholder theory (e.g. stakeholder theory) often do not clarify how and in what time companies should create value, with the risk to be vague and ambiguous, favouring the opportunistic behaviour of the insiders (i.e. managers and controlling shareholder) (Phillips, Freeman, & Wicks, 2003, p. 495);
3. The possibility to focus the attention on the concept of *azienda* (almost unknown outside the Italian context) using the heritage of teachings of some Masters of the *Economia Aziendale* (Amaduzzi, 1978; Ferrero, 1968; Giannessi, 1960; Masini, 1982; Onida, 1971; Zappa, 1957) about the finalism and the conditions that all *aziende* must achieve in order to survive and growth;
4. The ability to broaden the observation from the business entities (firms) to all types of economic entities (public administrations and non-profit entities), all considered as cells of the society (Amaduzzi, 1978, p. 19; Cassandro, 1969). Indeed all the economic entities can ensure the development of the economy and society (Cavalieri, 2009), participating to the common good (Caldarelli, Fiondella, Maffei, Spanò, & Zagaria, 2011);
5. With specific regards to for profit entities, the scope of analysis covers not only large, publicly held corporation, but also small and medium-sized companies, contrasting 'the tendency of management scholars more generally to concentrate on large, multinational corporations as the objects of their research' (Phillips et al., 2003, p. 495).
6. The *Economia Aziendale* connects the ethics with business decisions (Costa & Ramus, 2012; Signori & Rusconi, 2009), giving elements to support the integration thesis, in the sense that moving from the interest of the shareholders to that of the firm it can be said that not only 'good ethics is good business' (Davis, 1994), but also 'good business (for the firm) is good ethics (for all stakeholder)', in the sense that if you really care about stakeholders you should conduct the business in a profitable way.

It is then proposed the concept of 'primary interest of the *azienda*', as a principle of good governance for all organizations. This interest includes two elements: 1) the objective of the *azienda* (i.e. satisfy human needs through the production of useful goods and services); 2) a condition for the survival and growth of the *azienda* (i.e. ensuring a sustainable value creation in the short and long term). The primary interest of the *azienda* wants to support the so-called 'integration thesis' (Agle et al*.,* 2008), according to which business and ethics can be achieved together. The term "primary" is used in order to distinguish that interest from the particular (and sometimes temporary) interest of the stakeholders, which become secondary when in contrast with the primary interest of the *azienda*.

Such a proposal tries to answer the following questions which find only partial answers in the Anglo-American theories: "for whom", "how" and "in what times" companies should create value?

From a methodological point of view, the choice of the elements included in the primary interest is based on the following criteria:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Consider the effect of the objective of the *azienda* on its continuity as well as on the economic problem resolution and the ability to steer the governance toward the common good;
2. Mitigate the opportunistic behaviour against the *azienda* by the various stakeholders;
3. Avoid that the goal of the *azienda* coincides with the particular (and sometimes temporary) interest of a specific stakeholder or group of stakeholders, and at the same time avoid assigning more objectives, or an objective that is vague and ambiguous;
4. Promote the dissemination of a culture of sustainable value creation even in public administration and in non-profit organizations.

The methodological approach used in the analysis of the literature is descriptive/narrative and the points listed above represent the criteria that led to select certain authors instead of others. Thus the limit of that approach derives from the goodness of these criteria.

The chapter consists of five sections. In section two the main Anglo-American theories on corporate objective are analysed. Section three is dedicated to the description of the *Economia Aziendale* and to the concept of *azienda*. Section four proposes the concept of primary interest of the *azienda*. Section five concludes.

THE ANGLO-AMERICAN THEORIES ON CORPORATE OBJECTIVE

The Anglo-American theories on the objective (or purpose) of the corporation are shown in Table 1. The debate on what should be the most appropriate purpose of the firm aims to achieve the best solu-

Table 1. Anglo-American theories on the objective of the corporation: 'for whom', 'how' and 'in what time' create value

	Idea of Corporation as a Separate Institution	**"*For Whom*" Create Value**	**"*How*" Create Value**	**"*In What Time*" Create Value**	**Authors**
Shareholder theory	Absent	Shareholders	Resolving conflicts with stakeholders, in order to maximize profit for shareholders. The corporation is an instrument of the shareholders	Not specified, but the market pushes toward the short term	Friedman, 1970
Stakeholder theory	Absent	Stakeholders	Managing relationships with stakeholders who have conflicting interests, through the balance between contributions and rewards. The corporation is an instrument of the stakeholders	Not specified	Freeman, 1984
Enlightened value maximization theory	Absent	Shareholders	Managing relations with stakeholders, in order to maximize profit for shareholders. The corporation is an instrument of the shareholders	Long term	Jensen, 2001
Organic theory	Strong	Corporation	Not specified	Not specified	Arthur, 1987
Social entity theory	Strong	Community	Not specified	Not specified	Allen, 1992

tion, according to an utilitarian perspective (Singer, 2010), for what concern the effect that it may have on both the survival and growth of the firm and the social well being.

For example, according to the shareholder theory the welfare is maximized when firms create value for their shareholders, while for the stakeholder theory this purpose could be unsustainable, being necessary take into account and satisfy the expectations of all stakeholders.

Normally, the objective is referred to the individual, i.e. "for whom" the corporation should create value (e.g. shareholder, stakeholder, corporation itself). In addition Table 1 also contains "*how*" and "*in what time*" these theories suggest to create value. In this regards, Cavalieri (2010) argues that 'talk about creating value without any clarification on the content of that term is meaningless. Indeed, one must understand for whom, by what time references and how (i.e., under what equilibrium conditions) the *azienda* must create value' (p. 25, our translation). The specification of these elements is central for the continuity of the *azienda*, as well as for giving a guide to managers, mitigating their eventual opportunistic behaviour.

According to Meynhardt (2009) the term "Values" 'is one of those ambiguous container terms with enormous promise of insight but no widespread consensus' (p. 196). Rescher (1969) states that 'Philosophers and social scientists concerned with value questions have long recognized the need for a more precise value terminology to facilitate the exact formulations needed in scholarly and scientific contexts' (p. 2).

Only the enlightened value maximization theory explicits all the value creation conditions. As part of the theories mentioned, it is possible to distinguish those with a strong idea of the firm as a separate institution from its stakeholders and, therefore, with its own purpose, from those for which the company is an instrument to satisfy the interests of a group of individuals (e.g. shareholder or stakeholders).

The *shareholder theory* has influenced the attention of scholars of management and governance for several years clarifying strategies and behaviour of firms (Friedman, 1970; Rappaport, 1990). For that theory, the agents (managers) have a moral obligation to maximize the principals (shareholders) wealth, i.e. 'conduct the business in accordance with their desires, which generally will be to make as much money as possible' (Friedman, 1970). Being the firm a legal fiction, an instrument owned by the shareholders to maximize their profit (Jensen & Meckling, 1976), the interests of the firm and shareholders coincide (Allen, 1992). This is confirmed by the fact that in some cases the concept of creating value for the shareholders is used as a synonym for creating value of the corporation (e.g. Alexander & Cohen, 1999, p. 3). The short-term orientation of that theory comes from the fact that markets are not likely to capture the ability of the company to create value in the medium and long term (myopic market model), or they are simply interested in the short term (Dallas, 2011; Hayes & Abernathy, 1980).

Unlike the shareholder theory, the *stakeholder theory* (Freeman, 1984) draws attention to the need to balance the value creation for shareholder with the value creation of all the other stakeholders. The firm is an instrument to create value for all its stakeholders. The reason behind that theory derives from two approaches: normative and instrumental (Donaldson & Preston, 1995). The normative approach recognizes the existence of an ethical dimension (Phillips et al. 2003, p. 481) in addition to the economic and legal ones, a moral duty for those who governs the company to consider the rights of all those involved. According to the instrumental approach, managers have to pay attention to the other stakeholders because is the best way to create value for the shareholders (Jones, 1995; Plender, 1997).

However, one of the limits of the stakeholder theory is viewed as leaving too much discretion to managers (Keay, 2008, p. 20). In this regards (Tirole, 2010) states that 'management can almost always rationalize any action by invoking its impact on the welfare of some stakeholder' (p. 62). Moreover,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Jensen (2001) points out that stakeholder theory 'allows managers and directors to devote the firm's resources to their own favourite causes—the environment, art, cities, medical research (…) By expanding the power of managers in this unproductive way, stakeholder theory increases the agency costs in the economic system.' (p. 14). Phillips et al. (2003, p. 495), analysing the challenges of stakeholder theory, state that managerial opportunism still represents a threat to the organizational effectiveness.

The shareholders *vs* stakeholders debate has interested many scholars in the last decade (Asher et al*.,* 2005; Freeman, et al. 2004; Jensen, 2001; Keay, 2008; Sundaram & Inkpen, 2004; Tirole, 2010). Comparing shareholder theory and stakehodler theory, Jensen (2001) argues that shareholder theory and stakeholder theory can be considered jointly in what he calls '*enlightened value maximization*' (also called 'enlightened stakeholder theory'). This approach draws many concepts of the stakeholder theory, but at the same time puts the maximization total long-term firm market value as a necessary criterion to define a compromise between the various stakeholders. In other words, the long-term orientation is the element that allows, in maximizing the shareholder value, to take into account the expectations of the other stakeholders.

This orientation provides the solution to the problems that arise in the identification of multiple objectives of stakeholder theory, providing managers with the criteria for the right balance between stakeholders. In this regards, Jensen (2001) points out that 'telling a manager to maximize current profits, market share, future growth in profits, and anything else one pleases will leave that manager with no way to make a reasoned decision. Indeed, it leaves the manager with no objective. The result will be confusion and a lack of purpose that will handicap the firm in its competition for survival' (p. 11), increasing the agency costs and damaging the social wealth.

Unlike the settings that move between shareholder and stakeholder theory, organic theory and social entity theory consider the firm as a separate institution from all its stakeholders and with its own interest (Lan & Heracleous, 2010).

The *organic theory* does not accept that only the individual can be considered as a legal person worthy of protection. In fact, with specific reference to the corporation, they are separate legal entities with respect to the owners (Arthur, 1987). For this reason, corporations, having legal personality, should be compared to a citizen with its responsibilities (Dodd, 1932). The assumption that the enterprise is comparable to an individual is clearly opposed to the agency theory (Jensen & Meckling, 1976) and contractual theory (Coase, 1937, p. 311), which sees the company as a set of contracts, an artificial person created by the law.

The *social entity theory* considers the corporation as a social entity formed through political and legal processes, in order to meet social welfare (Allen, 1992). In this sense, the corporation can be considered as a political tool for social purposes. The company would be formed through political and legal processes, in order to meet social welfare (Allen, 1992; Arthur, 1987; Lan & Heracleous, 2010). The company, therefore, would not only have financial obligations towards the shareholders, but also to the community. As good citizens, businesses should contribute to the social well-being.

The problem with organic theory and social entity theory is that the concept of value creation is vague and ambiguous, since they do not clarify: 1) how the corporation should create value, in particular how to solve the trade-off between the interest of the company and the interest of its stakeholders; 2) what is the role of stakeholders in the value creation for the corporation; 3) in what time the corporation should create value; 4) how to minimize the managerial opportunism against the interest of the company and its stakeholders.

THE *ECONOMIA AZIENDALE* AND THE CONCEPT OF *AZIENDA*

Economia Aziendale (*EA*) is an Italian doctrine founded in 1927 by Gino Zappa (1927) who focuses on the '*azienda*' as a coherent unity (i.e. inseparability) of 'economic operations' (Cinquini & Marelli, 2007; Viganò & Mattessich, 2007, p. 25), which characterises institutions (i.e. for-profit organization, public administrations, and non-profit organizations). Zappa (1956) defines the *azienda* as an 'economic institution intended to last for an indefinite length of time and that, with the aim of meeting human needs, manages the production, procurement or consumption of resources in continuous coordination' (p. 37, our translation), and *EA* as a unitary science that studies the 'existence conditions and life manifestations of the *azienda*' (Zappa, 1927).

The Italian School of Accounting and *Economia Aziendale* (Sidrea, 2009) proposes the following three attributes that allow distinguishing the *azienda* from the world of economic organizations (see also Cavalieri, 1999):

- Systemic coordination;
- Decision-making autonomy;
- Economicità;

The *azienda* is a system in the sense that its parts (e.g. assets such as machinery, equipment) and participants (i.e. persons involved in the production process) are not separated; instead they are coordinated and integrated, they are bounded together in order to achieve the *azienda*'s interest (Bertini, 2014; Coda, 2010). The *azienda* 'is not identified with the owners, the capital, the assets, the people taking part in it or with the contracts or the relationships among its components, but rather it is an autonomous and real entity composed of all these elements and the relationships among them. It is very important to point out the concept of system which is used by Zappa but not fully explored (…) In the *azienda*, the components will change, the elements will modify, but the whole will persist' (Signori & Rusconi, 2009, p. 308). Onida (1971) emphasizes this concept, defining the *azienda* as a dynamic system in which the 'unity in the variety and permanence in mobility, comes true in a vital synthesis' (p. 4, our translation).

Amaduzzi (1936) points out that the *azienda* is 'a system with economic dynamics for the achievement of one given purpose' (p. 18, our translation). Such a system 'can be understood and studied only as a coordination of forces which act and change without interruption' (p. 18, our translation).

The systemic vision basically involves the integration of all operations in order to achieve the objective of the organization and allows understanding the importance and the relativity of each behaviour and operation.

The *azienda* should have a decision-making autonomy (the second attribute) in the sense that in achieving its purpose it should be not subjected to the direction of other individuals or organizations (Airoldi, Brunetti & Coda, 2005; Cavalieri, 1999, p. 119). In other words, the *azienda* must be independent from external dominant pressures. For instance, if Entity A controls and manages Entity B (i.e. Entity A and Entity B form a business group), thus entity B does not have a decision-making autonomy, being a sub-system of entity A, consequently A and B are parts of the same *azienda*. More precisely, the *azienda* has a decision-making autonomy when it can autonomously achieve its objective. The objective can be also assigned by other entities (e.g. entity A gives the objective to Entity B), what it is relevant is that the *azienda* is autonomous in achieving that objective and that its activity is not related to the activity of other entities (e.g. entity A has a business model related to that of entity B, since the former

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

produces cars while the latter trucks). Thus, if: 1) entity A controls entity B without manage it; 2) its objective is different from the entity B's objective and; 3) the activity of Entity A is not related to the activity of entity B (e.g. because of entity A produces cars, while entity B produces computers), thus entity A and entity B are two autonomous *aziende*, even if they belong to the same business group (Di Carlo, Fortuna & Testarmata, 2015).

The *economcità* (the third attribute) implies that the entire activity of the *azienda* is permanently inspired by the logic of strategic effectiveness and operational efficiency (Cavalieri, 1999; Onida, 1971, pp. 55-112). The strategic effectiveness is the ability of the *azienda* to allocate the available resources to the achievement of winning objectives, or, rather, to select suitable products to meet and satisfy the overall expectations of the customers/users. Operational efficiency is the *azienda*'s ability to achieve these productions reducing the use of resources.

The *aziende* can then be classified as: business entities, public administrations and non-profit organizations (Cavalieri, 2010). Business entities, unlike the other categories, operate in the market, both for the acquisition of factors production, and for the placement of products. From the legal point of view, there are three different types of business entities: sole proprietorships, partnerships and corporations. The corporation is therefore a type of *azienda* that has the legal status of corporation, that is, a juridical person with juridical personality. It means that the corporation is an incorporated business (i.e. the business is recognized as a separate legal entity).

However, unlike shareholder and stakeholder theories, according to the *EA* the *azienda*-corporation is an institution intended to last for an indefinite length of time. It allows distinguishing the particular (and sometimes temporary) interests of the stakeholders from the interest of the *azienda*.

Thus, all the *aziende* are organizations while there are some organizations that cannot be qualified as *aziende*, because they do not possess all the three attributes listed above. For instance a subsidiary within a group of companies is a productive organization but is not an *azienda* if, for example, its business model is integrated with that of the other affiliated group companies and/or is directed by the parent company of the group (Di Carlo, Fortuna & Testarmata, 2015).

The attributes of *aziendalità* are not always present and do not emerge, therefore, as a predetermined condition following the mere establishment of a legal institution (Cafferata, 2016). Conversely, they are rather difficult to possess, but at the same time necessary for a long-term continuity of the *azienda*.

THE PRIMARY INTEREST OF THE *AZIENDA*

The Need of the Organizations' Objective

Any type of productive organization must be oriented to the achievement of an objective (Parsons, 1960; Simon, 1964). For corporations, Keay (2008) points out that 'establishing the objective is critical. First, it provides some guidance for directors in the carrying out of their functions. Secondly, it enables us to assess whether directors have done what they should have done. Thirdly, it helps us to formulate corporate governance mechanisms' (p. 665).

Following the *EA* thought, the objective is important to give a sense to the three attributes (systemic coordination, decision-making autonomy and *economicità*) that allow recognizing the *azienda* among the world of organizations. Indeed, the *azienda* is a finalized system, in that it must be aimed at achieving a specific *objective*, its governing bodies must have decision-making autonomy in the attainment of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the assigned *objective*, and the *economicità*, as method of action, should have an objective as a guide for the behaviour. Indeed, two managers, both acting with *economicità*, may behave in different way considering the same situation, because of the different objective to achieve (e.g. Do an investment in research and development? The one oriented to the profit maximization in the short term will refuse it, while the other with a long term orientation will accept the investment).

The research of a single objective for the universe of all *aziende*, that is valid regardless of the context and time, cultural and regulatory system in which the *aziende* operate, should take into consideration at least the following elements:

1. The effect that the objective has on the *azienda* continuity and on the resolution of the so-called economic problem, i.e. the ability to meet – in a sustainable way, – unlimited needs in the presence of scarce resources, and thus the ability to orient the governance and management toward the common good of the stakeholders and community;
2. The answer that business entities can give to the pressure generated by contemporary business regulations towards 'internal mechanisms to bring management standards and business practices in line with prevailing legal requirements including corporate compliance and ethics programs and employee grievance procedures' (Peterson, 2003, p. 1029);
3. Avoiding that the objective of the *azienda* coincides with the particular interest of a specific stakeholder or a group of stakeholders (Koslowski, 2000, p. 138), since the *azienda* needs the contribute of all its stakeholders, and at the same time avoid assigning more purposes that could lead trade-off difficult to manage (Argenti, 1997; Jensen, 2001), increasing the agency costs due to the managerial opportunistic behaviour.

The first two elements are particularly relevant considering the global financial crisis, which saw its genesis in the lack of ethics in financial market as well as in the purpose of the corporation mainly focused on the profit maximization in the short-term (Kemper & Martin, 2010; Lazonick, 2011; Zamagni, 2009).

The *azienda* should be seen as a cell of the economic system that contributes to the social well-being. Indeed, there cannot be the growth of the country economy without the growth of the singular cells, the *aziende*, where national wealth is concretely produced (Amaduzzi, 1978, p. 19; Cassandro, 1969).

The sustainable growth of the economy asks for the 'sustainable growth of the *aziende* that can promote, slowed down or prevent the economic growth' (Cavalieri, 2010, pp. 10-11, our translation). This approach broadens the range of responsibilities, in the sense that the irresponsible (or unsustainable) behaviour of the *azienda* is determined not only by those who govern and manage it, but also by the irresponsible behaviour of the funders, customers/users, citizens (with their vote), politicians and so on.

The Primary Interest of the *Azienda* in Its Mission Statement

The mission statement is a key elements to orient the governance and management of the *azienda*, for both private and public sectors (Bolon, 2005).

According to Arthur (1987) a mission is 'the charter that defines the basic business or businesses in which the enterprise will engage, the type of products it will make or the services it will provide, the markets it will serve, and how the company will conduct its affairs' (pp. 65-66). In this definition, there

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

are two elements commonly identified in the company's mission, which are the 'what' the company produces and 'how' it produces.

Bart (2001) defines the mission statement as 'a formal written document intended to capture an organization's unique *raison d'etre*. It should answer such vital questions as: why do we exist, what is our real purpose and what are we trying to accomplish' (p. 360). That definition underlines the purpose of the organization, the 'why' it produces. The term '*unique*' indicates the necessity to differentiate the organization from other organizations that produce similar goods or services.

Even if there is not consensus as to what mission statements should include or should not include, the purpose appears to be the most common dimension (Baetz & Kenneth, 1998). The purpose (or objective) is central also because it allows to understand the responsibilities of the organization in conducting the activity (Gallino, 2005, p. 7). Omran, Atrill and Pointon (2002) point out that 'one way of discovering whether a company adopts a shareholder or stakeholder orientation is through an examination of its mission statement' (p. 319).

Since the aim of this chapter is to propose an objective that is able to orient the *azienda* towards the common good of the community, integrating business and ethics, we embrace the definition proposed by Melé (2009) who states that 'a corporate mission consistent with the principle of the common good becomes a practical way of introducing business ethics at the top of a company, and an effective implementation of such a mission a way of implementing business ethics' (p. 238). Moreover, 'the common good principle provides a compass for social life, including business. Business as a part of society should contribute to the common good through its specific mission. Within the business firm, all must contribute to the common good of the firm, which should be consistent with the common good of the society at large' (p. 238).

According to Argandoña (1998) the common good consists 'in producing useful goods and services, and producing them efficiently (so as to create wealth) and sustainably, so as to guarantee the conditions in which each participant receives from the company what he or she can reasonably expect' (p. 1097).

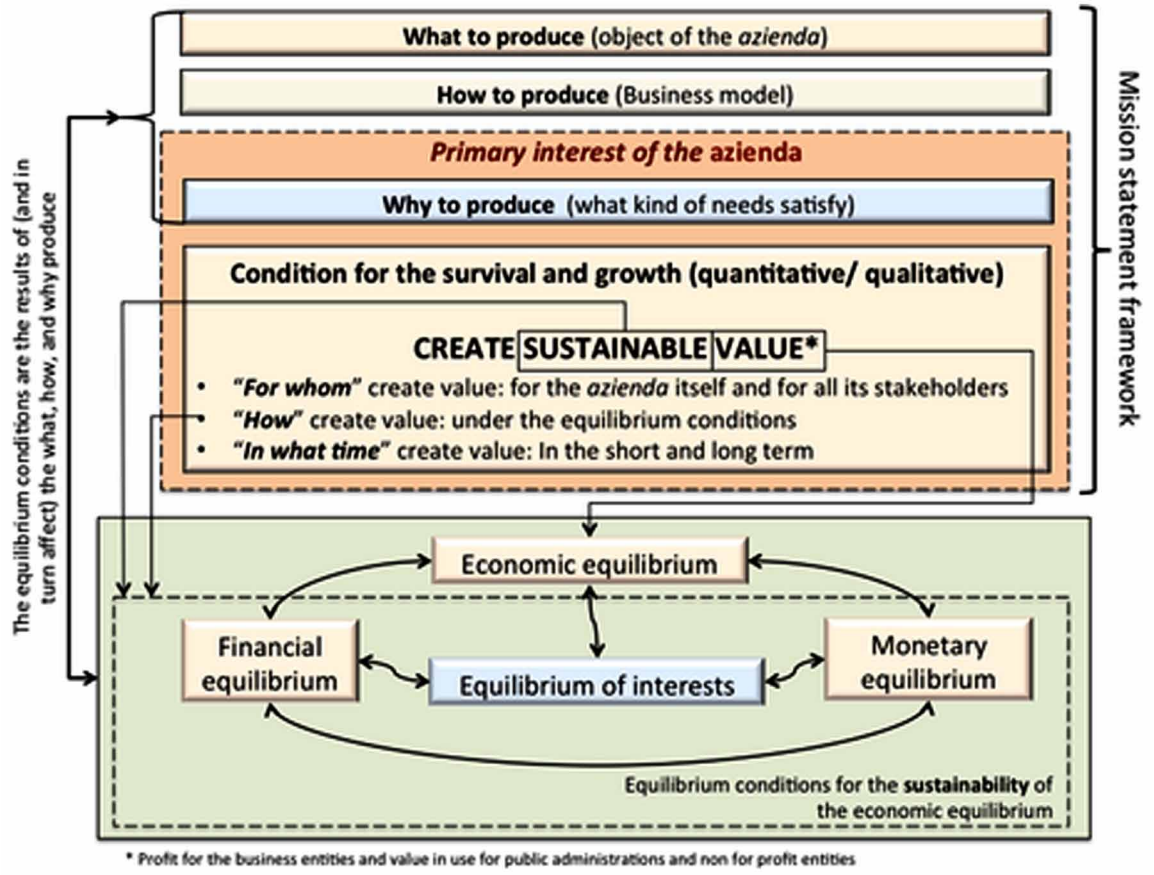

Figure 1 contains a purpose of framework for the *azienda*'s mission. The framework includes two elements: 1) the primary interest of the *azienda*; 2) as well the 'what' the *azienda* produces (i.e. the object), and the 'how' it produces (i.e. its business model).

The primary interest of the *azienda* includes two elements: the objective of the *azienda* (the 'why' produce i.e. satisfaction of client/user needs through the production of useful goods and services) and the condition of survival and growth, summarised with the term sustainable value creation. Thus organizations that meet human needs can be distinguished in two categories: those that create value and those that destroy value (and lives). The social function of the company lies in its primary interest, in the sense that achieving that interest contributes to the common good of the *azienda*'s stakeholders and community. In this regards, several articles compared the *EA* to the theory of the common good (Caldarelli et al., 2011; Costa & Ramus, 2012).

The proposed framework reduces the ambiguity and vagueness of the organization's objective leaving low margins of discretion in the interpretation of the company mission. This allows the mission to serve as a compass to guide both top and middle level managers and to limit their opportunistic behaviour also clarifying under which balance's conditions the firm must create value. Moreover the primary interest model gives a framework that allows an integrated thinking, connecting the management choices with the effect of those choices on the equilibrium conditions.

Figure 1. Primary interest as a part of the Azienda's mission
Source: Our elaboration

Distance Between the Interest of the Controlling Party and the Interest of the *Azienda*

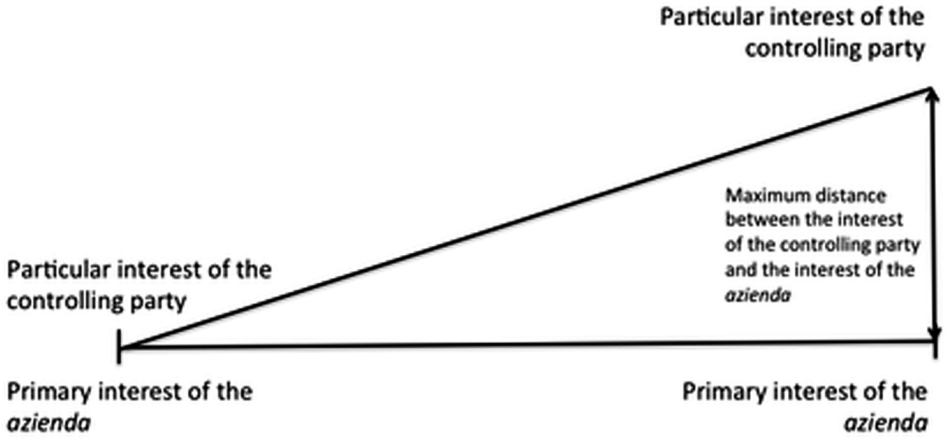
The framework proposed in Figure 1 allows measuring the eventual distance between the peculiar interest of the controlling party (e.g. the dominant shareholder in a company with concentrated ownership, managers in a widely held corporation, politicians in a public administration) and that of the *azienda*. Figure 2 shows two extreme situations: 1) perfect alignment between the two interests, as can happen in a company governed and managed by an entrepreneur who looks for the satisfaction of its customers' needs, posing as a condition for the survival and growth of his/her business the sustainable value creation (i.e. sustainable profit) over time, 2) maximum misalignment between the two interests as happens in widely held corporations where the controlling party is represented by managers who, in making the interests of shareholders motivated only by profit in the short term, run the company irresponsibly, leading the company toward the crisis.

The maximum misalignment can also occur in a municipality governed and managed, for political will, in uneconomic and predatory way.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sometimes, the controlling party while wanting to achieve the primary interest of the *azienda*, participating to the common good of the society, he/she is forced to move away from that interest as certain environmental variables could undermine the viability of the company. For example, consider the contexts in which the irresponsible companies have a better durability conditions than those responsible because of the poor legislation regulating deviant behaviours.

So, the primary interest of the *azienda* expresses an interest to which it is appropriate to tend, but the striving for such interest depends on internal and external variables to the company, not always under the control of the dominant party. In other words, not always the ethics expressed in the concept of primary interest is sustainable from an economic point of view.



From the Objective of the Corporation to the Objective of all *Aziende*: The Why to Produce Goods and Services

According to distinguished scholars of Italian *EA*, the general purpose of all *aziende* is to satisfy human needs, through the production of useful goods and services (Amaduzzi, 1978, p. 19; Amodeo, 1964, p. 12; Cavalieri, 1999, p. 118; Coda, 2006, p. 11; De Dominicis, 1966, p. 43; Ferrero, 1968, pp. 3-4; Onida, 1971, p. 3; Sidrea, 2009; Zappa, 1957, p. 37).

Often *EA* scholars do not specify to what needs they refer (Signori & Rusconi, 2009). However, the needs to be met can be divided into two categories: those of the recipients of goods and services produced by the economic activity and those of the other stakeholders. The aim of the *azienda* is here referred to the first category. Thus, according to the proposed framework, needs satisfaction is the first element of the primary interest of the *azienda* that is its objective, its *raison d'etre*.

Since the 'what' to produce is not included within the primary interest, the framework of the mission is more user-oriented than product-oriented. Indeed, the 'what' and 'how' are excluded from the primary interest (even if included in the mission statement) because the *azienda* must be ready, in its interest and thus in the interest of its stakeholders and community, to react (i.e. to change its own 'what' and / or 'how to' produce) when the productions are no longer able to meet the needs of the client/user.

Figure 2. Distance between the interest of the controlling party and the interest of the Azienda
Source: Our elaboration

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

An excessive focus on the 'what' and 'how' is likely to orient toward the short term, not to look at the real needs of the market (or users), and thus making difficult to get out of moments of economic crisis.

Needs satisfaction, through the production of useful goods and services, should be the objective of all *aziende*, not only of business entities. Coda (2010) points out that 'Each kind of productive institution – be it a for profit or not-for-profit organization as well as a local public entity – exists to implement and achieve its mission, consisting in the production of goods or services intended to meet specific needs, in compliance with certain rules involved in business. It follows that, if this mission comes to be vague and confused and the firm is not completely focused and devoted to its fulfilment, a crisis due to a lack of sense will have its way opened' (p. 25, our translation).

This approach is based on a broad concept of production that is separate from the fact that the production is destined to the market exchange. Therefore, even economic entities that do not sell on the market but give the produced goods and services to the users (i.e. public administrations and non-profit organizations), sometimes for free, are considered as productive economic entities.

Moreover, this approach allows interpreting the economic activity of all *aziende* as a phenomenon of production. Considering the production process also in the non-business entities gives relevance to the attribute the *economicità* and to the value creation condition also in those organizations. Indeed, also the non-business entities must be managed with strategic effectiveness and operational efficiency, guaranteeing a value creation in the short and long term.

This is the reason why, instead of distinguish the producing economic entities (in Italian, *aziende di produzione* or *imprese*) from the consuming economic entities, (in Italian, *aziende di erogazione*, such as public administrations and non-profit organizations), following Cavalieri (1999) *aziende* are distinguished in organizations that produce for the market (business entities) from those that do not produce for the market (public administrations and non-profit organizations). In this regard, according to Coda (2006) 'all *aziende* – whether business or government or non-profit organizations – perform a function of production (goods or services) to the satisfaction of certain needs' (p. 11, our translation).

Being an institution, the objective (the purpose) of the *azienda* is distinguished from the scope of the individual or group of people that establish the *azienda* (e.g. the entrepreneur, the owner, the founder of the *azienda*), as well as from the scope of all of those that participate in various ways to the economic activity (e.g. employees, lenders, suppliers).

The purpose of those who decide to establish the *azienda* becomes important to understand why he/she wants to meet certain needs: while in some cases individuals have the profit (particular interest of the owner) as an extrinsic motivation, in other cases is, for example, a philanthropic interest (e.g., in certain foundations or associations). As Adam Smith said with specific reference to the business entities, 'it is not from the benevolence of the butcher, the brewer, or the baker that we expect our dinner, but from their regard to their own interest' (i.e. the interest to the profit). Thus the butcher, the brewer and the baker want to satisfy their clients needs because they can earn profit from those activities. However, their economic activities are oriented to satisfy people needs. In other terms, the profit could be considered as the financial result of the needs satisfaction.

Value Creation as a Condition for the Survival and Growth (Quantitative and/or Qualitative) of the *Azienda*

In meeting human needs the *azienda* must achieve a condition of survival and growth (quantitative and/or qualitative), summarized by the term 'value creation' (Figure 1). This implies that 'the value of the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

resources consumed to make and distribute the product is systematically lower than the value of production, to be placed on the market or to assign to the users' (Cavalieri, 2012, p. 12, our translation). Thus, the value creation is referred to the typical input-transformation-output process (Argandoña, 2011), and according to our framework it is the second element of the primary interest of the *azienda* (Figure 1).

The condition of value creation that all *aziende* in satisfying human needs should meet can be summarized as indicated in Table 2 (Cavalieri & Ferraris Franceschi, 2008, p. 218):

Therefore, the value creation condition (the economic equilibrium in Table 2) requires that the utility generated (i.e. the economic value of the production to be placed on the market or assign to the users in case of a public administration or a non-for profit organization - vp^t) is systematically (in the short and long term) higher than the utility consumed (i.e. the value of input that are consumed in the production process - vf^t); the difference is the value created by the economic activity (v).

Thus, the economic entity could satisfy human needs creating and destroying value.

With specific reference to the business entities (i.e. the firms), since they operate on the market, the value of productive inputs (vf^t) derived from the purchase price multiplied by the quantity of inputs acquired (costs), while that of the output from the sale price multiplied by the quantity of products sold (revenues) (vp^t). For business entities meeting human needs is necessary but not sufficient for their survival and growth (Amaduzzi, 1978, p. 192; Cavalieri & Ferraris Franceschi, 2008, p. 221). For business entities 'v' is represented by the profit that is a difference between revenues and costs. Since the costs include the satisfactory remuneration of the owners in terms of distributed dividends, the profit (also called economic residual) is what remains after the remuneration of the various factors of production (such as labour, capital, and the State). According to the *EA* the 'pure' profit is what it should be left in the company in the form of non-distributed income, and then used by the firms to finance its quantitative and/or qualitative growth (Amaduzzi, 1948, p. 305; Cassandro, 1969; Onida, 1971 p. 84). Thus, the economic value is created when the net income (revenues minus costs) is positive (net profit) and includes two elements: a) the profit for the owners (distributed dividends); b) the profit for the firm and all its stakeholders (undistributed income that remains in the business entity allowing its growth).

Consequently the profit is not a positive net income, since it arises when revenues suitably remunerate all the factors of production, including the ownership and the entrepreneur for the work done in the firm. The undistributed profit increase also the value of the owners share – indeed, owners have a double remuneration: dividend and capital gain – as well as it satisfy all the stakeholders since it favourites the continuity of the firm. Thus, all stakeholders should be interested to the profit, not only the shareholders.

Table 2. Condition of Economic Value Creation (or economic equilibrium) applicable to all economic entities

$$\sum_{t=t_0}^{t_z} \mathrm{vp}^t = v + \sum_{t=t_0}^{t_z} \mathrm{vf}^t$$

where:
vp^t = value of production over time;
vf^t = value of factors of production consumed to enable the production (realized in the time frame of reference);
v = new value created by the economic activity;
t_0-t_z = entire lifetime of the *azienda*, tending to infinity

Source: *Cavalieri & Ferraris Franceschi (2008, p. 218)*

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

'Consider the profit, according to its true nature, as an indispensable means of the existence and growth of the firm it allows also to remove every weapon at those critics (…) who would attack it in moral terms, seeing it as something reprehensible' (Cassandro 1969, p. 828, our translation).

As a result, the firm is in economic equilibrium when it is able to congruously remunerate all the factors of production (Ferrero, 1968, p. 200; Onida, 1971, p. 18). The value creation condition must be met in the long-term. This obviously does not mean that the short-term equilibrium is not important, but rather that imbalances in the short term do not affect the going concern assumption, when it derives from accidental factors that will be absorbed by an effective and efficient management.

Following this logic, the profit is not the objective of the firm (which is, in the primary interest view, the needs satisfaction), but a condition for its survival and growth. The profit is what remains after suitably remunerated subjects who participated in the value creation, such as labour, capital, loan and property, and the State (Cassandro, 1969). According to Cassandro, with regard to the business entities, 'limiting the objective of the company to the profit maximization will diminish the fundamental economic and social functions of the company. The most important ones are to create new wealth for the community and distribute it among those that to it have contributed' (Cassandro, 1969, p. 826, our translation).

Therefore, profit and corporate objective should not be confused; it would be like saying, because I need to work for live the end of my life is work. In this regard, it was noted that 'profits and purpose are two different ideas, and collapsing them is like concluding from the fact that I need red blood cells to live, that the purpose of my life is to make red blood cells' (Agle et al., 2008, p. 166). 'The profit, even if it were, at best, the only stimulus for private initiative (...) could never constitute the objective of the business entity' (Ferrero, 1968, pp. 30-31, our translation).

It follows a central aspect that leads to distinguish the business entities from the non-business entities, i.e. the possibility to verify if the *azienda* is run with *economicità* (i.e. efficiently and effectively) using its financial results (for example, the result for the period, the revenue growth, return on investment). Moreover, for business entities meeting human needs is a necessary condition for the survival and growth, not being able to see their durability guaranteed by the support of third economies.

Explained the concept of 'value creation', it remains to be clarified 'for whom', 'how' and 'in what time' the *azienda* must create value.

The answer to this question wants to find inspiration in the proposal of Sidrea (*Società Italiana dei Docenti di Ragioneria ed Economia Aziendale*) that suggests that the *azienda* must create value for 'itself and for the different categories of stakeholders involved and socially recognized, in a long and short-term' (Sidrea, 2009, p. 31, our translation; see also Cavalieri, 2012, p. 12).

'For Whom' Create Value: The Azienda and Its Stakeholders

Stakeholders to take care during the value creation process are widely intended here, including the azienda itself, its primary stakeholders (owners, employees, customers, suppliers, lenders) and secondary stakeholders (media, activist, government authorities) (Clarkson, 1995). This approach is closed to the setting of those scholars who consider the corporation as a distinct stakeholder (Clarke, 1998; Kay, 1997; Magill, Quinzii, & Rochet, 2015; Metcalfe, 1998).

Stakeholders participate to the economic activity in the expectation of an adequate remuneration for their contribution. In this sense, they have a particular, and sometimes temporary, interest that motivates (intrinsically and extrinsically) their behaviour (Argandoña, 2011).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The primary interest logic has some important differences compared to the following theories on the company objective (see Table 1):

1. Shareholder theory and enlightened value maximization theory;
2. Stakeholder theory;
3. Organic theory and social entity theory.

With regard to the business entities, unlike the shareholder theory, according to the primary interest idea the agents are responsible not only towards shareholders, but also towards a plurality of stakeholders, and the profit is not considered as an end but as a condition of survival and growth of the firm. This last aspect also distinguishes the primary interest idea from the enlightened value maximization theory.

Thus, the proposed approach may seem to be aligned with the stakeholder theory of the firm. However, it also requires responsibility towards the survival and growth (qualitative and/or quantitative) of the azienda that is seen as an economic institution (Zappa, 1957) separated from its stakeholders.

In particular, following the EA, the azienda is not here conceived as a juridical fiction, as just a set of contracts with its stakeholders, instead it is viewed as an institution (Costa & Ramus, 2012) that is distinct from its stakeholders, with its own interest to survive and develop, in order to satisfy human needs and create sustainable value. According to this approach it can be also said, for example as regards to the business entities, that the shareholder interest toward the profit maximization is particular and should be compatible with the interests of the azienda and other stakeholders. In other words, when the profit is achieved in an irresponsible or fictitious way, it becomes secondary if compared to the primary one that considers the firm as part of the community, that contribute to the common good. Considering the azienda as an organization that contributes to the common good it allows adding the interest of the azienda among the peculiar interests of the stakeholders (Masini, 1970, p. 11), that is, the interest of the azienda becomes part of the interest of its stakeholders. 'The common good has to do with creating the conditions that will enable those involved in the business to achieve their personal goals, we can say that there is no conflict between the common good and the individual or personal good' (Argandoña, 1998, p. 1097).

The proposed approach is also different from the one followed by those who ask to create value for the company (e.g. organic theory and social entity theory), taken for granted that by doing so, they strive to create value for all stakeholders. Brief, Buttram & Dukerich (2001) state that belief in the sanctity of the firm is so a strong message that managers tend to believe that by serving the corporation's interests they are also serving the interests of the community: what's good for Microsoft is good for the country.

However, the corporate scandals show that this automatism does not always occur. For example, a company could improve its value destroying the environment, by failing to ensure appropriate working conditions for its employees especially if they have very limited possibility to change their job.

For this reason, in order to achieve its primary interest the azienda has to maintain good relations with the stakeholders, while stakeholders, including community, should understand the problems of the azienda. Thus, reciprocal duties exist among corporate stakeholders, as well as between stakeholder and the azienda. According Fassin (2012) 'Whereas stakeholders are widely seen as having rights, they may also have duties and obligations' (p. 85).

In other words, the proposed approach differs from the theory of value creation for the organization as it offers practical solutions to reconcile the interests of the azienda with those of its stakeholders.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Cavalieri (2010) argues that 'it is just in this subtle game of balance between the value recognized to different stakeholders and the value recognized to the organization itself useful to ensure it's survival and growth, that the professionalism of those who do business is expressed' (pp. 26-27).

As pointed out by Adams, Licht and Savig (2011), 'we contrast shareholderism with stakeholderism as ideal-type, polar strategies. Between them resides a continuum of intermediate stances that find merit in both views. There may be purists who subscribe to strong versions of either view regardless of the circumstances. Most decision makers, however, will follow their principles to find a middle ground depending on the context' (p. 1332). It is almost evident that this middle ground derives from the consideration of a further interest, which can only be that of the firm.

'How' Create Value: The Sustainability of the Economic Equilibrium

The 'how' question wants to specify under what conditions the economic equilibrium expressed in Table 2 should be achieved and it is related to the sustainability of that equilibrium over time. Two organizations can be distinguished by the different ways on how they create value, even if they make the same product and satisfy the same needs. The answer to the 'how' question is necessary in order to mitigate the opportunistic behaviour of the management.

Indeed, the economic equilibrium condition does not say anything yet about the sustainability of that value. In other words, a car company, while operating with efficiency and effectiveness, may not be ethical, social and environmental responsible, as well as a public administration that create an economic value, it may not behave in a sustainable way in respect to certain stakeholders (think of the delay in payments to suppliers).

- *Financial, Monetary and Interests Equilibriums*

The conditions to achieve in order to create sustainable value, or sustainable economic equilibrium, are: financial, monetary and interests equilibriums. The first three conditions (economic, financial and monetary equilibriums) derived from the theory of the business entity equilibrium proposed by Aldo Amaduzzi (1948), one of the Zappa's pupils. The theory of equilibrium, which initially covered only the business entities, was later revisited by Cavalieri (2010), an Amaduzzi's pupil, who expands the scope of the theory of equilibrium to all types of organizations, adding a fourth condition, the so-called *overall strategic equilibrium* intended as 'equilibrium position simultaneously against the different social partners and the markets' (Cavalieri, 2010, p. 28, our translation). However, in the primary interest model the *overall strategic equilibrium* was substitute with the equilibrium of interests. For non-business entities the concept of revenue is substitute by that of value of production over time, while the concept of cost by the value of factors consumed in the production process.

In particular, the sustainability over time of the economic value creation includes three conditions: 1) have a balanced capital structure (financial equilibrium) in order to guarantee the solidity of the *azienda* and overcome unfavourable economic periods that have a negative impact on the economic equilibrium, because of losses that decrease the level of the equity; 2) meet regularly its payments (monetary equilibrium); 3) be socially and environmentally sustainable (equilibrium of interests).

- *Financial equilibrium* is the necessity (of the *azienda*) to develop appropriate correlations (in quantitative and qualitative terms) between investments (assets) and financial sources (liability

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and equity), in order to maintain a systematic capability to satisfy its obligations timely and in a correct manner, without prejudice in the future.

- *Monetary equilibrium* is achieved when the company is able to meet at any time, the payment commitments, for example, with employees, suppliers, financiers. This equilibrium then binds to the concept of liquidity, through which measures the company's solvency in the short term.
- *Equilibrium of interests* is intended as a balancing of interests of stakeholders who participate in various ways to the value creation. This equilibrium is connected to the shared value creation and it is reached when the rewards (not only monetary) received by stakeholders are aligned to the contributions they provide to the *azienda*.

Under the *azienda*'s equilibrium model the stakeholder management does not see any contrast between normative and instrumental approach (Donaldson e Preston, 1995), due to the fact that the instrumental approach is not referred to the shareholder's interest, but rather to the company's interest. Indeed, managers have to deal with the stakeholders – in order to achieve the equilibrium of interest – in accordance to the company's interest and, by trying to find (according to internal and external contingencies) the right balance between a fair behaviour (regardless of the economic results) and a behaviour that has to be instrumental to the survival and growth of the company itself. However, going deeply in the investigation, the primary interest theory sees the instrumental approach as a way to exalt the fairness approach toward all other stakeholders. The need to preserve the business continuity has to be considered in fact the right behaviours even if a possible consequence could be the short-term sacrifice of some stakeholders' expectations.

- *The Overall Equilibrium*

The *azienda* achieves the *overall equilibrium* when it cannot improve a single equilibrium (economic, financial, monetary and interests) without damaging, in the long term, its condition of survival and growth. It can be also stated, in the mathematical sense, that the overall balance is a system of four interrelated equilibriums that the solution of the system (survival and growth in the long term) should meet simultaneously. The equation is solved when it has chosen the best composition of the balance for the survival and/or growth of the *azienda*. The manager can evaluate the impact of his/her choices on the overall equilibrium. Improve that equilibrium is a fair behaviour towards all the stakeholders.

Thus, an increase of welfare of a single stakeholder is acceptable when it has a positive effect on the overall balance. Indeed, the unitary vision of the *azienda* suggests connecting the effect of the stakeholder management to the economic, financial and monetary equilibrium. If increasing the well being of a stakeholder improves, in the long term, the overall equilibrium the *azienda* the manager should do that, also because increasing the possibility of the *azienda* to survive and growth is the right thing to do for all the actual and future stakeholders.

'In What Time' Create Value

The last element of the value creation condition is referred to the period in which that value should be created. The short-termism has been considered as one of the causes of the global financial crisis (Dallas, 2011; Treviño & Nelson, 2011).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The value creation condition must be achieved in the short and long term. Cavalieri (2010) observes that 'the simultaneous long and short-term management of a business has to belong to the set of task of a conscious management team' (p. 27, our translation). The short, as well as the long run, can be referred to the economic, financial, monetary and interest equilibriums. The value creation condition should be read in the short and long term, in order to understand how today's behaviors may impact on the overall balance of tomorrow. An orientation to the income in the short-term reduces the importance assumed by the other equilibriums, necessary to ensure that the former is durable and sustainable in the long term.

The azienda is not an organization with a short life-time, instead is an organization set to continue. In this regard, the term azienda is normally translated with the term 'going concern'.

Bertini (2013) argues that 'on one hand, whether management uncertainties are experienced focusing on a long-term perspective, all issues are reconsidered in the light of the company continuity dominant theme. (...) profit in turn becomes an instrument useful to ensure to the company an higher level of stability. (...) On the other hand, if a short term approach prevails, everything tends to be exasperated: the daily search for profit would sacrifice future profit opportunities; conflicts of interest among different stakeholders would be dominated by the need for an immediate and self-interested achievement of each related expectations; therefore, the entire system equilibrium would be close to reach the point of crisis' (p. 99, our translation).

'The organization durability goes beyond the permanence of that people constituting in a specific moment the organization itself. A group or a single individual who is committed to tie the life of the organization to its own interests or specific objectives, would surely produce economic damages with moral effects both for other organization's members as well as for the whole economy' (Airoldi et al., 2005, p. 163, our translation). Thus, 'human beings could not defeat the course of time while aziende could reach the immortality' (Anselmi, 2014, p. 39, our translation).

In other words, it is the consideration of the azienda as an economic institute interested in its time continuity and in the creation of a sustainable value that lead to a long-term focus rather that a short-term one.

The 'how' and 'for whom' create value assumes a significant relevance in the choice between short and/or long-term orientation. Creating value in a sustainable way means having a better perception of how an irresponsible behavior (i.e. disequilibrium of interests) of today may affect the survival and growth of the azienda. In other words, sustainability can bring out future costs and benefits associated with the current choices.

The temporal problem of the value creation becomes particularly relevant looking to the peculiar interests of the party (or parties) that govern the azienda. Indeed, a dominant party that is oriented to the short term will lead the company following this logic, jeopardizing the azienda's continuity, while long-term oriented dominant party might not realize the effects that poor management of the short term may have in the long term and indeed hope that in the long run the short imbalances can be reabsorbed. In other terms, it cannot be underestimated the effect of the short term on the long-term. However, sometimes the problem is not thinking to the long term, but have adequate decision-making tools to link the effect of short-term choices with long-term consequences, and to contrast psychological factors that lead the agent to the short term even if he/she is oriented to the long term (Ariely & Zakay, 2001).

In this regard, an important factor that may caused the corporate fraud – at least in the initial stage – was that related to the good profitability condition of the defrauded corporations (think of Parmalat, called after the default "the European Enron"), and the prospects for future growth that they would have to absorb, in the long term, the costs of expropriation generated by the controlling party (the so called

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

wishful thinking effect). In other words, the predators "entrepreneurs" seem not to have perceived the risk that the destruction of the economic equilibrium in the short-term could cause catastrophic consequences in the medium-long term. Moreover, the manipulation of the financial statements gave to the market just the appearance of equilibrium conditions, not allowing the external observers, even to the actors involved in the expropriation, to understand the severity of the situation and, therefore, to take action to avoid disaster.

To conclude, what it has to be underlined is that, the long-term orientation, thus, the endless life of the firm, concerns the survival and growth conditions of the azienda (that is the creation of sustainable value) and not the achievement of those goals useful to reach these conditions.

All economic and extra-economic goals could concern even very short periods. The sustainability of value creation in a long-term perspective allows to set goals that are coherent with such condition, solving possible trade-off between economic and extra-economic purposes.

CONCLUSION

The analysis of the main Anglo-American theories on corporate objective shows several weak points for what concern 'for whom', 'how' and 'in what time' corporations must create value.

The most critical aspect is connected to the fact that some theories ask for the value creation of specific actors (e.g. the owners in the shareholder theory), or for several stakeholders, without considering the distance between those interests and the primary interest of the corporation to survive and growth. On this aspect the Italian doctrine Economia Aziendale gives an important contribution.

From the critical review of the thoughts of the Masters of the EA, at least three significant aspects emerge: 1) having considered the interest of the all the economic organizations as a central governance issue, instead of the peculiar (and sometimes temporary) interests of certain individuals (e.g. shareholders, managers, politicians), emphasizing the importance of protecting the azienda equilibrium over time and, therefore, its survival and growth (quantitative and / or qualitative); 2) having had as object of study not only the entity that produce for the market (i.e. the business entities, or for-profit organization), but also the non-business entities (i.e. public administrations and non-profit entities) 3) having assigned to all the aziende the common goal of meeting the needs, while the distinction between profit, non-profit organizations and public institutions is based on the scope of the individual or group of people that establish the azienda; 4) providing different insights on 'for whom', 'how' and 'what time' such organisations should create value, specifying that the azienda must create value not only for its stakeholders but also for itself.

The main contribution of this chapter is to propose a principle of governance (an objective) common to all types of organizations. The nature of this need comes from the proliferation of the last twenty years' corporate scandals and economic crisis, whose origin lies in the violation of those rules of good conduct recommended and transmitted by Economia Aziendale. Indeed, the searching for common rules and principles is one of the main objectives of this discipline.

The main point of the analysis is the distinction between the primary interest of the azienda and the interests of the controlling party as well as of the other stakeholders. The corporate governance literature is often focused on conflict of interest between owners and managers in companies with disperse ownership (i.e. the agency problem type I, Berle & Means, 1932; Fama & Jensen, 1983; Jensen & Meckling, 1976) and between controlling shareholder and minority shareholders in companies with concentrated ownership (i.e. the agency problem type II, Claessens, Djankov, & Lang, 2000; Shleifer & Vishny, 1997).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

This study suggests a third type of agency problem, that is, the conflict of interest between the primary interest of the firm and its managers and/or shareholders. That third type of conflict may coexist with the type I and II. Thus, further studies should explore this type of conflict in different types of ownership (e.g. widely held corporation, family firms, State owned firms).

Another key aspect of the Masters of Economia Aziendale is reflected in their consideration of the azienda as a mean for the improvement of the collective welfare, thus its consideration as a common good, rather than as an instrument for some groups to achieve their personal (and sometimes temporary) interests. Therefore, the discipline of corporate behaviours cannot be only left in the hands of the market and regulators, finding some interesting guidance in the Economia Aziendale rules of good conduct.

KEY TERMS AND DEFINITIONS

***Azienda*:** Economic organization with three attributes: systemic vision, decision-making autonomy, and *economicità*.

Business Model: An organization's business model is its system of transforming inputs, through its business activities, into outputs and outcomes that aims to fulfil the organization's strategic purposes and create value over the short, medium and long term.

***Economia Aziendale*:** Is an Italian doctrine founded in 1927 by Gino Zappa as a unitary science that studies the 'existence conditions and life manifestations of the *azienda*'.

***Economicità*:** Is one of the attributes used to define the concept of *azienda*. It is a method of action, in the sense that the *azienda* operates with *economicità* when it is effective and efficient.

Primary Interest of the *Azienda*: Is a principle of good governance for all organizations. This interest includes two elements: 1) the objective of the *azienda* (i.e. satisfy human needs through the production of useful goods and services); 2) a condition for the survival and growth of the *azienda* (i.e. ensuring a sustainable value creation in the short and long term).

Chapter 46
Green Brand Personality: Its Relevance to the Green Marketing Practices

Anitha Acharya
ICFAI Foundation for Higher Education (IFHE), India

Manish Gupta
ICFAI Foundation for Higher Education (IFHE), India

ABSTRACT

The main purposes of this chapter are to define a green brand, describe its characteristics, and outline its implications. This chapter would help readers understand the need for studying green brand personality and appreciate its importance in the current market scenario. Moreover, it provides a detailed outline of the ways and means that companies can use to market such brands. It highlights the steps companies can take to increase the sales of green brands and get an edge over non-green brands. In addition, it explores certain best practices in the industry to illustrate how well green products can be sold without compromising on sales targets.

INTRODUCTION

Marketing strategists have long achieved competitive advantage by assigning a set of personality characteristics to their brands (Aaker, 1997). Conventional brand-personality strategies focus on products or services and their corresponding utilitarian benefits. However, a recent sharp rise in the number of similar brands coupled with globalization has made it difficult for the marketers to distinguish their brands on the basis of functional attributes alone.

Therefore, the marketers are increasingly realizing the need of attaching symbolic meanings to their brands to achieve brand distinction. One of the emerging ways to fulfill the need for brand distinction is by promoting green marketing – a set of activities to generate and facilitate an exchange to satisfy human needs or wants so that the products cause minimal damage to the environment (Acharya & Gupta, 2016; Polonsky, 1994). Marketers need to know when and how do customers relate themselves to green

brand personality and its impact on the purchase decision. The objective of this chapter is to identify the benefits of green brand personality on companies marketing practices. It helps the companies to promote their products and also attracts new customers to switch to products which are environmental friendly. This will benefit the company in the long run by way of profits and also helps them to distinguish their products from that of their competitors.

The six dimensions of green brand personality proposed by Acharya and Gupta (2016) were security, sincerity, competence, sophistication, compassion, and excitement. Dimensions sincerity, competence, and excitement, capture the innate part of human personality, whereas sophistication, security, and compassion tap a dimension that individual's would like to have.

NEED FOR GREEN MARKETING

Companies are now getting inclined to green marketing mainly because of four reasons. These include rise of green consumers, government initiatives, thrust by non-governmental organizations (NGOs), and change of lifestyle. Each of these has been detailed below:

- **Rise of Green Consumers:** Consumers are aware of the environmental degradation that can happen if they use non-green products (Zhu & Sarkis, 2016). Not surprisingly, according to a survey conducted by Cone Communications in 2013, as much as 71% of Americans are inclined to buy green product (Walker, 2013). More recently, Nielsen global online study reported that almost three out of four respondents were willing to pay extra price for buying green products in 2015 (Global, 2015). It was also found that Millennials were also particularly passionate about sustainability while shopping and were interested in buying green products in order to save the environment.
- **Government Initiatives:** Governments around the world are responding positively to the call of the United Nations (UN) for taking green initiatives to control global warming (Bhattacharya, 2016). Indeed, the main agenda for the UN conference in September, 2015 in Paris was to give countries an opportunity to join Paris Agreement to overcome climate change. A major decision was that developed countries would share a major chunk of monetary cost relating to supporting green initiatives (Davenport, Gillis, Chan, & Eddy, 2015). Countries have already started providing funding for this purpose. For example, the Federal Government of Canada offers incentives and funding to boost research and development in Canada. These are relating to conducting research on those products that run on clean energy (Natural Resources Canada, 2016).
- **Thrust by Non-Governmental and Non-Profit Organizations:** NGOs and nonprofit organizations have come forward in support of going green (Kleindorfer, Singhal, & Wassenhove, 2005). These organizations are popularly termed as green NGOs (Herrera, 2010). For example, Carbon Trust, a nonprofit organization based in UK helps companies in formulating strategies with respect to overcome climate change. It had worked with product carbon footprinting which contributed to PAS 2050, a standard for product life cycle. Similarly, Conservation International a NGO advises Starbucks on issues relating to sustainability. EarthShare, another NGO, is famous for developing package of services which helps its clients in implementing green activities in their organizations. Rainforest Alliance has been working with leading brands which produces chocolate, coffee, and tea in sourcing raw materials which are sustainable.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Lifestyle Change:** Consumers feel that the presence of green element in an ordinary product makes it extra-ordinary because of the uniqueness it involves (Rao & Bhargav, 2016). These consumers are labeled as 'eco-fashion' consumers. Marketers have started capturing the pulse of these 'eco-fashion' consumers. They do not use raw materials which are hazardous to the health of their workers and the environment. They also ensure that the working conditions of the workers are good (Chan & Wong, 2012). Popular brands which incorporate these strategies are study NY, Alabama Chanin, Titania Inglis, Feral Childe, Awamaki Lab, Carrie Parry, Loomstate, M. Patmos, 100%NY, And Elroy (Phelan, 2012).

WHAT IS GREEN MARKETING

According to researchers Kärnä, Hansen, & Juslin (2003), the definition of marketing considers a utilitarian approach to social responsibility by emphasizing on maximizing the shareholders wealth. Several, marketing epitomizes voracity and they are responsible for the consequences which is arising from over development and over-consumption, where the main motive is to maximize their personal wealth instead of society's welfare and good quality of life. However, marketing helps in promoting consumption which is environment friendly as well they help consumers in leading a better life. Since the scope of marketing is very vast it helps consumers in finding a suitable trade-off between economy and environment. According to (Charter, 1992) the objective of a green marketing philosophy is long term sustainability and for those companies whose main objective is to create sustainable businesses, then green marketing is the way ahead. Peattie (1995) defined green marketing as management practices which considers satisfying the needs of the consumers and the society in such a way that it is profitable and sustainable in the long run. In similar terms, Charter (1992) conceptualized green marketing as management practices that fulfills the needs of the stakeholder and also considers the safety of the consumers and the environment. The supporters of green marketing and sustainability thinking actively take part in wide range of activities in which the company is involved. Holistically, the process of green marketing should not be concerned merely about the end product they should also place more emphasis on activities like developing new products, logistics planning, packaging of the products, etc. (Ottman & Books, 1998; Wasik, 1996). According to Fuller (1999) green marketing must consider the impacts of the entire product life cycle on the environment, because how a product is produced cannot be secluded from how it is consumed and its impact on the environment. If such a vision is lacking, the company can be accused of greenwashing. Its portrayal of a green image will backfire, and this might harm the environment (Grant, 2007; Peattie, 1999).

EMERGENCE OF GREEN BRAND PERSONALITY

Marketing practitioners and advertisers are the first ones to coin the term 'brand personality', much before the concept was studied and accepted by academics. Martineau (1958) used the word brand personality to refer to the dimension which is not materialistic and which makes the store special — its character. According to King (1970) consumers do not look for physical characteristics in a brand but they like brands as people and they choose their brands the same way they choose their friends.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The notion of brand personality can be traced back to its origins through the theory of symbolism (Smith, Graetz, & Westerbeek, 2006; Sirgy, 1982). It is argued that consumers view their preferred products as an extension of themselves, and therefore they purchase only those products which have symbolic value (Elliott, 1994). The self-esteem of the consumers is enhanced when they use products which have symbolic value (Hong & Zinkhan, 1995). The self-concept theory elucidates the motives behind consumers buying products which have symbolic value (Sirgy, 1982). While making a purchase decision consumers try to appraise the degree of similarity between the personality traits communicated by a particular product and the personality which they want to project themselves (Dobni & Zinkhan, 1990).

Though consumers have difficulty in assigning human personality traits to inanimate objects, the theoretical explanation of product personality is relatively underdeveloped (Allen & Olson, 1995). Theories from anthropomorphism (Boyer, 1996) help us to understand why people endow brands which are inanimate objects with qualities of human personality. To interpret the outside world people use their own self-schema as a basis for concepts and labels. Sparks & Guthrie (1998) argued that humans do not want to be associated with objects which are non-human. Prior studies have given evidence that in social gatherings, people are attracted to those who possess similar personality because they feel that it is emotionally rewarding. Emotional and cognitive needs motivate humans to form humanlike models to understand and mitigate events. According to Blackstone (1993), consumers form relationships with brands based on their symbolic value, which results in brand becoming alive and it is no longer considered as a passive object but an active partner in the minds of the consumer.

In practice, celebrity endorsements have helped brands in being personified. With the aid of celebrities and their personalities marketers position their brands in such a way that they can attract consumers who can identify themselves with these celebrities. In other words, consumers perceive a fit between their ideal or actual perceived selves and that of the celebrity, and get attracted towards the brand (Sirgy et al., 1997). According to Levy (1959) this personality endowment gives the brand a meaning in the eyes of the consumer. In fact, consumers perceive brands as having personality traits. In a study conducted by Kapferer (1998) on medical doctors, the results revealed that medical doctors had no difficulty in attributing personality traits to pharmaceutical brands; in addition, the results also revealed that these traits were actually significantly correlated to medical prescription itself. Due to which brand personality has an important role to play in managing the brands.

According to Geuens et al. (2008) brand personality forms a major component of brand identity. Brand identity is defined as a brand's meaning as put forward by the firm (Kapferer, 2008). In other words it is defined as how the company wants to present its brand to its target customers. Customers who give importance to branded possessions value their relationships with companies that own and manage the brand (Alexander, Schouten, and Koenig, 2002). The brand identity of a company needs to focus on differentiating their products from that of their competitors so that they are able to attain sustainable competitive advantage (Aaker & Joachimsthaler, 2000). A thorough understanding of competitor, environment, and customers can form the base for companies brand identity. The brand identity should reflect that the brand will live up to the promise it has made to the customers. The benefits of building strong brand identity are greater customer satisfaction, greater share of customer's wallet, and brand equity (Aaker & Joachimsthaler, 2000). Brand image is defined as the consumer's perception and interpretation of the brands identity (Geuens, Weijters, & De Wulf, 2009). Researchers have conceptualized brand identity and brand image as a multidimensional construct with brand personality as one of the important component. According to Keller, Apéria, & Georgson (2008) brand image consists of: (a) values and personality, (b) profile of the user, (c) history, heritage and experiences of the consumers, and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(d) consumers purchase and usage situations. Aaker & Joachimsthaler (2000) identified four elements of brand identity namely: (1) the brand as a symbol (2) the brand as an organization, (3) the brand as a product, and (4) the brand as a people. Building on prior research Kapferer (2012) developed a brand identity prism in which brand was considered as a message flowing from the sender to the receiver. The dimensions of brand identity prism were physique, personality, reflection, self-image, culture, and relationship. He further stated that brand identity dimension physique which is defined as physical features and qualities and personality which means human personality traits depict the sender. Whereas the brand identity dimensions reflection which focuses on the image of the target group and self-image which refers to how the brand makes consumers feel depict the receiver. The dimension culture which refers to values and relationship forms the link between the sender and receiver.

To date, the focus on the application of the brand personality scale on management was only on restaurant settings (Siguaw, Mattila, & Austin, 1999), consumer goods (Kim, 2000), and web sites (Müller & Chandon, 2003). However, green brand personality has recently evolved as an emerging area of research in the field of brand management (Acharya & Gupta, 2016; Goh & Wahid, 2015).

THE KEY CHARACTERISTICS OF GREEN BRANDS

Before elaborating the characteristics of green brands, it is important to know the characteristics of a brand personality in general that include sincerity, excitement, competence, sophistication, and ruggedness (Aaker, 1997); (a) Sincerity which represented attributes like wholesome, honest, cheerful, and down-to-earth; (b) Excitement which consisted of attributes like spirited, up-to-date, daring, and imaginative; (c) Competence which represented attributes like successful, reliable and intelligent; (d) Sophistication consisted of charming and upper class; and (e) Ruggedness comprised of outdoorsy and tough. The innate part of human personality is captured by dimensions Competence. Sincerity, and Excitement. Whereas Sophistication and Ruggedness tap a dimension that individual's desire but do not necessarily have.

However, these dimensions do not refer to the way consumers relate to a brand but rather how consumers view the brand (Brakus, Schmitt, & Zarantonello, 2009). Of these dimensions, excitement and sincerity are fundamental to the marketing landscape because these comprise two of the three partner ideals in intimate personal relationships (Aaker, Fournier, & Brasel, 2004). In a study conducted by Aaker et al. (2004) it was found that consumers form stronger relationships with sincere brands such as Ford and Coca-Cola than exciting brands such as Yahoo and Virgin. The rationale is that for short-term relationships exciting brands are more suitable, whereas for long-term relationships sincere brands are more useful (Aaker, 1997). Sincere brands are considered warmer such as Gateway and more down to earth such as MetLife, Coke, whereas exciting brands are related with a younger demographic such as Mountain Dew and are viewed as possessing cultural vitality such as BMW. Interestingly, exciting brands are often considered as appealing, attractive, and capable of bringing about interest and trial (Altschiller, 2000). In quintessence, a brand's personality influences how its actions and behaviors are professed by the consumers. Such consumer actions can be inferred from consumer reviews, company advertisement, and prior experiences.

According to Acharya and Gupta (2016) the dimensions of green brand personality are: security, sincerity, competence, sophistication, competence, and excitement. In comparison to the original brand personality dimensions, 'security' and 'compassion' emerged as new dimensions in their study. These new dimensions require confidence and protection (security) and concern and humanity (compassion).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ADVANTAGES OF GREEN MARKETING

Some of the advantages of green marketing that are listed below include customer betterment, innovative products, and customer participation.

- **Customer Betterment:** Marketer should give the best to customers; this is possible only if they use green marketing strategy. They can use environmental friendly packages to pack their products and if they are into manufacturing food product they can give more attention to consumer health benefits. This will help them to attract more customers through positive word-of-mouth. According to Carrie Walsh, Marketing Director, Frito-Lay: "Our customers are consumers who care about their personal health and planetary health".
- **Innovative Products:** Marketers can come out with innovative green products to attract customers. Successful product innovation can lead not just to products that satisfy the existing needs of customers; the company can be the market leaders and have a competitive advantage compared to the other players in the market. Some of the benefits of product innovation are
- **Increased Market Share:** An innovative product that satisfy the needs of the customer and which disrupts the target market can greatly enhance market share, which in-turn can lead to economies of scale and augment a company's market power.
- **Increased Profit:** According to Forbes report (2015) developing an innovative product that's exceptional and of better-quality to what the competition offers can lead to profit growth. In fact, more than 90% of the world's 100 most innovative companies have experienced increased profit due to innovation.
- **Customer Participation:** Green marketing activity campaign by the marketers will allow the customers to participate in the campaigns. There are very few people who realize the importance of safeguarding the environment, this opportunity can be used by marketers by providing them a platform which will allow them to work directly in preserving the environment, for example use of social media like Facebook, Twitter are some of the medium which are considered to be more effective than any other medium.

ROADMAP FOR GREEN MARKETERS

The green marketers need to generate convincing, pertinent, and efficient messaging that differentiates a company and its products and services from its competitors. As Gbadamosi (2016) points out, the first and foremost thing is to include the green elements in the business strategy such as striving hard to achieve sustainability goals, believing integrated thinking, taking a long-term orientation, relying on mutual responsibility, and accounting ecological costs. In all these efforts, the marketers need to convey a message which is convincing, pertinent, efficient, and different (Ottman, Stafford, & Hartman, 2006), as detailed below:

- **Convincing:** Companies need to provide convincing messages by supporting their statements with appropriate facts and figures. The level of information may depend on the image or environmental history of their sector and the target audience. One of the best ways is by using eco-labeling schemes. A product with an eco-label is a product that is proven environmentally preferable.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

It shows that the manufacturer is adhering to the guidelines that are required to manufacture an eco-friendly product. Marketers need to highlight the eco-friendly benefits that the product has on the consumers as well as on the society.

- **Pertinent:** A pertinent message reports sustainability success that is in line with the company's impacts. For instance, if a pharma company focuses on advertising its efforts to green its facilities while not delivering on quality of its medicines then its green message is not relevant to its key environmental impacts. If a company, markets its strong community benefit programs but does not provide good working condition for its employees then its advertising message will be misleading.
- **Efficient:** An efficient message translates the sustainability information to make sense of the extent of your achievements. For example, a company may have used its limited resources in an efficient manner then the same has to be communicated in such a way that it is easily understood. The efficiency of the message also depends on how the message is communicated to the intended audience.
- **Differentiate:** Companies often strive hard to make their message unique and distinct from competing products and services. Since their target segment is limited to the green consumers. They often face the challenge of differentiating their products not only from the producers of green products but also from their non-green counterparts. For this, the marketers are required to highlight the uniqueness of their products both in terms of the benefits it promises for the environment and in creating brand value by placing their brand as an in thing.

ALIGNING GREEN MARKETING WITH BUSINESS STRATEGY

In order to shift its focus from conventional marketing to green marketing, companies need to align their new business strategy with that of the existing one. It can be done in several ways including reducing greenwashing, increasing transparency, promoting green culture, assisting other environmental causes, and getting into third party collaborations. Each of these is elaborated in the subsequent sections.

- **Greenwashing:** It is a technique in which an organization spends more money on advertising green, sustainable behaviors instead of putting them into practice. For example an automotive company may call itself environmental friendly since it uses battery to run the car. But they might dispose their waste in sea, by doing that they are harming the environment, consumers, and finally their business.
- **Environment**: Greenwashing is bad for the environment because it can promote consumers to do the opposite of what's good for the environment. Greenwashing makes claims that are neither good nor bad for the environment. In order to increase their sales company makes false promises.
- **Consumers**: When it comes to money consumers do not like to be cheated and taken for granted. They avoid spending more money on a product or service which they believe is going to harm the environment.
- **Businesses**: Companies have realized that by being environmental friendly does increase their profits. Even though there are many ways to produce goods and use processes that do not harm the environment, it is saddening to know that the companies still do not do it. It is even worse when they don't make changes and claim to be a green company only to push their products in the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

market. Environment friendly consumers can see right through their green screen. It backfires and harms the company's reputation and profits.

- **Transparency:** In order to gain the trust of the consumers, companies should conduct their business in an open way. Being transparent is the new goal for many businesses, which will help them to win over shareholders, employees, and the general public. If a business is open about its operations, it can earn a level of trust that it wouldn't have established otherwise. For example Starbucks company prides itself as the world's largest environment friendly company by proving it in the marketing campaign 'Transparency'. For Starbucks, 'Transparency' is a company-wide philosophy in which customers are treated honestly and where prices are actually low.
- **Green Culture: "**Going green" motto should be practiced and embedded in the organization's culture. For example, Go Lite, an outdoor clothing and equipment maker in Boulder, CO which was founded in the year 1998 by Kim and Demetri, the company specializes in ultra-light packs, sleeping bags and down jackets. The main objective of the company is to mitigate 100% of its environmental footprint. To do this, it uses so-called Environmentally Preferred Materials" (EPMs) like recycled nylon and polyester, instead of newly-produced petro-chemical-based fabrics and parts. Till date, 67% of its materials are EPMs and it is aiming for 100% by 2016. It also encourages customers to return their old clothes where it pledges to recycle and reuse items returned by its customers. The company is also trying to make its headquarters a zero waste facility, where it composts or recycles all of its garbage. Some of the strategies which the companies can follow are:
- **Sustainability***:* Companies should identify sustainability as a core corporate value. Companies should carry this theme through all of their communication and environmental activities.
- **Company Tradition**: It should be company's tradition of encouraging and constantly pursuing environmental programs. As a result, it will be well ingrained in the company's operations and understandings. For example, Aeon has been running programs for 25 years.
- **Founder's Philosophy**: Some companies, such as IKEA and LUSH, have imbued their employees with the founder's long-held ethical thinking.
- **Engaging Employees**: More recent adopters of environmental best practices create a sustainability culture in their organization. For example, Wal-Mart and Sam's club have introduced Personal Sustainability Projects (which is now called as My Sustainability Plan) which encourages employees to develop goals to improve their health and also the health of the environment.
- **Communication**: Companies can communicate their sustainability goals to every employee to develop a common understanding and a culture of sustainability.
- **Amenities to Encourage Employee Participation:** Companies should actively encourage and facilitate sustainable practices for employees. For example, Mountain Equipment Co-op (MEC) provides change rooms, showers and lockers for their employees, and currently 82 per cent of their employees use alternative transportation to travel to work every day.
- **Assist Other Environmental Causes:** Organizations should give back to the community. This helps the organizations in building a good overall image of caring for the betterment of society and the environment in the eyes of the consumer. For example Patagonia, Inc. headquartered in Ventura, California, is an American clothing company founded by Yvon Chouinard in the year 1973 it sells and showcases mainly sustainable outdoor clothing with more than 1,300 employees. The company uses organic raw materials which are environmentally preferred. The company also set asides 1% of their profits to environmental preservation groups. It also encourages its employ-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ees to volunteer for an environmental organization with two months full pay. It also buys wool only from farmers who use sustainable gazing practices.

- **Collaborating:** Collaborating with third parties is a good way. For example Adobe developed a Green Team that works on corporate sustainability initiatives. They came out with a project which allowed its employees to volunteer to help with the solar installation process for a low-income family. There are several other examples (Makower, 2014) that follow such as (1) General Motors working with Honda to develop cars that can run on hydrogen fuel, (2) Nestle joined hands with beverage company Coca-Cola and other beverage companies to form an alliance of Bioplastics Feedstock that encourages formation of plastic material from plants. Universities are also taking collaborative route to promote green activities. It includes 'Penn Green Campus Partnership' in which Penn has collaborated with a number of organizations such as Delaware Valley Green Building Council. The students have formed a group called Student Sustainability Association at Penn for spreading awareness among students and teach them sustainable practices (Penn, 2016).

LEARNING FROM THE BEST PRACTICES

Starbucks has extensively used green marketing campaign to defeat its competitors. Starbucks Corporation is an American coffee company and coffeehouse chain. Starbucks was founded in Seattle, Washington in the year 1971. The company believes in the importance of caring for the planet and working with and encouraging others to do the same. Some of the strategies which they follow include recycling, energy saving, water conservation, making green building, and addressing climate change issues. All these are discussed below:

- **Recycling:** The organization is trying to develop more environmentally friendly cups, and is working hard to expand their recycling program in an effort to reduce the waste they create. A lot of their customers are also working to reduce their own environmental impact. The company offers 10-cent discount to the US and Canada customers to encourage them to use their own reusable mugs or tumblers for their beverages. Customers staying in a store are also encouraged to use ceramic mug for their beverage. By doing this they are helping in keeping the natural resources i.e forest intact.

The company also introduced Grounds for Your Garden in 1995, which offers customers' complimentary five-pound (2.27-kilogram) bags of used coffee grounds to enrich garden soil. And where commercial composting is available, many stores are able to divert other food waste and coffee grounds from the landfill as well.

- **Energy Saving:** The organization has minimized their energy consumption by using renewable sources of energy to lower their impact on the planet. They have installed Energy Management Systems in approximately 4,000 stores. Energy Management Systems optimize heating and cooling and they enable the company to identify additional opportunities for savings going forward. They are also continuing to focus on driving energy savings in their stores through optimization of equipment and lighting specifications.

- **Water Conservation:** Since water is one of the most valuable natural resources, Starbucks understands its responsibility of preserving it. The company is evaluating their store design, equipments, and operations to identify ways to continue to reduce the amount of water they use. The company installs efficient fixtures, monitors consumption to identify spikes in water usage and targeting leak repairs, and upgrades the water filtration systems in the stores.
- **Green Building:** Starbucks is making its stores as green as they can by using responsible building materials and energy efficient designs to reduce their environmental footprint. It is often termed as the 'green building leader'. It employs around 300 Leadership in Energy and Environmental Design (LEED) certified designers. LEED is given by US Green Building Council to the organizations that follow its rules for green construction and design (GBES, 2015).
- **Addressing Climate Change Issues:** Because climate change poses a serious threat to the world's coffee-growing regions, the company is aggressively pursuing strategies to address this problem and help farmers mitigate the impact. It encourages programmes that facilitate farmers' right to use to carbon markets. It allows them to make additional income while helping to prevent deforestation.

CONCLUSION

Due to the increased awareness of the people toward environment, the growing inclination of consumers to green products is apparent. The emergence of green marketing is all set to modify the existing norms of the marketing strategies. It not only has the ability to address the profitability concern of the companies but also has the potential to attract the society to opt for green solutions and participate in this movement. Governments across the globe are increasingly taking steps to promote eco-friendly products. However, the marketers need to take the lead and innovate ways or follow existing best practices to promote green brands. The private players are also expected to collaborate with the local governments to ensure a greener future for the next generation.

Future studies can investigate whether culture has any impact on green brand personality. In addition future work can investigate the antecedents and consequences of green brand personality. They can also investigate the moderating role of relationship length.

Chapter 47
A Temporal Case Study of Green Business Initiatives of a Leading Firm in the Indian Hydrocarbon Industry

Kamalika Chakraborty
Indian Institute of Management Calcutta, India

Nishant K. Verma
Indian Institute of Management Bangalore, India

ABSTRACT

The effective functioning of modern business in the current day and age is incomplete without taking into consideration its extended impact on society and environment. In this respect companies need to continuously revisit and analyse their green initiatives to keep them relevant and contribute positively to the global cause. This book chapter provides a capable framework for organizations to conduct temporal analysis of their green initiatives and enable them to reflect on their current positions and strategize their future course of actions. Further, we analyse the green initiatives of the Indian Hydrocarbon Industry leader: Indian Oil Corporation Limited (IOCL) and trace its green journey across defined time periods thereby depicting the use of the developed framework in addressing the gap of temporal analysis in the literature.

INTRODUCTION

The consideration of society and environment in the world of business is becoming an integral part of the wholesome picture. We can trace the roots of the same in 1930s when Theodore Kreps realised the need of considering business activities and public welfare together. Then came the book 'Social responsibilities of the Businessman' in 1953 by H.R. Bowen, which stressed upon the obligation and responsibility on the part of the businessman to think for the society while doing the business. However, Friedman in 1970 opposed the notion by saying that the only social responsibility a company has, is to make money

which is in its shareholders' interest. Around the same time, the concept of corporate social responsibility had emerged. It was placed on the notion that a company is responsible towards all their 'stakeholders', rather than just the shareholders. With time, a broader concept, 'Sustainability' has emerged which also encompasses the consideration of future generations. The definition of sustainability given by World Commission on Environment and Development (WCED) in 1987 is still very apt:

Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs.

It talks about considering "the ability of future generations to meet their own needs". In this respect maintaining a healthy natural environment is one of the most important factors for future generations to come. In this light, businesses around the world need to constantly revisit their operations and devise strategic green initiatives to help maintain the natural environment around them. The present work is focused on the "green thinking" in businesses.

"Green thinking" has gone through a major shift in the recent decades. While the decade of 60s and 70s saw firms dealing with huge environmental crises, the 80s was characterized by taking steps towards meeting environmental compliances set by the regulatory bodies and minimizing compliance costs (also called reactive approach). The decade of 90s saw firms taking a proactive approach towards the environment by "anticipating the environmental impacts of their operations, take measures to reduce waste and pollution in advance of regulation," (Rondinelli, 1998, p. 39) and also identifying business opportunities through adoption of green initiatives (Rondinelli, 1998).

The motivation behind this book chapter was to develop a conceptual framework of green initiative by a firm. The second objective of the book chapter was to analyze the leading firm Indian Oil Corporation limited (IOCL), in the Indian hydrocarbon industry (an under-researched field) in the purview of the developed framework. In doing so the authors address the absence of temporal analysis of green initiatives in the extant literature. The authors specifically analyze the green initiatives of IOCL across three time periods- a) pre-2000, b) 2000-2007 and c) 2007-2015. Based on the analysis of the initiatives taken during this period along with the changes in the regulatory environment in the Indian Hydrocarbon Industry, the authors find that IndianOil was following a fit approach in the early pre-2000 era by complying with the necessary regulations. However, due to changes in practices in the business practices in the hydrocarbon industry post 2000 era, the organization redefined itself to adopt efficient practices across its core value chain which were internally driven and pro-environment and hence showed signs of stretch. This move was consolidated further in the 2007-2015 phase when the intensity of such initiatives increased further. Being responsible and ethical market leaders, coupled with increasing presence in the global market and being an integral player in the global hydrocarbon industry, they stretched themselves and adopted sustainability initiatives in non-core areas as well thereby making pro-environment operations an integral part of their corporate identity.

The case study therefore serves as example to other firms to reflect their current positions and strategize their future course of action with the help of the suggested framework. By addressing the stated objectives, the authors contribute to a greater understanding of practitioners in their greening actions.

LITERATURE REVIEW

The literature on green business initiatives can be broadly divided into two major categories viz., the drivers behind such initiatives and the actions taken by a firm towards its set environmental objectives.

The authors briefly discuss the literature related to the drivers below and refer readers to Dhull and Narwal (2016) for the detailed literature review of the same.

The drivers behind the green initiatives are primarily classified into external and internal. External drivers result from the fact that firms are always embedded in a network of various social and institutional relationships. Therefore, any action taken by a firm cannot be delinked from the various institutional forces it is subjected to. It is these external pressures that make a firm adopt certain practices or resist other (Powell & Dimaggio, 1991). Various external drivers have been identified in the green business literature over time and one may refer to Walker et al. (2008) for an exhaustive list of external drivers in the extant literature. Although, the drivers may vary according to the context considered, most commonly cited external drivers can be put as follows:

1. **Regulatory Pressure:** Government plays an important role in shaping a firm's business practices by providing the necessary technical and financial support (Porter, 1990). It is also true in case of green business practices where government plays an important role in terms of providing a regulatory push to the companies. Studies have found government regulations as one of the major external drivers that can force a firm to adopt a compliance or a proactive approach. Unlike a compliance approach, proactiveness in responding to regulatory pressure is found to result into successful green initiatives (Carter and Dresner, 2001).
2. **Customers and Competitors Pressure:** Customers and competitors pressure also play a major role in realizing firms to adopt green practices. Firms may put efforts in going green if either its customers provide the necessary encouragement (New, 2000) or they are conscious of their customer's country context. For example, Rao (2007) finds that Asian firms put extra effort towards their green initiative when their customers are from Europe. Similar observation is also made by Zhu et al. (2005) for the Chinese fabric firms when their customers belong to Europe or Japan. Competitors might also set industry norms which forces everybody to start green initiatives (Henriques and Sadorsky, 1999).
3. **Public Pressure:** Consumer awareness of the relevance of green initiatives in today's world also put extra pressure on the firms to adopt such initiatives. Lau (2001) finds in this regard that the American consumers are more aware than their Chinese counterparts, creating extra pressure on the American firms to adopt green practices. However, in their recent study on the green initiatives by Chinese SME firms, authors Huang et al. (2015) find public pressure to be one of the significant external pressures.
4. **Supplier Pressure:** The research over considering suppliers as a potential external driver has documented contradictory observations over time. On one hand suppliers are not found to influence a firm's green initiatives positively (Carter & Dresner 2001). However, focused collaboration with supplier has been found to positively impact a firm's green initiatives (Theyel, 2001; Vachon and Klassen, 2006). Recent research by Large and Thomsen (2011) in the context of Germany also seems to support the positive role of focused supplier collaboration.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Other external drivers include society, suppliers and global competiveness or multinational pressure (Ben Brik et al. (2013) and Walker et al. (2008)).

Internal drivers can be broadly divided into three categories i.e. a) individual commitment: Commitment shown towards environment by the leaders/ top management (New et al., 2000), investors of a firm (Walker et al., 2008) and employee involvement (Hanna et al., 2000), b) Environmental friendly image and c) Value creation through green initiatives.

Among the above three categories of internal drive, the possibility of value creation serves as a strong motivation for firms to invest in green thinking. Value creation can be in many forms including cost reduction, new revenue opportunities, etc.

There are studies that show the economic benefits of going green (such as cost reduction). Porter and van der Linde (1995) pointed that curbing on the pollution related activities while going green can lead to noticeable reduction in cost and waste which was hidden. However, not all firms have been able to generate cost advantage while implementing green practices. In this regard, Christmann (2000) has found that unless there are complementary assets present in the company to give helping hand to the green practices, it is difficult to realize the full economic potential of such practices.

Lanoie and Tanguay (2000) discuss some industry cases where green initiatives have been implemented while increasing the profitability at the same time. They try to find out some common factors among the various cases to better present the picture to the managers who have the idea of going green in their mind. Stefan and Paul (2008) specifically list down the opportunities for revenue growth and cost reductions while going green. They also mention the suitable circumstances under which such opportunities really pay for going green.

Another economic incentive of integrating such practices to the core business strategy can be for gaining competitive advantage in the arena of sustainable business (Brik et al., 2013).

The value creation associated with going green in your business can also be measured by how much the green initiatives create shareholder value. In their research, Klassen and McLaughlin (1996) find that there is a significant positive impact on the share prices of the firms that have taken strong environmental management initiatives. Moreover, they find that there is a negative impact on the share prices for the firms that have faced environmental crises due to weak environmental management at their workplaces.

Other market value indexes, such as Tobin's q have also been used to understand the relation between sustainable initiatives and their capability to generate value for the firms. Lo and Sheu (2007) in this regard find significantly positive relation between corporate sustainability and market value. It indicates that firms that are committed to find sustainable ways of doing business are valued higher in the financial markets by the potential investors.

Researchers have also tried to develop various frameworks liking sustainability with value creation to help businesses to develop new strategies for going green and become sustainable. Hart and Milstein (2003) develop a framework to link the sustainable development to the shareholder value creation through various business lenses. The framework works as a tool to develop appropriate sustainability strategies while simultaneously driving shareholder value. Another framework is suggested by York (2009), that tries to incorporate environmental ethics in business decisions through the help of the notion of classical American pragmatism. Other major studies in this regard include Russo and Fouts (1997), etc.

One may refer to Jain and Sharma (2014) for the complete literature review on the drivers of green supply chain management. For the recent studies related to the drivers of green initiatives in the Indian context, one may refer to Qadri et al. (2011) and Bhool and Narwal (2013).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The next set of literature deals with actions taken by firms in relation to environmental issues. Handfield et al. (1997) summarize the key responses by organizations to environmental issues. These responses have been time variant since the pressure from regulatory groups and the gravity of environmental issues have become more prominent with time. Hence in the early years, i.e., from1970- 90s the response by firms had been to merely comply with the standards in the cheapest and quickest way possible without internalizing them. Such responses have been described as "resistant adaptation, embracing without innovation" and "reactive". In these responses, the nature of initiatives is mostly end of pipe in nature without making any change to the internal technology or system.

In the next set of responses, there appears to be a major shift in the basic approach toward dealing with environmental issues from being merely compliance oriented towards embarking on taking responsible initiatives for the environment. These responses could be receptive, constructive or proactive.

In the receptive phase, firms start looking at the potential of adopting environmental issues and developing competitive advantage out of these initiatives. Often adoption of such initiatives is dependent on the interest of the "policy entrepreneur" who is willing to invest in skills needed to leverage the issues into competitive potential. In the other two responses, the degree of internalization of these issues is greater. In case of the constructive approach, a shift is observed in adopting approaches other than end of pipe initiatives and integrating current systems and technologies keeping in mind environmental concerns. In the proactive stage, green thinking is embedded at the very early stages in planning or designing a product. Such firms integrate the environment as a key variable in their decision making and implementing processes.

Kolk and Mauser (2002) review different typologies and continuum models derived conceptually or based on empirical case studies. In this case, the continuum models usually focus on responses by firms to environmental issues over time while typologies indicate the various ideal strategies based on some key defining criteria available to organizations to deal with the environment. While these models offer some ideal types for organizations, yet most of these models are unidimensional in nature and indicate development over time. Also in case of typologies, the time element appears to be missing in such a case. Most of these models also remain at the conceptual level only with few being tested by data to prove the validity of the model proposed. In this regard, Orsato (2006) explains "when does it pay to be green" by providing a framework of a set of environmental strategies which corporations can adopt based on their position in the industry in which they operate. These environmental strategies can be used to achieve competitive advantage. The two key defining criteria are competitive advantage on one hand and competitive focus is the other.

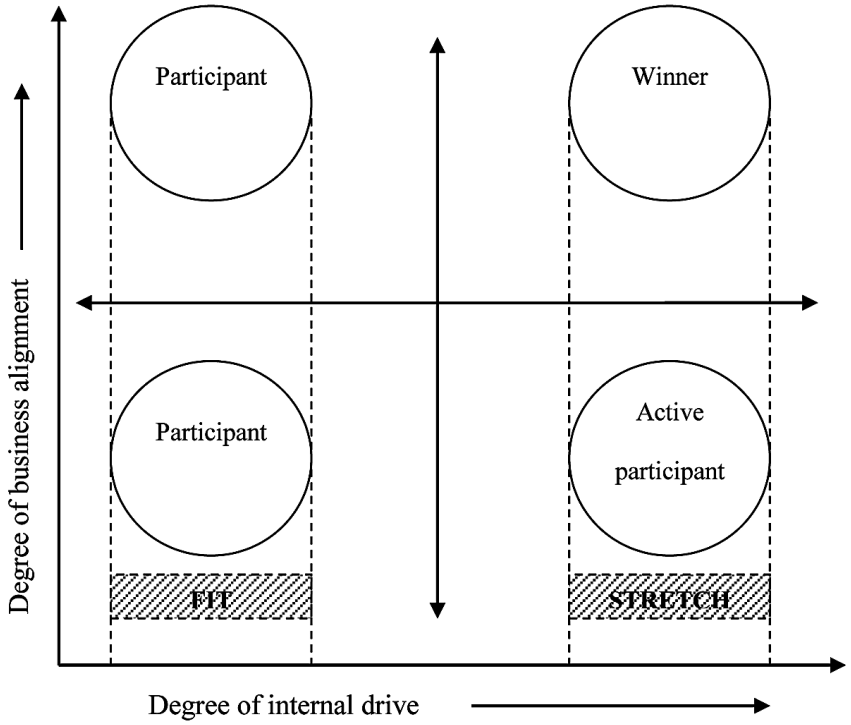
While the above set of literature discusses the varied responses by firms, Sharma (2000) emphasizes that it is the interpretation of the manager who sees environmental issues as opportunities rather than threats in order to develop them into environmental strategy. Also, managerial interpretations are influenced by several factors such as the legitimization of certain issues within the organization, the slack resources (time and resources) for enabling creative solving and incorporating environmental performance criteria in the employee evaluation systems. When the environment is seen as an integral aspect of corporate identity, environmental issues become legitimate concerns which cannot be easily disowned. Secondly, the availability of time and resources also enables managers further to engage in problem solving once these issues are framed as legitimate concerns to be addressed by the organization. Also, the ambiguity and uncertainty associated with looking for environmental solutions can be offset by incorporating defining criteria in the employee evaluation criteria which would encourage managers to view environmental issues as opportunities rather than as threats.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Also, Sharma (2000) talks about the perceived benefits of adopting environmental strategies by proactive firms while reactive firms perceive such responsiveness to environment as moving away from their overall objective. Proactive firms perceived the benefits as competitive strengths that they developed as a result of their engagement with the environmental issues. The capabilities that the firms developed were found to be "stakeholder integration", "capability for higher order learning" and "capability for continuous innovation". These capabilities were found to be aspects associated with proactive firms who saw these capabilities as essential and advantageous to providing them with competitive edge over other competitors.

Fineman (2003) documents some case studies on corporate greening in case of water and electricity utilities. The author traces the changes at the individual, organizational and the wider social and economic contextual level. At the individual level, the drivers of adopting environmental systems were mostly from top management. Significant greening can take place with the commitment of the top management team. Also, the role of environmental champions was stressed whose ability to persuade and influence was seen as more important than the formal role processes in the firm. Also, at the organizational level, it was the implementation of tangible systems in place along with the development of an organizational culture where all the members felt associated and involved in greening the organizations. While policies themselves may not bring about much change but it is the implementation of these policies along with the environmental management system which can help in achieving set targets which can reduce incidents of environmental damage. Also environmental reporting alerted organizations to collect data in a more organized way to find out and focus on issues which they had not considered earlier.

The author also reports an important finding related to the trigger for adopting environmental systems in the organization. The trigger for bringing about change within the organization was external. This was more evident in the water industry where higher degree of environmental legislation along with public awareness drove the organizations to adopt compliance measures. In the case of electricity companies, the increased awareness of public acted as a strong pressure for the firms to take action in relation to the external drivers in order to avoid the backlash in case the company fell short of environmental expectations. The authors conclude that irrespective of the drivers, the higher degree of environmental management system operating in the companies reflects a growing awareness among companies to take environmental issues seriously.



CONCEPTUAL FRAMEWORK

A reading of the literature shows the absence of temporal studies on the gradual transformation of a firm's green initiatives. Out of the limited evolutionary studies in the literature most of such papers remain only at the conceptual level and are unidimensional i.e., they only incorporate the type of actions taken by a firm towards greening their business. However, drivers of green initiatives play an equally important role in determining the firm's possible future course of action. In this respect, the authors bring in the two major dimensions of green business studies (as discussed above) to develop the framework. The same is shown in Figure 1.

One of the dimensions taken is the degree of business alignment (DBA). It is indicative of the degree of alignment of green initiatives with the core business value chain of the firm. The greater the proportion of total green initiatives (at any given point of time) incorporated in the value chain, the greater is the DBA of a firm. The other dimension is the degree of internal drive (DID). At one extreme, a low

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Conceptual framework

DID means that the firm is taking green initiatives solely because of the external drivers. On the other extreme, a high DID indicates that a greater motivation for firms to take green initiatives comes from a strong internal drive along with the external drivers. In such a two-dimensional setting, a participant is a firm which is only complying to the external pressures and in doing so all its green initiatives are completely unaligned to the core business strategy of the company. Most of the firms can be thought of as a participant when they start their green journey. A winner is a firm which has reached a stage where its green initiatives are driven by internal factors (along with constantly present external factors) and all those initiatives are aligned with the core value chain of the firm. A winner is the expected destination status for a firm in its green journey. A firm might be a smart participant (intermediary stage) which denotes that the firm is aligning its green initiatives with their core value chain under the presence of external pressures. Similarly, a firm might be an active participant (intermediary stage) which denotes that the firm is more internally driven in its adoption of green initiatives which may be not aligned with the core value chain of the firm.

With regard to the framework discussed above, the authors use the analogy of strategic fit and stretch to comment on the kind of strategic approach a firm is taking while adopting green initiatives. A firm is said to be in a strategic fit when it configures its resources to merely respond to the external forces in its business environment. On the other hand, under strategic stretch a firm leverages its resources in such a way so that it is able to create new opportunities and in turn gain competitive advantage (Hamel and Prahalad (1992), Hamel and Prahalad (1994)). In this respect, firms which are either participant or smart participant follow a strategic fit approach and those which are active participant or winner follow a strategic stretch approach.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

As stated earlier the literature lacks a proper temporal case study of the green initiatives taken by a firm and the above two dimensional framework is an attempt towards the same. In this regard a case study on the green journey of Indian Oil Corporation Limited (IOCL) in the purview of the framework suggested above is presented in this chapter. Hydrocarbon industry has a major impact on the environment and therefore has a greater responsibility towards the greening of their operations. Moreover, studies on green initiatives within the hydrocarbon industry in the context of developing countries are very few which only list the myriad initiatives taken by firms. Such studies do not analyze the trajectory of the firms in greening the value chain and thereby are devoid of the scope to enable theorization from such temporal analysis. In this respect, IOCL being the market leader in the Indian refinery sector (IBEF India Oil and Gas industry report) with a long history therefore serves as an exemplar for the case study.

In the next section the authors discuss the hydrocarbon industry briefly which serves as a contextual background for the study.

Hydrocarbon Industry

Hydrocarbon industry in India plays an important role in the national economy. It contributes to around 15% to the GDP of the nation. The activities of the hydrocarbon industry can be broadly divided into two parts. The upstream part is focused on exploration and recovery of crude oil and gas. The downstream part is based on refining the crude oil, manufacturing other products from oil, selling and distributing through a huge network of retail outlets to the customers. A brief history of the Indian Hydrocarbon industry is given below.

The industry has gone through many changes while meeting the burgeoning demands of a growing nation. In post-independence era with the growing focus on industrialisation, modernisation, self-reliance, the hydrocarbon industry started growing through the establishment of public sector companies such as Oil and Natural Gas Commission (ONGC) in upstream, Indian Refineries Limited (IRL) and Indian Oil Company Limited (IOC) for marketing. Also, India's first efforts for research and development for the hydrocarbon industry were paid off with the formation of the Indian Institute of Petroleum (IIP) at Dehra Dun.

With the onset of the first Five-Year Plan on April 1st 1951, there was some investment in the petroleum sector during that period. Further, the new Industrial policy was confirmed on April 30th 1956. As per the new resolution industries were divided into three categories. Schedule – A, consisted of 17 core industries of basic & strategic importance which included oil and these were considered to be the responsibility of the Government Schedule – B companies consisted of 12 categories including aluminium, road, sea transport etc. which would be Government owned but private enterprise participation was also expected. The remaining would be expected to be taken up by private enterprises.

Over the years, the Indian petroleum industry has seen huge growth with the growth of public sector refineries and private sector enterprises also with the onset of deregulation and liberalization. With very little in house expertise at the time of independence, the petroleum sector has grown by leaps and bounds with skills and knowledge at par with global standards.

In the last 65 years, the petroleum product consumption has increased by around 59 times from 3 million tonnes during 1948-49 to about 176.9 million tonnes during 2015-16.

Also, several bodies with specialized knowledge have come up to support the development of the sector such as such as the Indian Institute of Petroleum, Petroleum Conservation Research Association, Oil Industry Safety Directorate, Centre for High Technology and Directorate General of Hydrocarbons.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, oil companies have also set up their own research and development centres. In this regard, the R&D centre of Indian Oil Corporation Limited in Faridabad finds worth mention which has done pioneering work in formulation of lubricants and greases. It is also considered to be the best in Asia. Refer to the Appendix for the list of refineries in India with their respective capacities.

INDIAN OIL CORPORATION: THE CASE

Indian Oil today is the flagship national petroleum company of India. It has the largest refining capacity in India with 35% refining market share. Also, the petroleum product market share corresponds to 46% and is the highest in India. Indian Oil is ranked 161st among all the world companies in the fortune 500 list as on the year 2016.

History

In 1958, the Government of India established its own refinery company named as "Indian Refineries Ltd" and with assistance of Soviet and Romanian groups, the company built its own refineries at Noonmati, Barauni and Koyali. In 1959, "Indian Oil Company" a statutory body was started for supplying oil products to state enterprises and selling products of the refineries. Post 1961, Indian Oil company became the major marketing organization for exporting and importing oil and gas. In September 1964, Indian Oil Corporation Limited was formed through the merger of Indian Refineries Ltd. and the Indian Oil Company.

The broad businesses of Indian Oil Corporation include:

Refining

Indian Oil processes crude oil in its refineries with the help of advanced technologies to produce products like gasoline, diesel, naphtha, lubricants and many others which enable the smooth running of the economy. It controls 11 out of 23 refineries. They are briefly described below.

- **Digboi Refinery, Assam:** The oldest refinery in India is Digboi Refinery in north-east India which was commissioned in 1901. The capacity of the refinery was increased to 0.65 MMTPA after necessary revamping.
- **Guwahati Refinery, Assam:** Guwahati Refinery was commissioned in 1962 with a present capacity of 1.0 MMTPA.
- **Barauni Refinery, Bihar:** Barauni Refinery was commissioned in 1964 and presently it's capacity today is 6 MMTPA.
- **Gujarat Refinery, Gujarat:** The Gujarat Refinery at Koyali in Western India has a capacity of 13.70 MMTPA. The refinery was commissioned in 1965-1966.
- **Haldia Refinery, West Bengal:** Haldia Refinery was commissioned in January 1975 and is now operating at a capacity of 7.5 MMTPA.
- **Mathura Refinery, Uttar Pradesh:** Mathura Refinery was commissioned in 1982 to satisfy the requirement of petroleum products in north western part of the country including National Capital Region. The present capacity has been increased to 8.0 MMTPA.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Panipat Refinery, Haryana:** Panipat Refinery is presently operating at a capacity of 15 MMT/yr.
- **Bongaigaon Refinery, Assam:** The Bongaigaon Refinery processes crude with a capacity of 2.35 MMTPA.
- **Paradip Refinery, Odisha:** Paradip refinery has been built with a capacity of 15 MMTPA and is touted to be Indian Oil Corporation's most ambitious project till date.
- **Chennai Petroleum Corporation Limited (CPCL):** CPCL has two refineries with a combined refining capacity of 11.5 Million Tonnes Per Annum (MMTPA).

Pipelines

A network of crude oil and product and gas pipelines runs across the country with a capacity of 80.490 million metric tonnes of oil and 10 million metric standard cubic meter per day of gas.

Marketing

Indian Oil has around 43000 marketing touchpoints with its distribution networks stretching across the length and breadth of the country. Also, based on Readers digest-AC Nielsen survey, Indian Oil was adjudged as the "most trusted brand" in the gasoline category.

Indian Oil R&D Centre

R&D centre is one of the best research centres in Asia with currently around 384 patents in different areas, of which 270 are international patents. The centre has developed several in house technologies which are made available for licensing. The centre works on several areas such as lubricants, engine testing, refinery technologies, environmental sciences and a host of different other topics.

Apart from the above, Indian oil has also successful ventured into both upstream and downstream activities. Through backward integration Indian Oil has ventured into exploration and production of crude oil as well. IOCL has also forward integrated into petrochemicals business given the huge demand for petrochemicals in India and other countries as well.

Data

For the purpose of the above study, the authors resorted to data available in the public domain, i.e., company sustainability reports, newsletters, government policy reports, business magazines, hydrocarbon industry reports as key sources of data. Overall, we referred to more than 35 reports which included the above. One of the authors had a prior working experience in the organisation giving the authors an advantage in terms of understanding the organisational structure and technical aspects of the various initiatives in general and green initiatives in particular.

GREEN INITIATIVES BY IOCL

In this section, the authors discuss various pro-environment initiatives taken by IOCL over the last 15 years.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Initiatives Under Fuel Production

Fuel policy norms in India came in a big way after 2000 in the form of Auto fuel policy in 2003. These were based on European regulations. Initially, in the year 2000, Bharat Stage (BS) - I norms which were based on Euro I norms were introduced in entire India. At the same time, National Capital Region (NCR) was introduced with Bharat Stage - II norms which were loosely based on EURO II. After the Auto fuel policy came in 2003, BS-I was slowly phased out with BS-II taking its place, which got implemented in entire India. Simultaneously, BS-III norms were introduced in 13 major cities in India. From September 2010 onwards BS-III norms were implemented throughout India and BS-II was phased out. BS-IV norms were implemented in the 13 major cities from April 2010. Currently, BS-IV norms are being implemented throughout India and this process is expected to be completed by April 2017. In 2016, the Indian government decided to skip BS-V norms altogether. Instead it was decided to implement more stringent BS-VI norms from 2020 onwards.

In this regard, Indian Oil has undergone major changes in its existing process through installation of relevant technologies in the refineries to comply with the standards set by the Auto Fuel Policy of India while producing petrol (Gasoline) and diesel. This initially began with removal of lead content in gasoline since lead was a harmful component and was associated with health issues. Lead content was removed in phases and finally brought down from 0.56 g/l to 0.013 g/l. Secondly benzene content was also drastically reduced since benzene is carcinogenic. Benzene in gasoline has been kept in line with BS III/IV norms. Also, sulphur, an important pollutant besides causing damage to the exhaust systems in vehicles, has been subsequently brought down to very lower levels, i.e., 500 ppm (BS-III) and 50 ppm (BS- IV) through installation of state of the art technologies by Indian oil refineries to comply with the norms. With 35% in national refining capacity of Indian Oil, the organization has played a proactive role in implementing the BS norms successfully over time and ensuring a cleaner environment to the citizens of the country.

Energy Conservation Initiatives

Post 2002, over the time IOCL has taken various initiatives in making their operations more efficient by consuming less fuel for the same output through process modification. Operational efficiency and improvements in the existing processes were already a part of Indian Oil's philosophy. Such measures/actions gained more attention after the dismantling of the three decade old Administered Pricing Mechanism (APM). Under APM, oil marketing companies were compensated at the rate of 12% irrespective of their successful/unsuccessful investments. Dismantling of the same meant that IOCL had to become more efficient in their operations in order to face the market competition and forces. All this led to IOCL taking a focused approach towards saving cost in various ways, one of them being energy conservation. Energy conservation initiatives meant lesser fuel consumption which in turn would lead to lesser environmental pollution. Therefore, energy conservation initiatives have become one of the important parts of sustainability strategy of IOCL.

In this regard, energy conservation schemes have increased from 20 in 2007-08 to 126 in 2013-14. MBN which is an energy performance indicator, has also decreased from 77 in 2003-04 to 56 in 2012-13. Lower value of MBN signifies the better performance as far as energy conservation is concerned.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Water Conservation Initiatives

Water is an essential component in refinery process. There is a specific demand of water in all refinery operations. However, IOCL has taken specific measures to reduce their dependence on regular water sources. In this regard, IOCL initiatives can be divided into two categories viz., refinery specific and non-refinery specific. Refinery specific initiatives consist of reusing/recycling the treated effluent for purposes like fire water, cooling water towers, etc. 75% of the treated effluent was reused in the refinery in 2013-14. The treated effluents comply with the MINAS standards set by MoEF (Ministry of Environment and Forests). Non-refinery specific initiative consists of rain water harvesting. Rain water harvesting has been adopted in R&D centres and the marketing and pipeline installations as well.

Waste Management

Indian oil has been prompt in its dealing with solid waste management by operating on the principle of prevent, reduce, reuse and recover. The organization treats it waste and complies with the regulations set by Hazardous Waste Act and Biomedical Waste Act. The main types of waste generated are oily sludge at the crude oil and product tanks at pipelines and marketing sites, used catalyst in the refineries and bio-sludge. In the refineries, strategies to minimize waste have been reduction of waste generation at the source, tank cleaning methods, safe disposal methods, bio-treatment of sludge. The sludge after being treated is used as manure in the green belts and the used catalyst is sold to cement industry for use as a filler material. Also, in the marketing division any kind of hazardous waste is treated as per the pollution control norms.

Emission Reduction

Emissions by Indian oil can be broadly be classified into two categories. The first category caters to reduction of gaseous emissions emitted from the core operations like handling, transporting of crude, products, leakages of hydrocarbons refinery operations etc. Several strategies have been developed to ensure that the emission standards are met in line with the Air pollution control norms. These include monitoring tail end emissions through the installation of analyzers, installation of necessary technologies to treat the gases before discharging them to the atmosphere, development of technologies through the involvement of research and development wing of Indian Oil Corporation.

Also, in addition to that above, there has been a renewed focus on reducing greenhouse gas emissions under the Kyoto Protocol which came into force in 2005 to protect the environment from the harmful effects of CO_2, CH_4 etc. In this regard, the Government of India had also proposed the "National Action Plan for Climate change" in 2008 to develop country specific strategy to mitigate climatic changes. The Government has therefore emphasized companies to reduce their carbon footprint.

In this regard, Indian Oil has also developed projects to reduce carbon footprint in its core operations. One such process is through the implementation of clean development projects in refinery installations. Clean Development projects are those projects which are designed to reduce the emission of greenhouse gas emissions through appropriate process modifications in their existing setup. Till now around four such projects in the refineries have been registered under UNFCCC, United Nations Framework Convention on Climate Change by Indian Oil Corporation. Once these projects are operational then the reduction in emissions is quantified by a type of emission unit called certified emission reduction unit

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

or carbon credits based on the approval of the CDM Board members. These carbon credits can be traded with countries listed under the scheme as provided to earn benefits from the investments made in such sustainability initiatives.

Alternative Energy Initiatives

In complying with its environmental objective, Indian Oil has taken steps in investing in alternative renewable energy initiatives. In this regard, Indian Oil successfully installed a 5MW solar power project at Rajasthan under the Jawaharlal Nehru National Solar Mission Phase – 1, Batch - 1. Indian Oil won the competitive bid among 350 participants to install the solar power project at Rajasthan. Also, a 21 MW wind power plant has been installed in Gujarat in 2009 and has been registered as a CDM project in May 2011. A second wind power plant is under implementation at Andhra Pradesh. Indian Oil has been instrumental in setting up a joint venture company with Nuclear Power Corporation of India to establish a nuclear power plant at Rawatbhata, Rajasthan. Among these, Indian Oil has also ventured into Bio-fuels with Jatropha cultivation of around 6000 hectares in association with Chattisgarh Renewable Energy Development Authority (CREDA) at Chattisgarh. This project has also created more than 3.5 lakh man days of rural employment. With a view to providing electricity to the rural populace, Indian Oil has distributed solar lanterns through its retail network and Kisan Seva Kendras to provide the rural masses from a smoke free environment and other health related issues. Around 115.66 crore worth of investment has been spent on renewable initiatives in the year 2012-13 which demonstrates their commitment to invest in such sources for future generation and consumption.

Biological Park Initiatives

Indian oil has also been committed to developing green belts in all its refineries not only for aesthetic purposes but also to act towards controlling pollution. The number of tree plantations has also increased manifold (19-20 times) from 2010-11 to 2015-2016. Over 10 lakh trees have been planted around refinery locations such as Mathura, Koyali, Digboi, Bongaigaon and Barauni. These green belts also serve as a natural habitat for various bird species.

Green Buildings

Indian Oil has also taken measures to ensure that its buildings are green and energy efficient. Presently, one such administration building has been awarded the “green building certification” and the “gold rating” award under LEED (Leadership in Energy and Environmental Design) system, which stands for leadership in energy and environmental drive, which is an international green building rating system providing green rating status.

Organizational Structure

While the organization has taken several initiatives towards greening, what appears striking is also the internal commitment of the organization by dedicating specific roles and responsibilities at various levels. At the corporate level, a board committee exists for CSR (Corporate Social Responsibility) and sustainable development followed by a department for renewable energy and sustainable development.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are also nodal officers appointed at the various divisions to look after the initiatives to suggest ideas and proposals for taking sustainability drive of Indian Oil ahead.

ISO 140001

ISO refers to a series of environmental management standards that have been developed by the International Organization for Standardization (ISO). The framework provided by ISO 140001 also called the Environmental Management System is a series of guidelines to enable a company to manage their environmental efforts and also run their operations more efficiently keeping the environment in mind. In this regard, Indian Oil has been certified as an ISO 140001 company which means that the organization has adopted a systematic approach towards managing its initiatives. ISO certification is not mandatory in nature and is a voluntary endeavour.

Data Analysis

In this section, we explain the rationale behind the classification of the various green initiatives based on the driver and the degree of alignment.

THE FUEL INITIATIVES

The fuel initiatives adopted by Indian Oil were based on meeting the stringent Auto fuel policy commissioned since early 2000s. As discussed in the literature review we see that one of the external drivers is the regulatory pressure which plays a major role in shaping a firm's actions. Such kind of pressure serves as a key push factor to take necessary actions. In this case also the Auto fuel Policy can be seen to act as a mandatory push factor for Indian Oil to take necessary actions to comply with the norms.

Given the external push, Indian oil adopted major technological changes to meet all the necessary norms for gasoline and diesel. In this regard, Indian Oil had to undergo major revamp of its existing

Table 1. Classification of the various green initiatives based on the driver and the degree of alignment

S No.	Initiative	Internal/External	Aligned/Not-Aligned
1	Fuel initiatives	External	Aligned
2	Energy conservation initiative	Internal	Aligned
3	Water conservation	Both	Non-aligned
4	Waste management	External	Non-aligned
5	Emission reduction	Both	Aligned
6	Alternative energy initiatives	Internal	Non aligned
7	Biological Park initiatives	Internal	Non aligned
8	Green buildings	Internal	Non aligned
9	Organizational structure	Internal	Aligned
10	Implementation of 140001	Internal	Aligned

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

process technologies to produce the acceptable quality fuels such as the installation of diesel hydrotreating units. These changes were made to the core operating process in the refinery installations which forms a key part of their business space. Hence all the necessary changes made were aligned with the core value chain of the firm

Energy Conservation Initiative

As discussed earlier, Indian oil has always focussed on improving its operational efficiency. However, with changes in the regulatory environment post 2002 in the form of dismantling of APM, the organization had to start looking for opportunities to become more efficient and more competitive. Since the Government was no longer compensating the oil companies through subsidies, therefore the companies had to look for ways to save costs. According to our literature review, reduction in costs which lie hidden in the pollution related activities of the firm form one kind of internal drivers. Hence the energy conservation initiatives taken by Indian Oil were voluntary and driven internally to generate savings. Consequently, implementation of these schemes involved process modifications in the core processes in the refineries and other core activities which indicate that changes made were aligned with the core value chain of the firm

Water Conservation

Water conservation efforts can be broadly divided into two parts as discussed in the previous section. Treatment of effluent water follows specifications provided under the Water Act for the quality of effluent water to be discharged. Such Acts are push factors which the organization has to comply thereby making such actions externally driven. However, complying with the standards does not require making any changes to the core processes or technologies. Secondly, water is mainly used as an ancillary agent to the core processes. The effluent is basically treated with relevant equipment before discharging and reuse purposes. Hence, we argue that changes made in this case are not aligned with the core value chain of the firm.

The next set of initiatives is rain water harvesting which has been installed in refinery, marketing and pipeline installations to collect rainwater to recharge the groundwater. Such activities are therefore internally driven based on the commitment of the organization to conserve water and infiltrate the groundwater level.

In light of the above two broad kinds of initiatives, therefore it is found that both kinds of drivers exist i.e. external and internal

Waste Management

Such initiatives are again based on regulatory acts which require Indian Oil to comply with. Hence, the driver is this case is external. Also, the actions taken also are based on such external drivers. In this case also, the treatments conducted do not bring about any alteration in the core processes of the organization. The organization however, responsibly deals with waste management to comply with Hazardous Waste Act and take necessary measures. However, those actions do not require any change in the core operation of the organization. Therefore, these set of initiatives are non-aligned.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Emission Reduction

There are broadly two kinds of emission reduction initiatives. The first set of initiatives refers to the controlling of those gases which are emitted during the processes in the refineries. Since, there are again mandatory regulations, the driver is definitely external. In this case the actions require making changes to the key technologies of the firm. Hence the initiatives are linked to the core value chain of the firm.

In the second set of initiatives, Indian Oil has taken up efforts at reducing greenhouse gas emissions through reduction in CO_2 (Carbon dioxide) Levels. The organization sensed an opportunity in the clean development process of Kyoto Protocol. This could enable the organization to reduce carbon dioxide emissions as well as earn some carbon credits. Hence the approval of four refinery projects as CDM project show the internal driver of "cost saving through identifying hidden costs in pollution related activities of the firm" and also conducting pollution free operations. In this case, Indian Oil's efforts at reducing carbon dioxide made them see the benefits of adopting CDM projects and derive economic benefits as well. Also, implementation of these projects involve making changes to the core processes making the initiatives aligned with the core value chain of the firm.

Alternate Energy Initiatives

Alternative energy initiatives were started by Indian Oil as a response to the conducive environment provided by the Government of India through the National Action Plan on Climate change in 2007-08. In the initial years, the Government had provided several incentives and subsidies for engaging in renewable initiatives. Hence Indian Oil entered this domain with great energy and enthusiasm and plunged into the renewable energy initiatives. An indication of such internal drive is indicated in Indian Oil competing with 350 other project participants in bidding to set up a Solar Plant in Rajasthan. Indian Oil has also developed solar lanterns and used its vast retail network to distribute to the rural population.

However, in the last two years the regulatory environment with respect to renewable energy sources has taken a mandatory path, i.e., 0.25% has to be solar power and 6.75% has to comprise other renewable sources of energy of the total energy generated and consumed by the refinery. However, Indian oil had already plunged into renewable energy much before the Government had made it mandatory for firms to adopt renewable energy initiatives. Since implementation of these activities do not alter the core value chain, these activities are therefore non-aligned.

Biological Park Initiatives

Tree plantations have been conducted in and around refineries to reduce greenhouse gases and also provide a natural habitat for flora and fauna. Such kind of activities also give visibility to the organization in terms of maintaining a rich bio-diversity by maintaining such ecological parks. Although these initiatives do not form a part of their core value chain, they occupy a huge place of pride among other initiatives as well.

Green Buildings

Indian Oil has also started to adopt green thinking in their design of building architecture as well and have been awarded the "Gold Rating" under the LEED system of rating (Leadership in Energy and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Environmental Design) indicating their early efforts at greening their habitats. Hence this shows that even though these initiatives do not for a part of their core value chain, yet Indian Oil is leaving no stone unturned in becoming environmental friendly.

Organizational Structure

Successful implantation of the various initiatives is only possible through the dedicated efforts of a team comprising of top management and various other appointed officers to plan and implement the initiatives. In this regard, it can be seen in the reports, that the organization has a dedicated department to handle sustainable initiatives along with nodal officers appointed across the various aspects of the core value chain. This indicates a high degree of internal drive by the organization which has its own implementing and monitoring body (i.e., at the corporate level) to ensure the successful completion of its initiatives. The organization sees sustainability as a key part of their corporate identity and that perception itself is visible in the dedicated administrative positions.

ISO-140001

ISO-140001 indicates the organization's efforts at streamlining their environmental efforts by adopting the guidelines under ISO 140001. ISO adoption is a voluntary initiative and is not mandatory. Hence by adopting the framework under ISO 140001 Indian Oil has systematized their efforts in managing, calculating the losses in hydrocarbon, energy etc. to ensure better operations and focus on those issues that have been left unattended. Therefore, this initiative is definitely aligned with the core value chain of the organization.

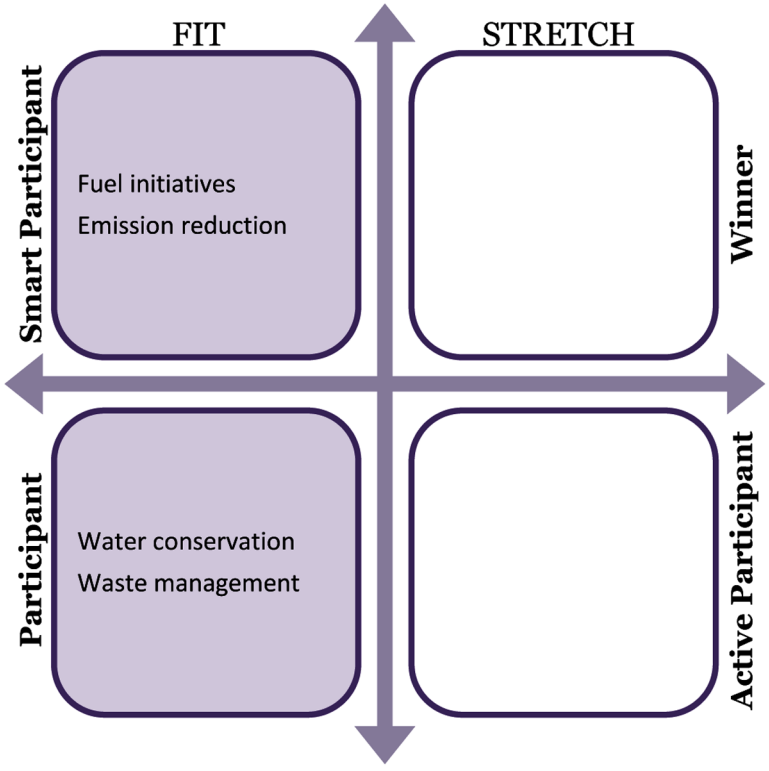
TIME PHASE ANALYSIS

The awareness around conducting sustainable business operations in India has increased tremendously over the last 10-15 years. This period has been marked by some of the major policy changes to build a conducive environment to engage in sustainable business operations along with firms also evolving in their responses to the changes in the regulatory environment. In this regard, the present study focuses on the green initiatives taken by IOCL for the following three time periods Pre-2000, 2000-2007, and 2007-2015. We specifically chose year 2000 as it marked the onset of key regulatory fuel policy initiatives by the government around that time. The rationale behind choosing the year 2007 was due to the fact that the authors see an increase in the number of initiatives post 2007 which therefore becomes a key point in setting the time period for our analysis.

Pre-2000

Pre-2000, Indian Oil complied with mostly environmental regulations in the areas of fuel emission standards, water effluent quality, waste disposal. In these areas, the regulatory acts by the several monitoring bodies called for taking measures to adhere to the emissions. The driver was mostly external and the actions taken were both aligned and non-aligned, therefore the organization was following a fit strategy. In this case, the organization was mainly complying with the norms, i.e., the emission norms and other

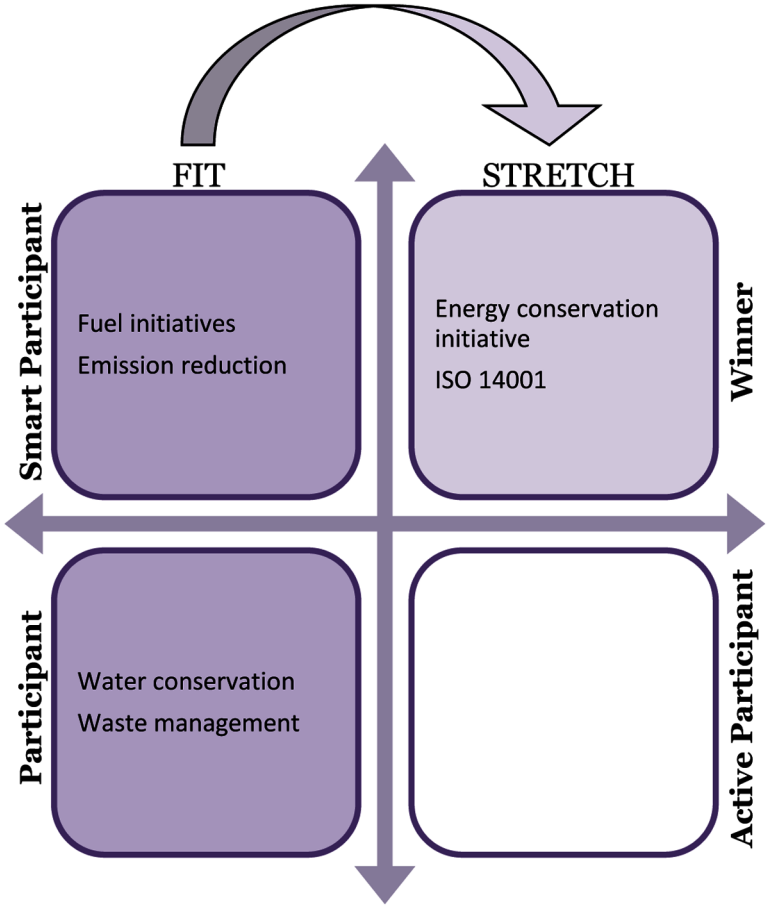
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



water and waste related norms. Hence the organization was mostly a "smart participant" in areas of alignment and a "participant" in areas of non-alignment as can be seen in Figure 2.

2000-2007

Beginning of 2000, some key changes took place in the regulatory environment. The authors now explain these changes and Indian Oil's corresponding actions in this regard. From early 2003, fuel policy norms became even more stringent with the commissioning of the Auto Fuel Policy. In this period (2000-2007), Indian Oil's position as a "smart participant" solidified further. Moreover, the company was still in the strategic fit approach. This meant that the IOCL's green initiatives that were aligned with their core value chain were externally driven. However, as compared to the pre 2000 era, this period saw some signs of strategic stretch by IOCL. This is clear in Figure 3, where IOCL had two initiatives in the winner quadrant, i.e., such initiatives were not only aligned with the core value chain but also were internally driven. The internal drive behind such "winner" initiatives was motivated by changes in some of the key hydrocarbon industry practices such as dismantling of Administered Pricing Mechanism (APM).



As mentioned earlier, dismantling of APM meant that Oil companies had to face new challenge of making their operations more efficient in order to reduce cost and be able to compete in the open market and make profit. The two "winner initiatives" in this period emerged as a consequence of making necessary changes to adapt to the changed scenario. Hence this shows the organization's pro-activeness in responding to the changed scenario. By the end of the period 2000-2007, IOCL no longer just restricted

Figure 2. Conceptual framework depicting Pre-2000 era

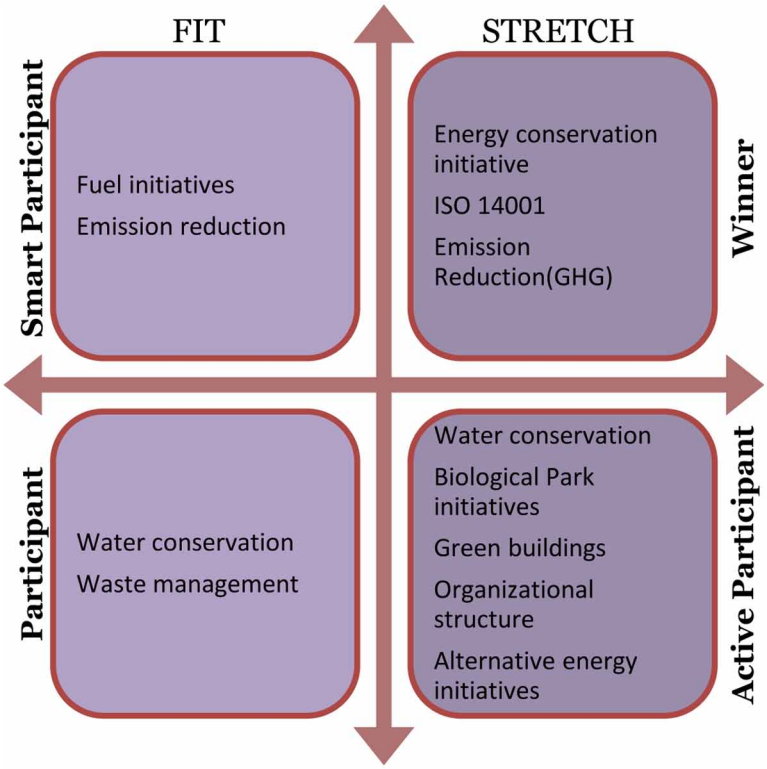
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Conceptual framework depicting 2002-2007 era

themselves to only the fit approach but also started to stretch themselves as far as green initiatives were concerned. In this regard, the ISO 14001 certifications for IOCL refineries also increased substantially.

2007-2015

During this period, Indian Oil now started stretching in green initiatives in other non-aligned areas. As we can see from Figure 3, the initiatives can be seen concentrated in the active participant quadrant.



By the end of the last time phase, Indian Oil had already taken started to take green initiatives by stretching themselves. With Indian Oil operations spreading across business spaces, and increasing global reach, this led them to consider green initiatives on a larger scale and make it an indispensable part of their future journey. The organization was now more focused on making the environmental initiatives an integral part of its identity. It can be observed in the way Indian Oil has expanded their organizational structure to include additional specific departments and appoint nodal officers across various divisions to plan and implement green initiatives. Specifically in this space one of the major set of initiatives were the renewable/alternative energy. In their reports the authors see that the organization considers renewable energy as one of their potential future business space.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Also, as seen in the last phase (refer Figure 3) they made their presence felt in the winner quadrant with the onset of ENCON initiatives and engaging in ISO initiatives. Further in the present phase, it can be seen that the number of initiatives have further increased in case of energy conservation initiatives. The number of schemes went up from a mere 20 in 2007-08 to 126 in 2013-14. Therefore, the momentum continued to build in case of taking green initiatives. Hence by taking an internally driven pro-environment approach in the last era, the organization capitalized on its green ventures and started building on its capabilities at saving costs through energy efficient operations leading to a further solidification in their position in the "winner" quadrant. Also, after successful adoption of ISO 140001, the organization also went for ISO 14064 which was meant for greenhouse inventorization and reporting by the refineries. All the refineries got the certification in and around 2010. All the above figures as found in the reports indicate their drive to conduct green and sustainable operations. All of the above reflects the increased intensity of the winner quadrant.

Being a market leader in the country, also serves as a key internal drive to motivate the organization in adopting green initiatives whole-heartedly and setting an example to other organizations. This factor explains their efforts at embracing the sustainable business practices in all spheres of their activity and making their presence felt both in the active participant and winner quadrant.

Figure 4. Conceptual framework depicting 2007-2015 era

CONCLUSION

The need for addressing environmental concerns is more than ever before. In this regard, literature on green initiatives is also growing at a fast pace. Academicians are also trying to understand various aspects of such initiatives. Various authors have tried to understand the key drivers behind green initiatives and the nature of such initiatives. Very few studies provide a conceptual framework to assess a firm's approach regarding green initiatives over time. The current work is an attempt towards proposing a framework to study a firm's approach in taking green initiatives in different phases of time. Authors choose IOCL as the exemplar for studying its green journey over time through the lens of the conceptual framework suggested in this work.

The three phases show the journey of Indian Oil in their efforts towards green initiatives. IOCL was initially in the fit mode with compliance of set regulatory standards in the pre-2000 era. Based on the regulatory standards Indian Oil ensured their commitment to the standards. However, with changes in the business practices in the industry, Indian Oil had had to go that extra mile to incorporate fuel efficient practices to save costs which consequently led them to undertake more environmental friendly initiatives related to their core value chain. Being a market leader and with an increasing global reach, the organization started venturing in other non-core areas as well with regard to green initiatives while intensifying their presence in the core activities. Hence in the latter part, the organization became an active participant and also mobilized its efforts in the winner quadrant as well.

The above case study demonstrates how an organization has moved over time with respect its green initiatives. The framework helps to understand the position of the organization at different phases. Hence it serves as an example for other organizations to learn and understand the trajectory of Indian Oil in order to reflect upon their own position and how they can improve in greening their operations.

Chapter 48
Environmental Sustainability Practices for SMEs

Gurudas Nulkar
HRD, India

ABSTRACT

The rate and scale of environmental degradation, through economic activities, has triggered widespread awakening among businesses, governments and civil society. The world over, corporations have responded by adopting sustainability practices and reporting. However, much of these happen within the premises of the corporations. As larger organizations outsource their manufacturing and service operations to small and medium enterprises (SMEs), they effectively shift their environmental burden on their vendors. In most developing countries, poor regulations and weak enforcement of environment laws leave the SMEs on their own, to improve their environmental practices. However, their limited resources and managerial capabilities are often inadequate to undertake sustainability practices. This chapter presents the findings of a research conducted among engineering SMEs in India. It proposes a lifecycle approach towards environmental practices and discusses potential business benefits and value creation from this. The chapter gives a roadmap for green business strategies, which SMEs can implement within their organization.

1. INTRODUCTION: WHY SMEs?

In our lifetime, we have witnessed some of the worst natural calamities. Warnings of polar ice melt, tsunamis, hurricanes and snowstorms are increasingly frequent. Death and destruction from such causes are steadily on the rise. Are these the vagaries of the planet or is this a response to human activities? This question has been extensively debated in the last few years, but has ended up creating more questions than answers. Should the environment be prioritized over industrial growth? Does the planet come ahead of people? Is technology leading to faster depletion of natural resources? Many such uncomfortable questions are now challenging the very structure of free markets.

However, the argument that unbridled consumption on a planet with finite resources, will inevitably lead to collapse, is gaining momentum. History offers ample proof of civilizations collapsing because

they had overlooked resource overuse (Diamond, 2000). Over the last decade, many corporations have come to terms with this prognosis and have taken up the path of sustainability. Many global corporations now have sophisticated sustainability programs indicating a level of acceptance to the environmental imperative. However, even as the awareness grows within society and governments, small enterprises seem to be spared. Their small size is effective in warding off attention and on the other hand their sheer number poses an enforcement challenge for authorities. Although their scale of operations renders a proportionately small environmental impact, it is estimated that their collective impact may be as much, if not more, as that of large industry. Moreover, many SMEs are part of global supply chains of large corporations and undertake manufacturing activities for them. As key suppliers to the large corporations, a significant portion of their environmental burden is thus transferred to the SMEs. They contribute significantly to a nation's economy and its GDP and from a precautionary principle then, it is imperative that SMEs be encouraged to improve their environmental performance within their own operations. The potential benefit from this is far too large to be neglected.

SMEs generally adopt reactive strategies which focus on compliance rather than sustainability (Hobbs, 2000). Recent studies show that the firm size is one of the major determinants of a firm's green strategy – environmental actions undertaken are inversely proportional to the company size (Bianchi & Noci, 1996). In the 2011 survey on Sustainability and Innovation, the MIT Sloan Business School too had similar findings (MIT Sloan Sustainability Dashboard). SMEs generally follow business instincts to reduce resource use and waste and are keen to save costs through efficient resource usage. But those practices which need investments or inflict costs are not popular among them. Employing clean technologies and life-cycle analysis often does not find favor among small firms. When faced with the prospect of no business gains, SMEs tend to disregard environmental improvement as a non-priority expense (Esty & Winston, 2009). In most developing countries, the potential contribution of SMEs to a cleaner environment may not have been realized yet. Taking the case of India, current policy and legal frameworks do little to encourage or support SMEs in this direction. As the adoption of sustainable practices by SMEs is critical for national environmental goals, they must be encouraged to go beyond the usual eco-efficiency practices. While the magnitude of impact on the environment of an individual SME will depend on the technologies employed, packaging used, energy consumption patterns and distribution and supply chain usage, there is no doubt on the necessity of them improving their environmental performance.

The author's research with SMEs shows that green business practices offer distinctive business benefits for SMEs. Large corporations increasingly demand environmental management systems from their suppliers since greening their supply chains contributes directly in their own sustainability efforts. Similarly, environmental management certifications are integral part of vendor qualification criteria for many companies. Moreover, in many developed economies, bankers and financial lending institutions require environmental risk assessment from their loan applicants. Similarly, many insurers charge higher premium from SMEs who are exposed to environmental risks. In the European Union, extended producer responsibility (EPR) requires corporations to be responsible for their products, no matter where they are produced. This has prompted large companies to disqualify SME suppliers who do not meet the environmental standards. On the other hand, SMEs in consumer businesses have witnessed growth in green consumerism not just in developed economies but also countries like India. To serve this market, SMEs must go beyond green manufacturing. This requires technical and managerial skills, but will extend the first mover advantages to those early in the game. These are just some of the obvious business benefits accrued through green practices.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The objective of this chapter is to help SMEs understand the benefits of green business practices and offer them a simple framework for greening their businesses. The chapter is draws upon the results of a three-year study undertaken by the author with engineering SMEs in India. The research examined green business practices of over 70 SMEs from the product lifecycle perspective. Additionally, in depth interviews with large corporations, who have SMEs in their supply chains, helped gain deep insights into environmental practices. The study has been published in international journals and has received a positive response from policy makers, industry associations and SMEs themselves. This chapter builds on the findings and discussions in the research and intends to help SMEs realize how green business strategies can result in competitive advantage for them. Consequently, this would help transform what are today cost burdens into strategic investments for tomorrow. The central argument of the chapter is that businesses must recognize the value arising out of the firm's environmental impact and strategically position itself to gain competitive advantages.

2. COMPETITIVE OPPORTUNITIES POSSIBLE WITH GREEN BUSINESS PRACTICES FOR SMES

The ability of SMEs to create, access and commercialize new knowledge in their own markets is fundamental to their sustained competitiveness. The formation of strategy and its implementation are at the core a competitive business. Competitiveness is a comparative concept of the ability and performance of a firm to sell and supply goods and or services in each market. In almost all literature on strategy, the leading hypothesis is that sustained superior performance of firms arises from sustained competitive advantages (Powell, 2001). Competitive advantage implies that firms can satisfy customer needs more effectively than their competitors. This can be achieved through lower costs or differentiated advantages which customers value and are willing to pay for. Both these situations were evident in the author's research on SMEs adopting green business practices. Thus, green strategies can potentially lead to the traditional generic outcomes of business strategy - cost leadership and differentiation. Responses in the research showed the presence of both forms of benefits in firms which practiced environmental management. It is important to note that these benefits were a result of green practices and could not have been achieved by other means. Porter and Linde (1995) have argued that the most competitive firms are not the ones with cheapest inputs or largest scales, but ones which have the capacity to innovate more. They discuss several examples where environmental regulation has caused firms to innovate for solutions thereby creating a cost advantage. Firms which proactively pursue green strategies stand to benefit in many ways than just profits. A green competitive advantage is the potential for environmental performance to improve long term profitability.

2.1 Benefits of Going Green

Based on research conducted in other countries and the author's own research with SMEs in India, it was found that SMEs enjoy several benefits from environmental management. These benefits vary with the extent of practices, nevertheless, they offer compelling reasons for small firms to undertake green business practices. The list of benefits arising from green practices is shown in Table 1.

Unique combinations of benefits were experienced by many SMEs. These covered the generic strategic positions which lead to competitive advantages for firms. Such advantages are gained because of an in-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Business benefits of green practices

Business Benefits of Green Practices	Generic Advantage
Savings from reduced consumption of materials and resources	Lower Cost advantage
Savings from use of increased recycled content	Lower Cost advantage
Improved productivity of resources	Lower Cost advantage
Financial incentives from lending institutions	Lower Cost advantage
Lower premium from insurers	Lower Cost advantage
Lowering environmental risks in business	Lower Cost advantage
Improvement in quality of products	Differentiation advantage
Advantage with some current customers	Differentiation advantage
Advantage in acquiring new customers	Differentiation advantage
Export opportunities due to environmental management	Differentiation advantage
Improved image with customers	Differentiation advantage
Attracting better employees	Differentiation advantage
Better morale of employees	Differentiation advantage

novative and resourceful organization and are difficult to observe by competitors. The collective learning of the organization is hard to observe and imitate, effectively turning it into a competitive advantage. Our research shows that the benefits of lower costs are commonly observed in SMEs. These are a result of reduced usage of resources, lower waste, increased recycled content and lower environmental risks. Most of these benefits are realized in the short-run and are easiest to undertake, without much disruption in daily operations. As this is important for SME operations, the research showed cost saving benefits to be the most common within SMEs.

However, as each firm practices resource productivity, there is a limited scope for a competitive advantage from low costs. On the other hand, differentiated products or a differentiated firm image can be harder to imitate and is sought after through competitive strategy. However, the benefits of differentiation from green practices, were less evident in this research, than those of cost saving. At the current levels of green performance, cost benefits seem to be more than differentiation benefits.

2.2 Perils of Not Going Green

As a part of supply chains of global corporations, SMEs are obligated to meet the qualification criteria set by their customers. Increasingly, large corporations are demanding environmental management practices and in some cases certifications from their vendors. On the other hand, some companies value green performance but do not make it mandatory. In both the cases SMEs who have overlooked going green stand to lose. Many large corporations that the author interviewed during the research indicated a preference for green performance. Some companies set environmental standards which suppliers must meet, some demand environmental reporting while many are planning green qualification for their vendors in the near future. For example, companies like Walmart are keen to source from India but require a high degree of environmental management from their vendors. Those SMEs that already are on the job stand to gain a competitive advantage straight away.

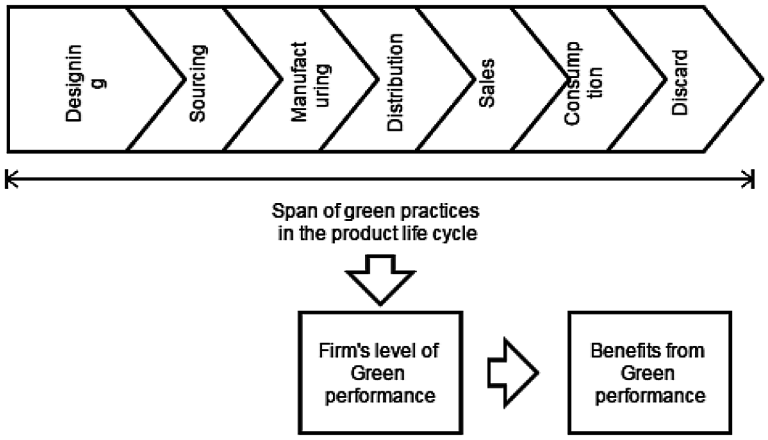
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The benefit of lower environmental risk is perhaps least understood among SMEs. Firms may find it challenging to invest in mitigating risks which cannot be quantified in many cases. While in developed economies firms would invest in compliance and in some cases beyond compliance, only to reduce environmental threats; this was not evident in India. SMEs may fall in either one of these situations: (i) environmental risks are not perceived at all due to poor environmental awareness (ii) environmental risks are not considered significant. 'Won't happen with me' is not a mitigation of environmental risks, as statistics from other countries shows.

Several studies conclude that SMEs lag in environmental practices when compared to large firms (Studer, Welford, & Hills, 2008). Most are agreed that SMEs are motivated more by compliance and cost saving than gaining a competitive advantage (Rowe & Hollingsworth, 1996) (Worthington & Patton, 2005). However, SMEs must realize the business case for going green and move in to gain early mover advantages.

3. BEYOND MANUFACTURING: GREENING THE PRODUCT LIFE CYCLE

Lean manufacturing, Six Sigma and a host of other such techniques help firms to improve resource utilization and reduce waste. These practices that help save costs are prevalent in SMEs already. However, these low hanging fruits are observable and imitable by competitors, and firms operating at high efficiencies hardly enjoy its benefits, since most competitors would do the same. Moreover, for the environment, these are generally located towards the end of the pipe. Most of these practices fall within the scope of manufacturing, are tangible, measurable, and offer something "to act on."



On the other hand, greening the other stages of the product life cycle is not always obvious and requires a certain degree of environmental awareness and knowledge. Moreover, as green practices in these stages may not lead to cost reductions, they are likely to be overlooked by SMEs. SMEs can gain significant benefits by greening not just the manufacturing stage, but the other parts of the life cycle. Designing for the environment and manufacturing with cleaner technologies has more beneficial impacts than end-of-pipe greening. Sourcing from suppliers who practice environmental management, distributing with green supply chains, designing the product for low resource use in its lifetime and finally designing the product for safe discard and making it suitable for reuse or recycle, are all ways in which the SME can stand to gain. The author's research examined the green practices of SMEs in all the generic stages of a product life cycle- planning, design, sourcing, manufacturing, and sales.

The research employed a conceptual framework developed based on the literature review and in-depth interviews (Figure 1). The framework proposes that the level of green performance of a firm depends of the green practices across the generic product life cycle and that the business benefits accrued are a result of the level of green performance that the firm practices. The research supported this proposition and showed firms with green practices in stages other than manufacturing enjoyed several benefits shown in table 1. On the other hand, firms which practiced green behavior mainly in the manufacturing benefited from cost savings, which is a necessary, but not a sufficient condition to enjoy a competitive advantage.

Figure 1 shows the generic stages in a product life cycle. This conceptual framework makes a proposition that the benefits a firm can expect from greening are related to the level of green performance it undertakes. This level is decided by the scope of green practices that the firm employs in the generic product life cycle. The author's research supported this proposition. The benefits are indeed correlated to the activities within the product life cycle. Firms which employ green practices in all the stages would

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Green practices in the product life cycle

benefit the most. However, the research also showed that most SMEs are good at green practices in the manufacturing stage, but very few consider the other stages. SMEs keen to enjoy the benefits of going green then need to increase their scope of green activities in the product life cycle. This can be easily accomplished through the questions which the firm can ask itself at each stage. An easy to use Green Questionnaire is shown in Table 2.

A planned approach is recommended. The following steps will ease the process.

1. **Set Up Environmental Vision, Objectives and Targets:** The first step towards a greener organization starts with setting goals, objectives and targets. The establishment of quantitative goals provides a clear point of reference for developing and applying metrics. Unless management and employees have a clear understanding of exactly what is expected from the process and what will be evaluated for ascertaining this, attention to environmental issues will be unfocused and motivation will reduce over time. The old English adage works here - "What's measured, improves." Precise and measurable objectives are also set. A useful guide for setting objectives is the Coalition for Environmentally Responsible Economies (CERES) publication of "The Ceres Principles"1. This is a ten-point code of corporate environmental conduct. Similarly, the International Chamber of Commerce (ICC) has prepared the 'Business Charter for Sustainable Development'2 which sets out 16 principles for environmental management. These documents can be used as guiding principles.

Based on the research, the author suggests a simple three level approach to setting green targets for SMEs. This is shown in Table 3.

Another useful tool for SMEs is the Environmental Policy check-list which is available free at International Network for Environmental Management (INEM) website here http://www.inem.org/default.asp?Menue=94

2. **Make an Empowered Cross Functional Team:** This is an important step. Many SMEs have limited managerial and technical capabilities. These can be overcome by making a cross functional team. a team should be formed. This team will comprise personnel across departments and specializations. The team will be empowered to facilitate achieving targets. Their first task is to communicate the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2.

Product Life Cycle Stage	Questions on Green Activities Within Each Stage
Planning	Does the environment find a mention in the SME's Vision or Mission?
	Does the firm set environmental targets?
	Do any formal environmental management systems exist?
	Is there a designated officer for environmental activities?
	Are the strategic objectives and targets communicated within the organization?
	Do we need to modify any products to reduce their environmental impact at any stage?
Design	Can we design products to use lesser materials?
	Can we design our products to be able to use any clean technologies?
	Can we design products to use more recycled content?
	Can we design products to use lower consumables in their use?
	Can our products be recycled or reused at end of life? Whole or part?
	Can our products be discarded in an environmental safe manner?
Sourcing	Can we source from vendors with environmental management systems?
	Can we set environmental targets for our suppliers?
	Can we incorporate and input regulations - RoHS[26], REACH[27], etc.?
Manufacturing	Are any of the following tools and techniques employed in manufacturing? Lean management, Six Sigma, clean technologies, GreenCo Rating System, etc.
	How is environmental compliance and regulation dealt with?
	Do we monitor the following - Water consumption, Material use, Waste generated, Emissions, Effluent, Energy consumed?
Distribution	Can improve packaging for reducing transport load?
	Can we monitor fuel consumed in distribution and storage?
	Can we take back any packaging material for reuse/recycle?
Sales	Are our environmental efforts communicated to customers? How?
	Can our firm take a up a green competitive position?
	Is the firm's environmental performance used to influence buyers during the sale?
Consumption of my products	Does my product consume energy or other resources during use? Can we design the products for efficiency in its use?
	Is my product designed to last a lifetime of use?
Discard	Can my product be recycled? Whole or parts?
	Can my product be reused? Whole or parts?
	Can my product be discarded safely and within the laws of the land?

Table 3.

Level	Basis	What to Measure
First	Compliance and Control	Pollutants, emissions, energy
Second	Prevention and Reduction	Materials use, direct energy, indirect energy, water, non-product output
Third	Design for environment	Life cycle assessment

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

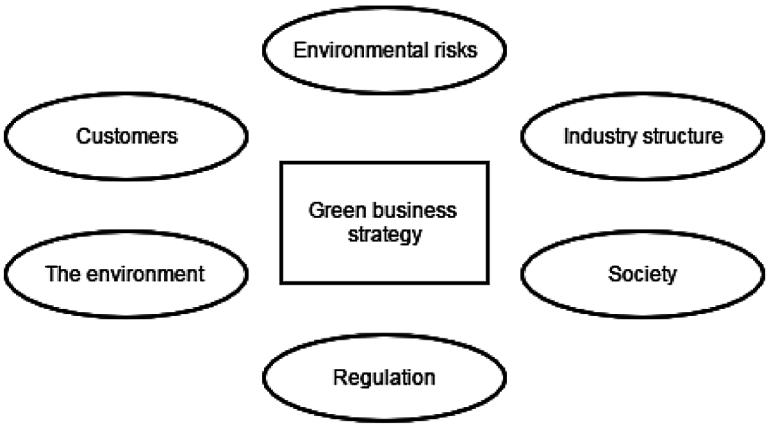
targets, efforts and benefits expected, across the organization. To reach the organizational goals, they will identify tools and technologies, disseminate best practices and measure the progress. This is an add-on duty for existing employees and the author recommends remunerating the efforts.

3. **Planning with the Green Questionnaire:** The team then takes up the Green Questionnaire. In many cases SMEs may not have all the stages of the product life cycle within their own firm. Some SMEs may be an outsourced manufacturing rather than a complete product design and manufacture partner. In this case the firm would have no control on the design stage and in some cases, may be even the sourcing stage. The important part here is to establish which of the stages can the firm work upon and then ask the suggested questions in those stages. Some questions may require support from environmental consulting firms. Especially decisions on product design, clean tech and discard. The firm will do a cost-benefit trade off when considering external help.

The Eco-design health check is a useful online tool available free at the International Network for Environmental Management (INEM) website here http://www.inem.org/Default.asp?Menue=190

4. **Prioritize the Stages:** Going green throughout the firm's activities, all at once, can be highly strenuous to small firms. This requires advanced technical capabilities and managerial band width. Such a large-scale intervention may result in operational disruption consequently leading to customer dissatisfaction. Prioritizing the firm's activities by stages is a less risky approach to greening. For example, in phase one, the firm may choose to spend the next six months in greening manufacturing and operations, followed by sourcing and distribution. In phase two, the firm may decide to work on its product design and clean tech solutions. In this manner, the risks of business disruption are lowered.
5. **Make an Implementation Plan:** This is not the same as the planning exercise. Some of the key reasons why project implementation fails with SMEs are ambiguity in communication, absence of empowerment to the member and lack of strategic will to complete the project. These risks must be mitigated to ensure an effective implementation. A key aspect of successful implementation is use of relevant and appropriate measures. If you wish to improve something, then you must measure it. Identifying key metrics is not a simple task, managers may be tempted to take up low hanging measures. However, it is important to spend time on identifying the right measures, some of which may not be obvious. For example, if water is the resource being worked upon, there could be various metrics:
    a. Water consumption at machine level;
    b. Water consumption at department level;
    c. Water consumption at aggregate plant level.

What you select will be specific to your business. Often, measuring water consumption at machine level may be too expensive and may not be required. On the other hand, if the firm makes ready to drink beverages, then measuring water consumed at each machine might be very important.



EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. FROM GREEN BUSINESS STRATEGIES TO A COMPETITIVE ADVANTAGE

For green strategies to work up a competitive advantage, they must take a holistic approach to integrate all the obligations towards the environment. The planning process must be able to address the following factors (Figure 2):

- **Regulation and Compliances:** Staying within rules is the primary responsibility of a firm. Governments have been increasingly pressing producers to improve their environmental performance. The REACH legislation (EUR, 2009) in the EU makes it mandatory for producers to register every chemical they make, is one such example. The Bharat Stage 4 emission norms force automobile manufacturers to design their products to meet the standards. Extended producer responsibility is on the horizon already. New 'take-back' laws may soon find their way in the Indian markets. They emphasize "producer responsibility" that holds manufacturers responsible for their packaging.
- **The Environment Itself:** The firm's green management process must focus on reducing its impact on the environment – in terms of consumption of natural resources and pollution of air, water and soil. A strategic focus will drive firms to redesign their products and processes for the environmental. As SMEs form a large segment of the Indian industry, it is imperative for them to indulge in sustainable practices.
- **The Customers:** SMEs have been facing pressures from their large buyers to improve environmental performance. In the automobile industry in India, car makers are increasingly pressurizing their vendors to align them to achieve their own green goals. Those SMEs which are proactive in green performance can offer the differentiated advantage. For example, when Toyota Kirloskar Motors in India wanted self-adhesive foam parts for the dashboard of Innova, the pre-qualification was meeting strict VOC norms in manufacturing. This led to automatic disqualification of most of the small firms making such components without considering these high standards. Only a few large ones who had invested in these technologies stood to benefit. Similarly, many cost leaders with excellent quality records, in the electro-plating industry are disqualified from supplying the

Figure 2. Factors which must be addressed by green strategies

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

airline industry, which is known to follow very high waste and pollution standards. Much research has shown that here is a growing class of customers who care for how the product they buy is made and what is let out in the process. Green strategies will help firms choose their customers, decide the products and manufacturing processes and invest in sustainable practices.

- **The Business Risks of Environmental Violations:** These can cripple a small firm. Risks of litigation can result in loss of man-hours in SMEs and penalties can be expensive. The social license allowed by the society to do business, can be taken away by them. A proactive strategic focus to the environment can help mitigate the environmental risks of businesses.
- **Industry Structure:** Large companies with strong research base can influence policy makers to strengthen or modify current industry standards. SMEs may find it challenging to respond in short times and often with large unbudgeted cash outflows which can potentially make them weaker. Competitive playoffs can change in an industry when competitors bring out changes in their product design which can drive down lower production. The EU made it mandatory for cell phone manufacturers to use the micro USB charging pin. This is done to produce and sell fewer chargers. Many SMEs make phone chargers for European markets. Those with low sunk costs will be more competitive.
- **Community Awareness and Social Initiatives:** Are much more visible. NGOs have been successful in creating customer awareness about environment. For example, the WWF "Check Your Paper" campaign is a a global database of eco-rated papers. It helps paper buyers find products with the lowest environmental impact. This campaign includes about 100 paper products with "good" or "excellent" environmental score. Customers can easily pick out green businesses by such awareness drives. Public opinion is increasingly being influenced by social initiatives. International public opinion also matters in issues with a high impact potential (Elkington, 1994 Winter).

5. SETTING YOUR GREEN STRATEGY

To make the transition from a compliant firm to a strategic environment managed one, may seem to be a herculean task for many SMEs. However, it can be simplified by following well defined paths which the firm can take. Orsato (2006) suggested that the generic competitive strategies can be superimposed on environmental framework and by cross tabulating the two generic strategic positions with internal processes or products the result is four generic green strategies (Figure 3). It is for each SME to decide its own course to reach the strategy 3 or strategy 4 quadrants. Some of the key aspects of each strategy are discussed below.

Strategy 1: Eco-Efficiency

This makes an easy starting point for SMEs. The intention is to lower costs while improving environmental performance within the firm's operations. Many of these practices are easy to observe, measure and improve. This strategy emphasizes regulatory compliance and industry compliance, but does not make product changes. This strategy places low demands on managerial capabilities and investments,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Generic green competitive strategies
Source: Competitive environmental strategies: When does it pay to be green? Renato Orsato, California Management Review; Vol 48, no. 8, Winter 2006.

while yielding cost benefits. This is the least disruptive step for an SME and many SMEs may already be at advanced stages in this step. Benchmarking your operations with industry leaders and continuous seeking of new opportunities to reduce environmental impacts is the hallmark of a good firm.

Strategy 2: Beyond Compliance

After setting the path of continuous process improvement, the firm can now seek out differentiation in their operations. This strategy may need investments in clean technologies or may need to discard age old practices making way for more efficient ones. This strategy needs clear understanding of technologies and their capabilities. In the author's research, some SMEs worked closely with their customers to differentiate their operations. This is an effective way of cooperating for mutual benefits. Your customer benefits from a cleaner supplier and the firm benefits from a differentiated image.

Strategy 3: Eco-Branding

Differentiating with green products is not the easiest strategy for many SMEs and hence this must be preceded by the first two strategies. This stage requires substantial work within the firm's products' life cycle. Green differentiation could be based on the design of the product, manufacturing or consumption of the product. Each requires different capabilities from the firm. Moreover, green products need a customer buy-in. The value brought on the table must be important to them. It is not unusual for customers to forgo green products for a cheaper one and therefore pulling off the eco branding in the market could be a bigger challenge, requiring strong marketing capabilities.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Strategy 4: Environmental Cost Leadership

This could be the last strategy which a small firm may want to explore. Most industry structures do little to support green businesses and hence firms in the green business may need to realign their value chains to suit their sourcing, production and distribution. There are many examples of green products which are cheaper than conventional or lowering costs of consumption. Environment friendly packaging using high recycled content can be cheaper than virgin materials. On the other hand, this strategy can be viewed as getting a higher price realization for environmentally designed and manufactured products.

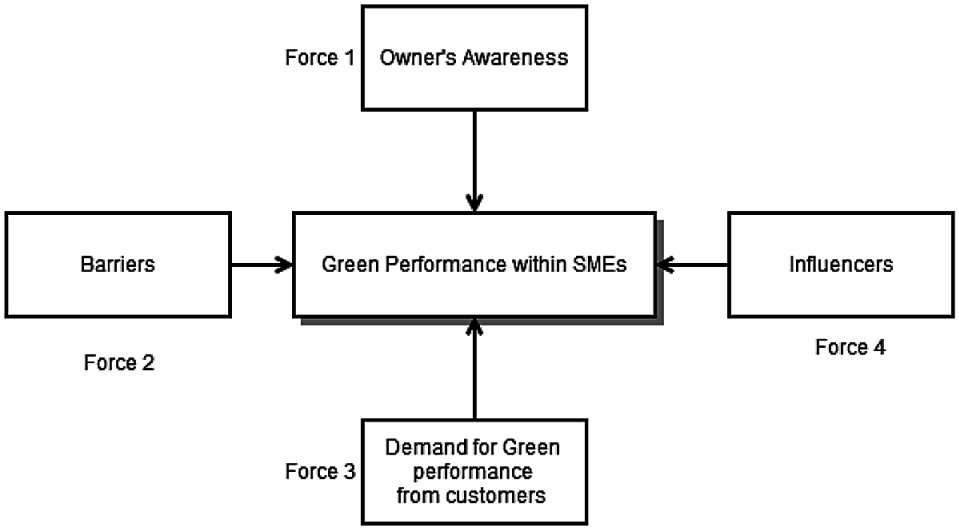
6. NETWORKS ORGANIZATIONS FOR SMES

Several international organizations offer free and paid advice to SMEs for improving their environmental management systems. A small selection is given here.

- **International Network for Environmental Management (INEM):** Is the world federation of non-profit environmental management associations and cleaner production centers. Their network has over 30 members and affiliated environmental management associations and 10 cleaner production centers in more than 25 countries worldwide. The main goal is to minimize the environmental impacts of industrial operations, and to help business and industry reconcile the imperatives of development and the environment. www.inem.org
- **European Environment Agency (EEA) Sustainable Development Online (SDO):** This gives access to significant sustainable development sites. It provides descriptions of, and links to, many hundreds of sites covering the broad subject of sustainable development, including networks and tools for business. http://sd-online.ewindows.eu.org
- **The Environmental Management Navigator:** This is a capacity building package on environmental management tools. It is devised as a response to SMEs' need for assistance in selecting the most suitable environmental management tools per internal organizational and external market demands. Tools covered range from environmental management systems, cleaner production assessment and environmental cost accounting to environmental performance measuring and reporting. www.em-navigator.net
- **EMAS Tool Kit for SMEs:** This is a simple guide to assist small companies to implement an environmental management system that meets the requirements of EMAS. EMAS requirements are demanded by many EU clients, and Indian SMEs who wish to export will need to comply with EMAS. For such SMEs, this is an invaluable site. www.inem.org/emas-toolkit.
- **Environmental Management Tools for SMEs – A Handbook:** This Handbook discussed how SMEs can use environmental management to improve business performance. It focuses on three questions: What is environmental management? Why should SMEs use it? How is the tool used? http://reports.eea.eu.int/GH-14-98-065-EN-C/en
- **Environmental Good Housekeeping Guide for Small and Medium-Sized Enterprises:** This guide is specifically designed for SMEs to identify simple, practical, common sense good housekeeping measures that can reduce the costs of production, enhance the company's overall productivity and mitigate environmental impact. www.inem.org/htdocs/inem_tools.html#Anchor-Environmental-51548

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

7. FOSTERING GREEN BUSINESS STRATEGIES IN SMEs: RECOMMENDATIONS FOR OTHER STAKEHOLDERS



One of the objectives of the SME research undertaken by the author was to suggest a framework for policy makers to encourage the SME sector to go green. The era of enforcement is over. The new age must be fostering towards a greener economy. The policy makers and other stakeholders of the SME sector have a large and important role to play. The author proposes guidelines for policy makers. The recommendations are based on the Four-force Framework which the author had prepared from the research. This frame work is shown in the figure.

The framework shows that an SME's green performance depends on four forces namely – awareness, barriers, influencers and customer demand. Every firm is subjected to these four forces act in varying strengths depending on the sector. Force 1 can result in a proactive behavior, while the other three forces are likely to elicit a reactive behavior. Based on this framework, the recommendations are made to improve awareness, reduce barriers, strengthen influencers, and encourage customer demand. For this, not only the SME owners must participate, but also various other stakeholders too. The recommendations are specifically directed to be beneficial for SME owners and policy-makers.

Force 1: Awareness – The Backbone of the Dilemma

Throughout the analysis, various sections of this questionnaire have more than once revealed a singular aspect, which, the author feels, is the backbone of the problem. The environmental performance of an SME is highly dependent on the owner's environmental awareness. This seems to be the single most critical factor in improving SME green performances. The statistical analysis of responses shows a highly significant dependence among the two variables. And thus, the SME owner's awareness seems to be the

Figure 4. Four forces acting on green performance of firms

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

key to change. This is an importance discovery for policy makers, trade associations, environmentalists and chambers of commerce. Concerted efforts to improve environmental awareness among SMEs are not required. It is possible when all these stakeholders plan towards this goal.

Role of Government

A similar situation was successfully handled by the Indian government some decades ago. This was about creating safety awareness in industries. The Indian industries had a high accident rate compared to other countries and this was attributed to low awareness levels. The National Safety Council of India was set up in 1966 with the vision of creating a safety and preventive culture in organizations. NSC, along with local chambers of commerce, played a vital role in spreading awareness in industries and SMEs. This helped improve the safety standards over the next decade and today, Indian industries have vastly improved safety standards. The government can consider a similar organization which is aimed only at spreading awareness in industry. This council can work with local bodies, trade associations or chambers of commerce, to spread awareness within SMEs. This council will have a 3-point mission (i) Spread awareness of industry-environment linkage (ii) Highlight the current environmental situation, need for healthy environment and what is environmental degradation (iii) Communicate with workers, managers and owners in SMEs, through posters, slogans and case studies (iv) Engage the attention of SMEs with contests, events and activities.

Role of Industries

The local chambers of commerce and trade association can facilitate environmental awareness programs and training on environmental performance improvement. Within an SME cluster, these bodies have sizeable membership of local firms. For example, in Pune, the Mahratta Chamber of Commerce, Industries and Agriculture (MCCIA) is the largest chamber of commerce in Maharashtra. They have influential industrialists and politicians on their advisory boards and panels. This organization has, over the last few decades, helped local industries in several challenges – improving quality, competitiveness, knowledge of taxation, government schemes and subsidies etc. They are well suited to focus their efforts on helping create awareness among local industries as well as holding advanced environmental training programs.

Role of Bankers

Many SMEs build relations with their bankers. For some small firms, the bankers lend financial advice and may even sound an alarm on potential financial threats. Bankers are often accorded a high credibility by SME owners, who acknowledge the critical role of the financer in their firm's progress. This puts bankers in a unique position – one that can be leveraged to improve environmental awareness. The PCBs have not been effective in communicating environmental standards and norms. Banks can help spread awareness about compliance, since they stand to benefit from it. If their customers (loan beneficiaries) can lower their risks of environmental violation, then banks in turn lower their business risks. With this motive, they can diffuse environmental awareness and help in improving SMEs performance.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Force 2: Reducing Barriers

The barriers which came up in the research are unique to SMEs and their constraints. Finance has been the biggest barrier. Even in the other section, SME owners considered this barrier important in diffusing green practices. The following recommendations are proposed to reduce this barrier

Subsidize Green Certifications

During the 1980s, the government subsidized ISO 9000 certifications in within SMEs. Those who received a certification could claim Rs 75000 as a partial refund of expenses. This helped SMEs finance a certification which they did not consider a business priority. The TQM movement enhanced the competitiveness of many SMEs. While this is 'private profit' as opposed to 'public good' (Orsato, 2006) of environmental practices, nevertheless, this provides a compelling argument. The rate of diffusion of environmental practices within SMEs can be accelerated by incentivization. In one section of the questionnaire, 68% respondents strongly and 24% respondents somewhat agreed that such a financial incentive would benefit SMEs.

Preferential Financing of Green Activities

Costs associated with green strategies are significant for SMEs. The finance and other scare resources must be diverted from mainstream business activities to unproductive areas. Here, three stakeholders have a role to play. Government, Bankers (money lending institutions) who can offer lower interest rates for green capital expenditure and investing in clean tech and Insurers who can offer lower insurance premia for conditions of lower environmental risks.

Direct financial assistance programs for environmental equipment purchase can promote purchasing such equipment as well as stimulate a demand for environmental technologies. This has been successfully implemented in France, where Environment and Energy Management Agency (ADEME) provides direct financial assistance to projects going beyond compliance for an investment projects in air pollution reduction, waste management, soil remediation, renewable energy, energy efficiency, and cleaner transportation. Similarly, the German public bank "Kreditanstalt für Wiederaufbau" has a "Special Fund for Energy Efficiency in SMEs[3]" which covers up to 80% of costs for SMEs to receive professional advice on energy efficiency improvements. The Korean Ministry of Environment provides financial support to SMEs in the priority areas of air pollution reduction and increased recycling. SMEs that voluntarily install low-NOX (Nitrogen oxide) boilers can get a 90% subsidy from the Ministry, which also operates a Resource Recycling Promotion Fund to provide grants to eligible small businesses (Mazur, 2012).

Low-interest loans are granted in several countries in the European Union. The loan policy can be used to provide both positive and negative incentives to businesses. The Development Bank of Japan uses environmental screening to evaluate the level of corporate environmental management. India has SIDBI[4], a public financial institution whose objective is *"to be the principal financial institution for the promotion, financing and development of industry in the small-scale sector*". They are thus in a unique position to offer low interest loans for environmental technologies. The Energy Saving Trust[5] a non-profit organization in the UK, provides zero-interest small business loans of up to GBP 100,000 to help businesses install renewable energy technologies or measures that reduce energy consumption. The

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Deal[6], a UK government program, provides businesses with loans for energy efficient equipment without down-payment and with payback tied to cost savings obtained over the course of its operation.

Facilitation Centers to promote environmental awareness and green benefits.

Here again awareness shows up. This time as admitted by SME owners themselves. 98% agreed that owner's awareness needs to be improved while 95% agreed that green benefits are not easily understood by them. There is highly significant agreement among respondents on both these points. To add to this, the statistical testing showed a highly significant dependence of owner's awareness and level of green performance of the firms. This further strengthens the recommendations that there must be investment in promoting industrial awareness. CII has played a seminal role in Green building standards in India. Their stewardship is widely accepted across industries which this gives them a favorable position to promote environmental awareness too. State governments can open facilitation centers specific to SME clusters. Since SMEs in a region generally learn from each other, this characteristic can help diffuse practices of one firm within the cluster. These centers can facilitate sharing of best practices across industries. For example, in France, 21 Technical Industrial Centres[7] covering 32 SME dominated industry sectors, act as facilitation centers. They work with support from different business organizations and funded through fees paid by businesses. The National Industrial Symbiosis Programme (NISP)[8] was launched in the UK in 2005, and provides information, networking and matching service for firms. In this research, 93% respondents felt that green practices should be shared within SMEs, and this can be facilitated by the facilitation centers. A similar role was played by the National Productivity Council (NPC) in increasing awareness about productivity. This can be replicated on the environmental performance improvement.

Improve and Enlighten State Pollution Control Boards (PCBs)

The PCBs offices are understaffed and under skilled (Sahu, 2010). Increasing awareness should start with the enforcers. Improving the knowledge and awareness of its employees is the first step. Are they periodically trained for skills improvement? Are they evaluated and mentored? Are they sensitized towards the environment? These efforts would result in more credible officers visiting SMEs. The PCB should assume the role of a facilitator and shed its image of an inefficient and unaware enforcer. At the very least, there is an immediate need of simplifying regulations, making them more understandable in common language; establishing SME specific cells within the regulators to facilitate enforcement and increasing the number of staff.

The CPCB can learn a pick up some successful ideas from the US EPA. For example, the US EPA has substantial experience in measuring outcomes of environmental compliance assistance to demonstrate the effectiveness of preventing non-compliance. Direct compliance assistance is provided by the EPA through on-site visits, workshops, training programs, distribution of guidance documents and assistance provided through sector-specific, web-based Compliance Assistance Centers. Their Small Business Environmental website[9] is sectoral, user friendly and comprehensive. It is handy for small businessmen and is the single point gateway of most SME requirements.

Force 3: Strengthening Influencers

Merely reducing barriers is half the story. This research has established the role of influencers to green practices within SMEs. Each of these influencers can be strengthened with a view of promoting greener SMEs. The recommendations are:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Personal Awareness, the Biggest Influencer

In this section, too, awareness comes up as the biggest influencers towards green practices. The earlier recommendations can be implemented to improve personal awareness.

Bankers and Insurers as Influencers

This research shows that banks and insurance firms have had the least influence on SMEs. Finance is the single factor agreed upon across various industries and SME size. Therefore, without support of financing institutions, the movement will lack 'teeth'.

SMEs rely on auditors, banks and insurance firms as credible sources of information. SMEs frequently interact with them and this provides an opportunity to have them influence their SME customers. These institutions can disseminate information and exert pressure on SMEs to pursue environmental improvements to achieve greater business success. Banks can ask for an environmental checklist during loan approval and insurers can ask for environmental risk identification and control plans. Banks and insurers can also offer favorable loan or insurance policy conditions to businesses with green credentials. At the international level, the United Nations Environment Program has published policy documents to promote sustainability in the banking and insurance sectors[10]. On the ground, the Royal Bank of Scotland follows the Equator Principles guidelines for assessing environmental and social risks of project finance transactions The Irish EPA has started discussions with the Irish Insurance Federation to try to make sure that insurance companies introduce environmental requirements for their clients, although this process is at an early stage. Similarly, insurance companies in Korea are considering the differentiation of insurance premiums depending on the level of environmental risk. In Netherlands, the ABN Amro bank played a key role in influencing new project financing to have an environmental report. Banks, lending institutions and insurance firms can have a positive influence on undertaking green practices.

The Influence of an Aware and Enlightened Society

Without human resources, it is inconceivable for firms to create products or services. The human resources firms employ are an integral part of the society. The same society which stands to gain from a better environment. From this position, they can influence SMEs to go beyond compliance. This requires environmental education at the school and college level. As children are the future of the nation, they must be aware how a healthy environment is the key to human health and happiness. For this, they must learn how industry can improve or degrade the environment. This researcher browsed the various school text books on environmental education. None of them had any direct mention of how industries have harmed the environment till today. They talk about consumption of natural resources, and about polluting industry. The pollution created by consumption is not dealt with in depth and undermines the impact on the environment. This needs a correction and teachers trained to teach these courses. Only then can we expect responsible citizen who have the power to influence industries into improved behavior.

Encourage Firms to Seek Greener Vendors

Large firms have been influential on SMEs on many occasions. They have demanded quality, productivity, safety and social good. It is imperative that they now influence environmental performance in SMEs. It

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

is possible for government to encourage large firms to do so. Here too, associations like CII and FICCI can play the lead role. They have the power to influence their members and the government, and have a history of commendable efforts which have benefitted Indian industry. This can promote emerging export opportunities for SMEs. ISO 14001certification is now an integral part of the European Union's Eco-Management and Audit Scheme (EMAS, 2013). Such requirements will increasingly be essential for exporting to developed countries and those who are prepared can secure such opportunities. In the European Union, there are several examples of government encouragement to diffuse green practices within the supply chain. In Ireland, a Business-to-Business (B2B) Green Mentor Programme[11] was launched in 2003 by Regional Waste Management Office. This program encourages large companies to provide guidance on waste prevention to their SME vendors. In Scotland, the Zero Waste Program promotes voluntary agreements with retail companies who then pass on the resource efficiency requirements down the supply chain.

Influencing Green Behavior Through Awards and Recognition

There is no dearth of awards for good business practices, quality and productivity achievements. This must be supplemented with recognition of environmental practices. Awards and social recognition promote a competitive atmosphere and one that leads to innovation. Instituting regional, sectoral and national awards can help spread innovative and competitive practices within SMEs. Recognition offers several benefits. Business leaders have an innate desire to be recognized as the best or at least better than the competition. This is possible with awards and therefore this recommendation finds credence.

Influencing Through Good Governance

What Indian industry lacks today is a system of uniform and strict enforcement. Currently, there is a limited liability of environmental violation. Many researchers feel that violators are not made to bear the full costs of environmental degradation liabilities. The perception of PCBs with SME owners has to be corrected. If they do not improve their own knowledge and awareness, their credibility is at stake. If they do not do their job of enforcement effectively then SMEs will believe that their competitors may not strictly follow norms. This can prompt them to follow suit, since not doing so will increase their costs. On the other hand, a just enforcement system can encourage SMEs to undertake green practices without the fear of a competitor getting away and reducing expenses.

Certification as an Influencer

There are numerous instances of unscrupulous firms taking advantage of green consumers. In absence of clear definitions, green labels and eco-branded products can be manipulated to the advantage of the seller. '*Greenwashing'* is the term given to such incidents. One way to avoid this is that policymakers can introduce green certifications which are specific to an industry. Electroplating industry certifications will be different from security services industry. To start with, the industries on the Red List[12] are suggested for introducing such certifications. The certifications will have levels to help buyers to make a choice.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Influencing Greener Firms Through Public Sector Demand

As a start, the governments itself can enforce green purchasing polices for its own companies. Introduction of green requirements as a condition for tendering for government contracts is feasible. The contractors can commit to maintaining specified environmental standards up and down the supply chain. Such green procurement can also increase market acceptance of green products by demonstrating their commercial feasibility. The Scottish Government's *"Public Procurement and Sustainable Development: Guidelines for Public Purchasers*[13]*"* dictates that those who fail to comply with environmental legislation may be excluded from selling to the Scottish Government. This guideline explicitly mentions that firms producing environmentally preferable goods and services and use of recycled/renewable materials are likely to offer a competitive advantage. The European Commission had proposed that 50% of all public tenders be "green", i.e. compliant with common core Green Public Procurement criteria.

8. CONCLUSION

The diversity and complexity of SMEs' activities within and across different sectors affect the nature and intensity of environmental problems. Moreover, the number of SMEs and their varied organizational capabilities pose a colossal challenge, one which cannot be addressed by voluntary strategy alone. A more effective approach would be one that is pulled by a firm's customers will be more effective for SMEs, than one which is based on external supervision and compliance. Given the size of the SME sector in any country, it is very challenging for external supervision and regulation to be an effective approach.

Although this author concludes that a competitive advantage can be gained by green performance, this alone is not enough encouragement for SMEs to improve green performance. Various barriers have been identified which act upon SMEs. The low awareness and indifferent attitudes of SME owner's also need to be dealt with. There are numerous reasons why SMEs do not or cannot improve their green performance. While each one can be justified from the SME's perspective, the loss from a degraded environment will be shared by all, including the SMEs. This will require more than good intentions to rectify.

Chapter 49
Institutional Perspective on the Drivers of Green Innovations in Firms

Wiboon Kittilaksanawong
Saitama University, Japan

ABSTRACT

In recent years, firms have increasingly engaged in green innovations in response to mounting pressures on environmental protection. Regulative and normative institutions are the main drivers of this response, while its strength is contingent upon a firm's deficiency gap and resource profile. The entry into this emergent industry of diversifying incumbents is usually determined by regulative and economic opportunity while the entry of entrepreneurial start-ups is more influenced by the sociocultural environment. Under the industry deregulation, most incumbents tend to become more focused on their core competencies developed during the regulated period unless they have prior experience in green innovations. Corporate governance plays an important role in implementing green innovations because these environmental initiatives go beyond compliance and require substantial long-term resource commitment that has significant strategic implications.

INTRODUCTION

In recent years, firms have increasingly experienced pressures from their stakeholders on environmental protection. Governments have introduced more regulative policies, adding costs to corporations that release environmentally unfriendly substances. Consumers have increasingly considered a company's environmental philosophy when deciding to purchase its products. Investors have largely discounted stock prices of environmentally irresponsible firms. In response to these mounting pressures, many companies have increasingly emphasized the implementation of environmental innovation projects such as green innovations. These projects are considered risky because they usually require large financial commitments that mostly accrue returns only in the long term (Ahuja, Lampert, & Tandon, 2008).

Green innovations are associated with new designs, and novel products and processes (Berrone, Fosfuri, Gelabert, & Gomez-Mejia, 2013). These innovations are therefore a potential source of a firm's competitive advantage. The value of green innovations to the society at large is widely acknowledged, however it is less clear as to what drives firms to pursue these innovations. Building on the institutional- and resource-based perspective, and the corporate governance literature (Peng, Wang, & Jiang, 2008), we highlight conditions under which firms are likely to pursue green innovations and reasons why some firms engage in more or less green innovations than other firms.

From the institutional perspective, we discuss to what extent the regulatory pressures (e.g., from governments) and normative pressures (e.g., from non-governmental organizations, professional organizations, and societies) influence firms to engage in green innovations (Berrone et al., 2013; Chen, Kittilaksanawong, & Weng, 2015). Given that green innovations are an emergent market, its potential entrants comprises of both entrepreneurial start-ups and diversifying incumbents. We then discuss how these institutions in terms of economic, political, and socio-cultural environment differently influence these two types of firm to enter in this emergent market (York & Lenox, 2014).

As governments have increasingly introduced deregulation in many industries, firms are pushed to adapt to an unprecedented increase in the competitive, new operating environment to achieve cost leadership or differentiation to outperform their rivals (Porter, 1980). We further discuss how incumbent firms formerly in the less competitive, regulated institutional regime should strategically react to this changing competitive landscape by engaging green innovations in their products (Flammer, 2015; Kim, 2013). Particularly, it is important to explore whether and how these incumbents should use green innovations as a differentiation strategy to compete against new rivals that increasingly enter the industry as a result of the deregulation.

Institutional pressures from environmental concerns are also directed toward the governance of corporations. Corporate governance plays an important role in responding to these pressures because green innovations go beyond compliance and these innovations require substantial long-term resource commitment that has significant strategic implications on firms (Hart & Ahuja, 1996). In particular, corporate governance plays an important influential role in determining whether a firm should include such environmental responsibility as a part of its corporate missions or it should focus instead largely on maximizing shareholder returns (Margolis & Walsh, 2003). We therefore discuss how corporate governance structures can effectively influence green innovations of organizations (Walls, Berrone, & Phan, 2012).

In sum, the following sections discuss in order these four critical questions related to green innovations from the institutional perspective. In particular, first, whether and to what extent would firms pursue green innovations? Second, to what extent entrepreneurial start-ups and diversifying incumbents would differently pursue green innovations in their competitive strategy? Third, how does the industry deregulation affect competitive strategy of firms via green innovations? Fourth, how does corporate governance play role in decisions to pursue green innovations of firms?

INSTITUTIONAL PRESSURE AND GREEN INNOVATION

Institutional perspective emphasizes the social influence on conformity of organizational actions (Scott, 1995). To survive and prosper, organizations try to maintain or enhance legitimacy toward their stakeholders (Deephouse, 1999; Scott, 1995). Such institutional pressures are resulted from economic, regulatory,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and sociocultural factors (Shane, 2004). These pressures are broadly derived from regulative, normative, and cognitive institution (Scott, 1995). However, regulative and normative institutions deserve special attention as far as institutional pressures for conformity on organizations are concerned. Both regulatory agents (e.g., governmental agencies) and normative agents (e.g., professional and non-governmental organizations) are potential actors that importantly shape strategic choices of firms in industries that are environmentally sensitive (Kassinis & Vafeas, 2006).

When the environmentally offensive behaviors are involved with high social costs, firms that comply with governmental regulations could be sheltered from political risks and legal coercions (Deephouse, 1999). Such regulatory compliance is usually in the form of requirements for firms to rectify or improve pollution emissions to the environment. This regulatory pressure may drive firms to go beyond compliance to pursue green innovations. In particular, green innovations are a proactive initiative that requires long-term commitments, and thus potentially has large social benefits. Green innovations thus not only strengthen legitimacy of firms but also safeguard them from penalties for poor compliance with governmental environmental regulations. While green innovations are costly and with uncertain financial returns, firms are likely to have greater incentives to pursue these innovations when they are faced with a higher probability to be detected for illegal behaviors that are subject to severe sanctions (Berrone et al., 2013).

To achieve normative legitimacy, firms try to behave in accordance with prevalent practices among members in their professional organizations (Scott, 1995). The presence and activities of non-governmental organizations (NGOs) also push firms to go beyond meeting minimum regulatory requirements through their mobilization of resources and coordination of activist groups for such purpose. NGOs are likely to applaud green innovations because they signal a firm's long-term commitments to meet or exceed environmental performance standards (Berrone et al., 2013). NGOs can trigger internal tensions within the firm, thereby creating institutional environments for firms to pursue innovations and changes (King, 2008). When normative pressures for environmental responsibility increase, firms are therefore more likely to involve green innovations in their strategic decisions (Berrone et al., 2013).

DEFICIENCY GAP AND RESOURCE PROFILE

Because of concerns over legitimacy, firms are usually pressured to behave in similar ways that are socially acceptable (Scott, 1995). However, strong institutional pressures may not always force firms to become more alike. These deviant behaviors occur because firms are heterogeneous in terms of their deficiency gap with respect to environmental legitimacy and their available resources for achieving conformity. Although firms are subject to the same set of regulative and normative institutional pressures, they may differently exhibit responses to these pressures due to these heterogeneities. Such deficiency gap and available resources can differentiate behaviors of firms with respect to whether or not and the extent to which they will engage in risky green innovations.

Firms with a larger deficiency gap in terms of complying with prevalent environmental emission requirements are likely to be more active in engaging in green innovations (Berrone et al., 2013). In particular, firms that are perceived to cause more environmental damage than their industry peers are usually more visible to external regulative and normative institutional actors (e.g., the government and NGOs). Particularly, managers in these firms whose reputations have suffered from pollution emissions are likely to be more sensitive to environmental pressures. These firms tend to face higher risks of business

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

interruptions and legal costs because of their poor relationships with regulators and social actors. Such deficiency gap is therefore a critical driver for firms to pursue green innovations in the hope that these innovations will improve their relationships and thus legitimacy toward these external institutional actors.

Resources provide firms with the flexibility in choosing appropriate strategic choices in response to external requirements (Sharfman et al, 1988). A firm's strategic choices are thus constrained by its resource profile (Bourgeois, 1981). However, only organizational slack (i.e., uncommitted resources) allows an organization to adapt successfully to internal and external pressures, and to initiate strategic changes in response to the external environment (Bourgeois, 1981). This resource slack allows firms more latitude to experiment risky strategic initiatives. Firms with higher levels of resource slack, when faced with environmental pressures, are therefore more likely to engage in green innovation projects, which are a long-term initiative, going beyond minimum requirements but without clear economic benefits to them (Berrone et al., 2013). Firms without sufficient resource slack are however likely to be able to respond to these pressures only at the minimum required level in order to survive.

The likelihood for firms to engage in green innovations also depends on specificity of their resources. Resources with high levels of specificity are durable, specialized assets that are difficult to be redeployed from existing uses (Dierickx & Cool, 1989). Organizations that are heavily invested with this type of resources bear a greater risk from business failures. In particular, organizations with a larger share of firm-specific assets are exposed to a higher loss in their value in case of default and asset liquidation. These firms are therefore more vulnerable to risks of poor compliance with regulations and norms. Accordingly, firms holding a larger proportion of assets with higher specificity are more responsive to institutional environmental pressures and are more likely to invest in green innovations than those largely holding non-specific general assets (Berrone et al., 2013).

ENTREPRENEURIAL START-UP VS. DIVERSIFYING INCUMBENT

The regulatory actors such as the governments may issue regulatory policies that mandate or forbid firms to use specific environmental products, whereas the normative actors such as professional organizations and NGOs may also expect firms to behave in environmentally acceptable ways. Green innovations are an emergent market that has become increasingly legitimized. Therefore, there is an increasing number of both entrepreneurial start-ups and diversifying incumbents entering this emergent market (Scott, 1995). However, such regulative and normative institutions have different impacts on the likelihood that these two types of firms will enter this emergent market (York & Lenox, 2014).

In particular, regulatory actors such as the government can influence the entry of firms in emergent industries through economic incentive policies. Such policies can have a strong effect on the development of emergent industries. For diversifying incumbents, with incentive policies, diversifying into green innovations not only provides an economic opportunity for them, but also allows them to signal to stakeholders about their environmental commitments (York & Lenox, 2014). This signal can thus in turn reduce the likelihood for the government to impose stringent environmental regulations and other normative stakeholders to initiate activisms against them.

The identity of entrepreneurial start-ups pursuing green innovations is more closely tied to larger sociocultural norms (York & Lenox, 2014). Normative actors such as NGOs are more likely to applaud firms that voluntarily engage in environmentally responsible projects through non-economic incentives (Berrone et al., 2013). Because of the newness, entrepreneurial start-ups lack legitimacy toward their

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

stakeholders. They are more likely to invest in green innovations as a means to gain more normative legitimacy from their stakeholders (Hannan & Freeman, 1984). While economic incentives are a driver for both entrepreneurial start-ups and diversifying incumbents to enter in this emergent industry, social normative expectations are more likely to have a direct and strong influence on the entry of entrepreneurial start-ups in the green innovation markets (York & Lenox, 2014).

In particular, normative actors influence entrepreneurial start-ups to pursue green innovations through the entrepreneur's perception that normative legitimacy received from entry into this new field will assure the success of founding their venture even without clear evidence of economic opportunity or regulatory supports. For diversifying incumbents, however, their key decision makers are likely to be embedded within an economic logic rather than a sociocultural environment (Gladwin, Kennelly, & Krause, 1995). Social norms represent a normative, rather than economic or regulative incentives. Therefore, diversifying incumbents are less likely to be influenced by social norms to pursue green innovations.

Diversifying incumbents rely on their existing resources and capabilities to establish legitimacy to access to valuable resources (Hannan & Freeman, 1984). They possess legacy identities that are often related to economic profitability. When these incumbents involve in green innovations, their external and internal stakeholders including existing customers, investors, and employees may question legitimacy of making such decision. Diversifying incumbents are likely to struggle to position their multiple and even conflicting identities when diversifying into an industry that does not promise profitability in the short and long term. Unless targeted for activisms, these incumbents are likely to focus on satisfying their existing stakeholders or they may diversify into emergent green innovations only when there are sufficient economic promises (Hannan & Freeman, 1984).

Normative legitimacy in terms of social movements may also have a strong influence on entrepreneurial start-ups (York & Lenox, 2014). These collective actions are however less influential to diversifying incumbents because these incumbents are embedded in existing customers' needs. This embeddedness creates inertia in incumbent organizations to respond to social movements by engaging in green innovations. Such competency trap causes diversifying incumbents to disregard feedbacks from social movements (Levitt & March, 1988). Entrepreneurial start-ups however often more voluntarily respond to these movements as a means to promote their legitimacy. This legitimacy can in turn persuade stakeholders that their products are superior because they are delivering social benefits through green innovations (Carroll & Swaminathan, 2000).

INDUSTRY DEREGULATION

When the government introduces deregulation in an industry, firms operating in that industry are likely to experience an unprecedented increase in the competitive pressures. Industry deregulation opens up previously untapped opportunities in the regulated era by removing regulatory constraints, which increases competition among firms (Winston, 1998). In regulated industries, industry-specific regulatory bodies monitor behaviors of firms. These regulators can influence profitability of firms by constraining or enabling their certain actions. In the regulated regime, managing the relationships with such regulators is thus critical for a firm's strategic choices and performance. As the industry is increasingly deregulated, however, such relationships may not be as important as before. Firms are mostly required to deal more directly with competitors and customers rather than with regulators.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Industry deregulation increases pressure for price competition while decreasing incentives of firms to differentiate their products through investing in risky green innovations (Kim, 2013). Firm resources and capabilities are path-dependent (Dierickx & Cool, 1989; Levitt & March, 1988). Incumbents may therefore not perceive greater opportunities under such deregulation because their strategic choices are likely to be constrained by existing resources and capabilities, and past learning. Further, green innovations are usually more costly than other conventional environmental technologies. Incumbents may thus choose to focus on their existing competencies developed during the prior regulated period, which inherit economies of scale to achieve efficiency and cost leadership. In particular, incumbents capable of using brown technologies are less likely to enter into an unfamiliar emergent market for green innovations (Kim, 2013). However, by pursuing such cost-driven strategy, incumbents may also be vulnerable to leaner entrants who try to build up stakeholder relationships via differentiated green innovations.

In addition to the path dependency, strategic choices of incumbents between cost leadership and differentiation are also constrained by managerial discretion. Managerial discretion refers to the latitude of managerial actions (Hambrick & Finkelstein, 1987), which can be a driver for investment in green innovations (Andersson & Bateman, 2000; Sharma, 2000). Such discretion is influenced by managers' perceptions of their firm's external environment and internal resources. If managers interpret environmental issues as an opportunity while the company also has sufficient discretionary resources, they are likely to invest in green innovations as a source of their company's competitive advantage (Andersson & Bateman, 2000; Sharma, 2000). Such resource slack allows firms to more effectively deal with risks and uncertainties associated with investments in green innovations (Sharma, 2000).

The deregulation may also attract new entrants who are experienced in green innovations into the industry. If incumbents diversify into green innovations on their own, they are likely to compete directly with these experienced new rivals. Incumbents may thus choose to outsource green innovations to these rivals and resell innovative green products to their final customers. Instead of treating these new entrants as rivals, incumbents may therefore collaborate with them as the supply sources of green innovations. Investments in green innovations to successfully achieve firm-specific productivity gains are essentially path-dependent. Because of time compression diseconomies as the result of deregulation, incumbents may want to avoid direct competition with such experienced new entrants and instead choose to establish the supply chain by collaborating with them (Dierickx & Cool, 1989; Kim, 2013).

The deregulation not only increases competition among domestic companies, it also opens up the opportunity for foreign entrants to compete in the local market. Firms can sustain their competitive advantage by leveraging resources and capabilities in which they have a comparative advantage (Wernerfelt, 1984). In particular, faced with deregulation and increased competition from foreign entrants, domestic companies can exploit their comparative advantage over these foreign rivals through their closer relationship with local stakeholders. Local social responsibility and sustainability can become a critical element for competitiveness of domestic companies vis-à-vis foreign entrants (Flammer, 2015). Therefore, domestic companies can strengthen their relationship with local stakeholders through differentiation strategy by investing in green innovations. This environmental initiative can be an entry barrier against foreign competitors.

However, such stakeholder strategy would be more effective for companies operating in the business-to-consumer sector, where the purchasing decision is more sensitive to socially responsible behaviors of the company (Flammer, 2015). Firms should prioritize their stakeholders and direct their investments in green innovation projects toward core stakeholders rather than peripheral stakeholders. Because product

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

market competition fosters efficiency, companies are not likely to respond to higher competition by investing in any environmental projects that is value destroying (Stigler, 1958). Therefore, investments in green innovations in response to fiercer competition from foreign entrants should not reduce the firm's overall values.

CORPORATE GOVERNANCE

Institutional pressures from environmental concerns are also imposed on the governance of corporations. Corporate governance plays an important role in driving green innovations in firms because such environmental initiatives go beyond compliance to the regulative institution and require substantial long-term resource commitment that has significant strategic implications (Hart & Ahuja, 1996). Addressing such environmental initiatives requires that a firm extend coordination across organizational boundaries to include its supply chain actors and stakeholder groups (Marcus & Geffen, 1998). Corporate governance involves the mechanisms, processes, and relations by which corporations are controlled and directed. Therefore, corporate governance constituents including ownership, board of directors, and management can influence a firm's decision to invest in green innovations (Walls, Berrone, & Phan, 2012).

In terms of the ownership, firms that are more exposed to investors with long-term horizons are likely to be more involved in green innovations (Walls et al., 2012). The levels and frequency of shareholder activisms also affect such socially responsible behavior (Walls et al., 2012). Shareholder activisms are likely to occur when a firm's environmental performance is poor because firms with poor environmental performance are exposed to more risks including violations, fines, and remediation costs. Firms with concentrated ownership may have less managerial discretion and thus be less active in pursuing green innovations, which go beyond environmental compliance (Walls et al., 2012).

With respect to the board of directors, outside directors may strengthen people and product aspects of green innovations (Johnson & Greening, 1999) while reducing risks of firms from environmental litigations (Kassinis & Vafeas, 2006). When the board is more independent, larger, and less diverse, its ability to monitor environmental performance is worsened (Walls et al., 2012). Independency of the board is favorable for financial performance, but not for environmental performance (Walls et al., 2012). While a reduction of insider directors is an effort to increase governance independence, and thus to improve financial performance, it concurrently weakens expertise, experience, and reputation of insiders, which are a critical element to superior environmental outcomes.

Regarding the management, the duality of chief executive officer (CEO) may discourage firms from investing in green innovations (Webb, 2004). The proportion of shares held by top management team may be positively related to such corporate philanthropy (Coffey & Wang, 1998). The establishment of environmental committees not only strengthens environmental capability of firms by providing expertise and resources but also helps firms mitigate environmental problems (Walls et al., 2012). Firms with higher CEO salaries perhaps emphasize shorter-term financial goals at the expense of long-term environmental goals (Walls et al., 2012). When the fixed component of compensation is large, executives tend to be conservative and thus avoid risky investments in green innovations.

The combination of investors with long-term orientation and an independent board of directors therefore has both pros and cons for environmental performance. Powerful CEO duality works well with the board that consists of insiders. Therefore, the combination of CEO duality and insider directors may

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

be positive for environmental capability. However, when CEO duality is absent and the board has more outsiders, environmental performance may suffer. Since green innovations can be highly technical and industry-specific, insiders in the boards may possess relevant expertise to support the CEO in formulating and implementing environmental strategy.

DISCUSSION AND CONCLUSION

Regulative and normative institutions are two major drivers of the extent to which firms will respond to environmental issues. The strength of such response is contingent upon a firm's past environmental performance relative to its industry peers (i.e., deficiency gap), and the availability and specificity of its internal firm resources (i.e., resource profile) (Berrone et al., 2013). Instead of compelling conformity, institutions can therefore be a source of firms' strategic heterogeneity. This heterogeneity explains why some firms are more or less likely to pursue green innovations than other firms. In particular, institutional pressures can influence allocations of firms' internal resources toward investing in risky green innovations, which can be a source of their competitive advantage. With sufficient institutional pressures, and expected legitimacy gains, managers should consider pursuing such differentiation strategy in their firm's products.

Government regulators should be aware that their enforcing mechanisms and legitimacy sanctions may not be as effective as pressures generated by other normative institutions (Berrone et al., 2013). Firms may use resource slack to resist regulatory obligations while acquiescing social demands. In particular, firms with sufficient resource slack may choose to pay legal and economic sanctions rather than to voluntarily invest in risky green innovations. Such resource slack may be used as a buffer for the regulatory pressure rather than for investing in green innovations. Normative pressures however require that firms provide fundamental responses to knowledgeable people or organizations that exert these pressures.

Diversifying incumbents are more likely to be pushed by regulative and economic opportunity to enter in emergent industries such as green innovations while the entry of entrepreneurial start-ups tends to be more influenced by the sociocultural environment (York & Lenox, 2014). Entrepreneurs entering an emergent market that is culturally aligned with its venture may avoid direct competition with diversifying incumbents. However, if such entry is driven by regulatory and economic opportunity, they are more likely to compete with the diversifying incumbents. Therefore, entrepreneurs should try to understand social norms in a region and enter areas earlier before these norms are endorsed and become policies. Diversifying incumbents should always be aware of the sociocultural environment in a region to predict new entrants and to maintain their competitive edge. Government regulators should be aware that state-level policies might not be as effective as regional cultures and norms in promoting entrepreneurship in the region.

Under the industry deregulation and resulting higher price competition, incumbents are likely to focus more on their core competencies developed during the regulated period (Kim, 2013). In particular, incumbents that are more capable in brown technologies are likely to continue exploiting these technologies to strengthen economies of scale and efficiency rather than pursuing differentiation strategy by diversifying into unfamiliar green innovations. Due to strong inertial pressures, only those with prior experience in green innovations may increase their investments in green innovations to strengthen their products' competitiveness under the deregulated regime. By focusing on green innovations, mangers of these domestic companies can leverage comparative advantage in their relationships with local stakeholders to

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

compete more effectively with increasing foreign entrants (Flammer, 2015). However, managers should be aware that such differentiation strategy requires that there is a sufficient number of consumers, who demonstrate sufficiently high levels of environmental sensitivity and actually value the green attributes in their company's products (Kim, 2013).

Finally, executives should be aware that corporate governance system has a significant influence on environmental strategy and firm performance (Walls et al., 2012). Investors with long-term orientation may push firms to invest in green innovations. However, such a long-term horizon per se may not be sufficient to stimulate environmentally responsible behaviors. To realize the benefits of good environmental performance, firms also need an effective board monitoring, management, and control mechanism. Particularly, the board of directors has to prioritize the allocation of resources to particular core and peripheral stakeholders. Appropriate resource allocations with respect to investment in green innovations can safeguard firms from environmental violations and penalties.

Chapter 50
The Leading Practices of Green Mobile Telecommunication Base Station Design

Yazan Migdadi
Yarmouk University, Jordan

ABSTRACT

The aim of this study is to identify the green mobile telecommunication base station design practices as adopted by leading cases, four cases were analyzed; Ericsson, ZTE, Huawei, and Bharti. The data were collected from the published data. This study reveals that; the design attributes could be classified to; primary and secondary design attributes. A lot of relationships are reported between the design attributes. This study helps the academics in understanding the relationship between design attributes and actions, so they can use the reported model of this study for teaching purposes or for further extended survey study. The base stations developer and mobile communication services providers have a good insight about the sustainable design alternatives. The green operations practices are still new and the research contribution is limited, the research contribution of green mobile telecommunication base station deign is very limited.

1. INTRODUCTION

Mobile telecommunication base stations have been a crucial telecommunication technology spread everywhere as a result of wider use of mobile phone communication. The telecommunication industry consumes a large amount of energy as reported by some telecommunication social responsibility reports, further some operators are listed as the largest energy consumption in their countries, as more and more industries introduces more ICT the situation will get worse. More local and international pressure on the telecommunication operators and equipment vendors will increase in the future (Huawei 2011), accordingly, the developers of base stations have concerned about the green initiatives; the CO2 emissions over the product life cycle are traced and different actions have been made (Lu 2008; Jianguo et al., 2008). One of these important actions made is the green design of base stations; system developers have made

a lot of actions to reduce the energy consumptions, improve the using of green energy and reduce the need air conditioning of base stations. The concern about the green design of base stations is reasonable since the energy consumption of radio sites usually accounts for more than 75% of the energy consumed during the telecommunication process (Huawei 2011).

The majority of green product design previous studies have concerned about the process of green product development instead of reporting the attributes and actions (e.g. Wimmer et al., 2008; Bard et al., 2011; Lamore 2011; Cagno and Trucco 2013), further, the studies of green supply chain management practices have not reported in-depth the relationship between design attributes and between design attributes and actions (e.g. Zhu et al., 2005; Zhu et al., 2010; Green et al., 2012; Perotti et al., 2012; Shi, et al., 2012; Lee et al., 2012), accordingly, this study decided to report in –depth the green mobile telecommunication base stations design attributes and actions, to realize this aim the following objectives were realized.

1. Identifying the base stations design attributes.
2. Identifying the relationship between the base station design attributes.
3. Identifying the green design actions are made to realize the base station design attributes.

This paper is organized as follows; the second section discuss the literature and represents the research contributions, the third section represents and discusses the research methodology, the next section is data analysis and findings, the fifth section is the discussion and the last section is the conclusions applications and future researches.

2. LITERATURE REVIEW

The concept of design for environment is a new concept, according to this concept the product has not a negative impact on the ecological environment, whether the product is used by customers or when the product is used and disposed, according to this concept, the product could be made from ecological components, which are disposed in the ecological environment without negative consequences, or the hazardous materials are eliminated from the product, or the product is easy to disassembly for recycled or remanufactured, the product size and weight could be reduced; further, the product consumes less energy during usage, or the product emission less greenhouse gases (Zhu et al., 2005; Zhu et al., 2010; Green Jr. et al., 2012; Perotti et al., 2012; Shi et al., 2012; Lee et al., 2012), design for environment is a critical success factor in a green supply chain management strategy and can help firms realize economic benefits (Shi et al., 2012).

The studies have investigated the green product design focused mainly on the process of green product development; for example one of these studies decided to investigate how to develop eco-products using Eco-design approach (e.g. Wimmer et al., 2008), another study has developed a new design tool for green product development process which is called “Integrated Green and Quality Function Deployment” (IGQFD) (Cagno and Trucco 2013), moreover, another study focused on developing a methodology which guides the decision makers toward a superior balance between quality, cost, environmental issues in product design (Bard et al., 2011), also a new process of product development which combines both the market requirements and social responsibilities toward stakeholders have been developed, this

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

process is called "Green Ocean" (Lamore 2011), another study have developed an ecodesign product and the performance of this product is evaluated by using product life cycle assessment approach (Schneider et al., 2008).

Other studies decided to investigate the factors determine the process of product design development, for example one of these studies has investigated the willingness of designers to adopt the eco-innovation tools (O'Hare et al., 2010), another study examined the impact of market and customers on adopting more eco-designed product (Jeswiet and Hauschild 2008; Short and Harvey 2008).

The green product design attributes have been investigated by green supply chain management practices studies; these studies decided to report the relationship between the green intra-organization and inter-organization practices and green supply chain key performance indicators (operational performance, environmental performance and financial performance) (Zhu et al., 2005; Zhu et al., 2010; Green et al., 2012; Perotti et al., 2012; Shi et al., 2012; Lee et al., 2012). Green product design has been defined as inter-organizational environmental practices, these studies have not reported the relationship between green product design attributes in details, and the actions affected the green design attributes (e.g. Green et al., 2012).

Accordingly, it is required more sophisticated models and more in-depth analysis of green product design attributes of particular industries, since some industry requires different design requirements, for example the producers of mobile phone concerns about the size, weight, reducing hazard materials, easy to recycle product. These attributes are secondary for mobile telecommunication base station design. So this study bridges the gaps of limited studies regarding green product design in general and green mobile telecommunication base stations design in particular.

3. RESEARCH METHODOLOGY

The methodology adopted by this research was qualitative case study methodology, the practices of four cases were investigated; this methodology was adopted since the aim of this study is to identify the relationships between design attributes and actions, which requires in-depth analysis of particular cases. The quantitative survey methodology will be used if the relationship between design attributes and actions are well understood, further. In the following sections the phases of study are presented, under each phase a clear discussion is presented.

3.1. First Phase: Selecting the Cases

The cases investigated by this research are; Ericsson, Huawei, ZTE and Bharti, the cases were selected carefully to have more reliable conceptual model. The cases are leading cases in constructing the mobile telecommunication base stations, also, the cases are leading in green base stations design (for example ZTE Corporation has already developed into the fifth largest telecommunication equipment provider, ranking among one of the Top 5 in the world, and is the largest mobile phone terminal manufacturer of China), so some cases won international or local awards of green mobile telecommunication practices (for example Bharti won **"**Green Mobile Award' at the 2011 GSMA Global Mobile Awards of driving one of the largest green power initiatives for mobile towers, also, Huawei won InfoVision Award from the International Engineering Consortium (IEC) for its innovation and "Green Design"), other cases

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

are strongly involved in green mobile telecommunication research projects, or main contributed to the standards of mobile telecommunication green practices (for example Ericsson is strongly involved in the EU research project EARTH, also has been active in the ITU-T LCA standard, L.1410).

3.2. Second Phase: Collect the Data

The data used are collected from secondary sources; the published data via websites and data published data in the annual sustainability and social responsibility reports were collected.

3.3. Third Phase: How to Realize the First Objective: Identifying the Base Station Design Attributes

The reported practices of the selected cases were revised, the focus was on identifying the general classification categories of design attributes and the detailed attributes, then the attributes adopted by each case was summarized, then the general titles were identified and checklist was used to report and count the attributes adopted. Then the result was summarized on a table as presented in Table (1).

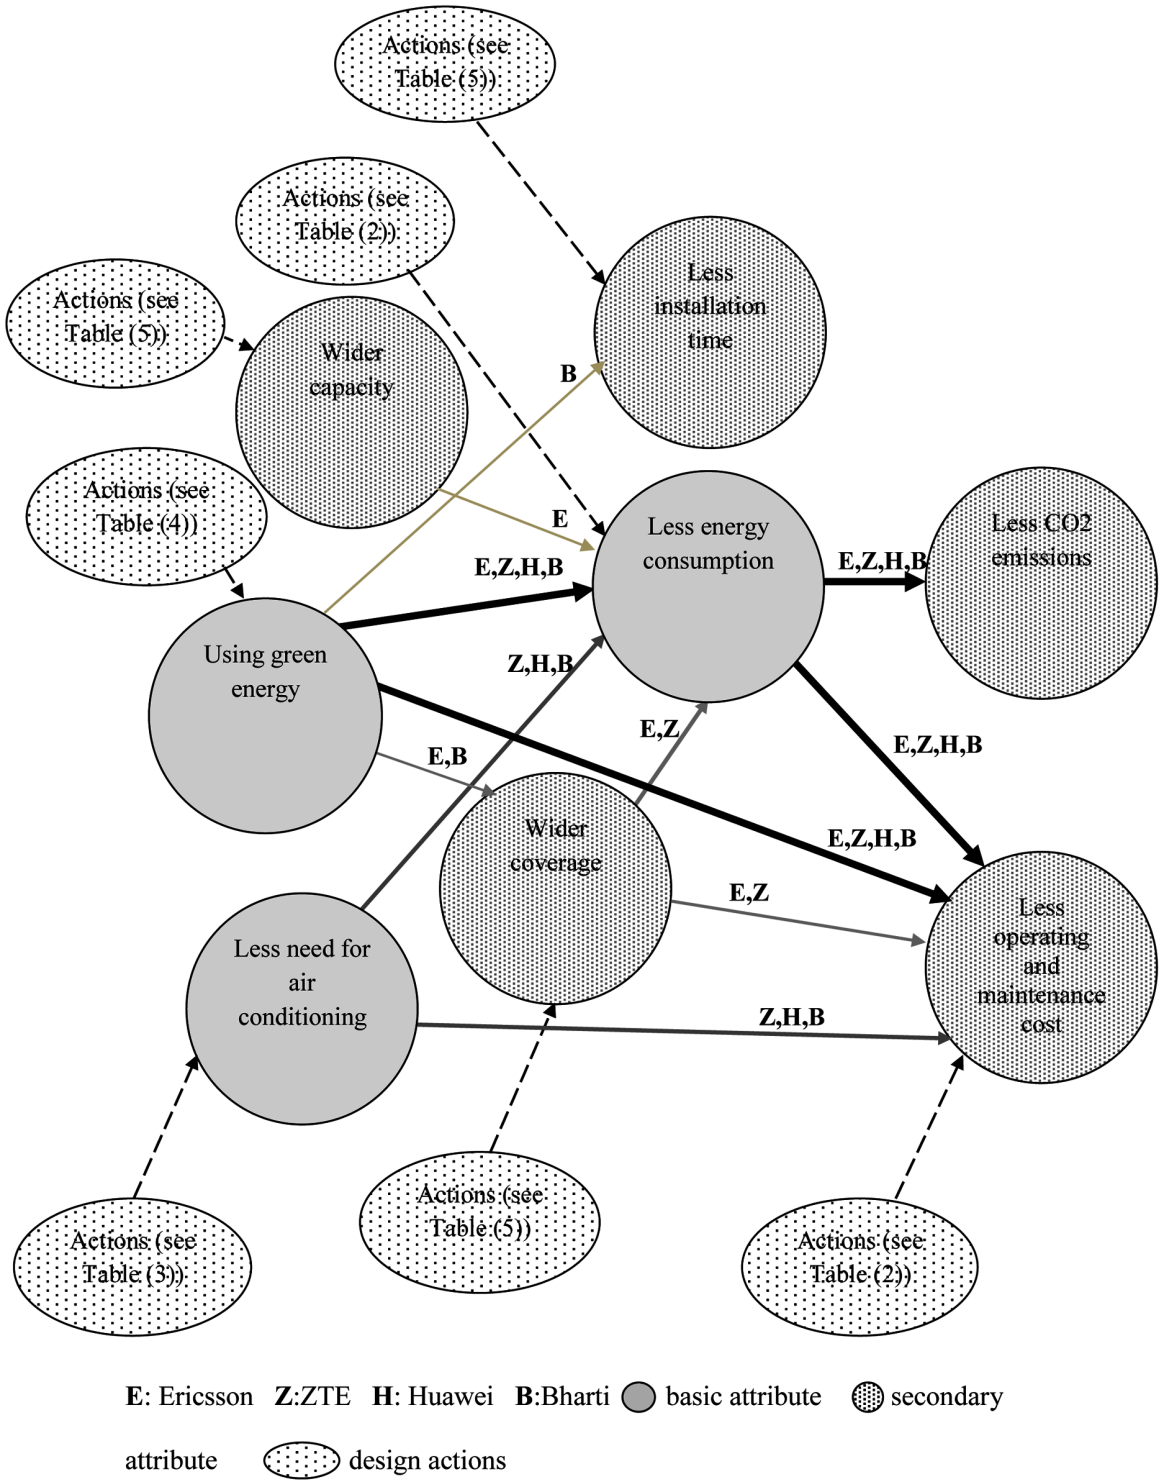
3.4. Fourth Phase: How to Realize the Second Objective: Identifying the Relationship Between Design Attributes

A model which combines the relationship between attributes was developed for each case, the content of summarized facts of each fact was analyzed and represented by using arrows and circles. Then, the models were combined to form a general model, over each arrow an abbreviation represents each case was written. The arrows colours and thickness were distinguished according to frequency of cases adopted the relationship (see Figure (1)).

3.5. Fifth Phase: How to Realize the Third Objective: Identifying the Green Design Actions Are Made to Realize the Base Station Design Attributes

The actions adopted by each case to realize a particular design attributed were identified by revising the summarized facts related to each case, the check list was used for this purpose, then, the actions adopted to realize each design attribute are summarized in separate tables (see Table (2) to Table (5)).

4. DATA ANALYSIS AND FINDINGS



This section is classified to two main sections; the first one is identifying the base stations design attributes, and identifying the actions made to realize the design attributes.

4.1. Identifying the Base Stations Design Attributes

Table (1) show the design attributes as reported by the investigated cases, it can be seen that; the design attributes could be classified to two categories; the primary design attributed and the secondary design attributes. The primary design attributes are those mainly intended by the designers, so these are the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The relationship between green attributes as adopted by the surveyed cases

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Base stations design attributes

Design Attributes	Ericsson	ZTE	Huawei	Bharti	Frequency of Attributes
Primary design attributes					
Less base station energy consumptions	X	X	X	X	4
less need for air conditioning		X	X	X	3
using green energy	X	X	X	X	4
Secondary design attributes					
Less CO2 emissions	X	X	X	X	4
Wider coverage	X		X	X	3
Less installation time	X			X	2
Wider capacity or less capacity per subscriber	X	X			2
Less maintenance and operating cost	X	X	X	X	4

X: Attribute is reported by the case

core attributes, however, the secondary attributes are those realized as a result of adopting the primary design attributes.

After revising the practices of selected cases it is found that; the base stations primary design attributes are; less base station energy consumptions, less need for air conditioning, using green energy. The most frequently primary attributes which adopted by all cases are; less base station energy consumption and using green energy.

The secondary deign attributes are; less CO2 emissions, wider coverage, less installation time, wider capacity or less capacity per subscriber, and less maintenance and operating cost. The most frequently attributes which adopted by all cases are; less CO2 emissions and less maintenance and operating costs. However, the least frequently attributes which adopted by two cases are; less installation time and wider capacity.

4.2. The Relationship Between Base Station Design Attributes

The saving of energy is affected by the using of air conditioning, using green energy and wider coverage. However, less energy consumption reduces CO2 emissions. The using of green energy improves the coverage of base stations, and reduces the base station installation time. On the other hand, the saving of operating or maintenance costs is affected by less energy consumption, less need for air conditioning, using green energy and wider coverage of base stations.

4.3. The Base Station Design Actions

4.3.1. Less Base Station Energy Consumption and Reduce the Operating and Maintenance Cost Actions

Table (2) shows the actions made to reduce the base station energy consumption and reduce the operating and maintenance cost, it can be seen that; the actions adopted to reduce the energy consumption are the same as the actions made to reduce operating cost. The most frequently actions are made by two cases

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Less base station energy consumption and operating and maintenance cost actions

Action	Ericsson	ZTE	Huawei	Bharti	Frequency of Actions
Multi-standard radio base station (RBS), SDR based wireless solution	X	X			2
Eco-mode features for traffic use, traffic usage adopted stations	X	X			2
Remote site management	X				1
Intelligent management system			X		1
High sensitive receiving technology for wireless devices		X			1
High frequency digital power amplifier			X		1
Integrated system power management				X	1
Antenna integrated Radio	X				1

X: Action is adopted by the case

only, these actions are; multi-standard radio base station, and eco-mode features for traffic use. However, the remaining actions are made by one case, these actions are; remote site management, intelligent management system, high sensitive receiving technology for wireless devices, high frequently digital power amplifier, integrated system power management, and antenna integrated radio. The majority of actions made are not shared.

4.3.2. Less Need for Air Conditioning Actions

Table (3) shows the actions made to reduce the reliance on using air conditioning, it can be seen that; the actions adopted are; direct ventilation, intelligent ventilation, heat exchange for heat dissipation, wider operating temperature and free cooling unit. The first three actions are adopted by one case which is ZTE however the wider operating temperature is adopted by Hauwei, but the free cooling unit is adopted by Bharti, so no shared actions between cases.

4.3.3. Using Green Energy Actions

Table (4) shows the actions made to use green energy, it can be seen that; the actions adopted are; using solar energy, using solar-wind hybrid energy, using solar-diesel energy. The first actions which is using solar energy is made by all cases, however, the remaining actions are made by Huawei only.

Table 3. Less need for air conditioning actions

Actions	Ericsson	ZTE	Huawei	Bharti	Frequency of Actions
Direct ventilation		X			1
Intelligent ventilation		X			1
Heat exchange for heat dissipation		X			1
Wider operating temperature			X		1
Free cooling unit				X	1

X: Action is adopted by the case

Table 4. Using green energy actions

Actions	Ericsson	ZTE	Huawei	Bharti	Frequency of Actions
Using solar energy	X	X	X	X	4
Using solar-wind hybrid energy			X		1
Using solar-diesel energy			X		1

X: Action is adopted by the case

4.3.4. Wider Coverage Actions

Table (5) shows the action made to expand the base site coverage, it can be seen that; the action adopted is high sensitive receiving technology for wireless devices; this action is made by one case which is ZTE.

4.3.5. Wider Capacity Actions

Table (5) shows the actions made to expand the capacity of base station, it can be seen that; the actions adopted is using heterogeneous network which is adopted by the Ericsson.

4.3.6. Less Installation Time Actions

Table (5) shows the action made to reduce the installation time, it can be seen that; the action adopted is using the antenna integrated radio; this action is made by one case which is Ericson.

5. DISCUSSION

The basic design attributes are the most important since the sources of CO2 emissions of base stations is the energy consumption; furthermore, more than 90% of the power consumption of the station comes from the communications equipment and air conditioning system (Qiang, 2008). These are two key fac-

Table 5. Actions made to realize secondary design attributes (wider coverage, wider capacity and less installation time)

Actions	Ericsson	ZTE	Huawei	Bharti	Frequency of Actions
Wider Coverage Action					
High sensitive receiving technology for wireless devices		X			1
Wider Capacity Action					
Heterogeneous network	X				1
Less Installation Time Action					
The antenna integrated radio	X				1

X: Action is adopted by the case

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

tors in optimizing energy conservation: lowering the power consumption of communications equipment and the air conditioning system, plus simultaneous use of new energy based on the situation at the site.

The using of green energy will improve the coverage especially for the rural areas since the energy sources are limited in the rural areas. Further, the operating cost will be reduced since the green sources are available for free. The using of base stations powered by green energy required less installation time since it is not required to be linked with electrical energy power by cables which consume significant time.

The investigated cases concerned about improving radio system to reduce energy consumption since the radio part is the largest energy-consuming entity of the base station, it is consuming more than 80% of the base stations energy demands. On the other hand, some cases concerned about intelligent management systems remote site systems, these actions reduce energy consumption since the intelligent system is able to monitor the power supplies, fire alarm systems, and temperature, also the intelligent system is able to capture every fault in site so reduce the operating and maintenance costs.

The using of Eco-mode features for traffic use or traffic usage adopted stations will reduce energy consumption since the systems will adjust the power required according to the used output power in the radio in the radio interface, so during low usage the energy used will be reduced and operating and maintenance cost will be reduced in accordance. The using of high sensitive receiving technology will improve the coverage so the number of base stations in a particular area will be reduced so the energy consumption will be reduced and the operating and maintenance cost will be reduced in accordance.

The majority of producers adopted solar power energy rather than hybrid sources, or wind energy, since the solar power equipment are easier for installation in comparison with wind and occupy smaller area. Heterogeneous network will improve the capacity of base stations since it is a powerful macro-radio base stations are complemented by smaller radio base stations (pico and micro) which provides extra capacity during the high demand, further, it is serving users with a nearby low power node, so it is possible to off-load the high power nodes, thus saving energy.

6. CONCLUSION

6.1. Contribution and Results

The majority of green product design previous studies have concerned about the process of green product development instead of reporting the attributes and actions, further, the available literature of green supply chain management practices have not concerned about reporting in-depth the relationship between green product design attributes and actions.

The main result of this study is the design attributes are classified to primary and secondary attributes; the primary design attributes are those mainly intended by the designers, so these are the core attributes, however, the secondary attributes are those realized as a result of adopting the primary design attributes. The primary design attributes are; less base station energy consumptions, less need for air conditioning, using green energy. The secondary deign attributes are; less CO2 emissions, wider coverage, less installation time, wider capacity or less capacity per subscriber, and less maintenance and operating cost.

There are relationships between design attributes; the saving of energy is affected by less using of air conditioning, using green energy and wider coverage. However, less energy consumption reduces CO2 emissions. The using of green energy improves the coverage of base stations, and reduces the base station installation time. On the other hand, the saving of operating or maintenance costs is affected by

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

less energy consumption, less need for air conditioning, using green energy and wider coverage of base stations. The realization of design attributes is affected by stream of actions which are reported by this study.

6.2. Implications and Future Research

This study helps the academics in understanding the relationship between design attributes and actions, so they can use the reported model of this study for teaching purposes or for further extended survey study. The base stations developer and mobile communication services providers have a good insight about the sustainable design alternatives.

This study developed a model of base stations design according to practices of four cases, the results of this study could not generalized, so it is recommended to conduct a survey study, this study reports the design attributes as reported by the producers of base stations, it is recommended to evaluate the effectiveness of green base stations by surveying the mobile telecommunication service providers, also, it is recommended to evaluate the effectiveness according to country context.

Chapter 51
Green Innovation and Ethical Responsibility: Do They Improve Customer's Green Purchase Intentions?

Harsh Tullani
SRM University-Delhi NCR, India

Raiswa Saha

Richa Dahiya
SRM University-Delhi NCR, India

ABSTRACT

The article aims at finding whether it's green innovation or ethical consideration of the business that predominantly affects consumer's choice for green purchase intentions. Does it act as a precursor to green marketing practices, and how it can impact consumers green purchase intentions? This article contributes a conceptual model focusing on three main variables under study i.e., green innovation, ethical responsibility and green purchase intentions. The study employs qualitative literature review followed by a quantitative survey of 250 consumers through 7-point Likert scale. The study results support that ethical responsibility has a positive impact on green purchase intentions. Green innovation has also got a positive relationship with green purchase intentions. However, green innovation and ethical responsibility are also significantly associated with green purchase intention. In a nutshell, both factors conjointly affect consumer's green purchase intentions. The study has functional and social implications for policymakers, citizen action public, businesses, stakeholders and the public in general. Environmental awareness, sense of trust & corporate image can be studied as a mediator or moderator to get a holistic view of the phenomenon. As per the understanding of the researchers, this is a naive study that explores, tests and contributes an empirically tested conceptual model supporting the combined effect of ethical responsibility and green innovation on green purchase intentions.

INTRODUCTION

The Brand inclination is imperative for distribution of the innovative product as it offers a lot of profits for such a unique position in the market, strong competitive power, & market share. These interests constrain the companies to acknowledge the environmental accountability (Chen et al., 2006). In the ancient time, firms' only liability was to capitalize on their owners' welfare and profit, rather than giving regards to the social and environmental effects (Sinthupundaja, & Kohda, 2017). It has been observed currently that ecological issues are rising progressively owing to the enormous amount of environmental pollution which is caused by manufacturing units (Chen, 2008). This is also applicable to green innovation in provisions of consumer goods, industrial supplies and services (Polonsky, 1994; Ottman, 1998). In today's globalized, rapidly-changing world, innovation is becoming ever more important as changes in technology, skills and knowledge increasingly affecting countries' competitiveness externally as well as the well-being of their people internally. Spillovers in R&D means that private firms (and individual countries) are unable to capture the full value of their investments in the competitive market. Indeed, innovation studies suggest that the social returns to private R&D are often much larger than the (already large) private returns. This means in such cases firms will undervalue such investments and so be motivated to underinvest relative to what might be good for society as a whole. Fostering positive spillovers is a "primary justification for government R&D-support policies". Key externalities like congestion, environment and CO_2 emissions may not be properly priced or regulated in the market. Firms thus, undervalue innovations that would address such externalities. For this reason, energy innovation has been called "a tale of two market failures" — i.e. it is undervalued due to both spillovers and the lack of adequate CO_2 pricing. Imperfections in risk-sharing institutions and capital markets hamper the extent to which innovation and innovative approaches can diffuse. Therefore, the time-to-market of environmentally friendly products may be an intermediate outcome of effective green external integration, which ultimately leads to improved performance. Green innovation and ethical responsibility of businesses have seamlessly integrated towards the development of green purchase intention and green consumerism.

Green Purchase Intention

Green purchase intention is the intentional purchase of products and services with an idea of minimal harm to the natural environment. Some free market advocates claim that the market automatically gives people all the choices, want and all the information they need, but what consumers are demonstrating is that they are more environmentally acceptable choices than the market has been delivering, and more worthy information about the social and environmental impact of the products they might buy.

Need for the Study

Businesses use "green" as a symbol to sustain within the public relation opportunity. They use green as a brand positioning strategy such as energy efficient, organic and eco-friendly (Parker et al., 2009). Chen et al. (2006) found that the competitive advantage of the business depends upon the green product as well as green innovation. The sustainable businesses depend on the way how to tackle the environmental

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

problems (Baker, & Sinkula, 2005). Many business houses view their green activities as different, isolated and fragmented sets of activities such as energy conservation, recycling & reducing pollution. Therefore, businesses provide the economic and competitive opportunities after the environmental improvements take place; those improvements work as a value added instrument to both organization as well as the customers buying pattern (Porter, & Van der Linde, 1995). To achieve Green purchase intention organizations should be connected with the green supply chain in a sustainable manner.

Research Question and Problem Statement

Awareness about Green products is scattering day by day in India. Customers, companies as well Government is getting concerned about the environment which breeds Green purchase intention in India. Now, the question arises:

RQ1: Do green innovation influence green purchase intention of consumers?

Business firms have understood the vital roles of green marketing practices to strive in the market and gain a competitive position over rivals in the industry. Green marketing has received a tremendous increase with the revitalization of environmental awareness among customers. Green marketing, in fact, carries a paradigm move approach in many business firms since it has changed the manner in which a business goes about reaching out to the customers. These days, the supervision of green marketing and innovation is obligatory in influencing the consumers' decision of purchasing. This is due to the impact of consuming chemical-based products towards health. Consumers of organic farm products tend to pay attention on the products' characteristics which are environmentally-friendly and give benefit to their health as defined in terms of green purchasing by Lee. According to the research discussions, consumers within the age group of more than 50 years tend to pay more attention towards purchasing organic products. Recently, since organic products are not sold in many places and they have higher prices, these products seem to be affordable merely for middle to high-class communities. The label "Go Green" and physical appearance of organic products, which differs from those of non-organic ones, support in the promotion processes. In the coming years, organic products which are environmentally-friendly will be able to compete in the market with other nonorganic products. This will enable companies to gain their own specialty and ability in winning marketplace competition.

RQ2: Do ethical responsibility influence green purchase intention of consumers?

Consumers who are aware of environmental issues & interested in buying ecological products are called 'green consumers' (Soonthonsmai, 2007). Ottman (1992) reported that consumers acknowledge green products only when they are satisfied with their primary needs for quality, convenience, affordability & performance and when they are aware of the working of a green product that how it could solve their environmental problems. Krause (1993) reported that consumers were becoming more concerned about their routine and its impact on the environment, therefore, many of the consumers transformed as a Green consumer.

LITERATURE REVIEW AND HYPOTHESES DEVELOPMENT

Green Innovation

While undergoing Green purchase intention-behavior exploration, numerous studies have depicted a "gap" between consumers' favorable attitudes and real purchasing habit (Vermeir, & Verbeke, 2006; Vermeir, & Verbeke, 2008; Tanner, & Kast, 2003). Hughner (2007) in a study have found that whereas, consumers irrespective of showing an optimistic outlook towards organic food purchases, just a limited number of consumers actually purchases. It is thus, evident from past researches being undertaken that there exist customer's thoughts and real actions gap (Wheale, & Hinton, 2007; Chen, & Chai, 2010) which is referred to as 'green attitude-behavior gap'. If green innovation is ignored or has given comparatively less importance it can affect the purchase decision of the customers and can lead to brand switching by the customers. Therefore, green innovation shows that consumers positive attitude towards green purchases does not always lead to buying behavior and is essential to examine why environmental attitudes have a weaker influence on consumer green purchase behavior; that leads to the discrepancy between consumer attitude and purchase behavior.

Previous research has not been capable of recognizing the consumer attitude towards the green purchase (Gupta, & Ogden, 2009) as no inclusive examination of environmentally responsible purchasing (Memery et al., 2005) has been studied vastly. Thus, the authors felt the necessity of conducting this study on consumer behavior towards the green purchase, and this encouraged the authors to evaluate the existing pertinent literature on consumers' green purchase behavior. An increased attention towards environmental damages (pollution, depletion of resources, etc.) has raised an increased level of concern and emphasis on sustainable products.

Green Innovation

H1: Green Innovation has a significant positive impact on Green Purchase Intention

The word 'green' has turned out to be a significant reflection of a company owing towards public concern in respect of ecological issues, which has enthused rising attention among researchers in investigating green marketing concepts. An assortment of environmental topics has been studied giving focus towards green market orientation (Hong et al., 2009), ecological social accountability (Siegel 2009), corporate social responsibility (Ambec, & Lanoie, 2008), and ecological administration (Florida, & Davison, 2001; Molina-Azorin et al., 2009). Therefore, green supervision will be possibly more to create radical innovation than incremental innovation.

Ethical Responsibility

H2: Ethical Responsibility has a significant positive impact on Green Purchase Intention.

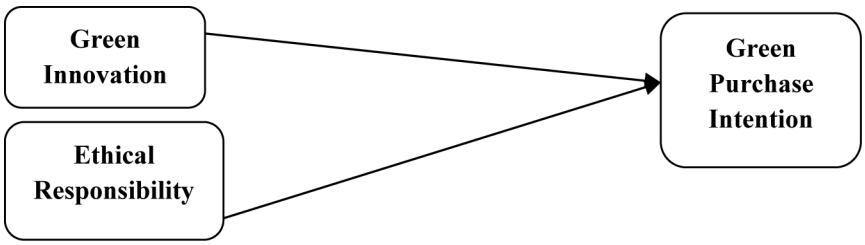
Consumers generally express their apprehension about the company's ethical performances by means of ethical buying and ethical consumerism. Thus, an ethical consumer feels a true sense of socially responsible by means of his or her purchasing intentions. Green purchases and ethical responsibility

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

have received a positive relationship as it explains the ethical consumption and several dimensions of consumers' perceptions towards an ethical firm. There are various benefits that accrue to green purchases and ethical responsibility by benefitting the natural environment (environmentally friendly products, fair-trade products, etc.) Consumer perceptions and attitudes influence purchase behavior, which is tested in several ethical consumption models (Shaw, & Clarke, 1999; Vitell, Singhapakdi, & Thomas, 2001).

Green ethical consumption relates to an important consumers' responsibility with respect to their purchasing actions not only as individuals but, also on their social value systems (Uusitalo, & Oksanen, 2004). Thus, consumers' ethical behavior can also be reflected in their involvement pattern (Carrigan, & Attalla, 2001). Company's unethical behavior has an impact on consumer attitudes according to previous studies done by Folkes, & Kamins, 1999. It has been well established that customers do give due importance to ethical products (Carrigan, & Attala, 2001; De Pelsmacker et al., 2005) and are highly worried about the companies' ethical roles to pay off which leads to widespread purchasing behavior.

METHODOLOGY



Research Objective

- *To analyze the relational impact of Green innovation on Green purchase intention.*
- *To analyze the relational impact of Ethical responsibility on Green purchase intention.*
- *To develop a comprehensive model encompassing all the developed constructs.*

Proposed Conceptual Model

This study has done the summarization of the literature on green innovations and ethical responsibility into an innovative and novel management outline leading towards Green purchase intention. Many past research studies have explored the construct of Green purchase intention and innovation, but no research has still found the dual effects of green innovation and ethical responsibility towards green purchase intentions or green consumption. This present study explored explicitly and found the constructs to be worth researching in order to fill the research gap and propose a novel model framework and design i.e., green innovation with ethical competencies of companies. This study, hence, explored the positive and significant effects of innovation and ethical perspectives of firms to build their consumer consumption study pattern (see Figure 1).

Figure 1. Conceptual framework. Source: Authors compilation

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Constructs, Participants and Procedure Measurement

The current research discusses the conception of Green purchase intention and its linkage with ethics and innovation. To meet the aims and objectives of the research, this study has employed a quantitative research technique to find out the interrelationships among Green innovation, ethical responsibility and Green purchase intention of consumers in India, thereby, formulating an all-inclusive representation for the purpose. Turker (2009) scale have been used for studying ethical responsibility. Steenkamp & Gielens (2003) scale was used for green innovation and for green purchase intentions or consumption, Maro & Oliver (1993) scale was used.

Field surveys of 250 consumers through 7-point Likert scale from strongly disagree to strongly agree (1 to 7) self-administered structured questionnaire is filled, to understand their attitude towards Green purchase intention and Green products. Non-probability sampling approach has been adopted by the researchers, whereas, convenience and judgment-based sampling methods have been employed in order to select the subjects representing both the genders, educational levels, diverse age groups, monthly income and marital status. Demographic categories such as income, gender, age and qualification have been taken into consideration along with urban classifications. Various published reports of Government of India, various rating agencies, Indian Chambers of Commerce and Industry, business publications and reports made available by various companies were selected for secondary data reviews. Exploratory factor analysis and Structural equation model (SEM) have been used with the help of software like Amos 20 and SPSS 21.0 for data analysis. Standard editing and coding techniques have been utilized to analyze the data.

Case Analysis

Coca-Cola

Coca-Cola is the leading retailer brand in the world with the purpose of creating economic, social, and environmental value. They are involved in packaging innovations, to make bottles lighter and friendlier with the environment by promoting recycling and make sure that their operating waste is managed adequately. There 2020 goal is that 25% of the materials they use in their pet packages include recycled or renewable components.

State Bank of India: Green IT@SBI

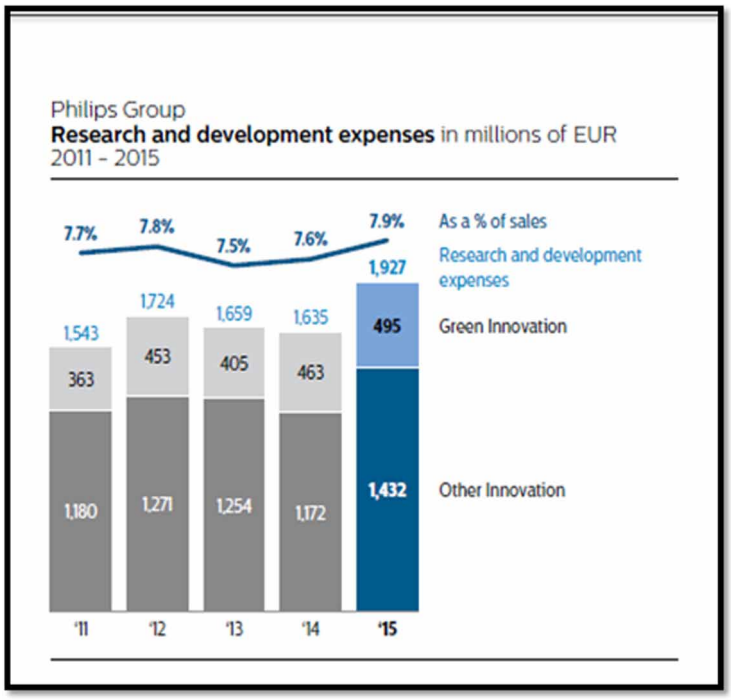
SBI entered into green service known as “Green channel counter”. SBI provides numerous services like paperless banking, no deposit slip, no withdrawal form, no checks, no money transactions form which can be done through SBI shopping & ATM cards. State Bank of India turns to wind energy to reduce emissions.

Philips

Philips’ innovation efforts are closely aligned with their business strategy. It does so through cooperation among research, design, marketing, strategy and business in interdisciplinary term along with the innovation chain, from front-end to first-of-a-kind product development. Philips LifeLight, the new

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

zero-energy, Solar powered LED lighting range designed for homes in off-grid rural and semi-urban communities are all part of Philips drive to deliver innovations (See Figure 2 Philips group Research and Development expenses).



Samsung

Samsung commits to provide eco-friendly products & services based on green management to prevent world through business initiatives. Their vision is "providing a green experience, creating a sustainable future" with the slogan "Planet First". They have reduced 70% of GHG emissions. According to the EM2020 goal as compared to 2008 even they are continuously improving the energy efficiency level in the manufacturing process Samsung works for the safety of employees as well as customers by increasing their recycling & creating innovative products & services.

LG

South Korean consumer durable major LG Electronics recently introduced LG LED E60 and E90 series monitors in the Indian market. The LED E60 and E90 series monitors are packed with the eco-friendly features such as 40 percent less energy consumption than the traditional LCD monitors. Also, the use of hazardous materials such as halogen or mercury is kept to minimal in this range. Globally, LG has launched a range of eco-friendly products 'Eco-Chic' such as the platinum coated two-door refrigerator and washing machine with steam technology.

Figure 2. Philips group research and development expenses (Source: 2015 Annual Report of Philips)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

HCL

Last year, HCL launched its range of eco-friendly notebooks, HCL ME 40. HCL claims that this was India's first PVC free and eco-friendly notebook. This notebook is completely free from polyvinyl chloride (PVC) material and other harmful chemicals. Further, the bureau of energy efficiency has given HCL eco-friendly products a five-star rating, and they also meet REACH (REACH is the European Community Regulation on chemicals and their safe use) standards and are 100 percent recyclable and toxin free.

DATA ANALYSIS

Empirical Results

The precursor of this research study and model framework are green innovation and ethical responsibility with the consequent effect on green purchase intention. Two levels of analysis - the measurement model and the structural model have been specified which covers basically the structural equation modeling.

SEM of this study has included:

Validation of Measurement Model

This research shows the standard deviations and means of the respective variables and also the correlations amongst them in Table 1. There exist significant positive correlations among the three variables: Green Innovation, Ethical Responsibility and Green Purchase Intention. The results of exploratory factor analysis are shown in Table 2. The three constructs in this study can be categorized into only one factor in Table 2. Next, the study has applied confirmatory factor analysis (CFA) to confirm the reliability and validity issues in the measurement model. The results of the Confirmatory Factor Analysis point toward that the measurement model depicts the satisfactory levels to attain model robustness (chi-square=151.8, DF= 97, chi-square /DF = 1.556, IFI = 0.934, CFI = 0.914, RMSEA = 0.071).

To substantiate the validity and reliability of the measurement model, there are several measures like examining the factor scores of individual items. The item loadings are shown in Table 3 which are found to be all significant. Table 3 also lists the Cronbach's alpha values which measure the reliability values. The minimum threshold value of Cronbach's alpha according to Hair et al. 1998 is 0.7. In our model, each and every Cronbach's alpha coefficient values are more than 0.7, which indicates acceptability in reliability issues. For checking the validity of the study, this research has applied Fornell and Larcker's measure of the average variance extracted (AVE) which measures the quantity of variance explained by a construct through its items. For meeting the threshold values of discriminant validity, the square root of a construct's AVE must be greater than the correlations between the construct and other constructs. For instance, the square root of the AVEs for the two variables, green innovation and ethical responsibility are 0.764 and 0.765 which are more than the correlation, 0.445, between them in Table 1. This result shows that there is enough discriminant validity between the two variables, i.e., green innovation and ethical responsibility. Next, the AVEs of the three constructs, i.e., green innovation, ethical responsibility and green purchase intentions are all more than 0.5 in Table 3. It is, therefore, proved that the convergent validity of the three constructs is acceptable.

The Results of the Structural Model

Structural model results are shown in Table 4 and Figure 3. The overall fit measures of the structural model is acceptable (chi-square = 93.615, DF = 90, chi-square/df. = 1.031, GFI = 0.905, NFI = 0.900, CFI = 0.996, RMSEA = 0.021). Table 4 presents the results of the two paths. Figure 3 shows the results of the full model. According to Table 4 and Figure 3, the results point to wide support for the two hypothesized effects in the research model. As a result, this study verifies that green innovation is positively related to green purchase intentions and ethical responsibility of firms is related to green purchase intentions.

DISCUSSION AND IMPLICATIONS

By undergoing a broad and descriptive literature study, several factors affecting consumer green purchase intentions were recognized. Consumers' concern towards the adoption of social and environmental issues was found to have a significant impact on green purchase intentions (Makatouni, 2002). It is clearly evident from our research that green innovation and ethical responsibility play a very important role in designing consumer-oriented strategies towards green products. Particularly, social and ethical perspectives of companies were established to stimulate the purchases of green products (Padel, & Foster, 2005). The existing research focuses on the factors which can impact the green purchase intentions of customers. If a product is lacking in any aspect of innovation it can lose the opportunity to gain market competitiveness. Therefore, consumers normally relate green product characteristics with environmentally responsive processes (Makatouni, 2002). It shapes the individual's ethical or moral responsibilities towards the society (Doran, 2009). Customers, who display constructive attitudes towards green purchases, feel a strong individual compulsion towards the environmental concerns in selecting green products, particularly when they have diverse product categories.

Ethical norms and values such as universalism, benevolence and altruism were found to have positive relationships with ethical obligations (Eze et al., 2013; Chen et al., 2012; Padel, & Foster, 2005). Hence, it can be also stated that strong social and environmental values guide consumers in their product and purchase involvement. Consumers high involvement leads to better and vigorous contribution in the course (Vermeir, & Verbeke, 2006; Agrawal, & Rahman, 2014. Future research is required to address

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the issues that act as barriers between consumers' positive approach towards green purchase intentions. Green product prices seem to have a significant bearing on the purchasing of environmentally sustainable goods (Young et al., 2010). Consumers are frequently susceptible towards price which companies charge for green products (Eze et al., 2013), higher than their expectations, will result in an attitude-behavior gap in green purchase intentions.

Additionally, complexity in accessing innovative and environmentally sustainable products was found to be major reasons behind lower levels of purchases (Padel, & Foster, 2005; Lea, & Worsley, 2008). According to surveys, consumers usually access products which are in proximity and appreciable range (Young et al., 2010). When there is a gap in accessibility and price, consumers are found to resist their purchasing habit of such green products (Young et al., 2010; Connell, 2010).

Theoretical Implications

This kind of a research study explains the gap between green innovation strategies and sense of ethical responsibility. The key drivers of green purchase intentions of consumers in perspective of green purchasing alongside with a variety of attitudes and behaviors affecting green purchase behavior are important to consider. The research thus, identifies green innovation, marketing strategies as potential explanations for the discrepancy in green purchase intentions. Additionally, it provides an empirical analysis of the outcomes and independent variables in future studies to examine their influence on green purchases (dependent variable). Future researchers may also suggest various frameworks and models based on their own results, taking our findings and analysis as a model base.

Managerial Implications

It guides the corporate bodies to design the key predictors of consumers' green purchase intentions. Marketers can better devise their innovation strategies and take ethics as a core driver for understanding the consumer psychology of green purchase behavior as this understanding will equip them to frame their product contributions. The present study has functional as well as social implications for policymakers as well as considers the environmental values and concerns which can act as the prime factors for environmental education. Consumers generally remain unconvinced about environmental claims made by manufacturers and find it hard to recognize green products but, through ecological awareness of these products can generate a sense of trust and attachment with the companies.

CONCLUSION

This research contributes a view on the relationship of green innovation and ethical responsibility with green purchase intention. We have utilized Factor analysis & SEM to explore the positive effect of Green innovation and Ethical responsibility leading to Green purchase intention. Although various studies have been done to understand Green purchase intention, but no study has integrated Green innovation and Ethical responsibility by way of Green purchase intention. Many companies have transformed their businesses into a Green business model worldwide either by modifying their product or technology. Now, businesses are willing to promote the green attributes of products and customers are claiming about be-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ing skeptical (Makower, 1995). Further studies need to tackle the problem of lack of awareness among customers about green products which is the crucial area of working in Green marketing discipline. This study will help the marketers to revamp their strategies and to draw consumer pattern and gain competitive advantage. This study can further be tested in different market segments and would be valuable to investigate the Green purchase intentions by adding more factors which influence the buying behavior or pattern of the customers for Green products.

Chapter 52
Driving Green Marketing in a Developing Country:
Reducing the Attitude–Behaviour Gap

Shweta Pandey
International Management Institute, India

Deepak Chawla
International Management Institute, India

ABSTRACT

Despite having a pro-environment attitude, customers may not consistently reflect the same in their behaviour. This chapter explores the applicability of the social-normalisation theory to reduce the attitude-behaviour gap of customers for driving green behaviour in India. The theory argues that green behaviour can be driven by positioning green activities as normal. The chapter details the findings of an empirical study done across 496 customers pan India. Analysis done based on various techniques (Heat maps, factor analysis and regression) indicates that while a broader consensus existed among customers about what is green, the conceptions of normality of the activities vary thereby, corroborating the existence of an attitude-behaviour gap. Results shows that perceptions of what is normal have a significantly higher impact than perceptions of what is green and hence, social-normalisation theory can be applied to drive green marketing in developing countries like India.

INTRODUCTION

Rapid pace of growth and burgeoning population has bought unmindful and irresponsible consumerism leading to several environmental challenges for emerging economies in Asia (Zhao and Schroeder, 2010; Lee, 2009). Asian markets like India and China face growing challenges like resource scarcity, rising consumption levels and fast pace of urbanisation resulting in sustainability issues for both consumers and companies (Accenture and UN Global Compact, 2013). As per World Bank estimates, the cost of environmental degradation from various sources (urban air pollution; inadequate water supply, poor sanitation, hygiene; indoor air pollution, natural resource damage) in India was USD 80 billion or 5.7%

of GDP in 2009 (The World Bank, 2013). In a survey conducted across 178 countries by World Bank, India ranked 155th overall and almost last in the level of air pollution exposure (The World Bank, 2014). Greendex 2008 survey findings show that consumer choices have a big role in ensuring sustainable pro-environment practices (phys.org, 2008). For example, customer choices regarding lowering household energy consumption by using energy-efficient devices, reduction of fuel consumption by walking or using public transport instead of individual transport, use of organic or lesser polluting products can impact environment positively. Individuals need to accept pro-environmental products which may impact their lifestyles and beliefs. Thus, many of the environmental issues are embedded in human behaviour and therefore, need to be managed by changing the relevant behaviour (Vlek and Steg, 2009).

While there is an increase in environmental issues in emerging Asian markets like India, yet researchers find a higher proclivity towards the future purchase of sustainable products by customers of these emerging markets (Khare, 2015; Kumar and Ghodeswar, 2015; Accenture and UN Global Compact, 2013). Further, the rising economic and social costs of environmental pollution resulting in business sustenance issues, stricter enforcement of environmental regulations, higher awareness and penchant for customers to adopt pro-environmental practices and have led Indian firms to explore green marketing for sustainable growth (Saxena and Khandelwal, 2012; Mishra and Sharma, 2010; Jain and Kaur, 2004).

Green marketing is the marketing of pro-environment products or products that are presumed to be environmentally preferable (Barbarossa and Pastore, 2015). Green marketing can create value for corporates as it yields a triple bottom-line of social, environmental and financial performance for the firms (Elkington, 1997). It can help companies manage risk of operational disruptions like resource scarcity and climate-change. It can reduce operating costs through better internal resource management like minimisation of energy consumption and higher carbon credits, which can result in improved value propositions for products. Driving green appeal can further mitigate risks, capture opportunities from regulation (Barbarossa and Pastore, 2015) and can drive higher brand equity (Trott and Sople, 2016). Additionally, it can drive sustainable competitive advantage, for example; the 3Ps (polluting prevention pays) program of 3M has been recognised as a significant step in corporate environmental practices.

Indian companies have also been making progressive efforts towards green marketing. Tata Motors has taken steps for introducing alternate fuel based cars like hybrid-electric cars, CNG based Nano and the greener Indigo; ITC is promoting green hotels; Samsung India and LG are building eco-friendly and energy-efficient electronics, etc. (Trott and Sople, 2016; Mishra and Sharma, 2010). Similarly, durable, non-durable and service industries are pursuing green marketing in India to ensure sustainable growth (Saxena and Khandewal, 2012).

RESEARCH CONTEXT: THE ATTITUDE-BEHAVIOUR GAP

Numerous studies done across the world as well as in India indicate that despite having a pro-environment attitude, customers do not consistently reflect the same in their behaviour (Carrington, et al., 2014; Rettie et al., 2014; Black, 2010; Gupta and Ogden, 2009). Similarly, while several pro-environmental products have been introduced to the market by the Indian companies, green product's adoption has often met with more verbal appreciation from stakeholders and customers than actual purchase (Khare, 2015). Nittala (2014) finds that while educated university teachers in India are aware of impact of pro-environment consumption yet their beliefs do not necessarily result in purchase of green products. She states that product

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

recycling has a positive influence while comfort, eco-labelling, and lack of information has a negative influence on the willingness of teachers to purchase green products. Manaktola and Jauhari(2007) find that while Indian consumers show positive attitude towards hotels practising green marketing, they are not willing to pay additional money for the same. Jain and Kaur (2004) find that Indians (sample limited to Delhi) have high willingness towards pro-environment behaviour but feel that individual contribution may not do much towards the cause and therefore, their pro-environment behaviour is confined to themselves. Thus, the attitude-behaviour gap precludes adoption of green practices in India. Marketers need to understand how to bridge this attitude-behaviour gap to ensure sustainability of green marketing.

Several approaches have been explored to address the attitude-behaviour gap. Moser (2015) suggests that green marketing needs a complete blend of economic, technological and cultural adoption to manage the attitude-behaviour gap. Ottman et al. (2006) critique the myopic sense of green marketers and state that marketers focus on the positioning of green products as environmental friendly and do not focus on customer satisfaction resulting in consumers not purchasing green products. Other researcher's highlight issues like high pricing and scarce availability (Eckhardt et al., 2010; Finisterra do Paco and Raposo, 2010; Bhate, 2001), lack of consumer knowledge or information (Ottman et al., 2006) and improper communication (Barbarossa and Pastore, 2015) as reasons for customers not adopting green products. Researchers argue for the need to refocus on consumer value, enhancing consumer knowledge, environmental concern and ensuring credibility of product claims (Ottman et al., 2006; Finisterra do Paço and Raposo, 2010). Social norms i.e. complying with community beliefs and practices are stated to have a significant impact on green behaviour of customers across the world (Fiske and Taylor, 2013; Alcott, 2011; Nolan et al., 2008). However, consumption-practices change over time and are shaped by what is considered normal within a social group or a community or a reference group (Gupta and Ogden, 2009). Thus, an emerging area beyond customer attitudes, knowledge and product characteristics is the process of social-normalisation for driving sustainable green marketing in India (Rettie et al., 2014).

Social-normalisation relates to gradual acceptance of green activities as normal by the consumers leading to better adoption and sustainability of such practices (Rettie et al., 2014). However, conception of what constitutes normal practice changes over times and thus, there is a need to assess them continuously. Diverse cultures, regions and social classes have varied opinion about activities being green versus normal and consequently, the social-normalisation theory needs to be explored across different national and cultural contexts (Rettie et al., 2012). However, the social-normalisation process remains unexplored in the Indian context. Further, social norms may be driven by various factors like gender, marital status, income, region, education, etc. (Uddin and Khan, 2016; Kumar and Ghodeswar, 2015; Khare, 2015; Saxena and Khandelwal, 2012; Jain and Kaur, 2006). Diamantopoulos et al. (2003) suggest that factors like legislative norms, social norms and situational impact factors should be analysed along with socio-demographics to understand the green customer profile. Thus, there is also a need to understand the impact of socio-demographic factors on green behaviour to drive better marketing strategies (Lee, 2009).

Given the above research gaps, this chapter has two objectives:

1. Explore the impact of social-normalisation theory in the Indian green marketing context.
2. Understand the impact of socio-demographic factors on green marketing strategies in India.

This chapter explores the social-normalisation process and its impact on adoption of green practices in India based upon an empirical study.

LITERATURE REVIEW

Social-normalisation is the process of green activities and products being gradually perceived as mainstream or normal over a period resulting in higher acceptance and sustainability of the practices by the customers (Rettie et al., 2014). Researchers argue that green practices, which are considered as normal, become a habit for consumers and are pursued more often than the ones which are positioned on just environment benefit and therefore, such normalisation of practices can lead to reduction in the attitude-behaviour gap in the green marketing context (Shove, 2003).

The impact of social norms on adoption of pro-environment behaviour has been observed in several studies. For example, Barr et al. (2001) state that "putting out recyclable material for collection" is a socially-visible activity and is replicated by others due to it being perceived as a social norm. Social norms are also known as subjective norms. Several studies show that such socially visible subjective norms impact pro-environmental behaviour (Wang et al., 2011; Park & Ha, 2012) like purchase of green products and recycling. Johnstone and Tan (2015) state that making green as the social norm can lead to bridging of the green attitude versus behaviour gap as it leads to the collective goals being prioritised over individual goals. Comparative feedback on energy consumption of oneself versus others in society has been stated to motivate people for energy consumption (Alcott, 2011). Adoption of ecology-friendly practices into the normal routines of consumers impacts their sustainability. For example, Shove (2003) highlights that patterns of consumption of energy and water (depicted through examples of laundering and showering) reflect people normal habits and routines. Some studies done in the Indian context also highlight the impact of social norms on adoption of green practices in India. Khare (2014) finds that normative influences, i.e. compliance to social norms to avoid negative consequences, impact green attitude of Indian consumers. Kumar and Ghodeswar (2015) find that social appeal, environment protection and responsibility, green product experience and environmental friendliness of companies drive green behaviour in India. Consumer conceptions of normality are driven more at a social level than individual (Shove, 2003) and therefore, sustainability of green consumption requires such green practices to be perceived as normal by the individual. These examples indicate that social-normalisation can be extended to pro-environmental behaviour.

However, green practices and their perceptions may vary across countries. For example, people in developed countries use household heating/cooling systems whereas the same is yet to be adopted across larger parts of India. Similarly, tumble drying is a normal practice in the US and UK households whereas Indians practice drying in sunlight as the norm, resulting in different energy consumption requirements. Hence, such changes in social norms needs continued focus and research (Khare, 2015; Varman and Costa, 2008).

Some researchers have explored the impact of socio-demographics on adoption of green practices in India. Saxena and Khandelwal (2010) find that compared to males, females have a higher positive attitude towards green marketing. They also find that married people, people living in metros and big cities, better educated and older people have a more positive attitude toward green marketing. Krishna and Qaim (2008) find that higher level of wealth and education impact sustainable acceptance and consumption of genetically modified crops. However, given the attitude-behaviour gap there is a need to further explore impact of socio-demographics on the actual green behaviour.

RESEARCH METHODOLOGY

A study was conducted to explored customer conceptualisation for some common environment-related activities. These activities consisted of a mix of activities adapted from existing literature (Rettie et al., 2012) and new activities added based on the Indian context and expert opinion. The research steps are explained below.

Step 1: Visualising Consumer Perceptions of Green vs. Normal.

All respondents were asked to rate each pro-environmental activity across green and normal scales. The results were plotted graphically using heat maps to visualise consumer perceptions of activities as being green versus normal and draw insights based on the same.

Step 2: Exploring Perceived Green and Normal Dimensions.

The activities were grouped into green and normal dimensions using exploratory factor analysis to identify the key green and normal perceptions existing in the Indian context.

Step 3: Exploring Actual Green Behaviour Dimensions.

Exploratory factor analysis was done to identify green behaviour dimensions in the Indian context.

Step 4: Impact of Green and Normal Perception Factors on Actual Green Behaviour Dimensions.

Expert opinion was used to identify activities relevant to each of the green behaviour factors found in step 3. Then green and normal perception factors were formed using the average of ratings given on the normal and green scales respectively for the above identified activities. Each green behaviour dimension was regressed upon the green and normal perception factors to assess the impact of green and normal perceptions on the actual green behaviour.

Step 5: Impact of Socio-Demographics on Green Behaviour Dimensions

The detailed methodology and results are discussed ahead.

Survey Development

A quantitative survey was developed containing four key sections. Section I of the questionnaire had items related to socio-demographic data like age, gender, occupation, income, marital status, etc. Section II and III captured customer perceptions of 23 sustainability related activities being normal and being green respectively using a 5-point Likert scale (Strongly disagree = 1; Strongly agree = 5). Section IV captured the level of green behaviour exhibited by customers using 15 items drawn from previous research (Robert, 1996). The questionnaire was rolled out both online and offline across all four regions in India.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Selection of Activities

23 sustainability related activities were selected from a mix of previous studies on sustainability (Rettie et al., 2012) and post discussions with experts. Some activities like "drying clothes in a tumble dryer," "using patio heaters" and "eating meat or fish" (Rettie et al., 2012) were not considered. This was done in consultation with experts as use of tumble dryers or patio heaters is not prevalent across all regions in India due to varying climatic conditions and level of technological acceptance. Further, "eating meat or fish" may be driven by religious beliefs in India and hence, was removed from the list of activities. Some activities like "Showering/bathing on alternate days," "Monitoring electricity consumption," were modified to reflect the Indian context and reworded as "Using a bucket of water instead of a shower while bathing" and "Switching off lights and fans when not in use." In addition, new activities that were not included in the research by Rettie et al. (2012) were added to the study based on expert opinion. These were, "Use of cosmetics made from herbs and plant extracts," "Sometimes using a solar cooker for cooking," "Using both sides of paper and waste envelopes for rough work," "Purchasing lead-free petrol," "Switching-off vehicle ignition at red lights" and "Reusing plastic bags obtained at time of shopping for other purposes." These statements reflect some of the prevalent pro-environment practices, which may be the result of several communication campaigns done by pro-environmentalists in India. Furthermore, some statements depicting anti-green behaviour statements were added. For example, "Use of mosquito repellant liquids at night instead of mosquito nets," "Driving in a self-owned vehicle to the office every day," "Using disposable dishes for picnic/outings" and "Purchase of canned food." This was done to ensure inclusion of activities, which may have been adopted by people in certain regions or areas due to benefits like time-saving and personal convenience, but the level of adoption may differ across regions. These anti-green activities were reverse-coded for factor analysis.

ANALYSIS

Data Profile

Out of the 578 questionnaires collected, 514 were complete and usable. Post removal of outliers, 496 were retained. The data points showed varying levels of socio-demographic factors like age, occupation, income, region, education, etc. as given in Table 1.

Visualising Consumer Perception Gap Using Heat Maps

Heat maps are two-dimensional representation of data, which visually indicate the percentage of customers selecting a level of rating (green/normal) using a continuous range of symbols. Cells with hollow dots and light grey shaded background depict a lower percentage of customers selecting a rating and cells with full black dots and darker grey shade background indicate the highest percentage selecting a rating (Figure I). In addition, mean, standard deviation of each activity is also depicted (Figure I). The grid helps understand the distributional patterns of responses against each activity. A quick look overall shows that there are differences across many activities in terms of being green versus being normal, which points towards differences in the social-normalisation process across activities.

	1	24.30%
	2	19.00%
	>2	3.00%

Note: The professional category denotes people who run their own business setup and Service denotes people who work for other organisations.

Green Perceptions

Several activities are perceived as green/very green (Figure 1) by a large percentage of respondent base. This is depicted by the similar dark grey shading with solid dots in the green/very green rating category. This consensus is also confirmed by the fact that these activities have a high mean (showing they are

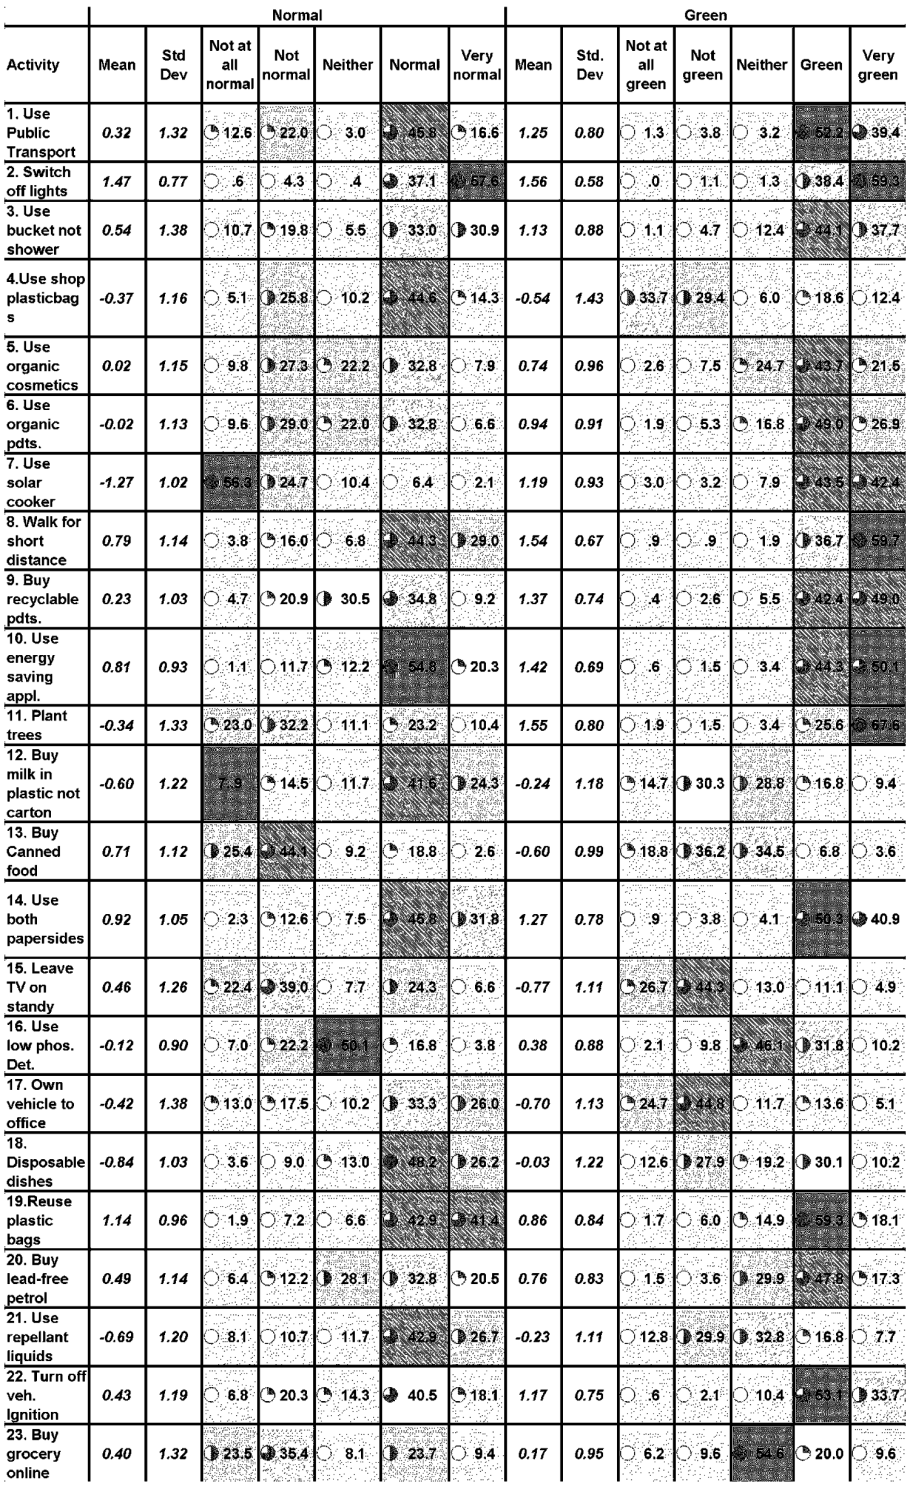
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

green) and low standard deviation (showing agreement between customers). Such activities include "using public transport," "switching off the fans and lights when not in use," "using a bucket of water instead of shower for bathing," "using organic products," "using a solar cooker," "walking for short distances," "buying recycled products," "using energy-saving appliances," "planting a tree," "using both sides of paper" and "switching off vehicle at red lights."

There is another set of activities, which are not perceived as green by customers. These are depicted by the dark grey shading with solid dots in the "not green"/ "not at all green" scale ratings. These include, "using a self-owned vehicle to the office," "using plastic bags given by shopkeepers instead of taking your own" and "leaving TV on standby." The rating on the activity, "buying grocery online," shows that customers have no clarity on it being "green" or "not green." This is visually depicted by the dark grey shading with solid dots in the "neither" rating category. The activity has a mean close to 0 and standard deviation less than one showing that most customers do not know how to rate the activity- green or non-green.

There are some activities where the customers did not seem to have a consensus as a similar percentage of them marked the activity as "green" versus "not-green" (activities like buying milk in plastic pouches, buying canned food and using mosquito repellent liquids instead of nets at night). These activities have negative means close to 0 and high standard deviation. Similarly, another group of activities, like "using low phosphate detergent" and "buying lead-free petrol" has ratings between "neither" to "green," depicting the possibility of multiple groups. The activity "using disposable dishes for picnic/outings" has ratings spread across all categories showing dispersed opinion among customers. This may also indicate the presence of different groups of respondents having divergent views and needs further analysis.

Normal Perceptions



Analysis of the heat map for normal scale for all activities shows that opinion about the 23 activities being normal is dispersed. Only few activities like, "switching off lights and fans when not in use," "using a bucket of water for bathing instead of a shower," "walking short distances," "using both sides of paper," "using energy-saving appliances" and "reusing plastic bags for other purposes" are rated as normal by a high proportion of the customers. These activities are also clearly understood as green by customers indicating that they have gone through the social-normalisation process.

While there is a consensus among customers on the activity "using a solar cooker" being green; yet, it is not rated as normal. Further, "using a self-owned vehicle for office" is understood to be a non-green activity but is rated as normal. This attitude-behaviour difference indicates that perceptions about activities being pro-environment may not result in their being incorporated into the normal routines of consumers and vice versa.

Further, different levels of social-normalisation exist for a larger number of activities as depicted by the variation in customer perceptions of the activities being normal or non-normal. For example, activities like "using public transport," "using plastic bags given by shopkeeper instead of carrying own," "using organic ingredient based cosmetic products," "using organic products," "buying recyclable products," "planting a tree," "leaving TV on standby," "switching off vehicle at red lights" and "buying grocery online" have varying perceptions of normality. Similarly, "buying milk in plastic packets" is rated as a normal activity by most respondents whereas the opinion on it being green/non-green is divided. This is indicative of different levels of social-normalisation process for these activities across diverse groups and therefore, a need for understanding various segments associated with it.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perceived Green and Normal Dimensions

To explore key green and normal dimensions perceived by the customers, exploratory factor analysis (EFA) was conducted for the 23 activities for green and normal ratings respectively.

Green Dimensions

EFA on the 23 activities (green rating) was done using varimax rotation. KMO (0.694) and Bartlett's test for sphericity ($p < 0.00$) indicated factor analysis was appropriate (Hair et al., 2013). All items with loading < 0.5 or cross-loading on other items, were removed resulting in three dimensions. Each dimension had Cronbach alpha >= 0.6 (Nunnally, 1978) and the overall variance explained was 58.62% (Hair et al., 2013).

The three green dimensions obtained were (Table 2) as follows:

- Using pro-environment packaging
- Saving resources
- Using organic products

While all 23 activities were rated on the green scale by customers, agreement in terms of categorisation of these activities was limited to only three dimensions (Table 2). These groupings can be argued to be driven by the mass pro-environmental campaigns done by various sectors like government and private organisations over time, which have eventually moved people to perceive these as green activities.

Normal Dimensions

EFA was done on the 23 activities (Normal ratings) using varimax rotation. KMO (0.534>0.5) and Bartlett's test for sphericity ($p<0.00$) indicated factor analysis could be conducted for the normal scale items. All items with loading<0.5 or having a cross-loading on other items were removed resulting in

Table 2. Perceived green dimensions, factor loadings for each item and Cronbach alpha values based on EFA on 23 activities (green ratings)

Dimension	Items	Factor Loading	Cronbach Alpha
Use of pro-environment packaging	Using plastic bags given by shopkeeper instead of carrying your own- R	.697	.608
	Buying milk in plastic packets versus cartons- R	.692	
	Use of mosquito repellent liquids instead of mosquito nets-R	.674	
	Purchase of canned food- R	.638	
Saving resources	Using energy saving appliances at home	.771	.632
	Walking instead of using own transport while going for short distance	.764	
	Switching off lights and fans when not in use	.675	
Using organic products	Use of cosmetics and toiletries made from herbs and plant extracts	.860	.742
	Using organic products	.854	

Note: R denotes that the item was reverse coded

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

two dimensions with a Cronbach alpha >= 0.6 for each dimension and an overall variance explained of 65.55%, which indicated satisfactory results (Hair et al., 2013). The two normal dimensions obtained are given below and shown in Table 3:

- Use of private vehicles.
- Use of organic products.

While the study found three green dimensions (Table 2), only two normal dimensions were found (Table 3). "Use of organic products" was the only common dimension having similar green and normal ratings.

Actual Green Behaviour Dimensions

Next, EFA was done on the 15 green behaviour items using varimax rotation. KMO (0.836 > 0.5) and Bartlett's test for sphericity ($p < 0.00$) indicated appropriateness of factor analysis. All items with loading < 0.5 or having a cross-loading on other items were removed resulting in two actual green behaviour dimensions with a Cronbach alpha >= 0.6 (Nunnally, 1978) for each dimension and an overall variance explained of 61.22%, which indicated acceptable results (Hair et al., 2013). The green behaviour factors are given in Table 4.

- Consumption of pro-environmental products
- Consumption of less electricity

Next, the study analysed the impact of green or normal perceptions on the actual green behaviour.

Impact of Green and Normal Perception Factors on Actual Green Behaviour

Expert opinion was used to identify activities relevant to each of the green behaviour factors found in step 3. Then green and normal perception factors were formed using the average of ratings given on the normal and green scales respectively for the above identified activities. Each green behaviour dimension

Table 3. Perceived normal dimensions, factor loadings for each item and Cronbach alpha values based on EFA on 23 activities (normal ratings)

Dimension	Items	Loading	Cronbach Alpha
Use of Private vehicles	Using public transport wherever possible	.836	.600
	Driving in own vehicle to office everyday- R	.726	
	Walking instead of using own transport while going for short distance	.655	
Use of organic products	Use of cosmetics and toiletries made from herbs and plant extracts	.894	.754
	Using organic products	.890	

Note: R denotes the item was reverse coded

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Green behaviour dimensions, factor loadings for each item and Cronbach alpha values obtained from EFA done on 15 green behaviour items

Dimension	Items	Loading	Cronbach Alpha
Consumption of pro-environmental products	I avoid products made by those companies which are irresponsible towards keeping ecological balance	.800	.826
	I make every effort to buy paper products, for example, paper napkins, made from recycled paper	.764	
	I do not buy household products that harm environment	.756	
	I have convinced members of my family or friends not to buy some products that are harmful to the environment	.733	
	When I make choice between two similar products, I buy one which is less polluting	.727	
Consumption of less electricity	I conserve energy by turning off lights and electrical appliances when I am not using them	.837	.722
	I try to minimise the use of electricity to save energy	.820	
	I use those bulbs which use very little of electricity	.711	

was regressed upon the green and normal perception factors relevant to it to assess the impact of green and normal perceptions on the actual green behaviour.

Green Behaviour Dimension 1: Pro-Environmental Product Consumption

To understand whether perceptions of green versus normal impact the consumption of pro-environmental products, 10 activities related to green behaviour factor of pro-environmental product consumption were chosen from the list of 23 activities for each of the green and normal scales. The items are listed below.

- Using plastic bags given by shopkeepers instead of carrying own bag
- Use of cosmetics and toiletries made from herbs and plant extracts
- Using organic products
- Sometimes using a solar cooker for cooking
- Using low-phosphate detergent for cleaning clothes
- Not using disposable dishes for picnic/outings
- Buying products that are recyclable
- Not buying milk in plastic packets and using cartons instead
- Not purchasing canned food
- Use of mosquito repellent liquids at night instead of mosquito nets

Ratings of the above activities on the green and normal scales were taken and averages of items for the green and normal scales respectively were done to arrive at the following factors.

- **Normal Pro-Environment Product Consumption:** This indicates the rating of the above stated activities on the normal scale by respondents. The factor reflects the level of normalisation of pro-environment product consumption related activities.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Green Pro-Environment Product Consumption:** This indicates the rating related to the level to which the customers assess the above activities to be green.

The pro-environmental product consumption dimension was then regressed upon the green and normal perception factors identified. The regression results are given in Table 5.

The regression is significant with a R^2 value of 0.143 indicating that 14.3 percent of the variation in green behaviour is explained by the two independent variables (green and normal pro-environment product consumption factors). The results show that only the normal pro-environment factor has a significant impact on the pro-environment product consumption behaviour whereas the impact of the green factor is insignificant ($p>0.05$). This supports the social-normalisation theory wherein as green activities become more embedded in the normal routines of society, people have a higher tendency to confirm to the same, even if they do not have very strong pro-green beliefs (Rettie et al., 2014). Hence, marketers can look upon using the social-normalisation theory to drive pro-environment product consumption sustainability behaviour.

The heat map of each of the 10 items forming the normal pro- environment consumption factor shows that there are two items among the ten items for normal pro-environment product consumption (using disposable dishes for picnics and using mosquito repellent liquids instead of nets) on which there is a consensus among a large percentage of customers with respect to the same being normal. For the other 8 items contributing to this factor, there are different groups, which look upon the activity as being normal/non-normal and therefore, there exist groups for which these activities need to be positioned as normal to ensure pro-environment consumption behaviour. Thus, the impact of socio-demographics on pro-environmental product consumption behaviour is analysed later in the chapter.

Table 5. Regression results for green behaviour related to pro-environment consumption

Model Summary						
Model	**R**	**R Square**	**Adjusted R Square**	**Std. Error of the Estimate**		
1	.379[a]	.143	.140	.69392

Pro-environment consumption	**Constant**	0.617	.055		11.173	.000
	Normal pro-environment product Consumption	0.697	.079	.379	8.805	.000

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Behaviour Dimension 2: Lower Electricity Consumption Behaviour

To understand if attitude towards the activity or normalisation of the activity impacts the lower electricity consumption behaviour, two activities related to lower electricity consumption were chosen from the list of 23 activities for each of the green and normal scales. The activities are:

- Switching off lights and fans when not in use
- Using energy-saving appliances at home,

The average of the ratings of the above two activities on the normal and green scales was done to form the following factors.

- **Normal Lower Electricity Consumption**: This indicates the rating given on the normal scale for the above two activities. The factor reflects the level of normalisation of the above two activities.
- **Green Lower Electricity Consumption:** This indicates the level to which customers assess the above activities to be green.

The lower level of electricity consumption behaviour was then regressed upon these green and normal perception factors. The regression results are given in Table 6.

The regression is significant with a R^2 value of 0.171 indicating that 17.1 percent of the variation in green behaviour is explained by the two independent variables (green and normal lower electricity consumption factors). The results show that both the normal and green lower electricity factors have a significant positive impact on actual lower electricity consumption behaviour. However, the impact of the normal factor is higher than the green factor as indicated by the coefficient values for each. This shows

Table 6. Regression results for green behaviour related to lower electricity consumption

Model Summary						
Model	**R**	**R Square**	**Adjusted R Square**	**Std. Error of the Estimate**		
1	.414[a]	.171	.168	.51815		
ANOVA						
1	Regression	25.888	2	12.944	48.212	.000[a]
	Residual	125.110	466	.268		
	Total	150.998	468			
Variable	**Predictor**	**B coefficient**	**Standard error**	**Std. B coefficient**	**t**	**Sig.**
Lower electricity consumption	Constant	.705	.079		8.944	.000
	Normal lower electricity consumption	.296	.037	.344	8.048	.000
	Green lower electricity Consumption	.196	.047	.179	4.185	.000

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

that as a green activity becomes a part of the normal routine of people, more people start confirming to it and thus, marketers need to position green activities as normal for them to ensure sustainability of such practices.

Impact of Socio-Demographic Factors on the Green Behaviour Dimensions

Next impact of socio-demographic differences on the green behaviour factors was analysed. The ANOVA results for the same are summarised in Table 7.

Table 7. Results for ANOVA for green behaviour factors

Factor	Group	Pro-Environment Consumption			Lower Electricity Consumption		
		F value	p value	Mean value	F value	p value	Mean value
Gender	Male	0.419	0.518(ns)	0.479	0.748	0.388(ns)	1.316

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Gender:** There is no significant difference across gender for each of the two green behaviour factors (Table 7).
- **Marital Status:** There is a significant difference by marital status for each of the green behaviour wherein married people have higher mean scores than singles for both pro-environment product consumption and lower electricity consumption green behaviour factors (Table 7).
- **Income:** The ANOVA result (Table 7) shows that there are significant differences across income categories for green pro-environment product consumption factor. The post-hoc analysis based on mean differences across the two groups (< 15 lacs and >= 15 lacs) reveals that the < INR15 lacs category has higher mean scores than >= 15 lacs income category for pro-environment product consumption behaviour. However, there are no significant differences across income categories for lower electricity consumption behaviour.
- **Region:** The ANOVA result (Table 7) shows that there are significant differences across regions for green pro-environment product consumption factor. The results show that mean green scores across India are in the following order South>East>West>North, i.e. South has the highest score and North the lowest score. The post-hoc results reveal that North is significantly lower on green consumption behaviour as compared to South and East. Further, South and East form one homogeneous subset. However, there is no significant difference across region mean scores on the consuming less electricity behaviour.
- **Occupation:** Although the ANOVA result shows a significant difference in lower electricity consumption behaviour by occupation (Table 7), the post-hoc results show no significant differences among each of the groups. This could also be due to the unequal group sizes.
- **Age Group:** The ANOVA results show that there are significant differences across age groups for both green behaviour factors (Table 7). The post-hoc analysis results reveal that the older age group (>45 years) has significantly higher pro-environment consumption behaviour than the other three age groups (<25 years, 26-35 years, 36-45 years). The age group greater than 45 years forms a subset considerably different than the other three age groups. Further, for the second green behaviour factor related to less electricity consumption, the age groups <25 years and 26-35 years form a homogeneous subset which is significantly different from the other subset consisting of 36-45 years and >45 years wherein the subset 2 mean scores for lower electricity consumption are significantly higher than the score of subset 1 which is similar to findings by Wang et al. (2011) in Beijing.
- **No of Family Members:** There is no significant difference based on family size for both green behaviour factors.
- **Children:** There is a significant difference across the groups having no child versus groups having 1 or more children for the pro-environment consumption green behaviour factor. Here, the mean score for green behaviour is higher for group having 1 or more children as compared to people having no children. However, there is no significant difference between the two groups for the factor of lower electricity consumption behaviour.

The study finds that pro-environment consumption behaviour (Table 7) is higher for people who are married, have less than INR15 lacs income, have children as compared to those who are single, having income of INR15 lacs or more and having no children. Further, the group with age of 45 years and above has higher pro-environment consumption behaviour than lower age groups. In addition, South and East are higher in pro-environment consumption behaviour than North. Therefore, the 10 activities need to

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

be reinforced by positioning them as normal for the following geo-demographics: lower age groups with respondents less than 46 years of age, marital status as single, income greater than or equal to 15 lacs and belonging to the North region.

FINDINGS AND MANAGERIAL IMPLICATIONS

The study finds that there exists a gap between green-attitudes and actual green behaviour of customers.

This gap may be driven by the fact that customers often find it inconvenient to practice pro-environmental behaviour and hence, do not adopt some of these practices (Carrette et al., 2012; Laroche et al., 2001). For example, Rettie et al. (2011) found that although consumers perceived flying for foreign holidays as not green, they regarded it as a normal part of their routine and did not envisage changing it. Conversely, other researchers suggest that customers are driven by social norms for environmentally friendly activities (Barr et al., 2011). For example, this study indicates that while some of the activities like "walking for short distances," "reusing plastic bags for other purposes," etc. may not be convenient, a high proportion of customers rate them as normal. This can be argued to be a result of customer habituation of these activities as depicted by the normal ratings attached to these activities. Such normalisation may have been driven through several initiatives like banning of plastic bags in some parts across the country by the Indian government, routine of collection of garbage by specific people in societies, shortage of water supply in some regions, etc. It could also have been driven by the economic cost of buying garbage bags for the lower-income group and the issue of not getting plastic bags easily for the higher-income groups. Thus, by using varied methods for different target groups, the same activity can be normalised across the society and result in higher green behaviour among customers. Similar results have been found in other research studies as well, for example; Gregory and Leo (2003) found that households with lower water usage show a higher involvement in water conservation issues and tend to form habits associated with lower water usage thereby entering a self-sustained cycle of conservation.

The study also finds that activities, which are perceived as non-green (driving in a self-owned vehicle to the office), are still part of normal activities. This could be driven by the fact that in many cases, people act habitually and may be guided by automated cognitive structures in their mind rather than reasoning (Steg and Vlek, 2009). Such habits can, however, be modified through some interventions. For example, Fujii et al. (2001) found that temporarily forcing car drivers to use alternative travel modes by closing the freeway access, reduced the level of their individual car use by modifying their beliefs about the alternate transport modes.

The study shows that there is a significant and relatively higher impact of normal factors on both the green behaviour dimensions i.e. pro-environment product consumption and lower electricity consumption factors.

The study finds that perceptions of activities being green do not impact pro-environment product consumption whereas perceptions of activities being normal have a significant impact on actual pro-environment product consumption. This corroborates the applicability of social-normalisation for driving green marketing in India. Further, the study finds a higher level of pro-environment product consumption green behaviour for respondents who belong to higher age group, are married and have children. These results corroborate previous findings (Saxena and Khandelwal, 2010; Laroche et al., 2001). This may be driven by the fear of environment degradation impacting the future of their children. Parents may care for their children and therefore, values of family welfare need to be stressed on pro-environment products

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

related communication. Further, people in the lower-income bracket (income of 15 lacs or less) exhibit higher level of pro-environment product consumption. This contrasts with the findings by Khare (2015) who states that higher income positively impacts pro-environment behaviour of the Indian consumers. This can be argued to be a result of unaffordability of products like canned food or disposable dishes and therefore, such activities may not have been adopted by the lower-level income groups. Thus, higher income levels may not automatically drive pro-environmental behaviour and therefore, incorporating green practices into normal routines of people may be a better way to sustain the same. In addition, pro-environment product consumption is highest in South region followed by the Eastern region in India. The same can be correlated with the fact that government in Southern states like Kerala have heavily focussed on driving green behaviour and promoted policies like organic farming. Government, political systems and institutions have a huge impact in emerging markets like India as they can use both direct and indirect measures to drive both demand and supply of green products (Stevens, 2010). Therefore, public-private partnerships can be used to drive green practices, for example, non-governmental organisations have worked with Spice board to enhance organic production of spices in Kerala, Tamil Nadu and Andhra Pradesh apart from North-eastern states. Further, social practice of relying on the Ayurveda treatment is embedded in traditions in these regions making them prone to buying products, which are green. Therefore, marketers need to have their communication and distribution for pro-environment products implemented in a socially embedded manner (i.e. working with the local community, using local human capital and through developing their relationships with government and non-government stakeholders) to ensure that social-normalisation process is faster and easier. This is especially important as people from different strata of society in a developing country like India may not be able to afford organic products, which are priced higher than normal ones but may adopt the practice based on social norms. Environmentally harmful products can be made less feasible (example, by incorporation of higher taxes or through legal prohibitions) and pro-environmental products can be made widely available (example, recycled paper, organic products, etc.). Marketers need to target specific-groups (as highlighted before) to reinforce social-normalisation of green activities resulting in long-term sustainability.

The empirical study results show that lower electricity consumption behaviour is impacted by both green and normal factors with the latter having a higher impact. Thus, the study finds that social-normalisation of green practices like switching off lights and fans when not in use or using energy saving appliances at home can drive lower electricity consumption in India corroborating the results from previous studies (Alcott, 2011; Nolan et al., 2008). Electricity consumption is different from product consumption as electricity is intangible and consumed only indirectly and as a by-product of other practices. It is not easily measurable in comparison to say price of a product and not socially visible as a lifestyle product. Information on social norms and individual electricity consumption can therefore, be given to customers for them to take steps towards meeting the norms and gradually make it part of their routine. On analysing items in the green and normal factors for lower electricity consumption (switching off lights and fans when not in use; purchasing electricity-saving appliances) there seems to be a consensus amongst customers on the same being green and normal respectively (Figure 1). However, comparison of the individual items shows that a lower percentage of customers rate the use of energy-saving appliances as normal. This essentially points to the need for introduction of higher incentives for people to buy such appliances. Companies selling green-rated products can highlight the savings attained by customers through use of lower-energy consumption electrical fittings/ appliances. Further, government can roll out policies, which necessitate the use of lower energy consumption fittings in corporate buildings to make it part of normal course of life. They can also introduce lesser taxes for such appliances, which

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

may lower the prices of such appliances and lead to their adoption by a higher number of individuals. Rewards like incentives for reduced electricity consumption can be launched, and these may be redeemable as points for purchasing lower electricity consumption products. In this way, the lower consumption behaviour will enter a cycle of self-reinforcement. Additionally, people can be showcased as a role model for others (Schultz et al., 2007) or could be given special memberships to socially important societies or clubs so that the behaviour becomes a social norm and over time is incorporated into routine of larger parts of society. Further, lower electricity consumption has a higher score for higher age group (36 years and above) and retired people. This may be driven by prior experience of these higher aged individuals where they have faced higher frequency of electricity shortfalls and therefore, developed a habit of saving electricity. Younger people may have experience of lesser electricity cuts and hence may not be so conscious about saving electricity or using energy-saving devices. Hence, effort should be made to drive awareness of electricity demand-supply gaps. Further, having price variations based on consumption levels can increase the electricity saving behaviour. Special marketing campaigns and events should be targeted towards youth and should stress on the need for saving electricity and purchase of energy-saving appliances.

In summary, the study concludes that as green activities become part of normal routine of customers, they start confirming to them. Hence, social-normalisation theory can be applied to the context of green marketing. Everyone can contribute to the environment by adopting pro-green behaviours as part of their routine life. The challenge for marketers is to facilitate such transition of activities from being construed as only green to becoming green and normal.

FUTURE RESEARCH DIRECTIONS

The empirical study done has used a limited number of activities in context of green marketing resulting in only two green behaviour dimensions. Therefore, future studies can explore other pro-environmental activities relevant to the green behaviour being researched. Social-normalisation is a continuous process and thus, categorisation of the activities as normal can change over a period thereby, necessitating further research. The research was limited to the four regions of India and therefore, needs to be replicated across other contexts- region, nation, society and culture. In addition, qualitative research can be done to corroborate or identify what is conceived as green or normal by consumers. Further, effect of various contextual factors, for example, physical infrastructure, technical facilities, availability of products, product characteristics, etc. in driving green behaviour need to be explored using techniques like experiments to get greater insights into which interventions can drive targeted behaviour.

Chapter 53
Customers' Perceptions of Green Banking:
Examining Service Quality Dimensions in Bangladesh

Mehree Iqbal
North South University, Bangladesh

Nabila Nisha
North South University, Bangladesh

Syed Ali Raza
IQRA University, Pakistan

ABSTRACT

Banks today promote eco-friendly financial services by widely adopting the concept of green banking. This is generally done to minimize the impact of environmental degradation in their business activities. Besides its usefulness for environment, green banking also acts as a competitive edge for banks by offering customers with new channels of financial services delivery. However, service experiences and quality of service delivery often defines customers' perceptions towards the adoption of such services. This paper aims to study service qualities and other underlying factors that influence customers' behavioral intentions towards using green banking in Bangladesh. Under PLS-SEM technique, factors like reliability, privacy, responsiveness, empathy and information quality has significant positive effect on performance expectancy; while, performance expectancy, effort expectancy and facilitating conditions significantly influence customers' behavioral intention. Implications of these findings can provide practical recommendations and directions for further work to banks in Bangladesh.

INTRODUCTION

The influence of service quality factors is generally overpowering for banking services, since banks often use it as a means of differentiation for their survival in the competitive environment as well as to gain a competitive edge. Particularly, for alternate customer interaction channels like green banking, it is crucial to address the issues relating to customer expectations regarding service encounter experiences and the quality in service delivery for developing customers' intentions to use green banking. The acceptability of green banking services thus depends on the assessment of customers' perspective of the banks' overall service quality.

In response to the global initiative to save environment, many emerging economies today promote environmental-friendly practices by implementing various forms of green banking services. Green banking involves the environmental and social responsibility of banks in terms of the contribution they make towards ensuring sustainability of the environment and ecological system, through their in-house operations and the wide range of financial products and services that they offer (Nisha, 2016). Beyond its usefulness for the environment, green banking also benefits the clients by offering new channels of financial services delivery (Hossain et al., 2015).

However, technology is a vital element of green banking, since the design and delivery of its financial services vastly depends on it. The major objective behind this change is to attract more customers, improve customers' perceptions, and encourage loyalty towards alternative delivery channels (Sharma & Malviya, 2011). This rapidly changing technology in the service delivery of the banking sector has profoundly changed the way customers today interact with their financial service providers (Sulaiman et al., 2007). Moreover, an increase in the use of wireless telecommunications like mobile phones and Internet-enabled Smartphone has also contributed to the change in customer behavior to a large extent (Nisha et al., 2015). With the shift of the banking sector from the traditional brick-and-mortar model to the branchless mode of banking, the interest of researchers shifted towards the examination of green banking services on the grounds of service quality.

Bangladesh has been particularly successful in implementing the green banking approach particularly in the country's banking sector. This is because most of the leading banks today offer mobile banking, internet banking services in Bangladesh following the trend of financial globalization. As a result, customers often need to choose among different banks by making a trade-off between relationships and economies, trust and products, or service and efficiency (Sachdev & Verma, 2004). Additionally, customers are increasingly aware of the different offerings of electronic banking and this knowledge makes them more critical of the quality of service provided by the banks (Sharma & Malviya, 2011). As such, it is very important for banks to understand the service qualities that can influence customers' behavioral intentions towards the use of green banking services in Bangladesh.

The importance of various service qualities for customer satisfaction and subsequent adoption of banking services has been evidenced in numerous studies, but there is a paucity of research that explores the linkage between green banking service quality perceptions and customer adoption intentions in the context of Bangladesh. This study fills into the void by aiming to conceptualize selected factors of electronic service quality (E-S-QUAL) to identify the service quality dimensions, as perceived by customers, in the case of green banking services. To pursue this purpose, a proposed research model has been designed in this study by combining the factors of E-S-QUAL and the unified theory of acceptance and use of technology (UTAUT) constructs. This study, therefore, has both theoretical and managerial implications. Theoretically, this hybrid model is a contribution to the literature since it is capable of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

understanding the service quality determinants, along with other factors, behind the adoption of green banking in Bangladesh. From a managerial perspective, the findings of this research should provide further insights into understanding and managing potential and current users. This study can also assist banks to discover the qualities that existing users demand and potential users anticipate from the existing green banking system in Bangladesh.

LITERATURE REVIEW

To further the objectives of this study, the theoretical background of the proposed service quality determinants, followed by the research platform and finally, the current practice of green banking services and its implications in Bangladesh has been discussed to determine the gaps for the study.

Proposed Constructs of the Model

A number of previous studies identified service quality as one of the important attributes of service providers when regarded from the customers' perspective. This is because service quality has repeatedly been linked to the perceived performance of that service by researchers like Lin (2007), Aghdaie and Faghani (2012) and Islam (2012). Moreover, studies by Zhao et al. (2012), Cheng et al. (2013) and Ozer et al. (2013) found that service quality has a significant effect on behavioral intentions of customers through their level of satisfaction regarding the service performance. On this note, two important research models related to customer perception of electronic service quality and technology acceptance and usage intentions of customers has been considered to develop a conceptual hybrid model for this study.

Initial efforts in defining and measuring service quality was largely originated by Parasuraman et al. (1988), who proposed a service quality measurement scale, commonly known as 'SERVQUAL'. Following this innovation, Brady and Cronin (2001) and Brady et al. (2001) argued that the specific characteristics of electronic services are completely different from those of the physical service industry. Accordingly, Zeithaml et al. (2002) developed the electronic service quality (E-S-QUAL) scale to measure the service quality of websites. Later, Parasuraman et al. (2005) modified this scale and developed a multi-item scale for the assessment of electronic service quality on the basis of the service quality literature in general. This E-S-QUAL model consisted of two different scales, wherein the factors of efficiency, fulfillment, system availability, privacy, responsiveness, compensation and contact with the service provider were included. Researchers like Lin (2011), Sharma and Malviya (2011), Rejikumar and Ravindran (2012) and Lau et al. (2013) then used the scales of E-S-QUAL and examined the quality perceptions of customers in areas of internet and mobile banking services. Recent applicability of the E-S-QUAL model for banking services includes studies by Swaid and Wigand (2009), Bedi (2010), Munusamy et al. (2010), Ganguli and Roy (2011), Aghdaie and Faghani (2012), Cheng et al. (2013) and Ozer et al. (2013). Findings of Swaid and Wigand (2009) suggested that only the dimensions of reliability and assurance clearly influence customers' behavioural intention towards electronic banking services. Bedi (2010) and Munusamy et al. (2010), however, identified factors like assurance, empathy, responsiveness, tangibility and interactions with the bank as important dimensions of e-service quality from the customers' perspective. Ganguli and Roy (2011) reported similar findings highlighting e-service quality factors of responsiveness, assurance, security, easy to use and reliability in their studies. Other studies by Aghdaie and Faghani (2012), Cheng et al. (2013) and Ozer et al. (2013) further supported these

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

findings by claiming that dimensions of tangibility, responsiveness, reliability, empathy, availability, ease of use and assurance can define customers' intentions to use green banking services to a large extent.

Research Platform of the Study

Most of the previous studies' findings stressed upon that fact that the perception of both positive and negative service quality was related to the customers' future behavioral intentions towards various green banking services. In fact, since the possibility of direct interaction with human involvement is absent in such services, the service quality perceptions here purely includes a system-oriented evaluation. In such a context, service quality is typically decided by system quality, network quality and information quality as suggested by Rejikumar and Ravindran (2012). Accordingly, the current study selected seven dimensions of E-S-QUAL along the lines of system quality, information quality and interaction quality of different green banking services from these previous studies.

While service quality perceptions has been used in past studies as an antecedent to assess customers' intentions to use green banking services, there are other influencing factors that can further explain the acceptance and use of such services from the customers' perspectives. Following this notion, this paper used the concepts of the UTAUT2 model where factors has been primarily used to predict the behavioral intention of customers to use a technology, moderated by individual difference variables like age, gender, experience and voluntariness (Venkatesh et al., 2012). Against this backdrop, this study has selected the original UTAUT2 model as a theoretical foundation and combined the scales of E-S-QUAL to develop a proposed research model for this study. Since quality perceptions of customers are interrelated to the performance of a service, dimensions of the E-S-QUAL model has been linked to the factor of performance expectancy of the UTAUT model in order to demonstrate the influence of service quality along with other factors on customer acceptance and use of green banking services.

Green Banking Services in Bangladesh

The financial sector is nowadays aware of and concerned about all environmental problems of Bangladesh and considers the sustainability of the environment as part of their corporate social responsibilities (Kaeufer, 2010). As a result, the central bank of Bangladesh formulated Green Banking Policy which aims to ensure environment-friendly business practices by banks and financial institutions by promoting sustainable financial and economic growth across the entire country (Nisha, 2016).

The most important aspect of this Green Banking Policy is actually directed towards the bank clients. Bangladesh Bank has mandated the commercial banks to introduce rigorous programs in order to educate clients and influence them to comply with the environmental regulations as well as to undertake activities which are going to benefit the environment (Islam & Kamruzzaman, 2015). The common green banking services that all banks offer in Bangladesh today includes the use of e-statements instead of printed statements or e-mails instead of paper documents, internet banking, SMS banking, mobile banking, the use of Automated Teller Machines (ATM), Bangladesh Automated Cheque Processing System (BACPS), Bangladesh Electronic Fund Transfer Network (BEFTN) or other mobile financial services in the form of e-currency like bKash, mCash, EasyCash, etc (Masukijjaman & Aktar, 2013).

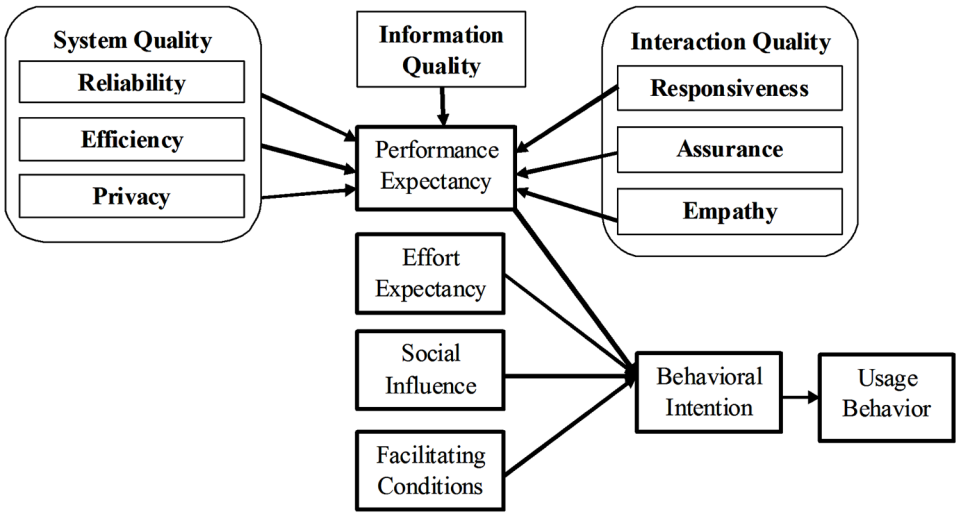
According to Bangladesh Bank, all these green banking services are necessary for the sustainability in the long-run. However, the application of green banking chiefly requires the involvement of the bank clients, since they are the ones who are at the forefront of using such initiatives to conduct their banking

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

transactions. Therefore, it is crucial to address the issues relating to customer expectations regarding service encounter experiences and the quality in service delivery for developing intention to use green banking by the customers.

RESEARCH MODEL AND HYPOTHESES

In conceptualizing the hybrid model for exploring the dimensions of green banking service quality, the four key constructs of the original UTAUT2 model (i.e. performance expectancy, effort expectancy, social influence and facilitating conditions) and the seven factors of service quality, drawn from previous literature of mobile banking and E-S-QUAL, has been incorporated. Figure 1 shows the proposed research model. In addition, all the variables hypothesized in this study and their likely relationships towards consumers' behavioral intention and usage of green banking services in Bangladesh has been discussed next.



System Quality

System quality is referred to as the overall measure of the information processing system of the mobile banking service and is often perceived to be closely related to service quality (Rejikumar & Ravindran, 2012). As such, three most significant dimension of system quality has been drawn from previous E-S-QUAL literatures to be included in the hybrid model, as discussed.

Reliability

Reliability of green banking services refer to the probability that the banks will satisfactorily perform as intended and consistently provide the same service through internet/mobile phone as it did through physical branches (Sharma & Malviya, 2011). In other words, whenever a customer will attempt to do

Figure 1. The Proposed Research Structure

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

banking transactions through a technological device, the service will have technical availability and it will provide error free services (Ganguli & Roy, 2011). Often, consumers' perception of reliability for a service plays a vital role in measuring the performance of that service (Munusamy et al., 2010). Particularly, for countries like Bangladesh where the concept of green banking is relatively new, consumers' perception of reliability regarding such service needs to be investigated.

Efficiency

From a consumer's perspective, green banking services can only be considered efficient if the system is simple to use, structured properly, and requires minimum information to be input by the customers (Sharma & Malviya, 2011). To be precise, how quickly consumers can access the service, how flexible is the user interface of the system and how quickly or timely the system responds to requests for banking information or transactions by the customer – all these attributes define the efficiency of green banking service (Ganguli & Roy, 2011). These attributes generally have a strong influence on performance expectancy of a service as they guide the perceptions of system quality and ultimately affect the usage intention of customers (Nelson et al. 2005). As such, efficiency of green banking service can be an interesting determinant for this study.

Privacy

Privacy can be defined as the degree to which the green banking service is safe and protects customers' banking information from any intrusion (Sharma & Malviya, 2011). Countries like Bangladesh tend to suffer from technological shortcomings – a reason why customers often object to the transmission of their personal bank account or transactional information over any other alternate channels outside the physical branches of the banks (Ganguli & Roy, 2011). Hence, if privacy issues related to green banking can be assured by the banks, customer will automatically be convinced of the performance of the service – thereby, leading to an increased use of such services in Bangladesh (Angst & Agarwal, 2009). In this regard, privacy can be an important quality determinant of green banking services.

This study, therefore, proposes the following hypotheses:

$H1_A$: Reliability positively influences performance expectancy of green banking services.
$H1_B$: Efficiency positively influences performance expectancy of green banking services.
$H1_C$: Privacy positively influences performance expectancy of green banking services.

Information Quality

Information quality can significantly predict users' perception regarding the use of technology-based services like green banking (Lee & Chung, 2009). This is because certain information regarding such services is very confidential in nature and it is crucial that such information is accurate, complete and up-to-date. Customers often determine the performance of a service on the basis of their satisfaction from the information available from that service (Swaid & Wigand, 2009). Also, the quality of information available can play a critical role in building user satisfaction and customer loyalty for services like green banking. Thus, the study hypothesizes:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

H2: Information quality positively influences performance expectancy of green banking services.

Interaction Quality

Customer perceptions of the interactions that take place during service delivery are known as interaction quality. Past studies like Lin (2011) and Aghdaie and Faghani (2012) claim that the quality of interactions between customers and the alternate banking systems can affect customers' intentions directly towards the use of services like green banking. As a result, three element of this quality from previous E-S-QUAL literature has been taken into account.

Responsiveness

Responsiveness can be defined as the willingness to help customers and to provide prompt services (Lau et al., 2013). In terms of green banking, it can be further explained by the banks' ability to understand the customers' problems and to provide precise financial services (Bedi, 2010). Munusamy et al. (2010) and Lau et al. (2013) found a positive relationship between responsiveness and customer satisfaction, as in, the more responsive the service is the more satisfied the customer will be for that service. Based on this evidence, this study used responsiveness as a factor that will guide customers regarding green banking service adoption.

Assurance

Often, the providers' knowledge, competency and courtesy levels and their ability to inspire trust and confidence in a service can influence customers' perception regarding the use of that service (Lau et al., 2013). Such assurance by the providers can inspire customer satisfaction as well and this satisfaction time and again can determine the performance of a particular service (Munusamy et al., 2010). For instance, banks' ability to provide their promised and accurate service and their tendency of keeping commitments within a given time frame can provide assurance to customers to consider the adoption of green banking services (Aghdaie & Faghani, 2012). Evidence of a positive relationship between assurance and consumers' acceptance of such services by many researchers has thus made it an influencing factor in this study.

Empathy

The dimension of empathy generally involves care and personalized attention that a firm can provide to its customers in terms of accessibility, communication and understanding of the service being provided (Bedi, 2010). Particularly for sensitive services like banking transactions, customers always appreciate a friendly and considerate environment. Hence, if the banks show genuine interest, enthusiasm and seriousness toward the customers' modern banking needs, it will automatically lead customers towards the usage of alternate financial delivery services like green banking (Ganguli & Roy, 2011). Based on this perspective, past studies like Aghdaie and Faghani (2012) and Lau et al. (2013) argue that empathy from the service provider can act as a determinant of the performance of that service. As a result, empathy has been considered as an influencing factor in the hybrid model of this study.

This study, therefore, hypothesizes the following:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$H3_A$: Responsiveness positively influences performance expectancy of green banking services.
$H3_B$: Assurance positively influences performance expectancy of green banking services.
$H3_C$: Empathy positively influences performance expectancy of green banking services.

Performance Expectancy

Several empirical evidences like Amin et al. (2008) and Dasgupta et al. (2011) argue that when a user perceives a technology useful, the likelihood of adopting that technology increases. As such, this factor can significantly influence individual's intention to adopt any technology-based services. Also, since it has been empirically demonstrated to include factors like relative advantage and perceived usefulness, this study hypothesizes that performance expectancy can have a considerable impact on the intention to use green banking services (Holden and Karsh, 2010). In fact, past studies like Lu et al. (2009) supports this claim of performance expectancy significantly influencing the adoption of green technology-based services. Thus, the proposed hypothesis is:

H4: Performance expectancy significantly affects individual intention to use green banking services.

Effort Expectancy

Effort expectancy is the degree of ease associated with technology use, particularly during the early stages of adopting a new technology (Phichitchaisopa & Naenna, 2013). Prior empirical studies of green banking adoption like Dasgupta et al. (2011), Moores (2012) and Nisha et al. (2015) have employed the construct of effort expectancy in various setups and found evidence of it being a determinant that can influence customers to use such services. Based on these findings, this study hypothesizes that:

H5: Effort expectancy significantly affects individual intention to use green banking services.

Social Influence

Venkatesh et al. (2003) defines social influence as the degree to which an individual perceives that important others believe he/she should use a technology. Customers often intend to use a new technology only because they believe it will enhance their image among their family and peers (Venkatesh & Davis, 2000). Singh et al. (2010) and Nisha et al. (2015) claim that the adoption of green banking can help people appear special and gain a personal and social identity in the society at large. Empirical findings thus suggest that the individual intention to use green banking services can significantly be affected by the people around them. Accordingly, the following hypothesis has been conceived:

H6: Social influence significantly affects individual intention to use green banking services.

Facilitating Conditions

Facilitating conditions is the degree to which an individual believes that an organizational and technical infrastructure exists to support technology use (Venkatesh et al., 2003). According to Venkatesh and Zhang (2010) and Venkatesh et al. (2012), facilitating conditions like the access of respondents to

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

internet/mobile and banking services are necessary in order to build proficiency for the use of green banking. In other words, facilitating conditions indicates the prospective conditions that may restrain or facilitate adopting a technology. In recent times, Nisha et al. (2015) empirically identified that facilitating conditions is a determinant of green banking intention and usage behavior. Taking this concept into account, the next hypothesis is:

H7: Facilitating conditions significantly affects individual intention to use green banking services.

Behavioral Intention

Many empirical studies like Venkatesh and Zhang (2010) and Nisha et al. (2015) claimed that the behavior of using any technology is often influenced by the intention to use that technology. Particularly, findings of these past studies argue that individual behavior is predictable and can be influenced by individual intention that, in turn, can have a significant influence on technology usage. Now, in the context of green banking, the ultimate goal of banks is to ensure that customers adopt their services rather than just having an intention to adopt it. Following the lead, Sripalawat et al. (2011) and Nisha et al. (2015) took this relationship between behavioral intention and actual use into consideration against the backdrop of green banking services. Accordingly, this study hypothesizes that:

H8: Behavioral intention significantly affects individual behavior of using green banking services.

RESEARCH METHOD

Data Collection

The population selected for this study represents customers of the young age group of Bangladesh who are more aware about environmental problems these days compared to the other age groups. As such, they are more concerned about the use of green technologies as well. Moreover, it is generally the young people who are the most active and innovative users of technology and more critical of the quality of technology-related services in any country (Kinnally et al., 2008).

A structured questionnaire has been used in order to gather the data from a sample of 700 respondents who resides in Dhaka - the capital city of Bangladesh. Respondents for the sample were selected by probability sampling, using a stratified random sampling method.

Measurement

All the items used to measure the research variables of the survey were adapted from previous studies, with minor changes in wording to tailor them to the different green banking context in Bangladesh. This ensured the content validity of the questionnaire used to assess each constructs depicted in Figure 1.

The quantitative survey contained 40 statements in order to evaluate the original constructs of the UTAUT model and the seven quality dimensions proposed for the hybrid model of this study, as given in Table 1. The scales for the UTAUT constructs (performance expectancy, effort expectancy, social influence, facilitating conditions and behavioral intention) were adapted from Venkatesh et al. (2003),

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Venkatesh and Zhang (2010) and Lin (2011). Alternatively, the scales for system quality (reliability, efficiency and privacy), information quality and interaction quality (responsiveness, assurance and empathy) were drawn from Nelson et al. (2005), Lee and Chung (2009), Lin (2011), Sharma and Malviya (2011), Rejikumar and Ravindran (2012) and Lau et al. (2013). All these items were measured using a five-point Likert scale, ranging from "strongly disagree" (rated 5) to "strongly agree" (rated 1). After a six-week survey starting from January 2016 till mid-February 2016, 575 completed and usable responses were obtained from the structured questionnaires.

Table 1. Constructs and Corresponding Items

Constructs	Corresponding Items
Reliability	[Ry1] I believe green banking services operate reliably [Ry2] I believe green banking services perform reliably [Ry3] I believe the operation of green banking is dependable
Efficiency	[Ey1] I feel green banking makes my banking information easy to access [Ey2] I feel green banking provides me banking information in a timely fashion [Ey3] I feel green banking takes too long to respond to my banking problems
Privacy	[P1] I trust the ability of green banking services to protect my privacy [P2] I feel safe to release my banking information to green banking services [P3] I feel matters on security has no influence in using green banking services
Information Quality	[IQ1] I believe green banking provides me complete banking information [IQ2] I believe green banking provides me up-to-date banking information [IQ3] I believe green banking provides me relevant banking information
Responsiveness	[Rs1] I think green banking provides me precise banking services [Rs2] I think green banking has the ability to understand my banking needs [Rs3] I think green banking services are helpful
Assurance	[AS1] I think green banking provides me banking services as promised [AS2] I think green banking provides me accurate banking services [AS3] I think green banking services will keep their commitments
Empathy	[E1] I think green banking has the knowledge to solve my banking problems [E2] I think green banking has the enthusiasm to understand my banking needs [E3] I think green banking services will put my banking needs in the first place
Performance Expectancy	[PE1] Using green banking can make my banking transactions more efficient [PE2] Using green banking can save me time in conducting banking transactions [PE3] Using green banking can make my banking transactions more convenient [PE4] Using green banking can be useful in managing my finances
Effort Expectancy	[EE1] Learning to use green banking is easy for me [EE2] Becoming skillful at using green banking is easy for me [EE3] Interaction with green banking is easy for me [EE4] Overall, I think green banking is easy to use
Social Influence	[SI1] People who are important to me think that I should use green banking [SI2] People who are familiar with me think that I should use green banking [SI3] People who influence my behavior think that I should use green banking [SI4] Most people surrounding me use green banking
Facilitating Conditions	[FC1] Using green banking suits my living environment [FC2] Using green banking fits into my working style [FC3] Using green banking is compatible with my life [FC4] Help is available if I have problems in using green banking
Behavioral Intention	[BI1] I prefer to use green banking [BI2] I intend to use green banking [BI3] I believe it is worthwhile for me to use green banking

DATA ANALYSIS AND RESULTS

This study applied SmartPLS to analyze the empirical data by using the structural equation modeling (SEM). The method of partial least squares (PLS) was primarily chosen to conduct this analysis since a number of interaction terms have been included in the research model and PLS is capable of testing these effects. To pursue the analysis, the Likert scale was transformed into numerical ratings, as suggested by Fornell and Larcker (1981). A two-stage analysis process was followed in order to include both outer model analysis (measurement model) and inner model analysis (structural model). Outer model mainly examined the reliability and convergent validity, whereas the inner model evaluated the hypotheses testing.

Measurement Model

The measurement results presented in Table 2 shows that all standardized factor loadings and composite reliability are larger than 0.7 on a stand-alone basis, as recommended by Nunnally and Bernstein (1994). The AVE was also greater than 0.5 in all cases and greater than each square correlations. Table 3 further shows that the internal consistency reliabilities (ICRs) of multi-item scales modeled with reflective indicators was 0.75 or greater. AVE values thus indicate that the model has convergent validity for all the constructs while the values of composite reliability and internal consistency reliabilities (ICRs) display adequate reliability in all selected cases. The pattern of loadings and cross-loadings too supported internal consistency and discriminant validity for the model, with few exceptions: one item from each construct of information quality, empathy (interaction quality), social influence, facilitating conditions and two items from reliability (system quality) and efficiency (system quality) were deleted due to their low loadings and high cross-loadings.

Structural Model

The path coefficients and significance levels in the structural model are presented in Figure 2. Among the three constructs of system quality, reliability [0.241, $p<0.05$] and privacy [0.133, $p<0.05$] showed significant and positive path towards performance expectancy, while efficiency [0.086, $p>0.05$] reported an insignificant path. The factor of information quality [0.101, $p<0.05$] also displayed a significant and positive path towards performance expectancy. On the other hand, responsiveness [0.147, $p<0.05$] and empathy [0.078, $p<0.05$] under interaction quality had a significant and positive path towards performance expectancy, but assurance [0.170, $p>0.05$] showed an insignificant path.

Other factors like performance expectancy [0.325, $p<0.05$], effort expectancy [0.199, $p<0.05$] and facilitating conditions [0.125, $p<0.05$] too showed significant and positive paths to the behavioral intention of using green banking, in their order of influencing strength. However, the construct of social influence [0.108, $p>0.05$] reported an insignificant path towards the individual behavior of using green banking services.

Therefore, all hypotheses [except H1B, H3B, H6] dealing with behavioral intention to use green banking services are supported. Subsequently, the hypothesized relationship between behavioral intention and usage [0.394, $p<0.05$] is found to be statistically significant, thereby supporting hypothesis H8.

FINDINGS AND IMPLICATIONS

This study systematically explores whether the service quality of the green banking system can influence the behavioral intention of customers by providing them the satisfaction expected from such alternate financial delivery service. Results conclude that quality dimensions like reliability, privacy, information

quality, responsiveness and empathy can significantly affect the performance of the green banking. The performance of the system can develop customer satisfaction which can then positively influence the behavioral intention of customers towards the use of green banking services. The observations from this study generally supports the results of various recent studies in the field of service quality like Sharma

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and Malviya (2011), Aghdaie and Faghani (2012), Rejikumar and Ravindran (2012), Cheng et al. (2013) and Ozer et al. (2013).

Apart from performance expectancy, the study additionally identify factors like effort expectancy and facilitating conditions to saliently influence the behavioral intention of customers, which in turn, has been found to directly stimulate the use of green banking in Bangladesh. This finding is also in line with past studies like Venkatesh et al. (2003), Venkatesh & Zhang (2010), Lin (2011) and Nisha et al. (2015). The inclined reason behind such findings has mostly been shaped by the local culture and infrastructure of the country and has certain implications for the banking sector as a whole.

Findings of this study reveal that most of the current and potential users of green banking facilities judge the importance of using this service based on the relative advantages this form of banking can provide them. As such, the better the performance that people can expect from the use of green banking services, the more people are likely to use green banking in Bangladesh. This is particularly true if customers are satisfied with the performance of the system and satisfaction can only be achieved when certain quality dimensions are present in the green banking service. For instance, if banks consider the need of their customers when designing new services like e-currency, global fund transfers, international bill payments, mobile banking, internet banking under the green banking system, customers will be convinced of the responsiveness of the system. Again, if customers observe that banks are taking the responsibility for environmental degradation and acting responsible, they will be satisfied with the system's reliability and empathetic quality of the service. Often, banks may need to upgrade their system programs and in the process if the banks maintain the system stability and transaction security, customers will be assured of the privacy and reliability qualities of the green banking service. Similarly, the more accurate and complete information that banks can provide their users with, the more positive feeling the customers will have regarding the information quality of the service.

As such, the takeaway for the banks will be to adopt or improve these five qualities of their green banking services in order to achieve customer satisfaction and thereby, result in an increased growth rate in the use of green banking services in Bangladesh. For this, banks should maintain a safe online communication, electronic currency transfer, mobile banking and internet banking transaction platform to protect the privacy of the customers, resolve problems quickly if transaction errors occur and provide assistance to all new or confused green banking users. Also, the banks should actively inform their customers about the processes and time needed for certain services under the green banking system in order to aware user regarding the time saving and ensure quality information. The better quality of efficient transaction services due to more integration in the services the banks will provide the higher satisfaction their customers will have and this will ultimately result in higher behavior intention to use green banking. In fact, exploring the dimensions of service quality in one way also falls under the Performance Measurement System (PMS) that can later be used to evaluate and improve the performance of banking services (Michael, 2015). Banks should thus enhance their service quality if they expect an increase in the behavioral intention of the customers towards the use of green banking services.

Furthermore, the results of this study claims that respondents who expect less effort input in the service consuming process are more likely to show positive attitude in embracing the concept of green banking services. In green banking, users requires less effort as online transactions and communications are widely used which requires less time and the user do not physically has to go to the banks to avail any services. The underlying cause behind this can be the newness of the green banking in the culture of Bangladesh, since most of the banking transactions are still traditionally offered from physical bank

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

branches. Adoption of any new technology initially shows such similar pattern in Bangladesh, since this country is neither technologically-sound nor does it have a technology savvy culture. Along the same line, facilitating conditions is found to be yet another determinant that can influence respondents' behavioral intention and use of green banking services. Facilitating conditions generally tend to be the wide availability of computers, strong mobile networks and fast internet services in the context of Bangladesh. Banks thus need to emphasize upon the compatibility between the offered services and the working/living styles of their target users.

The takeaway for the banks in this case will be to create the right perception in the mind of the customers regarding the use of green banking services. For instance, a common misconception among people in Bangladesh is that green banking services will be expensive and complex compared to the traditional banking. However, most banks in Bangladesh only need the support internet and mobile network operators and their network services for green banking. It is, thus, important for banks to inform customers that only internet, mobile phone and a mobile network connection is required to take the benefits of green banking services. On the other hand, since effort expectancy demonstrated a strong significance in influencing the behavioral intention of people in using green banking in Bangladesh, it is imperative that banks design simplified user interface or customized account query rules that can be useful for convincing new banking users of the ease of use of this service.

Interesting findings of the research also include the fact that quality factors like efficiency and assurance by the banks does not significantly impact the behavioral intention of people in using green banking in Bangladesh. This may imply that since banking is an essential service, respondents are willing to accept the service even if it is inefficient or non-committal at times. Moreover, society's perceptions regarding green banking was not found to contribute to the shaping up of people's behavioral intention towards the use of such services in Bangladesh.

Implementation of green banking might be a long-term project in emerging economies, but the fairly positive perception and an equally positive attitude of customers towards such services clearly paves the way of a higher rate of adoption of green banking in Bangladesh. However, since green banking has been initiated very recently (year 2011) and is still in the adoption process, the marginal adoption and usage rate currently reported by the banks for such services is rightly justified. Consequently, it may be argued that the perception of customers can be altered if banks in Bangladesh can design various green banking services with desired quality dimensions and other influencing factors identified in this study.

LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

Like most empirical research, this study has several limitations. First, the conclusions drawn from this study are based solely on the young population of Bangladesh. Future research can explore the behavioral intention of other age groups so that their perceptions regarding the service qualities of various green banking services can be considered by the banks. Second, a longitudinal study can be adopted in future works to examine and compare the hybrid research model in different time periods, thereby providing a better insight into the quality of services expected from green banking in Bangladesh. Finally, other than the quality dimensions included in this study, there can be more constructs characterizing green banking services or moderator effects like that of age, gender, voluntariness, etc that can be added in the research model to enhance the understanding of service qualities that customers expect from green banking.

CONCLUSION

This paper contributes to the literature by combining selected factors of electronic service quality (E-S-QUAL) and the unified theory of acceptance and use of technology (UTAUT) constructs to identify the service quality dimensions and other factors, as perceived by customers regarding green banking services. It is a unique study in itself, since there has been no such study conducted in the context of developing countries like Bangladesh. Moreover, no previous study has made green banking the focus of research while examining service quality perceptions of the consumers.

In particular, this study is important since customers are very rational in this era and they only want those services or products which give them maximum utility. They also prefer those services that are high in quality. Results of this study show that service quality has a significant effect on customers' intention to use green banking services. The more the banks improve their service quality, the improved will be the customer performance which ultimately increases customers' intention to use green banking.

The banks can improve their service quality by timely informing their customers the actions taken by them on the customer issue. They can increase their communication through the website, leaflet, and poster, seminars etc. with their present or prospective customers. To improve the service quality, management of the bank should ensure error-free transactions and monitor customer satisfaction level regularly. Information quality is another important factor that affects customer's intention via performance expectancy to use the product or service. The managers of the banks should ensure that information provided should be accurate, timely updated on the websites and circulated among the customers.

The UTUAT constructs, i.e. performance expectancy, effort expectancy, facilitating condition, has a significant positive effect on the customer intention to use green banking as well. So, the managers should provide user-friendly interface, 24/7 support and emphasize on security and privacy aspects in order to improve the association with the customers. The interactive quality dimensions too play an important role in enhancing the performance of the customers. The banks can upgrade their website so that it is more efficient, more secured, and responsive. They should personalize their website according to the needs of the users and improve the information quality. The bank can also explain their online transaction procedures, guidelines on how to tackle with the security procedures to the customers as this will increase their intention to use the system. The banks can even hire motivated and enthusiastic employees who will solve customers' complaints and problems effectively.

All these necessary and pro-active steps by the banks can ultimately influence customers' intention to adopt and use green banking service at an increased pace. So, the banking sector of Bangladesh should understand the importance and monitor its service quality by developing a systemic assessment program.

Chapter 54
Evaluating Factors Affect Green IT Readiness (Part 1)

Yas A. Alsultanny
Arabian Gulf University, Bahrain

Fatma M. Alnassar
Arabian Gulf University, Bahrain

ABSTRACT

The IT departments must have green IT readiness to control emissions from data centres and selecting equipments of low power consumption. The purpose of this study is to evaluate the factors affecting green IT readiness. A questionnaire of developed to evaluate green IT readiness from the perspective of the IT staff. The questionnaire divided into two parts. The first part is for demographic information and general questions. The second part for green IT dimensions; technology, practice, policy, governance, and attitude. The data collected from 401 respondents. The results showed that the factors; technology, practice, attitude, and maintenance have an agree degree of agreement, while the factors; policy, governance, and green IT readiness have neutral degree of agreement. The governance has the highest correlation and influence on green IT readiness. The study recommends organizations, to setup strategies for implementing green IT as short-term solutions, and the government needs new laws and policies to implement green IT as a long-term solution.

INTRODUCTION

Since the advent of information technology, the power consumption is continuously increasing, and the consumption of fuel in turn has increased pollution. The disadvantages have reached the stage of risk for human health. Green technology has emerged to protect the environment from pollution.

The greenness of IT mostly depends on societies' readiness to adopt the green IT approach throughout the business. Green-readiness is referring to the use of technology by individuals in an organization, and easily identified by the indicators; green business infrastructure, development of green IT standards, server consolidation and virtualization, green buildings, and green power sources (RMIT, 2007).

Green IT auditing is one of the methods used to measure power consumption; its benefit will reduce costs, and improve energy efficiency (Ambtman, 2011). Green IT emissions are considered the major interest of concern, which could be related either to the rate of production or consumption of carbon dioxide (CO_2). There are many sources of CO_2 emissions; one of them is the emission from the use of IT technologies (Jonathon, 2012). IT assessment is a method used to reach green IT implementation, and the government plays an important role in monitoring green IT (Jongsaguan & Ghoneim, 2013).

ICTs have estimates around 2% of global CO_2 emissions that is equal to the quantity generated by the airline sector (Goasduff & Forsling, 2007). The enlargement in IT emissions were expected to reach 6% at the end of 2020, while data centre emissions are expected to grow by 7% each year if no action is taken (Mingay, 2006).

The first section of this paper provides an introduction. The second section is for the motivations for this study. The third section is for the literature review. The fourth section is for the study objective. The fifth section is for research methodology. The sixth section describes data analysis. The final section is for the conclusion.

MOTIVATIONS FOR THIS STUDY

Two main factors that motivate any size of organizations toward green IT, these are the lack of natural resources demands and the stakeholders' environmental awareness (Esty & Winston, 2009). The motivational factors cause public employees to go for green theoretical framework based on connectedness to nature, organizational commitment, public service motivation, and organizational citizenship behaviour (Stritch & Christensen, 2014).

In the future, the expected demand for ICT will be increased, thus increasing power consumption and air pollution, critical issues that affect human life. Organizations must try to gain competitive advantage by practicing green IT readiness. Green IT readiness becomes very important in terms of the performance of any organization, saving money, and power consumption. In addition, it is necessary to provide IT staff an awareness of the importance of the green IT readiness, and reducing the misuse of IT facilities. All of these justify the needs of evaluating the green IT readiness factors.

LITERATURE REVIEW

Green IT defined as; an organization's ability to systematically applying environmental sustainability criteria to the design, production, sourcing, use and disposal of the IT technical infrastructure as well as within the human and managerial components of the IT infrastructure (Elliot, 2007).

Green IT contributes to reducing the environmental impacts of business IT activities (such as; adopting green technologies), green IT support for environmentally sustainable business practices (such as; enabling green supply chain management through building tools for energy management) and its role (such as; supplanting high CO_2 emitting business practices) in the low-carbon economy (Molla et al., 2009).

Greening IT mean that organizations have to be efficiently design their data centres and IT technologies in order to reduce energy consumption as well as cost (Graaf, 2008). The Energy Star is is an international standard for energy efficient consumer products which originated in the United States in

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

1992 by the Environmental Protection Agency (EPA) under the authority of the clean air, to help in protecting the environment by reducing energy consumption in an efficient way, for manufacturing and trade association, to retail and small business, to homebuilder.

ICT is a key driver for improving both business and private undertakings. E-readiness regarded as critical qualities that companies have to continue upgrade, in order to operate in the digital economy (Molla & Licker, 2005). Economically, ICTs have a vital role in improving and creating various economic opportunities. This explains why there are many national and international initiatives to measure the e-readiness of countries regarding access, connectivity, network security, and regulatory environments (Mia & Dutta, 2007).

Green IT readiness is the firm capability and state of maturity in applying environmental criteria to its IT technical infrastructure, as well as within its IT human infrastructure and management across the key areas of IT sourcing, operations, and disposal. Molla et al. (2008) developed a green IT readiness model. It consists of five factors. These factors are; attitude, policy, practice, governance, and technology. A green IT attitude means an organization has an IT sentiment towards environmental sustainability. The green IT policy means that the organization measures its IT impact on the environment. Green IT practice means the application that organizations consider in order to reduce emissions or enhance environmental awareness. Governance related to the organization's infrastructure required to implement green IT. Green information technology is about an information system that needed to reduce the end users' usage of energy and its consumption, as well as optimizing the power efficiency (InfoTech, 2007; InfoTech, 2008; Molla & Cooper, 2009).

Molla et al., (2009) compared the green IT readiness between Australia, New Zealand, and USA implemented the five dimensions; technology, attitude, governance, practice, and policy. Data collected from 143 respondents by surveying the chief information officers and other IT managers, the results showed that USA ranked the first in governance, technology, and practice dimensions but not policy, while New Zealand implemented the green IT policy. Hooia et al. (2012) explored the readiness of a green university framework in Malaysia. The results showed, that in order to be successfully green, the organizations and countries have to measure IT user readiness and the motivation for organizations to move toward green. The study recommended; awareness, acceptance, and assimilation to mechanism to achieve a sustainable and successful implementation. Jonathon (2012) found in his study that the green IT benchmarks sustainable in the USA, India, UK, and Australia, the development of an overall green IT readiness index for any IT organizations depends on five keys of green IT: Green IT Lifecycle, end user IT efficiencies, enterprise and data centre IT efficiencies, usage of IT as a low-carbon enabler, and green IT measurement and monitoring. The best performing was the United Kingdom and USA rated second, followed by Australia and India.

Wabwoba et al. (2013) looked at difficulties in adopting green IT in Kenya. Their result showed that green IT is a solution to countries and firms to overcome various difficulties and hence satisfy the need of stakeholders to protect the environment, there is an urgent need to make sure of the high level of green ICT readiness among end users as well as IT managers to enhance business sustainability. Buchalcevova (2015) showed a design of a green ICT maturity model for assessing green ICT capability in small and medium enterprise companies. He recommended a model that has six maturity factors; carbon emissions management, smart motors, smart logistics, smart building, and smart energy.

In Kuwait, the estimated increase of electricity consumption per capita is 16,090 Kw/hr per person. Kuwait ranked the third highest consumable country over the world in the year 2012. This increase cre-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ated emissions such as CO_2, which has an impact on the environment. In addition, the mobile phones increased the Internet usage. The Kuwaiti mobile users according to information index was ranked 17th in the world in year 2012 (www.indexmundi.com).

STUDY OBJECTIVE

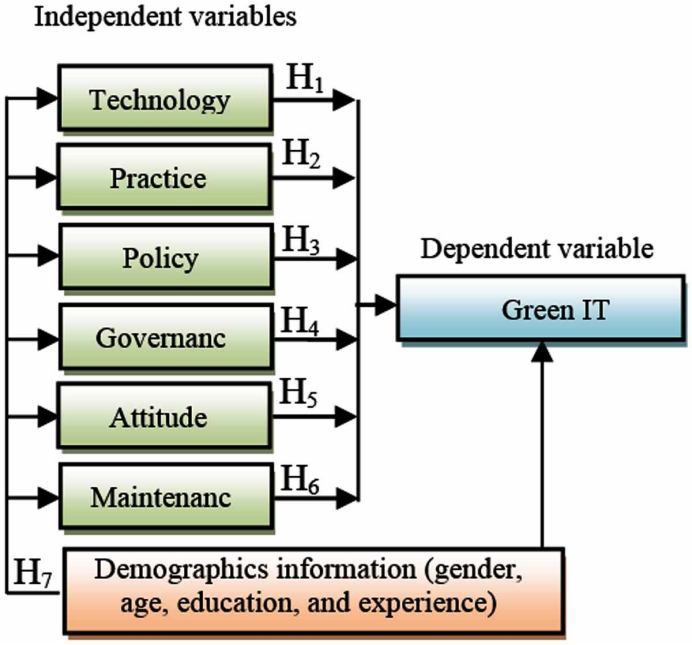
The main objective of this study is to evaluate the factors affecting green IT readiness in the Kuwaiti public sector from the perspectives of the IT staff, by identifying the factors that effecting green-IT readiness and study the effect of demographics information on the green IT readiness factors.

From the study objective the following questions derived;

1. What are the factors that affect green IT readiness from the perspective of IT staff?
2. Does the demographics information of IT staff have significant effect on green IT factors and green IT readiness?

RESEARCH METHODOLOGY

Research methodology is a plan of actions, processes or design lying behind the choice and use of particular methods to execute studies Crotty (1998). This study used descriptive and quantitative methods. The descriptive method used in order to provide descriptive information about the topic. Quantitative analysis is the processing and manipulating of raw data into meaningful information. A questionnaire designed for evaluating the factors impact on green IT readiness, from the perspectives of IT staff who are working in IT departments to install, configure, and optimize operating system, test security patches, develop, backup, and oversee maintenance.



This questionnaire divided into two parts. The first part was for demographics information. The second part for green IT dimensions. These dimensions adopted from Molla et al., (2009), which had five dimensions (technology, practice, policy, governance, and attitude). Maintenance as a sixth dimension added to this model, these dimensions are the independent variables of the study, the statements of dimensions measured by 5-points Likert Scale, where; Strongly Disagree (SD=1 points), Disagree (D=2 points), Neutral (N=3 points), Agree (A=4 points), and Strongly Agree (SA=5 points). The demographics information (gender, age, education, and experience) used to find their effect on the green IT readiness and on the six dimensions of this model. Figure 1 shows the conceptual model of the study.

The hypotheses of the study are;

H_1: There is a statistically significant effect of technology on green IT readiness.
H_2: There is a statistically significant effect of practice on green IT readiness.
H_3: There is a statistically significant effect of policy on green IT readiness.
H_4: There is a statistically significant effect of governance on green IT readiness.
H_5: There is a statistically significant effect of attitude on green IT readiness.
H_6: There is a statistically significant effect of maintenance on green IT readiness.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The IT staff conceptual model

H_7: The IT staff demographics information (gender, age, education, and experience) have a statistically significant differences in (technology, practice, policy, governance, attitude, maintenance, and green IT readiness).

The questionnaire evaluated by universities experts. The degree of respondents' agreement ranked by the following scale: Strongly Disagree (SD) ranged from 1-1.8, Disagree (D) ranged from 1.81-2.6, Neutral (N) ranged from 2.61-3.4, Agree (A) ranged from 3.41-4.2, and Strongly Agree (SA) ranged from 4.21–5.

The correlation coefficient represented by R in this study. According to Gerstman (2003) coefficient with a value of more than ±0.7 indicates a strong association between variables, values ±0.7>=R>=±0.3 are moderate correlation, and values less than ±0.3 have weak correlation.

The population of the study is from the Kuwaiti Public sector. The questionnaire distributed online and manually, 401 respondents used in the analysis.

The validity checked by a correlation as shown in Table 1; the Spearman indicates a statistical linear relationship between each dimension and its statements for all the dimensions. Since the coefficient R>0 and p-value≤0.05, it is clear that all the correlations of the questionnaire are positively and significantly ranging from 0.103 to 0.886 and the sig. are significant and equal to zeros.

Cronbach alpha used to measure reliability. Yin (2003) determined that the cut-off-point for Cronbach alpha is 0.7. Table 2 shows the results of testing Cronbach alpha. The highest alpha value is in the maintenance dimension (0.917), and the lowest alpha value for green IT readiness dimension is (0.701), the total alpha value for this questionnaire is (0.851). This indicates the data collected by this questionnaire is reliable for analysis.

Table 1. Spearman correlation for questionnaire validity test

Dimensions	Spearman correlation	Sig.*
Technology	0.271**	0.000
Practice	0.364**	0.000
Policy	0.103**	0.000
Governance	0.315**	0.000
Attitude	0.539**	0.000
Maintenance	0.886**	0.000
Green IT readiness	0.893**	0.000

Sig*: significant value
** correlation is significant at the 0.01 level (2-tailed)

Table 2. Cronbach alpha for reliability

Dimension	No. of statements	Alpha	Reliability
Technology	6	0.751	0.851
Practice	7	0.844	
Policy	4	0.767	
Governance	3	0.857	
Attitude	6	0.911	
Maintenance	5	0.917	
Green IT readiness	3	0.701	

Data Analysis

This section is for analyzing the data collected from 401 IT staff respondents. The demographics information of the respondents is as shown in Table 3.

The second section of the questionnaire contains 34 statements divided into 7 dimensions. For each statement the average of each statements calculated by the responds values [(SD+D+A+A+SA)/5], where its ranges are from 1-5. The standard deviation (Sd) calculated for each statement. The rate (degree of agreement), and rank (sorted from the highest average to lowest average) were calculated. The rank is the order of agreement of each statement in the dimension.

Table 4 shows the descriptive statistics of respondents for the seven dimensions. The table shows that for the technology dimension, the first rank goes to the statement (3), which states, "Data was stored in optimal utilization methods", with the highest average (3.72) and standard deviation (1.644). The average of this dimension is (3.456) with a standard deviation of (1.244). The results of this dimension indicates an agree degree of agreement, which means the respondents are agreeing with the level of the technology used in their organization like optimal storage utilization, data centres are cooled efficiently, and satisfaction with the IT equipment size.

The table shows the first rank of the Practice dimension goes to the statement (7), which states, "Prefers IT suppliers that have green track record", with the highest average (3.61) and standard deviation

Table 3. Respondents' demographics information

No.	Demographics Information	Type	F	%
1	Gender	Male	311	77.6
		Female	90	22.4
2	Age	Less than 20 years	44	11.0
		21-30 years	174	43.4
		31-40 years	106	26.4
		41-50 years	47	11.7
		Above 50 years	30	7.5
3	Education	Diploma degree	35	8.7
		Bachelor degree	245	61.1
		Higher education degrees	121	30.2
4	Experience	Less than 1 year	119	29.6
		1-5 years	77	19.2
		6-10 years	60	15.0
		11-15 years	113	28.2
		More than 15 years	32	8.0

F: Frequency
%: Percentage

(1.099). The practice dimension average is (3.442) with a standard deviation of (1.136). The result of this dimension indicates an agree degree of agreement, which means that they prefer IT suppliers that have a green track record, and switch off unnecessary equipment when not needed.

The table shows the first rank of the Policy dimension goes to the statement (14), which states "Dispose of old IT items in an environmentally friendly manner", with the highest average (3.43) and standard deviation (1.190). The dimension average is (3.295) with a standard deviation of (1.190). The results of this dimension indicated a neutral degree of agreement. They agreed with disposal of old IT items in an environmentally friendly manner, their policy must be directed toward using IT in an efficient manner to save energy, which is the responsibility of managers and government.

The table shows that the first rank of the Governance dimension goes to the statement (19), which states, "The organization is applying green IT policy", with the highest average (3.43) and standard deviation (1.175). The dimension average is (3.220) with standard deviation (1.181). The results of this dimension indicated a neutral degree of agreement, which means that the IT staffs needs more awareness for green IT governance to shift to green sources of energy and apply green IT policy.

The table shows that the first rank of the dimension Attitude goes to the statement (23), which states "My responsibilities on green IT are clearly defined", with the highest average (3.58), and standard deviation (1.174). The average of this dimension is (3.516) with a standard deviation of (1.161), which is an agree degree of agreement. The IT staff agreed that their responsibilities on green IT are clearly defined which means they are aware of the green IT concept, and they are concerned with green IT and IT energy consumption.

The table shows that the first rank of the dimension Maintenance goes to the statement (31), which states "your organization has an information system to monitor workloads and to shutdown components

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

when unused", with the highest average (3.97) and standard deviation (1.094). The dimension average is (3.896) with a standard deviation of (1.052). The results of this dimension is an agree degree of agreement, which means the IT staff agreed that their organization has an information system to monitor workloads and to shutdown components when unused. It also removes the energy of the inefficient IT components.

The table shows that the first rank of the dimension Green IT readiness goes to the statement (33), which states, "Set target for implementing green IT factors", with an average (3.37) and standard deviation (1.189). The dimension average is (3.320) with a standard deviation of (1.171). The results of this dimension indicates a neutral degree of agreement, which means the IT staff are neutral satisfied with target setting for implementing green IT in their organization. Also the IT staff is neutral satisfied whether the CEO`s role is active in leading green IT initiatives.

The data distribution of the statements was tested by Kolmgrov-Simirnov, the results showed that the data distribution for the statements had non normal distribution, because the sig. values of the statements are less than 0.05. Therefore, the Spearman association used to test the correlation between the dimensions of the statements. Table 5 shows the matrix of correlations. The results indicated a positive and significant correlation between the seven dimensions. There is a strong correlation between governance and green IT readiness with a value 0.742; this indicates that governance is an important factor affecting green IT readiness. The maintenance dimension has the lowest moderate correlation effect on the green IT readiness with a value of 0.341.

A simple linear regression test carried out for testing the hypotheses (H_1 to H_6). Table 6 shows the result of testing the effect of technology on green IT readiness.

The table shows a moderate correlation *R=0.397*, with determent factor *R square=0.158*, between technology and green IT readiness, and sig. value is 0.000, which is less than (α=0.05). It indicates there is a significant effect of technology on green IT readiness. Therefore, hypothesis H_1 is accepted. The regression equation is: Green IT readiness=1.869+0.419(technology). Molla et al. (2009) stated that all of the technology components of green readiness focus on technological solutions that improve IT energy.

The table shows a moderate correlation *R=0.672*, with determent factor *R square=0.451*, between practice and green IT readiness, and sig. value is 0.000. It indicates there is a significant effect of practice on green IT readiness. Therefore, hypothesis H_2 is accepted. The regression equation is: *Green IT readiness=0.808+0.729(Practice).* Which shows a linear relationship between the two variables. Murugesan (2008) stated in his study the benefits of using and implementing green IT practices design for environmental sustainability, energy efficient computing, and responsible disposal and recycling.

The table shows a moderate correlation *R=0.473*, with determent factor *R square=0.223*, between policy and green IT readiness, and sig. value is 0.000. It indicates there is a significant effect of policy on green IT readiness. Therefore, hypothesis H_3 is accepted. The regression equation is: *Green IT readiness =1.806+0.459(policy)*, which shows a linear relationship between the two variables. There is a need for policy to direct staff to use IT in an efficient manner to save energy in their organization. Molla et al. (2009) stated the maturity of policy dimension affect the green IT and guide the use of IT in reducing carbon footprint.

The table shows a strong correlation *R=0.742*, with determent factor *R square=0.550*, between governance and green IT readiness, sig. value is 0.000. It indicates there is a significant effect of governance on green IT readiness. Therefore, hypothesis H_4 is accepted. The regression equation is: *Green IT readiness=1.289+0.631(governance)*, which shows a linear relationship between the two variables, because governance has a major role in set the rules and laws for the country so governance had the highest ef-

Table 4. Descriptive statistics for the questionnaire dimensions

No	Statements	Average	Sd	Rate	Rank
1.	There is a power shut down system after the end of the official working hours.	3.11	1.331	N	6
2.	The organization use right sizing IT equipment.	3.51	1.112	A	3
3.	Data was stored in optimal utilization methods.	3.72	1.644	A	1
4.	Data was used virtualization storage.	3.39	1.189	N	5
5.	Highly efficient cooling system for data center used.	3.52	1.138	A	2
6.	More energy efficient lights were used.	3.49	1.051	A	4
Technology dimension average		**3.456**	**1.244**	**Agree**	
7.	Prefers IT suppliers that have a green track record.	3.61	1.099	A	1
8.	Consider environmental factors in the design of the IT site infrastructure (lighting, power, and cooling systems).	3.42	1.155	A	4
9.	The organization switch off data center lights.	3.33	1.161	N	7
10.	Switch off unnecessary equipment when not needed.	3.51	1.120	A	2
11.	There is a system for recycle consumable equipment (e.g. batteries, ink cartridges, and paper).	3.45	1.182	A	3
12.	The organization organizes print optimization.	3.38	1.123	N	6
13.	To what extent your organization practices double sided documents.	3.40	1.114	N	5
Practice dimension average		**3.442**	**1.136**	**Agree**	
14.	Dispose of old IT items in an environmentally friendly manner.	3.43	1.190	A	1
15.	Applied green data centers policy.	3.20	1.215	N	4
16.	The policy of directing staff to use IT in an efficient manner to save energy.	3.23	1.161	N	3
17.	Relocation of data center near clean sources of energy.	3.32	1.194	N	2
Policy dimension average		**3.295**	**1.190**	**Neutral**	
18.	The organizations consider shifting to green sources of energy for IT equipment.	3.15	1.247	N	2
19.	The organization is applying green IT policy.	3.43	1.175	A	1
20.	Analyzing IT`s energy bill separately from the overall corporate bill.	3.08	1.123	N	3
Governance dimension average		**3.220**	**1.181**	**Neutral**	
21.	I am concerned with green IT.	3.54	1.086	A	3
22.	I am concerned with IT energy consumption.	3.56	1.169	A	2
23.	My responsibilities on green IT are clearly defined.	3.58	1.174	A	1
24.	Your organization is concerned with the energy consumption for lighting and cooling data centers.	3.51	1.206	A	4
25.	Your organization is concerned with the efficiency of powering our IT infrastructure (storage, servers, and network).	3.43	1.192	A	6
26.	Your organization is concerned with the environmental impact while disposing of IT items at the end of their lifecycles.	3.48	1.142	A	5
Attitude dimension average		**3.516**	**1.161**	**Agree**	
27.	Your organization manages data center airflow efficiency.	3.86	1.083	A	5
28.	The power system was upgraded to more efficient transformers.	3.90	1.029	A	3
29.	Your organization uses highly efficient stand-by power systems.	3.83	1.053	A	4
30.	Remove energy of the inefficient IT components.	3.92	1.003	A	2
31.	Your organization has an information system to monitor workloads and to shutdown components when unused.	3.97	1.094	A	1
Maintenance dimension average		**3.896**	**1.052**	**Agree**	
32.	CEO plays a leading role in green IT initiatives.	3.35	1.099	N	2
33.	Set targets for implementing green IT factors.	3.37	1.189	N	1
34.	Purchase IT components more environmentally friendly.	3.24	1.226	N	3

fect on green IT readiness. Molla et al. (2009) mentioned in his study that governance had the highest impact on green IT readiness in the USA.

The table shows a moderate correlation *R=0.447*, with determent factor *R square=0.200*, between attitude and green IT readiness, and sig. value is 0.000. It indicates there is a significant effect of at-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. IT staff matrix of correlation

Dimension	Technology	Practice	Policy	Governance	Attitude	Maintenance	Green IT readiness
Technology	1						
Practice	0.421*	1					
Policy	0.395*	0.348*	1				
Governance	0.299*	0.698*	0.239*	1			
Attitude	0.224*	0.454*	0.132*	0.460*	1		
Maintenance	0.175*	0.421*	0.125*	0.309*	0.579*	1	
Green IT readiness	0.365*	0.678*	0.413*	0.742*	0.456*	0.341*	1

Means statically significant at the level of significance (α=0.05) *

titude on green IT readiness. Therefore, hypothesis H_5 is accepted. The regression equation is: *Green IT readiness=1.847+0.419 (attitude)*. This shows a linear relationship between the two variables. This indicates that the IT staffs are more concerned with power consumption, and they are responsible for using the IT in a green method. This corresponds with results of the Tenhunen (2011) study, that green IT readiness is more characterized as an attitude rather than a set of planned tasks.

The table shows a moderate correlation *R=0.347*, with determent factor *R square=0.120*, between maintenance and green IT readiness, and sig. value is 0.000. It indicates there is a significant effect of maintenance on green IT readiness. Therefore, hypothesis H_6 is accepted. The regression equation is: *Green IT readiness=2.007+0.337(maintenance)*, which shows a linear relationship between the two variables, because the organizations have information systems to monitor workloads and to shutdown components when unused. This is compatible with Boudreau et al., (2010) results, which showed regular maintenance increase the performance of the IT product through time, decrease repair, and minimize disposal items.

Table 7 shows the IT staff gender variance test, by using the Independent T-test on the dimensions of the questionnaire. The table shows that gender would have different perceptions regarding practice only, with sig.=0.036, which indicate that males have more practices on using green IT than the females. All the other dimensions have sig. values greater than (α= 0.05). Therefore, the gender has no statistically significant differences in these dimensions.

Table 8 shows that the IT staff age, education, and experience variance tests, by using one way ANOVA on the dimensions of the questionnaire. For age, the table shows that only the attitude has no statistically significant differences, while the other dimensions have statistically significant differences according to age.

For educational, the table shows that the IT staff education has no statistically significant differences in the dimensions policy, governance, and attitude dimensions. The other dimensions have statistically significant differences for the IT staff education on the other dimensions.

For experience, the table shows that the IT staff experience variance test. The table shows that the IT staff experience have statistically significant differences on the dimensions; practice, policy, governance, attitude, maintenance, and green IT readiness.

CONCLUSION

Green IT readiness is one of the most important subjects in daily life, because it is related to the environment. The dramatic increasing of IT equipment, especially through ICT, requires increasing power consumption. To evaluate green IT readiness, this study measured the factors effect on green IT readiness from the perspective of the IT staff.

To answer the first question of this study; what are the factors that affect green IT readiness from the perspective of IT staff? The results showed that the technology, practice, attitude, and maintenance have an agreed degree of agreement, while the; policy, governance, and the green IT readiness have a neutral degree of agreement. The highest correlation coefficient was between governance and green IT readiness. The strongest dimension with a significant effect on green IT readiness was governance, followed by practice.

For the second question; Does the demographics information of IT staff have significant differences effect on green IT factors and green IT readiness? The results showed that gender has no statistically significant differences in green IT readiness dimensions except practice. Age groups have statistically significant differences in green IT dimensions except attitude. Educational level has no statistically significant differences on (policy, governance, and attitude). Years of experience have statistically significant differences in green IT readiness except technology.

The recommendations of this study are; the government must setup strategies for implementing green IT as a short-term solution. Moreover, the government needs new law and policies to implement green IT and became part of the employee behavior as a long-term solution. The cloud computing may be one of the solution if the security available to the extent that satisfying public sectors.

Chapter 55
Created Shared Value and Sustainable, Inclusive Development of Developing Countries

James Odia
University of Benin, Nigeria

ABSTRACT

The created shared value represents a paradigm shift in business corporate social responsibility (CSR) and sustainability strategy. Apart from addressing the limitations inherent in the traditional CSR which is mainly philanthropic, short-lived and separated from the core business strategy and activities, it enhances the company's competitiveness while simultaneously advancing the economic and social conditions in the community of operation. Companies can create shared values through re-conceiving products and markets, redefining productivity in the value chain and building supportive industry clusters at the company's locations and solving society problems. Despite the criticisms and challenges of the shared value concept, there are convincing evidences that the created shared value is a veritable instrument for addressing the bottom of the pyramid resulting in inclusive, sustainable development of developing countries and it has the potentials to unleash the next wave of global economic growth, prosperity and sustainable development when governments, companies and non-government organizations in developing countries demonstrate commitment to their roles in shared value creation and companies start to think and take long-term views of social investments and economic prosperity, and look at corporate decisions and opportunities through the lens of shared value by incorporating social and societal values into their economic agenda.

INTRODUCTION

The concept of Created Shared Value (CSV) has been pioneered by Professor Michael Porter and Mark Kramer of the Harvard University since 2011. Although the idea of shared value was first expressed in their publication in the Harvard Business Review on "Strategy and society: The link between competitive advantage and corporate social responsibility" in 2006 where they advocated a mutual dependence

between corporations and society or a win-win business-society relationship. There would be a symbiotic relationship and reciprocity between business and society as firms redefine and readjust their concept of value in a broader, more "shared" perspective (Davenport, 2011). It is business paving ground for its own success by curing the defects of a dysfunctional society through provision of infrastructure (such as roads, water supplies, schools) required for its production and produce shared value for the whole area (Kleemann & Krieger-Boden, 2011).

The CSV is a new revolutionary way of business thinking in the business-society relationship, which integrates social goals within business practice without distracting a firm from its primary purpose of achieving profit (Porter & Kramer, 2011; Rocchi & Fererro, 2014). This could trigger once again the greatest economic wealth, growth and innovation for humanity and business (Porter & Kramer, 2011). According to Porter and Kramer (2011), shared value can be defined as policies and operating practices that enhance the competitiveness of a company while simultaneously advancing the economic and social conditions in the community in which it operates and companies can create shared values through re-conceiving products and markets, redefining productivity in the value chain and building supportive industry clusters at the company's locations.

Porter and Kramer's propositions for the CSV have been laudable and applauded by many supporters (Bockstette & Stamp, 2011; Hills, Russell, Borgonovi, Doty, & Lyer, 2012; Pfitzer, Bockstette & Stamp, 2013; Visser, 2013) in re-connecting the disconnected corporations' successes to society's development, particularly in the advancement of social causes to strategic level, specifying the roles of government in enhancing shared value and introducing a broader conception of capitalism- the "caring or conscious capitalism". Without doubts, the world has experienced unparalleled prosperity following the industrial revolution and the free-market economy. Nevertheless Ringmar (2005) argued that although capitalism has produced comparable levels of economic prosperity, it has brought to human beings and societies the consequences of income inequality, erosion of non-market values, commodification and alienation of people and hence it should be controlled.

The arguments on CSR have revolved around the CSR continuum of Professor Friedman's neo-classical economic theory and Professor Freeman's stakeholder theory. Although Porter and Kramer (2011) argued that CSV is not social responsibility, philanthropy or even sustainability, it does appear that CSV is beyond CSR of business! In fact, In every country, particularly the developing ones, CSR has become inescapable priority for businesses (Porter & Kramer, 2006; Jean & Yazdanifard, 2015) and they are being blamed for every society's failures (Porter & Kramer, 2011), as corporate prosperity at the expense of the society's deep poverty and problems. Moreover, most of companies' efforts have not pay off greatly in their productivity due to the disconnect from or the ditch against society and the failure to link CSR to their strategy (Porter & Kramer, 2006). Porter and Kramer (2011) argued that there is a growing perception of companies' successes at the expense of society's social, environmental and economic problems. The companies' CSR have not been strategic to be a source of business opportunity, innovation, revenue growth, competitive advantage and benefits to society (Moore, 2014).

The CSV represents a win-win situation where an organization creates value for the society by tackling its needs and challenges in a way, which also creates economic value to them. Epstein (2012) remarks that CSV will grow future markets as well as strengthen economies and communities The CSV challenges the academic literature on corporate social responsibility as well as business practice in the few years of its existence. No wonder, CSV has been studied from different point of views, contexts such as industrial sectors and multinationals, social entrepreneurship (Pirson, 2012) and countries e.g. Brazil (Spitzek & Chapman, 2012), India (Vaidyanathan & Scott, 2012), and Australia (Leth & Hems,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2014). Some have tried to reconstruct/redesign or extend the original CSV framework by Porter and Kramer (Michelini & Fiorentino, 2012; Moon, Pare, Yim & Park, 2011) and/or widely applied the CSV to regional development, poverty reduction and to other disciplines like finance and banking (Bockstette, Pfitzer, Smith, Bhavaraju, Priestley & Bhatt 2014), education (Kramer &Tallant, 2014), global health (Peterson, Rehrig, Stamp & Kim, 2012), oil, gas and mining companies (Hidalgo, Peterson, Sith & Foley, 2014), agriculture, business corporate strategy, low-income markets and emerging markets (Hills, Russell, Borgonovi, Doty & Iyer, 2012).

A global assessment of CSV projects by Kreckova (2015) shows that CSV by regions is very uneven with South America, Central America and Caribbean region (22%), Africa (18%), North America (14%) and Asia (14%). The top social incidents are health and nutrition projects (21%), education, including workforce development (19%), financial inclusion, human rights and poverty with 9% each. Again AT Kearney (2015) study of over 200 social impact initiatives of United Nations Global Compact led companies reveals that 40% was shared value, 35% fall into philanthropy and 25% in community investments. This study was different from 2011 study where 75% of corporate social investment was philanthropy. The reason for the shift was attributed to the increased focus on minimizing environmental impacts and expanding employment and educational opportunities.

There are lots of literature and empirical evidences that the CSR approach in the developing countries of Africa including Nigeria has been mainly philanthropic and normative CSR (Visser, 2006, 2008; Visser, Matten, Pohl & Tolhurst, 2007; Amaeshi, Adi, Ogbechie & Amao, 2006; Odia, 2016). There are also increasing expectations by various stakeholders that corporate organizations, especially the multinational companies (MNCs) and transnational companies (TNCs) should go beyond profit maximization and regulatory compliance to take up responsibilities that make significant impact on society by helping to remedy the social problems including the ones caused by them (Odia, 2016). Some of the multinational oil companies in Nigeria like Shell Petroleum and Chevron have tried to move towards value sharing in their social responsiveness to oil producing communities in the Niger Delta region through partnership and social investments in host communities. Chevron's Partnership Initiatives in the Niger Delta (PIND) through the collaborative venture with the United States Agency for International Development (USAID), the Department for International Development (DFID), and others was aimed at enabling economic growth in the nine (9) oil-producing States of the Niger Delta area of Nigeria through investment of over $100 million in five years to create opportunities in other areas other than its value chain.

The CSV may just be the desired solution that the stakeholders have been waiting for to make corporations break away from the restricted CSR involvement to embrace the broader view of "caring, conscious capitalism" and respond to social issues and problems (Visser, 2013; Kreckova, 2015). While there are social and economic benefits, and prospects associated with CSV to the society and businesses at least from evidences of companies that have keyed into the CSV, a research gap exists on how CVS is linked to the sustainable, inclusive development of developing countries. There are also numerous limitations and criticisms regarding CSV such as: measurement issues, changing corporate mindsets to view environmental and social problems not as constraints but as business opportunities, gaining support of top management of MNCs, TNCs and other companies to key in and their voluntary CSV compliance and getting support of governments and agencies at the local, national and international levels to encourage more businesses to adopt shared value strategies.

Therefore, based on the review of extant literature and case studies on CSV, the objective of the chapter is to examine the relationship between CVS and sustainable, inclusive development from the perspective of developing countries like Nigeria. The rest of the chapter is divided into four sections:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The immediate section clarifies the concept of CSV and differentiates it from CSR. Section three considers the issues, controversies and problems relating to CSV such as the problems with the presents CSR, the creation of shared value, shared valued opportunities in the extractive industries including the roles of government, extractive industries and civil society in creating in-country shared value, CSV opportunities and benefits in developing countries, criticisms and limitations of CSV measurement and the inclusive, sustainable development through CSV. Section four proffers solutions and recommendations to the constraints of the effective implementation of CSV in developing countries. Section five is the conclusion and suggestions for further study.

BACKGROUND

The Concept of Created Share Value

According to Porter and Kramer (2011), shared value can be defined as policies and operating practices that enhance the competitiveness of a company while simultaneously advancing the economic and social conditions in the community in which it operates. Shared value was born due to the need to address societal needs, mostly in the bottom-of-the-pyramid segments of the customers (Kreckova, 2015). Shared value creation focuses on identifying and expanding the connections between societal and economic progress. It describes how firms can incorporate CSR activities to their overall business strategy so that they not solely represent a cost but also create value for the firm in terms of a unique market position. Creating shared value implies ethical standards and complying with the law, and it also considers any mitigation after harms that may affect results of business practices. Shared value involves creating economic value in a way that also creates value for society by addressing its needs and challenges. It aligns CSR activities with core business activities to generate business returns and thereby create a business case for sustained commitment and investment (Porter & Kramer 2011). Shared value positions social engagement as a "long-term investment that is intrinsic to business success." (Bockstette & Stamp 2011, p. 21). A shared value perspective recognizes the interdependency between business and society. It is creating economic value in a way that also creates value for society by addressing its needs and challenges. The idea is combining "traditional objectives with additional benefits for society" (Altman & Berman, 2011).

Again shared value is being referred to as a new way to address the underlying root causes of community concerns and unlock economic opportunities for companies in the extractives sector which have made little progress using current approaches (philanthropy, reputation building, local content requirements), with rising disputes, unending conflicts, violence and militancy like in the Niger Delta Region of Nigeria. CSV is a differentiation strategy (Spitzeck & Chapman 2012) that creates business value by tackling social issues or converting social issues into tangible business opportunities based on three pillars of (i) re-conceiving products and markets, (ii) re-defining productivity in the value chain and (iii) enabling local clusters development (Porter & Kramer, 2011; Porter, Hills, Pfitzer, Patscheke & Hawkins, 2012).

Although there are numerous social issues as generic, value chain social impacts and social dimensions of competitive context impacts, the CSV concept focuses particularly on those issues within the business context that have significant impact on firm competitiveness. The CSV is about creating social and business values simultaneously. The social values refer to positive improvements in the social issues targeted by the firm, and social outcomes or social changes that are needed to be achieved. The business

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

values are the actual economic benefits to the firms (Porter et al., 2012). According to Porter and Kramer (2011), the most pressing social issues that could be targeted by shared value strategy include supplier access and viability, employee skills, worker safety, employee health, water use, energy use, and environmental impact. It is argued that businesses acting as businesses, not as charitable, philanthropic givers, are arguably the most powerful force to address pressing society's issues. It is believed that businesses' quest to create economic value while simultaneously creating shared value for society will give rise to far broader opportunities for strategy and profitability that would drive the next wave of innovation, productivity and economic growth while also motivating and attracting consumers, business partners, employees, shareholders, and the public to them (Porter, 2014). This is because only the companies who address social issues strategically and understand the interdependence between business and society (Porter & Kramer, 2006, 2011) would be able to compete in this new world (Bockstette, 2011; Porter & Kramer, 2011). It must be emphasized that solving social problems requires innovation (Pfitzer et al., 2013), collective impact (Kania & Kramer, 2011) and changes to the traditional CSR mindset.

While many researchers have presented corporate responsibility with regard to social and environmental problems as an ethical duty (Donaldson & Dunfee, 1999), a political responsibility (Scherer & Palazzo, 2007, 2011; Whelan, 2012; Néron, 2013; Whelan, 2013; Scherer, Palazzo & Matten, 2014) or a response to business risks (Fombrun, Gardberg & Barnett, 2000), the CSV makes corporations to see social and environmental problems not as disconnected and externally imposed but as real opportunities and serious strategic targets for genuine business decisions. According to Brown and Knudsen (2013), the shared value replaces and expands the notion of CSR, which as a practice has too often become affiliated with misguided initiatives, costly sideshows and shallow public relation activities.

Camilleri (2012) has argued that there seems to be Adam Smith's "invisible hand" in force with regard to the CSV conceptualization since businesses contribute to society's value creation when they pursue their own interests. Thus the CSV argument tends to support Adam Smith's (1776) remark that it is not from the benevolence of the butcher, the brewer or the baker, that we can expect our dinner, but from their regard to their own interest. Again, Moczadlo (2015) argues that taking into account the examples cited by Porter and Kramer in their 2011 article, their understanding of CSV seems to correspond in some respects with strategic CSR. Strategic CSR can be located between strict compliance of given rules and regulations and good corporate citizenship (Windsor, 2013). Nonetheless, CSV is going beyond the pure business case approach of CSR because it requires integrating shared value into the core business and the long-term strategic alignment of companies. Porter and Kramer (2011) posit that strategic CSR, value co-creation, social innovation and inclusive business model follow the principle of the CSV. Young (2012) argues that CSV represents one particular model for implementing strategic CSR in larger organizations. Like CSV, strategic CSR reframes sustainability and social benefits as a driver of business innovation, value creation and competitive advantage.

The Differences Between CSR and CSV

CSV goes beyond CSR because shared value creates long-term potential for a company's profitability and competitive position in the market, while corporate social responsibility is a short-term remedy that is hard to justify in the long run. While CSR is based on being responsible, philanthropy and doing good for society, its impacts are too reactionary and cursory to make a significant impact in improving either society or the company's earnings potential. On the other hand, CSV is a readjustment of the company's overall operations in order to create new value. Again, whereas CSR is a short-term solution,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

CSV is a long-term realignment of the company‘s entire budget, market position and overall mission. CSV is distinct from CSR where companies are challenged to sponsor the (costly) production of social goods, or like social businesses and social entrepreneurs that refrain from profit maximization in favour of a social goal and accept forgoing a higher income. Nevertheless, compliance with laws and ethical standards and reducing harm from corporate activities are assumed in both CSR and CSV (see Table 1).

The European Commission changed the definition of CSR in 2011 to include CSV as a core element for companies with their owners and shareholders respectively, as well as for other stakeholders and the society. Moreover, the Commission sees strategic CSR as an important tool for the competitiveness of companies and a measure for business to contribute to inclusive growth, employment and well-being of the society. Therefore, companies should take into account economic, social and environmental targets including ethical human rights and consumer concerns when developing their long-term business strategy. Maczaldo (2015) differentiates between the CSV of the European Commission and Porter and Kramer (see Table 2). First, the CSV of Porter and Kramer goes beyond the pure business case of CSR because CSV is a long-term measure integrated systematically into the strategic core business of companies. The Commission sees the shareholders as just one common group of a company’s stakeholders and gives no preference to them. For Porter and Kramer the simultaneous creation of profit and societal value are decisive. While the European Commission sees CSR as a driving concept, Porter and Kramer differentiate CSV from CSR-development of a new strategic business concept which can simultaneously create economic and societal value as well as increase the competitiveness of companies.

Table 1. Differences between CSR and CSV

	Bases	CSR	CSV
1	**Motivation/focus**	Corporate reputation	Competitive advantage
2	**Main driver**	External stakeholders	Corporate strategy
3	**Approach**	Reactive and defensive	Proactive
4	**Measurement**	Spending, standard ESG metrics	Social and economics values
5	**Management**	CSR/ public affairs	Across the firm
6	**Business Benefits**	Risk reduction and goodwill	New business opportunities
7	**Social benefits**	Successful projects	Large scale, sustainable chain
8	**Value**	Doing good	Economic and societal benefits relative to cost
9	**Type**	Citizenship, philanthropy, sustainability	Joint company and community value creation
10	**Profit definition**	Separate from profit maximization	Integral to profit maximization
11	**Motives**	Discretionary in response to external pressures	Integral to competing strategy
12	**Budget**	Impact limited by company’s footprint and CSR budget	Realign the entire company’s budget.
13	**Agenda**	Defined by external reporting and personal preference	Company’s specific and internally guidelines
14	**Person(s) in charge**	Typically led by CSR, marketing, corporate communications, external/public/government affairs, community relations, sustainability and foundation departments	Typically led by CEO, senior executive team and individual champions across the company in close collaboration with corporate affairs and sustainability departments
15	**Example**	Fair trade purchasing	Transforming procurement to increase quality and yield

Table 2. Distinction between European Commission (2011) CSR and Porter and Kramer (2011) CSV

Category	European Commission (2011)	Porter and Kramer CSV
Role of business in society	CSR as core element for legitimation of business	
Pre requisite	Companies fulfill their legal obligations; collective between social partners	Companies fulfill their legal obligations
Aims	Contribution to inclusive growth and well-being of the society; triple-bottom	To reach simultaneously economic and social progress through value creation quantified by the relation of benefits to costs
Stakeholder	Shareholders, other stakeholders, the whole society	Varied with the concrete projects
Strategic orientation	CSR/CSV is a long-term strategy and included in the core activities of business	
Role of government	No strict regulation but flexible for businesses; Government procurement directives can be used to enhance CSR	Government should set clear and measurable social goals; public authorities should support business rather than over-regulate them

Source: Maczaldo (2015)

ISSUES, CONTROVERSIES, AND PROBLEMS

What Is Wrong With the Present (Traditional) CSR?

Basically, traditional CSR activities in most developing countries of Africa encompass employment benefits, community development and philanthropy which is not linked to the core business strategy. Porter and Kramer (2006) argued that the prevailing approach of CSR is so fragmented and so disconnected from business and its strategy that many of the greatest opportunities of companies to benefit society are obscure and lost. Again all four schools of CSR (moral obligation, license to operate sustainability, reputation) focus on the tensions between society and business rather than the interdependence; and they are not sufficient enough to enable a company to identify, prioritize and address social issues it can make the biggest impact.

According to Browne and Nuttall (2013), this CSR has failed to fulfill its core purpose in building stronger relationships with the external world because of the following. First, the head-office initiatives rarely gain the full support of the business and tend to break down in discussions over who pays and who gets the credit. Second, centralized CSR teams can easily lose touch with reality- they tend to take too narrow view of the relevant external stakeholders. Firms' investments in CSR are moderate and minimum because they consider such investments as a cost or expense factor only which takes its share of the firm's profit (Christmann & Taylor, 2006). Corporate social responsibility is considered as a means to an end, and the bare-minimum mentality de-motivates companies from further pursuing any other sort of contributory value to society (Davenport, 2011). Third, CSR focuses too closely on limiting the downside. Companies often see it only as an exercise in protecting or enhancing their reputations- to get away with irresponsible behavior elsewhere. Fourth, CSR programs tend to be short-lived and because they are separated from the company's commercial activity, they survive on the whims and caprices of senior executives rather than the value they deliver. Therefore the programs are vulnerable when there are changes in management or costs are cut. Besides, they fail to see the future business opportunities and competitive advantages that may accrue to them over their competitors in the longer term. Fifth, there is wrong perception of CSR and lack of top management support. Also, it is hard to determine the social impact and business benefits of CSR.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Many MNCs do only what they must in order to please stakeholders and obtain legitimacy, seeking to keep their actions to a minimum (Chen & Bouvain, 2009; Christmann & Taylor, 2006). According to Salzmann (2004), firms are only interested in making profits while supporting employment, investments, purchases, wages and taxes without any consideration of the welfare of the community around them. The responsible actions were due to external pressure and reputation enhancing, public relation and gaining a positive score on CSR scorecards which ultimately failed to connect CSR activities to their core business strategy; and not the desire to do good (Aspelund, Fjell & Rødland, 2015; Milliman, Ferguson & Sylvester, 2008). Porter and Kramer (2006) summed up the traditional CSR as a hodgepodge of uncoordinated CSR and philanthropic activities disconnected from the company's strategy that neither make any meaningful social impact nor strengthen the firm's long-term competitiveness.

Furthermore, scholars have argued that CSR has not proved itself in businesses of the current century because it lacks criteria of differentiation for businesses to follow this theory (Szmigin & Rutherford, 2013). The benefits of traditional CSR are often nebulous, difficult to define and measure, externally influenced, and only indirectly connected to the action being taken (Bockstette & Stamp, 2011). The traditional CSR is differentiated in motivation, implementation, and impact from strategic CSR (Werner, 2009). The CSR is carried as a reactionary and reputation-enhancing agenda with no clear strategic framework link to core business. Hence the result has suboptimal economic or social impacts on stakeholders and society. The present CSR does not fully comply with the society needs; CSR means a reduction of profits for the sake of an environmental or social environmental end (Bosch-Badia, Montllor-Serrats & Tarrazon, 2013), and stakeholders' interests are being ignored (Székely & Knirch, 2005). Although CSR has some potentials to deal with environmental issues such as carbon emission, pollution, waste disposal and oil spills (Frynas, 2009), and also emphasizes various activities including corporate governance, sustainability, stakeholders management, relationship with employees, unions, suppliers and community representatives, commitment to transparent reporting and harm reduction (Petrovic-Lazarevic, 2008), it is reactive, defensive, lack active strategic choices within companies, and fail to deal with key challenges in the business-society relationships (Frynas, 2009). Jonikas (2013) contends that CSR can often create use-value for stakeholders and society but little value for companies in terms of profit increases. He suggests that CSR should become more oriented towards CSV to help companies gain sustainable competitive advantage and make significant social impact on society.

Salzmann (2005) argues that corporations currently used both social benefits theory and practice to fulfill the requirements of environmental and social issues by rising up, at the same time, the financial aspects of the firms themselves. There has been a shift from philanthropic or ancillary CSR to a more strategic perspective because the current models of CSR have been largely ineffective at addressing society's pressing and urgent challenges (Visser, 2010; McWilliams & Siegel, 2011; Young, 2012). This requires that firms should move away from the emphasis on image to emphasis on substance; from fragmented, defensive CSR posture to an integrated, affirmative approach; go beyond good corporate citizenship, philanthropy and pre-occupation with measuring shareholders' satisfaction to creating shared value by becoming more selective in mounting initiatives whose social and business benefits are larger and distinctive (Porter & Kramer, 2006). Strategic CSR helps firms to build trust and reputation, increase financial performance, minimize risk, gain competitive advantage, enhance strategic positioning and synergistic value creation (Porter & Kramer, 2006; Juscius & Jonikas, 2013; Fleming & Jones, 2013). Strategic CSR unlocks shared value by investing in social impacts that strengthen company's

Table 3. Philanthropic and created shared value approach

Philanthropic Approach	Areas of Investments	CSV Approach	Business Benefit	Social Benefit
Drinking water/wells for local communities	Infrastructure e.g. water	Develop sustainable water utility leveraging business process	Reduce water treatment costs by charging commercial water rates	Provide water to communities that lack access to it
Provide broad- based skills training with no link to employment opportunities	Training	Create training program based on business and supplier needs and link it to jobs	Reduce employee costs by reducing on expatriate employees	Improve employability and wage-earning capabilities of local workforce
Invest in Environmental restoration unrelated to the business	Environment	Restore degraded coastlines or wetlands to reduce risk of a natural disaster to the business	Protect assets (e.g. pipelines) near coastlines from disasters	Improve the resilience of host communities to natural disasters
Funds construction of local clinic	Health Care	Develop program to reduce disease burden among population living in mine catchment area	Improve employee productivity and reduce company's health care costs	Reduce the disease burden in local communities
Provide scholarship for local students	Education	Catalyze coalition to improve secondary school educational outcomes in host community	Improve the quality of the future talent pool in host communities	Improve educational achievement and job prospects for students

Source: Hidalgo et al. (2014)

competitiveness. The CSV theory recognizes the social needs rather than focusing only on the economic needs to define markets. It also goes beyond the strategy theory by motivating companies to look at opportunities that strive to satisfy fundamental social needs of the community (Porter & Kramer, 2011).

Creation of Shared Value

Bockstette and Stamp (2011) identify ten common building blocks to create shared value to include: articulate a vision, prioritize key issues, set specific ambitious goals, deploy a wide range of assets to address the issue, manage efforts holistically across the organization, collaborate with partners, measure progress on key indicators, learn from measurement to improve efforts, address issues at scale, and communicate progress to internal and external audiences. Pfitzer et al. (2013) provide a five-step framework in the development of shared value strategy as (a) embedding a social purpose; (b) rigorously defining the social need;(c) measuring the social and business value; (d) creating the optimal innovation structure; and (e) co-creating with external stakeholders like government, universities, NGOs, and other companies. There are usually many values created but Jonikas (2013) argues that only shared value creation through CSR seems to be sustainable.

According to Porter and Kramer (2011), companies can create shared values in three levels as: re-conceiving products and markets, redefining productivity in the value chain and building supportive industry clusters at the company's locations. In order to re-conceive products and markets, companies should re-evaluate the relationships they have with their consumers, and then incorporate shared value

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

into the process of goods exchange. They can use strong advertisement, rebrand their mission to be more socially conscious and address many unmet needs in order to attract consumers to their company and products/services. This level focuses on revenue growth, market share and profitability that arise from the environmental, social, or economic development benefits delivered by a company's products and services (Porter et al, 2012). For example, Shell has established a sustainable utility company on Bonny Island, Nigeria, that serves and supply energy to over 93,000 customers (Hidalgo et al 2014).

Redefining productivity can be done in the value chain through: (a) energy use and logistics, (b) resource use, (c) procurement, (d) distribution, (e) employee productivity, and (f) location. It could also be by sub-contracting. The level focuses on improvements in internal operations that improve cost, input access, quality and productivity achieved through environmental improvements, better resource utilization, investment in employees, supplier capability and other areas. For instance, Intercontinental Hotels Group (IHG), the largest hotel company in the world, launched its Green Engage programmes in 2009 with the objective of testing dozens of options for reducing energy use, water consumption, and waste disposal in pilot hotels, and providing a detailed ranking of all possible shared value opportunities in terms of returns to IHG through substantial reductions in hotel operating costs, including energy savings of up to 25%.

Clusters include not only businesses, institutions such as academic programmes, associations and standards organizations but also broader public assets in the surrounding community such as schools and universities, clean water, fair-competition laws, quality standards and market transparency. Creating shared value from enabling local cluster development derives from improving the external environment for the company through community investments and strengthening local suppliers, local institutions, and local infrastructure in ways that also enhance business productivity. As the world's largest food and beverage company, Nestlé created clusters by implementing a rural development strategy that trains, assists and supports small diary Indian farmers with better technology in order to increase the productivity of their cattle thereby ensuring the reliable supply of high quality raw materials. In fact without a supporting cluster, productivity suffers. According to Porter and Kramer (2011), a focus on clusters and location has been all but absent in management thinking. Cluster thinking has also been missing in many economic development initiatives which have failed because they involved isolated interventions and overlooked critical complementary investments. While a key aspect of cluster building in developing and developed countries alike is the formation of open and transparent markets, companies can support cluster development in the communities in which they operate by identifying gaps and deficiencies in areas such as logistics, suppliers, distribution channels, training, market organization and educational institutions. Delgado, Porter and Stern (2010) argue that clusters help to reduce the costs and risks associated with new venture formation, and they can also increase the likelihood of survival during early years of a business' development.

They drive local competition by not only increasing operational effectiveness and strategic positioning (Porter, 2000) but also resulting in more resilient competitive advantage.

Porter and Kramer (2006) argued that firms can create shared value by using CSR strategically to achieve a competitive advantage. Companies can create and sustain a competitive advantage by cooperating with other companies in a supply chain by nurturing and building competencies through collaborative partnerships. In fact, the success of every company is affected by the supporting companies and infrastructure around it. Gradl and Jenkins (2011) noted that inclusive business model acts as a catalyst for the CSV concept. Bisgaard (2009) consideres cross-sector partnership, collaboration and alliances with non-governmental organizations (NGOs), governmental bodies and other business companies, co-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Social and business benefits associated with the levels of shared value

Levels of Shared Value	Business Results	Social Results
Re-conceiving products and markets: How targeting unmet needs drives incremental revenue and profits	-Increased revenue - Increased market share - Increased market growth - Improved profitability	- Improved patient care - Reduced carbon footprint - Improved nutrition - Improved education
Redefining productivity in the value chain: How better management of internal operations increases productivity and reduces risks	-Improved productivity -Reduced logistical and operating costs -Secured supply -Improved quality -Improved profitability	- Reduced energy use - Reduced water use - Reduced raw materials - Improved job skills - Improved employee incomes
Enabling cluster development: How changing societal conditions outside the company unleashes new growth and productivity gains	-Reduced costs - Secured supply - Improved distribution infrastructure - Improved workforce access - Improved profitability	-Improved education - Increased job creation - Improved health - Improved incomes

Source: Porter et al (2012)

creation with stakeholders and development of new business models as the strategic dimensions to create shared value. Saul (2011) focuses on social innovation to enhance shared value creation.

Fjell and Rødland (2015) found that MNCs can create shared value by pursuing the two different methods of responsible differentiations to obtain competitive advantage over competitors, and by sustainable value innovation to have a blue ocean based on responsible actions (green planet strategy). Also a company can instigate shared value by solving problems through the products and services it creates, addressing problems through company operations, including better use of natural resources and a business investing outside its operations in order to solve problems connected with company growth and productivity, such as improving growing techniques. According to Porter and Kramer (2011), to create social value companies must invest in areas that address social and environmental objective; to create share value they must invest in long-term business competitiveness that simultaneously address social and environmental objectives and to create business value, they should invest in long-term competitiveness. Effective internal communication of CSR implementation is one essential ingredient to embed value creation in a company. Companies with economies of scale can also use pricing to create shared value (Bertini & Gourville, 2012).

Shared Value Creation and Appropriation

There is distinction between value creation and value appropriation; organizations that create new value may lose except they share this value with other stakeholders such as employees, competitors or society (Nohria & Ghoshal, 1994; Makadok & Coff, 2002; Chatain & Zemsky, 2011; Porter & Kramer, 2011). According to Di Gregorio (2013), value appropriation is a two-step process through which a firm first competes against other firms to create and protect appropriation streams (inter-organizational value appropriation), and then managers, employees, shareholders and other stakeholders compete to capture the value that has been retained within the firm (intra-organizational value appropriation). Companies will not only benefit by creating and capturing value, but also by sharing or appropriating it. Both value creation and value appropriation capabilities are required for achieving sustainable competitive advantage and superior financial performance (Ghemawat, 1991; Mizik & Jacobson, 2003). But a firm must strive

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

for balance (March, 1991; Mizik & Jacobson, 2003) or integrate the two (Di Gregorio, 2013) depending on its choice. It is argued that value appropriation is the more relevant process since it only impacts firm profitability (Barney, 2001); it is also of more immediate concern to managers and researchers than value creation (Di Gregorio, 2013).

Basically, societal value created is captured by the innovating firms, consumers, communities and other firms-competitors and non-competitors (Mansfield et al., 1977). Value creation often entails the development of strategic resources while value appropriation entails the extraction of value that is embedded in resources. Whereas value creation influences the potential magnitude of the advantage, value appropriation influences the amount of the advantage the firm is able to capture and the length of time the advantage persists. Nevertheless there is a trade-offs in the strategic emphasis by firms between developing customer-value creation and value appropriation capabilities. Various organizational resources and capabilities such as technological (R&D), financial, physical, legal, human, organizational, informational, and relational capabilities influence value creation and value appropriation (Mizik et al., 2003). Di Gregorio (2013) argued that value is not created by resources, but by the actions of individuals and organizations in factor markets, internalized transactions, and product markets (dynamic capabilities). However, resources plays key role because they are the result of value creation processes and they are exploited in value appropriation processes. Di Gregorio (2013) identifies four elements of value appropriation that apply to both inter- and intra-organizational contexts to include: market-based bargaining power, relation-based power, isolating mechanisms, and opportunity-based action.

CREATED SHARED VALUE IN THE EXTRACTIVE INDUSTRIES: FROM LOCAL CONTENT TO CREATED SHARED VALUE

According to Porter (2014), the extractives sector represents a significant opportunity for impact on society given its unique characteristics which include: $3.5 trillion in annual revenues (about 5% of global GDP as at 2012); long time horizon for operations; multiple points of interaction with local communities; and often located in remote areas with major societal needs and poor infrastructure, generate employment, revenues for the government and with significant impact on procurement and the gross domestic product (GDP). The economic value created by extractive companies can transform the lives of millions living in resource-rich, cash-poor countries. The extractives sectors are a critical source for economic and social development in many of these countries. But most developing countries have failed to fully capitalize on the societal opportunities created by oil and gas or mining companies. Instead there are increasing conflicts, agitations and militancy in this sector and countries like the Niger Delta region of Nigeria and the platinum mines in South Africa. Consequently, 23 out of the 25 nations that depend most heavily on minerals and fuels are poor with low Human Development Index (HDI) and GDP.

The local content, "non-technical" risk management and current CSR approach used by the extractive industries have largely limited the actualization of this objective. Therefore, shared value is advocated as a new way to address the underlying root causes of community concerns and unlock economic opportunities for companies in the extractive sector including the oil and gas industry (Hidalgo, Peterson, Sith & Foley, 2014; Organization for Economic Co-operation and Development-OECD, 2016; Swartout, 2016). The concept of shared value is becoming a linchpin of the modern mining and extractive sectors (Crosbey et al., 2016). Given advances and changes in technology, it is predicted that the mining of the future will involve decreased local equipment-related procurement resulting in drop in benefits derived

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

from local procurement and employment. The consequence is of critical concerns to firms, host communities and countries like Nigeria which depend and earn a greater part of their revenues from the sector. Therefore, firms and countries are expected to focus on other ways in which mining can contribute to the host economy and communities. Table 5 indicates the shared valued opportunities in the extractive industries.

Outside the realms of procurement and employment, there are four other avenues through which shared value can be created (Cosbey et al., 2016). These include:

- **Downstream (Forward) Linkages:** Relate to the beneficiation of extracted commodities through refining, smelting and further downstream processing of the commodity before reaching the final consumer(s).
- **Horizontal (Lateral) Linkages:** Relate to the development of new non-mining-related industries adapting the capabilities developed to serve the mining-related value chain.
- **Knowledge (Technological) Linkages:** Relate to the transfer of knowledge and technological know- how to state-owned companies, the employees of the mine and to the labour force involved in the mine's value chain.
- **Spatial (Infrastructure) Linkages:** Relate to the benefits associated with the infrastructure developed for an extractive-industry project (such as railways) profiting other actors in the economy.

There might be revision to the fiscal element of shared value, adoption of more progressive fiscal regimes, changes to the fundamental relationship between investor and host governments and evolution of a more collaboration and commitment to defined roles for government, extractive industries and civil societies. National or host governments can help companies create shared value by creating enabling policies and regulations as well as show collaboration by acting as knowledge broker, serving as convener of interested stakeholders, acting as operating partner for shared value strategies and incentivizing shared value investments. On the other hand companies can take a long-term view toward solving societal issues to benefit the business; they should invest in improving business unit operations' knowledge of societal issues and vice-versa, measure societal outcomes and their impact on the business, and work with other multinational companies in the extractive sectors, NGOs, and governments. The five actionable steps specified in the OECD (2016) framework on collaborative strategies for in-country shared value creation of extractive projects and the roles of government, extractive industries and civil societies are shown in Table 6.

Table 5. Shared values opportunities in extractives and mining industries

Re-Conceiving Products and Market	Re-Defining Productivity in the Value Chains	Creating Enabling Local Environment
Build local markets for intermediate products created by extractive activity (e.g., water, electricity, transport, housing)	Improve local workforce capabilities Develop local suppliers Improve the health of employees Improve utilization of water, energy and other resources in operations Increase local emergency response capabilities	Develop the local cluster supporting the extractives sector Invest in shared local infrastructure and logistics networks Partner with other local clusters and government in building community infrastructure Play an active role in broad-based regional economic and community development

Table 6. Actionable steps and roles of government, extractive industries and civil societies for in-country shared value creation

Actionable Steps	Roles of Government, Extractive Industries and Civil Societies			
	Government	**Extractive Industries**	**Government & Extractive Industries**	**Government, Extractive Industries & Civil Societies**
1.Adopt a comprehensive long-term vision and implementation strategy to build competitive and diversified economies and create in-country shared value out of resources	Articulate vision, coordination; limit rent seeking opportunities; enhance economic competiveness; transparent reporting; counter macro-economic policies	Take long-term approach, engage with relevant stakeholders; understand local dynamics and power structures in resource-bearing communities; share best practices developed		Build inclusive fora for continuous dialogue; forecast the necessary infrastructure and capacity to achieve extractive stage; identify opportunities to which business activities can make a significant positive contribution
2.Build an empirical basis to inform decision making through an inclusive participatory process	Serve as conveners and identify the stakeholders; Identify trade-offs and associated costs/benefits; create the conditions for proactive interventions and reduce conflicts recognize areas of value creation	Provide information on an individual basis (to avoid any anti-competitive issues) to governments on future demand		Assess the extractives sector's collective current and future needs; map out potential economic opportunities and potential negative impacts and constraints of project; Identify barriers to entry for production of goods/
3.Unlock opportunities for in-country shared value creation: local workforce and supplier development; shared infrastructure (power, water and transport)				
3A. Shared Power	Take a long-term perspective of potential synergies, affordability and willingness to pay design appropriate power pricing mechanisms consider other partners in development of power generation capacity; engage in regional and sub-regional policy co-ordination for infrastructure development and power sharing	Provide forecasts regarding anticipated demand for power and sourcing of power; implement energy efficient operations; develop electricity self-supply plans that align with government's plans	Undertake early discussions regarding power infrastructure needs, synergies, efficiencies and other opportunities for shared value creation with respect to power generation and distribution; articulate government and company responsibilities and liabilities for any project undertaken; consider power usage and distribution	
3B.Shared value for water	Adopt an integrated approach to water resource management; have a well-designed, adjustable and transparent plans for allocating water resources among competing uses; ensure policy coherence and adequate institutional framework for used water	Engage with local communities and water users to understand water-related issues and risks and offer solution; collaborate with other extractives; collaborate with other extractives companies for water management and allocation	Devise mutually beneficial arrangements; share knowledge, information and expertise	
3C.Shared use for transport infrastructure	Provide a clear and effective regulatory framework for multi-purpose and multi-user infrastructure; avoid exclusive access or monopoly pricing; effective coordination and policy encouraging investment in transport infrastructure	Collaborate with other extractive companies from the same basin to determine the potential for shared value by developing shared transport infrastructure	Devise mutually beneficial arrangements concerning transport infrastructure	
4.Support and contribute to innovation leading to new products and services	Identify changing trends in global consumption and production patterns; consider trade-offs associated with technological innovation; support R&D efforts to identify, adapt, and transfer technology	Invest in specialized technologies that reduce environmental impact; increase use of renewable energy; Contribute to improving the innovative capacity of subsidiaries and subcontractors and finding solutions to challenges shared by extractive industries	Engage in co-operation based on project life cycle analysis, covering the entire value chain and offering the opportunity to build on best practices of several sectors	
5.Establish effective and transparent monitoring and evaluation systems and regularly review the collaborative strategy		Integrate the standardized methodology and reporting procedures into internal local monitoring and evaluation system; Provide detailed reporting to better measure and manage company activities		Build on existing structures e.g. EITI, MSG develop governance mechanisms to ensure effective and transparent monitoring and evaluation; evaluate impact, local industry participation, efficient use of limited resources and creation of value for all stakeholders; re-evaluate measurements from time-to-time communicate results to stakeholders

CSV Opportunities and Benefits in Developing Countries

Despite the criticisms, CSV has been applauded for the strengths in appealing to practitioners and scholars, elevating social goals to a strategic level, defining a role for government in responsible behaviour and propagating the idea of "conscious and caring capitalism" (Crane, Palazzo, Spence & Matten, 2014). Moreover, there is growing consensus that through CSV firms can better respond to the societal, environmental and market needs, support business activities, and develop innovative capacity. Moczadlo (2015) argued that Porter and Kramer's CSV bring the business world closer to society's issues as it focuses on unmet needs and under-served markets or Blue Ocean Strategy (Kim &Mauborgne, 2005) and the business model innovation which is a key factor in competitiveness (Scott-Kemmis, 2012). In fact, the shared value has already made some companies like WEG Corporation in Brazil and HP to be industry leaders, improved companies' value chains as well as strengthened local economies in companies such as Intel, Nestle, Unilever and Nepresso, and led to long-term company's profitability, competitive advantage and sustainability like the case of Coca Cola Company.

There are numerous examples of multinational organizations that are either already implementing and investing in CSV or making efforts to implement CSV as part of their business strategies such as: Coca-Cola, Nestlé, Nepresso, Unilever, Intel, Nutreco, McDonald's, IBM, Cisco, Dow, Intel, Becton Dickinson (BD), Novartis, Wal-Mart, Inter-American Development bank, General Motor (GM), General Electric (GE), Google, Johnson and Johnson, InterContinental Hotels Group (IHG) and social entrepreneurs like Gramen Bank in Bangladesh among others (Porter & Kramer, 2011; Porter et al. 2012; World Bank, 2013).

A typical example of CSV is the corporate Water Stewardship Programme particularly the Replenish Africa Initiative (RAIN) water for schools created by Coca-Cola Company in 2009 but presently in 37 African countries. The programme has the intention to provide sustainable and safe water access to 6 million people across Africa by the end of 2020.Similarly, the WASH programme, particularly the RAIN Water for Schools, not only creates social value and but also indirectly promotes business value and contributes to virtuous cycles of creating value for local communities (Mitler, Rostorfer & Ledbetter, 2015). The Coca Cola Company also launched a two-month Coletivo Retail training programme for Brazilian low-income (including youth and students) in 2009 to enable retailers gain hands-on experience, placement and enhance their performance. By 2015, about 25,000 youths have graduated with over 10% of Coletivo graduates setting up their own retail stores with micro-credit support as well as the Coletivo Retail community sales growing on an annual average of 9.5% (Coca-Cola Supports, 2015). Moreover, the Coca Cola Company's 5by20 Initiatives aim to improve the economic empowerment of five million women entrepreneurs within the company's global value chain by 2020 through a combination of core business operations, cross-sector partnership and strategic social investment mostly in developing countries. The Coca-Cola Company began working toward its 5by20 commitment in Brazil, India, the Philippines, and South Africa in 2010. Over, 300,000 women have participated in 5by20 initiatives in 12 countries (Brazil, China, Costa Rica, Egypt, Haiti, India, Kenya, Mexico, Nigeria, Philippines, South Africa, and Thailand) as at 2013. The company expects 5by20 initiatives to reach 1.5 million women in 20 to 30 countries by 2015 and 5 million women in 100 countries by 2020. The Coca Cola's 5by 20 initiatives include: Coletivo Recycling and Artesians in Brazil, Project Nurture in Kenya and Uganda, the STAR Programme in the Philippines, and Kwanza's Micro Distribution Center Model in Tanzania (Jenkins, Valikai & Baptista, 2013).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The CSV of Nestle for joint value optimization with society encompasses three areas of water, rural development and nutrition. Nestlé aligned corporate vision with a social purpose and set enterprise-wide shared value goals to guide business planning. For instance, Nestlé trains and assists smallholder farmers to foster rural development while ensuring a reliable supply of high quality raw materials. Nepresso's collaboration focuses on three commitments: Coffee, Capsules and Carbon Footprint as well as creating shared value for society. The areas where value was created and shared in McDonald were: employee welfare, waste, climate/energy, animal welfare, water, raw materials and community impact. Unilever's poverty eradication, women empowerment, education of rural dwellers and hand-washing campaigns have recorded a huge success in bringing profitable micro-enterprise opportunities for rural women, reducing diseases and saving many lives of children in Asia and Africa (Kreckova, 2015). Intel tied a portion of incentive compensation to performance on social and environmental priorities.

BHP Billiton invested $50M in northern Chile to create a cluster of world-class mining suppliers. BHP created the "World Class Supplier Program" in Chile which engaged local suppliers to develop innovative solutions to manage various areas of BHP Billiton's operations such as water, energy, human capital, maintenance, air quality, acid mist control, and leaching. The goal of the initiative was for Chile to have at least 250 world-class suppliers that can export their services to mining projects around the world by 2020.The 36 suppliers involved employ 5,000 people, and BHP Billiton has achieved $121m in net present value of cost savings as at 2012 (Porter, 2014) and generated combined sales of $400 million. The social and economic benefits for BHP Billiton include: creation of world-class suppliers for the mining sector and high-quality employment, and reduced cost of inputs, goods, and services. Rio Tinto's Diavik Diamond Mine in Northern Canada worked with communities, contractors, local governments and education institutions to develop a local workforce and supplier base which enables it to hire 62% of its employees, and sources 71% of goods and services locally, saving transportation costs (Porter, 2014). For SNC-Lavalin with interest in mining and metallurgy, oil and gas, infrastructure and environment and power, the Local Resource Development Initiative ™ (LRDI) helps to maximize local benefits and create shared value with communities as the LRDI aligns project objectives with community objectives whenever possible, promotes sustainability opportunities, reduces project costs and generates values for farmers, communities and operating company in many countries of Africa, Latin America and Asia.

Criticisms of Porter and Kramer's CSV

Despite the many benefits and opportunities acclaim to CSV, there are also many critics of Porter and Kramer's CSV (such as Crane, Palazzo, Spence & Matten, 2014; Mohammed, 2013; Denning, 2011 & 2012; Hartman & Werhane, 2013; Wilburn & Wilburn, 2014; Rocchi & Fererro, 2014; Escudero, 2013 and others) who argued that CSV is not new or original; CSV ignores the tensions inherent to responsible business activity, naïve about business compliance and it is based on a shallow conception of the corporation's role in society (Crane et al., 2014). CSV is "undercooked", ignores tensions and differences between societal and economic goals, lacks specific framework upon which shared value creation can be measured (Crane et al., 2014; Mohammed, 2013), can't fix capitalism (Denning, 2011, 2012), incomplete mental model (Hartman & Werhane, 2013), misunderstood concept (Wilburn & Wilburn, 2014), incomplete and process-orientation ignoring the people in the work process (Rocchi & Fererro, 2014), akin to strategic CSR and not a new approach (Escudero, 2013). It has also been argued that the CSV is not different from Elkington's (1998) that focused on the triple-bottom line of economic, environmental and social goals. Again, the main idea is not so different from strategic CSR concept

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Examples of created shared value social and economic benefits in developing countries

S/no	Company/ Organization	Country	Initiatives	Social Benefits	Economic/Business Benefits
1	Coca Cola	37African countries including South Africa	Corporate water stewardship and Replenish Africa Initiative (RAIN) water for schools	-Improvements across a wide range of capabilities, both directly and indirectly -Increase in the value of natural capital	Every US$1 invested would yield at least US$2 in benefits, and in some locations it could be over US$11 in benefits for every US$1 invested
		Brazil	A two-month Coletivo Retail training programme for Brazilian low-income (including youth and students employment) in 2009	- 30% of the young people trained immediately land their first job with Coca-Cola or one of its partners - 10% set up their own business with micro-credit support from the company	- Increased sales of Coca-Cola products - Higher penetration of consumers among the emerging lower middle class segment - Better retailer performance and a stronger Coca-Cola brand connection
2	Chevron	Nigeria	Niger Delta Partnership Initiative (NDPI) and Partnership Initiative in the Niger Delta in 9 oil producing in the Niger Delta region and creation of addition value chains	Development of economic opportunities outside of Chevron's direct oil and gas supply chains	Reduction in business disruptions due to greater economic opportunities outside of oil and gas; potential reductions in supply chain costs
			Chevron's General Memorandum of Understanding (GMOU) approach in the Niger Delta for building local governance and decision-making capabilities through delivering value for the business via reduced risk and a stronger operating environment	- Community-led disruptions to Chevron operations dropped from 81 in 1998 to 11 in 2011 to zero in 2012 - Create a platform for communities to debate, discuss, and agree on their priorities	- Create enabling environment for the company to do its business -Significant cost saving in company's operations - Saving of tens of millions of dollars in lost revenues in vandalism and theft
3	BHP Billiton	Chile	Creation of at least 250 world-class suppliers that can export their services to mining projects around the world by 2020	Creation of world-class suppliers for the mining sector and high-quality employment	Reduced cost of inputs, goods, and services
4	AngloGold Ashanti	Ghana	Addresses health problems (endemic malaria) by implementing an integrated control programme involving multiple community-level interventions	Decrease in disease incidence by over 72% in the first two years of the programme	Improved employee productivity, lowered treatment costs, with the number of person-shifts lost per month falling from 7,500 to around 90 in 2012 and declining treatment costs resulting in cost savings to the company of around $600,000 per year by 2013
5	Anglo American	South Africa	Water Reclamation Plant for treatment of water for drinking and irrigation water by the local municipality in the Malahleni and Mpumalanga provinces	Access to potable water in local community, generating 25-30 million liters per day or 12% of the water requirement	Over 60% offset of treatment costs from revenues in water sold to BHP Billiton and local community, reduction in the cost of responsible environmental management and compliance with regulation
6	Banka BioLoo	India	Bio-toilet system to dispose human waste in eco-friendly manner	Improved hygienic sanitation, treated, recycle human wastes and bio-toilet for millions of people	Increased employment opportunity, growing revenues in multi-fields
7	Capital Diamond Star Group with Action Aid	Myanmar	Provide farmers with necessary training, technical and financial skills for optimal productivity, quality livelihood and increased bottom line.	Improved livelihoods through empowerment of farmers, sustainable agriculture and better access to finance and to markets for rural communities	More productive, better quality and more reliable supplier base; stronger, more loyal and better educated customer base

earlier defined by Porter and Kramer in 2006 (Neves, 2013). Nevertheless, Drucker (1984) has argued that the proper "social responsibility" of business is to tame the dragon, that is, to turn a social problem into economic opportunity and economic benefit". Wheeler, Colbert & Freeman2003 (2003) have also defended that "in certain circumstances the creation of communities and social networks or value-based networks is a pre-requisite to economic pay-off'. The idea that businesses should address new markets based on social issues, being profitable had been presented by Prahalad and Hart (2002) arguing that "low-income markets present a prodigious opportunity for the world`s wealthiest companies to seek their fortunes and bring prosperity to the aspiring poor".

Hartman and Werbane (2013) see Porter and Kramer's CSV as an incomplete mental model with imprecise conception of "profit," overemphasis on the novelty of their theory, and broadly negative description of prior attempts to achieve social progress through private enterprise. They argue that there was no explanation on the calibration of shared value from profits. Besides, some have argued that Porter and Kramer were not the first and novel to propose alternative to the single-minded pursuits of shareholders' gain, and that "shared value" is just one of the many viable means to reconstruct a corporate worldview to tackle new-world social, environmental and economic problems. Moreover, many profitable companies have been successful in addressing social problems through profitable business ventures without the need of the shared value approach. Again, the CSV omits the revision of companies' core mission to reflect the pursuit, not of "profit per se," but "profits involving social purpose". Beschorner (2013) argued that Porter and Kramer's CSV is "neither so radical nor such a departure from standard management thinking" and their ultimate reliance on economic arguments is too normatively thin to reconnect businesses with society. He suggested that prospects for a genuine reinvention of capitalism lie elsewhere. There is also criticism that ethics and integrity is left out of the CSV as well as its measurement. Companies that are most advanced in pursuing shared value lack the data they need to optimize its results. Besides, some of the companies that claim to implement CSV are not doing the right thing (Brown & Knudsen, 2013).

Challenges and Limitations of CSV

Cane et al. (2014) concluded that the short comings of CVS take us further from the solution to a challenge that we are already struggling to address. Although shared value has gained momentum, it is still largely experimental and short-term. Only a few companies particularly multinational companies like Coca-Cola, Novo Nordisk, Nestlé, Intel, and InterContinental Hotels Group among others have enshrined the shared value into their corporate objective and core business strategy due to CSR fatigue. Most companies around the world remain unaware of shared value improvement opportunities and are ill-prepared to capitalize on them when they materialize thereby limiting the company's bottom line and short- changing society of the much needed innovation to solve social problems (Porter et al., 2012). Brown and Knudsen (2013) have argued that failure to appropriately manage shared value could result in wasted resources, unsustainable projects, and in the worst cases, marred corporate reputations thereby resulting in negative social and environmental consequences. This could be as a result of companies' failure to (1) carry through responsible practice in its implementation, (2) change their overall business model to address a social or environmental problem, and (3) discuss how they should manage the complexities and trade-offs required to address social issues.

Again, studies from various sectors (food, beverages, agriculture, pharmaceutical, health care, financial services, extractives, and natural resources) advocated that firms can enhance their competitiveness by embracing the CSV concept in their business strategy (Hills et al., 2012). However, the results are

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

mainly based on successful individual cases from large Multinational corporations and the nature of the relationships between CSV and firm competitiveness in those studies is still unclear and has not been verified empirically. Also, examples and number of local listed companies as well as small and medium scale enterprises embedding CSV in their core business or moving beyond traditional CSR to the shared value in their CSR are limited. Haxby, Compela and Weperen (2014) argued that CSV can be complicated because of the diverse interests of each stakeholder and attempts to optimize value for one stakeholder can have a negative effect for others.

It is not easy to measure social activities and their impacts on a company and the economy. There are also several problems in finding reasonable and significant key performance indicators (KPIs) or metrics to measure shared value of the social and business outputs, outcomes and impacts (Giddens, 2011). In fact, the lack of understanding of the interdependency between social and business results by companies limit the opportunities for innovation, growth and social impact (Porter et al., 2012). Despite lot of suggested frameworks and approaches to measure shared value including employee engagement, stakeholder feedback, scalability, growth opportunities, risk mitigation, public policy impact, and brand and reputation impact, there is no holistic framework or universal tool on how to measure value created through CSR. Besides decision making on CSR implementation still remains subjective and one-sided in most cases (Jonikas, 2014). Again, Porter et al. (2012) argued that the framework to link social progress directly to business success and vice versa is still missing Moreover, the relationship between social welfare and company profitability is complex (Lin et al., 2009). The analysis of sustainability results is complicated "due to the wide range of reporting practices for environmental, social and corporate governance risks/opportunities and also due to the difficulty of verifying the accuracy of the information provided by companies" (Székely & Knirsch, 2005). Hidalgo et al. (2014) summarized four interrelated and entrenched challenges that inhibit creation of shared value to include: inadequate organizational structure and behavior or culture, incomplete measurement costs and benefits, low motivation for collaboration and lack of alignment with government.

CSV AND SUSTAINABLE, INCLUSIVE DEVELOPMENT OF DEVELOPING COUNTRIES

The Brundtland Report of the World Commission for Environment and Development (1987) defines sustainable development as development that meets the needs of the present generation without compromising the ability of the future generations to meet their needs. In 2015, the world leaders agreed that the realization of the sustainable development goals (SDGs) by 2030 needs governments' partnership with businesses and other stakeholders. A recent survey by Fleishman Hillard and the U.S. Chamber of Commerce Foundation in May, 2015 identified top 5 SDGs as important to business in the post 2015 to include: build resilient infrastructure (67%), sustain economic growth (65%), achieve gender equality (60%), ensure quality education (52%) and strengthen global partnership (44%). The 'My world 2015' survey by the United Nations put the three top concerns the world over to include: good education, better health care and better job opportunities. The CSV tends to be moving corporations towards the direction of achieving these goals through shared value approach which is premised on the simultaneous realization of economic, social and societal progress. Through the inclusive business strategy, the CSV helps to integrate poor and low income communities into the leading companies' value chains in order to create

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

new opportunities for poor people at the bottom of the pyramid, increase their incomes, improve the living standards and create a competitive value chain and long term economic value for the companies.

At its heart, the notion of shared value pertains to the sustainable development of the host community and countries. For instance, the OECD (2016) framework for collaborative Strategies for in-country shared value creation in the extractive sector is a tool for forging a public-private alliance which can be used to advance the sustainable development agenda of 2030 adopted by the United Nations in 2015. Specifically, the OECD framework supports the achievement of SDGs 8 (promote inclusive and sustainable economic growth, employment and decent work for all), 9 (build resilient infrastructure, promote sustainable industrialization and foster innovation), 6 (ensure access to water and sanitation for all) and 7 (ensure access to affordable, reliable, sustainable and modern energy for all). According to Cosbey et al. (2016), the shared-value paradigm, by promising to deliver benefits to host communities, regions and countries, has become increasingly critical for mining companies in securing their social license to operate. The delicate balance inherent in the shared-value paradigm is especially relevant for developing countries and other states (most of which are resource-driven countries) where poverty eradication, social development and environmental protection are urgent development challenges.

Due to the expectations that the application of the shared-value paradigm in the mining and extractive sector would bring substantial developmental benefits to large populations and the link to sustainable development, it has been endorsed to become the mainstay of most major mining policy frameworks such as: the Africa Mining Vision (African Union, 2009), the Mining Policy Framework (Intergovernmental Forum (IGF) on Mining, Minerals, Metals and Sustainable Development (2012), and the OECD Framework on Public-Private Collaboration for in-Country Shared Value Creation from Extractive Projects (OECD, 2016).The International Council for Mining and Metals (ICMM) also reference the shared-value concept in their good practice guidance (ICMM, 2015).Leading civil society organizations working in the area of mining and sustainable development like Columbia Center on Sustainable Investment (CCSI), 2015; International Institute for Environment and Development (IIED); International Institute for Sustainable Development (IISD), 2014; and Natural Resource Governance Institute (NRGI), 2015 have fully subscribed to shared value. Both the developed and developing countries are benefiting and enjoying from the shared value concept as more and more corporations are keying into the social change. While the focus in developed markets is less on poverty but more on education, income inequalities, health and wellness, environment and sustainability, the CSV focus by corporations in developing markets is building capacity and financing, empowerment and entrepreneurship, expansion of the value chain and raising the standard of living in the communities of operations.

Shared value approach has the potentials to foster sustainable development of developing countries as CSV concept is embraced and promoted not only by the few multinationals but all companies. For instance, the activities of Novartis to provide the locals in remote villages with health services and train some of them to be health educators in India, Vietnam, Kenya and Indonesia resulted in over 10 million receiving health education and 750,000 direct health services. The '+' projects by Phillips a multi-sector partnership with governments, NGOs and consumers in Southeast Asia reached over 50 million people in Indonesia, Thailand and Singapore, generating 28,000 social media conversations. The goal was to increase Philips' bottom line and simultaneously have positive social impact. Phillips sourced ideas from local consumers to provide insights that enabled the company to accelerate innovation and ultimately improve the health and well-being of consumers. Vodafone partnered with a Kenyan telecoms firm, Sarifoam and created a new market by launching M-Pesa in Kenya in 2007.Vodafone's goal was to support financial inclusion in Kenya through a money transfer solution with a simple key message, "Send Money

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Home", which enabled customers to send money directly between each other using mobile technology. By 2015, M-Pesa is now available in many countries including India, Egypt, Tanzania, South Africa, Democratic Republic of Congo, Lesotho, Mozambique, Romania and Albania with over 19.9 million active customers who used M-Pesa with over 3.4 billion transactions processed yearly.

Following the challenges of a quadruple burden of disease, an undersupply of doctors and an egalitarian healthcare system presented a significant challenge to the healthcare industry in South Africa, Discovery Insurance Company developed Vitality, a behaviour based wellness solution that incentivized healthier behavior by giving customers access to wellness partners such as gyms, empowering them with healthcare knowledge and tools, and offering financial incentives that increased as members engaged with the Vitality programme. The increased health and fitness levels, lowered the frequency and cost of hospitalization and reduced the disease burden of customers improve the financial incentives and rewards that by 2015, the company currently serves over 5.1 million clients across South Africa, the United Kingdom, the United States, China, Singapore, Australia and Hong Kong. Discovery is globally acknowledged as the pioneer of shared value insurance. The shared value presents an open window of opportunities and benefits not only for economic prosperity of business but also the sustainable development of developing economies. Therefore a high level corporate commitment to the shared value concept, and ingenuity of the private sector and business leaders in forming alliances would lead to the actualization of the United Nation's sustainable development goals (UN SDGs) by eradicating poverty in all its forms by 2030.

SOLUTIONS AND RECOMMENDATIONS

In an era of increasingly stakeholders' knowledgeable demands and expectations amidst the increasing global challenges, integrating economic and social goals will demonstrate corporation's real concerns and ability to achieve the "win-wins" of the shared value model, long-term sustainability, competitive advantage and economic prosperity. In order to give concrete meaning to the concept of CSV in developing economies, the companies must change the philanthropic way that CSR is presently conceptualized and organized because of its limitations in helping them to achieve competitive advantages and adequately address societal problems. Based on the shared value approach, companies in developing countries should restructure and prioritize CSR to be part of their organizational culture, value and core business strategy that emphasizes sustainability by redefining corporate leadership and integrating economic and social goals in their business pursuits in addressing societal problems. The integration makes CSR a core element of strategy, structure and process, eliminates distinct CSR functions in the organization and makes CSR a mutual responsibility across the firm - from top down and thereby increasing its credibility and implementation.

However, achieving shared value will require a radical and collective rethinking of management practice by all parties. There must be strong commitment at the executive, top management level and employees; Leading managers of global players as well as of small and medium companies in developing countries must discuss and take CSR very seriously by going beyond "green washing" or "window dressing". They must begin to embrace and transmit the CSV vision and ideology among all employees of their organizations through re-conceiving new products and services in new markets, improving productivity and developing clusters. Therefore, companies would need to incorporate shared value thinking into the operations of employees at all levels of their businesses to really transform capitalism and bring about

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

inclusive and sustainable development. The realization of the SDGs in 2030 requires that companies in developing countries have a major mindset change towards the adoption of the CSV agenda. This will involve the companies working inside out and embracing top down leadership, commitment and strategy as well as a bottom up overhauling of the operating models to reflect total commitment; CSV takes time, energy, tenacity and patience to embed and thus the process requires change managers and skilled leaders rather than programme managers (Bockstette & Stamp, 2011; AT Kearney, 2015). In fact, achieving a successful, sustainable and scalable shared value requires significant changes in the way that corporations do business. Therefore, businesses in developing countries must change their business models and current CSR philosophy to include shared value creation and business value sustainability.

Government and regulators in developing countries should recognize their roles in helping businesses to create shared value by focusing on measuring environmental performance and introducing standards, phase-in periods and support for technology that would promote innovation, improve the environment and increase competitiveness of business simultaneously. They would need to limit the pursuit of exploitative, unfair or deceptive practices in which companies benefit at the expense of society. Governments can help companies create shared value by: creating enabling policies and regulations, showing collaboration by acting as knowledge broker, serving as convener of interested stakeholders, acting as operating partner for shared value strategies and incentivizing shared value investments. Regulatory authorities like the National Hydrocarbon Agency (NHA) in Columbia must promote shared value creation through its regulatory framework. Although local content presents one of the clearest opportunities to create shared value, governments in developing countries particularly those with rich minerals and extractive industries must collaborate with companies to access opportunities to deliver real value for business and society across different areas of investments based on shared value approach.

On the other hand, companies must take a long-term view toward solving societal issues that would benefit the business by investing in improved business unit operations' knowledge of societal issues. They should measure societal outcomes and their impact on the business, and work with other multinational companies, NGOs and governments to create shared value. They must also take concrete actions to shift the current dynamic relationships between the corporations and government from one that views for instance extractive companies as contractors who pay for the privilege of carrying out extraction to one that sees these companies as development partners who could help solve societal issues of concern to government and create shared values through direct engagement with various levels of governments and communities, capacity building and indirect support for independent, third-party efforts. Faculties and business schools would also need to broaden their curricula and teaching to include: efficient use and stewardship of all forms of resources, human and societal needs and how to serve non-traditional customer groups; because these would define the next-generation thinking on value chains.

CONCLUSION

The chapter examines CSV and the inclusive, sustainable development of developing countries The CSV is a (r)evolutionary strategic management thinking meant to enhance the companies' competitiveness while simultaneously advancing their economic and social conditions in the society they operate. It challenges the constrained corporate mindset of lip-service philanthropic CSR activities of business over half a century to making it a major solver of society's problems in a much beneficial and profitable ways through creation of shared values. Created shared value tasks companies in developing countries

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to go beyond CSR to addressing social and society's issues in addition to their pursuit of profits by incorporating social and societal values into their economic agenda. The shared values created by these companies in developing countries would give rise to long-term corporate profitability, competitiveness and sustainable development of host communities and countries. Interestingly, evidence abound of companies at least of global multinational and transnational companies in developed and developing countries, which have already keyed into the CSV enjoying immense profits, sales growth and sustainable competitive advantages through integration of social and economic goal while also addressing societal needs. Therefore, companies including extractive and mining industries in developing countries must begin to take a long-term approach to social investments and prosperity of company, host communities or countries by embracing the pillars of shared value of re-conceiving new products and services, identifying new market opportunities and enabling clusters development. It has been demonstrated that the created shared value has the potentials to foster unparalleled economic growth, prosperity and sustainable development in countries when companies start to think a new and look at decisions and opportunities through the lens of shared value.

Although, the created shared value approach is being embraced and applied by most global multinational corporations, there is no known study in Nigeria. Therefore a study of the current CSR practices is recommended on whether the shared value concept is already being practiced by indigenous companies in Nigeria, the influencing factors and challenges of creating shared value in turbulent environments.

KEY TERMS AND DEFINITIONS

Corporate Social Responsibility: This refers to the continuing commitment by business to contribute to economic development while improving the quality of life of the workforce and their families as well as of the community and society at large.

Created Share Value: This is a paradigm shift in corporate social responsibility and sustainability strategy where business create economic values and values for societies through the simultaneous pursuit of economic, social and societal goals. Companies can create shared values through re-conceiving products and markets, redefining productivity in the value chain and building supportive industry clusters at the company's locations.

Shared Value: This can be defined as policies and operating practices that enhance the competitiveness of a company while simultaneously advancing the economic and social conditions in the community in which it operates.

Sustainable Development: This refers to development that meets the needs of the present generation without compromising the ability of the future generations to meet their needs.

This research was previously published in Value Sharing for Sustainable and Inclusive Development edited by Mario Risso and Silvia Testarmata, pages 122-153, copyright year 2018 by Business Science Reference (an imprint of IGI Global).

Chapter 56
Green Entrepreneurship in Transitional Economies: Breaking Through the Constraints of Legitimacy

Yang Gao

ABSTRACT

With environmental pollution, climate change and resource scarcity being serious global issues, green entrepreneurship is increasingly seen as an approach to simultaneously address economic performance, environmental impact and social responsibility. As green entrepreneurship needs to consider both venture performance and social responsibility, it will be subject to legitimacy constraints at the institutional level. Especially for transition economies in different countries, institutional uncertainty is a key factor. Better green performance can be easily achieved if green startups have a higher level of legitimacy. However, against the background of transitional economies, the increase in institutional uncertainty will damage the promotion of political legitimacy and make the enterprises subject to political legitimacy constraints lose their green performance. Overall startups in different industries need to develop green actions under the pressure of institutional constraints, and governments also need to improve policies and regulations quickly.

INTRODUCTION

With the deterioration of global environment and the worsening energy contradiction, balancing the conflicts between economic development and environmental protection has caused great difficulties for governments, academia and industries all around the world. Multiple events, including the oil spill of British Petroleum in the Gulf of Mexico and serious PM2.5 in China, have made the governments and enterprises realize the inevitability and urgency of a green transformation. As the subject of production, enterprises play a significant role in the development of national economic and product market. However, when enterprises provide consumers with products and service bringing convenience for them, many production processes will destroy the sustainable development of ecological environment. Therefore, an important component of addressing sustainable development issues and environmental degradation will hinge on making up for and improving the lack of social responsibility of corporations (Rockström, J., Lannerstad, M., & Falkenmark, M., 2007; Lin, C.S., Chang, R.Y., & Dang, V.T., 2015). As the society's sensitivity to environmental problems, energy consumption and pollution continues to rise, these elements become the important factors threatening enterprise legitimacy. So, there is an increasing voice for corporations to develop green businesses that takes both ecological benefits and economic benefits into account, that is, GE. It is recognized by governments, ventures, customers and other stakeholders, as well as integrates business entrepreneurship and sustainable development, simultaneously considering the sustainable development of environment, economy and society (Allen & Malin, 2008; Isaak, 1997, pp.80-90). Therefore, whether enterprises with GPO can really obtain green performance and how legitimacy constraints influence the achievement of green performance in green companies have drawn the attention of business and academia.

GE refers to entrepreneurial behavior in an enterprise's green innovation of products, services and market development to generate profit while considering environmental protection (Cohen & Winn, 2007; Dean & McMullen, 2007). Green entrepreneurship theory gradually developed with the integration of entrepreneurship theory and social enterprise theory. Under the dual functions of eco-orientation and market-orientation, enterprises are not likely to be burdened by GE as it will provide vast resources for enterprise development (Hartman & Stafford, 1997; Soto-Acosta, P., Cismaru, D.M., Vătămănescu, E.M., & Ciochină, R.S., 2016). According to the definition of EO by Miller and Friesen (1983), this study believes that green entrepreneurial corporations need to own green entrepreneurial orientation (GEO), which contains green innovation, green risk taking and green proactiveness. As green entrepreneurial corporations need to undertake social responsibility, it is particularly vital for them to gain legitimacy. Suchman (1995) proposes that legitimacy refers to the overall evaluation of external stakeholders about appropriateness of corporate behavior. The content involves both social responsibility and other standards such as competitive advantage and enterprise scale. Breaking through legitimacy constraints and achieving green performance have been the main purposes of enterprises which launch green entrepreneurship activities.

Because proactive green-oriented businesses not only concern about business performance but also consider social responsibility, the relationship between GEO and green performance will be restricted by institutional environment. As an institutionally embedded binding mechanism, the study of enterprise legitimacy has attracted attention (Shirokova, G., Bogatyreva, K., Beliaeva, T., & Puffer, S., 2016). However, present research encompasses two views. The first takes strategic theory as a starting point and treats legitimacy as a strategic resource which ventures are prone to lose, as well as claims that the ultimate purpose of seeking legitimacy is to obtain mobilized resources and securing approval and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

legitimacy from external stakeholders will be beneficial for start-ups to realize opportunity and value; this 'legitimacy—resources—business growth' model of causal relationships is widely accepted (Zimmerman & Zeitz, 2002; Lounsbury & Glynn, 2001; Navis & Glynn, 2011). Nevertheless, a large amount of scholars questioned it and indicated that legitimacy couldn't be regarded as the key resource for start-ups to overcome the disadvantage of starting anew because experienced and rational entrepreneurs are more likely to pursue more easily obtained resources in order to build their business models (Aldrich & Fiol, 1994; Zimmerman & Zeitz, 2002; Delmar & Shane, 2004). Combining the above arguments, this chapter tends towards the latter view and believes that legitimacy should exist as a limiting mechanism embedded in the institution and green-oriented entrepreneurship should not deem legitimacy as a necessary resource but take appropriate strategic action according to different contexts.

Because the causal model of 'GEO– legitimacy – resources - business growth' does not reflect the essence of legitimacy in GE, a comparative exploration about the effects on varying degrees of legitimacy on the impacts between GEO and green performance appears to be more valuable, meanwhile, this kind studies are rare. As a result, this chapter will explore the relationship between GPO and green performance and reveal the moderating effect of legitimacy. More importantly, the premise upon which it is possible to integrate legitimacy theory and green entrepreneurship theory is the existence of stable and effective systemic rules on which legitimacy evaluations depend. However, this isn't consistent with lots of transitional economies, including China. Due to the substantial institutional uncertainty created by economies, judging legitimacy guidelines produces higher heterogeneity in transition economies (Scherer, A.G., Palazzo, G. & Seidl, D., 2013). Thus, this chapter combines the situation of transition economy in China and explains the relationship among GPO, legitimacy and green performance under institutional uncertainty.

Apart from the introduction, the paper is structured along eight sections. Sections 2-4 provide a description of GE and relevant content, legitimacy and transitional economy. Section 5 is devoted on the methodologies and data for the model. Section 6 provides the results. And Section 7 provides the approaches to achieve green performance. Finally, the last section just summarizes the key issues that have arisen in this paper.

GEEEN ENTREPRENEURSHIP AND RELEVANT CONTENT

Green Entrepreneurship and Green Entrepreneurial Orientation

Green entrepreneurship (GE), also known as environmental, ecological or sustainable entrepreneurship, primarily represents the process of identifying, evaluating and utilizing economic opportunities which arise during market failure and facilitates sustainable developments of enterprises (Shane & Venkataraman, 2000; Gibbs & O'Neill, 2014). The core of GE is to discover the future market opportunity in order to develop a green market through innovation and commit to corporate social and ecological responsibility (Shepherd & Patzelt, 2011; Cohen & Winn, 2007). Because of GE's longer payback period coupled with its social responsibilities, GE often requires policies that encourage, support and are widely recognized by society, and the enterprises also play a double role in ecological construction and entrepreneurship (Ndubisi, N.O. & Nair, S.R., 2009). In addition, enterprises dedicated to GE must proactively achieve the twin objectives of marketing and ecology, making both green participation orientation and entrepreneurial orientation important (Nelson, O.N. & Sumesh, R.N., 2009; Al-Saleh, Y. & Mahroum, S.,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2015). Thus, in the study of GE, the GEO and the recognition of legitimacy under institutional theory of enterprises are significant factors in determining the success of GE enterprises.

GEO is derived from the concept of entrepreneurial orientation (EO). The proposition of EO is mainly to show the distinctive characteristics between enterprises and other conservative enterprises, that is, innovation, risk taking and proactiveness (Miller, D., 1983, 2011; Wales, W.J., 2016, pp.3-15). This not only illustrates unique entrepreneurial strategic position of enterprises but also represents the inherent entrepreneurial orientation of start-ups (Lumpkin, G.T.; Dess, G.G., 1996; Hall, J.K., Daneke, G.A, & Lenox M J, 2010). EO indicates the overall competitive orientation and tendency of organizational behavior in entrepreneurial enterprises which is applicable to GE. GEO embodies not only the market competition orientation of GE enterprises but also their green participation orientation (Kuckertz, A. & Wagner, M, 2010). GEO contains green innovation, green risk-taking and green proactiveness, respectively representing the tendency of GE enterprises to keep ahead of the competitors by implementing green technological innovation, make risky investment decisions in the face of uncertainty and lead the industry through upfront actions. GEO proposed in this chapter is a concept at the organizational level.

At present, although there are many studies about EO and entrepreneurial performance, the results vary widely. Some scholars indicate that EO is conducive to enhance entrepreneurial performance, and this impact is particularly obvious in the initial start-up phase and growth phase (Kreiser, P.M., 2011, pp.1025-1050; Eshima, Y. & Anderson, B.S., 2016). Others states that EO may have a negative effect or no effect on entrepreneurial performance (Stam, W, 2008, pp.97-111). The difference between EO and entrepreneurial performance stems from the entrepreneurial activity itself, which is dynamic and highly uncertain (Cope, J., 2005, pp.373-397; Schepers, J., Voordeckers, W., Steijvers, T. & Laveren,E, 2014). Whether enterprise performance is enhanced relies largely on specific entrepreneurial behaviors under different circumstances (Bruton, G., Susanna, K., Donald, S., & Wright, M., 2015). Therefore, there are few studies about whether enterprises with high GEO can realize high green performance. Meanwhile, compared with financial performance, green performance is only reflected in product, production process, customer safety and other aspects. So, the relationship between EO and green performance should be different.

Green Proactiveness Orientation and Green Performance

As an important dimension of GEO, green proactiveness orientation (GPO) represents the tendency of enterprises to be more proactive in adopting GE behaviors compared to its competitors (Miller, D. & Friesen, P.H., 1983). Green proactiveness-oriented enterprises tend to be industry leaders, examine industry trends, seize opportunities in advance, thus taking early actions to cope with change (Deng, Q. & Ji, S., 2015). GPO is a combination of initiative and behavior orientation and on behalf of the enterprises that take the initiative in order to have an effect on environment, rather than passive acceptance. It reflects a forward-looking tendency of enterprises, including accurate prediction of industry trends, avoidable production of low green-potential products, and guidance of customer acceptance about green products and consumption patterns, etc. (Cohen, B. & Winn, M.I., 2007). Thus, taking green actions before competitors, such as pushing out new green products, new service patterns, new green management modes and green technologies, along with having the foresight to examine development of the industry, can reflect the meaning and nature of GPO (Boulding, W. & Christen, M.,2001; Morris, M.H., Kuratko, D.F., & Covin, J.G., 2010).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green performance represents a reduction in negative impact of an enterprise on the environment while achieving a balance between business and environment interests (Wagner, M. & Schaltegger, S., 2004; Huang, M. & Wang, B.). Therefore, green performance measures an enterprise in which business and environmental needs interact (Mavragani, A., Nikolaou, I.E., & Tsagarakis, K.P., 2016; Olsthoorn, X., Tyteca, D., & Wehrmeyer, W., 2001). Achieving green performance requires ventures not only to decline pollution, waste and energy consumption, and improve customer safety but also to survive and develop (Zhu, Q. & Sarkis, J., 2004; Yang, C.S., Lu, C.S., & Haider, J.J., 2013). Based on the decreasing negative impact on the environment, green performance includes multiple measurement indicators, each representing a variable (Wagner, M. & Schaltegger, S., 2004). These variables contains reduced use of water, solid waste, energy, soil contamination, toxic inputs, non-renewable resources, wastewater emissions, and emissions into the noise, air, smell/odor emissions, risk of severe accidents and landscape damage.

The main objective of proactiveness-oriented enterprises is to gain proactive advantage and a demand premium (Boulding, W. et al., 1988; Alonso-Almeida, M.D.M., Bremser, K., Llach, J., 2015). Advantages contain deep and lasting customer impressions, strong brand recognition and high cost of customers switching to other start-ups. Meanwhile, early entrants of industry will also gain a low-cost advantage from having a lead in technology, thus downshifting the learning curve (Makadok, R., 1998, pp.683-696; Lopez, L.E. & Roberts, E.B., 2002). Enterprises who take proactiveness orientation can gain significant performance advantages. Similarly, GPO inherits the nature characteristics of proactiveness orientation, reflected in taking GE actions before competitors. Choosing advance actions of green orientation as the objective will achieve the green proactive advantage and the lead in green performance.

In the study of EO, which doesn't consider green performance as a prerequisite, an enterprise that takes proactive orientation will not necessarily achieve entrepreneurial performance (Cope, J., 2005, pp.373-397). The proactive advantage of pioneers is likely to become a proactive disadvantage eventually, and the relationship between proactiveness orientation and entrepreneurial performance is not a simple linear one. However, there is a linear relationship between GPO and green performance, which won't be influenced by the behaviors or the number of the followers. Therefore, enterprises having higher levels of GPO will have better green performance improvements.

LEGITIMACY AND ITS MODERATING EFFECT

Legitimacy

Several scholars have defined legitimacy (Parsons, T., 1960; Meyer, J.W. & Scott, W.R., 1983; Scott, W.R., 1995). Suchman (1995) conducted a comprehensive review of previous and put forward the concept of legitimacy which is widely recognized in academia: legitimacy is the general perception or assumption that the activities of an entity are appropriate, proper or desirable within the socially constructed system of norms, values, beliefs, and definitions. Enterprises are confronted with the constraints of legitimacy, incorporating the restraints of sociopolitical legitimacy and cognitive legitimacy (Becker-Blease, J.R. & Sohl, J.E., 2015). Sociopolitical legitimacy refers to the level of acceptance of key stakeholders, the public and government officials about the behavior and products, and low social legitimacy will result in registration difficulties, public rejections of product standards, financing problems, etc (Palmås, K., Andersson Schwarz, J., & Larsson, S., 2014). Cognitive legitimacy refers to the level of social understanding and acceptance of start-ups, which is largely determined by the degree of external recognition

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of new ventures and their products and services. Low cognitive performance is reflected in a low level of society-wide knowledge or difficult acceptance of products or services by the ventures, or in a low customer evaluation of products or services (Delmar, F. & Shane, S., 2004; Li, X., Wang, C., Xu, X., 2014).

Cognitive legitimacy pertains to the category of external legitimacy which is capable of being obtained by enterprises. External legitimacy is from outside an organization, in line with the support of suppliers, partners and customers for companies and the evaluations of companies by government, public media and regulators. Most existing studies emphasize legitimacy from an external perspective (Kostova, T. & Zaheer, S., 1999; Rottig, D. & ReusT, H., 2009). According to this, the study measures external legitimacy from two aspects: PL (government and regulatory agencies) and CL (suppliers, customers and partners).

The Moderating Effect of Legitimacy

In the field of entrepreneurship, it is common to discover the integration of legitimacy and opportunities. For realizing the business value of opportunities, experienced entrepreneurs tend to view commercial legitimacy (CL) significantly, regarding low CL as a key factor that leads to the difficult realization of opportunity value. This situation makes experienced entrepreneurs concentrate on CL because a higher level of legitimacy ensures a more intense spirit of innovation, and the more likely it is that a start-up will obtain the competitive advantage (Li, X. et al., 2014; Shane, S., 2000, pp.448-469; Czinkota, M., Kaufmann, H.R., & Basile, G., 2014). And in green research, compared to the value of ordinary entrepreneurship opportunities, the value of GE is more difficult to realize, because green enterprises are faced with the dual constraints of sociopolitical legitimacy and CL (Fraser, S. & Greene, F.J., 2006). Therefore, particularly for experienced entrepreneurs, constant learning behavior makes them less optimistic and focus on the evaluation of green opportunities (Kuckertz, A. & Wagner, M., 2010; Westhead, P., Ucbasaran, D., & Wright, M., 2005). As a result, when an enterprise selects GE to be ahead of its competitors, entrepreneurs should carefully think of the degree of recognition by external stakeholders because to a large extent, the level of political and commercial legitimacy will affect the realization of green opportunity value and green performance. In other words, for green entrepreneurs, various stakeholders rely on different standards and specifications to judge the legitimacy of GE, so the pressure of legitimacy will push enterprises to engage in GE more actively. Furthermore, when an enterprise perceives the level of political and commercial legitimacy goes higher, it will receive more attention and more transparent information. Thus, enterprises with higher political and commercial legitimacy own much more pressure to improve their green performance, which subsequently helps proactive green enterprises obtain green performance.

TRANSITIONAL ECONOMY AND INSTITUTIONAL UNCERTAINTY IN CHINA

Transitional Economy

'Transitional economy' refers to the transitional process from a planned economy to a market economy. Unlike developed western countries, a lot of developing countries coexists planned and market economies, government intervention and market mechanism, as well as traditional and modern economic development modes (Walder, A.G., 1995, pp.263-301; Li, Y., Peng, M. W., & Macaulay, C. D., 2013). In the situation of transitional economy, enterprises also have characteristics of ambidexterity, such

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

as continuously swaying and balancing between commercial economy and environmental protection, diversification and specialization, entrepreneurship and keeping (Oi, J.C., 1995, pp.1132-1149; Tan J., 2001, pp.359-376). The transitional economy makes firms in developing countries, including China, to show the unique features in the selection of entrepreneurial behavior, and mature western theories are no longer suitable for transitional economies. Undoubtedly, a systematic study in entrepreneurship behavior and GE behavior of a corporation in transitional economy will offer a vital theoretical contribution for entrepreneurship management and green management, and a realistic guidance for getting rid of economic crisis.

Institutional Uncertainty

Institutional uncertainty is an important feature of transitional economies (Wu, K.J., Liao, C.J., Tseng, M.L., & Chou, P.J., 2015). It is a broad concept, encompassing various forms of uncertainties within the political environment (Kelly, B., Pástor, Ľ., & Veronesi, P., 2016). Because such uncertainties are hard to measure, which means only fewer proxies can be used in systematic cross-country investigation (Brunetti, A. & Weder, B., 1998; Simón-Moya, V., Revuelto-Taboada, L., & Guerrero, R.F., 2014). From the analysis of existing empirical results, we know different scholars used a variety of indicators to measure, containing political violence, governmental instability and policy uncertainty (Barro, R. J., 1991, pp.715-721; Mauro, P., 1991, pp.681-712; Brunetti, A., Kisunko, G., Weder, B., 1997). Although stability and few political conflicts are unique advantages of China, policy instability is a severe disadvantage caused by transitional economy. Such disadvantages include existing policy gaps in some areas, unclear government definition of key issues in the policy implementation process and poorly detailed observations and recommendations of many policies (Puffer, S.M., McCarthy, D.J., & Boisot, M., 2010; Sheng, S., Zhou, K.Z., & Li, J.J., 2011). Due to scarce innovation, stability and effectiveness in some policies, it is hard to turn them into valid entrepreneurship behavior. Therefore, to some extent, policy uncertainty is representative of institutional uncertainty under the transitional economy in China.

The Moderating Effect of Institutional Uncertainty

For enterprises carrying out green entrepreneurship, transitional economy has a substantial impact. Because institutional transition breaks through the restrictions of a planned economy, adding a private economy greatly stimulates the vitality of market competition. In the fierce competition, ventures tend to pursue short-term performance goals but long-term ones, and corporation behavior tends to be conducive to business performance rather than environmental performance (Orlitzky, M., Siegel, D.S., & Waldman, D.A., 2011). When institutional uncertainty is high, policy shackles for enterprises become less strict, and companies will continue to seek for and drill loopholes and gaps of policies. Particularly when the industry standards are not clear, institutional pressure on green enterprises declines along with the power to obtain political legitimacy (PL), resulting in damaged green performance. Nevertheless, in the study of institutional theory, formal and informal institutions show a mutual substitution effect on the process of guiding economic behaviors. When formal institutions are incomplete, informal norms and values will play a stronger role (Li, Y., Peng, M.W., & Macaulay, C.D., 2013; Peng, M.W. & Heath, P.S., 1996). Thus, when institutional uncertainty is high, it's more significant for enterprises to obtain recognition from the suppliers, partners and the public (Huang, T., Wu, F.; Yu, J., & Zhang, B., 2015).

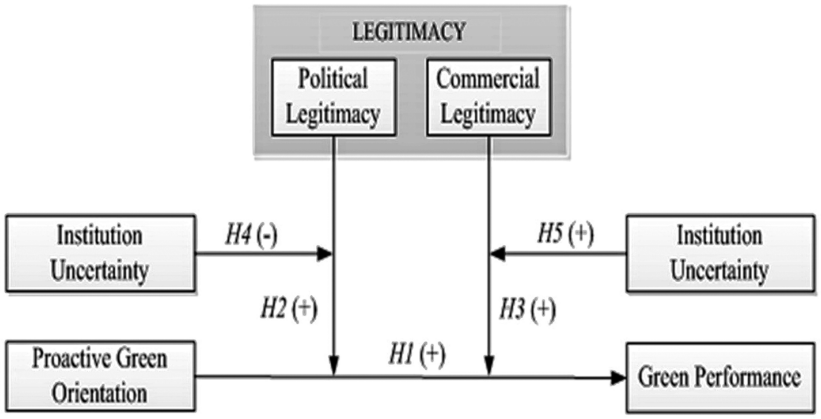
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In this context, influences of informal institutions are more vital and the facilitating roles of CL become more obvious between GPO and green performance.

The Moderating Effect of Institutional Uncertainty in Transitional Economy

Connecting the institutional theory and green entrepreneurship theory under transitional economy, this study finds out that the moderating effect of PL on the relationship between GPO and green performance becomes more negative as institutional uncertainty increases, such that the three-way interaction of GPO, PL, and institutional uncertainty is negatively related to green performance. However, the moderating effect of CL becomes more positive. That is, as a positive indicator, legitimacy is able to promote the relationship between GPO and green performance, but this conclusion will alter under the background of transitional economics. Under a high level of institutional uncertainty, CL will become a stimulus, while the promotion of PL will be restricted. In addition, this chapter analyzes the influences of institutional uncertainty on the moderating effect of legitimacy between GPO and green performance in a transitional economy. On one hand, this chapter finds that institutional uncertainty strengthens the moderating effect of CL. On the other hand, this uncertainty damages the moderating effect of PL. Considering this issue in the context of transitional economy in China, where there are few political conflicts and a stable government, the instability of policies can have a serious impact on business. Policies in many sectors are not stable due to gaps in policies. And it is difficult to implement certain standards because green start-ups must pay attention to both business performance and social responsibility, and institutional uncertainty has an even greater impact on them. In an institution environment which is highly uncertain, because of the gaps in policies and regulations, and incompletely specific green standards for implementation, pioneering GE start-ups will continue to drill policy 'loopholes' without being punished. As a result, the institutional pressure on those companies declines a lot and the impetus to obtain PL will reduce, suppressing the catalytic effects of PL between GPO and green performance. On the contrary, with the increase of institutional uncertainty, enterprises need to obtain recognition from stakeholders to achieve higher business performance. In this circumstance, the drive to gain CL will aggrandize and the power of CL exerts greater pressure on those ventures, thus making CL play a more prominent role in elevating the relationship between GPO and green performance. To a certain extent, this interprets the reason why in transitional economy in China, the enterprises find it so difficult to implement green standards, drill policy'loopholes', prefer to seek'Guanxi', and excessively focus on business performance, thus leading to the profit pursuit, malicious competition and serious product homogeneity.

DATA AND METHOD



Development of Survey Instrument

According to Murphy (1996), using appropriate control variables in the study of entrepreneurial performance can avoid performance measurement prejudice. Thus, this chapter chooses enterprise size, business scale, sector, establishment time and stage of development as control variables.

On account of the extensive theoretical background in previous section, this chapter identified the following demanded measurements. All items were measured on a Likert five scale, where an evaluation

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The model

of one exhibits that the statement doesn't fit the reality of the start-up to which the respondent belongs and an evaluation of five shown a high fit. Besides, the measures of EO have been mentioned in previous study. This chapter adopts the scale of proactiveness orientation from Covin and Slevin (1989) and uses three statements to measure GPO. Table 1 presents the specific statements and factor loadings of GPO, and the extraction method of Table 1 to Table 5 is Principal Component Analysis.

PL and CL belong to external legitimacy of enterprises, including the recognition of governments, suppliers, partners, regulators and customers. We select four statements from the discussion about legitimacy of Suchman (1995) and Rottig (2008) to measure PL and CL. Tables 2 and 3 present these statements and corresponding loading factors, indicating a high significance affirmative of the statements.

Institutional uncertainty and market uncertainty are main characteristics of transitional economies. Puffer et al. (2010) and Sheng et al. (2011) have carried out the thorough researches on institutional

Table 1. Rotated factor matrix for factor analysis of GPO

Factors		Cronbach's Alpha
1. We usually launch green initiatives which peers followed or reacted to.	0.848	0.806
2. We tend to be the industry 'leader', often offers new green products, new technologies or green management models before peers.	0.855	
3. Corporate executives look at future trends of industry frequently, understand opportunities for green development and take early actions to manage changes.	0.842	

Table 2. Rotated factor matrix for factor analysis of political legitimacy

Factors		Cronbach's Alpha
1. The corporation was highly praised by government departments.	0.855	0.884
2. The corporation was recognized by regulators.	0.873	
3. The government recommended us as a model enterprise frequently.	0.874	
4. The government visited our enterprise regularly.	0.842

Table 3. Rotated factor matrix for factor analysis of commercial legitimacy

Factors		Cronbach's Alpha
1. The corporation is widely recognized by customers.	0.847	0.864
2. The corporation is widely recognized by suppliers.	0.824	
3. The products of enterprise have been highly evaluated by peers.	0.882	
4. The products of enterprise have been highly evaluated by customers.	0.831	

uncertainty from the aspects of policy completeness and operability. On the basis of their results, we select five questions to measure institutional uncertainty (Table 4). Moreover, Zhu and Sarkis (2004) and Yang et al. (2013) put forward four items to evaluate green performance, which contains six questions expressed in Table 5.

Data Gathering

This chapter conducted a questionnaire survey. And our sample concentrated on data from start-ups within the last eight years due to Li and Atuahene-Gima's (2001) definition of start-ups as enterprises that have been established for no more than eight years. The survey distribution lasted six months, from February to July 2016, and the research areas contain Beijing, Shanghai, Shenyang, Hangzhou Changchun and Xiamen. These areas have various levels of development (i.e., central developed cities, coastal cities in South, and economically less active cities in North) to avoid the impacts of different degrees of regional

Table 4. Rotated factor matrix for factor analysis of institutional uncertainty

Factors		Cronbach's Alpha
1. Key policies related to business operation are incomplete.	0.786	0.854
2. Relevant industry standards are unclear.	0.766	
3. Relevant industry policies are fuzzy.	0.821	
4. There are gaps in related institutions and policies.	0.832	
5. Relevant policies are short of specific guidance and operational suggestion for implementation.	0.776	

Table 5. Rotated factor matrix for factor analysis of green performance

Factors		Cronbach's Alpha
1. Compared to peers, we release less air pollution.	0.820	0.897
2. Compared to peers, we cause less sewage.	0.797	
3. Compared to peers, we have less solid waste.	0.823	
4. Compared to peers, our cost of dealing with poisonous, harmful and hazardous materials is lower.	0.724	
5. Compared to peers, our cost of energy consumption is lower.	0.865	
6. Compared to peers, we have a lower rate of environmental accidents.	0.849	

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

economy development. Enterprises involved in this research include green construction and materials, low-carbon energy sources, eco-friendly materials, green furnishing, green process transformation, waste disposal services and training, and energy-saving equipment.

The data collection process was divided into three procedures. In the first procedure, the survey questionnaires were distributed through e-mails, and 120 responses were collected. In the second procedure, questionnaires were given to MBA students and 110 responded. In the third procedure, questionnaires were obtained onsite from mid-level and senior managers of solicited firms and from researchers completing the questionnaire face to face, with 63 responses gathered. In a word, 297 responses were collected, and 62 of which were eliminated due to incomplete or insufficient responses. A total of 235 samples were valid and utilized in the study of 22 variables, explaining the valid combination according to the requirements stated by Bentler and Chou (1987) that the sample number must be at least ten times of observed variables (Bentler, P. M. & Chou, C.P., 1987). A t-test was also conducted on enterprise size, sector, year established, ownership and business size of the three groups and no striking difference was found. As a result, they can be used in combination.

General Descriptive Analysis

After the gather of large samples, descriptive statistical analysis was carried out. On one hand, the results of a general descriptive analysis could reflect the fundamental features of sampled corporations. On the other hand, these results could also confirm the versatility and reproducibility of other findings. The results of a general descriptive analysis would help the study by providing salient characteristics of samples, thus replenishing the assessment of the research objects.

Examination of Validity

The study measured both content validity and construct validity. Content validity indicates whether the content of the scale can accurately cover the range or extent of the concept or meaning to be measured, and this can usually be measured subjectively(Zikmund, W. G., Babin, B. J., Carr, J. C., & Griffin, M., 2013) . Construct validity encompass both convergent validity and discriminant validity. Convergent validity, which can be explained by composite reliability (hereinafter referred to as CR) and average variance extracted from latent variables (hereinafter referred to as AVE). As for discriminant validity, this study referenced Fornell and Larcker (1981) and carried out tests by comparing the average root mean square values of AVE with different latent variables and the correlation coefficients of these variables.

Examination of Reliability

The reliability test refers to the degree of consistency in measurements by different measurers taken with the same instruments, reflecting the level of approximation of repeated measurements under the same conditions, that is, whether a series of projects measure the same concept or not. Generally, this test can be implemented by observing the internal consistency of the measurement instruments (Dawson, J.F. & Richter, A.W., 2006). In the Likert-scale method, the most commonly used method is the L.J. Cronbach α coefficient. Although an α coefficient value of 0.70 is on the lower boundary of the scale, it is still acceptable.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Correlation Analysis

Correlation analysis concentrates on the correlation among dependent variables, independent variables and control variables. The correlation coefficient is a commonly used measurement and the method is able to be the Pearson's product moment correlation method and the two-sided test. If the correlation coefficient among independent variables is greater than 0.75, the variables are considered too similar and collinearity might be present.

Harman's single-factor test was applied to analyze the entire questionnaire. In the absence of rotation, the explained variance of the first indicator extracted exceeded 50%. So, it could be believed that there was a severe bias in the common measurement method.

Regression Analysis

In this chapter, regression analysis was used to verify the relationship among GPO and business performance and the moderating effect of legitimacy and institutional uncertainty. The study used three factors for regression analysis. First, the determination coefficient of the model reflects the explanatory power of the regression equation for the dependent variables. This chapter used R2 to reflect the fitness of regression equation in order to avoid the influence from the number of independent variables on R2. Second, the regression model is said to be valid when the regression coefficient is not 0 at significance value of less than 0.05 or 0.01. Third, the variance inflation factor (VIF index) reflects the collinearity between independent variables. Collinearity is exhibited by a large VIF index. When $0 < VIF < 10$, multicollinearity generally does not exist.

EMPIRICAL RESULTS

Results of General Descriptive Analysis

Table 6 presents the features of the samples gathered. In summary, most enterprises have small and medium scale; the year number of enterprises were founded clustered around 3 to 8 years; the sector distribution was relatively dispersed; the proportion of companies with turnover under 5 million yuan was about 70%; enterprise ownership was primarily foreign funded; and domestic ownership was privately funded. On the premise of involving green businesses, the samples satisfied the demand of diversity and the overall descriptive statistics reflected basic features of the objects under observation, laying the foundation for further analysis. Numbers present in Table 6 is percentage (%).

Results of Validity Examination

To verify content validity, this chapter conducted a literature review. Two expert representatives were also invited to examine the research questions and determine whether they were scientific and reasonable, and each of them is from academe, business and government sectors. According to suggestions from the expert panel, this chapter adjusted some indicators to enhance the clarity, technicality and reliability of the survey tools. The questionnaire designed by this study was in line with scientific and rational demands, that is, it met the demands of content validity.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Characteristics of survey samples

Enterprise Size		**Sectors**			
1-50 people	17.9	Real estate			18.5
50-100 people	43.4	Agriculture, forestry and livestock			3.0
100-300 people	17.4	Energy, environmental protection			20.2
300-500 people	20.0	Environmental transformation and training			3.8
More than 500 people	1.3	Materials			14.5
		Accommodation, catering			3.8
		Manufacturing			28.5
		Construction			7.7
Business Size		**Ownership**		**Year Established**	
1 million or less	34.0	State-owned	11.5	1 year or less	7.6
1 million 3 million	19.6	Foreign investment	40.4	1-3 years	26.8
3 million to 5 million	15.3	Private	31.1	3-5 years	24.7
5 million to 10 million	18.5	Joint venture	17.0	5-8 years	40.9
10 million to 30 million	11.5				
More than 30 million	1.1				

The questionnaire passed the demands of convergent validity test, discriminant validity and test factor analysis. Average values gained in the convergent validity test for all five factors were greater than 0.5 (Tables 1 to 5), which meets the research standards. The load factors obtained in the factor analysis are all greater than 0.5 and the proportion of the cumulative of variance explained is greater than 50% (Tables 1 to 5), successfully satisfying the research requirements. The discriminant validity test result exhibited good discriminant validity among these variables. As shown in Table 7, the diagonal values are representative of the square root of AVE, which is greater than the coefficients in the corresponding row and column.

Results of Reliability Examination

The measured alpha coefficients of Cronbach are as follows: the GPO Cronbach's alpha is 0.806, the PL Cronbach's alpha is 0.884, the CL Cronbach's alpha is 0.864 and the institutional uncertainty Cronbach's alpha is 0.854. The alpha coefficient values are between 0.80 and 0.90, indicating a good confidence level in the measured factors.

Results of Correlation Analysis

Table 7 shows the descriptive statistical terms and correlation analysis. Under a significance degree of 0.01, the four main variables in this chapter - GPO, PL, CL and green performance are obviously related to institutional uncertainty. The three major constructs of PL, institutional uncertainty and GPO exhibit significant correlation. Among the control variables, business size and number of years established and other research constructs have a general correlation.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Descriptive statistics and correlation matrix

	Mean	Std. Deviation	Enterprise Size	Year Established	Sector	Business Size	Ownership	GP	GPO	PL	CL	IU

Ownership	2.54	0.907	0.292**	0.539**	-0.067	0.306**	N/A					
Green Performance	3.1887	0.96600	-0.038	-0.090	-0.039	0.014	-0.203**	0.773				
GPO	3.1319	1.10042	0.041	-0.143*	-0.085	0.091	-.153*	0.424**	0.758			
PL	2.538298	1.0035308	0.055	0.034	-0.009	0.020	.185**	-0.171**	-.305**	0.81		
CL	2.520213	.9492271	0.090	0.094	0.029	0.050	.164*	-0.112	-.327**	0.587**	0.789	
Institutional uncertainty	3.934468	0.8377595	-0.043	-0.056	-0.086	-0.043	-0.173**	0.140*	0.255**	-0.224**	-0.212**	0.737

**. Correlation is significant at the 0.01 level (2-tailed), *. Correlation is significant at the 0.05 level (2-tailed).
N=235, N/A indicates analysis not applicable; the diagonal line lists root square values of average.

Correlation analysis exhibits that the correlation coefficients among variables are all less than 0.65, according to the standards put forward by Tabachnick and Fidel (Tabachnick, B.G., Fidell, L.S., Osterlind, S.J., 2001). The possibility of the results that may be threatened by multi-collinearity is small. Single-factor method of Harman is to test common method bias. In the absence of rotation, the first extracted factor illustrates only 28.75% of the variance, which is less than the 50% common standard. A single indicator doesn't appear, and the independent and dependent variables are loaded on different indicators, suggesting there is no single indicator to illustrate multiple variances. Thus, the issue of common method bias isn't discovered.

Regression Analysis Results

When consider the control variables, this chapter uses regression analysis to judge causal relationships among dependent variables, independent variable and control variables. Before carrying out the regression analysis, threats influencing the accuracy of the results from multi-collinearity must be removed. The VIF of various regression coefficients is calculated in the process of regression analysis. The results display that the maximum VIF is 1.59, far below the critical value of 10, thus reducing the possibility of any threat from multi-collinearity.

The moderating effect of GPO on green performance and that of political and commercial legitimacy on the relationship between GPO and green performance are calculated through multivariate regression models. This chapter has established regression model 1:

$$Y=\alpha+\alpha_1X+\alpha_2X_1+\alpha_3X_2+\alpha_4X_3+\alpha_5XX_1+\alpha_6XX_2+\alpha_7XX_3+\alpha_8XX_2X_3+\alpha_9XX_1X_3+\mu_m$$

where Y represents green performance, X represents GPO, X_1 represents PL, X_2 represents CL, X_3 represents institutional uncertainties, μ_m represents error, α represents a constant, α_i represents the regression

coefficient and XX_n represents the interaction of two constructs (e.g., XX_1 represents the interaction between GPO and PL).

In inspecting the moderating effects, this chapter refers to the method proposed by Baron and Kenny (1986), utilizing multiple variable regression to verify our views.

In the regression model, the adopted means contains four steps:

Step 1: Only consider the effects from control variables.
Step 2: Consider the primary impacts of independent and control variables.
Step 3: Add the interaction between PL and CL, and think over the moderating effect.
Step 4: Investigate the sub-mediating effect between institutional uncertainty and legitimacy in institutional economy.

In step 2, the significant coefficient is 0.416, p <0.001, indicating that the green proactive effect has an obviously positive impact on green performance. In step 3, the significant coefficient of the interaction between GPO and PL on green performance is 0.224, p=0.007, and the significant coefficient of the interaction between GPO and CL on performance is 0.184, p=0.024, displaying that PL and CL have significant promotional effects on GPO and green performance, as shown in Figures 2 and 3. Further-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

more, after the two interactions introduced in step 3, the influence of GPO on green performance is still significant, with the significant coefficient value being 0.355 at p <0.001.

In step 4, Table 7 exhibits that the significant coefficient GPO × PL × institutional uncertainty has a value of -0.394, p=0.001, while the significant coefficient GPO × PL has a value of 0.321, p <0.001, indicating that institutional uncertainty inhibits the moderating effect of PL between GPO and green performance (Figure 4). Moreover, the significant coefficient GPO × CL × institutional uncertainty has a value of 0.211, p=0.066, while the significant coefficient GPO × CL has a value of 0.201, p=0.020, indicating that institutional uncertainty contributes to the moderating effect of CL between GPO and green performance (Figure 5).

HOW TO ACHIEVE GREEN PERFORMANCE

Because proactive green-oriented enterprises have taken advantages of achieving green performance, this conclusion encourages both business managers and entrepreneurs in various industries to take GE actions ahead of their competitors, encompassing the early launch of new and environmental products, technology and green management models. Senior managers ought to usually look at the future industry trends, know green development opportunities and act early in order to respond to changes. Compared to their peers, these actions are beneficial for enterprises to obtain the lead in emission, energy efficiency and safety.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

As for green ventures in various industries, proactiveness is correct, however, the constraints of external legitimacy shouldn't be ignored. Pioneering green enterprises must not only manage their perception of governments and regulators but also attach great importance to the evaluations made by their suppliers, partners and customers. The two legitimacies are both institutional restricts and positive drives to proactive green enterprises in obtaining green performance. Nevertheless, for the governments, the lower the legitimacy of green start-ups, the more likely they will carry out non-green business activities. So, this kind of enterprises should gain the focus of green supervision and inspection.

For some western developed countries, the institutional context is relatively stable. As a result, enterprises that develop GE activities must focus on the constraints of government and market simultaneously, which is useful for green ventures to seek for achieving green performance. In contrast, in a mount of developing countries, the high level of institutional uncertainty lead to poor PL restricts. Numerous companies will excessively pursue CL, resulting in vicious competition and homogeneous products. Therefore, this provides a warning for some governments: Apart from promoting institutional standards as soon as possible, increasing the strengths of moral propaganda, the government also ought to accelerate the embedment of green standards into society through extensive publicity, so that the social norms of informal institution can participate in promoting operations of green enterprises.

CONCLUSION

This chapter reviewed entrepreneurship theory, green entrepreneurship theory, legitimacy theory and transitional economy theory. And this chapter also verified the relationship between GPO and green performance empirically, the moderating effect of institutional legitimacy between the two and the influences of institutional uncertainty on the moderating effect of legitimacy. Our conclusion provides another perspective on GE, not only in systematically integrating institution theory and entrepreneurship theory but also enriching the entrepreneurial scenes, which contribute to green entrepreneurship theory, situation theory and legitimacy theory.

In addition, this chapter finds out that there is a positive correlation between GPO and green performance. It also confirms that an enterprise engaging in GE actions ahead of its competitors is able to gain the advantages in green performance, encompassing the gains in pollution emissions, energy costs and unexpected incidents. Besides, this chapter concludes that both political and commercial legitimacy play a promoting role in achieving green performance of proactive green-oriented enterprises. That is to say, the pressure exerted by legitimacy restrict is also a powerful force, and institutional restrict is a positive variable: green ventures need to not only gain recognition from government and regulators but also concentrate on the evaluations from suppliers, partners and customers. These two legitimacies are both institutional restrict and positive powers for proactive green enterprises to obtain green performance. Considering the transitional economy in China, institutional uncertainty would strength the promoting effects of CL between GPO and green performance while impairing that of PL. For GE needs to balance the relationship between business performance and social responsibility, it will be subject to the influences of institutional legitimacy. And the institutional uncertainty existing in transitional context can have an effect on the impacts of institutional legitimacy on green enterprises. This chapter sufficiently proves that when institutional uncertainty is high, Chinese green companies will tend to seek for'Guanxi', drill policy 'loopholes' and pursue profit and malicious competition. As a result, institutional uncertainty under the context of transitional economics will inhibit the relationship between GPO and green perfor-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

mance, even aggravating market uncertainty and making green strategies become no longer suitable for developing countries. Therefore, the findings will be vital warnings for the governments.

Conclusions of us enrich the entrepreneurship theory. Unlike the findings about the relationship between proactiveness orientation and entrepreneurial performance, a unique perspective emerged from the study that supports a particular conclusion - GPO and green performance have a significant positive correlation. Different from the causal relationship of 'legitimacy—resources—business growth', this chapter treated legitimacy as an institutionally embedded binding mechanism and explored how different levels of legitimacy affect the relationship between GPO and green performance. This chapter also added the factor of a transitional economy and revealed the influence of institutional uncertainty on the moderating effect of legitimacy on the relationship between GPO and green performance. This conclusion enriched entrepreneurship research scenarios, expanding and improving the universality of green entrepreneurship theory and institution theory.

Chapter 57
Customer Satisfaction in the Consumption of Green Products

Violeta Sima
Petroleum-Gas University of Ploiești, Romania

Ileana Georgiana Gheorghe
Petroleum-Gas University of Ploiești, Romania

ABSTRACT

This chapter aimed to identify those factors that determine the green consumer satisfaction, having as the emerging point the consumer behavior definition and the sustainable development concept. The authors propose a new approach of the dimensions of the evaluation model for customer satisfaction including a new one, called The Green Dimension. An important goal was identifying the drivers of the consumer purchasing. The authors identified three main areas of the green dimension of customer satisfaction. They are related to Company, Product/service, and Price. Then some considerations regarding an integrated approach of strategic mix from a 'green' perspective have been presented. According to research from Boston Consulting Group, in order to obtain a Green Advantage, companies should enhance their strategic mix taking into considerations green planning, green processes, green product, and green promotion. The authors added two more elements, namely people and eco-efficiency, resulting "The Green Strategy Mix".

INTRODUCTION

Green Economy involves the use of natural resources, energy, new technologies, and cleaner production methods in order to promote economic growth and create new jobs. To implement this concept, new models for sustainable consumption and production should be developed, which does not force the ecosystem.

In order to operationalize the Green Economy concept, the three aspects of sustainable development (environmental, economic and social) should be incorporated, to obtain a multi-dimensional outcome changing consumption patterns will require a multi-prong strategy focusing on demand, meeting the basic needs of the poor, and reducing wastage and the use of finite resources in the production process.

In order to implement the green economy at the national level, it is required close involvement of consumers and producers, along with the implementation of the main measures proposed and adopted at the national and international governing bodies.

The green economy requires changing consumer habits.

In order to assess consumer satisfaction, it is important to know the degree to which they are willing to pay extra for green products and services. This chapter is a theoretical approach to this problem.

The authors identified three main areas of the green dimension of customer satisfaction. They are related to Company, Product/Service, and Price.

The objective of this study is to highlight the links between green satisfaction and the three mentioned elements but also the transformations they bring in consumption patterns.

Background

The concept of satisfaction has been a subject of study for many researchers. However, satisfaction is still difficult to be defined, as Oliver asserted in 1997 in his book, "Satisfaction: A Behavioural Perspective on the Consumer" (p. 13). Thus, although satisfaction seems to be a widely-known concept, when a definition is required it is difficult to obtain.

The subject of this thesis is to reveal multiple senses of customer satisfaction emphasizing the Green Dimension (Sima & Gheorghe, 2009).

Customer satisfaction is subject to study not only for scholars but also for companies. The purpose of this analysis is very pragmatic, namely to determine its maximizing in order to increase customer loyalty. To achieve this, it is essential to identify key factors which determine customer behaviour.

Although in the literature of specialty there is widely accepted the opinion that satisfaction represents a response to consumption related experiences (Yi, 1990; Anderson, Fornell & Lehmann, 1994; Oliver, 1997; Giese, & Cote, 2000), it has a wide range of definitions and assessment ways (Peterson & Wilson1992; Giese, & Cote, 2000).

A customer who has achieved a high level of satisfaction will be tempted to repeat the purchase, thus becoming loyal. The final effect will be the customer retention (Zairi, 2000). Moreover, he will be prompted to provide positive recommendations to other potential customers. On the contrary, a dissatisfied customer will give up in the future buying the product or service or even he will return it. Another possibility to reduce dissonance is also searching for information that confirms the high value of the product or service (Kotler, 2000).

In the research studies for satisfaction more operationalizations of satisfaction were used (Westbrook, & Oliver, 1981; Hausknecht, 1990; Peterson, & Wilson, 1992; Wirtz, & Lee, 2003). Thus, Hausknecht (1990) listed 34 measures, including measures of behaviour (namely, behaviour registrations, such as a number of complaints about the main product) and self-report measures (namely, survey items, such as rating scales).

Also, the marketing studies showed that customer satisfaction depends on the specific psychological construction such as reliability, quality, customer loyalty, commitment, word-of-mouth and image, and customer profitability. It has been shown that quality and reliability are required by satisfaction, which in turn is necessary for customer loyalty and customer profitability (Yi, 1990; Anderson et al., 1994; Oliver 1997; Verhoef, 2001; Hennig-Thurau, Gwinner & Gremler, 2002).

The meaning of the concept is context-specific satisfaction (Giese & Cote, 2000).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

As a result of a learning process which can be developed only in the presence of a permanent client, who asks repeatedly for a particular product, brand or company, in order to meet a specific need, as a form of attachment to the benefits provided by the company, static vision of the satisfaction resulted from the client-producer relationship, has been replaced gradually and improved by cumulative satisfaction paradigm.

Satisfaction refers to the fact that a particular feature of a product or the product itself offered a "pleasurable level of consumption-related fulfilment, including levels of under or over fulfillment" (Oliver, 2006).

According to Rust and Oliver, "consumer satisfaction can be seen as the consumer's fulfilment response" (1994).

In 2001 Parker and Matthew referred to the existence of two complementary approaches to the concept of consumer satisfaction, namely satisfaction as a process and respectively satisfaction as a result of consumption experiences.

In 1977 and two years later, in 1979, Olson and Oliver asserted that in terms of process, customer satisfaction can be defined as an assessment of the significance of what was received and what was expected. Vavra, in 1997, emphasized that perceptual, psychological and assessment processes determine consumer satisfaction.

Consumer satisfaction, as a result, can be defined as a final state resulting from the consumption experience. This condition may be the result obtained without comparing expectations (Oliver, 2006) or a cognitive state obtained as a result of comparing the expected and actual performance or cost comparison of rewards and anticipated consequences (1997).

In marketing literature two main groups of models evaluation of consumer satisfaction can be identified:

- Models that put in relation the concept of customer satisfaction with concepts such as quality, value, and loyalty behaviour complaints. These models have an essential role at the level of organizational policy. Thus, they provide the strategic context for designing a marketing research on consumer satisfaction.
- Models based on the constructs of the customer satisfaction concept such as the discrepancy between expectations and actual results, attribution, equity, affect, and regret. These models allow proper operationalization of measurements of customer satisfaction providing appropriate constructs.

In order to measure consumer satisfaction with a broad range of organizations, indexes have been developed. Thus, at the national level, customer satisfaction index (CSI) is used in order to measure how companies and organizations are able to satisfy customer needs. The CSI Model is also used for comparing the services and products within a sector. Most countries have developed their own customer satisfaction indexes. The first such model was the national Swedish customer satisfaction barometer (SCSB), developed in 1989. It has included 31 major industries in Sweden. This model used perceived value as a single measure of customer expectations (Fornell, 1992). In 1992, in Germany, Deutsche Kundenbarometer (DK) was introduced, which in 1994 also included 31 industries.

In USA American Customer Satisfaction Index (ACSI) is being used since 1994. This model takes into account both the field of production as well as the field of public area. Thus, seven economic sectors, nearly 40 industries, 200 private sector companies and two local public services are taken into account.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Customer satisfaction index is calculated by taking into account proportional role of three categories of variables, namely: overall satisfaction, satisfaction expectations and satisfaction with the organization "ideal".

A model used to assess customer satisfaction is European Customer Satisfaction Index (ECSI) Model. This is an econometric model that links customer satisfaction index with a set of causal latent variables (such as customer expectations and customer perceptions about quality and value), being based on the verified theory of consumer behaviour modelling. It aims to determine the perceived quality and the company image to customers and customer loyalty.

Kristensen et al. (2000) described it as "a structural equation model with unobservable latent variables ... that link customer satisfaction to its determinants and, in turn, to its consequence, namely 'trust' and 'repurchase intention".

Customer satisfaction study aims at four main aspects, namely:

1. Identifying the means of measuring customer satisfaction;
2. Finding the ratio of the number of satisfied clients and the total number of customers;
3. Identifying key indicators for the satisfaction assessing;
4. Finding the evolution of the level of customer satisfaction.

In order to answer those questions, the relationship between actual performance and desired performance must be considered. The Bender Model (1991) and The Rapp Model (1995), cited by Schneider, emphasized five dimensions to be considered when assessing customer satisfaction:

1. Technical quality of the product;
2. Reputation quality;
3. Service quality;
4. Quality of personal relationships;
5. Price perception.

According to Meyer-Waarden (2004), satisfaction is an essential element for modelling customer purchasing behaviour, based on three categories of variables:

1. Cognitive variable;
2. Affective variables;
3. Co-native variables.

In the beginning, pro-environmental models have started from the premise that between environmental knowledge and concern about this there is a direct linear relationship, leading to pro-environmental actions as a consequence (Kollmuss & Agyeman, 2002).

Ottman (1993) has defined "environmental consumerism" as a reaction of the consumers, who, noting environmental problems, increasingly buy more eco-friendly products, gradually abandoning classic products. The stated purpose was to protect "themselves and the planet".

Thus, marketers should address this category of products similarly to the target market (Ottman, 2006) because consumers look for them, especially (Pickett, 2008).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Consumers claim to be well informed about the benefits of the products they intend to purchase. In doing so, marketers must consider this aspect in establishing the communication strategy and use instruments which best matching with the beliefs and behaviour of consumers, determining thus interest for the product (Kilbourne, 1995).

Ottman (1993) defined green consumers as "those who actively seek and support those products satisfy their needs that are having less impact on the environment". Besides that, Macdonald, S. et al. (2006) said that all consumers are potential green consumers, because when a consumer has the opportunity to choose between two products that satisfy the same need, he will prefer to buy green products.

If gender is taken into account, it was found that there is no a "significant relationship between women and men and green behaviour" (Kreidler & Joseph, 2009). However, there are studies which showed that women are generally more concerned about the environment are more willing to buy green products (Mainieri et al., 1997).

If the geographic region is taken into consideration, it is demonstrated on the basis of consumer surveys that across Europe consumers express concern for the environment. Thus, they look for eco - friendly products and services, being at the same time willing to pay more for environmental features. This obvious serious concern of the European consumers for green products has led to 90% of European multinationals to adopt programs of environmental sustainability (Peattie & Crane, 2005).

People can be induced to adopt green consumption model if additional benefits, cost effective or environmentally friendly solutions are offered (Ottman, 1993).

In marketing literature is shown by research (Pickett, 2008) that product perception is influenced by situational variables and social reference groups. Also, there are studies which showed that many of the consumers perceive organic products having a high price and low quality (Mendleson, 1994; Ginsberg, and Bloom, 2004).

Gupta, S.et. al. (2009) referred to the „green buying behaviour". Thus, he showed that the concern for the environment and about pollution, willingness to recycle, and to pay more for environmentally friendly products form this behaviour. Many studies on this topic have been performed starting from the analysis of the willingness of the consumer to pay more for green energy (Wiser, 1998; Hansla et. al., 2007).

Marketers may contribute to change consumer behaviour by emphasizing benefits and desired features of the products in the messages communicated by the producing companies to their potential customers. In relational marketing „long term benefits" of the product are submitted, leading to attract and retain consumers for long periods (Antonies & Raaij, 1998).

Thus, consumer behaviour can be shaped by emphasizing relative advantages of eco-friendly products in comparison with those products which create environmental damages (Peattie, 2001).

Related to this, Ottman (1993) stated that consumers can be the emotionally motivated to get involved because they want to differentiate themselves from other members of society or in their groups.

Another issue taken into consideration by the American scientist J. Ottman is the period of life when certain purchasing and consumption behaviours are induced. Thus, she stated that "habits are decided early in life" (1993). The conclusion is that consumers will take more favorable to environment decisions if environmental education will start early.

Instead, Peattie (2001) believes that to form such habits, companies should be those that should get involved. Thus, in the early stages of forming purchasing habits, they should use some systems to reward customers.

Mass media is another factor that can contribute decisively to the formation of buying habits. This, as a stakeholder (Ottman, 1993) and opinion promoter, can effectively convey environmental information.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

However, in practice consumers tend to become suspicious in some cases when companies put too emphasis on the environment in their communication systems.

The label is another factor to be taken into account in substantiation of the decision to purchase (Chase & Smith, 1992). The label may highlight specific environmental information that can contribute to an attitude of buying an eco-friendly product.

In other words, we can say that a system of an environmentally friendly communicating system can lead to a favorable attitude to green products (Baldwin, 1993).

It follows from the above that the companies need to pay great importance to develop long-term strategies (Darling et al., 2009).

There are a number of studies have shown that environmental issues have become important issues for the population. This, also, led to changes in purchasing and consumption behaviour. Thus, consumers become more aware of environmental issues, giving more time for the prospection stage, seeking, primarily those energy efficient products. These behavioural patterns suggest the intention of engaging in a green consumer behaviour (Roberts, 1996; Kalafatis et al., 1999). However, the explanation may come from increased energy prices.

Factors which consumers take into account in substantiation the purchasing decision, ultimately support marketers when they design the marketing mix. Thus, if environmental factors are considered, sustainability goals can be more easily pursued. In order to achieve these objectives criteria of compatibility of the ecosystems with production systems should be considered. In this respect, Fuller stated that „Customers need to learn to base purchasing decisions not only on how well the products meet the individual needs but also on how these products affect the natural environment" (1999).

Regarding the evaluation of the substantiation of the decision to purchase, Ottman (1993) stated that the products or services are evaluated not only in terms of "performance and price," but also on the "social responsibility of manufacturers."

Consumers tend to repeat purchase in those cases where post-purchasing evaluation gives them satisfaction (Wood & Neal, 2009).

Thus, the concept of customer loyalty is related to environmental concerns and decisions having an impact on them.

IMPLICATIONS OF THE SUSTAINABLE DEVELOPMENT IN CONSUMER BEHAVIOUR

Sustainable Development: Frame for Sustainable Consumption

Sustainable development offers a frame for communities for an efficient use of the resources, in order to create new commercial activities, to protect and improve the life quality, to create new commercial activities which consolidate their economy. It can help to create a healthy community, which can sustain even the actual generation, and the next one. The concept of the environmental degradation unplumbed from the economic growth by eco-efficiency promotion and by interpretation of the high standards of environmental protection as a challenge to innovation, new markets and new business development, if we take into consideration the fact that a healthy environment is essential to ensure the welfare and quality of life.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are increasingly more voices claiming that production and consumption of goods would become sustainable if consumption of raw materials would be reduced. Consumption should be reported to the ecological potential of the environment. Sustainable non-inflationary growth thus became one of the economic objectives of the European economic model. An economy which would meet these conditions is called "dematerialized." To that context, consumer behavior gets a more important role in this economic model (Beatley, 2000).

Lester R. Brown argued that the economy is part of the environment, showing that considering that the environment is part of economy generated a destructive economic model. He showed that if China would adopt the American lifestyle, demand for oil would increase by 80 million barrels per day, and paper consumption would exceed the global production capacity. Extrapolating this reasoning, he says that this economic model based on fossil fuel consumption is not suitable for any other developing countries, nor for the world. Eco-economy is presented as an optimistic alternative model. Thus, the main concern of the theoreticians in economics consists in integrating the ecological principles. Brown shows that the seeds of this new sustainable economic model can be seen even today, as new wind turbines, solar panels, electric cars or networks of bike trails, which are becoming increasingly visible in the big cities. This new economic model should be integrated into ecosystem so that allowing further economic and social development (Brown, 2001).

Sustainability principle designates the gear of three dimensions – ecology, economy and social sphere. Mixing up the consumer behavior with the ecological dimension of sustainability is very important. Economic development and social welfare are possible in long-term, only in a well-established frame which involves nature as a vital element. The economic and social aspects are important in order to make ecology becoming feasible: ecological manufacturing and consumption are elements that can be realized only if the consumer is able to afford them and if both are realized under acceptable social guidance. 30-40% of the environmental problems are based directly or indirectly on some prevailing consumption models (Using UBA, 1997, p. 1).

In this context, new strategies must propose a way for the sustainable development:

- Quality and preservation of the environment and natural resources essential elements of the sustainable development;
- Management of the manufacturing flow, so that, taking into consideration the finite character of resources, to facilitate and encourage reuse and recycle at an optimum level, in order to avoid loss and depletion of natural resources;
- Modification of the planned society concordant to the confined character of the natural resources, so that their consumption or use to be not made in another's detriment, so that exploitation by a generation of the natural resources to not confine consumption possibilities of the future generations.

The global expansion of environmentalism is ascertained in the current period. The objectives envisaged aim, on the one hand, to improve the efficiency of production processes, using, and recycling of consumer goods and, on the other hand, further progress in global governance policies. This means greening of the corporate codes of conduct, international environmental law increasingly tougher or stronger cultural norms of "appropriate" consumption (Dauvergne, 2008). However, the current pace of implementation of these policies is considered too slow and the real involvement, too sporadic to prevent the negative effects of the excessive consumption.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to Dauvergne (2008), the expenditures for environmental rehabilitation and human health are increasingly larger and require immediate action. In this regard, measures are required at the legislative level, both on the production and market. These measures have already begun to generate changes in customer behavior and society in general. But for this environment-oriented behavior could be generalized globally improvement of communication is required.

The regulatory policy tools must be chosen so that they outcrop a matched mix of their, adapting them to specific application situations. They include:

- Persuasion policy, which assumes promotion of the ecological technologies and research, awareness and education and use of market mechanisms;
- Information transfer policy encompasses tools for social communication - education, mass-media and public relation – informational systems affordable for the public.

Traditional policies pursuing minimization of the environment harmfulness, policies having as main goals demand satisfaction with a minimum input are added, in manufacturing area, production policies with a minimum output of wasted resources and, also changes in the demand profile.

Nowadays, urban environment became more and more crowded especially by increasing the frequency of the transportation activities. Urbanities specialists are highly concerned with problems of the territorial use. Planning of the territory use needs to be closely correlated with regulatory for activities of the transportation services, which must accurately reflect costs of the needs of environment rehabilitation and social costs of maintaining or development of the transportation infrastructure.

A more deepened knowledge of the premises of consumption structuring for other goods and services, is, also, necessary, as a response to the multitude of needs expresses by different consumers' categories. For instance, option for replacing an old product with a new one can be underlined by many motivations – that the old one can't be mended, that the new one has superior properties, that there is a use for periodic shopping. The emergency of the consumerism era, in occidental countries, was possible just as a complexity of the consumption behavior of modern people and his striving for innovation (Stanciu, 2006).

The paper is a consumer good, which manufacturing depends on, essentially of the exploitation of wooded lands. Paper consumption clearly reflects the level of civilization and economic development for a country. But the industry of cellulose and paper is not only the biggest wood consumer in the world but, also the third industry in the world in respect of the financial results, being, at the same time among the first ten most polluting industries. Therefore, in the next 50 years, the demand for cellulose and paper is expected to increase with a hundred percent, according to The National Institute of Statistics of Romania, 2004. But, on the other hand, there are still over a billion of illiterate people and over 100 millions of children who don't yet benefit of primary school education.

Generally, encouraging of goods and services demand, mass-media and advertising industries play a decisive role. Mainly, advertising industries affect consumers' motivations, having a decisive role for consumption structuring and modelling of the concepts regarding goods and services. Some recent studies of the consumption habits sustain that manufacturing response for some consumption needs can become more sustainable, by encouraging the taking up some services destined to contribute to the raising of sustainability of the goods already purchased, instead to encourage purchasing of new goods. These kinds of practices lead to diminishing pressure of the extractive industries to the environment that can lead to a new conceptualization of the life quality increasing. Also, some recent analyses of companies

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

affirmed that consumers' loyalty for a brand seems to be more encouraged by a bid for services destined to extend the life of the goods in use and less by encouraging of the purchasing new products.

Sustainable consumption and manufacturing models represent important determinants of the environmental problems at every level, from the local level to the global level. For this reason, Changing Consumption Patterns was a main object in Agenda 21 (The World Conference in Rio de Janeiro, 1992). Sustainable consumption represents a very wise area, requesting an interdisciplinary approach. The change of the consumer behavior is a process involving many social groups: ménages, which represent the biggest group of consumers, authorities, economy, educational institutions, NGOs and many others.

In September 2015, the United Nations adopted the Agenda 2030 for Sustainable Development which established a comprehensive framework for eradicating poverty and achieving sustainable development by 2030, based on the Millennium Development Goals (MDGs), adopted in 2000. Thus, the 2030 Agenda includes an ambitious set of 17 Goals for Sustainable Development (SDG). Among them, goal no.12 aims to "ensure sustainable consumption and production patterns". Paragraph 28 of the 2030 Agenda states the clear commitment of signatory countries on the implementation of fundamental changes in the how societies produce and consume goods and services. Thus, the involvement of all categories of stakeholders, namely, international organizations, governments, business sector and other non-state actors and individuals is required. Each of them must be involved in changing the unsustainable patterns of production and consumption. The involvement must target both technical plan, and the financial sectors. Developed countries must assume the role of leading this movement. At the same time, protecting economies in developing countries should be considered. In this regard, new investments must be carried out. They must contribute to "strengthen developing countries' scientific, technological and innovative capacities" of these weaker economies, to enable their evolution towards more sustainable consumption and production patterns. (United Nations, Transforming our world: the 2030 Agenda for Sustainable Development, retrieved on January, the 10th, 2016, from https://sustainabledevelopment.un.org/post2015/transformingourworld)

EU leads the efforts for a sustainable world. The EU has already adopted the leading position in terms of efforts for a sustainable world. In this context, the EU was committed carrying forward this agenda, both internally (e.g. through the future EU initiatives such as the strategy for circular economy, designed to tackle more sustainable patterns of production and consumption), and through its external policies, by supporting implementation efforts in other countries, especially those with the most urgent needs. The most important EU's Contribution to the Millennium Development Goals for the 2004-2014 period, in terms of ensuring environmental sustainability, consist of:

- Connecting more than 74 million people to improved drinking water;
- Connecting 27.5 million people to sanitation facilities;
- Protecting 1.9 million km2 of forest;
- Continuing conservation of 1.1 million km2 of protected areas.

A change of the consumers' behavior means primarily a fundamental transformation of the values and life style. The change of the thinking and acting kind of the consumers can't be imposed by the authorities. The emergence of new and durable traditions in consumers' behavior requests a wise informing and consulting campaign. As regards of the consumer, goods and transportation ways must become more transparent, the price of the ecological true need to be clearly expressed and those alternatives for the environment protection must be as soon as possible shown.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Ways to Ensure a Sustainable Consumption

- Development by companies of products and services that maximize social value and minimize environmental effects. This requires strengthening the role of research and development function at the micro level.
- Education in this regard and influencing consumer choice of goods and services. Important roles in this regard can play promoting and raising awareness of consumer options. Companies can encourage consumers to choose environmentally friendly products and services and to consider the sustainable way to use them.
- Changing of the demand's characteristics and elements related to the dominant lifestyle, especially in developed countries - decreasing the quantity of purchased goods and services.

Areas of Activity of the Sustainable Consumption

Question about the concrete measures for the implementation of the sustainable behaviour regarding consumption appears only in a second stage. A very important role was allotted for areas as:

- Avoiding of the waste products accumulation;
- Energy and water consumption;
- Mobility;
- Feed;
- Reuse of the objects.

In order to attain a sustainable growth, material consumption of the industrialized countries must be diminished. This is possible because of the fact that in the last period goods having a low content of raw material were introduced in market, for the automobile industry, for the equipment industry and for that of the wrapper. There are motives for which a decrease of the material and energy consumption doesn't necessarily lead to a diminution of the total consumption. Thus, increasing total quantity of the used merchandise cancel savings obtained in technology of their realization. Secondly, motivation for producers to realize ecologic goods is related mainly with economic interest, which operationalizes the new sustainable technologies. The classic case is represented by the fridge with low energy consumption, but more expensive than the conventional one. Another solution for the sustainable consumption consists of realization of goods having long term of working. This is only a part of the new approach, which imposes a new vision to merchandise, according consumers' needs.

There are many problems: it is not clearly how the consumers are prepared to accept prizes of the ecologic goods. A strict legislation in this area imposes serious pressures to the economic agents.

They began to understand that not only attention paid to different goods separately seen. This imposes a new approach, named metabolic, which approach the whole anthropic system.

Also, they began to understand that the attention paid to different goods separately seen is not sufficient.

Some specific studies showed the ecologic impact of the services, building the concept of services efficiency meaning to offer a maximum result for consumers by use a minimum quantity of raw materials and energy. The most important feature of this concept consists of the fact that in our days, satisfaction is generated not only by the products but even by services which they provided. In other words, products offered represent only tools for services obtaining.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The 12th goal of Agenda 2030 aims to "encourage companies, especially large and transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle". In this context, colleges and universities could become very important actors. Thus, it would be appropriate for them to upgrade their curricular areas by introducing disciplines and developing specializations able to confer appropriate competencies for their graduates, especially in developing countries.

Reducing waste is another issue that has been also taken into account at UN summit in September 2015. In this regard, a proposed measure consists in the rationalization of inefficient fossil fuel subsidies.

Restructuring taxation and gradual reduction of harmful subsidies are expected mentioned as methods for implementing these measures. Each country must take into account the specificities of the national economy. UN document clearly stipulates "minimizing the possible adverse impacts on their development in a manner that protect the poor and the affected communities".

Implications for the Elementary Processes Which Define Consumer Behaviour

All the same, consumer behaviour is influenced by numerous variables acting tightly. Consumers' behaviour is influenced by many factors:

1. Directly observable influences:
    a. Demographic factors
    b. Economic factors
    c. Factors specific for the marketing mix
2. Endogenous influences:
    a. Perception
    b. Information/learning personality
    c. Motivation
    d. Attitude
3. Exogenous influences:
    a. Family
    b. Membership group
    c. Reference group
    d. Social class
    e. Culture
    f. Sub-culture

In the last two decades, social analyses focused on goods and services consumption of the occidental people. These were significantly changed in terms of a general sense of the message, leaving pro-consumerist messages in favour of those anti-consumerist.

Some papers published after 2000, underlined a new criticism current in the area of consumption patterns in the occidental area, highlighting more clear tendencies of some social categories, to engage in activities less oriented to consumption. Some authors, as Zavestoski (2002), Schor and Holt (2000) or Hamilton and Mail (2003) was concerned even to initiate market studies for anti-consumeristic attitude or for return to some extremely simple consumption practices, protective with maintaining the environmental ecologic equilibrium. There are analysts of the consumption patterns like Lunt & Livingstone

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(1992) or Humphery (1998), who study a new orientation of the consumers – to limit satisfaction of the consumption needs by different good and services markets, as a consequence of the high critic attitudes.

Perception

The most important feature of perception is the fact that is selectivity, as being complementary to needs, because of the consumers' features.

A useful concept is just a difference indistinguishable, for instance, in cases of price increasing motivated by different factors, such as green tax. If the increasing of price doesn't exceed the difference just indistinguishable, it is possible that demand for a specific good to be not affected.

"An environmentally sustainable economy — an eco-economy — requires that the principles of ecology establish the framework for the formulation of economic policy and that economists and ecologists work together to fashion the new economy. Ecologists understand that all economic activity, indeed all life, depends on the earth's ecosystem — the complex of individual species living together, interacting with each other and their physical habitat." (Brown, 2001)

The Need for Comprehensive Regulations

The ecological manufacturing and sustainability can gain a certain influence on consumers' decisions, but the price still represents the key variable. All researchers agree on this. Nobody will pay, for instance, fourfold for a fridge just for its less energy consumption. Central administrations need to establish specific regulations, to recommend minimal prices for the unfriendly goods for the environment, in order to make certain the fact that they are not cheaper than those being friendly for the environment. These could increase consumers trust.

In the context of the 12th goal of the 2030 Agenda, mentioned above, the implementation of a 10-year framework program on sustainable consumption and production is envisaged. Developed countries are asked to take the lead of these programs.

Currently, the use of renewable energy resources, ecological agriculture and implementation of an intelligent management of urban waste must be major objectives for both environmental policies as well as those relating to the quality of life.

Feelings and Emotions Consideration

There is a real potential in this area, for instance that demonstrated by the success of some brands in the cosmetic industry. Companies should recognize opportunities and gains generated by the sustainable goods and shouldn't only pertain to risks and costs.

Another example in this area is represented by the fact that some studies demonstrated that those advertisings which highlight the fact that the good had in sight don't encompass children' work are irritating for consumers because they assume a priori that manufacturing is correctly from the point of view of the policies. Furthermore, terms like children exploitation have negative connotations and can cause damages to the positive experience of goods or its purchasing, irrespective of context.

In marketing terms, it is vital, the fact that green goods meet their goals, this making consumer fell that he does the right things.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Selection of the consumers' perceptions is much influenced by their attitudes in the moment of their reception.

Consumers' expectations are closely linked to the process of perceptual selection, implying them percept goods and their performances from the point of view of the benefits they expect to obtain. Market researches show that consumers consider first personal benefits and not these for the environment. For instance, in a supermarket consumers don't wonder first: Do I the right thing buying this? But: If I will buy this, it will be good for me? Thus, they are ready to pay more for this kind of goods. And only after that, they consider that the good must be manufactured in ecological conditions.

Reasons can play an essential role, too, in the perceptual selection, being known the fact that people perceive good related their needs and desires. An intense need determines a person to ignore some perceptions and select only those are related to this satisfaction.

Information

Perception is first, related to the awareness/learning process, which represents an ensemble through people know goods.

In awareness process, specialists pay attention to information sources.

Researches upon consumers' behaviour and attitudes in last decades showed a real interest in problems of environmental harmfulness. But there is still a long distance from attitude to their transformation in practices. In real life, consumers almost don't possess information about present and future effects of consumption decisions to environment or to other people.

In the same time, consumers manifest their decisions in a world where merchandise already are in last processing stage a major change being hard to obtain. The observed changes in consumer behaviour can be seen only in tight areas; they must be supported by strong awareness campaigns in order to become dominant market behaviour being significant for producers. But there is another dike: market is already saturated with advertising messages that increase chances that these campaigns be fast forgotten.

Generating important changes will occur only after a radical change of consumers' attitude. This requests a redesigning of prices policies in order that non-harmful for the environment goods to be chosen and opposite policies to be punished. These request other policies for consumers' information. A study performed in 1990 by Winkler and Voller identified a correlation between consumers' attitude and environmental impact of goods. This correlation was revealed related domestic energy consumption which decreased in those countries where ecological attitude increased, Holland, Germany, Denmark and Sweden.

Goal no.12 of the 20130 Agenda refers the issue of "the relevant information and awareness for sustainable development and lifestyles in harmony with nature". These should be available by 2030 for people everywhere.

Attitude

Attitude was accepted more and more as a multidimensional concept, as a syndrome of constant reactions against social objects (WBCSD, 1996).

An interesting fact is that, in fact, consumers are not concerned directly with reducing energy consumption, but in a specific choice about buying daily goods. Consumers take decisions when they use

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

or discard concrete goods. This means that concrete manifestations of these mental attitudes need to be analysed.

Globally, specific studies identified phenomena of take-over consumption models from developed countries by the developing countries; there is a problem regarding this because first habits related goods having most important impact against environment (cars, steel, and electricity), whilst consumption models for less harmful goods are less convincing. Though, solution consists of modelling consumption attitudes.

Care for environment protection is confronted with interest for personal satisfaction obtaining.

There are researches showing that people have familiar attitudes towards environmental consciousness in terms of factors related to awareness and action, environmental friendliness and willingness to act to act environmentally friendly (Mostafa, 2007; Tuna & Özkoçak, 2012).

Awareness of environmental issues grows day by day. This led to an increased demand for green products. Nowadays globalization is a key feature of the business environment. The technology and information boom represent, also current features of its. These elements have contributed to increase awareness of environmental issues and to generate a favourable attitude toward environmentalism, causing consumers' inclination to purchase green products. But, although the environmental concerns play an important role on consumer intention to buy green products, they are not the only determining factor for purchase (Phau & Ong, 2007; Agyeman, 2014). There are many factors which have been identified as influencing this process, namely, company's environmental reputation (Schwepker & Cornwell, 1991), credibility of environmental advertising (Thøgersen, 2000), environmental knowledge (Mostafa, 2006), and perceived product price and quality (D'Souza et al., 2007).

Investments for Sustainability

Transparency and accessibility of goods and producers are essential both for consumers and stakeholders. Many companies accomplish increasingly sustainability criteria. A specific degree of this criteria knowledge can determine consumers of the goods they offer to identify themselves with these companies' values.

In order to achieve its stated objective of ensuring sustainable consumption and production patterns, the Agenda 2030 takes into account, too, supporting countries developing to strengthen scientific and technological capacities to evolve towards more sustainable consumption and production.

Motivation

Motives have a broad multidimensional character, being built between biologic and social, between internal manifestations and knowledge, between subjective necessity and values as a reference system, between objects and their linkages with people. Because of these, they can't be reduced only at a determinant factor. In order to design an efficient marketing policy, it is important to concern that motives are learnt and they have stability in time, being hardly changeable.

Effective Behaviour

Effective behaviour is not an autonomous process though it can be studied relatively independent; it is a specific resultant of a system constituted by the above-mentioned elementary processes.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are numerous studies on green consumption behaviour. Wu and Chen (2014) have attempted to translate several descriptive variables in such a model. Thus, a positive relationship between attitude and perceived benefit and a negative relationship between perceived risk and attitude were highlighted. This result shows that consumers' evaluation of green consumption is affected by uncertainty; role of perceived benefits is much greater than that of perceived risk, which confirms results of previous research (Rohm & Swaminathan, 2004). Also, positive relationships between normative beliefs and moral obligation and respectively, subjective norm were highlighted. Another significant positive relationship was emphasized on control strength and control belief and behavioural control, supporting the findings of Ajzen's (1991; 2002) that availability of time and financial resources influence the green consumption behaviour, which makes consumers to practice green consumption as they are more confident of their resources. The findings of Cheng, Lam, and Hsu (2006), Baker, Al-Gahtani, and Hubona (2007), and Cronan and Al-Rafee (2008) regarding the significant positive relationship between attitude, subjective norm, and behavioural control and behavioural intention were also supported by Wu and Chen (2104). Also, a significant positive relationship was revealed between behavioural intention and behavioural control, respectively real behaviour, confirming the conclusions of Mostafa (2007) and Norman and Conner (2005).

Avant-Gardist Demand

As consumers become more informed and more educated, increasingly more of them are beginning to realize the impact that their consumption habits have on the environment. On the other hand, green marketing began to gain importance both in theory and in business (Ryan, 2014).

According to Obermiller and Spangenberg (1998) and Marques and Almeida (2013), the consumers' skepticism about the green features is no different compared to general skepticism towards the features usually communicated by marketers.

There are practical demonstrations of the fact that avant-gardist demand establishes trends which involve most of the consumers. In this respect, female consumers play a decisive role as follows they manifest much more responsibility and involvement in buying acts. They stand on utility, longevity and social or ethical standard.

ECOLOGICAL CONSCIOUSNESS

The ecological consciousness has complex character multidimensional. Thus, consumers should be informed about several aspects as follows.

Consumers must know the environmental consequences of their consumption behaviour. At the same time, they must understand the consequences of their behaviour as a result of attitudes towards environmental issues and products. The first effect consists of changing the consumption patterns; behaviour resulting from their ecological attitude will contribute to solving environmental problems and increasing the quality of life.

In the current conditions, the environmental awareness as a form of social consciousness plays an important role. Thus, ecological consciousness must contribute to building the ecological culture of human personality. Ecological culture requires deep knowledge of the laws of nature and society development,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the interdependence between man and the environment, of the awareness of the need to protect nature and to use the natural resources as rationally and efficiently as (Uhl, 2004; Schendler, 2009).

In summary, ecological consciousness can be defined as a form of social consciousness reflecting the correlation between society and nature, the actions of man over nature and consequences of these actions, as well as the substantiation of the ways and means of environmental protection.

Ecological consciousness comprises two distinct components, namely: a theoretical component and another one with practical character. The theoretical part of the ecological consciousness is a system of ideas, concepts and theories about the forms of interaction between society and nature. These ideas and theories expand and deepen the spiritual basis of the ecological design that reflects the character and the purpose of the environmental activity. Ecological consciousness with practical character is formed spontaneously as a result of practical activities of the people. It is the primary form of perception by a man of his place and his role in relation to the environment. These components are reflected in the multidimensional nature of the ecological consciousness (Gray, 1985).

The Dimensions of the Ecological Conscience of Consumers

- Informative Dimension
- Cognitive Dimension
- Operative Dimension

THE GREEN DIMENSION OF THE MODEL OF CUSTOMER SATISFACTION

Drivers of the Green Dimension of the Model of the Assessment of Consumer Satisfaction

Reality has shown that proactive, long-term, visionary strategies, companies bring more benefits for companies than those based on classical management based on traditional resources. The companies concern for the environment represents, from this perspective, an opportunity. Thus, an organization will gain a competitive ecological advantage over the competition ecological if it is "better" than this, in terms of environmental issues, at least in a specific area.

The companies' interest for environment first appeared in campaigns for social responsibility inspired by the multinationals model. The adoption of "green" strategies has been boosted, too, by environmental regulations in certain areas.

In the current context, economic organizations are evaluated not only in terms of economic performance, but also in relation to their contributions to economic and social development of the community. Thus, the concept of social responsibility (SR) emerged. WBCSD World Business Council Sustainable Development) defined corporate social responsibility as "the Continuing Commitment by business to contribute to economic development while improving the quality of life of the workforce and Their Families as well as of the community and society at large" (WBCSD Business Solutions for a sustainable world). Thus, SR aims to help companies to become actively involved in local community life, enabling them to assume roles as global citizens and local neighbours in a fast-changing world. Such programs have become, genuine marketing tools designed to bring image benefits for their proposers. Corporations acquire "human face" is more than just products and services (Sima & Gheorghe, 2007).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

"Greener means cheaper." Investment in "green products" is manifested as an eco-trend in business. Some players have already intuited this trend and began to pay attention to this segment.

Companies that make the step to launch organic products want to achieve consumer awareness by associating their image with clean products, but they also look for new customers.

People want an ecological approach to everyday life, but they seek, primarily, personal gain, which can be transposed into incentives and facilities.

On the one hand, green customers and the public generally are more aware of the ecological behaviour of organizations and to their social involvement.

On the other hand, organic products and environmental activities are not easily accepted by a large part of the audience, especially by the one who does not have a strong and clear ecological awareness.

The degree of concern for the environment has increased significantly so that environmental problems have come to represent now an essential factor in making consumer decisions.

The items presented above have led us to take into account a new category, in modeling and evaluation of customer satisfaction, which the authors have called Green Dimension. (Figure 1).

ECSI model was the starting point. In relation to the determinants of ECSI model, green dimension can be justified at least by a few elements namely:

- In terms of image, the green dimension can be expressed in the concept of Corporate Social Responsibility. CSR activities of a company provide benefits at two levels: the social level and the company level. The social benefits are related to the welfare and the public interest. In terms of benefits of the company, at least four issues are to be mentioned, namely:
  - Possibility of differentiation over the competition and achieving brand loyalty. There are studies which have shown that when consumers have to choose between similar products, their preferences are turning to those brands perceived as being "responsible". Thus:
    - 70% of European consumers believe that the responsibility of a company is important in the decision to buy a product or service (MORI 2000);

Figure 1. A new model of the assessment of customers' satisfaction
Source: Sima, 2010.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

        - 86% of Americans were inclined to change a brand in favour of another similar, but involved in a social cause (2004 Cone Corporate Citizenship Study).
    - Improving the company reputation.
    - Currently, companies' success depends directly on the trust given them by the authorities, media, partners and the community in which it operates.
    - On the other hand, if a company demonstrates its responsibility to the community, the related to reputation benefits have immediate consequences. Thus:
        - 61% of opinion leaders around the world are willing to recommend the products of a responsible company (The Insightpoll.com Opinion Elite Panel, 2004);
        - 84% of Americans believe that social responsibility is important when they think about the companies they agree to see operating in their community (2004 Cone Corporate Citizenship Study).
    - Increased sales and market share of the company.
    - Attracting and retaining valuable employees.
- In terms of perceived value, The Green Dimension may be considered in many respects. Thus, in Romania, Daedalus Consulting and Green Report conducted the first quantitative Romanian research on environmental issues. The result of the survey was published in February 2008 and showed a high willingness of Romanian people to pay more for green products. Compared to values at international level, almost 90% of Romanian citizens have expressed willingness to pay more for environmentally friendly products. After Romania, according to the TGI survey the highest availability was recorded in Brazil, India and Mexico. Countries that were not subjected to the rigors of environmental discipline are top ranking. This result can be explained by the fact that those countries, not having the costs experience of these measures, have a higher receptivity to them. Thus, a few results are noticeable:
    - Over 73% of respondents are willing to pay more for organic food.
    - Over 49% of respondents are willing to pay more for renewable energy.
    - Over 36% of respondents are willing to pay for products with biodegradable compounds. (Daedalus Consulting, Green Thinking, prepared for Green Report, 2008)
- In terms of customer expectations, The Green Dimension can be primarily expressed by their expectations about the energy efficiency of products, meaning that they seek products operation of which does not require high energy consumption. Also, customers have expectations regarding low emission of pollutants. A good example is the case of passenger cars, for which the level of the paid taxes is inversely proportional to the emissions level. It appears, therefore, that customer expectations related to green product features are primarily determined by the pragmatic attitude of the new consumer.
- Regarding perceived quality of the green products, the green dimension can be recognized in the low polluting level of the eco-friendly products, due to the use of new production technologies.

Specific Issues of the Green Dimension for Customers Satisfaction

People seek personal benefit rather than an ecological approach to the everyday life. Beyond awareness, the ecological approach should be assumed by consumers (Sima, Gheorghe, 2009).

The question arises is: How strong is consumer interest in environmental issues?

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Based on the results recorded in The 2009 BBMG Conscious Consumer Report: Redefining Value in a New Economy, Raphael Bemporad, co-founder of BBMG, said that brands would be able "to close the green trust gap" if they would take into account new customer expectations, which evaluates acquisitions "based on both value and value" (BBMG Conscious Consumer Report: Redefining value in a new Economy, June 2009, p.34). Thus, they have to provide performance products that match consumers' goals; with acceptable prices that for them.

According to Sivesan, Achchuthan and Umanakenan (2013) there is a significant positive relationship between green marketing practices are positively and customer satisfaction. The green customer satisfaction is strongly influenced by the quality of the product (Johnson & Ettlie, 2001).

Taking into account the above, we can identify three specific levels of customer satisfaction green dimension, namely (Figure 2):

- Company
- Product/Service
- Price

The Company Level

Consumers reward those brands which are based on the best practices of the company.

In addition to the classical requirements such as economic performance, quality management and communication policies, a modern assessment of a company is also considering specific issues such as the organization's involvement in the social life of the community. Modern organization as a legal entity - has primarily, duties to society.

Customer satisfaction is considered by Scott M. Smith as "a reflection of the expectations and experiences that the customer has with a product or service".

Evaluation of products and services is actually made following customer expectations. They are found in the rules of performance that reflects accepted environmental standards set by the business

Figure 2. Tree of customer satisfaction for the green dimension
Source: Adapted after Sima & Gheorghe, 2009.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

environment, other companies, industries, and even organizational and national culture. The most effective strategic approach seems to belong to those companies that have adopted social responsibility and sustainable development as a business philosophy. Integrating social and sustainability principles in their operation provides long-term value for the shareholders through practices that are, in fact, satisfactory to all stakeholders. Social Responsibility was developed by taking into account environmental and social opportunities as business opportunities. In this respect, the strategic capacity of organizations is adapted in order to efficiently exploit such opportunities.

The new consumer is increasingly more concerned about his image that reflects the image of his suppliers. Therefore, their reputation becomes, in turn, increasingly more important to the consumer. Thus, elements which are subject to social responsibility activities such as concern for health and safety as well as customer requests, ensuring environmental conservation, supporting philanthropy, come to be positioned in the core of companies concern. The result of such strategic approach is to eliminate barriers to communication with the customer, such as mistrust, negative perceptions, lack of information, low availability, leading, ultimately, to increase sales of environmentally sensitive products. The importance of each factor varies by product, industry and geographic area.

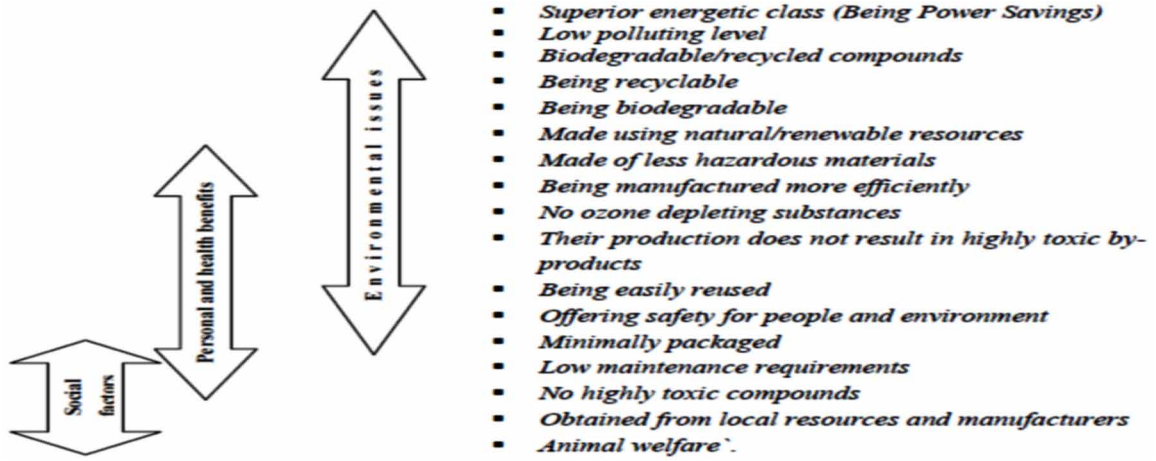
The 2009 BBMG Conscious Consumer Report: Redefining Value in a New Economy has found that 77% of American consumers agree that "can make a positive difference by purchasing products from socially or environmentally responsible companies".

There are differences between proactive and reactive companies, in terms of performance. These differences are starting to decrease as the environmental education becomes more important. This highlights the role of governments. They can support cooperation between companies and provide educational programs to help companies in understanding the benefits of involvement in environmental protection. This is especially true in the case of small and medium enterprises in developing countries, which should encourage and reward innovation at all levels (El Dief & Font, 2010).

The Product/Service Level

Consumers are looking for "green" features of the products and services.

Climate changes seem to be those that have drawn attention to environmental issues to the greatest extent. At the same time, rising energy prices is another factor that appears to significantly influence the buying decision. Thus, the consumers are getting more and more interested, firstly, in products of high energy efficiency classes. At the same time the low level of environmental damage may represent an important factor in the decision of purchasing. The conclusion is that, firstly, the personal benefits are tracked and only after that the ones affecting the environment.



The most popular and demanded "green products" are:

- Organic food
- Renewable energy

But in addition, other important ecological features of the products / services may be considered to represent important factors in purchasing decisions: "superior energetic class, low maintenance requirements, low polluting level, biodegradable/recycled compounds, no highly toxic compounds, being easily reused, recyclable or biodegradable etc." (Sima & Gheorghe, 2009).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Green satisfaction sources
Source: Sima & Gheorghe, 2009.

Thus, in terms of involvement in purchasing decisions, environmental issues can be classified into three categories, namely: environmental issues, personal benefits and social factors (Figure 3).

The Price Level

At this level, the main issue is about consumers' willingness to pay more for "green products/services".

There are numerous studies conducted all over the world that show the green procurement volume is increasing, but the question that arises is: Are the consumers willing to pay more for green?

A McKinsey survey of 1,000 consumers in Europe and the United States performed in 2012, showed that many people would pay more, but only up to a point (Miremadi et. al., 2012). The study took into account acquisitions in the automotive, building, electronics, furniture, and packaging categories. Between 70 and 80 percent of the respondents said they would pay an additional 5 percent for a green product if it is at the same level of performance as a non-green alternative. But as the premium increase first, willingness to pay decreases.

The "historical" reluctance to pay a bonus for ecological products is reduced as consumers associate the responsibility for protecting the environment to their health and other direct benefits.

The core of this internal belief system is ecological value.

Ecological value can be explained by the implicit or explicit philosophy of desired value and it may be placed as a behavioral variable within the system of values.

The Green Strategy Mix: A New Holistic Approach

Two international studies, conducted in 2009 (Sustainability in the 2009 Recession and Green Brands Survey 2009) showed that the recession has not lowered the interest in 'green' products or services, quite the contrary. Worldwide consumers associate ecologic products with the idea of reducing consumption and saving, despite the fact that the main barrier for purchasing of these products is the perception that their price would be higher than that of the classic ones.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In January 2009, the Boston Consulting Group presented the results of a study entitled "Capturing the Green Advantage for Consumer Companies". The aim of this study was to discover if and how consumer attitudes towards green products and services has been affected by the economic crisis. The conclusion was that during the crisis, consumers remained interested in organic products. Determinants of this behavior were represented by the benefits that eco-friendly products have, on the one hand, upon the environment and, on the other hand, at the personal level. As a conclusion, BCG advised companies on how to respond to consumer expectations regarding environmental protection being, at the same time, able to reach, their business targets.

It should be noted that the study was conducted in a gray period, characterized globally by uncertainties, among others, regarding the appropriateness of investing in a new environmental strategy.

As a concrete result of the study a best practice guide for the company was drawn up.

In this guide guidance for companies was offered, divided into four categories, based on which companies can meet consumer requirements on environmental protection and their business objectives. The four categories are Planning, Process, Product, and Promotion.

From our point of view, "the green products and services are designed, manufactured, priced and promoted by people for people" (Sima & Gheorghe, 2009). This approach has led us toward a holistic approach to green satisfaction, according to which people and their double the role of producers and consumers should be in the same time considered.

Some analysts say that for companies, there is only one thing which is more important than environmental initiatives, namely the ability to communicate it to consumers.

Thus, in terms of green strategy, we consider that a fifth element can be added, namely the People.

Another observation we had regard was that the eco-efficiency represent a production principle requested by the green products. It refers to less polluting production systems used to produce goods and services which have a lower environmental impact, which better corresponding with customer needs, being, thus, more competitive.

Starting from this, the authors, also, integrated Eco-Efficiency into a strategy mix that they named "The Green Strategy Mix" (5P+EE) (Figure 4).

- Planning Strategy
- Processes Strategy
- Product Strategy
- Promotion Strategy
- People Strategy
- Eco-Efficiency Strategy (Sima & Gheorghe, 2009)

The first four was highlighted by the Boston Consulting Group into a recent study, aiming to assess green attitudes and shopping behaviors. They call them The Four Ps of Green Advantage.

Being "green" has become a business plan itself. Producers attempt to differentiate the competition and gain a large share of the market. There is a "green" competition, in which each company tries to move forward, aiming to move forward having regarded the continuous growth of the customer preferences for 'green' products.

Nowadays, producers, not just consumers, seem to show a wave of interest in the environmental aspects of the business, because they realized that eco-environmental production methods can be profitable. So we can say that in a comprehensive approach, the strategic mix can be improved.

Figure 4. The 'Green Strategy Mix'
Source: Adapted after Sima & Gheorghe, 2009.

Given the continued growth of customer preferences for 'green' products, the existence of a product having a less impact on the environment, in the company's portfolio, it is often better in terms of quality and marketing.

Being "green" has become a business plan itself.

Solutions and Recommendations

Four main determinants of population's attitude towards the green dimension can be identified:

1. Phenomena with negative environmental effects;
2. Activities to protect environment;
3. Willingness to save and motivation for it;
4. Willingness to pay extra for green products and justification for it.

Phenomena With Environmental Impact

According to the above-mentioned study conducted by Daedalus Consulting in Romania in 2008, atmospheric pollution and deforestation are considered to have the highest environmental impact (Over 84% of respondents placed this issues on the first and second place). Respondents considered that pollution can be greatly influenced by each of us.

These two results seem to be in a relationship of interdependence that can be verified in future research through correlation analysis.

Genetically modified foods are ranked third, nearly of the above mentioned two categories.

Regarding how respondents considered that they might influence each of these phenomena, it can be observed that in all cases the population is considered largely unable to act.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Activities for Environment Protection

As regards activities for the environmental protection, there is a clear correlation between the activities about which respondents say they have performed over the past 12 months and those who declare that they intend to undertake in the next 12 months.

There is also an increase of approximately 10% of those who declare that they intend to be involved in such activities in future, which may suggest a tendency to declare rather act or to reflect the behavioural changes induced by the economic recession.

Willingness to Save and Justification for It

Regarding products that respondents say they save, the most name energy (over 70%). On the second place, they considered water (60%).

Regarding the reasons for showing this kind of attitude, most respondents stated that they try to reduce costs (85%) and only 13% say they care about the environment.

This shows serious problems in society and requires a deep study in order to identify determinants of this behaviour to improve.

"Green Products" and Willingness to Pay More for Them

The products were grouped into three categories:

1. Organic food;
2. Renewable energy;
3. Products with biodegradable compounds.

Organic foods are outlined of these, almost three-quarters of the respondents (73.1%) saying they were willing to pay higher amounts. About a half (49.1%) were willing to pay more for renewable energy and almost a third (36.3%) for products with biodegradable components.

And this result matches to the behavioural pattern mentioned above, showing that for Romanian people care for the environment not prevail, but rather care for them.

A mismatch occurs when respondents are asked to respond if they are willing to pay more for "green products". On this question, nearly two-thirds affirmative answer, and if we add them those who are in partial agreement, we achieve a percentage of over 84%. This response comes, however, contradict the results mentioned above. Thus, this it seems to support, too, the conclusion that the people of Romania are well in words, but less than in facts.

FUTURE RESEARCH DIRECTIONS

All of these above-mentioned elements determine a model of an ecological community, including:

- **Resource Ecology:** Identifying local resources that can be ecologically exploited;

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Activity Ecology:** Directing investment towards non-polluting activities (ecological agriculture, "clean" technologies, ecological services, ecological tourism, etc.) and writing and implementation of local development projects that take into account ecological constraints;
- **Ecological Behavior:** Building awareness within the local community regarding the serious long-term consequences of non-ecological behavior (development of ecological citizenship);
- **Ecological Culture:** The introduction of ecology information in school curricula, as a support for the formation of ecological culture.

Given the above, we believe that an investigation should be conducted in order to help us to shape and measure the consumer green behavior. The ultimate goal is to develop a system of indicators which may be used to measure the green satisfaction of the consumers, namely, Green Dimension Index.

The starting point of this research will be the model shown in figure 5.

CONCLUSION

Operationalizing studying of the needs, values, behaviours, psychology or aspirations of goods and services consumers is a laborious and complex process because every chapter of people consumption as well as market dynamic of every good or service follow specific laws and there are necessary separate investigations for every good or consumption chapter, in order to explain or forecast general or sequential behaviour of the consumers.

Nowadays, there is no exhaustively understood of consumption components or of real motivations for adopting specific consumption practices, even in this area there already are accumulated many studies, observations and methodical researches.

But it was never possible an investigation totally satisfying in respect of the rationality of the consumers, so much the less in respect of the unconsciousness impulses lying the effective consumption

Figure 5. Model for green dimension index evaluation
Source: Enhanced after Sima & Gheorghe, 2015.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

behaviour. Anyway, the social and economic theory of consumption made important steps in respect of the delimitation between rational and emotional motivations of goods and services purchasing.

Changes dynamic in goods and services markets was very high in the last two decades. In those countries having market economies, where profile if demand rapidly changed, these lead to a rapidly change of the offer parameters and default changes of some elements of the research methods and techniques of the consumption patterns.

Adoption of some sustainable practices of consumption involves the use of correlated goods and services which answer to the satisfaction of basic needs, under conditions of minimization of the natural resources exploitation, avoiding resources waste and polluting emissions, along an entire life-cycle, so that these don't affect life chances of future generations.

Desirable changes of some features of the consumption patterns as follow as new exigency imposed to manufacturing processes involve:

- Promotion of the examination of those consumption patterns which block sustainable development, as well as of the modalities of changing this behaviour, at the global level, endorsing especially those people having a consumerist life style.
- Identification of the most efficient policies and tools for break-up the unsustainable consumption/ manufacturing patterns, including by information dissemination and ecological alert.
- Performing a more equitable distribution of developing resources inside and between countries.

KEY TERMS AND DEFINITIONS

Green Behavior: A pro-environmental behaviour, people being good administrator of natural resources.

Green Customer Satisfaction: A state which results from the green consumption experience, including: green product satisfaction, companies reputation and image satisfaction, and less harmfulness satisfaction.

Green Dimension: A new category proposed in order to model the customers' satisfaction. The main elements need to be had in sight are: superior energetic class, renewable energy, low polluting level, products with biodegradable compounds, organic food.

Green Product: An ecological product. It's manufacturing process and its use does not generate negative environmental effects.

Green Strategy Mix: A strategic system which integrates Planning Strategy, Processes Strategy, Product Strategy, Promotion Strategy, People Strategy, and Eco-Efficiency Strategy.

Sustainable Consumption: A consumption model which seeks to preserve resources for future generations to be able to satisfy their needs.

Sustainable Development: A concept 'that meets the needs of the present without compromising the ability of future generations to meet their own needs' (Brundtland Commission, 1987, Report of the World Commission on Environment and Development, United Nations). It includes economic development, social development and environmental protection.

Chapter 58
Perception of Romanian Consumers on Ecological Products

Violeta Sima
Petroleum-Gas University of Ploieşti, Romania

Ileana Georgiana Gheorghe
Petroleum-Gas University of Ploieşti, Romania

ABSTRACT

This chapter aimed to investigate perceptions and attitudes of Romanian consumers about organic products, in order to study the connection between knowledge and attitudes of consumers and their place in purchase decision-making system to understand their behavior toward organic food. In the first part, after a brief introduction, the authors tried to perform a review of the literature in the field, starting from the presentation of the concept of green or ecological consumption behavior and the notions related to it. A synthetic scheme of the drivers of the green market was proposed as a conclusion of this introductory part. The main concern is about consumption of the ecological products in Romania. The authors identified a number of 17 relevant studies performed in Romania in order to help them substantiate their work. They took into account two issues, namely, Ecological Non-Food Products and Ecological Food Products.

INTRODUCTION

During the last years significant changes occurred within the trinomial including economic environment, ecological environment and social environment.

The economic environment together with the social one - represented in the new patterns of consumption - have influenced the ecological environment - represented by the environmental dimension of the consumption of goods and services.

Sustainable Consumption represents “that form of consumption which uses goods and services that respond to basic needs, enhancing the quality of life, improving resource efficiency and minimizing

emissions of waste and pollutants over the life cycle, so as not affect the future generations' lives" (Sima, V., Gheorghe, I. G., 2015).

In this context, the followers of eco-economic and eco-social models attempt to make their mark on consumerist tendencies, aiming to determine the orientation of both economic operators and population, towards more pronounced ecological and eco-social consumption patterns.

We can assume that the model of green economy begins to require and determine changes in consumer habits. The sustainable consumption models or the green consumption patterns began to dictate market trends.

A change of the consumers' behavior means primarily a fundamental transformation of the values and life style. Changing the thinking and action of consumers cannot be imposed by the authorities. The emergence of new and durable traditions in consumers' behavior requests a wise informing and consulting campaign.

The objective of this chapter is to investigate perceptions and attitudes of the Romanian consumers on ecological products, in order to study the connection between knowledge and attitudes of consumers and their place in purchase decision-making system to understand their consumption behavior.

BACKGROUND

The issue of organic products and how they are perceived in the market have become topics of general concern for researchers worldwide. The end of the twentieth century and beginning of XXI century were marked by a growth of the concerns in this area worldwide. Thus, new concepts have emerged and have been developed, such as: eco-attitude, sustainable consumption patterns, green behaviour, green attitude, green intention, green purchase, eco-consumer, eco-products (with many divisions), green market.

A large number of studies on green or ecological consumption behaviour found that consumers who concern more on environmentally friendly are characterised by a specific *eco-attitude*. This concept contains notions related to:

- Ecological Citizenship
- Environmental Citizenship
- Green Citizenship
- Ethical Investment
- Social Economy
- Sustainable consumption patterns
- Green Purchase
- Green Purchase Intention
- Green Purchase Behavior
- Green Purchase Attitude
- Eco–Consumer
- Eco-Products
- Green Market.

Ecological Citizenship, Environmental Citizenship, Green Citizenship

In a study published in 1994, Polonsky emphasized that citizens should be more involved at the individual level, in environmental issues, stressing that this is not only the problem of businesses and governments.

In the specialized literature Andrew Dobson is considered as playing a decisive role in defining these concepts, combining political discourse with economic theory (Hayward, 2006).

Ecological Citizenship refers to the orientation towards nature, given mainly two aspects, namely (Dobson, 2003):

- An action way that aims at valuing and protecting the natural environment;
- Awareness of the environmental balance of the activity at the individual level (individual ecological footprint).

In terms of theoretical discourse, there is a consensus regarding the need for an active environmental citizenship model. It is accepted that the transition to the sustainable society imposes in addition to institutional restructuring, changes at individual level of their convictions, attitudes and behaviour (Carter, 2007).

The concept of *environmental citizenship* was introduced by Environment Canada.

Environmental citizenship represents a way to build the sustainable society by determining people to move towards public environmental good, by giving up the traditional methods of stimulating the market dynamics.

According to Bell, McGillivray, Donald and Pedersen (2013) Environmental citizenship imposes individual responsibilities - a green lifestyle, direct participation in environmental decision making and holding businesses to account – and individual rights - access to environmental information, access to justice in environmental matters and clean and healthy environment.

Dobson (2004) makes a distinction between environmental citizenship and ecological citizenship. He argues that the environmental citizenship can be understood in the context of the relationship between rights and obligations at social-governmental level, having in sight a management-based approach. The ecological citizenship refers to the relationship between rights and obligations at the individual level.

Seyfang (2006) has highlighted relationships between ecological citizenship, local organic food networks and sustainable consumption, starting from the hypothesis that ecological citizenship represents an "an innovative new force" able to lead to sustainable consumption by involving local organic food networks.

In Dobson's opinion (2007), a distinction must be made between attitudes and behaviors. Thus, he considers that attitudinal changes are deeper - manifesting on long term - than behavioral changes – manifesting on short term. Dobson argued that the behavioral changes, caused by environmental citizenship considerations, take longer than those determined by classical fiscal stimulus.

A form of ecological citizenship is *the ethical investment*. The notion of *ethical investment* is widely used in the UK (Carter, Huby, 2004). It defines the type of investment that determines the implementation of the strategies for social responsibility.

According to Graham (2005), the concept of green citizenship includes both the environmental citizenship and the ecological citizenship as Dobson defined them in 2003.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Graham considered that the social economy is a framework for developing green citizenship, because the features of specific organizations offer the best possibility for citizens to express their environmental orientation. The social economy gives opportunities to the people to act on governance models, production and consumption, which directly affects their livelihood at individual and community level.

Sustainable Consumption Patterns

Considering the theory and practical reality, we can say that a new green model of consumption emerges, based on certain sustainable types of production. According to this model, consumers prefer to purchase green products because they can satisfy several eco-needs at the same price. This will determine the manufacturers to rethink classical products (Sima, 2014). But, consumers do not buy these products especially, because they will become more thoughtful and will look for obtaining certain advantages. Thus, they will consider the possibility to rent or share the products with other customers.

According to Sima and Gheorghe (2015) people should shift to a new model of consumption specific to the green economy. This sustainable consumption model is shaped by two main features, namely long term thinking and technological innovation. Taking responsibility for the current actions is important for keeping of the best possible development opportunities of future generations. Technological innovations aim to develop new products or new manufacturing methods, new technologies in order to meet the above mentioned needs.

Sustainable consumption patterns require a multi-level approach (Sima and Gheorghe, 2015):

- The administrative level. The correlation of the demographic policies with the economic, educational, and social ones is important. This may contribute to achieving an optimal balance between resources and needs of the population.
- The business level. Companies should assume more responsibilities in the environmental field. In their development strategies should be found more often specific goals, such as generating innovation and creating green jobs, implementing healthier and less polluting production processes, using the principles of eco-efficiency.
- The civil society level. Ecological citizenship should be promoted.

Green Purchasing

The concept of green purchasing can be found in theory as Environmentally Preferable Purchasing (EPP). It considers purchasing mostly of those products which generate less negative effects or, preferably, positive effects on human health and environment compared to similar traditional products.

Specifically, green purchasing refers to the entire production chain, from raw material acquisition, continuing with manufacturing, packaging, and distribution. But, also, operation, maintenance, and removal of the products are taken into account. Thus, this concept is related to other concepts, such as recyclable or reusable products, energy conservation and natural resources preservation.

Straughan and Roberts, in 1999, and Cornelissen et al., in 2008, showed that buying green products (Green Purchase Intention) is positively correlated with environmental concerning, i.e. Green Behavior.

In our opinion, the main advantages of green purchasing consist in:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Costs reducing and improving the environmental condition.
2. Developing of the markets for recycled materials.
3. Promotion of eco products (less toxic products) in order to protect health and safety of employees.
4. Energy saving and green products promoting.

Green Purchase Intention, Green Purchase Behavior, Green Purchase Attitude

These notions began to emerge in theory after 1990.Thus, since 1991, Schwepker-Jr. and Cornwell highlighted the importance of communication about environmental issues in order to determine buying green.

Yam-Tang and Chan, in 1998, and Fraj and Martinez, in 2006, revealed a direct link between concern for the natural environment and green purchasing behavior. A similar conclusion results from the study of Haron et. al. (2005), which states that sustainable consumption, can be correlated with awareness of the environmental issues.

There are studies (Chan, 2001, Beckford et al., 2010) demonstrating that Green Purchase Behavior is strongly determined by Green Purchase Intention.

Eco–Consumer

An eco-consumer can be defined as a person who is aware of environmental issues and obligations, and who supports its causes. He is willing to pay more for purchasing an eco-product compared to a classic one with similar features (Reitman, 1992).

Some researchers distinguish two categories of green behavior, namely, behaviors related to reduction of consumption of energy resources and green purchasing decisions and behaviors. Regarding the first category, it is about lowering use of private cars, reducing the temperature of the heating devices or reducing the consumption of water and electricity). In such cases, consumers are not obliged to additional expenses, but often changing of personal habits is imposed. But there are cases when green purchasing behaviors are followed rapidly by additional costs. In the second category purchasing of new equipment for home heating, purchasing and installation of insulation materials, energy-efficient household purchasing, substitution of classical lighting systems with CFL or LED systems etc. are included (Shabani, N., Ashoori, M., Taghinejad, M., & Beyrami, H., 2013).

In order to improve the efficiency of organic products marketing, green consumer segmentation is required. For this purpose, the traditional segmentation variables are used, namely, geographic, demographic, psychological and behavioral variables. One of the most often mentioned variables takes into account the ecological behavior theory. Thus, five types of green consumers have been identified.

In a study conducted in 1993, five categories of green consumers were identified, taking into account the behavioral, attitudinal and demographic variables. The five categories are (Iyer and Banerjee, 1993):

- **The True-Blue Greens:** They manifest the highest level of environmental awareness, being very willing to change their buying and consumption behavior;
- **The Green-Back Greens:** They are also committed to take green decisions, but not to the same extent as those in the first category;
- **The Sprouts:** They admitted that a change of the behavior is needed, but they are just started this journey;

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **The Grousers:** They let environmental responsibility on behalf of companies;
- **The Basic Browns:** They do not wonder about the difference between behavioral patterns or do not even care.

In 1990 the Natural Marketing Institute (NMI) market has performed a segmentation of the green consumers market, considering more than 100 criteria. Five categories resulted:

- **The "LOHAS" Group (16%):** They have very innovative visions relating to the environment and society, generally, are always looking to find new possibilities to do more and do not care that they have to pay extra;
- **The "Naturalists" (25%):** They are the ones who are primarily concerned about themselves and their families health and wellbeing and then about the environment protection;
- **The "Conventionals" (23%):** They are interested in solving environmental problems, but they want a pragmatic approach, following return on of their actions;
- **The "Drifters" (23%):** They are not too concerned about the environment. Although they accept that there are problems, they prefer to postpone them, aiming firstly to obtain a more favorable social image;
- **The "Unconcerned" (14%):** They are the least interested in environmental issues. Their purchasing decisions are based mainly on price, value, quality and comfort (Molyneaux, 2007).

Applying the principles of social economy generates obligations to the business environment. Thus, companies must increase the degree of transparency. It is their responsibility to show clearly and correctly characteristics of the products offered, highlighting their environmental characteristics. The task for marketers is to identify green consumers. A correct and effective communication is the tool that can help in achieving this objective. (Rex and Baumann, 2006, Mintz, 2011).

Eco-Products, Ecological Products, Green Products

Green products refer to products presenting the highest ecological / environmental criteria and concerns, according to the EU eco labeling schemes or other similar protective instruments and initiatives (e.g. EMAS, Energy Star, Carbon Neutral etc). Green products also refer to non-food products which respect the highest ecological / environment criteria during their entire life cycle, according to the EU eco-labeling schemes or other similar initiatives to environmental labels (such as Blue Angel, Energy Star, EU energy labels or Carbon Neutral).

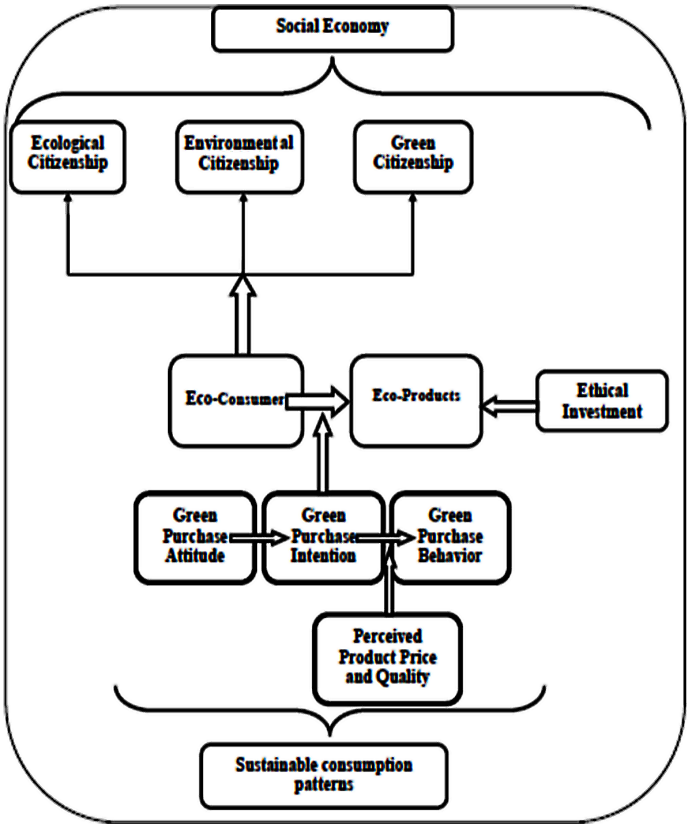
In terms of food products, promotion of green products will reduce the environmental impact caused by the production and consumption of non-organic products, since consumers will identify them and they will prefer them to other products. As a result, more and more real "green" will be produced and consumed, and thus increasingly fewer "non-green" goods will be cultivated and consumed. It is obvious that this will change models / patterns of production and consumption and environmental pressure will be minimized.

Ecological products have to meet certain evaluation criteria, such as weight reduction, product longevity, ease of disassembly, reusable components, recyclable package materials, energy efficiency, resource recycling, and conservation. The evaluation criteria depend on the product area.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Most studies have shown that most of the people consider that green product prices are higher than those of similar conventional products. However, an increasing number of people are willing to buy these organic products (Bhate and Lawle, 1997).

Therefore, it is found that clients have expectations about that all products should meet environmental safety without reducing their quality. This means that, in terms of product quality, eco-consumers have high expectations from the business. The producers of green products must be concerned about the products quality and their environmental benefits. Meanwhile, in order to obtain the best possible image in the market, they need to consider an as effective as communication of these concerns to customers. D'Souza, Taghian and Lamb, 2006).



Consumers look for personal benefits in chosen products and, consequently, in the green products, too.

Most often mentioned 'green products' are:

- Organic food
- Renewable energy.

But, besides these, we identified some important green issues for products/services: superior energetic class, low maintenance requirements, low polluting level, biodegradable/recycled compounds, no highly toxic compounds, being easily reused, recyclable or biodegradable etc.

Figure 1. The Drivers of Green Market
Source: Proposed by the Authors

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Thus, Sima and Gheorghe (2009) identified three types of green issues:

- Environmental issues, which appear having less resonance with consumers than other factors in the 'ethical space'
- Personal and health benefits offered by more sustainable products
- Social factors, like animal welfare, which weigh in more heavily with mainstream consumers than broader environmental factors such as carbon footprint, according to some recent research.

Customers are increasingly drawn to businesses, products and services that are green, organic, natural, clean, and sustainable (Sima and Gheorghe, 2009):

- Organic retail sales have grown
- Green buildings are forecast to grow
- Growth of sales of organic food products with antioxidants, fiber, no preservatives
- Natural and mineral water and nonfizzy drinks have grown.

Green Market

Green market features arise from specific relationship between supply and demand. The demand starts from the eco-consumer and the supply is provided by the manufacturer of eco-products.

CONSUMPTION OF THE ECOLOGICAL PRODUCTS IN ROMANIA

Motivation

The ecological products have demonstrated that they are positively distinguishable from the classical ones. Thus, supporting the eco-markets development should be based on the knowledge of demand for organic products. Promoting of permanent education about responsible consumption is essential.

This analysis is justified by the following considerations:

- In recent years at the level of the world market and of the Romanian one, an increasing demand for organic products was recorded.
- Knowledge of the ratio between imports and exports of organic products in Romania is important for the analysis of the specific market.
- Knowledge of the factors influencing consumption of organic products constitutes a key - element in order to formulate the marketing - mix of these products:
    - The development of products which correspond as much as possible to the requirements and expectations of the Romanian eco-consumers;
    - Development and implementation of an appropriate pricing strategy, especially given the fact that there is a perception that organic products have higher prices than similar classical products.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Concerning promotion, a decisive role could play consumer education and their correct and transparent information on the potential advantages and disadvantages of organic products compared with similar classical ones.
- The distribution of organic products should take account of certain issues such as:
  - With regard to food products, they do not have preservatives, additives, which require providing certain conditions of storage and transport.
  - The packages must be also recyclable.

Objectives

Recent studies based on statistical data and market research have shown that, currently, the market for organic products show an upward trend in Europe and globally. In Romania ecological agriculture represents a niche market that is not exploited enough, but which has a great development potential. In this context the role of the consumer is crucial for trends and perspectives for future development of environmental markets.

Our demarche has envisaged understanding of some certain issues:

- Knowing how consumers define ecological products;
- The advantages offered by the organic products;
- Knowledge of the main factors which stimulate consumption of organic products;
- Knowledge of the main factors impeding consumption of organic products;
- Description of the profile of the consumer of ecological products.

Studies About Consumption of the Ecological Products in Romania

We have identified a number of 17 relevant studies performed in Romania in order to help us substantiate our work. These studies aimed to identify the main determinants of green purchasing decisions of eco-products, knowledge of the factors influencing green consumption and determining increase the role of green orientation. Their conclusions were a starting point for our work (table no. 1).

Ecological Non-Food Products

Green began to be increasingly fashionable not just on the food market, but also on the market of non-food products. Both retailers and discounters make plans related to organic products and both food and non-food. Thus, in early 2012, the Cora retailer launched the first organic cotton textiles line. Other examples are: the automotive market (Dacia is developing a hybrid engine; it's about Dacia Hamster Hybrid Electricway), the tourism sector (hotels such as Saturn Vega and Meitner), and also, the real estate sector. Thus, the Ozone Homes Company, part of the South Pacific Construction already sells green houses with diminished utility bills up to 35%.

Also, ecological furniture of solid wood is well represented in Romanian exports. Cosmetics market also reflects the transformation of ecological culture in Romania. Creams with parabens are now replaced with olive oil creams. Romanian consumers adapt to novelty. They got to the border between "fad" and "it should be conscious". Beyond this border the market will increase due to the growing interest for healthy lifestyles.

Table 1. Brief presentation of the studies about consumption of the ecological products in Romania

No.	References	Period	Method	Results
1	Green Thinking. (2008). Daedalus Consulting Public Study Prepared for: Green Report	2008	• Quantitative research • Sample consisting of 1003 people	• In terms of willingness to pay more for "green products", the organic foods were most often mentioned, probably because they have the most direct impact on human health.
2	Popa, M., Popa, Al., Drăghici, M., Miteluț, A. (2008). Preliminary research on the situation at national and European level in the production and marketing of ecologic food products on the determinants of eating behavior and methods of investigation used/	2008-2011	• Exploratory research • Qualitative and quantitative market studies: • Four focus group interviews, • 55 in-depth interviews, • Visits to outlets in 20 locations • A survey research, using questionnaires - sample consisting of 1350, of which 1252 completed questionnaires	• Development of a complex behavior pattern of the consumer of food ecological products, enabling the development of specific methods and marketing tools for a possible international niche market for Romanian food eco-products. • Drafting a guide of best practices for business development of the agri-food producers.
3	Popa, Al., Hubbard, C., Gorton, M. & Du, F., Consumer perception about ecological products in Romania and China	March 2009	• Qualitative research • Four focus groups • Semi-structured interview • Interview participants: buyers and un buyers	• The ecological products were defined as products without pesticides / fertilizers and without "ingredients" (additives or preservatives). • The ecological products have been associated with health. • In terms of attraction, the ecological products are considered as being less attractive and having some "defects". • The ecological products are considered as expensive, luxury, addressing to a small part of the population. • An interesting finding is the lack of confidence in this product labels. • The main features of the ecological products market are: a poor supply, a reduced variety and a poor accessibility. • The profile of the customer of organic products: well informed, high educated, with knowledge about organic products and diets and about their impact on health, with a monthly income above average, less interested in the environment and animal welfare, being more concerned about his health and his family health (particularly, about his children health).
4	Boldureanu, G.,Consumer behavior of Romanian Ecological Products	09-14 March 2009	• Sample consisting of 64 people • Oral face-to-face interview in a supermarket in Iasi	• The high prices of organic products and a very small number of producers in Romania are the main determinants of the very low dimensions of the specific market. • Price is a very important criterion in consumer purchase decision. • There is a low degree of consumer information about the importance of environmental criteria in purchasing decisions of organic goods.
5	Dinu, V., Schileru, I., & Atanase, A., Attitude of Romanian Consumers Related to Products' Ecological Labelling	April 2009	• Analytical report of the Europeans' attitudes towards the issue of sustainable consumption and production	• Romanian consumers have a low level of understanding of their environmental impact. This leads to a low level of social pressure on companies to transform their products or procedures. The conclusion is that there are necessary measures to raise public awareness on these issues.
6	- The First Phase of the "Promoting Green Products" project (LIFE+08/INF/RO/0005) - Green Pro, a project funded by European Commission through LIFE + Program	July 2010 -October 2010	• 1140 questionnaires filled in shops and commercial areas by randomly selected people all over Romanian territory.	• The results showed clearly that people need help in order to identify green products and understand their benefits.
7	Pál, Z., Considerations Regarding the Relation between Final Consumers' Knowledge and Attitudes toward Organic Foods and their buying Behavior	2011?	• Sample consisting of 431 people, but 24 questionnaires were eliminated because they were uncompleted. • - The sampling method was empirical, however, considering certain details obtained from previous research. These research showed that the people who show stronger interest towards these products are young, married and with children, with high income and high education level.	• A favorable attitude toward organic food leads to stronger purchase intention. • In addition to basic elements of the theory of planned behavior, the subjective knowledge owned by consumers has a positive impact on the intention to buy organic products. • In absence of clear information, especially from certification, consumers form their own image about how an organic product should be.
8	Kane, K. & Chiru, C. & Ciuchete, S. G., Exploring the Eco-attitudes and Buying Behaviour of Facebook Users	July 2011 -August 2011	• An online, unrepeated survey • Sample consisting of 421 Facebook users. • The snowball sampling technique was used.	• "Facebook represents an effective and innovative environment that could build the necessary links between green attitudes and consumers' hearts and minds."
9	Research Report. Image organic food products (ECO) on the Romanian market and Moldavian	December 2011 - January 2012	• Quantitative research • Sample consisting of 225 people, structured according to the main demographic criteria • Face-to-face interview	• The main perceived qualities of ECO foodstuffs which should be considered in the promotion strategies are: a reduced content of artificial chemicals, a better tasting, a better quality and the fact that they are healthier than the usual ones. • Also, labeling and appearance are factors which influence the purchase decision and should be considered in the marketing strategies of ECO products.

10	Pastiu, C. A., Green Purchase Intentions of Romanian Consumers	2012*	• Probabilistic quantitative research • Sample consisting of randomly selected 110 students from the "1 Decembrie 1918" University of Alba Iulia	• The Green Purchase Intention is influenced by the knowledge level of organization's *green image*, *perceived price* of the product, and perceived quality of the product. The most important are product quality and price, being followed by the production company image. • There is a trend of consumers to buy and consume organic products. Branding and companies' efforts to shape a green image contributed to the increase of using these types of products.
11	Simionescu, M.,A Profile of Romanian Highly Educated Eco-Consumers Interested in Product Recycling. A Statistical Approach	2012*	• Sample consisting of 500 people with high education from Romania • The method used for data collecting is the questionnaire	• The well-educated eco-consumer, interested in recycling is a determinant factor of the economic efficiency in Romania.
12	The Second Phase of the "Promoting Green Products" project (LIFE+08/INF/RO/0005) - Green Pro, a project funded by European Commission through LIFE + Program	March 2012 – May 2012	• Sample consisting of 1055 people • The Second Phase of the "Promoting Green Products" project	• The proportion of consumers who consider themselves fully informed about the environmental impact of products used by them has increased significantly. • The numbers of people who take into account the environmental impact when they buy different products increased. • The reliability of buyers for environmental information found on labels has increased significantly.
13	The Third Phase of the "Promoting Green Products" project (LIFE+08/INF/RO/0005) - Green Pro, a project funded by European Commission through LIFE + Program	February 2013 – May 2013	• Sample consisting of 1066 people • The Third Phase of the "Promoting Green Products" project	
14	Tănase, L. D., Roşca, M. I. & Jurcoane, Al., The Perception on Ecological Products - A Research on the Urban Consumer	*	• Three focus groups consisting of 25 buyers were interviewed. • The segmentation criterion of the buyers was the products certification: certified organic products, uncertified organic products and both certified and uncertified organic products.	• There is a difference between those who buy certified green products and those who buy uncertified green products in terms of the trust in the seller. Those who buy certified products are more educated and do not trust the sellers while the others focus more on the direct relationship they develop with the seller – producer, having not confidence in the current certification label.
15	Dinu, T. A., Stoian, E., Micu, M. M., Condei, R., Niculae, I., Study regarding consumption of organic products in Romania	2013*	• Quantitative research about organic products consumption • Sample consisting of 488 respondents	• The study showed an increasing interest of consumers for "healthy" products, so this should lead to an increase in the Romanian organic products market.
16	Roman, T., Bostan, I., Manolică, A., & Mitrica, I., Profile of Green Consumers in Romania in Light of Sustainability Challenges and Opportunities	2014*	• Quantitative research • The tool used was the questionnaire • Sample consisting of 150 respondents • A quota sampling method was used, using two variables: sex and age.	• Green marketing practices have recently increased, leading to the fact that consumers largely know about the concept of green consumption. It can be argued that an increase of the level of information and of the degree of influence to adopt such behavior, are possible. • Although there is a willingness to adopt a behavior with a much lower environmental impact, there is the issue of a price too high of the organic products and of the lack of information about them. This lead to an inadequate behavior towards the environment. • The best "green" customers are young well educated women with children, with high incomes.
17	Voinea, L., Popescu, D.V. and Negrea, M.T., Good Practices in Educating and Informing the New Generation of Consumers on Organic Foodstuff	March - May 2014	• Exploring marketing research • The tool used was the questionnaire • A pilot survey designed to test the questionnaire • Sample consisting of 62 people	• Among the new generation of Romanian consumers there is a favorable image of the ecological food products, especially based on the provenance from the ecological agriculture, certified by the logo • "eco"/ "bio"/ "organic".

* For these studies the authors were not able to clarify the data on which research was conducted.
Source: based on authors` own literature studying

A study conducted in 2008 (Green Thinking, Daedalus Consulting Public Study Prepared for: Green Report) showed that among non-food ecological products renewable energy and biodegradable products were those for which people were willing to pay on average 11% more. 90% of Romanian consumers claimed to have the willingness to pay more for environmentally friendly products, ahead of countries like Germany, USA and UK. These results were explained by the fact that those countries, being subjected to the rigors of environmental discipline, they have experience of higher costs. Therefore they exhibit a lower receptivity to these products.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

An ecologic label is a helpful tool for producers in order to communicate as effectively. Eco-label procedures and conditions of use are clearly regulated. Thus, in Romania, as in the EU, there are specific criteria for each product category (Dinu, Schileru and Atanase, 2012).

A study published in 2014 showed that in terms of organic products bought by Romanian people, green light bulbs stand out, being purchased by 81% of respondents. These are followed by natural cosmetics (60%) and energy efficient appliances (43%). Romanian people are less interested in recyclable packaging (24%), rechargeable batteries (13%). However, quite numerous people said they are not aware of any ecologic product.

Considering the relationship between concern for environmental issues and purchasing behavior, the natural assumption is that a proactive attitude towards caring for the environment should determine it. However, the study results mentioned above showed otherwise. This was demonstrated by regression analysis, which showed that concern for the environment does not explain satisfactorily the adoption of an ecologic purchasing behavior, but other factors should be considered.

Analysing the relationship of the Romanian consumers with ecological products, three issues were highlighted, namely:

1. They have confidence in this type of products because natural ingredients are used for their manufacture - is most often the cosmetics case;
2. They consider beneficial to health;
3. They perceive them as having higher prices than the similar classical ones.

Reasons for Romanian consumers to buy ecological products are, in order, the following:

1. The ecological products are considered healthier compared to the classic similar ones;
2. The use of ecological products reduce costs on long term, as they are more energy efficient than the similar classic ones - is most often the energy efficient appliances case or the fuel-efficient cars case;
3. The ecological products have a positive impact on the environment;
4. Purchasing ecological products represents a modern trend.

Demographic variables occupy an important place among observable influences acting on consumer behavior (Cătoiu and Teodorescu, 2004). Thus, identifying the relationship between green behavior and demographic variables is essential. Four demographic variables were considered most often, namely, age, gender, education level and income.

In terms of age, there are several studies that have stated that, generally, young people show a higher tend to adopt environmentally responsible behavior. Regarding the buying and consumption behavior of ecological non-food products, it was highlighted that young people are more likely to unplug electrical appliances when they are not in use.

Regarding gender, Romanian consumer behavior is similar to that of consumers abroad. Thus, women appreciate more than men the green values, being more willing to adopt green purchasing behavior. They are willing to give up the use of certain products only for environmental reasons, they have a value system in which the environment is important, and they are more willing than men to buy less polluting products, such as cars with small capacity engine.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Regarding the level of education, the results of the studies carried among Romanian consumers are similar to those of studies conducted abroad. Thus, as the level of education is higher, the probability of adopting an ecologic consumption and buying behavior is more. This behavior can be attributed to a growing awareness and level of demands with increasing the level of education.

In terms of income, the results of the studies carried among Romanian consumers are somewhat contradictory. Thus, there are many studies (Green Thinking, 2008, Popa, Popa, Drăghici and Miteluţ, 2009, Tănase, Roşca and Jurcoane, 2012, Kane, Chiru and Ciuchete, 2012, Roman, Bostan, Manolică and Mitrica, 2015) showing that people who have a high income are more willing to adopt an ecologic behavior. But there are studies that say that any connection cannot be done between the two variables. The study published in 2014 (Roman, Bostan, Manolică, and Mitrica, 2015) showed a significant positive correlation between income and tend to reduce plastic bag use. However, this correlation failed to clarify whether this behavior was prompted by concern for the environment or just for financial reasons.

Ecological Food Products

Nowadays almost every product has an eco-version, whether we are talking about foodstuffs, cosmetics, baby products, clothing, appliances, electronics, automobiles or homes. Since 1 July 2010, the ecological products manufactured in the EU are identified by the organic logo "Euro-leaf".

A study published in 2009 (Popa, Popa, Drăghici and Miteluţ) aimed, among other things, to evaluate the respondents perception about three concepts, namely, natural, ecologic (organic) and traditional agricultural foodstuff. The answers show that the concepts are somewhat confusing for respondents. Thus, organic foods were defined as being characterized by the following attributes: no chemicals in their composition, use of green fertilizers, a certain process for their obtaining, natural, produced from a clean environment, without effects on the environment, certification, without genetic modifications, obtained from organic farms, other attributes ("expensive", "quality").

The Ministry of Agriculture officially designated the use of the word "ecologic".

Regarding whether respondents had information about organic products, in the above mentioned studies it was found that the majority was represented by people who knew nothing or had little information about organic products, totalizing almost 60%.

As regards the availability of information about ecological products, it was found that over 80% of the surveyed people consider that this kind of information is accessible or very affordable.

By age, the age group between 18 and 25 years, representing almost a half of respondents (48.8%), believe that information is accessible to very easily accessible. At the opposite end, are those aged under 18 and over 56 years. Under 0.5% of them believe that information about ecological products is accessible.

Although, in terms of the interest in consumption of ecological products, it is important or very important for more than a half of the respondents, in terms of consumption of organic products, over 90% of respondents said they had consumed such products.

The consumption of the ecological products could increase, first, whether the price of these products would become comparable to that of the similar non-ecological ones and, secondly, whether consumers would really be convinced that they have environmentally friendly features.

Organic food products have a positive image as compared with conventional similar for two-thirds of the respondents (67.8%). Most often nominated makers forming this positive image are (Voinea et al., 2015):

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The fact that they come from organic farming
- The fact that they that are certified ("eco" / "bio" / "organic") (87.1%),
- The fact that they that have additional nutrients having a positive impact on health (protein, vitamins, minerals, essential fatty acids, fiber),
- The fact that they that have added low-substances that have a negative impact on it - salt, sugar, saturated fat (in the processed food) (both 79%),
- The fact that they that shows greater food security (72.6%), and
- The fact that they that have superior organoleptic properties (66.1%).

The „AE" logo is the specific national logo for organic products. This, together with the EU logo can be used aiming a better viewing of the products obtained from organic farming.

The study published in 2009 showed that only a quarter of respondents knew this logo and its significance.

According to Voinea et al. (2015), organic food can be grouped by their origin and technological processing:

- primary unprocessed plant products of plant origin;
- unprocessed animal products;
- processed products for human consumption, prepared from one or more ingredients of plant origin and / or animal origin."

In a study on organic foods, conducted between 2008 and 2011, and funded by the FP7 program - Area 2.2.1. - Consumers, which had the general objective: understanding the consumer behavior and his preferences as a major factor in the competitiveness from the food industry and the impact of nutrition on health and well-being of European citizens, under 33% of respondents said that at least partially, they had good knowledge about organic foods, percentage who has far surpassed those that consider they had little knowledge about the organic products (over 44%).

The yield of ecological production is on average with 20% less than that of conventional agriculture. This is, moreover, why the eco product price is at least 30% greater than that of conventional ones.

In a study published in 2008 (Green Thinking, Daedalus Consulting Public Study Prepared for: Green Report) it is shown that, in terms of willingness to pay more for green products, organic foods receive the largest number of mentions, probably because they have the most direct impact on personal health. Thus Romanian consumers were willing to pay on average 17% more for organic foods to traditional.

In the study published a year later, in 2009 (Popa, Popa, Drăghici and Miteluţ), these issues were further analysed. Thus, more than three quarters of respondents said they were willing to pay more for a green product than for a classic product. Of these, almost a half would be willing to pay up to 10% more, almost a quarter would be willing to pay 10-20% more, and the others in varying proportions, percentages from 20% to over 70%. It should be noted that 2.1% of the respondents would be willing to pay even 50% more.

In the same study the drivers of this behavior are detailed. Thus:

The factors which stimulate such behavior are:

- The ecological products are healthy products (translated by consumers that they do not contain Es, GMOs, fertilizers or pesticides).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The ecological products are natural products.
- The ecological products are tastier (no artificial taste of supermarket products, but that of the traditional products).
- International certification schemes are reliable.

The factors which prevent such behavior are:

- The ecological products are expensive.
- The ecological products are difficult to differentiate of products from < peasants> uncertified.
- The ecological products have range restricted (especially fruits and vegetables and meat products).
- The ecological products are found only in a few specialized stores and premium retail supermarkets.
- There is no true ecological production (Romanian producers do not comply with the rules of organic production system).

The problem of consumption and purchasing of organic products began to attract increasingly more interest from Romanian researchers, especially in recent years, aiming the knowledge of the main advantages and barriers to buying organic foodstuff. Thus, a key element is represented by the correlation between the consumption of organic food and a better health.

A study conducted by the Institute for Life Quality Research showed that Romanians increasingly require green products and services. In addition to private households, which determines one of the major consumer groups, the army, the authorities, NGOs, institutions are major categories that use natural products. Researchers stress that the change of consumer habits primarily involves a transformation of values and lifestyles.

Another interesting finding of the study was that the above-mentioned hours of environmental education should be introduced in schools to expose the risks but also the benefits of organic life. The excessive industrialization, fleet of private and companies cars, without catalytic filters, very bad infrastructure, excessive use of fertilizers could be some of the main responsible for the pollution in Romania.

Domestic consumption of organic foods was below 0.1% far below the global average of 0.7%, according to a study published in 2008 (Green Thinking, Daedalus Consulting Public Study Prepared for: Green Report). The internal production of organic food was grown mainly (approx. 90%) due to export demand in countries like Germany, Austria or Greece. From the point of view of the Romanian consumer, an organic product meanings a premium price for a product that offers the same perceived benefits as classical product which could be obtained on the market for a price up to 70% below or in the countryside garden of his grandparents.

An analysis whose results were published in 2014 (Dinu, Stoian, Micu, Condei & Niculae), which aimed to study the consumer of organic products in Romania, showed that young people are the main consumers of these products. Regarding gender distribution of consumption, paradoxically, women are exceeded by men. This result is somewhat contradictory to the results of a study conducted between December 2011 and January 2012, which claims that a higher percentage of women consider that the eco-foodstuff are healthier than the classical ones.

The increasing the frequency of organic food consumption may be driven by price and by ensuring that the purchased product is really organic.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

With regards to understanding the decisional process of purchasing the ecological food, it was motivated basically by: consumer safety, the ratio quality-balanced price, high nutritional value, the presence of the mention "100% natural" on the package.

Regarding the purchasing points, ecological products are bought more often from specialized stores, but also from food stores or online stores. (Voinea et. al., 2015, REMBRANDT, 2011-2012)

The criteria that have the greatest influence on consumers in choosing organic processed foods are: the inscription with the logo of "eco" / "bio" / "organic", the list of ingredients on the packaging, the existence of nutrition label (Voinea et. al., 2015).

Regarding the image of organic products among consumers, we can say that it has become increasingly better. This is based, firstly, on the results of certain research which demonstrate that nutrient content of organic products has positive effects on people's health. Another important element is represented by the monitoring and certification, enhancing the consumer confidence.

Organic food is a growing market in Romania, which has growth potential even in crisis conditions. However, in our opinion there are some barriers to its development, which must be minimized by traders through:

- Communication of the differentiating elements which are relevant for consumers for certified organic products against products "from peasants", focusing on the guarantee and the confidence provided by a certification scheme
- Diversification of the market categories of organic products, especially vegetables & fruits and meat products
- Extending the availability of organic products for an easier access to these products.

FUTURE RESEARCH DIRECTIONS

A better clarification and education of the population is required regarding the notions of ecological, bio, organic and natural. Because they are considered healthier for the environment and people than the regular ones, a promotion opportunity is to inform people about the standards they must meet. Given the current trend of environmental protection, to promote and to raise the awareness of these issues could offer a better image and attractiveness for the ecological products.

Considering the above, we believe that a national representative research should be carried out in order to study consumer buying behavior and consumer Romanian green. In this respect, an approach by comparison with the EU consumer behavior should be appropriate.

Given these, we propose some future research directions:

- Identifying and categorizing the ecological products which are traded on the Romanian market, based on market studies;
- Promotion of the green products marketing by:
  - Specialized web sites;
  - The use of modern methods of communication: newsletters, online banners;
  - Awarding of the Top Rated green products;
  - Awarding of the companies which get the best results on the ecological products market;
- Educating and informing consumers about:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

  - Use of ecological products;
  - Advantages of replacing the non-ecological products with the ecological ones;
  - Financial and environmental benefits of the ecological products production and distribution, in order to provide a motivation for the consumers;
- Introducing at different levels into teaching curricula of the study subjects about ecological products;
- Initiation of informative workshops, in which the major benefits of the ecological products market should be presented and analyzed;
- Training of personnel in the spirit of the green values (values related to organizational culture directed toward environmental protection);
- Awareness and recognition by the consumers of the real benefits of the green products (here models of good practice of promoting the green products are important).

CONCLUSION

In a report released in 2009 (Popa, Popa, Drăghici and Miteluţ) it was stated that Romanian organic market "will reach about two percent in the next five years, Romania recording [...] higher development trends in this sector than other European countries".

Generally, the criteria underlying product purchase decisions are, in order: quality / price ratio, followed by the price itself and only then are taken into account aspects such as environmental impact, packaging, advertising.

In terms of willingness to pay more for a green product, a study conducted in 2008, by order of Green Report (Green Thinking, Daedalus Consulting Public Study Prepared for: Green Report), showed that nearly 59% of Romanians have declared a total agreement to do this. The percentage rose to 65%, according to results published in 2015 (Roman, Bostan, Manolică, & Mitrica, 2015). This shows an improvement of green purchasing behavior, although it is still room for improvement.

Related to the level of knowledge about the environmental impact of products, the results indicate the following: less than 40% of respondents had a high degree of knowledge, but the majority is represented by those having a low level of knowledge. This shows that people are not informed about these issues. One of the causes of this low level of awareness may due to the improper communication performed by the manufacturing companies about the products they sell. Another problem could be represented by the low level of promotion of the environmental issues among the population.

The idea that emerges from this is that the reason that stated intention to behave ecologically not necessarily materialized is that the environmental impact is not considered too much.

From the viewpoint of the manufacturing companies, the ecolabel is a key element in informing potential clients. This is primarily meant to signal an eco-friendly product. From the perspective of the Romanian customers, a high percentage of them, namely 80%, said they had seen / heard of green label, considering that it's most important significance is that it shows a proper product for the environment.

An important result, emanating from many studies, is that, in Romania, we cannot speak about a significant stream of those who buy green products or who have a green behavior, or at least not yet. This conclusion is supported also by the analysis of time period between two successive purchases of ecological products, which, in many cases, exceed six months.

KEY TERMS AND DEFINITIONS

Eco–Consumer: A person who is aware of environmental issues and obligations, and supports its causes.

Ecological Citizenship: The orientation of the people towards nature.

Ecological Product: It presents the highest ecological / environmental criteria and concerns, according to the EU eco labeling schemes or other similar protective instruments and initiatives It.'s manufacturing process and its use does not generate negative environmental effects.

Ethical Investment: It defines the type of investment that determines implement strategies for social responsibility.

Green Behavior: A pro-environmental behavior, people being good administrator of natural resources.

Green Market: The relationship between eco-supply and eco-demand.

Green Purchasing: A spending and investment process associated with eco-products and eco-behavior.

Social Economy: It gives people opportunities to act on governance models, production and consumption, which directly affects their livelihood at individual and community level.

Sustainable Consumption: A consumption model which seeks to preserve resources for future generations to be able to satisfy their needs.

Chapter 59
The Impact of Green Attributes From Suppliers on Supply Chain Performance

ABSTRACT

Nowadays, green supplier selection (GSS) is one of the most important activities for companies. Therefore, this research aims to demonstrate the relationship that exists between GSS and the marketing benefits of companies. The chapter proposes a structural equation model that integrates three latent variables. The two independent latent variables concern preproduction green attributes and process green attributes, and they are associated with a dependent latent variable: marketing indexes. Thus, three hypotheses are proposed to relate these latent variables. To validate such hypotheses, a survey is administered to 253 middle and senior managers from the manufacturing industry of Ciudad Juárez. Similarly, a descriptive analysis of the sample and the items is carried out. Results show direct and positive effects among the analyzed variables. However, the highest impact is caused by preproduction green attributes over production process green attributes.

INTRODUCTION

On one hand, the role of suppliers in the performance and competitiveness of supply chains has made their correct selection and maintenance two top priorities for companies. This is why activities associated with supplier selection, development, and management have notably increased in the last few years (Trapp & Sarkis, 2016). On the other hand, sustainability is also playing a key role in the competitiveness of companies, which consequently seek to adopt more green supply chains (Trapp & Sarkis, 2016).

Sustainability is an intergenerational philosophy that cares for the appropriate use of available resources without compromising the needs of future generations. Therefore, when companies make decisions related to their sustainability, they consider not only environmental, but also economic and social factors (Elkington, 1998; Trapp & Sarkis, 2016). Thus, sustainable practices range from actions that respond to regulations imposed by the government – such as the safe handling of hazardous materials – to the development of sustainable plans to gain competitive advantage from green practices (green design, green marketing, repair, recycling, remanufacturing, and reutilization of materials and products), which reduce the negative effects of industrial processes on the environment (Buysse & Verbeke, 2003; T. Wu, Jim Wu, Chen, & Goh, 2014). Therefore, product recovery, waste reduction along the supply chain, and the implementation of green practices have become essential to every company (Mangla, Madaan, & Chan, 2013).

From such a sustainable context, the concept of green supply chain management (GSCM) has emerged and can be defined as the integration of environmental concepts in the supply chain, including product design, material supply, green supplier selection, production processes, final product delivery, and product management after its use (Srivastava, 2007). Integrating these activities improves the environmental performance of the supply chain, enables companies to comply with government regulations, and contributes to a greener corporate image. All these benefits can later translate into greater financial or economic profits (Christensen, 2008). Moreover, rather than being costly practices, sustainable initiatives have proven to be a successful competitive advantage for companies (Hollos, Blome, & Foerstl, 2012), but their success also depends on the suppliers involved in the whole supply chain.

Companies from all industries are thus seeking to incorporate more and more green suppliers in their daily operations and processes (Meehan, 2011), since they help directly and indirectly to improve the environmental performance of companies, which must include specific green criteria in decision-making processes. That is, green supplier selection allows for the incorporation of environmental criteria in the supply chain (Igarashi, de Boer, & Michelsen, 2015).

Green Suppliers

Supplier selection and management can be applied along the whole lifecycle of the product; that is, from materials supply until the end of the product usage. However, since there is a great amount and variety of attributes, the supplier selection process may be complicated. Moreover, companies must take into account different operational, strategic, and economic features, which are intangible (Bai & Sarkis, 2010) and thus difficult to quantify.

Despite its complexity, green supplier selection is viewed as an important element to develop a sustainable system. Therefore, since sustainability is frequently interpreted as an important part in the economic, environmental, and social development of companies, the employment of green suppliers is rapidly increasing. Green suppliers can provide materials of good quality at a reasonable price. Moreover,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

they help manufacturers to meet the environmental factors in today's manufacturing environment of the GSCM (Kuo & Lin, 2011). Research has demonstrated that suppliers play a strategic role in companies (Jabbour, Frascareli, & Jabbour, 2015), they are vital to the development of a competitive advantage, and their actions positively impact on the performance of companies at all levels. Therefore, green supplier selection, including its evaluation criteria, has been implemented by manufacturers as an opportunity to improve processes and products. Thus, since suppliers are also accountable for raw materials and the final products, they become part of the technological development and environmental commitment of manufacturers (Çifçi & Büyüközkan, 2011).

Methodologies for Green Supplier Selection

The number of methodologies and techniques for supplier selection has significantly increased during the last two decades. An example of these tools are modeling methods, ranging from basic optimization models with traditional business criteria to more integrated techniques, which employ several methods that address a wide range of tangible and intangible criteria (Kasirian & Yusuff, 2013).

The green or intangible attributes that must be integrated in evaluation models include reputation, supply management risk, corporate image, social impact, government regulations, and green policies, among others (Govindan, Rajendran, Sarkis, & Murugesan, 2015). Some of the models traditionally employed in the selection of green suppliers are:

- Linear programming (LP) and nonlinear programming (NLP) (Liu, Ding, & Lall, 2000).
- Hierarchical fuzzy systems (P. Humphreys, McCloskey, McIvor, Maguire, & Glackin, 2006; Shaw, Shankar, Yadav, & Thakur, 2012; D. D. Wu, Zhang, Wu, & Olson, 2010).
- Fuzzy analytic hierarchy process (fuzzy AHP) (Choudhary & Shankar, 2014; Lee, Kang, Hsu, & Hung, 2009).
- Fuzzy extended analytic hierarchy process (FEAHP system) (Grisi, Guerra, & Naviglio, 2010).
- Fuzzy TOPSIS (Awasthi, Chauhan, & Goyal, 2010).
- Fuzzy Set Theory and Grey Relational Analysis (Chen, 2011).
- Data Envelopment Analysis (DEA) and Analytical Network Process (ANP) (Kuo & Lin, 2011).
- Fuzzy AHP – Fuzzy DEA (Kuo & Lin, 2011).

Green Attributes

Companies have always sought to identify the different green attributes along their supply chains (Çifçi & Büyüközkan, 2011; Rao & Holt, 2005). For instance, (Çifçi & Büyüközkan, 2011; Rao & Holt, 2005) highlighted the importance of using more environmentally friendly transport and cleaner production technologies. Similarly, they emphasized on the collection and recycling of packaging and containers, and they praised companies that informed consumers of their environmentally friendly products. Similarly, authors (Noci, 1997; Shaik & Abdul-Kader, 2011) designed a green vendor rating system that assessed the environmental performance of suppliers. The model considered four categories: green competencies, environmental efficiency, supplier green image, and net life cycle cost.

From a similar perspective, (Genovese, Lenny Koh, Bruno, & Esposito, 2013; P. K. Humphreys, Wong, & Chan, 2003) identified the environmental criteria that influenced on the purchasing decisions made by companies. Authors classified these criteria into two groups: quantitative environmental criteria

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and qualitative environmental criteria. The latter included categories of environmental management, supplier green image, products with high environmental impact, environmental management systems, and environmental competencies. Likewise, (Rao & Holt, 2005; Rostamzadeh, Govindan, Esmaeili, & Sabaghi, 2015) pointed out materials, energy consumption, waste, and green packaging as other environmental criteria.

Nowadays, many different attributes can be considered when evaluating and selecting a green supplier. Some of them include green design, the use of environmentally friendly technologies, green buyers, social responsibility, clean production, and environmental costs. All of them play different roles in each company, depending on the type of green supplier that is sought.

Preproduction Green Attributes

Green attributes must be considered from the moment a product is being designed thus, the environmental factors that are selected based on the manufacturing process are critical. Green attributes can be considered at any stage of the product life cycle, from raw materials extraction to manufacture, including the product usage, reutilization, recycling, and final disposal (Büyüközkan & Çifçi, 2011). However, as regards the product preproduction stage, the green attributes typically judged are green design, green process management, green customer, and green competencies.

Preproduction attributes assess all activities that seek to minimize the environmental impact of products (Govindan, Kannan, & Shankar, 2015). Such attributes integrate all environmental dimensions in the product design process and along the whole supply chain. Similarly, they can be considered from the purchase of raw materials to their management for the product manufacturing (Rostamzadeh et al., 2015). This is important, since most of the industrial practices that harm the environment emerge at the product design stage, and they thus alter the production goal and affect the consumption and elimination of products that are harmful to the environment (Eltayeb, Zailani, & Ramayah, 2011).

Process Green Attributes

Companies must also take into account green attributes for the production process. Green attributes at this stage aim to continuously improve industrial processes in order to minimize their environmental impact (Johansson, 2009). They typically assess energy consumption during the manufacturing process, clean production, the environmental collaboration with customers, the use of environmentally friendly technology, and green product manufacturing. Integrating process green attributes in product manufacturing can help reduce the costs of raw material, increase efficiency of production, and reduce costs of both environmental and occupational safety (Srivastava, 2007).

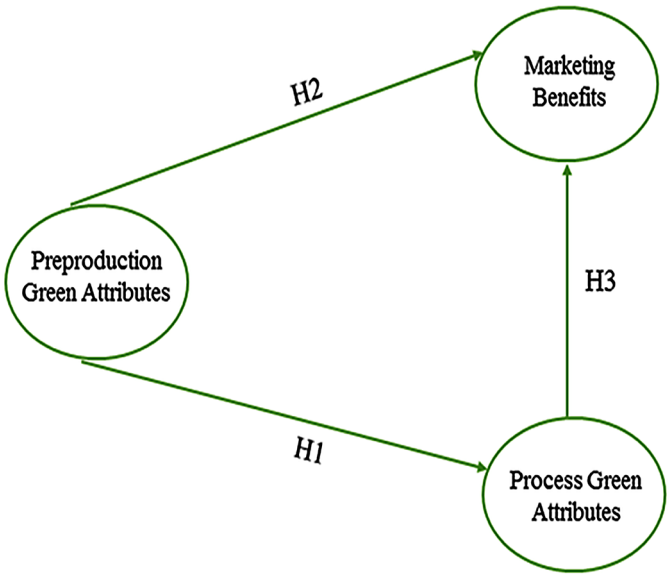
In conclusion, since damages caused to the environment occur at any stage of the supply chain and the manufacturing process, companies must ensure green initiatives in their systems in order to reduce their environmental impact (Tseng, 2011). However, the question now is: what is the impact caused by the attributes from the preproduction stage on the attributes from the process stage? To answer this question, the following working hypothesis is proposed:

H_1: *Preproduction green attributes* have a direct and positive impact on the *Process green attributes* considered in green supplier selection.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Benefits of Green Attributes

Benefits from green suppliers can be a source of motivation for companies to constantly improve their environmental practices. In addition to being helpful to comply with government regulations, green attributes are an important source of competitive advantage (Villanueva-Ponce et al., 2015). In fact, the lack of green practices or the absence of a suitable green system may be detrimental to companies, since important costs usually derive from the inability to regulate energy consumption, from a poor waste treatment, or because of an excessive waste generation. Finally, another benefit of green attributes from suppliers is that they help improve and legitimize a green corporate image, which is why companies are increasingly focusing on green suppliers (Lee et al., 2009).



For all these reasons, benefits that companies obtain in their market indexes from their products depend on the attributes that they consider from a supplier. This leads us to propose the following two hypotheses:

H_2: *Preproduction green attributes* have a direct and positive impact on the benefits that manufacturing companies obtain in their marketing indexes.

H_3: *Process green attributes* have a direct and positive impact on the benefits that manufacturing companies obtain in their marketing indexes.

Relationships established with these hypotheses are depicted in Figure 1 as arrows connecting one latent variable to another. As previously mentioned, the objective of this chapter is to demonstrate the importance of green attributes from suppliers (at both the preproduction and the process stages) for the marketing indexes of manufacturing companies.

Figure 1. Proposed hypotheses (Own creation)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

METHODOLOGY

The methodology followed to prove the hypotheses is divided into eight stages.

Step 1: Literature Review

Literature on green supplier selection (GSS) is reviewed by considering year 1990 as a point of departure. The research focuses on the most used attributes, those recently incorporated, and their classification. Similarly, it is carried out in databases such as Springer, Taylor & Francis, and Sciencedirect, among others. To refine the search, key words are used, including: *supplier selection, attributes used for supplier selection*, and *attributes used in supply chain management*. Then, the multicriteria models found in the literature are analyzed. However, the benefits that some authors mention. This literature review represents the rational validation for the questionnaire that is later designed. This means that research carried out overseas is adapted to the context of the Mexican manufacturing industry.

Step 2: Survey Design

For this research, a survey is designed as data collection instrument in order to determine the magnitude of the industrial phenomenon under study, which is the impact of green attributes from suppliers on the marketing benefits of manufacturers. Therefore, the survey aims to gather the opinion of Mexican middle and senior managers regarding the attributes that should be evaluated in suppliers (Martínez, 2002). The survey designed by (Villanueva Ponce, 2014) is considered as a reference.

The questionnaire is composed of three sections. The first section briefly explains the aim of the research and provides the directions to answer the survey. Demographic information is also demanded at this point, including the gender of participants, seniority, and the size and industrial sector of the company. These questions describe the overall characteristics of the sample, which merely involves middle and senior managers, since they are responsible for supplier selection.

The second section of the questionnaire includes a table listing 39 attributes that can be considered in the supplier selection process. These attributes were previously identified in the literature review. Items in this part of the questionnaire must be answered with a five-point Likert scale, where 1 indicates that an attribute is not important in green supplier selection, and 5 implies that the attribute is very important.

Finally, the third section of the survey also includes a table, but this table lists 12 benefits that can be attributed to the correct green supplier selection. A Likert scale is also used to answer these items.

Step 3: Administration of the Survey

The survey is administered to manufacturing companies in Ciudad Juárez, México, from January 2015 to May 2015. The sample is composed of middle and senior managers from different departments who take part in the supplier selection and evaluation processes. These departments include the engineering department, the purchasing department, the management department, finances, quality control, and warehouses among others.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 4: Information Capture

Data obtained from the survey are captured in a database with statistical software SPSS 20. This piece of software is one of the best known statistical programs, considering its ability to work with large databases as well as its simple interface for most analyzes. In the database, each row represents a case or answered survey, while columns stand for the variables analyzed.

Step 5: Data Screening

Data are screened in order to find missing values and outliers. On one hand, missing data can occur for different reasons. Typically, they imply that a respondent was not familiar with the response that he/she accidentally missed a question, or that he/she simply refused to answer it. However, the main issue with missing data is that if a respondent did not answer a lot of questions, other answers may be useless when it comes to testing causal models (Lynch, 2003). Thus, it is generally agreed that if more than 10% of answers in a particular variable are missing, these values can be problematic and the case must be discarded (Joseph F. Hair Jr., 2013). In this research, missing values were replaced by the median value of the variable in question, since a Likert scale was used to answer all the items (Lynch, 2003).

On the other hand, outliers are detected by means of box plots, where they appear at the edges. Then, data are standardized, considering any absolute value higher than 4 as an outlier (Kohler, Müller, & Walk, 2015). Similarly, the standard deviation is estimated in each case or survey, where values close to 0 suggest that a respondent assigned the same value to all questions. Thus, if the value of the standard deviation is lower than 0.500 for a scale of 5 points, the questionnaire is discarded (Leys, Ley, Klein, Bernard, & Licata, 2013).

Step 6: Statistical Validation

Any suitable instrument must comply with two requirements: reliability and validity. They both determine whether an instrument properly measures variables. On one hand, validity refers to the degree to which an instrument really measures the variable that aims to measure (González, 2008). On the other hand, reliability defines the probability of success of a system, which must necessarily depend on the reliability or success of its components (Niebel B. & Freivalds, 2009).

Several indices are used to validate the survey. First, the Cronbach's alpha is estimated. Although it is not accompanied by any P-value to reject the hypothesis of reliability of the scale, the closer its value to 1, the greater the reliability of the scale (George, 2003). Also, the reliability index is used to measure internal validity. Thus, if items are strongly correlated with one another, this means that they measure the same latent variable (the cause). Nevertheless, this does not imply that the latent variable stands for the construct these items intend to measure (validity). Finally, AVE measures convergent validity, while the R-squared, adjusted R-squared, and Q-squared are employed to measure predictive validity (Kock, 2013).

Step 7: Descriptive Analyses

In this research, the descriptive analyses include the description of the sample and the description of items.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Descriptive Analysis of the Sample

Cross tables are used to describe the sample. The table includes information regarding gender, seniority, and the industrial sector of companies. This information helps determine the level of experience of participants and, therefore, the reliability of information gathered.

Descriptive Analysis of Items

A descriptive analysis is carried out for all the items analyzed within the latent variables. The median is used as a measure of central tendency, while the interquartile range (IQR) is used as a measure of dispersion. High values in the median indicate that an item is important to participants in the supplier selection process (Silver, 2007). However, low median values imply that an item is not relevant. Similarly, high IQR values indicate no consensus among respondents regarding the significance of an item, while IQR values imply consensus about its significance (Rossi & Mirtchev, 2016).

Step 8: Structural Equation Model

In order to prove the hypotheses stated in Figure 1, the model is evaluated using the Structural Equation Modelling (SEM) technique. SEM is widely used to validate causal relationships, especially in the supply chain environment. For instance, it has been employed to measure the impact of JIT on supply chain performance (Green Jr, Inman, Birou, & Whitten, 2014), or the effects of flexibility, uncertainty, and firm performance on supply chain (Merschmann & Thonemann, 2011). Likewise, authors (Villanueva-Ponce et al., 2015; Yang, Albert, & Carlo, 2013) proposed a structural equation model to identify the effects of green supply chain management on green performance and firm competitiveness.

In this research, the SEM model is executed in WarpPLS 5.0® software, since its main algorithms are based on Partial Least Squares (PLS), widely recommended for small samples (Kock, 2013). Moreover, a bootstrapping resampling method is used to obtain better coefficients values convergence and diminish the effect of possible outliers. In addition, three model fit indices are analyzed: average path coefficient (APC), average R-squared (ARS), and average variance inflation factor (AVIF). These indices were proposed by (Kock, 2013) and used by (Ketkar & Vaidya, 2012) in the supply chain environment.

The P-values of APC and ARS are estimated by considering 0.05 as the maximum cutoff value. This means that causal inferences show a 95% of confidence level, testing the null hypothesis where APC and ARS are equal to 0, versus the alternative hypothesis, stating that APC and ARS are different from 0. As regards AVIF, values lower than 5 are desirable.

Finally, three different effects are measured in the structural equation model:

1. Direct effects (they appear in Figure 1 as arrows connecting one latent variable to another),
2. Indirect effects (paths with two or more segments from one latent variable to another), and
3. Total effects (the sum of direct and indirect effects).

To determine the significance of these effects, the P values are analyzed, considering the null hypothesis: $\beta_i = 0$, versus the alternative hypothesis: $\beta_i \neq 0$.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

RESULTS

This section is divided into three subsections addressed below:

Descriptive Analysis of the Sample

A total of 270 surveys were collected after five months. However, merely 253 of these questionnaires were used in the analysis, since the others were discarded due to an excessive amount of missing data. Table 1 shows information about the size of the companies as well as the industrial subsectors surveyed. As can be observed, 39.52% of the sample works in the automotive sector. Similarly, 61.65% of participants work in large companies, which have more than 500 workers.

Descriptive Analysis of Items

Table 2 shows the descriptive analysis of the items comprised in each latent variable appearing in Figure 1. As regards preproduction green attributes and process green attributes, all the eight items within these latent variables have a median value higher than 3. This indicates that manufacturing companies in Ciudad Juárez often consider these green attributes when selecting a green supplier.

Additionally, fourth column details the interquartile range, in this case the item with the highest RI corresponds to the item with the highest median, indicating their importance, since it has the least variability in that category.

Latent variable marketing benefits consists of six items, none of which obtains a value exceeding three, indicating that these benefits are rarely obtained. It is also noted that values of RI for items are high, indicating that there is no consensus regarding to the true value that they have.

Structural Equation Modeling

The structural equation model was evaluated according to the methodology described before. Figure 2 shows results obtained, where each of the segments represents the relationship between two latent variables, also are indicated the value of the beta parameter and p-value of statistical significance test. Note

Table 1. Size of companies and industries surveyed

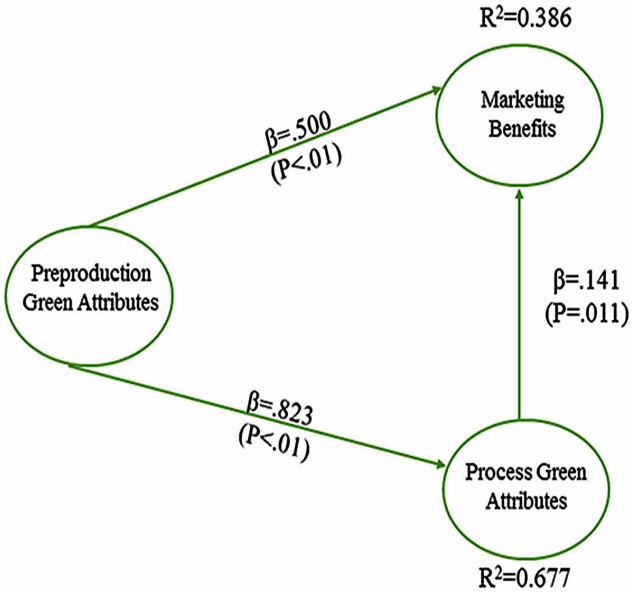
Size of the Company	Industry							Total
	Automotive	Electronics	Electrical	Medical	Plastics	Packaging	Others	
>500	65	15	16	21	9	2	28	156
201-500	27	4	4	3	6	1	11	56
101-200	5	5	0	3	4	2	6	25
51-100	3	1	0	0	1	2	3	10
0-50	0	0	0	0	0	1	5	6
Total	100	25	20	27	20	8	53	253

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Descriptive analysis

Preproduction Green Attributes	Median	Percentiles		Interquartile range (IR)
		25	75	
Green design	3.473	2.521	4.391	1.870
Green buyers	3.449	2.544	4.343	1.799
Green process management	3.613	2.603	4.553	1.950
Green competencies	3.375	2.496	4.245	1.749
Process Green Attributes				
Use of environmentally friendly technology	3.579	2.624	4.500	1.876
Green product manufacturing	3.525	2.601	4.387	1.786
Recycling systems	3.803	2.825	4.655	1.830
Environmental costs	3.796	2.900	4.635	1.735
Marketing Benefits				
How often has the company expanded its market thanks to a good supplier?	2.452	1.656	3.276	1.620
How often has been called "green" to company's image where you work due to its selection processes to choose suppliers?	2.642	1.814	3.612	1.798
How often the company has expanded to domestic market by selecting a good supplier?	2.468	1.615	3.439	1.824
How often the company has increased its economic gains by consider environmental aspects in the supplier selection?	2.727	1.915	3.688	1.772
How often the company has expanded internationally by selecting a green supplier?	2.553	1.665	3.547	1.881
How frequently the company has obtained economic profits due to choosing a green supplier?	2.695	1.821	3.631	1.810
How often has been improved the company prestige by electing green suppliers?	2.695	1.810	3.688	1.878

also that in each of the latent dependent variables, the R2 value is indicated for measuring the variance that is explained by the dependent variables.



The efficiency indexes of model are indicated following.

- Average path coefficient (APC)=0.488, P<0.001
- Average R-squared (ARS)=0.532, P<0.001
- Average adjusted R-squared (AARS)=0.529, P<0.001
- Average block VIF (AVIF)=3.076, acceptable if <= 5, ideally <= 3.3
- Average full collinearity VIF (AFVIF)=2.699, acceptable if <= 5, ideally <= 3.3
- Tenenhaus GoF (GoF)=0.621, small >= 0.1, medium >= 0.25, large >= 0.36

The APC, ARS and AARS indexes, present a p-value in order to determine statistical significance, it can be stated that the model has sufficient predictive validity and the dependencies between the latent variables analyzed on average is different from zero, because they are statistically significant at a confidence level of 95%.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Evaluated model

According to the collinearity between the latent variables, it is observed that the AVIF and AFVIF indexes are less than 3.3, thus there is no problem of collinearity in the model. Finally, the Tenenhaus index is considered an acceptable value because it is less than 0.36.

Direct Effects

Direct effects are used to test the initially hypotheses in the model in Figure 1 and Figure 2 shows results obtained. Based on them, the following conclusions are presented:

H_1: There is enough statistical evidence to state that Preproduction Green Attributes evaluated in suppliers have a direct and positive impact on Process Green Attributes, since when the first latent variable increases its standard deviation by one unit, the standard deviation of the second latent variable also increases by 0.823 units.

H_2: There is enough statistical evidence to state that Preproduction Green Attributes evaluated in suppliers have a direct and positive impact on the benefits that manufacturing companies obtained in their marketing indexes, since when the first latent variable increases its standard deviation by one unit, the standard deviation of the second latent variable also increases by 0.500 units.

H_3: There is enough statistical evidence to state that Process Green Attributes evaluated in suppliers have a direct and positive impact on the benefits that manufacturing companies obtained in their marketing indexes, since when the first latent variable increases its standard deviation by one unit, the standard deviation of the second latent variable also increases by 0.141 units.

However, it is worthy to mention that 67.7% of the latent variable "Process Green Attributes" is explained by the variable "Preproduction Green Attributes" since the value of R-square is 0.677. Given

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

those values, it is concluded that preproduction green attributes are very important to achieve the green attributes of processes, because they have a character of planning and forethought.

Sum of Indirect Effects

The model in Figure 2 shows that the latent variable called preproduction green attributes has an indirect impact on the latent variable called marketing benefits, which is given through the mediating variable denominated process green attributes it is obtained as a result of the product of effects of two segments. In this case, the indirect effect is 0.116 (P = 0.04), which is statistically significant with a confidence level of 95% and may explain more than 7.2% of its variability, since the size of the effect is 0.072.

Total Effects

The sum of the direct and indirect effects represent the total effects. Table 3 shows a summary of the effects. In this case, there is only an indirect effect. It is worthy to mention that in two of the relationships between variables, the direct effect is equal to the total effect. Only in the relationship between the variables Preproduction Green Attributes and Marketing Benefits, the effect includes both the direct and indirect effects.

CONCLUSION

Based on the results obtained from the model, the following conclusions are presented:

- By segmenting the green attributes in two different latent variables: preproduction and green process, it has been demonstrated that there is a relationship between them thus that these two variables have a positive impact on the benefits that manufacturing companies obtain in their marketing indexes. Therefore, managers and responsible of supplier selection process should focus on these attributes, primarily in preproduction, since it is associated with the planning of the production process of the article, distributing and recycling. Thus, this research is consistent with the results provided by (Gurel, Acar, Onden, & Gumus, 2015) and the techniques indicated by (Igarashi, de Boer, & Fet, 2013), who state that green suppliers be an essential part of the production process of the manufacturer.
- The organizations that evaluate green attributes in their suppliers, obtain benefits associated with their marketing indexes, such benefits may be a better imagen in both senses, organizationally and

Table 3. Total effects

	Preproduction Green Attributes	Process Green Attributes
Process Green Attributes	0.823 (P<0.001) ES = 0.677	
Marketing Benefits	0.616 (P<0.001) ES = 0.380	0.141 (P=0.011) ES = 0.078

socially, as it is the continuation of a green supply chain, but also adds value to all supply chain (Gopaldas, 2015; Igarashi et al., 2015).

- All department managers must share financial information associated with the integration of green suppliers as partners in the production process, due to is common that different opinions exist regarding to the benefits that can be obtained and some of them can be incorrect, especially those associated with costs.

KEY TERMS AND DEFINITIONS

Hypothesis: A tentative explanation for an observation, phenomenon, or scientific problem that can be tested by further investigation.

Interquartile Range: The range of values of a frequency distribution between the first and third quartiles.

Marketing: It is the activity, set of institutions, and processes for creating, communicating, delivering, and exchanging offerings that have value for customers, clients, partners, and society at large.

Reliability: Refers to the degree to which an assessment tool produces stable and consistent results.

Structural Equation Modelling: It is a statistical technique for building and testing statistical models, which are often causal models. It is a hybrid technique that encompasses aspects of confirmatory factor analysis, path analysis and regression.

Survey: A gathering information based in questions for obtain a sample of data or opinions of people previously chosen according to the needs of the study.

Sustainability: It is the ability to maintain rates of renewable resource harvest, pollution creation, and non-renewable resource depletion that can be continued indefinitely.

This research was previously published in Green Marketing and Environmental Responsibility in Modern Corporations edited by Thangasamy Esakki, pages 83-103, copyright year 2017 by Business Science Reference (an imprint of IGI Global).

Chapter 60
Evaluating Factors Motivate Users on Green IT Readiness (Part 2)

Yas A. Alsultanny
Arabian Gulf University, Bahrain

Fatma M. Alnassar
Arabian Gulf University, Bahrain

ABSTRACT

Due to the advancement of information and communications technology, most of the businesses and services have transformed into an e-businesses and e-services. The organizations are facing a great deal of pressure from regulators to move toward green IT. The aim of this article is to evaluate the factors affecting on green IT readiness from the perspective of IT users, a questionnaire designed for this purpose. The questionnaire divided into two parts, the first part for demographics information, and the second part contains 34 statements divided into 6 factors. There are 460 respondents to the questionnaire. The results of the data analysis showed that the factors, technology and attitude have an agreed degree of agreement, while the practice, policy, governance, and green IT readiness have a neutral degree of agreement. The governance factor has the highest effect on green IT readiness. The article recommends the ministries of electricity must be increasing the awareness for green IT as part of their awareness for power consumption saving.

1. INTRODUCTION

Reducing carbon dioxide (CO_2) is very critical and important to the protection of human health and the environment. The Environmental Protection Agency (EPA) developed the EPA equation to help in calculating the power consumption and CO_2 emissions. This equation depends on the finding value; to compare with the default values of CO_2 emissions measured in money cost per mega-watts-hours (MWh) of power consumption.

To minimize or eliminate the environmental impact of IT, that helps in creating a sustainable environment. IT hardware poses environmental problems during its production and its disposal. Each personal computer in use generates about a ton of carbon dioxide every year. Greening IT has the responsibility of creating a more sustaining environment. Green IT benefits the environment by improving energy efficiency, and encouraging reuse and recycling (Murugesan, 2008).

Consumer buying habits have become more driven by ethical concerns for environmentally friendly, products as it was found stakeholders react in a positive way toward greening ICT (Sen, Battacharya, & Korschun, 2006; Whitby, 2007). Moving toward green IT would benefit different stakeholders such as employees, capital market, consumer and the public. One great way to motivate people to go green is to make it easier. Many people find making greener choices is inconvenient to their daily lives, especially in regions that are less environmentally conscious (www.oureverydayearth.com).

The first section of this paper provides an introduction. The second section is for the motivations for this study. The third section is for the literature review. The fourth section is for the study objective. The fifth section is for research methodology. The sixth section describes data analysis. The final section is for the conclusion.

2. MOTIVATIONS FOR THIS STUDY

The association between environmentally friendly attitudes and the green IT movement reported that in order to encourage IT users to act with concern for the environment, emotional factors playing a significant role. Scientists in the field of Information and Communication Technologies have estimates that the ICT is the source of around 2% of global CO_2 emissions (Goasduff & Forsling, 2007). The enlargement in IT emissions are expected to reach 6% at the end of 2020. Green IT will be the main concern in future.

There are three types of motivations to go green. One is environmental risk management to reduce operational and financial concerns such as reducing emission from energy consumption. Upside benefit is one of motivation types to develop renewable energy solutions that are environmentally friendly. The third type of motivation is environmental stewardship, which is doing the right thing to be environmentally responsible (Hart, 1997). Power usage has emissions that influence the environment, which mainly concern human health and improve economics (Jongsaguan & Ghoneim, 2013).

3. LITERATURE REVIEW

Greening IT allows organizations to reduce their carbon footprint, greenhouse gasses and waste by following more environmentally healthy practices such as managing the PC power, server virtualization, recycling, disposal management, and contracting with green suppliers (Graaf, 2008). The Environmental Protection Agency in 2010 updated the output emission rate to $6.89551*10^{-4}$ metric tons CO_2/kWh (www.epa.gov). Jonathan (2014) showed that three states out of 50 USA states are implementing EPA best practices in CO_2 emissions from electric generating units. It creates CO_2 emission rate goals measured in pounds of CO_2 emissions per megawatts-hours (MWh).

For the customer, being green would increase their satisfaction, enhance their loyalty and enhance recruitment. It gives greater trustworthiness, appeals to new consumers and gives higher customer satisfaction. According to the public, it enhances the image, and enhances the implementation of Corporate

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social Responsibility (CSR) strategy as well as enhancing brand value (Hermann, Von Der Gathen, & Daus, 2010). Organizations, which adopt CSR, are considering sustainability and the mounting demands of greening ICT in order to satisfy diverse environmental groups and regulations. Firms uses sustainability and CSR hence consider greening technologies to show for the commitment that they have to the environment`s CO_2 emissions (Hendry & Vesilind, 2005; McWilliams, Siegel, & Wright, 2006).

Organizations were facing pressures from consumers, suppliers, rivals, regulators, and community groups to implement sustainable business practices. Hence, balancing needed services and IT performance to be environmentally green and competitive became a key issue in the strategic plan and operation (Molla & Cooper, 2009). Molla et al. (2008) developed the green IT readiness model. It consists of five factors. These factors are; attitude, policy, practice, governance, and technology. Attitude means, how business organizations as well as business leaders and personal are considering their effect on the environment, and to what extent their awareness pushes to reducing their negative effects (Molla, Cooper, & Pittayachawan, 2009). Policy, measures the degree that green and sustainability policies in organizations (Molla & Cooper, 2009). Practice, involves ICT infrastructure sourcing, operations, as well as disposal (Cooper & Molla, 2012). Governance, responsible for electricity and it holds accountabilities regarding energy efficiency, and how PC power must be managed (Molla & Cooper, 2009). Technology, organizations has to build a green technological infrastructure, and the organizations have to move toward green power supplies (Brocade, 2007). The results of Alsultanny and Alnassar, (2015) showed that the governance has the highest correlation and influence on green IT readiness from the perspective of IT staff.

The efficiency of cooling and lighting data centers and IT energy consumption are the top issues (Minsani & Imam, 2012). Information system assessment, including costs, benefits, and risks within a company plays a role in creating and raising awareness and incorporating green IT into all components of the business functions (Jongsaguan & Ghoneim 2013).

4. STUDY OBJECTIVE

The main objective of this study is to evaluate the factors affecting green IT readiness from the perspectives of the users, by identifying the factors that affecting green-IT readiness and study the effect of demographic information on the green IT readiness factors.

From the study objective the following questions derived;

1. What are the factors that affect green IT readiness from the perspective of IT users?
2. *Does the demographics information of IT users have statistically significant differences effect on green IT factors and green IT readiness?*

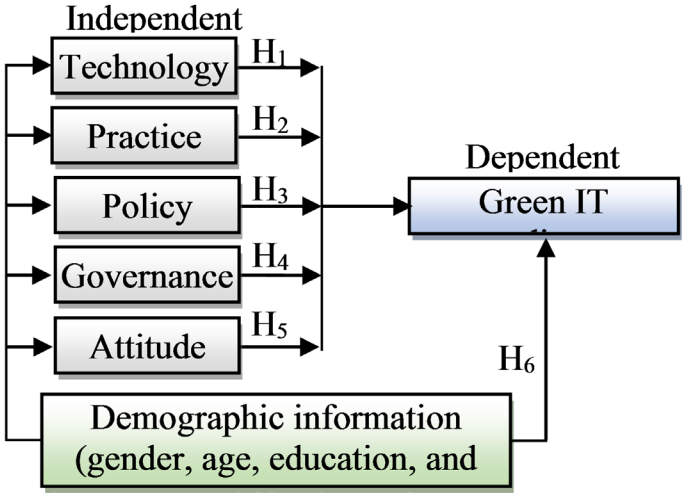
5. RESEARCH METHODOLOGY

This study used descriptive and quantitative methods. A questionnaire designed for evaluating the factors impact on green IT readiness, from the perspectives of IT users. This questionnaire divided into two parts. The first part was for demographic information (gender, age, education, and experience). The second part for green IT factors. These factors adopted from Molla et al. (2009), which had five

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

factors (technology, practice, policy, governance, and attitude). The demographics information (gender, age, education, and experience) were used to test their effect on the five factors and green IT readiness. Figure 1 shows the conceptual model of the study.

The hypotheses of the study are;



H_1: There is a statistically significant effect of *technology* on *green IT readiness*.
H_2: There is a statistically significant effect of *practice* on *green IT readiness*.
H_3: There is a statistically significant effect of *policy* on *green IT readiness*.
H_4: There is a statistically significant effect of *governance* on *green IT readiness*.
H_5: There is a statistically significant effect of *attitude* on *green IT readiness*.
H_6: The IT users *demographics information* (gender, age, education, and experience) have a statistically significant differences in (*technology, practice, policy, governance, attitude, and green IT readiness)*.

Six experts evaluated the statements for each factor of the questionnaire. The degree of respondents' agreement ranked by the scale: Strongly Disagree (SD)=1 to less than 1.8, Disagree (D)=1.8 to less than 2.6, Neutral (N)=2.6 to less than 3.4, Agree (A)=3.4 to less than 4.2, and Strongly Agree (SA)=4.2 to 5.

The correlation coefficient represented by r in this study. According to Gerstman (2003) coefficient with a value $r \geq \pm 0.7$ indicates a strong association between variables, moderate correlation when the values $\pm 0.7 > r \geq \pm 0.3$, and weak correlation for $r < \pm 0.3$. The population of the study is the IT users, whom are employees working in public and private organizations. The questionnaire distributed online and manually, data of 460 respondents used in the analysis.

The validity checked by Spearman, the results of testing showed the factors of the questionnaire are significant positive correlated with a range from 0.703 to 0.886. Cronbach's alpha used to measure reliability. Yin (2003) determined that the cut-off-point for Cronbach's alpha is 0.7. The results of testing showed the factors of the questionnaire have reliability ranged from 0.720 to 0.886, which indicates the data collected by this questionnaire is reliable for analysis.

6. DATA ANALYSIS

From the 460 IT users' respondents, there are 259 (54.1%) females and 211 (45.9%) males. Most of the respondent 334 (72.6%) are between 21 to 40 years old. Most of the 281 (61.1%) carrying bachelor degree, and 354 (77.0%) of the respondents have experience between 1 to 16 years for using IT.

The second section of the questionnaire contains 27 statements divided into six factors. For each statement the average, standard deviation (Std), rate, and rank were calculated. The rank is the order of agreement of each statement in the factor. Table 1 shows the descriptive statistics of respondents for the six factors. The average values of the statements of the first statement ranged between 3.39-3.45, while the values of standard deviation ranged between 1.071–1.145. The first rank goes to statement 1, with the highest average 3.45 and standard deviation 1.145, which means the IT users agreed that their organization shut down systems after the end of the official working hours.

The average values of the statements of factor *practice* ranged between 3.30-3.49, while the values of standard deviation ranged between 1.060–1.170. The first rank goes to statement 8, with the highest average 3.49 and standard deviation 1.078, which means the IT users agreed that their organizations may have recycle department for old IT equipment. The IT users have a restriction on the printing limit in their offices, because they are agreeing to the statement 9, which is "Organize print optimization" with average 3.45 that ranked second.

The average values of the statements of factor *policy* ranged between 3.02-3.25, while the values of standard deviation ranged between 1.155–1.247. The first rank goes to statement 14, with the highest average 3.25 and standard deviation 1.199. This indicated that maybe there is no policy set to use IT in efficient way to save energy. The results showed that the IT user's neutral satisfied with all policy factor items like "Disposal of old IT items in an environmentally friendly manner". May be the reason is the organizations not implement the policy of disposal consumable IT components in green environmental ways.

The average values of the statements of factor governance ranged between 3.14-3.26, while the values of standard deviation ranged between 1.163–1.217. The first rank goes to statement 16, with the highest average 3.26 and standard deviation 1.163. The results showed that the IT users were neutral satisfied with the governance factor items, so shifting to green sources of energy for IT components may be not applied in their organization, and neither green IT policy.

The average values of the statements of factor attitude ranged between 3.30-3.60, while the values of standard deviation ranged between 1.098–1.189. The first rank goes to statement 20, with the highest average 3.60 and standard deviation 1.101. The results showed that IT users agreed on IT energy consumption. May be the information technology users feel that climate change is an important issue.

The average values of the statements of factor green IT readiness ranged between 3.20-3.35, while the values of standard deviation ranged between 1.080–1.198. The first rank goes to statement 27, with the highest average 3.35 and standard deviation 1.080. The results showed that the IT users were neutral satisfied of the green IT readiness items. This indicates that the organizations were not taking care in their IT purchasing products the impact on the environment.

The data distribution of the statements tested by Kolmgrov-Simirnov, the results showed that the IT users' responses distribution of the statements is a non-normal distribution; therefore, the Spearman test used for testing the correlation between the factors of this questionnaire. Table 2 shows the matrix of correlations. The results indicated that the strongest positive correlation between green IT readiness and governance with value 0.785. This indicates that the governance is an important factor effect on green

Table 1. Descriptive statistics for the questionnaire factors

No	Factor	Statements	Average	Std	Rate	Rank	Factor Average
1.	**Technology**	There is a power shut down system after the end of the official working hours.	3.45	1.145	A	1	**3.416 Agree**
2.		Right sizing IT equipment were used.	3.41	1.092	A	3	
3.		Data was stored by optimal methods.	3.43	1.071	A	2	
4.		The organization removes inefficient energy systems.	3.40	1.120	N	4	
5.		More energy efficient lights were used.	3.39	1.100	N	5	
6.	**Practice**	Prefer IT suppliers that have a green track record	3.35	1.105	N	4	**3.378 Neutral**
7.		Electricity supplied by green energy providers	3.30	1.065	N	6	
8.		There is a system for recycle consumable equipment (e.g. batteries, ink cartridges, and paper).	3.49	1.078	A	1	
9.		The organization organize print optimization.	3.45	1.060	A	2	
10.		To what extent your organization practices double sided documents?	3.37	1.144	N	3	
11.		Switch off unnecessary equipment when not needed.	3.31	1.170	N	5	
12.	**Policy**	Dispose of old IT items in an environmentally friendly manner.	3.19	1.155	N	2	**3.122 Neutral**
13.		The employee has limitations when printing.	3.03	1.247	N	3	
14.		A policy directs staff to use IT in an efficient manner to save energy.	3.25	1.199	N	1	
15.		Green IT sustainability policy were applied.	3.02	1.186	N	4	
16.	**Governance**	The organization considers shifting to green sources of energy for IT equipment.	3.26	1.163	N	1	**3.193 Neutral**
17.		Green IT policy were applied.	3.18	1.194	N	2	
18.		Top management, discuss green IT issues as a priority	3.14	1.217	N	3	
19.	**Attitude**	I am concerned with green IT.	3.59	1.098	A	2	**3.448 Agree**
20.		I am concerned with IT energy consumption.	3.60	1.101	A	1	
21.		Responsibilities on green IT are clearly defined.	3.51	1.129	A	3	
22.		Your organization is concerned with the energy consumption for lighting and cooling IT equipment.	3.31	1.157	N	5	
23.		Your organization is concerned with the efficiency of powering IT system.	3.38	1.170	N	4	
24.		Your organization is concerned with the environmental impact in disposing IT items at the end of its lifecycles.	3.30	1.189	N	6	
25.	**Green IT readiness**	The CEO plays a leading role in green IT initiatives.	3.20	1.198	N	3	**3.276 Neutral**
26.		Set targets for implementing green IT factors.	1.161	N	2	1.161	
27.		Purchase IT components more environmentally friendly.	1.080	N	1	1.080	

Std: Standard deviation

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

IT readiness. The technology factor has the moderate correlation value 0.550 with green IT readiness, which indicates that the technologies used in the organization need to be changed, with technologies have less power consumption.

A linear regression test carried out for testing the hypotheses (H_1 to H_5) as shown in Table 3. For hypothesis H_1 the results show a moderate correlation r = 0.591, with factor of determination r square = 0.349, between technology and green IT readiness, and sig value is 0.000 it indicates there is a statistically significant effect of technology on green IT readiness. Therefore, hypothesis H_1 is accepted. The regression equation is: Green IT readiness = *1.086+0.642* (technology), which shows a linear relationship between the two variables because 36.5% of the IT users still using LCD 17 inch screen types, in their offices, this is corresponds with Molla et al. (2009) finding; which is technological components that follow green IT readiness are saved IT energy consumption.

For hypothesis H_2 the results show a moderate correlation r = 0.653, with factor of determination r square = 0.426, between practice and green IT readiness, which indicates a moderate effect of practice on green IT readiness. The sig value is 0.000 it indicates there is a statistically significant effect of practice on green IT readiness. Therefore, hypothesis H_2 is accepted. The regression equation is: Green IT readiness = 0.773+0.742 (practice), which shows a linear relationship between the two variables because 5.4% of IT users print in their office more than 50 sheets daily, which means they are too far from green IT. In addition, the IT users must recycle consumable equipment as mentioned in Molla et al. (2009) that implementation of practices enhance green IT readiness.

For hypothesis H_3 the results show a strong correlation r = 0.739, with factor of determination r square = 0.546, between policy and green IT readiness, and sig value is 0.000 it indicates there is statistically significant effect of policy on green IT readiness. Therefore, hypothesis H_3 is accepted. The regression equation is: Green IT readiness = 1.171+0.675 (policy), which shows a linear relationship between the two variables, because policy directed the IT users to use IT in an efficient manner to save energy as recommended by Minsani & Imam, (2012) that policy would have a big role in enhancing green IT.

For hypothesis H_4 the results show a strong correlation r = 0.794, with factor of determination r square = 0.631, between governance and green IT readiness, and sig value is 0.000. It indicates there is a statistically significant effect of governance on green IT readiness. Therefore, hypothesis H_4 is accepted. The regression equation is: Green IT readiness = 1.018+0.708 (governance), which shows a linear relationship between the two variables, because governance usually directed employees to follow rules and regulations, which is confirmed with Molla et al. (2009) result, that governance has the highest effect on green IT readiness in the USA.

Table 2. Matrix of correlation

Factor	Technology	Practice	Policy	Governance	Attitude	Green IT readiness
Technology	1					
Practice	0.708**	1				
Policy	0.557**	0.653*	1			
Governance	0.473**	0.582**	0.599**	1		
Attitude	0.413**	0.513**	0.556**	0.582**	1	
Green IT readiness	0.550**	0.638**	0.702**	0.785**	0.571**	1

**Means statically significant at the level of significance ($\alpha = 0.05$)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

For hypothesis H_5 the results show a moderate correlation r = 0.581, with factor of determination r square = 0.338, between attitude and green IT readiness, and sig value is 0.000 it indicates there is statistically significant effect of attitude on green IT readiness. Therefore, hypothesis H_5 is accepted. The regression equation is: Green IT readiness = 1.203+0.601 (attitude). This shows a linear relationship between the two variables, because most of the IT users concerned about IT energy consumption, and they need more awareness for using IT equipment in the right way. This indicates that they need training courses or workshops to inform them the typical methods of using IT equipment, because 69.6% of the IT users are not attending lectures or workshop in the green IT awareness field.

The hypothesis H_6 related to demographic information of respondents.

Table 4 shows the results of T-test used to investigate the effect of gender on green IT readiness and the five factors. The gender of IT users has no statistically significant differences in their perception regarding green IT readiness and the five factors.

Table 5 shows the results testing the effect of age, education and experience of using IT on green IT readiness and the five factors by using one way ANOVA. The results showed that age has no statistically significant differences on attitude, while the Green IT readiness and the other factors have statistically significant differences according to age.

Table 3. Regression test for the hypotheses H_1 to H_5

Hypothesis	r	r square	F value	Sig.
H_1	0.591	0.349	15.677	0.000
H_2	0.653	0.426	18.432	0.000
H_3	0.739	0.546	23.448	0.000
H_4	0.794	0.631	27.987	0.000
H_5	0.581	0.338	15.282	0.000

Table 4. T-test for the IT users' gender

Factor	Gender	N	Average	Std	T value	f	Sig
Technology	Female	249	3.12	1.098	0.195	458	0.846
	Male	211	3.40	0.841	0.196		
Practice	Female	249	3.33	0.951	-1.175	458	0.240
	Male	211	3.42	0.744	-1.193		
Governance	Female	249	3.20	1.024	-0.133	458	0.599
	Male	211	3.21	1.006	-0.133		
Policy	Female	249	3.16	1.031	0.010	458	0.923
	Male	211	3.16	0.910	0.010		
Attitude	Female	249	3.39	0.871	-1.547	458	0.123
	Male	211	3.52	0.958	-1.535		
Green IT readiness	Female	249	4.13	0.983	-0.617	458	0.502
	Male	211	4.18	0.908	-0.627		

N: number, df: degree of freedom

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. One way ANOVA test for the IT users' age, education, and experience

Factor	Age		Education		Experience	
	F value	Sig	F value	Sig	F value	Sig
Technology	5.923	0.000	1.287	0.274	1.847	0.119
Practice	6.714	0.000	2.411	0.048	2.711	0.030
Governance	3.122	0.015	0.724	0.576	2.124	0.077
Policy	7.412	0.000	2.670	0.032	1.492	0.203
Attitude	2.084	0.082	1.387	0.237	5.598	0.000
Green IT readiness	5.752	0.000	1.727	0.143	3.663	0.006

The results indicate that the technology, governance, attitude, and green IT readiness have no statistically significant differences according to the IT users' education, while the practice and policy have statistically significant differences according to education.

The results show that the technology, governance, and policy have no statistically significant differences according to experience, because these three factors do not need experience. These are rules and all employees must follow regulations, while the practice, attitude, and green IT readiness have statistically significant differences according to experience.

7. CONCLUSION

The awareness of green IT and energy saving by using products carrying the *Energy Star* label are very important for individuals and organizations to share, in reducing CO_2 emission, especially the IT users. The perspective of the IT users are employees selected randomly, from different public and private organizations. The factors of this paper identified with the help of previous studies related to green IT readiness and awareness.

For the first question: What are the factors that affect green IT readiness from perspective of IT users? The five factors determined from the related studies are; technology, practice, policy, governance, attitude, and green IT readiness. These factors tested from the IT users' points of view toward green IT readiness. The results showed that the technology and attitude have an agreed degree of agreement; the practice, policy, governance, and green IT readiness have a neutral degree of agreement. The highest correlation coefficient was between governance and green IT readiness. The strongest factor that has a significant effect on green IT readiness was governance, followed by policy.

For the second question: Does the demographics information of IT users have statistically significant differences effect on green IT factors and green IT readiness? The results of the IT users showed that the gender have no statistically significant differences on green IT readiness factors. Age groups have statistically significant differences in green IT readiness except attitude. Educational level has no statistically significant differences in green IT readiness except practice and policy. Years of experience have no statistically significant differences in green IT readiness except practice, attitude, and green IT readiness.

The recommendation of this study is; the governance needs setup strategies for green IT readiness. The user's needs encouragement to apply green IT readiness practices, in addition, enhance IT user's awareness regarding the concept of green IT, by training courses and workshops about green IT.

Chapter 61
Drivers and Barriers to Green Supply Chain Management Practices:
The Views of Turkish and Egyptian Companies Operating in Egypt

Selin Kucukkancabas Esen
Trakya University, Turkey

Sahar Sobhy El Barky
Arab Academy for Science, Technology, and Maritime Transport, Egypt

ABSTRACT

The main purpose of this chapter is to extend the literature on drivers and barriers to GSCM from a different cultural framework, namely Egypt. The chapter is structured as follows. First, the importance and the components of GSCM are discussed briefly. Next, the benefits of GSCM and the main pressures/drivers that force the business sector to migrate its traditional supply chain activities to be green are highlighted. Next, the key theme of this chapter, the barriers and challenges facing the global business sector for extending green supply chain practices are discussed. Then, the results of multiple interviews that were conducted in multinational Turkish and Egyptian companies operating in Egypt are revealed in order to explore the drivers, benefits and barriers of GSCM and to propose the strategies for overcoming the barriers toward green economy. Finally, the chapter concludes with discussion and recommendations.

INTRODUCTION

'Green' is the new slogan in today's business world. Global warming, increasing quantities of municipal solid waste, scarcity of natural resources, and many other factors impel regulatory and international bodies to take corrective and proactive actions towards the sustainability of the environment. The concept of sustainable development emerged to control these impending environmental, economic, and social crises

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(ElBarky & ElZarka, 2015). Businesses in return found themselves in the spotlight to make fundamental changes in their practices to fit into the 'green' era and achieve sustainable development objectives.

Many strategies, approaches, and standards have been proposed and implemented such as eco-design, green production, green logistics, and reverse logistics. All of these strategies contribute to green supply chain management. Consequently, Green Supply Chain Management (GSCM) emerged as a complement to Supply Chain Management (SCM), since many of its processes have a significant impact on the environment in the form of CO^2 and other toxic emissions, solid waste, and effluent water (Sarkis, 2012). The concept of a 'green supply chain' was first proposed by the Manufacturing Research Consortium of Michigan State University in the U.S. in 1996 for comprehensively considering environmental impacts and resource optimization in manufacturing supply chains. There is no existing standard definition of GSCM. However, for the purposes of this chapter, the concept is defined as "Integrating environmental thinking into supply-chain management, including product design, material sourcing and selection, manufacturing processes, delivery of the final product to the consumers as well as end-of-life management of the product after its useful life" (Srivastava, 2007, p.54).

Under the backdrop of globalization, supply chain involves partners across continents. Globalization of supply chain represents differences in economies, infrastructures, cultures, and politics in the competitive environment (Manuj & Mentzel, 2008). In other words, globalization puts added pressures on techniques and practices of SCM. Besides, international trade drives sustainable supply chains. A sustainable supply chain requires proactive relationship management, including organizational learning, transfer of knowledge and capabilities from the large players in the supply chain, as well as development of an appropriate organizational culture and trust (Ki & Rowlinson, 2011). On the other hand, GSCM helps businesses to reduce operating costs, enhance productivity, enhance business reputation and reduce the risk of being prosecuted for anti-environmental and unethical practices. Considering GSCM's expanded positive long term impacts on organizations, international trade promotes the transnational spread of green supply chains, and it is recognized as an effective mechanism to address environmental issues alongside the global supply chain.

Despite ample evidence of the benefits of GSCM, bigger portions of organizations in different industries are reluctant to adopt GSCM or fail to implement such advanced systems because of internal and external environmental barriers. Considering this, the main aim of this chapter is to explore the primary barriers to implementing GSCM in the international business sector.

Although there exists a well-defined body of evidence on barriers and their consequences on GSCM operations in various countries, research on GSCM in Egypt is rather limited. Therefore, one of the purposes of this study is to extend the literature on drivers and barriers of GSCM from a different cultural framework, namely Egypt. Interviews with companies operating in the same country with different countries of origin (Turkish and Egyptian) were used to arrive at a better understanding of drivers and barriers to implementing GSCM in Egypt.

IMPORTANCE OF GSCM

As stated by Gibson, Mentzer and Cook (2005) SCM is about the planning and management of all operations related with sourcing and procurement, exchange, value creation and fulfillment, and logistics. However due to recent changing environmental policies, companies face increasing pressures from government, customers, shareholders, and suppliers to improve environmental performances of their

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

supply chains. There is evidence in today's literature to suggest that implementation of all supply chain activities creates excessive emission of greenhouse gases, such as methane and carbon dioxide (CO2, Sox, Nox), different types of waste, such as solid and liquid wastes, and high usage of resources (Emmett & Sood, 2011). Companies need to give back more to their community and the environment than they take away (Delmas & Montiel, 2008).

Accordingly, the concept of GSCM has become a very serious and profound area of study in the past decade. Much of the early work in this area focused on the significant impact of GSCM on the well-being of the environment in which corporations operate. Porter and Van der Linde (1995) characterized companies' categorization of green investments as resource saving, waste elimination, and productivity improvement. Emmett and Sood (2011) argued for implementing GSCM to lower emissions of greenhouse gases, to optimize usage of resources, and for huge reductions in different types of wastes. They emphasized the importance of collaboration among all interested parties (supplier, manufacturer, retailer, consumer and logistics providers) in the chain to implement and maintain green management strategy. Likewise, Albino, Dangelico and Pontrandolfo (2012) found that collaborations with all internal and external stakeholders can enhance companies' environmental performances.

There is an abundance of literature exploring whether implementing GSCM leads to enhanced firm performance (Lee, Lee & Pennings, 2001; Sarkis, 2012). Seuring (2004) maintained that implementation of GSCM may result in a win-win situation and provides environmental and economic trade-offs for all supply chain partners. A study of US manufacturing companies carried out by Green, Zelbst and Bhadauria (2012) revealed that the adoption of GSCM practices by companies leads to improved environmental and economic performance, which in turn, positively impact competitiveness. In the literature GSCM practices are often promoted as a basis of sustainable competitive advantage (Barratt & Oke, 2007). Sen (2009) stated that companies can gain competitive advantage by being the first to adopt GSCM practices. Masoumik, Rashid and Olugu (2014) regarded strategic capability as a mediator between GSCM and competitive advantage. Rao and Holt (2005) noted that companies adopting GSCM in Southeast Asia eventually improved competitiveness.

COMPONENTS OF GSCM AND GSC INITIATIVES IN EGYPT

Given typical practices of companies, the main components of GSCM can be broken down as follows:

- Green Outbound Logistics.
- Green Packaging.
- Green Product Design.
- Green Inbound Logistics.
- Green Procurement.
- Green Production.
- Green Reverse Logistics.

Logistics as a part of the supply chain process plans, implements, and controls the efficient flow and storage of products and related information from the point-of-origin to the point-of-consumption in order to meet customers' requirements (Council of Supply Chain Management Professionals, 2016). However, conventional logistics systems do not cover environmental issues adequately. In an environ-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

mentally responsible logistics approach, managers need to expand their visions by adding minimization of total environmental impact to their objectives (Wu & Dunn, 1994). To achieve this objective they must take environmental costs and benefits into consideration from a total system perspective (Copacino & Rosenfield, 1987). The greening of logistics generally depends upon the extent of willingness and the intentions of three main players: government, enterprise, and consumer (Chunguang, Xiaojuan, Kexi, & Pan, 2008). Government should make law and regulations effective, enterprises should put supply chain management into practice, and consumers should promote green consumption.

Green outbound logistics contribute to the success of overall supply chain systems by involving activities such as eco-friendly distribution, packaging, and waste management. These activities can improve a company's overall environmental and economic performance (Rao & Holt, 2005).

Eco-friendly distribution systems enable companies to use traditional fuels more efficiently or to use more eco-friendly fuels, to use eco-friendly vehicle technologies, to minimize toxic emissions, and to adopt eco-friendly infrastructures. These essentials and the dynamics that unite them determine the environmental impact created in the logistics phase of the supply chain (Kam, Christopherson, Smyrnios & Walker, 2003). Establishing their own green outbound systems may well motivate companies to convince their distribution partners to adapt to more environmentally friendly and sustainable transportation systems (Ndubisi & Nair, 2009).

Today, Egypt's emissions represent almost 0.6% of global emissions, of which transportation has the largest share (Ahmed, 2015). It is crucial for Egypt to take concrete steps to reduce emissions arising from transportation. An initiative began in 2004 to develop an integrated plan to realize a long-term sustainable transport sector (Ahmed, 2015). The main objective of this initiative is to minimize the energy consumption and the related greenhouse gas emissions of the transportation. Establishing public-private partnerships is essential to achieve a more energy efficient transportation systems.

Packaging is also a very important component of green outbound systems. In order to address environmental impacts of packaging, many countries now attempt to create environmental programs and put packaging take-back laws into practice to minimize the amount of packaging that enters the waste stream. This legislation causes many companies to rethink the design of their packaging and to manage their delivery and logistics systems accordingly. Labeling is a particularly important aspect of green packaging. It provides customers information to support their recycling behaviors (Peattie & Charter, 2003).

Currently in Egypt, most products in the market come in eco-friendly packaging. However, like other developing countries, many organizations face the problem of the disposal of the waste. Despite government attempts to impose penalties or fines, as well as relying on academic studies and research centers to develop solutions for waste management, municipal solid waste (MSW) in Egypt gets produced at the rate of about 15 million metric tons annually (El-Haggar, 2010). To address the problem of industrial waste management in Egypt, many academics and NGOs try to promote sustainable waste and materials management, where the main focus is the active involvement of industrial waste generators in the reduction of waste volumes at source, supplemented by private sector participation in solid waste management services, particularly collection and recycling (Elfeki & Tkadlec, 2015).

Focusing on outbound shipments alone is not enough to achieve an environmentally responsible supply chain strategy. Logistics activities associated with the receiving, storing, and movement of raw materials, management decisions related to freight consolidation, mode and carrier selection, materials handling, warehousing, and backhaul management are essential parts of GSCM (Wu & Dunn, 1994).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Although implementation is not always easy, the greening of inbound processes can significantly reduce waste and cost and leads to third part involvement, which in turn encourage environmental innovation (Bowen, Cousins, Lamming & Farukt, 2001).

Greater parts of the green inbound system encompass green procurement strategies adopted by companies in response to increasing global concerns. Green procurement tries to reduce the environmental impacts of products and involves decisions regarding retailer choice, material selection, outsourcing, negotiation, delivery planning, and inventory. Accordingly, it addresses issues such as general waste reduction, material substitution, and waste reduction of pollutants. Nikbakhsh (2009) stated that green procurement processes should be the initial step in green supply chain management. During the procurement process, companies have a chance to persuade their suppliers to meet their requirements directly, which consequently may lead to greening the whole supply chain.

To contribute to the creation of a sustainable environment for future generations, some global companies in Egypt incorporate energy conservation in material selection, even in the equipment they use. Depending upon their environmental policy, the procurement department ensures the selection and purchasing of energy efficient electrical equipment, recyclability of packing materials, and remanufacturability of equipment.

The main goal of green production is to minimize environmental impacts of the products by using appropriate substances and technologies (Lund, 1984). Green production compromises largely the activities aiming to reduce energy consumption and waste emission such as clean and lean production, green design, and remanufacturing.

Clean production systems concentrate on the causes of pollution by integrating environment protection systems to companies' products, processes and services. This approach aims to prevent pollution at its very source as opposed to the end of the pipe solution practiced in many places (Rao & Holt, 2005). Lean production focuses on processes but similarly aims to eliminate waste by reducing or minimizing external and internal stakeholder variability (Shah & Ward, 2007, p. 791). Furthermore, green design concentrates on the design issues related to environmental health and safety over the product life cycle during new product design and production process design (Fiksel, 1996). Successful eco-design decisions require intra-organizational and inter-organizational decision support systems (Kumar & Chandrakar, 2012). Remanufacturing which might be considered as part of eco-design decisions, broadly includes collection of used products or materials, evaluation of their forms, and replacement of worn, broken, or obsolete parts with new or refurbished parts. Unlike recycling and re-use, the process of remanufacturing does not degrade the overall value of the substances used (Beamon, 1999).

Under Egyptian environmental law there are articles associated with recycling and remanufacturing, although they are not binding. The Egyptian Environmental Affairs Agency provides no incentives (Elbarkouky & Abdelazeem, 2013). That means a large amount of natural resources are wasted. The challenges cannot be adequately addressed without a green production model that takes into account the social and environmental dimensions in policy-making and decision-making.

On the other hand, there are some initiatives that may lead companies to adopt green production in Egypt. One of those was the establishment of the Egypt National Cleaner Production Center (ENCPC) in 2005 by the Ministry of Industry, Trade and SMEs in cooperation with the United Nations Industrial Development Organization (UNIDO) as a service provider for the Egyptian Industry. The aims of the center are to achieve cleaner production, energy efficiency, renewable energy and waste valorisation,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

increased environmental awareness, and the development of sustainable production. The center mainly targeted food and chemical industries. The other initiative was the establishment of the Egyptian Green Building Council in 2009. One of the objectives of the council is to provide mechanisms to encourage building investors to amend existing codes to satisfy both energy efficiency and environmental conservation.

Reverse Logistics is the process of planning, implementing, and controlling the efficient, effective inbound flow and storage of secondary goods and related information opposite to the traditional supply chain direction for the purpose of recovering value or proper disposal (Fleishmannn, 2000, p.7). The definition of reverse logistics from an environmental perspective focuses primarily on the source reduction, substitution; reintroduce recyclable or reusable products and materials into the forward supply chain (Wells & Seitz, 2005). The stages of all these processes may differ depending on the industry and product category.

Source reduction refers to conducting similar practices using fewer resources. This process helps companies to reduce total waste in their systems. Substitution means using more eco-friendly materials instead of customary ones that create toxic waste. Reuse employs the same item numerous times in its original form so that little is discarded (Wu & Dunn, 1995). Recycling is at the heart of reverse logistics and involves the chemical and physical processes that give discarded materials a new life (Gencer, 2015). Overall, a company's manufacturing processes, product components, and potential for designing reusable recyclable structures mainly determines its success with reverse logistics (Dowlatshahi, 2000).

Currently in Egypt there are few small-to-medium size companies like Recyclobekia that are responsible for collecting electrical and electronic waste from industry and households. They operate inspection processes to sort e-waste and assign appropriate recovery processes in terms of reuse, recycling, and remanufacturing. Third party logistics companies and dealers export e-waste for recovery processes. Unfortunately e-waste is recovered by original equipment manufacturers, which usually are outside Egypt. Multi-national companies use authorized dealer sites as collection centers for their used products. There are a large number of companies that recycle their packing and plastics waste for themselves and others.

Improving reverse logistics functions can help companies to increase their revenues across total sales, but if ignored, these vital tasks can cost companies millions in lost profits due to broken customer supplier relationships that could have massive impact on their business (Gencer & Akkucuk, 2015).

BENEFITS OF ADOPTING GSCM

Many companies recently started to consider greening the supply chain not as an unnecessary burden on companies, but instead as an elementary mechanism for innovation, uncovering new market opportunities, and wealth creation. The benefits of greening the supply chain are not limited to reduced usage and pollution. For instance, in a green world managers might redesign a product so that it uses fewer eco-friendly or resource-depleting raw materials—an effort that if successful could result in cuts in direct manufacturing costs and inventory savings (Clarke, 1999).

The literature reveals that companies do get involved with GSCM either because they can profit from it, because they have to, and/or because they feel socially and environmentally motivated to do it (Bowen et al., 2001; Holt, 1998; Rao, 2002). Accordingly, the benefits of GSCM are categorized under four main headings:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Financial benefits.
- Compliance with laws and regulations.
- Good reputation.
- Minimizing waste and energy use.

Despite ample evidence to the contrary, there persists a myth that greening the system costs additional expense. There are several factors that lead to the persistence of this myth, such as lack of a systematic approach and an unwillingness to engage in sustained and green thinking. Empirical evidence suggests that the most fundamental benefit of GSCM is a positive long term net influence on the financial performance of the company. Implementation of GSCM may provide new opportunities for competition, cost savings, operational efficiency, and innovation, which in turn impact profitability (Dodgson, 2000; Hansmann & Kroger, 2001). For instance in 2014, Cisco planted 3 solar photovoltaic (PV) systems at business facilities in Texas and Bangalore, India that produced savings of over $380,000 annually as well as 2 million kilowatt hours of electricity and prevented 1150 metric tonnes of carbon emission.

Several laws and regulations passed in the last 10 years highlight the significance of the environment, which in turn raises the need for environmental protection. Companies need to adopt green practices to comply with the laws and regulations. GSCM initiatives can help companies create policies that may take them beyond compliance with regulations and help them to gain advantage over competitors and to increase profitability in the long run. For example, Volvo set up refining operations for salvaging and dismantling vehicles to comply with Swedish laws that made automakers responsible for disposal of used vehicles, and eventually generated a significant return (Bose & Pal, 2012).

Environmental approaches can help companies to enhance their corporate reputations and improve market image. For example, Ford Motor Co. developed an environmental management system compliance with ISO 14001 standard as part of the organization's strategy to implement its environmental policy. In 2014, Ford ranked first on Interbrand's list of Best Global Green Brands, and in 2015 it was recognized by the Ethisphere Institute, for the sixth year in a row, as one of the World's Most Ethical Companies (Sustainability Report Summary 2014/15, 2015). All these awards and recognition extend its brand recognition to new audiences, contribute significantly to positive corporate image, and consecutively provide a competitive advantage.

Whether driven by cost savings, a principled strategy, or compliance with regulations, companies started to recognize the environment and implement many environmental and social initiatives voluntarily. Most of the companies are aware of the need to protect their community's goodwill and environment as a valuable resource, because long-term business sustainability depends on this. Minimizing waste and energy use is typically the most argued benefit of GSCM in literature. Several studies suggests that GSCM initiatives encourage companies to protect the environment by using alternative energy sources, keeping away the burning of fossil fuels, recycling, and reducing waste (e.g. Geffen & Rothenberg, 2000; Klassen & Vachon, 2003; Simpson & Samson, 2008). For instance, Starbucks has an environmentally friendly business plan that focus on environmental sustainability and GSCM practices. Through initiatives such as creating "green" stores by adjusting the temperature in its stores from the standard 72°F to 75°F, purchasing cabinetry made with 90% post-industrial material, incorporating low-flow water valves, and achieving EED® certification for all new company-owned outlets, Starbucks has taken positive steps toward environmental protection and established an environmentally friendly corporate culture (Lamm & Dimas,2016).

DRIVING FORCES BEHIND GSCM

Existing literature focuses extensively on different stakeholder pressures as the key drivers of GSCM initiatives. From a developing country perspective, the motives for adopting GSCM are grouped into six categories:

- Regulatory Stakeholders.
- External Stakeholders:
  - Competitors,
  - Consumers, and
  - NGOs.
- Internal Stakeholders.

Regulatory stakeholders include governments and trade associations that are able to force companies to adopt environmental practices or technologies (Henriques & Sadorsky, 1999). Several government agencies control environmental regulations and laws (e.g. the Egyptian Environmental Affairs Agency in Egypt and the Environmental Protection Agency in the USA). The Egyptian Environmental Affairs Agency formulates environmental policies, prepares necessary plans for environmental protections, and grants environmental relations between Egypt and national and international associates. Furthermore, there are a number of environmental regulations (e.g. in Europe, ELV 2000, RoHS 2003, EUP 2005, REACH 2007) and ISO certifications (9001, 14001) that force companies to reduce their use of natural resources, to reduce the amount of waste they create, and to transport their products for recycling (Baines, Brown, Benedettini & Ball, 2012). ISO 14001:2004 specifies requirements for an environmental management system to enable an organization to develop and implement a policy and objectives that take into account legal and other requirements to which the organization subscribes, providing information about significant environmental aspects. This certificate does not necessarily state environmental performance criteria. It is considered an initial management system for green supply chain implementation (ISO, 2015).

Some countries establish different environmental requirements for different industries and products. Japan, the Netherlands, Norway, the United States, Sweden and France have strict regulations and requirements in terms of fabrics and dyes of clothes imported from China (Zhu, Sarkis & Geng, 2005). Likewise, The Restriction of Hazardous Substances directive (RoHS) confines the quantity of lead and five other materials found in products sold to Europe after July 1, 2006 (RoHS Guide, 2005). All these regulations and agencies have a vast impact on a company's decision to adopt GSCM and assist companies to run GSCM operations more efficiently.

Today the business environment has become more competitive than ever before. This highly competitive global business environment encourages companies to compete through their supply chains. In the literature it has been argued that GSCM not only lowers the ecological impacts of business and but also can create a sustainable supply chain and higher profits (Martusa, 2013; Simpson & Samson, 2008). Consequently, companies place greater emphasis on their environmental practices and upgrade their supply chain management to a more strategic level to comply with environmental regulations and maintain a long-term competitive advantage (Shang & Marlow, 2005). Thus, competitors can be identified as a driver for GSCM as they are able to influence their industry's dynamics, innovation, performance and competitive advantage (Van Hoek, 1999).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In many cases consumers express emotional resonance, which reinforces cost and convenience factors and demands special products and treatment. Customers are one of the main driving forces for companies to engage in GSCM. However, despite ample evidence from studies regarding pressure to adopt GSCM, research shows consumer's pressure on GSCM adaptation is sometimes inadequate. One study showed that green practices in supply chain does matter to consumers when making decisions on intention to buy the product as well as their willingness to pay for that product (Schniederjans & Starkey, 2014). Similarly, Simpson, Power, and Samson (2007) found a relationship between supply chain sustainability and customers' environmental performance requirements. Accordingly, companies need to manage supply chains more effectively and work on greening their supply chains to meet their customer's expectations and to satisfy them.

Additionally, national and international environmental NGOs which are rapidly growing all over the world have a significant influence on companies' motivation to fulfill the environmental regulations and to adopt GSCM. Regarding the environmental practices of a company, NGOs may influence consumers, companies, and governments' attitudes and behaviors in many different ways. They may provide both negative information to critique companies' insufficiently green processes or unlawful operations and positive information to develop positive attitudes toward companies' products and services. In some cases without NGOs, substantial change is not likely to occur. For example, a report presented by a group of Chinese NGOs describing pollution created by Apple's China-based suppliers' illegal operations raised national and global awareness and thus damaged companies and their customer's reputations and caused economic loss (CCICED Annual General Meeting, 2011). NGOs act for the benefit of companies and contribute to the well being of society at large. Companies need to find ways to collaborate with NGOs in order to find more green solutions to ensure a positive corporate image (Vanpoucke, 2014).

In addition to external stakeholders, internal stakeholders such as top management, employees and shareholders significantly influence successfully implementation of GSCM initiatives by companies (Sarkis, 2012). Top management's control over management system enables companies to provide appropriate technologies and resources, motivate employees, and guide shareholders to implement GSCM activities towards environmental excellence. Highly qualified and talented professional employees are able help to adopt new technologies easily and successfully (Lin & Ho, 2008). Moreover, if a company addresses environmental risk in its supply chain, shareholders might buy more shares seeking a higher return (Henriques & Sadorsky, 1999). Hence, the impact of internal stakeholders to adopt GSCM should not be undervalued.

BARRIERS IN IMPLEMENTING GSCM

It is clear that there are many benefits to implementing GSCM, but many companies are still not adopting and implementing green practices. Consistent with the literature, the barriers of GSCM adoption and implementation broadly divided into two categories:

- Internal barriers, and
- External barriers.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Internal barriers mostly link to financial, human resources, internal stakeholder commitment, awareness, technical, and managerial constraints. With respect to external barriers, GSCM initiatives can be influenced by three constraints: legislation, external stakeholders, and resources.

Financial Constraints

Financial constraints are generally considered the most important barrier to green initiatives (Ravi & Shankar, 2005). Some argue that the level of financial investment required for GSCM may be beyond the reach of small and medium-size enterprises (Min & Galle, 2001). This is partly due to lack of bank loans to encourage green processes. Hazardous waste management regulations of collection, transport, treatment, and disposal of wastes greatly increase the cost of GSCM. Companies are reluctant to invest in GSCM because they feel that investments will generate a lower or slower return. These constraints create major hurdles against the adoption and achievement of GSCM.

Human Resource Barriers

As mentioned previously in this chapter, trained and highly educated personnel are one of the essential components to carry out GSCM requirements. Finding trained personnel is a major obstacle in developing countries. Budgetary restrictions and the cost of hiring qualified personnel are the biggest GSCM challenges in terms of human resources. Employee resistance to change is another issue facing companies in the adoption and the implementation of GSCM. One of the most common reasons for resistance is fear of failure (Jayant & Azhar, 2014). Large scale changes in the system can cause employees to doubt their capability, and they may resist changes without considering their potential benefits. Management needs to diagnose the sources of distress in order to minimize resistance. Offering incentives to employees may help managers to struggle with resistance before, during and after GSCM implementation.

Poor Internal Stakeholder Commitment

Inadequate internal stakeholder commitment may delay or prevent companies from becoming more environmental friendly. One of the primary reasons for this lack of commitment within the organization is poor top management involvement. Perception within an organization that taking steps toward environmental good-will is not their responsibility makes GSCM implementation unfeasible (Hillary, 2000; Shen & Tam, 2002). Previous research has underlined the role of top management as one of the most important elements of GSCM implementation and success (Sarkis, 2012). More involved, efficient and optimistic leadership can defeat the employees' and shareholders' views of green practices as not only political or moral responsibilities and develop good business sense to integrate green thinking into corporate decision making (Baines et al., 2012).

Poor Awareness

One of the initial steps in launching and implementing GSCM is to develop environmental vision and awareness about the benefits of GSCM within the company. Holland and Gibbon (1997) stated that there is a substantial gap between the environmental awareness of SMEs and the business benefits they can gain. Similarly, a number of studies maintained that lack of awareness of environmental issues and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

strategies, along with a perceived lack of information and support, has been a major barrier to GSCM implementation (Merrit, 1998; Tilley, 1999). Previous research has outlined important linkages between education/training and green awareness (Madsen & Ulhui, 2001; Perron, 2005). The particular qualifications and knowledge obtained by environmental education would help in changing attitudes towards environment and clarifying the goals and benefits of GSCM initiatives. Internal stakeholders with environmental knowledge and GSCM skills would create new ideas for environmental problems of companies and would be more motivated to take part in GSCM implementation.

Technical Constraints

From an operations perspective, GSCM initiatives must deal with the latest reconfigurable, recyclable, and cleaner technologies in order to create minimal environmental damage and maintain cost effectiveness (Koren, Heisel Jovane, Moriwaki, Pritschow, Ulsoy & Van Brussel, 1999). Many companies in developing countries still rely on conventional technology and lack access to green materials and processes (Perron, 2005). In an eco-transportation system, inadequate supply chain infrastructure can be a huge burden. Inadequate infrastructure is mainly related to budgetary constraints of the company. Lack of governmental research funds and inadequate R&D efforts by the company also contribute to this gap. Therefore, companies need to improve their R&D and technical capabilities to resolve these infrastructure problems and to find new and innovative ways for implementing GSCM (Ghazilla, Sakundarini, Rashid, Ayub, Olugu & Musa, 2015; Zhu & Geng, 2013).

Managerial Constraints

Managerial barriers as a result of poor institutional experience to manage all the mechanisms of GSCM have restrained green development in many companies. Poor inter-departmental cooperation and communication due to restrictions in information flow across organization hierarchy prevents companies from adopting green practices (Ravi & Shankar, 2005). Poor monitoring and evaluation of environmental practices of suppliers inhibit companies to control supplier's deviations from environmental standards. Hence, companies need to develop new auditing standards in order to establish a dynamic GSCM process, with an objective of increasing managerial effectiveness. As stated earlier in this chapter ISO 14001 is recognized as an important indicator of environmental intention of a company. Thus, lack of information on environmental standards such as ISO 14001 is one of the most common barriers to GSCM in developing countries (Mathiyazhagana, Govindan, NoorulHaq & Geng, 2013). Some companies who were already aware of environmental standards state that they are not certified because of the high costs. However, environmental decisions made without considering their impact on operations are generally more costly than having an ISO 14001 certification (Gavronski, Ferrer & Paiva, 2008).

Regulatory Constraints

Various environmental regulations and governmental control on the one hand would drive GSCM practices which were explained in detail previously. On the other hand they can act as a barrier to the process. This primarily depends on how a company manages regulatory trade-offs (Mollenkopf, Stolze, Tate & Ueltschy, 2010). Although regulations related with GSCM implementation may impose high environmental standards, companies need to seek integration of environmental policies and regulations

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

on a global scale in order to be a part of the competition and to gain more customer attention. Industrial differences in environmental regulations can impede GSCM efforts (Muduli, Govindan,, Barve & Geng, 2013). Governments and other regulatory institutions should harmonize environmental regulations and standards in order to establish a successful and feasible environmental management system (Luthra, Kumar, Kumar & Haleem, 2011).

External Stakeholder Constraints

Successful GSCM efforts call for active involvement and commitment of external stakeholders. Without governmental support to adopt environmentally friendly policies (e.g. incentives, low interest loans) companies cannot easily overcome the financial barriers and survive in a highly competitive marketplace (Dam & Petkova, 2014). Supplier relationships in GSCM are essential for the adoption and diffusion of green processes. In order to develop a green supply chain, companies need to select appropriate and committed suppliers based on the expected outcomes of the relationship (Hutchins & Sutherland, 2008). Companies establish high commitment and trust relationships with suppliers through open and transparent communication. The success of green efforts depends considerably on potential interests, motives and priorities of customers and NGOs as well (Stead & Stead, 2000). Companies seek ways to publicize their green activities to overcome customers' lack of faith in green claims (Reinhardt, 1999) and encourage NGOs to raise green awareness. As companies' operations are relocated around the world, key supply chain players and non-national employees face cultural challenges related to language and belief systems in each region creating misunderstandings, monetary loss (Hudson, 2005), information distortion (Setthasakko, 2009), and inability to participate and share experiences in the workplace. Cultural diversities tend to act as a barrier to the spread of green awareness in companies (Harris & Crane, 2002).

Resource Constraints

GSCM systems require a large number of resources due to the changes required in company structure, planning, practices, and processes in developing and implementing green practices. Hence, the resistance by companies to undertake GSCM is partly related to inadequate external resources such as clean fuel and recyclable materials markets, leading to additional barriers to implementation. In order to take effective steps towards saving fuel, finding critical environmental resources, and reducing the climate change impact of their businesses and supply chain activities, companies should maintain collaborative relationships with their suppliers and retailers. Lack of training courses, institutions to give training, and monitoring and mentoring services specific to each industry are major constraints, particularly in small and medium companies and companies operating in developing countries that do not hold the required expertise and knowledge to implement environmental systems (Govindan, Khodaverdi & Jafarian, 2013). Limited regulatory instruments and incentives have been identified as a barrier to GSCM (Chan & Yung, 2002). This has further been confirmed through research carried out by Massoud, Fayad, Kamleh and El-Fadel (2010) who found that "lack of government support and incentive is a significant barrier to acquiring an environmental certificate." Ninlawan, Seksan, Tossapol and Pilada (2010) also made the point that inadequate incentives to separate recycled or hazardous materials, ineffective law enforcement, and technology limitation at the community level are obstacles for green management.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

QUALITITATIVE STUDY

In this study a range of interviews were conducted with the managers of multinational Turkish and Egyptian companies operating in Egypt in order to provide greater depth and insight into drivers, benefits, and barriers of GSCM. Interviews carefully targeted companies in which green supply management was successfully implemented with positive outcomes. A structured interview method was used where all interviewees were presented the same questions and asked to choose answers from among the same set of alternatives but in a conversational/informal manner rather than a question-and-answer style. Interviews were conducted within a span of two months. In order to identify the relevant companies to be interviewed, lists provided by the office of the Turkish Commercial Counselor in Cairo and the Ministry of Industry and Trade were used. Purposive sampling was carried out to identify the common barriers of Egyptian and Turkish companies adopting GSCM in Egypt. The companies in the sample were chosen because they were:

- Experienced in adoption of GSC practices.
- Involved in environmental projects.
- Provided direct comparison between Turkish and Egyptian companies.
- Located in Egypt.

At the end of the sampling process, 18 Turkish and 9 Egyptian companies were chosen for the study. A total of 19 companies (12 Turkish and 7 Egyptian) agreed to take part in the study giving a response rate 70.3%. The companies were located in the geographical areas of Cairo and Alexandria. Of the 19 interviews, 14 were with the chief executive officer of the firm. The remaining five interviews were conducted with the procurement officer of the firm. These officers were considered the most knowledgeable firm-internal interviewees on the subject matter of GSCM.

Before conducting interviews, the questions were translated to Turkish and Arabic through the use of a back translation process. First the items were translated into Turkish and Arabic by researchers. They were then back-translated into English by a native speaker. Differences between them were then analyzed and some necessary modifications were made to improve the overall clarity of the items. Prior to conducting the full interviews, a pilot interview was conducted with a procurement officer.

Two university academicians and one practitioner were specifically asked to check for content validity of the interview protocol. Adjustments were made accordingly before final execution. The data from the pilot study were not included in the final analysis. The aim of the study and the domain of the constructs were specified to respondents at the start of the interviews, as recommended by Churchill (1979) and the respondents were offered full anonymity. Each interviews lasted 30-45 minutes.

The questionnaire of the interviews was divided into three parts. The first part of the questionnaire dealt with the demographic profile of the company, including industry category and employee size. In the second part of the questionnaire, respondents were asked about their GSCM practices and their views about the benefits and drivers of GSCM practices. In the final part of the questionnaire, respondents were asked to indicate essential internal and external barriers to implementing GSCM in their companies.

Interview instruments were designed using multiple items from previous studies, covering GSCM implementations and internal and external barriers of GSCM. Financial barriers of GSCM were measured by asking questions used in the studies of Mathiyazhagana et al. (2013), Govindan et al. (2013), Simpson, Taylor and Barker (2004), Zhu et al. (2005). Items in the studies of Mathiyazhagana et al.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(2013), Luthra et al. (2011) were used to examine barriers related to human resources. Barriers related to commitment of internal stakeholders were measured by questions adapted from studies of Mathiyazhagana et al. (2013), Luthra et al. (2011), and Tilley (1999). Items in the studies of Mathiyazhagana et al. (2013) and Shen and Tam (2002) were used to examine barriers related with awareness. Barriers related with technical capabilities were measured by items adapted from studies of Mathiyazhagana et al. (2013) and Perron (2005). Final internal barriers related with managerial systems were assessed by items adapted from Mathiyazhagana et al. (2013), Luthra et al. (2011), Govindan et al. (2013). Items used in the studies of Mathiyazhagana et al. (2013) and Tilley (1999) were used to constitute barriers related to legislation. Barriers related to commitment of external stakeholders were measured by asking the questions used in the studies of Mathiyazhagana et al. (2013), Luthra et al. (2011), Setthasakko (2009), and Orsato (2006). Finally, barriers related to environmental resources was measured by items adapted from the studies of Mathiyazhagana et al. (2013), Luthra et al. (2011), and Muduli et al. (2013).

Demographic Profile of Companies

Table 1 presents the demographic profile of companies. Among 19 companies, there are 12 Turkish companies and 7 Egyptian companies. Of the 12 Turkish companies, 50% of the companies were in textiles, 25% of them were in chemicals, 8% of them were in retail, 8% of them were in Food, and 8% of them were in household appliances/white goods industries. A profile of Egyptian companies shows a reasonable spread across the industries: automotive (14%), chemical (14%), food (14%), household appliances/electronics (14%), steel (14%), shipping (14%) and glass (14%). 41% of Turkish firms had less

Table 1. Demographic profile of the companies

	Value	Turkish Companies (n=12) %	Egyptian Companies (n=7) %
Industry	Textile	50,0	-
	Chemicals	25,0	14,3
	Retailer	8,3	-
	Food	8,3	14,3
	Household Appliances	8,3	14,3
	Automotive	-	14,3
	Steel	-	14,3
	Shipping	-	14,3
	Glass	-	14,3

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

than 250 employees, 25% had between 250-1000 employees, 25% had between 1001-2000 employees and only 8.3% had more than 2000 employees. Of all the 7 Egyptian firms, 57% had between 1501-2000 employees, 29% had more than 2000 employees and 14% had between 250-500 employees.

In the interviews, information about IS0 14001 series certification was also elicited. Out of 12 Turkish firms 83% stated that they were not certified. The most frequently stated reason for not having ISO 14001 certification was the firms' weak internal capabilities that restrain them to have the basic competencies to implement ISO 14001 organization-wide. In contrast 100% of Egyptian firms had ISO 14001 certification.

Results

Statistical calculations mainly based on the frequencies of collective judgments of all the participating companies were conducted to summarize the categorical data obtained from structured interviews. In the first part, firms' current GSCM practices, drivers/pressures behind GSCM practices, and benefits expected to be gained by practicing GSCM were computed for both Turkish and Egyptian companies. The results are presented in Table 2.

The data revealed that 75% of the Turkish companies and 100% of Egyptian companies had practiced several GSCM activities between 1-5 years. Currently 42% of the Turkish companies practice outbound logistics, and this was followed by inbound logistics (33%), "green procurement" (33%), "green production" (33%), "green packaging" (33%) and "product recovery strategy" (33%). Among Egyptian companies, green production (100%) was the most practiced green activity. Comparatively, 1 Turkish and 2 Egyptian companies out of 19 were the only ones that apply the full spectrum of green activities. Moreover, 42% of the Turkish companies stated outbound logistics as their first GSCM practice and that followed by inbound logistics (17%). All of the Egyptian companies' first GSCM activity was green production.

The majority of Turkish companies (75%) and all Egyptian companies (100%) identified ''regulatory stakeholders'' as the main driving force behind GSCM practices. This was followed by ''NGOs '' for Turkish companies (42%) and ''internal stakeholders'' for Egyptian companies (43%). One of the Turkish chief executives identified corporate global environment policy as one of the pressures for GSCM initiatives. These results indicate that the companies implement GSC mainly to comply with the laws and regulation to avoid any penalties and drawbacks from regulatory bodies such as the Ministry of Environmental Affairs that conduct regular audits on industrial companies to check their environmental performance.

As can be seen in Table 2, ''good reputation'' was the main expected benefit for both Turkish (67%) and Egyptian (100%) companies. This was followed by ''complying with legislation and regulations'' for Turkish companies (58%) and ''minimizing waste and energy use'' (58%) for Turkish companies and similarly "minimizing waste and energy use'' (86%) for Egyptian companies. One Turkish procurement officer indicated that enhanced employees' health was the main expected benefit of their GSCM initiatives.

In the second part of the calculations, essential barriers that companies faced during the implementation of GSCM were identified. Based on the judgments of all the participating companies, "total responses in each barrier category" and "average response per company" were computed. Then, by dividing "average response per company" to "total questions in each barrier category", "average response per company" was presented as percentage of "total questions in each barrier category" for assessing the significance of each barrier category. As shown in Table 3 awareness (36%) was the most important internal barrier category among Turkish companies. Legislation (50%) was the most important external barrier category

that Turkish companies encountered during the implementation of GSCM. Among Egyptian companies human resource (50%) was the most stated internal barrier which was closely followed by awareness (48%) whereas lack of resources (46%) was the most important external barrier.

In the final part, relative importance of specific barriers under each category was computed. In the financial constraints category "high capital investment" was the most important barrier for both Turkish (42%) and Egyptian companies (100%). In the human resources category "lack of trained personnel" was the most stated barrier by Turkish (83%). Similarly among Egyptian companies "lack of trained personnel" (100%) along with "resistance to change" (100%) was the most important barrier in terms of human resources. In the commitment of internal stakeholders category "perception of out of responsibility zone" was the most stated barrier by Turkish companies (33%). However during the interviews none of the Egyptian companies indicated any concern about commitments of internal stakeholders. In the awareness category "lack of awareness of potential advantages of GSCM" was the most stated barrier among both Turkish (58%) and Egyptian (100%) companies. In terms of technical constraints "lack of new technology, materials and processes" was the most stated barrier among both Turkish (58%) and Egyptian companies (29%). In general terms, interviewees complained about lack of consulting firms that could provide specialized advice about GSCM practices, processes and implementation. In the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

management system category "lack of adequate information about implementation" was the most stated barrier among both Turkish (42%). "Lack of inter-departments cooperation in communication" was the most stated managerial barrier among Egyptian companies (100%).

With respect to legislation category which was also found as the most important external barrier for Turkish companies, "environmental legislations & regulations" (58%), "industry specific legislations" (58%), "ineffective legal sanctions" (50%) were the most stated ones. In contrast interviewees from Egyptian companies did not put emphasis on barriers related to legislation. In terms of commitment of external stakeholders, "lack of customer awareness about GSCM" (58%) and "lack of governmental support to adopt environmental friendly policies" (50%) were the most stated barriers by Turkish companies. As for the Egyptian companies "cultural diversity" (100%) was the most and the only indicated one. Finally in the resources category "lack of direct incentives" was the most stated barrier by Turkish companies (50%). "Lack of clean fuel" (100%) was the most important resource related barrier among Egyptian companies which was closely followed by "lack of direct incentives" (86%). These results are presented in Table 4.

SOLUTIONS AND RECOMMENDATIONS

In recent years the green movement has reached out a broader base. Companies now realize that implementing green practices not only improves the environment but also can provide significant financial, environmental and social benefits by reducing waste, regulatory costs, and potential long-term liabilities. The results of this study revealed that for Turkish companies complying with legislation was the main motivation and expected benefit for taking up GSCM. Similarly, Egyptian managers' stated that they were expecting to enhance company reputation by complying with the environmental laws and regulations.

Greening supply chains is important for Egypt's green transformation but is not an easy task for companies operating in an environment lacking government incentives, industrial guidance, trained personnel, and a mature market of green consumption. Analyzing the main barriers of GSCM in order to address environmental problems of the companies operating in Egypt was the main objective of the empirical part of this chapter. In the exploratory study, 9 barriers that include 40 different constraints under 2 main categories were examined based on the findings of numerous studies.

A majority of the managers of Turkish and Egyptian companies stated that human resources and awareness are the main internal barriers for GSCM. Most of the interviewees openly mentioned that they are not aware of ISO 14001 certification. This finding is in line with earlier research indicating that environmental strategy requires trained, qualified and environmentally motivated and aware personnel in the first place (Jayant & Azhar, 2014; Merritt, 1998; Tilley, 1999). A number of managers believe that there is resistance by managers, employees and shareholders to undertake environmental management programs mainly due to fear of failure or the perception that such undertakings are outside of their responsibility zones. During the interviews solutions were discussed with the interviewees, who they stated that environmental information databases and training classes for internal stakeholders would help to raise awareness about the environment and GSCM practices. These initiatives would consequently support the companies in reducing the resistance to change which was indicated by interviewees as one of the most challenging barriers.

Regarding external barriers, Turkish managers indicated environmental legislation and regulations as the key factor for non-implementation of GSCM. This finding is also in line with studies in which

Table 4. Continued

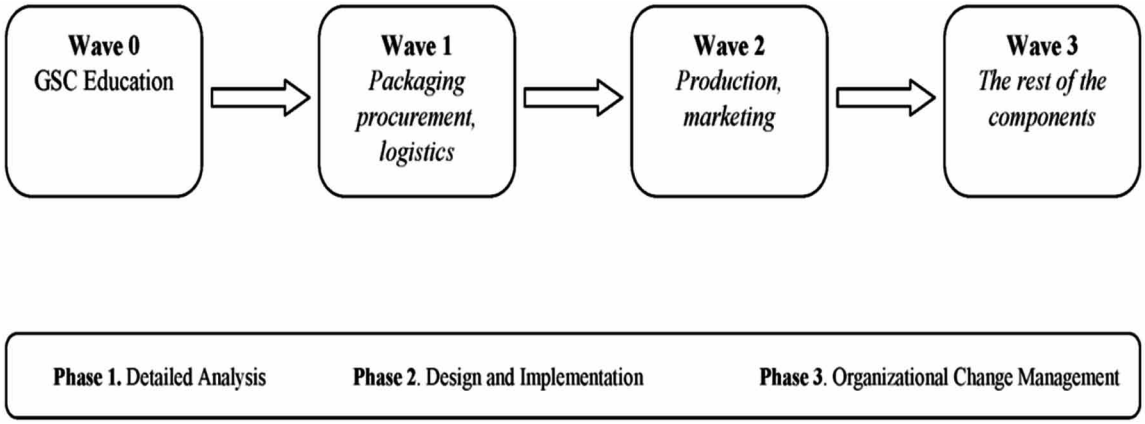
	Barriers		Turkish Companies (n=12) %	Egyptian Companies (n=7) %
EXTERNAL	**Legislation**	Environmental legislations & regulations	58,3	0,0
		Ineffective legal sanctions	50,0	0,0
		Industry specific legislations	58,3	0,0
	Commitment of External Stakeholders	Poor supplier commitment	33,3	0,0
		Lack of customer awareness and pressure about GSCM	58,3	0,0
		Lack of government support to adopt environmental friendly policies	50,0	0,0
		Inadequate pressure from NGOs	41,7	0,0
		Cultural differences	41,7	100,0
	Resources	Lack of consultancy institutions to train, monitor the progress specific to each industry	41,7	0,0
		Lack of critical environmental resources.	41,7	0,0
		Lack of clean fuel	25,0	100,0
		Lack of direct incentives	50,0	85,7

it was found that governments and other regulatory institutions can discourage the adoption of GSCM by setting time consuming, costly and industry-specific environmental regulations (Mathayazhagan et al., 2013; Zhu et al., 2006). Egyptian companies did not identify regulations as a barrier to green activities; instead they described their companies' green regulations as more uptight than those required by Egyptian environmental law. Differences in perception of legal pressures might be due to distinctive regulations faced by public regulators in terms of country of origins or industries, which should be explored in more depth.

Egyptian companies' major external barriers to GSCM implementation was related to inadequate environmental resources. During the interviews, managers mainly emphasize the importance of clean fuel and direct incentives in green practices. Most of the interviewees noted that lack of direct investment is the main obstacle for them in implementing GSCM. They feel that government financial support or increases in some incentives would be helpful in practicing green. The importance of collaborative relationships with their suppliers and retailers was also discussed in order to take effective steps towards saving fuel and finding critical environmental resources that companies should maintain. They felt that the Egyptian government should provide clean or less polluting fuels such as organic fuel and natural gas to help companies to comply with green principles in their decision making processes.

Solutions to overcome all these barriers were discussed with the interviewees, and interviewers proposed a model that delivers an enhanced probability of success in the implementation of GSCM. In the literature there a numerous models (Akkucuk, 2016; Lin & Ho, 2008; Rao & Holt, 2005; Sarkis, 2012; Wu & Dunn, 1995,) which seek to help companies to manage their supply chain's environmental impacts, resulting in more efficient operations. The authors proposed GSC migration model developed

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



by Elbarky and Elzarka (2015) as a point of reference due to its suitability for the identified barriers during the interviews. This model divides GSCM practices into seven key processes: green planning, green procurement, green execution, carbon management, migration strategy/approach, performance evaluation and continual improvement.

The migration strategy is one of the significant elements of the model and provides a practical road map to guide companies towards GSCM and overcome the stated barriers. The migration strategy includes four waves that last less than eighteen months, as shown in Figure 1. Each wave includes three phases of no less than 6 months. Waves help companies to implement green supply chain practices in a more controlled approach. In Wave 0, which was added to the original model as a foundation, companies should conduct a detailed analysis on the educational needs of their employees, stakeholders, customers, and other interested parties to determine the areas of development within the scope of sustainability and green supply chain management. Consequently, a detailed training plan should be designed to deliver the required knowledge for a period of no less than 12 months. Wave 1 should be started with greening packaging, procurement, and logistics. It is worth noting that it is not recommended to start the greening process with production, which involves high capital investment and very sophisticated processes that might discourage companies from executing their green initiatives. In Wave 2 companies should focus on production and marketing, and in the final wave the rest of the components should be well covered. Each wave should start with phase 1, which makes an initial assessment and a gap analysis for the current situation of the company regarding green practices. In phase 2, the companies should design their environmental programs to mitigate their environmental impacts and finally measure their environmental performances and progresses in terms of previous steps.

CONCLUSION

This chapter outlined the drivers, benefits that encourage, and barriers that prevent companies from implementing environmental practices within their organizations. It is clear from the literature and the results of the interviews that there are many motivators, but resistance by internal and external stakeholders to GSCM practices is undoubtedly a problem. Qualitative study of this chapter has thrown light

Figure 1. Green supply chain migration model

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

on some of the critical barriers that companies operating in Egypt face in implementing GSCM. Accordingly, the authors suggested a model to overcome these limiting conditions. Although the proposed model may help companies practicing GSCM in Egypt to cope with these constraints, it suffers from the flaw that it is based upon the authors' opinions which may lead to bias. Thus it is advised to be tested in a realistic scenario in the future.

Chapter 62
Effects of Corporate Social Responsibility and Creating Shared Value on Sustainability

Janthorn Sinthupundaja
Japan Advanced Institute of Science and Technology, Japan

Youji Kohda
Japan Advanced Institute of Science and Technology, Japan

ABSTRACT

This article describes how recently, there has been a shift in corporate social responsibility (CSR) to creating shared value (CSV), filling the gap between the strategies underlying competitive advantage and sustainability. Although the principles of CSR and CSV have been broadly studied and investigated, there is still little academic research focusing on the transitions regarding on economic, social, and environmental sustainability. In this article, literature and a case study were reviewed and analyzed to identify differences and contributing factors towards sustainability, based on value co-creation and collaboration approaches. The authors' findings present that the CSV emphasizing on co-created value with the cross-sector collaboration leads to the sustainability. Working together with local people or social organizations enables deep understanding of local context and understand the real social and environmental issues. The study contributes to sustainability and business literature by investigating insights into the sustainability of CSR and CSV, and strengthening the importance of social involvement.

INTRODUCTION

In the old days, firms' only responsibility was to maximize their owners' interests and profit, rather than concerning about social and environmental effects. However, nowadays serious climate changes, environmental disasters, and malnutrition around the world have been emphasizing the criticism toward capitalism and business management (Abdelkafi & Täuscher, 2016). Debates about the firm's responsibility for its economic, social and environmental impacts have also been raising (Motilewa et al., 2016). As a consequence, firms are requested to contribute to the achievement of holistic sustainable development,

which not only refers to economic sustainability for firms, but also ecological and social sustainability. Business management should think and support the innovative solutions that deal with environmental and social challenges, while creating economic simultaneously (Abdelkafi & Täuscher, 2016). Sheth et al. (2011) suggest that the performance of business does not only depend on economic performance but also environmental and social performance. Therefore, managing the relationship between business and society has become one of the important topics of academic research, business and sustainability management (Wilson & Post, 2013). In addition, there have been studies arguing that the growth of businesses encourages the growth of economic, as businesses have become a major driver of society in terms of, for example, creating employment, providing transportation and health care systems (Motilewaet al., 2016). On the other hand, society also plays an influential role in achieving a firm's economic performance i.e., making a profit (Lawrence & Weber, 2013; Motilewa et al., 2016).

Corporate Social Responsibility (CSR) refers to business management and operations that aim to enhance societal well-being (Jackson & Apostolakou, 2010). Traditional CSR has been associated with corporate philanthropy and could have used up the firm' slack resources such as working hours of employees and financial capital (Wójcik, 2015). Its practice is mostly about sacrificing profits for the social interests. Therefore, the creating shared value (CSV) concept was introduced to address this issue by re-conceptualizing the role of business in the society and offering a theoretical solution through the prism of value. It can be considered as a corporate framework to guide the thinking about the relationship between a firm and society (Porter and Kramer, 2011). Social activities are linked to a firm's goals, meaning that social and environmental responsibility is considered an internal function rather than external obligations. Nevertheless, it is difficult for businesses and academia to demonstrate how corporate responsibility could lead to improvements for the firms, society, and the environment (Camilleri, 2017). Many scholars have called for greater emphasis on value creation within the context of business responsibility (Wójcik, 2015). Socially responsible practices create value for the firm, it stakeholders including society and the environment (Camilleri 2017). Thus, firms should allocate and distribute corporate valuable resources and business capability that concern about social and environmental impacts (Camilleri, 2017; Porter and Kramer 2011). Competitive advantage and legitimacy related to social responsibility are important for firm's survival and growth, which hinges on value co-creation process for sustainable development that meet pressures and expectations from the society (Ahen & Zettinig, 2015).

Although the principles of CSR and CSV have been broadly studied and investigated, there is still little academic research focusing on the transitions regarding on economic, social, and environmental sustainability. Furthermore, academic research that links corporate responsibility with firm, social, and environmental sustainability is still limited. Therefore, this study aims at filling this gap by exploring the conceptual framework of the holistic sustainability and corporate responsibility and investigating the transitional CSR and CSV. This paper identifies, organizes, and analyses existing empirical research to highlight the economic, social, and environmental value creation and sustainability as well as exploring a case study implementing CSV. The main objective of this study is to address the research questions: how do CSR and CSV influence on economic, social, and environmental sustainability? The authors further aim at understanding the differences, and the drivers of these transitions from value-based and sustainability-oriented frameworks. The study contributes to both theoretical and managerial implications. The findings contribute to CSR and sustainability literature by improving the general understanding of the corporate responsibility and sustainability and provides the theoretical framework. The study thereby

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

contributes to the potential managerial implications for firms applying CSR and CSV based on value co-creation and sustainability and demonstrating on how firms may better implement corporate responsible practices in shared value creation for themselves and other stakeholders to attain the sustainability.

Next sections present our theoretical background and literature review exploring key themes of CSR, CSV, and their transitions and followed by the methodology section. The discussion section then explores our theoretical framework and offer insights into the links between CSR, CSV, value creation, and sustainability. After that, a case study is provided to better demonstrate our framework. Finally, the authors discuss and explain the implications, limitations, and directions for future research.

CORPORATE SOCIAL RESPONSIBILITY (CSR)

The concept of CSR was initially introduced in about 1920s when firms attempted to respond to shareholder and social pressures. The purpose was to increase their trust (Frederick, 1994). CSR was more often referred to as social responsibility in the early 1950s and later this idea was broader to business people in which responsibility should also be served to society and goes beyond their financial obligations (Bowen, 1953). The development of CSR has changed dramatically since Levitt in 1958 and Friedman in 1962 started to concern about a firm' responsibility and impacts on society and the environment because there were public pressures that called for social and environmental responsibility beyond their maximizing profit goals and legal requirements (Davis, 1973). In the 1960s and 1970s, firms began to consider about societal and environmental impacts (Camilleri, 2017). Initially, firms focused mainly on philanthropy and charity purposes (Camilleri, 2017). Later, in the 1980s and mid-1990s the concept of CSR was developed into different dimensions based on various academic theories, models, management, and purposes such as corporate social responsiveness, corporate social performance, business ethics, stakeholder theory and management (Carroll, 1999). There is still no universally accepted definition of CSR (McWilliams & Siegel, 2001). CSR has a wide range of definitions from very conceptual and normative to very practical definitions. However, CSR can be broadly defined as a commitment to improving societal well-being through business practices and contributions of corporate resources (Jackson & Apostolakou, 2010), which refers to firms' practices for economic, legal, moral, social and environmental responsibility (Barnard, 1938). It is primarily concerned with a firm's ethical and social behavior to its stakeholders (Motilewa at al., 2016), in which the practices CSR embraces responsibility for its actions and, through its activities, positively affects the environment, society, consumers, employees, communities, and other stakeholders.

CREATING SHARED VALUE (CSV)

CSV was first introduced by Porter and Kramer (2011), seeking to reconnect business with society by suggesting that firm strategies that respond to societal and environmental challenges can enhance the corporate competitive advantage from creating shared value with society. They argue that the more closely firms tied to a social issue, the greater the opportunity to make use of the firm's resources and capabilities to provide benefits for society. The CSV can be considered as a corporate framework to guide

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the thinking about the relationship between business and society, and firm' engagement in corporate responsibility (Høvring, 2017). Engagement in CSV is seen as a way to signal to stakeholders that the firm is cognizant of its implications on society. Social concern may become a source of shared value creation only when the criterion of the greatest possible benefits relative to costs is met (Voltan et al., 2017). The more social issue relates to the core business strategies, the greater the possibility to leverage the firm's resources and capabilities with mutual benefit (Høvring, 2017; Porter & Kramer, 2006).

CSV is a more action-oriented concept that attempts to translate traditional CSR postulates and practices into business practice (Wójcik, 2015). It is a proactive action and driven internally to pursue social and environmental responsibility (Wójcik, 2015). This means that the CSV strategy links social activities to the firm's goals, and that social responsibility is considered an internal function rather than an external obligation to society, emphasizing its functionalist roots (Høvring, 2017). The core idea suggests that the narrow and short-term economical perspective focusing only on corporate value needs to be replaced by a broader societal perspective focusing on shared value for both society and the firms. According to Porter and Kramer (2011), CSV is defined as the policies and operating practices that enhance the competitiveness of a firm while simultaneously advancing the economic and social conditions in the communities in which it operates. It has been shown as a way forward to regain legitimacy and advance the role of business in society (Voltan at al., 2017). Furthermore, the CSV concept includes both interacting with the internal stakeholders such as employees, technology and work environment and external stakeholders such as society, local communities, and the environment that has an impact on the environment, economic benefits, and social benefits (Lapina et al., 2012). This shared value creation is acted as a compensating point between social and environmental value, and corporate value (Høvring, 2017). CSV is also referred to a measure for alleviating poverty and enhancing social welfare (Porter & Kramer, 2011). Moreover, Chatterjee (2016) includes CSV in a collection of concepts that were initiated to confront the downsides of globalization such as the unequal sharing of benefits (Voltan et al., 2017).

TRANSITION OF CSR TO CSV

Challenges of CSR

In the past, traditional thinking about CSR has been mostly associated with corporate philanthropy, making donations, volunteering activities for society and environmental improvement, (Camilleri, 2017). CSR is traditionally defined and understood as generating social benefits without referring to costs of effort, i.e., the phenomenon is focused on sharing the value created by business and transferring it to the society (Voltan et al., 2017). Consequently, a recently shaped view is that CSR is mostly sacrificing profits in the social interest (Reinhardt et al., 2008) and the only concern is to what extent the private sector shares its profits to alleviate poverty (Clyde & Karnani, 2015; Wójcik, 2015). Certain discretionary expenses in corporate philanthropy could have usurped the businesses' slack resources, for example, financial assets, labour and time, without adding much value in terms of corporate reputation and customer value to the businesses. The corporate philanthropy should be deeply rooted in the firm's competences and linked to its business environment (Porter & Kramer, 2002). Visser (2010) claims that CSR logic cannot serve anymore as an analytical framework, nor as an approach that could conceptually reconcile a firm's goal and social goals.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Shifting to CSV

The CSV concept addresses the issue of scarifying firms' resources for society and the environment by re-conceptualizing the role of business in the society and offering a theoretical solution through the prism of value, i.e., a notion that can be more effectively analyzed than through the CSR concept. Traditional thinking of CSR should be extended and replaced by the CSV concept, which emphasizes into a firm's strategy. This leads to the creation of value for both business and society (Burke & Logsdon, 1996; Lantos, 2001; Porter & Kramer, 2011) and increase the financial performance of businesses in which it minimizes their costs through better operational efficiencies, boosts the employee morale, creates job satisfaction and reduces the staff turnover, along with other benefits (Abdelkafi & Täuscher, 2016; Camilleri, 2017). In response to the perceived conflict between business and social goals, the European Commission put forward a new understanding and defined business responsibility as the responsibility of enterprises for their impacts on society (European Commission, 2011), which means integrating social concerns into companies' business operations and core strategy with the aim of maximizing the creation of shared value. This definition underlined explicitly the balance between firm goals and social goals. The new European Union's CSR strategy, therefore, noted the importance of the problem of the difficulty of reconciling business and social goals and refers indirectly to the CSV concept (Wójcik, 2015). CSV also help to create new opportunities for creating new value. Instead of being forced by external factors, a company is motivated internally to pursue shared value creation (Voltan et al., 2017). CSV implies that the shared value involves corporate activities in at least one of the three areas including reconceiving products and markets, redefining productivity in the value chain, and enabling local cluster development that includes institutions such as universities, social organizations and other associations and that a mutually beneficial relationship exists between society and the firms (Porter & Kramer, 2011). CSV provides the theoretical possibility of a CSR-entrepreneurship synergy such as social entrepreneurship (Raimi et al., 2015).

Differences Between CSR and CSV

The concept of CSV originates from the corporate responsibility debate, it is often confused with traditional CSR (Wójcik, 2015). While business ethics scholars are skeptical about the novelty of the CSV concept, arguing that its core premises overlap with existing concepts within CSR, stakeholder management and social (Crane et al., 2014), management scholars celebrate the CSV concept as a powerful and valuable concept (Bosch-Badia et al., 2013; Høvring, 2017; Moon et al., 2011). The most significant differences between CSR and CSV notions may be distinguished when their conceptualizations are analyzed as summarized in Table 1.

METHODOLOGY

The paper is a theoretical interdisciplinary study, which combines insights from the framework of value co-creation within the application domain of CSR and CSV and looks into the impacts of economic, social, and environmental sustainability. This study is conceptual in character. To answer our research question, a review of relevant literature was first conducted. The paper has built on the previous theoretical underpinnings of the corporate responsibility for economic, social, and environmental dimensions

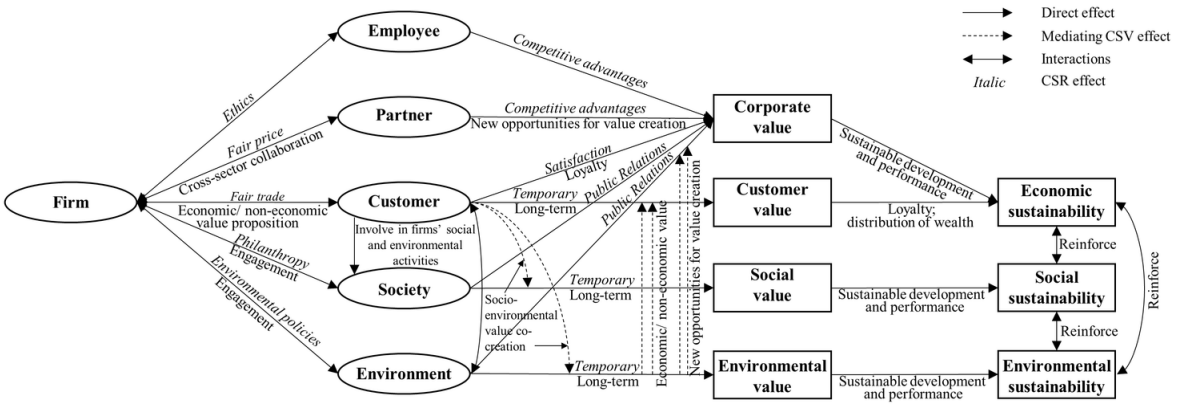
CSR	CSV
• Fundamentally about scarifying firms' slack resources for in being a good corporate citizen • Philanthropy, and moral, ethical and legal practices • Engaging employees in community works • Separating from the business strategies • Generating social benefits without referring to costs of effort • Represent unsustainable value with little or no business benefits and some social gains.	• Changing firm's strategies and how it operates • Creating economic, social, and environmental value returns. • Integrating social and environmental impact into the business • Internal motivation • Creating new opportunities for new value creation • Reflect a sustainable value with significant business and social benefits

from a collaboration approach, cross-sector collaboration, value co-creation and holistic sustainability. To better understand our theoretical model, a case study of Socialgiver which implementing CSV strategies into its business model is provided. The case-based approach has been used for understanding emergent phenomena (Miles & Huberman, 1994; Yin, 2009). The data in this study were analysed from the ground up, which rooted in the grounded theory approach. It is an exploratory approach where data are systematically gathered and analysed (Yin, 2009). This method is suitable when no explicit testable hypotheses yet exist and there is little research, as presented in business model innovation for sustainability (Rosca et al., 2016; Sousa-Zomer & Cauchick-Miguel, 2017).



TOWARDS SUSTAINABILITY: VALUE CO-CREATION PERSPECTIVES

The concept of value creation is central to all socio-economic analysis (Ahen & Zettinig, 2015). Value is seen as perceived service and satisfaction for the consumer and other stakeholders such as partners, society and the environment, which then creates value in return for firms such as in forms of reputation, customer perception, revenue and legitimacy. Therefore, the value is not referred to only economic or financial dimensions, which agency theory holds to be the only responsibility of agents (Ahen & Zettinig, 2015; Jensen & Meckling, 1976), but also non-economic/financial dimensions of value. Along with the transition to service-based societies and economies which emphasizes the value and understands exchange in terms of value rather than products or services (Vargo & Lusch, 2004). The service-dominant logic deploys a shift from the firm-centric view on the resource-based view (Barney, 1991), which sees the firm as a center for mostly producing and making exchanges, toward a relationship-based marketing for value co-creation (Ahen & Zettinig, 2015). Vargo and Lusch (2004) suggested that value is always co-created in all kinds of exchange. In addition, Mupepi, 2017 suggests the framework of value creation in socio-technical systems that consider both ethical and technical systems to prevent knowledge leakage during the process.

Figure 1 presents our theoretical model illustrating effects of both a traditional perspective of CSR and CSV strategies that interact with main stakeholders based on a value co-creation approach and a sustainability point of view. These practices may result in economic, social, and environmental sustainability for a firm, society, and the environment. Words or phrases of words in italic are referred to the traditional CSR practices only, which do not cover the CSV strategies. In the traditional idea of CSR, firms mainly focus on external-oriented practices. Their CSR strategies rely on the external environ-

ment and do not involve into core strategic management. They tend to focus more on economic, legal and ethical responsibilities, rather than real social and environmental issues. Thus, firms concern about ethical and legalized practices and have overlooked opportunities to co-create and enhance value with other stakeholders in society (Porter & Kramer, 2011). For examples, when firms treat ethically with their employees, trade fairly with partners or suppliers, set a fair selling price, donating money to society, or settling environmental policies according to law and regulations. These practices aim mainly for corporate value in return. Consequently, the value is created temporary, which restricts to achieve the long-term value creation for the sustainability. Therefore, CSR initiatives represent unsustainable value with little or no firms' benefits and some social gains (Wójcik, 2015).
