Conservation, characterisation, evaluation and utilisation of diverse crop genetic resources should facilitate the identification (selection) and breeding of climate-smart crop varieties (Heisey & Rubenstein, 2015; McCouch et al., 2013). Plants under abiotic stress are affected physiologically and biochemically and undergo changes in gene expression and regulation, in the short and long term, in response to unfavourable environmental conditions (Saibo, Lourenço, & Oliveira, 2009). Adaptation to water deficits (drought stress) can thus be mediated through morphological, physiological and biochemical mechanisms in crops (Beebe et al., 2011) and requires a diverse genetic base for the identification of favourable genotypes with adaptive traits for drought tolerance. The latter includes deeper root systems, stomatal control and improved translocation of nutrients within the plant. Beebe et al., (2011) advocated research to *fit the right root system to specific common bean production environments* under drought conditions, and reliable screening methods to evaluate waterlogging tolerance of genotypes under flooded conditions.

With regard to heat stress, acclimation to high temperatures in certain genotypes may favour selection of heat tolerant varieties. A method of screening pollen to determine heat tolerance in soybean was developed by Salem, Kakani, Koti, and Reddy (2007) and may be useful for screening of the common bean (Beebe et al., 2011).

Detailed data on the responses to climate change (changing temperature and rainfall patterns) of the pests and diseases affecting crops in developing countries are necessary. An understanding of these phenomena and the identification of adapted or tolerant genotypes will facilitate the implementation of adaptation strategies to deal with the biotic stress due to pests and diseases.

Marker-Assisted Selection and Genomic Breeding

Molecular markers are currently the most powerful tools for elucidating the inheritance of target regions of plant and animal genomes in breeding material, and environment-neutral markers allow marker-assisted selection (MAS) and genomic breeding (Edwards & Batley, 2010). Marker assisted selection could be a useful tool to identify (abiotic) stress tolerant traits such as specific rooting depth in common bean, once quantitative trait loci (QTL) for this quantitative trait have been located. It leverages the burgeoning available molecular data on completely or nearly completely sequenced plant genomes to select for candidate genes, protein sequences, and favourable genotypes, while taking into account genotype by environment interaction and targeting adaptive/morpho-physiological traits (Jha, Bohra, & Singh, 2014; Lasky et al., 2015). The advances in bioinformatics and computational molecular biology facilitate valid inferences to be made from the large and complex volumes of data involved in these processes. The usefulness of MAS is particularly outstanding in breeding programmes that involves polygenic traits. MAS allows quick progress in accumulating two or more genes (pyramiding) for desirable traits in segregating breeding material compared to conventional breeding methods. The latter is constrained

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

by the length of the breeding cycle and the dependence on screening, based on phenotypes, which often has to be conducted on mature plants when reproductive traits are involved. The time required to breed a new crop variety may be decreased by half when MAS is employed (Mba et al., 2012). The negative side is the cost involved (Ribaut, Vicente, & Delannay, 2010). However, high-throughput molecular biology assays are becoming increasingly available and costs are decreasing. Furthermore, human capacity building in using these techniques and putting the results at the disposal of farmers in developing countries is in progress.

High-Throughput Phenotypic Evaluations

High throughput imaging of living plant organs can also be valuable for unravelling complex traits affected by climate change such as drought and salinity tolerances (Ghanem, Marrou, & Sinclair, 2015). Access to the technology required for thermal infra-red and near-infrared fluorescence spectrometry and magnetic resonance imaging allow non-destructive physiological, morphological and biochemical assays that can be used to investigate these complex traits (Fahlgren et al., 2015). However, the high establishment costs and technical expertise required to conduct high-throughput phenotyping may also restrict access to it, in the short-term, by developing countries.

CASE STUDY

Harnessing Research and Technology to Combat Climate Change in Cacao (Theobroma cacao L.)

Research and application of research findings and technology to combat the threat of climate change in cacao[4] have been ongoing (Stigter, 2008). The impact of soil, water and climate (drought, flooding, high temperature and irradiance) pose a threat to sustainable cocoa production (Oyekale, Bolaji, & Olowa, 2009). There is a need to increase efficiency to manipulate water use, soil and microclimate and to use improved (climate-smart/well adapted) stress tolerant planting material. Technological approaches such as genome-wide association studies and breeding with genomics and other technological advances may be applied in developing superior cacao varieties to combat the impact of climate change. The completed mapping of the cacao genome will facilitate the identification of marker-trait associations in cacao germplasm that can be used to breed varieties with biotic and abiotic stress tolerance.

The selection of well-adapted varieties with drought, heat (high irradiance) stress and other forms of abiotic stress tolerance is a major goal of cocoa breeding in West Africa (Läderach, Martinez-Valle, Schroth, & Castro, 2013). Studies on the effects of soil water deficit (Antwi, 1994) and irradiance (Galyuon, McDavid, Lopez & Spence, 1996a, b) have been conducted in Trinidad & Tobago, and an investigation on climate change adaptation to drought and heat in cacao is currently in progress.

In Brazil, dos Santos et al., (2014) found that the best traits to screen for drought tolerance were leaf and total dry biomass, relative growth rate and magnesium content of leaves. These authors also found increased expression of drought tolerance candidate genes (as those associated with ABA biosynthesis and biosynthesis of proteins of PSII of the photosynthetic pathway) in genotypes classified as non-tolerant after exposure to soil water deficit for a period of time. dos Santos et al. (2014) also observed that in tolerant genotypes, there were significant increases in guaiacol peroxidase activity, reflecting a

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

more efficient antioxidant metabolism. This increased activity of oxidative stress enzymes is a response to soil water deficit.

In Ghana, where drought is the major abiotic stress affecting cacao (Anim-Kwapong & Frimpong, 2005), Ofori, Padi, Acheampong, and Lowor (2015) examined genetic variation and the relationship of traits associated with drought tolerance in cacao under shade versus non-shade conditions. These authors reported that stem growth, percentage survival, leaf chlorophyll content and plant vigour were important traits to screen for drought tolerance under these conditions.

In order to mitigate the potential adverse effects of climate change in cacao, Stigter (2008) stressed the role of good managerial practices (proper shade management, application of organic fertiliser and bio-control of pests), inter-planting with agro-forestry species and extension to educate farmers on good agricultural practices (GAPs), in Climate Field School classes (CFSs), to cope with the impact of climate change. In addition, biodiversity friendly cacao cultivation can be practised such that a favourable balance between yield, farmer income and biodiversity conservation is achieved, as prescribed by Waldron, Justicia, Smith, and Sanchez (2015). Farmer income can be supplemented by sustainability certification (eco-labelling) and incentives awarded to small farmers for managing eco-friendly cacao agroforestry systems based on the United Nations REDD (reducing emissions from deforestation and forest degradation) initiative (Millard, 2011).

SOCIAL REFORMS FOR OPTIMISED AND SUSTAINABLE AGRICULTURAL PRODUCTION AND DEVELOPMENT

Scherr, Shames, and Friedman (2012) identified several key social factors required in strategies for securing food production and achieve food security. These include:

- Strengthened technical capacities;
- Institutional and political support for multi-stakeholder planning;
- Good governance;
- Spatial targeting of investments and
- Multi-objective impact monitoring.

Sasson (2012) identified several social constraints to be addressed in order to increase agricultural production and achieve food security. These include lack of easy access to land, lucrative employment opportunities in the rural environment, lack of proper access to local markets (with proper road infrastructure and loan arrangements) and inadequate access to training and technologies that will increase production, productivity, food safety, improve food handling and storage, post-harvest activities (including packaging), distribution and marketing and promote sustainable value-addition initiatives. Access to training in best practices and technology (including agricultural diagnostic applications on smart phones) is particularly critical to implement climate change adaptation techniques to address drought, extreme temperatures and other abiotic stresses. Research and development along with dissemination of the resulting information to agriculturists are thus crucial (Ejeta, 2009). Gender inequality was also regarded as a constraint to achieving food security (Flachsbarth et al., 2015; Perez et al., 2015).

Thus a summary of social reforms that can impact positively on agricultural development and food security includes:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Poverty alleviation;
- Creating a shorter, more efficient supply and value chain for farmers
- Improving farmer livelihoods;
- Diversification of incomes;
- Adequate access to credit;
- Strengthening of women's position;
- Greater access to social amenities;
- Greater access to an adequate and reliable labour force;
- Improvement in production standards with regards to child labour;
- Attracting youth to agriculture;
- Stability of land ownership rights and land tenure;
- Improving infrastructure (particularly of access roads and bridges);
- Access to equipment and technology for farm/production efficiency;
- Improvement of access to schooling and education;
    - Access to extension services and training in GAPs and good manufacturing practices (GMPs) – through participatory learning;
    - Improving the business acumen of farmers – through farmer field schools (FFS);
- Adoption of food safety and quality assurance practices;
- Avoiding trade-offs between quality of produce and short term revenues;
- Improving access to market information and support services;
- Access to efficient transport/wholesaling markets, refrigeration and post-harvest practices to avoid food spoilage and wastage;
- Creation and strengthening farmer's organisations such as co-operatives to facilitate optimisation of all activities along the food value chain and facilitate sharing of costs among food producers and promoting value addition; and
- Addressing the disconnect between food producers and consumers.

Promoting food security is deemed feasible through the spread of modern farming, crop research and food processing in developing nations (Sasson, 2012). Farming communities must be educated in modern farming through knowledge and technology transfer and equipped to practise such methods.

Investment and resources must be supplied to rural farming communities, particularly of small farmers, and policies implemented to bring about the requisite social and environmental changes and human capacity building to combat climate change. Policy, legal and market environments that encourage innovation and capital investment must be fostered. The role of the International Convention for the Protection of New Varieties (UPOV) is also critical so that there is an equitable balance between Intellectual Property Rights (IPR) and contributions to public good (Mba et al., 2012).

THE ROLE OF EDUCATION AND INSTITUTIONS

Training and education are key catalysts to bring about environmental and social reform to promote agricultural development and food security, particularly in SIDS (Bekele & Ganpat, 2014). The areas of particular concern are:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Participatory approaches to social learning to persuade farmers to adopt new and improved agricultural approaches such as the climate-adapted push-pull system (Isaac et al., 2007; Midega et al., 2015) and integrated pest management;
- Technology transfer to food producers along the value chain;
- Sensitization of rural and urban communities to encourage proper nutrition, avoidance of food wastage (according to the FAO, one third of the food produced globally is discarded or spoilt) and adoption of healthier and more energy efficient eating habits;
    - including the acceptance of a diet with protein from vegan and non-red meat sources to reduce the consumption of red meat that contributes to carbon emissions (14% of the global total) and utilisation of large volumes of water; and
- Adoption of modified and healthy diets based on climate-smart agriculture.

Education to change public awareness and practices that affect agricultural production and food security is crucial. According to Bailey, Froggatt and Wellesley (2014), governments and environmental groups are reluctant to pursue policies or programmes to shift consumer behaviour.

Much research has and is being conducted in developing nations to facilitate more sustainable food consumption patterns. Boland et al. (2013) and Lukefahr (2005) identified rabbits as a suitable alternative for animal protein in developing countries, but the populace has to be convinced to utilise this and other alternative animal protein sources such as the collared peccary/quenk and agouti (Mollineau, Garcia, Samayah, Kissoonsingh, & Procope-Garcia, 2000) in future animal protein production and consumption systems. Alternatives for imported staples such as wheat are available in the developing world and consumer appreciation for tropical food crops such as breadfruit (*Artocarpus altilis*, Moraceae) and chataigne (*A. camansi*) is already fairly high (in excess of 61% in Trinidad and Tobago) (Roberts-Nkrumah & Legall, 2013). In other cases, consumer acceptance will have to be encouraged, taboos and fear of the new (neophobia, as explained by Cox and Evans, 2008) will have to be displaced, and ethical issues resolved. A concerted education drive is thus required for potential producers and consumers. Furthermore, accountability and responsibility are necessary to preclude public distrust (Boland et al., 2013).

Social systems could be valuable in addressing food waste. A well organised system for collection of food waste with acceptable nutritional value that is safe for animal consumption can serve the dual role of reducing food waste while providing a source of animal feed. There should be a review of legislation that currently forbids the use of human food waste in animal production (Boland et al., 2013). Education of personnel to sort and manage food waste and to monitor its safety for animal consumption is thus necessary. There will also be safety issues for humans operating the system and for consumers of the resulting animal products that will have to be addressed by research and knowledge transfer.

A key role of education and institutional support is to link science and policy on food security under climate change. This requires multi-stakeholder, participatory scenarios to bring the diverse actors and organizations together to create the necessary policy-making tools, as described by Chaudhury et al., (2013). The knowledge made available by scientists can thus be transferred to policy makers to facilitate implementation of necessary changes and programmes to address food insecurity and the negative impacts of climate change. Institutions such as regional universities and international organisations based in the developing world can undertake the credible, salient and legitimate boundary work required in this process. They can provide fora for assembling farmer representatives, scientists, policymakers, civil society, government and private sector so that multiple perspectives may be aired, scenarios created and policies drafted to implement approved practices and technology. In East Africa, the CGIAR

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

programme on Climate Change, Agriculture and Food Security (CCAFS) has adopted this approach to promote climate-smart agriculture and food security, bridging science and non-science boundaries, and have forged the link between knowledge and action (Chaudhury et al., 2013). At multi-stakeholder workshops, they were able to determine common outcomes of interest for food security, *viz*., food affordability, regional production, food distribution and nutritional value for food security, water and soil quality, forest cover, biodiversity status, water sufficiency for environment, and financial wealth, social capital, health, and knowledge and skills for livelihood.

CASE STUDY: SOCIAL ISSUES AFFECTING COCOA PRODUCTION

The cocoa industry, which supports the projected (by 2016) 98.3 billion USD chocolate and cocoa-based industry (World Cocoa Foundation, 2015), has been beleaguered by social as well as environmental challenges. Despite this, the International Cocoa Organisation (ICCO) recognised the importance of the cocoa sector for economic development and poverty eradication, particularly in West Africa, which produces 70% of the world's cocoa. The ICCO affirmed that to secure this important role, stakeholders in the cocoa chain are jointly facing the challenge to promote sustainable development in cocoa production, commercialization, processing, manufacturing and consumption (Ebai, 2004). To rise to these challenges, ICCO launched a Roundtable on a Sustainable Cocoa Economy in 2007 in Accra, Ghana, and a Second Roundtable was convened in Trinidad in 2009. The social issues of serious concern in the cocoa sector pertain to labour, farmer well-being and livelihoods and training in best practices. There is justification in concluding that the monetary benefits of the thriving global cocoa and chocolate industry have not trickled down to the farming communities adequately.

Child Labour: A Serious Social Issue

Child labour in cocoa production became the focus of international attention and disdain in 2002 (Mustapha, 2009). The International Labour Office (ILO) and the International Program on the Elimination of Child Labour (IPEC) presented statistics that indicated that 284,000 children were working under hazardous conditions in West Africa. Since then, the industry has made concerted efforts to address the situation and stop all forms of exploitative or the worst forms of child labour in cocoa production (Grossman-Greene & Bayer, 2009; Schrage & Ewing, 2005). Several initiatives have resulted and groups formed to achieve the goals of the Harkin-Engel law adopted in 2001 to address the worst forms of child labour (Berlan, 2009) as well as assure sustainability of cocoa production. These include the Sustainable Tree Crop programme (STCP) in West Africa and South-east Asia (Abbott, 2003), CocoaAction and Transforming Education in Cocoa Communities (TRECC), which was launched in May, 2015.

CocoaAction was launched in May 2014 to deliver a comprehensive package of services in both productivity and community development to cocoa farmers, their families and their communities. TRECC will reach nearly 200,000 individuals through a series of interlinked interventions in research, capacity building, policy formulation and influence, fundraising, and supporting matching grants to complement CocoaAction. It is an initiative of the Swiss Charitable Foundation, The Jacobs Foundation that will be executed in Côte d'Ivoire. A key element will be education to restrict child labour, which is currently still a serious problem in Côte d'Ivoire.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Farmer Education to Promote Sustainability in Cocoa Production

Farmer education is included in the aforementioned *CocoaAction*, *TRECC* and *STCP* programmes. In addition, the *Learn To Grow* programme was launched by Hershey and will include more than 60,000 West African cocoa farmers. It is intended to create both better farming practices and better cocoa communities. Hershey has a goal to purchase 100% certified cocoa by 2020. This is envisaged to provide premiums to assist farmers and farmer organizations in adopting modern farming practices, including organic farming, and to develop their communities.

In South-east Asia, (Sulawesi, Indonesia and Papua New Guinea), the Australian Centre for International Agricultural Research (ACIAR) conducted a project, SMAR/2005/074, entitled *Improving cocoa production through farmer involvement in demonstration trials of potentially superior pest/disease resistant genotypes and IPM*). The objectives were to select and test local cacao clones at different locations for disease and pest resistance (Vascular Streak dieback and Cocoa Pod Borer), evaluate IPM options and assess technology uptake by farmers (Neilson et al., 2014). The importance of addressing social and economic constraints in cocoa production, and in educating farmers on how to utilise the available information, based on empirical research as well as technology and improved methods, such as IPM, was emphasised.

Fairtrade in Cocoa

Approximately eighty-five percent of the world's chocolate comes from farms of 5 hectares or less, mainly in the developing countries of West Africa, South-east Asia and Latin America. Cocoa farming families earned as little as US$30 - $110 per family member per year, according to Knapp (2005). Fairtrade chocolate, made from Fair Trade certified cocoa, offers a solution for small farmers and their dependents to break the cycle of poverty. By cutting out middlemen and brokers, Fair Trade allows cocoa farmers to receive a fair share of the final market value of their products (Liu, Byers, & Giovannucci, 2008; Pay, 2009).

Fairtrade certification creates direct trade links between farmer-owned cooperatives and buyers, and it provides access to affordable credit. Fairtrade gives farmers the tools to access the market and to farm in a sustainable manner. In addition, under the terms of Fairtrade, there are strict labour standards that foster healthy working conditions and allow children under the age of 15 to work on their family's farm only if their education is not jeopardized. Children under the age of 18 are not allowed to work with machetes (or other dangerous tools) or to apply pesticides.

A Multi-Stakeholder, Cohesive Approach to Ensure Sustainable Cocoa Production

A structured, multi-sector, international approach to conserve cacao germplasm as a safeguard against the impact of climate change and other threats and to meet emerging needs of cocoa farmers has already been adopted. The United Nations Common Fund for Commodities/International Cocoa Organisation/ Bioversity International (CFC/ICCO/BI) executed a project entitled *Cocoa Germplasm Utilization and Conservation: A Global Approach* (1998 – 2004) (Eskes, Engels, & Lass, 1998; Eskes & Efron, 2006). The main objective for this project at the Cocoa Research Unit (now Cocoa Research Centre, CRC), a partner in the project, was germplasm enhancement for Black Pod (BP) and Witches' Broom (WB) dis-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ease resistance in cacao. Several primary germplasm varieties were identified, and enhanced genotypes (through pre-breeding (Guarino & Lobell, 2011)) produced at CRC with combined resistance to both WB and BP diseases. The yield potential, bean traits, precocity, vigour and flavour profiles of these individuals were or are still being assessed at CRC (Iwaro et al., 2010). The most promising enhanced cacao varieties were transferred to the International Cocoa Quarantine Centre, Reading University, U.K. to facilitate distribution to the other project partners in cocoa producing countries. Selected progeny are also being used in the Ministry of Agriculture, Trinidad and Tobago's successful Trinidad Selected Hybrid cacao breeding programme (Maharaj et al., 2011) to accumulate resistance genes for BP. This will facilitate the development of further improved, superior planting material to distribute to cocoa farmers in Trinidad and Tobago.

Launching of *Farmer Field Schools* (FFS) and *Farmer Participatory approaches* to improving cocoa production have also received considerable attention within the last decade. The CFC/ICCO/BI project entitled *Cocoa productivity and quality improvement: a participatory approach* was conducted from 2004 to 2009. This project was successful in educating farmers and assisting them in recognising and selecting the best trees within their fields for multiplication and conservation. Techniques to screen for disease and pest resistance and to assess traits of economic interest as well as quality and flavour of cocoa were also put at the disposal of rural cocoa farming communities (Eskes, 2011).

These two, aforementioned CFC/ICCO/BI projects involved 14 cocoa-producing countries, including Trinidad and Tobago, as well as manufacturers (consumers), government bodies and institutions. They are models for a successful, cohesive approach towards achieving agricultural development and food security.

In West Africa, South-east Asia, Latin America and the Caribbean, FFS are now routinely hosted. In Trinidad & Tobago, a project, funded by the Centre for the Development of Enterprise and implemented by the Cocoa Research Centre (CRC), resulted in the training of farmers and entrepreneurs in GAPs and GMPs practices (including for assuring food safety) in six Caribbean countries.

A COHESIVE APPROACH TO ACHIEVE AGRICULTURAL DEVELOPMENT AND FOOD SECURITY

Any strategy to achieve social reform and to foster agricultural development and food security in developing nations requires:

1. A cohesive approach to achieve agricultural development and food security in developing nations;
2. Proper fiscal/economic planning;
3. Social programmes and networking – encompassing collaborative, iterative social learning;
4. A proper environmental framework and
5. Public, private and community based approach.

A comprehensive, multi-sector approach towards addressing the challenges and potential impact of climate change on food security is advocated (Chaudhury et al., 2013; Maggio et al., 2015; Mba et al., 2012). Sonnino et al., (2014) urged that a sustainable food security framework should address the complex relationships between the various stages and actors in the food supply chain (refer to Figure 2) in a holistic manner. The conventional focus on individual components (supply and demand) will not ensure sustainable food security. Participatory, multi-disciplinary and demand-driven breeding programmes,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

which are nurtured by appropriate policy and legal environments and utilise scientific and technological tools to exploit crop and animal genetic resources, are recommended (Mba et al., 2012). Governance and policy structures must be put in place to support food security and sustainability efforts (Sonnino et al., 2014). Without the social support of extensionists, financiers, administrators and policy makers, the positive outcomes of participatory food production initiatives will not become transformative across the agricultural sector, but be confined to isolated sections of the rural and research communities.

Participatory breeding considers the views of farmers, consumers, extensionists, vendors, rural co-operatives and industry in crop improvement. The needs of the growers and stakeholders thus inform the design of the breeding activities, rendering them relevant and efficient. Furthermore, the role and achievements of farmers in selecting and conserving crop landraces can be harnessed in the process of selecting favourable candidates to use as parents in breeding. In addition, the adoption of improved varieties by farmers is facilitated and accelerated when farmers are part of the process.

The benefits of such an integrated approach have been supported by research findings based on analyses of various scenarios (Vervoort et al., 2014). The latter authors advocated more effective and efficient transformation of scientific results into a policy agenda for adaptive action on food security under climate change. Such an approach in SIDS has also been recommended and outlined by Maximay (2014). Integrated adaptation and mitigation strategies, under the umbrella of integrated landscape level planning, were recommended by Harvey et al., (2014) in order to avoid trade-offs that limit success.

There is thus compelling evidence that to achieve food security under climate change in developing countries, an organised programme to breed climate-smart varieties and practise climate-smart agriculture can only be achieved through collaboration. This should also involve international organisations such as the Global Crop Diversity trust, FAO, CGIAR and the Integrated Breeding Platform, the World Bank and the World Trade Organisation. Sonnino et al., (2014) presented a detailed graphic that depicts the key issues to be addressed for a future research agenda that can assure sustainable food security (refer to Figure 3). The broad scope of this agenda demands a multi-sector approach. McCouch et al. (2013) have costed the systematic, concerted, collaborative global effort to feed the future. They estimated it as US $200 million annually.

CONCLUSION

It has been projected by Flachsbarth et al. (2015) that the progress of achieving food security will vary from one developing region to the next. Their outlook for LAC and Southeast Asia and the Pacific is better than for Central-West Africa and other regions of Sub-Saharan Africa. Lobell et al. (2008) also predicted that South Asia and Southern Africa will most likely face negative climatic impacts by 2030 on several important crops if adequate adaptation measures are not adopted. This scenario may be attributed to the fast population increase relative to food production growth, particularly in Africa, as well as continued lack of access to safe water along with limited improvement in female secondary education. Policies are required to remove gender bias that *limits resilience of female farmers* (Perez et al., 2015).

The environmental and social priorities for increasing agricultural development and achieving food security in developing countries, which were identified in this chapter, are included in the CGIAR's strategy (Rijsberman, 2015) (refer to Table 2).

Thus, there are numerous factors that need to be urgently addressed in order to assure agricultural development and food security in developing nations. These include:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Sustainable food security pillars- key issues for future research
(adapted from Sonnino et al., 2014)

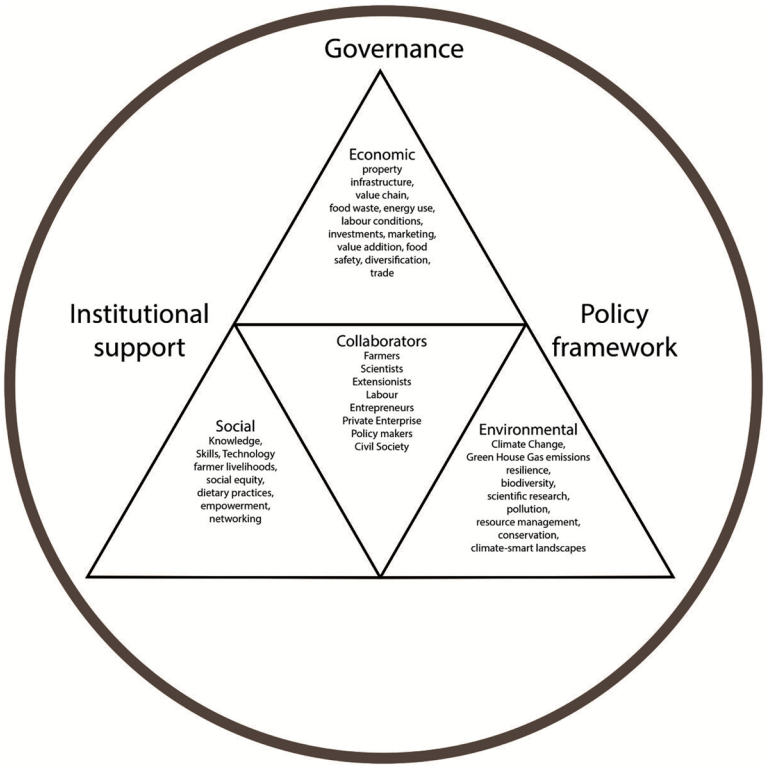

Table 2. Consultative Group for International Agricultural Research (CGIAR's) strategy for 2016-2030

Genetic improvement of crops, livestock, fish and trees, to increase productivity, resilience to stress, nutritional value and efficiency of resource use.
Agricultural systems, adopt a systems approach to optimize economic, social and environmental co-benefits in areas with high concentrations of poor people.
Gender and inclusive growth, creating opportunities for women, young people and marginalized groups.
Enabling policies and institutions, to improve the performance of markets, enhance delivery of critical public goods and services, and increase the agency and resilience of poor people.
Natural resources and ecosystem services, focusing on productive ecosystems and landscapes that offer significant opportunities to reverse environmental degradation and enhance productivity.
Nutrition and health, emphasizing dietary diversity, nutritional content and safety of foods, and development of value chains of particular importance for the nutrition of poor consumers.
Climate-smart agriculture, focusing on urgently needed adaptation and mitigation options for farmers and other resource users.
Nurturing diversity, ensuring that CGIAR in-trust plant genetic resources collections are safely maintained, genetically and phenotypically characterized to maximize the exploitation of these critical resources for food security, productivity, nutrient rich crops and resilient farming systems.

(CGIAR, 2015)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Social Factors

- Reform of social conditions for rural communities – improvement of basic amenities – health, education, housing and infrastructure;
- Technological knowledge transfer and farmer training and education in GAPs for primary production and GMPs for value chain initiatives along with training to ensure better health and fiscal management as well as socialisation;
- Support of rural communities in terms of financial aid and farmer livelihood enhancement programmes to optimise income generation, eradicate poverty and improve subsistence farming (as for the establishment of co-operatives and farming enterprises that shorten the value chain);
- Provision of technological tools to modernise food production;
- Public co-ordinated programmes to address inadequate access to credit and capital and insecurity of land tenure; and
- Application of science and technology in education to re-engineer the farming culture and inculcate innovative approaches to food production and value-addition enterprises that will attract the youth.

Environmental Factors

- Climate-smart agriculture and landscapes – identifying climate adapted or resilient planting material and adopting energy efficient, sustainable agricultural production practices;
- The application of technology in climate adaptation strategies (next-generation sequencing, genomic selection, marker-assisted selection and breeding with genomics to develop climate-smart varieties); and
- Harnessing conservation and utilisation of crop genetic resources in the face of climate change and other emerging threats such as new pests and diseases.

Meeting the challenges to secure agricultural development and food production in developing nations is indeed daunting. The complex social, environmental as well as economic issues that contribute to the dilemma cannot be addressed without a collaborative approach. Policies must be developed to engender trust and co-operation among the key stakeholders. Furthermore, an agriculture-energy-water nexus approach (Rasul and Sharma, 2015) must be adopted since the impacts of climate change dictate that agriculture can only develop and be sustainable when plant and animal genetic resources and materials, water, energy and land resources are not limiting (Hubert et al., 2010).

Fiscal and rural planning is a key parameter for success in achieving agricultural development and food security in developing nations. The strategies to be adopted require adequate financing along with research and development to benefit concerted genetic conservation efforts, human capacity building, technological applications in plant breeding and selection of adapted and superior plant varieties and animals, ongoing applied research such as genomics and a sophisticated network of food quality, safety, handling, processing, storage, marketing and transportation facilities.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The successful implementation of the aforementioned strategies should guarantee a stable supply of nutritious food, readily available to growing populations in developing countries into the future. Achieving food security cannot be accomplished without ending poverty in developing nations. Farming communities must be educated, well-equipped, able to access and utilise technology and superior planting material, livestock or fisheries, and practise sustainably intensive (based on natural agricultural processes and biodiversity), modern agriculture on a lucrative scale with the benefit of secure land tenure, co-operative structures, extension services and appropriate financial support.

KEY TERMS AND DEFINITIONS

Climate Change Adaptation: Human actions or responses in nature taken to adjust to risks posed by *climatic* changes or to benefit from any advantages.

Climate Change Mitigation: Action taken to permanently eliminate or reduce the long-term risk and hazards of climate change to the environment, human life and property.

Climate-Smart Agriculture: Agricultural practices that sustainably increase agricultural productivity and incomes, facilitate adaptation and build resilience to climate change and reduce or remove emission of greenhouse gases.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Conservation Agriculture: Encompasses cost-effective soil management practices that minimize the disruption of the soil's structure, composition and natural biodiversity. It takes advantage of soil fauna and properties that improve fertility that can improve crop yields while protecting the environment.

***Ex Situ* Conservation:** Protecting species of a plant or animal outside its natural habitat (*in situ*).

Functional Genomics: Study of genes, their resulting proteins, and the role played by the latter in the biochemical processes of plants and animals.

Gene Pyramiding: A process of combining or assembling multiple desirable *genes* from multiple parents into a single genotype.

Genomewide Association Analysis: Involves scanning markers across the complete sets of DNA or genomes for a particular species such as *Oryza sativa* subspecies (e.g. *indica*), examining many common genetic variants in different individuals to see if any variant is associated with a trait of interest.

Genomic Selection: A process used to identify potentially favourable organisms (animals or plants) based on specific genetic information they harbour.

Genotype: Genetic makeup of a particular organism or group of organisms.

Marker Assisted Selection: A process where a trait of interest is *selected*, not based on the physical trait itself (such as plant height), but on a molecular or genetic *marker* linked to it.

Phenotype: Observable characteristics of an individual (such as seed size) resulting from the interaction of its genotype with the environment.

ENDNOTES

1 Agriculture includes food crops, pastures and livestock, industrial crops and biofuels, forestry (commercial forests), aquaculture.

2 The Millennium Development Goals (MDGs) are the world's time-bound and quantified targets for addressing extreme poverty, hunger, disease, lack of adequate shelter, and exclusion while promoting gender equality, education, and environmental sustainability.

3 Riparian vegetation is composed of plant habitats and communities along river/stream margins and banks, and a riparian area is the interface between water and land.

4 'Cacao' is the term used to describe the plant of *Theobroma cacao* L. 'Cocoa' describes the commercial product - the nibs/seeds.

Chapter 60
Marketing of Agricultural Commodities in India

Rakhi Arora
Jaipur National University, India

ABSTRACT

Commodity market is a fast paced dynamic market with liquidity and Commodity Exchange providing a platform for trading in various agri and non agri commodities at nationalized exchanges for discovering the price of agricultural goods in India since 2003. This also provides an opportunity to farmers, manufacturers or individuals for hedging and arbitrage to minimizes the losses due to fluctuations in the futures as well as spot prices. Though the Government has taken many steps time to time to control the prices of listed commodities by imposing restrictions like imposing daily margin limits and banning futures trading in speculative commodity/commodities if required but it is still being questioned. This chapter emphasizes on the working of the National Level Commodity Exchanges in India in general, the share of major agricultural commodities traded across National Level Commodity Exchanges in India, the marketing mix for agricultural commodities in India and the benefits and challenges of commodity futures derivatives for investors in India.

OBJECTIVES OF THE CHAPTER

1. Agricultural commodities are listed and traded at various commodity exchanges in India and globally as well. Readers would understand the working of the National Level Commodity Exchanges in India.
2. Readers would come to know about the share of major agricultural commodities traded across National Level Commodity Exchanges in India.
3. Readers would understand the marketing mix for agricultural commodities in India that how commodities are bought and sold at warehouses of commodity exchanges in India.
4. The commodity exchanges provide benefits and challenges of commodity futures derivatives for investors in India.

CASE LET

Commodity market is a place where listed agricultural and non-agricultural commodities are bought and sold. There are nationalized and regional commodity exchanges in India. Indian commodity sector has also been experiencing tremendous surge since its inception. This has given a new option to investors to hedge their positions against fluctuations in the prices of commodities in near future. People are also using this platform for gaining from ups and downs in the prices without having commodities in physical but it is more specifically beneficial for farmers, jewelers and manufacturers who require raw materials and want to take delivery of traded commodities but they face warehousing issues. There are other different kinds of issues faced by participants in commodity markets such as legal, regulatory, infrastructural and others. Earlier the commodity market was regulated by the Forward Markets Commission (FMC), which has recently been merged with Securities Exchange Board of India (SEBI) on 28th Sep., 2015 after the scam of National Spot Exchange Ltd.(NSEL). This risk was faced by all the investors in this market and their confidence was also shaken which resultant in the low business of commodity exchanges but now SEBI is regulating this market and building up the confidence of the investors while implementing the more strict rules and regulations for commodity market in India.

INTRODUCTION

Indian markets have provided a new opportunity for retail investors and traders, who want to diversify their portfolios beyond shares, bonds and real estate, to participate on commodity exchanges. The spectacular growth of commodity markets has also attracted many investors around the world to expand their investment to emerging markets like India, as more and more investors are realizing the potential opportunities of these markets. Like any other market, the commodity market also plays a vital role in risk management of derivatives.

It is well-known that commodities are the foundation of the economies of most developing countries by way of providing food, creating income generating opportunities and export earnings to the people directly involved in agricultural activities. In most of the agriculture driven economy, it has been commonly observed that the agricultural policy made by the Government tends to protect and promote the agriculture sector through different procurement and administered price mechanism. Historically, the Government intervention is found at every stage of the marketing of major agricultural products. These includes, setting Minimum Support Prices for selected commodities, regulation of every activity of marketing such as transportation, storage, credit supply and international trading of these commodities, etc. But Government intervention has significantly declined after the initiation of liberalization and economic reforms since 1991. The impact of agricultural commodity is of great importance in the stabilization of Indian economy, as reflected through the share of primary goods, especially the food items in derivation of the price indices like inflation based on Wholesale Price Index and Consumer Price Index in India. This clearly indicates the necessity of significant growth and stability of agricultural sector to foster the overall growth of Indian economy. For managing the risk of pricing of agricultural goods because of commodities futures trading, regular attempts are made worldwide. It has been clearly observed that prices of agricultural commodities are determined increasingly by market forces of demand and supply. Hence fluctuation in demand and supply of agricultural commodities is expected to result in high price risk for agri-business. Application of several market-based instruments to deal with the commodity price

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

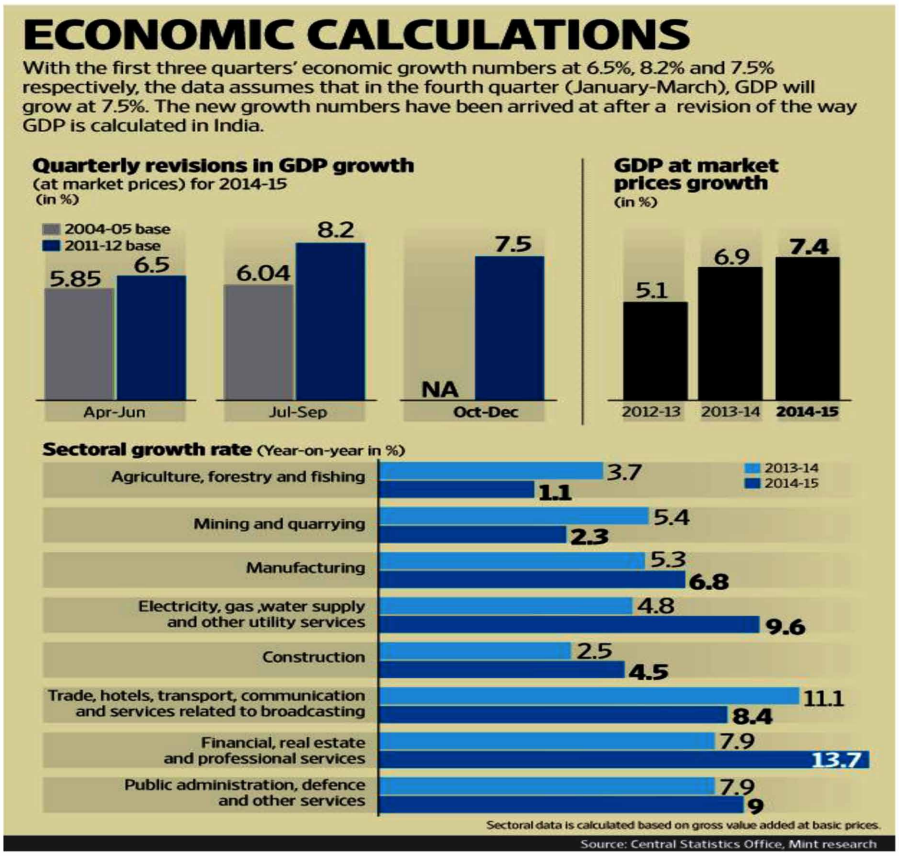
risk basically focuses on the introduction of derivatives viz. futures and options contract on several commodities. In other words, it is widely proposed to setup an efficient derivative market for commodities to strengthen the agricultural market. Generally trading in commodity derivatives and futures is done to get the necessary support from any variation in the commodity prices. This is called as Hedging. This strategy helps to offset the loss expected to incur from the adverse price movements of the underlying commodities. Therefore it is very important to develop futures and other forms of derivative trading in all commodities.

Commodity Market

Commodity market is a regulated place, in which listed commodities are bought and sold through the intervention of members (brokers) of commodity exchange, by following an open system of two way quotations; the settlement of trades is done according to the bye-laws of commodity exchange.

A commodities market serves the purpose of allowing two individuals to exchange the rights to goods without visual inspection. Commodity markets require the existence of agreed standards opposed to spot markets where delivery either takes place immediately, or with a minimum lag and normally involves visual inspection of the commodity or a sample of the commodity.

Figure 1. Sector wise growth rate in 2013-14 and 2014-15
Source: Testbook (2015).



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

According to Indian Forward Contracts (Regulation) Act (FCRA), 1952 "goods" means "every kind of movable property other than actionable claims, money and securities". Any product that can be used for commerce or an article of commerce which is traded on an authorized commodity exchange is known as commodity. The article should be movable of value, something which is bought or sold and which is produced or used as the subject or barter or sale. In short commodity includes all kinds of goods.

A forward contract is an agreement between two parties to exchange at some fixed future date a given quantity of a commodity for a price defined today (buy now, pay later). Forward contracts have evolved and have been standardized into what we know today as futures contracts.

A futures contract is a type of derivative instrument, or financial contract, in which two parties agree to transact a set of financial instruments or physical commodities for future delivery at a particular price. If you buy a futures contract, you are basically agreeing to buy something that a seller has not yet produced for a set price. But participating in the futures market does not necessarily mean that you will be responsible for receiving or delivering large inventories of physical commodities - remember, buyers and sellers in the futures market primarily enter into futures contracts to hedge risk or speculate rather than to exchange physical goods (Wilson, n.d.).

Commodity Derivatives

Commodity derivatives have had a long presence in India and it provides opportunities to investors for minimizing their future price risk.

A derivative is a product whose value is derived from the value of one or more underlying variables or assets in a contractual manner. The underlying asset can be equity, forex, commodity or any other asset (Bhat, 2009).

Derivative contracts are of different types. The most common ones are forwards, futures, options and swaps. Participants who trade in the derivatives market can be classified under the following three broad categories - hedgers, speculators, and arbitragers. In India, the National Commodity Exchanges are Multi Commodity Exchange, Mumbai (MCX), National Commodity and Derivatives Exchange, Mumbai (NCDEX), National Multi Commodity Exchange, Ahmedabad (NMCE), Indian Commodity Exchange Ltd., Mumbai (ICEX), ACE Derivatives and Commodity Exchange, Mumbai (ACE) and Universal Commodity Exchange Ltd., Navi Mumbai (UCX) but ACE and UCX have suspended their operations in India recently. These exchanges are playing very important role in the trading of agricultural as well as non-agricultural commodities in India. Derivative contracts in 113 commodities are available for trading. National Commodity and Derivatives Exchange (NCDEX) is the largest commodity derivatives exchange. Forward Markets Commission (FMC) introduced futures contracts on these exchanges in new commodities time by time for increasing trading level.

The Forward Markets Commission (FMC), established under the Forward Contracts (Regulation) Act, 1952, regulates commodity derivatives trading in India in the same way as Securities Exchange Board of India (SEBI) does for securities markets but FMC has been merged with SEBI on 28th Sep. 2015 and now SEBI will also regulate the commodity futures market in India.

The commodities traded at these Exchanges comprise the following:

- **Edible Oilseeds Complexes:** Mustard seed, Cottonseed, Soybean oil etc.
- **Food Grains:** Wheat, Bajra, and Maize etc.
- **Metals:** Gold, Silver, Copper, Zinc, Aluminium, Steel etc.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Spices:** Turmeric, Pepper, Jeera, Chilli etc.
- **Pulses:** Chana.
- **Fibres:** Cotton, Jute etc.
- **Others:** Sugar, Gur, Rubber, Natural Gas, Crude Oil etc.

BACKGROUND

Trading in derivatives started to protect farmers from the risk of the value of their crop going below the cost price of their produce. Derivative contracts were offered on various agricultural products like cotton, rice, coffee, wheat, pepper, etc. The first organized exchange the Chicago Board of Trade (CBOT) was established in 1848. In 1874, the Chicago Produce Exchange, which is now known as Chicago Mercantile Exchange, was formed (CME). These both are the largest commodity derivatives exchanges in the world. The Indian Commodity markets also have a long presence. The commodity derivative market has been functioning in India since the nineteenth century with organized trading in cotton through the establishment of Cotton Trade Association in 1875. Over the years, there have been various bans and suspensions on various contracts.

Commodity futures, which were introduced for risk management purposes in 2003, are now catching the eyes of investors as an investment tool. People, who are not having commodities in physical form and even don't require any commodity, are trading in the commodity derivatives market. They are just speculating in the direction of the prices of listed commodities for making money but it is affecting pricing of agricultural goods in India as many of the agricultural goods like pepper, jeera, channa, potato, guarseed, mustard oil, wheat are available for trading on commodity exchanges. Prices of these commodities are getting affected due to speculation done by the traders and it is leading to high inflation in India.

These markets are basically used to hedge commodity price risks and also provide transparent mechanism for discovering future prices by providing a platform for exchanging demand and supply information about all listed commodities. The hedging and price discovery functions of future markets promote more efficient production, storage, marketing and agro-processing operations and help in improvement in overall agricultural marketing performance. Foreign institutional investors, banks and insurance companies are not allowed to trade on the Indian commodity Markets and a majority of volumes come from jobbers, arbitrageurs, retail traders and corporates for hedging.

Although India has a long history of trade in commodity derivatives, this sector remained underdeveloped due to government intervention in many commodity markets to control prices. The production, supply and distribution of many agricultural commodities are still governed by the state. Free trade in many agricultural commodities items is restricted under the Essential Commodities Act (ECA), 1955 and Agriculture Produce Marketing Committees (APMC) Acts of various State Governments. The forward and futures contracts were, till April 2003, limited to only a few commodity items under the Forward Contracts (Regulation) Act (FCRA), 1952. However, in 2003, GOI removed all restrictions on commodities, which could be traded on commodity exchanges.

Important Milestones in Commodity Futures Trading in India

- **1875 - Bombay Cotton Trade Association:** While there is a viewpoint that Futures Trading has existed in India for thousands of years, the first organised futures market was established only in

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

1875 by the Bombay Cotton Trade Association to trade in cotton contracts. This occurred soon after the establishment of trading in Cotton Futures in UK, as Bombay was a very important hub for Cotton Trade in the British Empire.

- **1893 - Bombay Cotton Exchange Ltd:** Following widespread discontent amongst leading cotton mill owners and merchants over the functioning of the Bombay Cotton Trade Association, a separate entity, by the name "Bombay Cotton Exchange Ltd." was constituted.

Soon after the commencement of Cotton Futures, Futures trading in Oil Seeds was started by the formation of Gujarat Vyapari Mandali, which was established in the year 1900 in Mumbai. It is currently known as "The Bombay Commodity Exchange Limited" (BCE).

Futures trading in Raw Jute and Jute Goods began in Calcutta with the establishment of the Calcutta Hessian Exchange Ltd., in 1919. Later East Indian Jute Association Ltd. was set up in 1927 for organising futures trading in Raw Jute. These two associations amalgamated in 1945 to form the present East India Jute & Hessian Ltd., to conduct organized trading in both Raw Jute and Jute goods. Futures trading in raw jute suspended in 1964 reportedly on the insistence of the then State Government (WB Govt.) as there were too many reports and allegations of price manipulations which left the farmer in the lurch. The Government had no other alternative but to suspend it. The announcement to reintroduce it was made in February 2003 after the Union Government had pressed for its return (Essays, 2015).

The functioning of futures markets came under suspicion because of rising prices of some commodities during 2006–07 and the government ordered a possible delisting of futures contract commodities like Urad, Tur, Wheat and Rice to avoid the abnormal rise in their domestic spot prices. Followed by this, Sugar, Oil, Rice and Potato were also banned in 2007, but were subsequently delisted in 2008. In a similar way, the India Government again banned future trading in Chana, Potato and Soya oil in May 2008. However, a steady process of opening up has been visible in future market for commodities over the last two years. As a result of significant policy change, liberalization of world markets and other developments, Indian commodity markets have shown phenomenal growth in terms of number of products, participants, technology, transparency and volume of trade.

Characteristics and Scope

- Hedging is done in the commodity futures market with the objective of transferring risk related to the possession of physical assets through any adverse movements in futures and spot prices.
- Price stabilization along with balancing demand and supply position. Futures trading leads to predictability in assessing the domestic prices, which maintains stability, thus safeguarding against any short term adverse price movements.
- Flexibility, certainty and transparency in purchasing commodities facilitate bank financing. Predictability in prices of commodity would lead to stability, which in turn would eliminate the risks associated with running the business of trading commodities. This would make funding easier and less stringent for banks to commodity market players.

Scope

Researches done in this field are mostly related to overview of commodity market, price discovery of various commodities, behavior of investors and price volatility of some agricultural commodities but

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the problem of analyzing the impact of commodities trading on agricultural commodities at national level as a whole is still lacking.

Bhagwat Shree Dr., Maravi Singh Angad, More Ritesh, and Chand Deepak (2015) in their research paper have discussed the growth of commodity futures market in India, taking into consideration the history of commodity futures market as well as the mechanism of trading, segments and regulatory framework of commodity market in India. According to them, commodity futures market has witnessed several developments since 2002-03. There has been tremendous growth in commodity futures market in terms of volume of trade, number of products on offer participants and technology. Commodity futures market is instruments to achieve price discovery and price risk management as futures markets provide liquidity and facilitated to hedge against future price risk. Commodity trading also offers a change for financial leverage to hedgers, speculators and other traders. A structural system has been created for commodity trades. There are 26 exchanges operating in India and carrying out futures trading activities in as many as 146 commodity items. As per the recommendation of the FMC, the Government of India recognized the National Multi Commodity Exchange (NMCE), Ahmedabad; Multi Commodity Exchange (MCX); National Commodity and Derivative Exchange (NCDEX), Mumbai and Indian Commodity Exchange (ICEX) as nationwide multi-commodity exchanges. MCX has a major market share and the exchange turnover has been increased on every year. The growth of commodity futures market of India will lead to further development in the field of electronic warehouse receipts which may facilitate seamless nationwide commodity spot market. It would strengthen the Indian economy to face the challenge of globalization.

Dash, Solanki, and Shobana (2015) found in their study that derivative markets have attained more than eighteen times in trading volume when compared to the spot markets. They analyzed the impact of trading volume, inflation and other macroeconomic factors on spot and futures price movements using GARCH model. The study explored commodity prices from several different angles. First, they found the possibility of lead-lag relationships between commodity spot and futures prices of different categories of commodities such as Precious Metals, Base Metals and Agro products traded on MCX. Second, they analyzed the inter-relationship of spot and futures prices and trading volume, for the same commodity, and between substitute and/or complementary commodities such as between gold & silver, crude oil & natural gas, the base metals, and agricultural commodities. Third, another area they explored in the study was the impact of trading volume and inflation on commodity price volatility for selected commodities. While trading volume was found to have significant impact on volatility, inflation was found to have significant impact on crude oil price volatility only.

Bansal Rohit, Dadhich Varsha and Ahmad Naveed (2014) in their study found that in its long history of trading in commodities and related derivatives, Indian commodity market has seen several developments between two extreme scenarios: protection of the essential commodity market through government intervention and the opening up of the sector and getting the necessary protection through market based instruments like commodity futures contract. After a long period of suspension commodity derivative market was reintroduced in India in early 2000s. Since its resumption, however, the market has been growing at a very high pace. The growth is evident in the spread of market network as well as in volume of trade. Almost 100 commodities (agricultural and non- agricultural) are traded in different exchanges. The volume of trade has increased from Rs. 34, 84,485 crore in 2006 to Rs. 11948942 crore in 2011. It indicates a positive growth in the commodity market sector in India.

Dhole Suresh Sagar (2014) in his research paper investigated the antiquity of commodity futures market in India epoch back to the ancient times citied in Kautialya's 'Arthasastra', and have been commodity heard in Indian markets for centuries, seems to be coined in 320 BC, referred in Forward Contracts

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Regulation) Act, 1952. They found the markets have made enormous advancement in terms of technology, transparency and the trading activity. Interestingly, this has happened only after the Government protection was removed from a number of commodities, and market forces were allowed to play their role. Rational Government policies and the plinth of effective laws have benefited in many ways like Credit accessibility, improved product quality, predictable pricing, Import-export competitiveness, and price risk management and price discovery.

Rajamohan, Vethamanikam, Arul Hudson and Vijaykumar (2014) in their study examined that the commodity trading has a long history and it has been modernized in the market. The commodities trading are occupied an important place in the economy it depends on the international trade A structural system has been created for commodity trades. It is creating awareness and the more opportunity to the investors and public. They found the market volatility is based on these commodities performance. However the commodity market has provided huge support to the Indian economy.

Brajesh Kumar and Pandy Ajay (2013) in their research work investigated the short run and long run market efficiency of Indian commodity futures market. They had tested four agricultural and even nonagricultural commodities for market efficiency and un biasedness. The result confirmed the long run efficiency of commodity futures prices and inefficiency of futures prices in short run.

Chhajed and Mehta (2013) found that the price discovery mechanism is quite effective for most commodities, but may not be very effective for some commodities. In particular, causality in commodities markets can be used to either hedge or speculate price movements: if changes in spot prices drive changes in futures prices, efficient hedging strategies can be formulated; whereas if changes in futures prices drive changes in spot prices, efficient speculation strategies can be formulated. Further, causality can be used in forecasting commodity spot and futures prices.

As majority of Indian investors are not aware of organized commodity market; their perception about is of risky to very risky investment. Many of them have wrong impression about commodity market in their minds. It makes them specious towards commodity market. Concerned authorities have to take initiative to make commodity trading process easy and simple. Along with Government efforts, NGO‟s should come forward to educate the people about commodity markets and to encourage them to invest in to it. There is no doubt that in near future commodity market will become Hot spot for Indian farmers rather than spot market. And producers, traders as well as consumers will be benefited from it. But for this to happen one has to take initiative to standardize and popularize the Commodity Market.

Sehgal, Rajput, and Dua (2012) analyzed in their research study the destabilization effect which is a relationship of futures liquidity and spot market volatility by using Hedrick Prescott (HP) filter and unexpected variable (unexpected liquidity) on seven agricultural commodities. As per the results of the study, in case of Guarseed, Turmeric, Soybean, Maize and Castor Seed the study confirmed that Futures market liquidity (based on trading volume) tends to drive spot market volatility i.e. stating destabilizing effect. As futures and spot markets are interlinked, any information shock should affect both the markets. Results of the lead lag relationship between spot price volatility and futures trading activity (unexpected) suggested that in most of the commodities the unexpected futures trading volume causes spot price volatility confirmed by Granger causality test. In case of Black pepper reversed destabilization effect was observed because of strong speculative interest in the market and lack of transparency. In case of Barley the study confirmed that Futures market liquidity (based on trading volume) does not affect spot market volatility.

Malyadri G. Dr. and Kumar Sudheer B. (2012) studied the history of commodity market. Commodity derivatives arrived in India as early as 1875, barely about decade after they arrived in Chicago. The

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

commodity market in India has experienced an unprecedented boom in terms of the number of modern exchanges, the number of commodities allowed for derivative trading as well as the values of futures trading in commodities. However, there are several impediments to be overcome and issues to be settled for a sustained development of the market.

Agnihotri and Sharma (2011) studied the degree to which commodity spot prices have converged with future market with a view to measure this convergence, and to find out arbitrage opportunity in MCX, and NCDEX, the correlation, regression, and standard deviation was used for the period of five years from 2005 to 2010. The results indicated that correlation coefficients themselves are not capable of detecting convergence and that the regression – linear tests was more powerful detecting any convergence between the future and spot prices of Zeera, Zink, Chana, and natural gas. It was observed that there is a need of another commodity exchange to overcome many functional inadequacies of the existing three national online commodity exchanges, particularly with respect to delivery-based settlement as a mechanism of efficient price discovery as MCX and NCDEX do not trade in all the commodities and hence do not provide opportunity for arbitrage. There is a clear delinking of futures prices of commodities traded at these exchanges and the prevailing spot prices, thereby leaving arbitrage opportunities, because of which actual hedgers do not find these exchanges useful for managing their commodity price risks. Some commodities such as iron ore and coal, wherein India is a large producer, consumer, importer and exporter are not traded at these exchanges. Third, unlike the existing exchanges, which hardly promote delivery-based trading, the new exchange should aim to integrate warehouse delivery by providing an online trading platform so that it becomes a true platform for delivery-based hedging. All this has potential to improve India's share in international trade substantially. The new exchange will provide not only arbitrage opportunity but also attract more investors.

Dharmbeer and Singh Barinder (2011) emphasized the theoretical and empirical research on the growth and prospects of emerging commodity markets and the resulting implication on policy and regulation. They found from the previous studies that derivatives markets have supported the hedging role of emerging derivatives markets. All commodities are globally traded and the global demand-supply situation is widely known and available to anyone who reaches out for it. The commodity markets are nowhere as volatile as stock futures. Since commodity exchanges promote price transparency, he refuses to buy the story that commodity exchange fuel inflation.

The scope of the study revolves around the parties like Govt. & Regulatory bodies, intermediaries, investors, trading exchanges and other researchers. Agricultural commodities depend on rain fall, weather conditions, seasons and government support in terms of subsidies and minimum support price extended by Government to help the farmers. There is a much scope for researchers to find out the linkage between pricing behavior of future contracts and nature of agricultural commodities traded on national level commodity exchanges. There is also a scope related to analyzing the impact on working and efficiency of commodity exchanges after the merger of FMC with SEBI.

Growth of Traded Commodities at All National Commodity Exchanges and Share of All National Commodity Exchanges to Total Value Traded From 2004-14

The year 2003 was a watershed in the history of commodity futures market. The group of 54 prohibited commodities was opened up for forward trading, along with establishment and recognition of three new national exchanges with on-line trading and professional management in the year 2003. Not only

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

prohibition on forward trading was completely withdrawn, including in sensitive commodities such as wheat, rice, sugar and pulses which earlier committees had reservations about, the establishment of new exchanges brought capital, technology and innovation to the market.

Futures contracts are available for major agricultural commodities, metals and energy. Commodity group-wise value of trading since 2004-05 is given below in the table.

During the year 2013-14, forward trading in 113 commodities, was regulated at the 6 National Exchanges, viz. Multi Commodity Exchange, Mumbai; National Commodity and Derivatives Exchange, Mumbai, National Multi Commodity Exchange, Ahmedabad, Indian Commodity Exchange, Gurgaon, and ACE Derivatives & Commodity Exchange Limited (ACE). Besides, there were 11 regional exchanges recognized for regulating trading in various commodities approved by the Commission under the Forward Contracts (Regulation) Act, 1952. The total value of trade in agricultural commodities at all the exchanges during the year was 16.02 lakh crore as against 21.56 lakh crore in 2012-13 indicates a decline of 21.7% over the year. During 2013-14, NCDEX accounted for 11.30% of the total value of trade in the commodity market.

It is clearly shown in the above graph that MCX contributed major share 84.89% in terms of value in the total value traded across at commodity exchanges in the year 2013-14 and NCDEX accounted 11.30% during the year.

Challenges and Benefits

Commodity exchange is a platform for trading of agri and non agri commodities and providing a transparent price discovery to all the investors. Though it is beneficial for the participants, but commodity exchanges are also facing following challenges:

1. **Lack of Knowledge About Commodity Futures Trading:** Investors are finding commodity markets as an investment option where they can hedge their risk like farmers can hedge physical positions of their crops but they don't have proper knowledge about commodity futures trading. This is one of the disadvantages of commodity market otherwise more participation of the investors can be seen.

Table 1. Commodity group-wise value of trade (Rs. Lakh Crores)

Commodity Groups	2004-05	2005-06	2006-07	2007-08	2008-09	2009-10	2010-11	2011-12	2012-13	2013-14

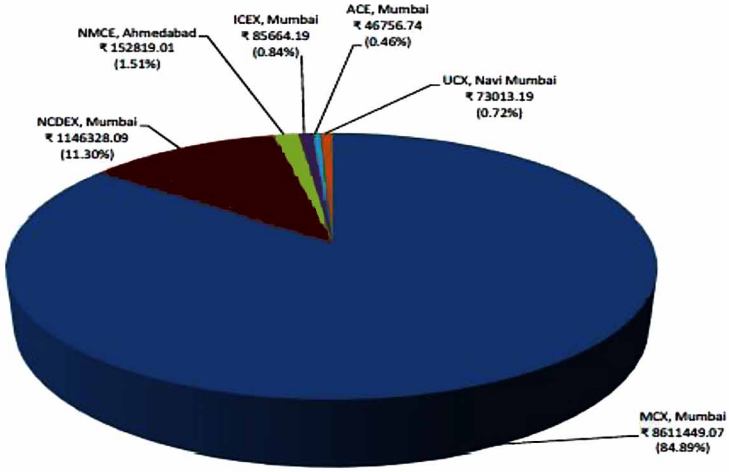

Figure 3. Challenges of commodity futures market

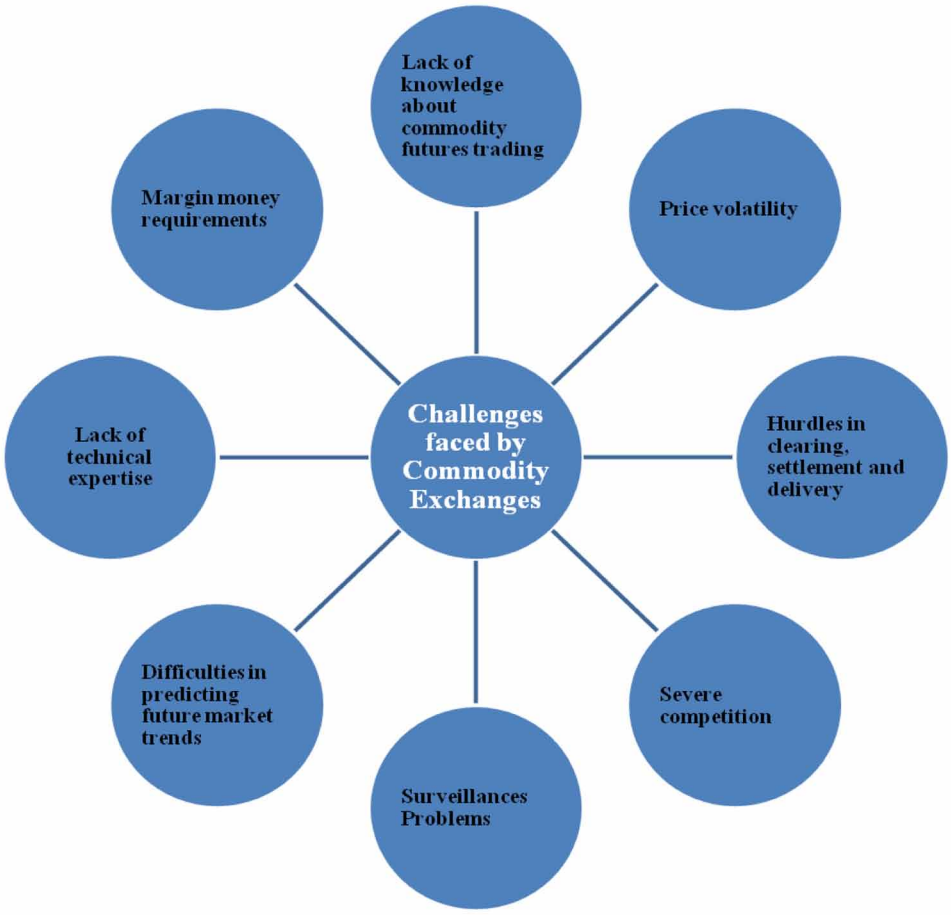

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. **Price Volatility:** People do futures trading on commodity exchanges to minimize their risk from the price fluctuations but as we know that no one can predict the future. Hence they incur loss sometimes.
3. **Hurdles in Clearing, Settlement, and Delivery:** The traders have to give intention to the exchange for taking/giving delivery for the commodities before expiry of a futures contract. In this context, they should know about warehouse clearing and settlement of commodities in physical form otherwise they face hurdles in this.
4. **Severe Competition:** Everyone has to face severe competition in this cut throat competition. There are regional and commodity exchanges in the market but existence of local commodity players can not be avoided in terms of brokerage and delivery charges.
5. **Surveillances Problems:** Monitoring of commodity futures market is necessary to avoid frauds such as scam of National Spot Exchange Ltd. in 2014-15. After this scam, the regulatory authority of commodity market Forward Markets Commission (FMC) has been merged with Securities Exchange Board of India (SEBI) on 28th Sep. 2015. So the surveillance problems faced by the participants in commodity derivatives market are one of the main issues.
6. **Difficulties in Predicting Future Market Trends:** No one can predict trends of futures market even though futures trading is based on technical and fundamental analysis but they also provides the support and resistance levels for trading in volatile futures market.
7. **Lack of Technical Expertise:** Experience is required to predict the trends of futures market. Technical expertise should be there to deal with high volumes of trading on the basis of market knowledge which is a lacuna and due to this; most of the investors don't get benefit from trading in commodity market.
8. **Margin Money Requirements:** Risk management is very important aspect of trading in futures market. Margin money is required for this purpose and it is fixed by the exchange for every traded commodity. A special margin is imposed by the exchange in case of volatility. So the investors and traders have to pay additional margin money in this case.
9. **Price Discovery:** Based on inputs regarding specific market information, the demand and supply equilibrium, weather forecasts, expert views and comments, inflation rates, Government policies, market dynamics, hopes and fears, buyers and sellers conduct trading at futures exchanges. This transforms in to continuous price discovery mechanism. The execution of trade between buyers and sellers leads to assessment of fair value of a particular commodity that is immediately disseminated on the trading terminal.
10. **Price Risk Management:** Hedging is the most common method of price risk management. It is strategy of offering price risk that is inherent in spot market by taking an equal but opposite position in the futures market. Futures markets are used as a mode by hedgers to protect their business from adverse price change. This could dent the profitability of their business. Hedging benefits who are involved in trading of commodities like farmers, processors, merchandisers, manufacturers, exporters, importers etc.
11. **Import- Export Competitiveness:** The exporters can hedge their price risk and improve their competitiveness by making use of futures market. A majority of traders which are involved in physical trade internationally intend to buy forwards. The purchases made from the physical market might expose them to the risk of price risk resulting to losses. The existence of futures market would allow the exporters to hedge their proposed purchase by temporarily substituting for actual

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

purchase till the time is ripe to buy in physical market. In the absence of futures market it will be meticulous, time consuming and costly physical transactions.

12. **Predictable Pricing:** The demand for certain commodities is highly price elastic. The manufacturers have to ensure that the prices should be stable in order to protect their market share with the free entry of imports. Futures contracts will enable predictability in domestic prices. The manufacturers can, as a result, smooth out the influence of changes in their input prices very easily. With no futures market, the manufacturer can be caught between severe short-term price movements of oils and necessity to maintain price stability, which could only be possible through sufficient financial reserves that could otherwise be utilized for making other profitable investments.
13. **Benefits for Farmers/Agriculturalists:** Price instability has a direct bearing on farmers in the absence of futures market. India is traditionally an agricultural economy and fluctuation in prices during the harvesting period has always been a major concern for the farming community. Futures trading have emerged as a viable option for providing a greater degree of assurance on the price front. For instance, a farmer growing soybean is exposed to risk of fall in prices when his harvest comes out. Using futures market, he can sell the soybean contract today at the futures platform and lock in the price which could eliminate his risk from price fluctuations.

Further, farmers sometimes go for distress selling during the harvest time due to lack of storage facilities. Using the futures platform, farmers can store their produce in the exchange designated warehouse till the time their produce fetches reasonable returns.

14. **Credit Accessibility:** The absence of proper risk management tools would attract the marketing and processing of commodities to high-risk exposure making it risky business activity to fund. Even a small movement in prices can eat up a huge proportion of capital owned by traders, at times making it virtually impossible to pay back the loan. There is a high degree of reluctance among banks to fund commodity traders, especially those who do not manage price risks. If in case they do, the interest rate is likely to be high and terms and conditions very stringent. These possess a huge obstacle in the smooth functioning and competition of commodities market. Hedging, which is possible through futures markets, would cut down the discount rate in commodity lending.
15. **Improved Product Quality:** The existence of warehouses for facilitating delivery with grading facilities along with other related benefits provides a very strong reason to upgrade and enhance the quality of the commodity to grade that is acceptable by the exchange. It ensures uniform standardization of commodity trade, including the terms of quality standard: the quality certificates that are issued by the exchange-certified warehouses have the potential to become the norm for physical trade.

Commodities have become an established asset class in the Indian markets in the past few years. While a future trading is relatively new to the Indian commodity markets, the global commodity futures exchanges have been functioning for several decades.

What has attracted investors to trading in commodity futures is the transparency in the price mechanism, low margins, risk management, benefits to farmers by way of price clarity and an organized marketplace. Other than these, commodities also offer a different investment avenue, are less volatile when compared with equities and bonds, are a highly liquid asset class and offer investors an opportunity to gain from the price movements in the commodity space.

Figure 4. Benefits of commodity futures market

Marketing Mix

The government intervened at every stage of the marketing of major agricultural commodities during last three decades. In order to protect farmers from risks and to maintain price stability, every activity of marketing of essential commodities such as procurement, distribution control and administrated price mechanism is under Government control. Government regulation has declined after implementation economic reforms in 1991.

Agriculture sector in India has always been a major field of government intervention since long back. Government tries to protect the interests of the poor Indian farmers by procuring crops at remunerative prices directly from the farmers without involving middlemen in between. This way Government maintains sufficient buffer stocks and at the same time provides the farmers safeguard against the fluctuating food crop prices. But government at the same time has restricted this traditional sector by fixing prices of crops at a particular level and also by imposing several other restrictions on export and import of agricultural commodities.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Agricultural marketing is mainly the buying and selling of agricultural products. In earlier days when the village economy was more or less self-sufficient the marketing of agricultural products presented no difficulty as the farmer sold his produce to the consumer on a cash or barter basis.

Today's agricultural marketing has to undergo a series of exchanges or transfers from one person to another before it reaches the consumer. There are three marketing functions involved in this, i.e., assembling, preparation for consumption and distribution. It is done under the Agricultural Produce (grading and marketing) Act of 1937. In India, there are several central government organizations, who are involved in agricultural marketing like, Commission of Agricultural Costs and Prices, Food Corporation of India, Cotton Corporation of India, Jute Corporation of India, etc.

Marketing Mix involves the decisions regarding product, place, price, promotion, people, process, and physical evidence.

Product

It is related to the design of the services offered to a customer according to the need as well as demand. Indian economy is based on agriculture. Farmers produce different agricultural products like cereals, pulses, spices etc. These are traded at commodity exchanges as well.

The products or agricultural commodities traded at National Exchanges comprise the following:

- **Edible Oilseeds Complexes:** Mustard seed, Cottonseed, Soybean oil etc.
- **Food Grains:** Wheat, Bajra, Maize etc.
- **Metals:** Gold, Silver, Copper, Zinc etc.
- **Spices:** Turmeric, Pepper, Jeera etc.
- **Pulses:** Channa.
- **Fibres:** Cotton, Jute etc.
- **Others:** Sugar, Gur, Rubber, Potato, Natural Gas, Crude Oil etc.

Place

It is related to the location for offering agricultural products. This involves all the regional and national commodity exchanges. Online and offline trading of agricultural commodities are done at these exchanges.

Currently 4 national exchanges are working in India and rests are regional commodity exchanges.

- Multi Commodity Exchange, Mumbai (MCX).
- National Commodity and Derivatives Exchange, Mumbai (NCDEX).
- National Multi Commodity Exchange, Ahmedabad (NMCE).
- Indian Commodity Exchange Ltd., Mumbai (ICEX).

Price

It is related to the price charged for trading of listed agricultural products offered by the commodity exchanges. Such as brokerage, commodity transaction tax, delivery chargers, warehousing charges etc Brokerage is decided by the broking firms but all other charges are decided by the regulatory authority.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Promotion

It relates to the type of media to be chosen by the commodity exchanges to make customers aware about their products and services. It is necessary to take decisions about communication media channel, so as to bring out the salient features of the traded products. The promotion of the product can be done by advertising in media such as radio, newspaper, TV commercials to make customers aware.

People

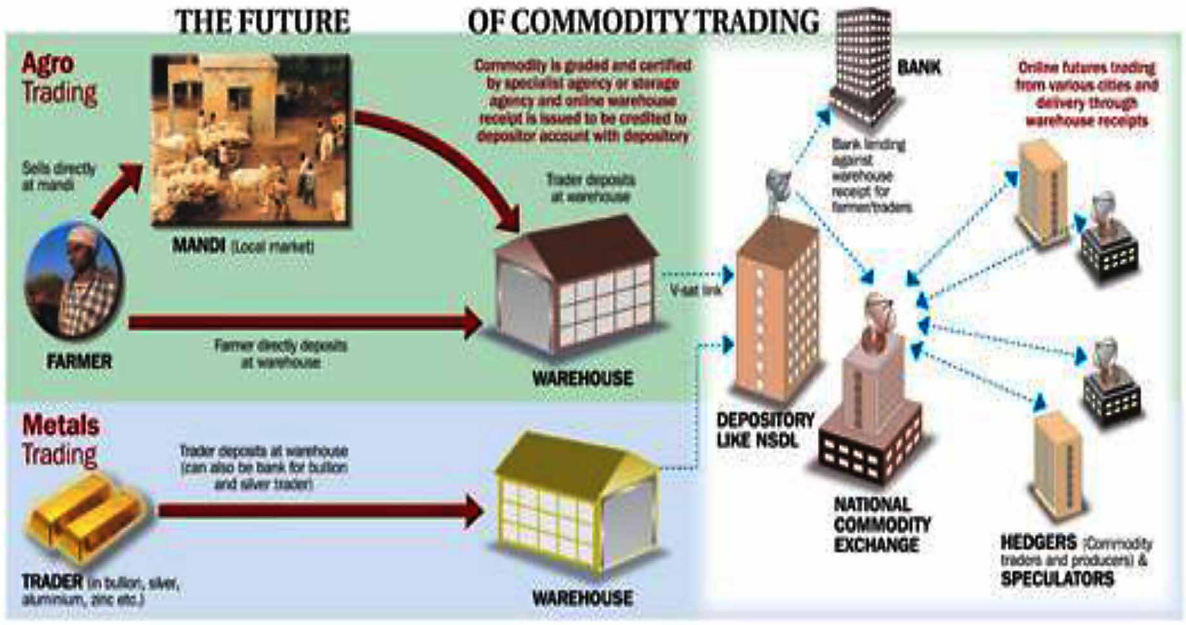
The target customers for all the regional and commodity exchanges are individuals, farmers, manufacturers, producers, and jewelers etc. who can invest in commodities.

Process

It is related to the flow of activities, rules and regulations. All the major activities of regional and national commodity futures market are followed by regulatory authority. Earlier Forward Markets Commission (FMC) was the regulator of commodity futures market but it is merged with Securities Exchange Board of India (SEBI). Now SEBI will regulate the commodities future market from 28th Sep. 2015 to strengthen the rules and regulations and control the speculative practices. There has to be adherence to certain rules and regulations in trading commodities related to the standardization and customization. This involves commodity transaction tax, delivery charges, warehousing charges etc.

Figure 5 gives a fair idea about working of the Commodity market.

Figure 5. Working of commodity futures market



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

A commodity exchange is a market place like a stock market to buy and sell the listed and traded commodities. This market eliminates the need for middle men and allows the market to fix up a price that is driven by demand and supply of the particular commodity.

Trading can be done in two ways:-cash/spot and futures market. The buyer and seller agree upon a common price of the commodity, and actual physical delivery of that commodity takes place in the cash/spot market. Where as, Futures contract do not compulsory involve physical delivery of commodities. Delivery of commodities is fixed for a future date at a price agreed by both the parties but for this, buyer/seller has to give intention before expiry of the futures contract to commodity exchange otherwise buyer or seller can close their positions by squaring off his buy/sell position. Squiring off is done by taking an opposite contract so that the net outstanding is nil. The broker maintains an account of all dealing parties in which the daily profit or loss due to changes in the futures price is recorded.

For the purpose of delivery, a person deposits certain amount of say, good X in a warehouse and gets a warehouse receipt, which allows him to ask for physical delivery of the good from the warehouse. For commodity futures to work, the seller should be able to deposit the commodity at warehouse nearest to him and collect the warehouse receipt. The buyer should be able to take physical delivery at a location of his choice on presenting the warehouse receipt. But at present in India very few warehouses provide delivery for specific commodities.

As spot prices are determined by supply and demand, they are very sensitive to various types of uncontrollable forces that affect commodity production. Bad weather conditions, political turmoil, government intervention, and changing consumer preferences are some of the factors that may contribute to a constantly fluctuating and unpredictable commodities market.

To counter this unpredictability, buyers and sellers created the futures contract. A futures contract is simply an agreement made that will take place some time in the future. These agreements between buyers and sellers include the date the commodity will be delivered, the price to be paid on a specific date, and the quantity and quality of the commodity. A ten percent margin deposit is required of both buyers and sellers to insure that neither of the participants backs out of the contract.

Trading in the spot exchanges is being done in the following ways:

- Farmer/Seller bring his goods to the warehouse.
- The stocks are assayed – Quality checked and the goods weighed.
- If the quality is validated, the warehouse receipt is issued.
- The seller goes to the designated Spot Exchange member with the receipt and a limit is opened for the quantity to be traded on the Exchange.
- Once the transactions are completed at the mutually agreed price between buyer and seller, the delivery and settlement aspects are done as per rules of the Exchanges.

Physical Evidence

Physical evidence is the material part of a service. There are many examples of physical evidence such as Financial Reports, Brochures, Furnishings, Business cards, Building, logo, punch lines, employee's dress code, other tangible items etc. But here in case of commodity futures market, financial reports and services provided by the broking firms in terms of protecting interest of the investors are considered in physical evidence.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Service Quality and Customer Satisfaction

Service Quality means the quality of service delivered by the commodity exchanges and how far the clients of broking firms are satisfied with that. As quality is an intangible concept therefore, it's very difficult to measure. It can be measured by calculating the difference in the expectation of the client from the service delivered by the broking firms and the perception of the clients about the service rendered by the broking firms. Service quality of a product depends upon the reliability, responsiveness, assurance and empathy. In a broking firm, services like daily buy & sell call, margin requirements, risk management of their clients by tracking their open positions are rendered by the brokers on daily basis. So, every broking firm makes sure about these services rendered by the brokers.

Customer Satisfaction

Investors always expect maximum return from their investment. So they should have an idea about the preferences available in the commodity market as investing in commodity market is one of the modes of investment which is catching eyes of the investors now a days. For which, it is required by the broking firms to assist the investors and bring out the knowledge of various investment opportunities available in the commodity market such as arbitrage, hedging etc. Investors are trading on commodity exchanges in online as well as offline mode as per their convenience. But they want proper follow up of their margin money as well as open positions because when they buy or sell an underlying asset, the value of that underlying asset is deducted from the margin money and profit or loss is also get adjusted. So the investors should know about their amount of margin money deposited and daily updates about market movements by the brokers on time to minimize their price risk.

FUTURE RESEARCH DIRECTIONS

There is a much scope for doing research related to the linkage between pricing behavior of future contracts and nature of agricultural commodities traded on national level commodity exchanges. Forward Markets Commission (FMC) had merged with Securities Exchange Board of India (SEBI) in the month of sep. 2015. Now SEBI is regulating the commodity futures market to strengthen and prevent from speculative practices. SEBI has to look at delivery of commodities from the warehouses as there is no physical settlement of stocks in cash market. This can also be the area for further research to find out the effect of followed rules and regulations of SEBI in commodity futures market after FMC.

CONCLUSION

Commodity Futures market has occupied a very important place in Indian economy. Agricultural commodity futures are market-based instruments for managing risks and they help in orderly establishment of efficient agricultural markets. Future markets are used to hedge commodity price risks. They also serve as a low cost, highly efficient and transparent mechanism for discovering prices in the future by providing a forum for exchanging information about supply and demand conditions. The hedging and price discovery functions of future markets promote more efficient production, storage, marketing and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

agro-processing operations and help in improvement in overall agricultural marketing performance. Although India has a long history of trade in commodity derivatives, this sector remained underdeveloped due to government intervention in many commodity markets to control prices. The commodities derivatives market has seen ups and downs, but seem to have finally arrived now. The market has made enormous progress in terms of technology, transparency and trading activity. Interestingly, this has happened only after the Government protection was removed from a number of commodities, and market forces were allowed to play their role.

Singhal, K. Praveen (2015, March 24). Manage Commodity Price Risk via Derivative Exchanges Retrieved January 14, 2016 from http://www.dnaindia.com/money/column-manage-commodity-price-risk-via-derivative-exchanges-2071404

United Nations Conference on Trade and Development (Feb.2013), Recent developments and new challenges in commodity markets, and policy options for commodity-based inclusive growth and sustainable development.

KEY TERMS AND DEFINITIONS

Arbitrage: It means the simultaneous buying and selling of securities, currency, or commodities in different markets or in derivative forms in order to take advantage of differing prices for the same asset.

Derivatives: These are financial contracts, which derive their value from an underlying asset. (Underlying assets can be equity, commodity, foreign exchange, interest rates, real estate or any other asset.) Four types of derivatives are trades forward, futures, options and swaps. Derivatives can be traded either in an exchange or over the counter.

Exchange: Central market place for buyers and sellers. Standardized contracts ensure that the prices mean the same to everyone in the market. The prices in an exchange are determined in the form of a continuous auction by members who are acting on behalf of their clients, companies or themselves.

Futures Contract: It is an agreement between two parties to buy or sell a specified and standardized quantity and quality of an asset at certain time in the future at price agreed upon at the time of entering in to contract on the futures exchange. It is entered on centralized trading platform of exchange. It is standardized in terms of quantity as specified by exchange. Contract price of futures contract is transparent as it is available on centralized trading screen of the exchange. Here valuation of Mark-to-Mark position is calculated as per the official closing price on daily basis and MTM margin requirement exists. Futures contract is more liquid as it is traded on the exchange. In futures contracts the clearing-house becomes the counter party to each transaction, which is called novation. Therefore, counter party risk is almost eliminated. A regulatory authority and the exchange regulate futures contract. Futures contract is generally cash settled but option of physical settlement is available. Delivery tendered in case of futures contract should be of standard quantity and quality as specified by the exchange.

Futures Market: It facilitates buying and selling of standardized contractual agreements (for future delivery) of underlying asset as the specific commodity and not the physical commodity itself. The formulation of futures contract is very specific regarding the quality of the commodity, the quantity to be delivered and date for delivery. However it does not involve immediate transfer of ownership of commodity, unless resulting in delivery. Thus, in futures markets, commodities can be bought or sold irrespective of whether one has possession of the underlying commodity or not. The futures market trade in futures contracts primarily for the purpose of risk management that is hedging on commodity stocks or forward buyers and sellers. Most of these contracts are squared off before maturity and rarely end in deliveries.

Hedging: Means taking a position in futures market that is opposite to position in the physical market with the objective of reducing or limiting risk associated with price.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Margin Money: Cash or equivalent posted as guarantee of fulfillment of a futures contract (not a down payment).

Mark to Market: The practice of crediting or debating a trader's account based on daily closing prices of the futures contracts he is long or short.

Spot Market: Here commodities are physically bought or sold on a negotiated basis.

Spot Price: The price at which the spot or cash commodity is selling on the cash or spot market.

Chapter 61
An Analysis of Mobile Phone Use in Nigerian Agricultural Development

Osadebamwen Anthony Ogbeide
Agribusiness Services, Australia

Ideba Ele
University of Calabar, Nigeria

ABSTRACT

This study used 328 smallholder farmer respondents to investigate its objectives of how farmers use mobile phone technology, what benefits they have gained from the use, and the constraints encountered during the process. The quantitative data collected through a process of questionnaire administration were analysed using Stata 12 software. The results indicate that mobile phone usage for farm and other social purposes has increased with farmers. The farmers also spend almost 40% of their phone bills on farm-related activities and that seeking market information represented 17.32% of the total phone bill in a month. Increased efficiency in input delivery, market access, and output distribution were reported as some of the advantages of using mobile phones. This study was conducted in a region where its general characteristics may not reflect that of the entire country thus generalisation of the study may be limited, so the data should be cautiously use.

INTRODUCTION

Sub-Saharan Africa's rural economy remains agriculture dependent relative to other regions and it employed 62% of the population in 2005 (Staatz & Dembele, 2007). In Nigeria, agriculture employed 70% of the work force and accounted for more than 40% of the Gross Domestic Product (USAID, 2013). It is mainly characterised by subsistent farming. The efforts at developing agriculture in Nigeria have taken many approaches such as rural development strategies which included formation of cooperative organisations, provision of access to credit and technical information, and others (Ogbeide, 2014).

The process of actualising rural development has led to the adoption of mobile phone technology as a farming tool for contact and business transactions. This study investigates how much the farmers have taken advantage of this technology and the benefits derived from it. In considering these objectives, the study is to provide answers to such questions as: (1) do farmers practically use mobile phone for agricultural purposes in Nigeria? (2) does mobile phone usage drive improvement in productivity? (3) what benefits do the farmers derive using mobile phone?

This study is important as it will help to capture and evaluate the progress of mobile phone adoption and uses and also identify, assess, and judge the benefits the smallholder farmers obtain with the device. It is critical that the success and use of this device be studied for improvement and adaptation purposes. The background to the study approach was to explore the three main interdependent players: the provider of inputs, the converter of inputs, and the users of the output and the relationships that exist among them. An understanding of the relationship amongst these players will help to show how important mobile phone is in the order. The providers of inputs in agriculture are diverse and often time distantly located away from the converters.

Farm input providers such as financial institutions, agribusiness/farm management organisations, technical services, chemical and planting materials suppliers, and donor agencies are often situated in the cities or local government headquarters (Karamagi & Nalumansi, 2009). The physical distance between the input providers and the users creates a gap in access and communication. The input converters are the farmers. Farmers particularly in Nigeria are mainly small-scaled with limited contacts to exchange and share crucial information, knowledge and skills needed for production, processing and marketing (Alleman et al., 2002; FAO, 2005). Consequently, yields are low, and incomes from agriculture leave little for the farmer to turn over. Access to crucial inputs is poor or denied due to difficulty in information flow either from the provider of inputs or the users of output (FAO, 2005).

The users of outputs include manufacturers that represent the secondary inputs providers and the final consumers of farm produce. The users of agricultural outputs in like manner to the input converters are most times geographically located far away from the farmers. The road network is poor and the distance from the farm to the market towns and other service providers is very long. The result of these slack relationships is high production cost, inefficiency, non-competitiveness, and corruption (Sebastian, 2008; Dorosh, 2009; WDI, 2010; Livingston et al., 2011).

For example, fertilizer distribution to farmers in Nigeria was hijacked by middle men with no farming interest who either divert them to un-intended markets or resell to the farmers at exorbitant prices (Allafrica, 2013). The diversion results in farmers not receiving the fertilizer at all or on time, and in most cases at a higher price. The delay in getting the inputs, the corruption in the process, and the increase in cost creates inefficiency in the supply chain and causes production to be uncompetitive (Chorn, Sisco, & Pruzan-Jorgensen, 2010; Livingston et al., 2011).

LITERATURE REVIEW

This study assumes readers have prior knowledge of the underlying theory of diffusion of innovation that defined how innovation is adopted by a social group with the result that the innovation becomes part of the existing social system. Adoption of a new technology does not happen instantaneously in a social system; instead, it is a process whereby some individuals are quicker to adopt the technology than others. However, innovation must have the capacity to improve and create better social economic

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

conditions for the adopters while leveraging on ability of the target group to apply it from an assumed or learned standpoint (Robinson, 2009).

Mobile Phone and Agriculture

Improving efficiency in agriculture production processes is important to increasing productivity and reducing poverty. Creating a more efficient value chain involves productive engagement of the members of the chain and how information around these members is managed. One of the ways to improve efficiency in the agriculture is the use of mobile phone technology (Halewood & Surya, 2012).

Mobile phone technology application in diverse agribusiness situations has recorded growth in Nigeria and many other developing countries; it provides different opportunities to transfer knowledge and information among players in the agribusiness value or supply chain, including government. Despite mobile phone being mainly used by urban residence, Aker and Mbiti (2010) found its social and economic usefulness for the rural populace in terms of information gathering on weather, market, and other related issues.

The Syngenta Foundation (2011) reported adaptation of mobile phone technology for agricultural purpose has been boosted as manufacturers and software designers had either aligned their products to suit agricultural use or created specific products for agricultural use. For example, in Nigeria Nokia has focused since 2010 on providing mobile learning (mLearning) applications for the transfer of production skills in crops and livestock management, and fisheries using state-of-the-art technologies. Additionally, national governments have worked assiduously towards comprehensive internet platforms extended on mobile phone to provide farmers access to all relevant information (Syngenta Foundation, 2011). According to Qiang, Kuek, Dymond, and Esselaar (2011), and Martin and Abbott (2011), mobile phone applications usage in Nigeria has increased tremendously. The potential benefits to farmers is diverse, aiding connection and communication with different stakeholders in agricultural value chain.

Mobile Phone as an Important Tool in Nigeria Agriculture

According to Livingston et al. (2011), more than one third of all Sub-Saharan rural Africans are so geographically and economically isolated from market towns that, at present, they are virtually condemned to a life of subsistence agriculture, regardless of their access to modern inputs, irrigation infrastructure or financial services. A spatial analysis of 5,000 people indicated 34% of the rural population in Sub-Saharan Africa live more than five hours from a market town (Sebastian, 2008). While Livingston et al. (2011) argued that the high price of road transport in Sub-Saharan Africa countries is widespread and that the high price of agricultural products has been attributed to the poor state of the transportation network, and inefficient logistics and endemic corruption.

The density of Nigeria's road network is low for agricultural purpose usually bush path or unsealed and with access difficulty. According to Tunde and Adeniyi (2012), and Ajiboye and Afolayan (2009), road transport despite its very poor state is the most readily available means of movement of goods and passenger traffic over short, medium, and long distances. Nigerian agriculture as the engine of economic growth runs below its potential because inputs, be they financial, agronomic or technical, are, all too often, not being delivered in a timely manner by the donor institutions, ministries of agriculture, the project implementation units, the banks or the agricultural cooperatives. This has had an extremely negative impact on productivity and decreased revenues of smallholder farmers. Therefore, successful

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

agricultural campaigns are all about planning and timing and rigorous project management, without which the farmers will not gain the full benefits of the new proffered solutions (FAO, 2009; Livingston et al., 2011; Inoncencio et al., 2007; World Bank, 2009).

Mobile Phone Innovation and Its Agricultural Usage

The theory of diffusion of innovations is central to the adoption, use, and the attendant benefits of mobile phone application to agriculture particularly by smallholders (Martin & Abbott, 2011). Robinson (2009) noted that when an innovation is introduced into any settings, it offers three valuable intuitions into the process of social change. Such intuitions include what are the quality attributes in the innovation that will make it to spread, understanding the needs of the different user groups and the role played by peer networks in ensuring the spread of adoption of the technology. According to Avgerou (2010), understanding the use of mobile phones to aid agricultural development requires an adequate knowledge of the technology and the perceived impacts it possesses, as well as an assessment of the opportunities and barriers reinforced by the local social structure of the user communities.

Aker and Mbiti (2010) and Aminuzzaman, et al. (2003) noted that mobile phone adoption by farmers is predicated on the perception that it is better than most other communication means, as it is convenient to handle, provides economic advantages, and enhances social status of users. The use of mobile phone rests within the core value of communities communicating within and between groups members for social or economic interactions. It enhances communication experiences by removing the cumbersomeness associated with other communication methods (Qiang, Kuek, Dymond, & Esselaar, 2011; Martin & Abbott, 2011). This perceived relative advantage of mobile phone arguably increases the rate of growth of mobile phone ownership among community members and farmers in particular.

Benefits of the Mobile Phone

Agriculture as a business or at least as a means of earning income involves many interactions which can include hiring labour, gathering market and price intelligence, procurement of farm inputs, seeking technical assistance from the extension or expert agents, or obtaining weather information (Okello et al., 2012). However, the location of the parties in the interaction, travel distances, and ineffective and costly transportation all inhibit the ability of the farmers to improve productivity and improve the family and community wellbeing (Okello et al., 2012; GSMA, 2013). Important to these interactions is the need for them to be done in a manner that is timely, effective, and efficient. Farmers must adopt a means by which they are able to gain access to required information and inputs at the appropriate time in a cost-effective manner.

According to FARM-Africa (2007) and Martin and Abbott (2011), the mobile phone is a handy tool for identification and management of livestock diseases, and for coordinating greater attendance and participation in organisations' meetings. Karamagi and Nalumansi (2009) noted that in Central Uganda, farmers adopting the use of mobile phones were able to connect to FoodNet – a service that supplies current price information on agricultural commodities, as well as contact details for interested buyers via short message service (SMS).

Mobile phones have been found to help improve the productivity of individuals and organizations within resource-constrained environments as it increases efficiency, effectiveness, and reach (Burrell, 2008; Qiang, Kuek, Dymond, & Esselaar, 2011; Hudson, 2006). The rapid uptake and popularity of

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

mobile phone applications by rural farmers have led to the development of unique and innovative approaches to using these applications in solving some salient issues faced by farmers. Several studies have revealed some innovative examples; it has been reported that farmers use mobile phones to coordinate access to agricultural inputs (Martin & Abbott, 2011; Ansari & Pandey, 2013; Syngenta Foundation, 2011; Das, Basu & Goswami, 2012); accessing market information (Odhiambo, 2014; Das, Basu, & Goswami, 2012; Martin & Abbott, 2011); for financial transactions (Qiang, Kuek, Dymond, & Esselaar, 2011; Martin & Abbott, 2011; Kirui, Okello, & Nyikal, 2010); and to seek agriculture emergency assistance and expert advice (Qiang, Kuek, Dymond, & Esselaar, 2011; Martin & Abbott, 2011; Churi, Mlozi1, Tumbo, & Casmir, 2012).

Mobile phones assist in mining information. According to Wyche and Steinfield (2015), efficient market information provision has positive benefits for farmers, traders, and policymakers. Current and updated market information is more easily obtained and enables farmers to negotiate with traders from a position of strength. It also facilitates spatial distribution of products from rural areas to urban areas and between urban markets by sending clear price signals from urban consumers to rural producers regarding quantities and varieties required.

Studies have been conducted on ways and which system applications best suit the rural dwellers for social and business communication. Martin and Abbott (2011), Okello et al. (2012), and GSMA (2013) argued that the mobile phone is best suited for rural people including the farmers. Interactions with mobile phones are cost effective ways for smallholder farmers to stay connected with other stakeholders while the phone itself provides them with a sense of security and social status.

Other studies have also analysed mobile phone to be a beneficial product whose access can be limited to socially excluded community members, and as a hazardous consumption (Moisio 2003; Chigona, Beukes, Vally, & Tanner, 2009). Moisio (2003) argued that the perceived negative consequences of mobile phone as a hazardous consumption is not a reflection of the properties of technology, but rather the ways in which it was consumed. While mobile phones may foster negative experiences on health, crime, and physical interaction, they merely do so in a set of categories of thought and practice that enable or disable particular consumption practices and their experiences. However, inequality among the farmers can hinder the use of mobile phone. Chigona, Beukes, Vally, and Tanner (2009) noted that for the socially excluded people in a community, the use of mobile technology may still be limited because the majority of people in that category cannot access or afford it (Chigona, Beukes, Vally, & Tanner, 2009).

Factors That Influence Mobile Phone Technology Application by Smallholder Farmers

In the review of the relevant literature, a number of factors were noted to affect the use the mobile phone by farmers for both social and agriculture related purposes. Mobile phone ownership in developing countries is still low despite the increase in the past several years. However, gender plays a role in mobile phone ownership and use. In short, a woman is still 21% less likely to own a mobile phone than a man and this figure increases to 23% if she lives in Africa (GSMA, 2013). Closing this gender gap would bring the benefits of mobile phones to an additional 300 million women, and by extending the benefits of mobile phone ownership to more women a host of social and economic goals can be advanced (GSMA, 2013).

According to Okello, Kirui, Njirani, and Gitonga (2012), young persons are more servile with technology irrespective of their locality and therefore have a positive correlation with the use of the mobile phone. Therefore, it is expected that young farmers will be inclined to use this technology for most of

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the day-to-day transactions. Kirui et al. (2010) noted the education level of smallholder farmers was low and had thus created challenges to adoption and use of modern technology such as mobile phones. The work of Kirui et al. (2010) corroborated that of Okello et al. (2009) which suggested the literacy level of the farmers was important to the use of mobile phones for information access and can also impact their level of difficulty in navigating through the phone menus, often written in international languages like English.

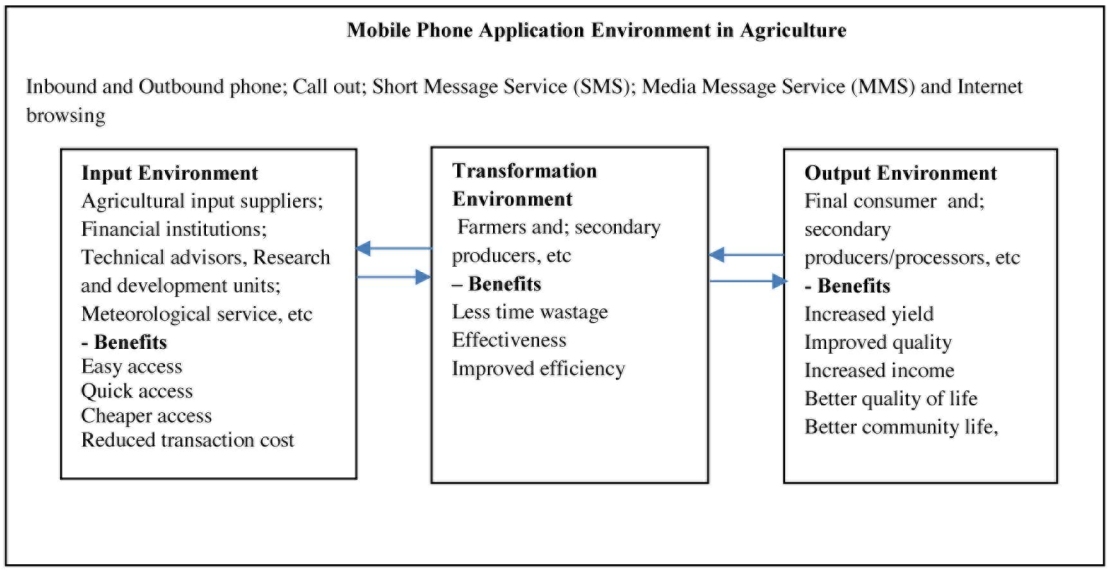
Therefore, the level of literacy and social inclusion of farmers had affected mobile phone use differently (Chigona, Beukes, Vally, & Tanner, 2009) and can influence the level of adoption across the various Nigerian communities. The high usage of mobile phone by adopter farmers buttressed its capability to act as a tool for education and gaining knowledge as well as spreading viewpoints and communication with family members and the larger social community (Okello et al., 2012).

CONCEPTUALISATION OF THE MOBILE PHONE ENVIRONMENT FOR THE STUDY

The essence of adopting an innovation such as mobile phone technology applications for agricultural purposes hinges on its ability to transform an existing way of doing things into a better and more efficient one. The ultimate result is to provide increased and quality output to the market, guaranteed income for farmers and a dynamic and prosperous community (see Figure 1).

The mobile phone use by farmers is well-known as an exemplary case of a technology enabling bottom-up empowerment through information access, driven by agribusiness and end-user innovation (GSMA, 2013; Sherry, n.d.). The major mobile phone functionalities applicable are the voice call, SMS,

Figure 1. Mobile phone application environment in agriculture



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

multimedia service (MMS), and the internet. The use of these functionalities is impacted by users' level of literacy generally and the specific knowledge of the technology available to the consumers.

The farmers often originate communication, but are generally in the middle of the communication chain transforming the information and inputs they source into products for the market. In this model, the inputs environment relates to where farmers and secondary producers are able to access inputs critical to production. Inputs such as weather information, insurance, localised geospatial and real time information, technical knowledge, and stock and machineries are not only required but must be acquired in a quick, easy, and inexpensive manner (Szilagyi & Herdon, 2006; Lio & ChunLiu, 2006). This creates efficiency leading to decreased cost of doing business, improved revenue and better market knowledge.

The farmers apply the inputs obtained from the different input providers and transform them into output. With the mobile phone, farmers and other stakeholders in the value chain can make a call or send SMS or MMS to each other. In this regard, inputs and outputs information are obtained faster with little or no travel time involved (Qiang, Kuek, Dymond, & Esselaar, 2011; Martin & Abbott, 2011). Farmers are able to convert the inputs on time; plant the seeds at the right time, get weather warnings before disaster happens and are able to communicate to the technical expert of any anomalies observed in their farms for quick intervention. Market information obtained on time helps the farmers to determine the cropping pattern, estimate inputs price, plan what to sell and at what price (Qiang, Kuek, Dymond, & Esselaar, 2011).

Obtaining and utilising inputs at the appropriate time is crucial to the success of any enterprise, particularly the ones that can be influenced adversely by weather. Mobile phone enables farmers to obtain quickly information that impacts on inputs transformation, thus causing them to act on time. The result is that all things being equal, maximum and quality yield can be reasonably guaranteed. The farmer can take advantage of the best market price leading to increased income, better social and community life (Odhiambo, 2014; Das, Basu, & Goswami, 2012; Ansari & Pandey, 2013).

METHODOLOGY

The study involved a quantitative analysis of data collected through a process of questionnaire administration that yielded 328 smallholder farmer respondents. The study was conducted in the Cross River State of Nigeria which politically has 18 Local Government Areas (LGAs). Agriculturally, the Cross River State is divided into three zones: the Calabar, the Ikom, and the Ogoja. A multi-stage sampling procedure was adopted to select the respondents for the study (see Figure 2).

First, a random sampling of the LGAs yielded two LGAs from each of the agricultural zones giving a total of six LGAs (Akpabuyo, Calabar Municipal, Abi, Yakurr, Bekwarra, and Ogoja). The second stage was comprised of a purposive sampling of five communities from each LGA. These communities are among those connected to the various mobile phone networks. A total of 30 communities were identified from the purposive sampling. Stage 3 involved the purposively selection of 12 farmer respondents from the communities based on ownership of mobile phones and engagement in agricultural production. The list of respondents from each community was compiled by the community leaders. Data analysis included sample descriptive statistics and regression model analyses and were all conducted using Stata 12 software.

Figure 2. Map of survey area: Cross River State of Nigeria

RESULTS AND DISCUSSION

The results presented in the study were comprised of descriptive statistics of the surveyed farmers, their mobile phone ownership status, and the associated operating cost and its structure. Others include an analysis of the benefits of using mobile phone and the factors that influence mobile phone usage by smallholder farmers.

Descriptive Analysis of Respondents

This study found there was an active involvement of people in the use of mobile phone for agricultural purposes across the age groups particularly the younger farmers, a majority of whom were married and educated. It is not uncommon that farmers within the combined age group of 18 – 49 will generally be mobile phone servile as they are young and would take advantage to apply the skill and technology in any situations. This is consistent with the finding of Okello, Kirui, Njirani, and Gitonga (2012).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

As more young people enter agriculture, it is expected that mobile phone use for its related activities will continue to increase. More and new applications will be utilised by farmers making them take advantage of the ever-increasing technology offerings available. Young farmers are more socially active and can share knowledge faster, thus creating a learning environment for themselves and the older farmers. Under this circumstance, the older farmers can break away from their traditional or conservative ways of interaction.

The older groups of farmers can be driven by the need to be more efficient in doing business and will apply every measure including mobile phone technology to improve efficiency. Table 1 also shows that more than 82 percent of the survey possess at least secondary school certificate; an indication that the farming population is increasingly becoming literate. This may not reflect the educational pattern across the entire country; however, a series of programs adopted by governments and other stakeholder are attracting more young people into agriculture. Therefore, the use of the mobile phone will not be a difficult task to learn and adopt for all purposes including agriculture. The farmers can read, understand, and apply instructions manually on how to use the various functionalities of the phone.

Mobile Phone Ownership and Duration of Ownership/Usage

This study investigated the farmers' mobile phone ownership and the duration of ownership/use of mobile phone to determine its acceptance as an essential tool for agricultural development (see Figure 3). The result shows that all the surveyed farmers possessed a mobile phone and more than 65 percent of the surveyed farmers had used mobile phones for more than six years. This is an indication of strong adoption of the technology and confirmed Qiang, Kuek, Dymond, and Esselaar (2011) finding that the adoption of information technology in agriculture is increasing in Sub-Saharan Africa.

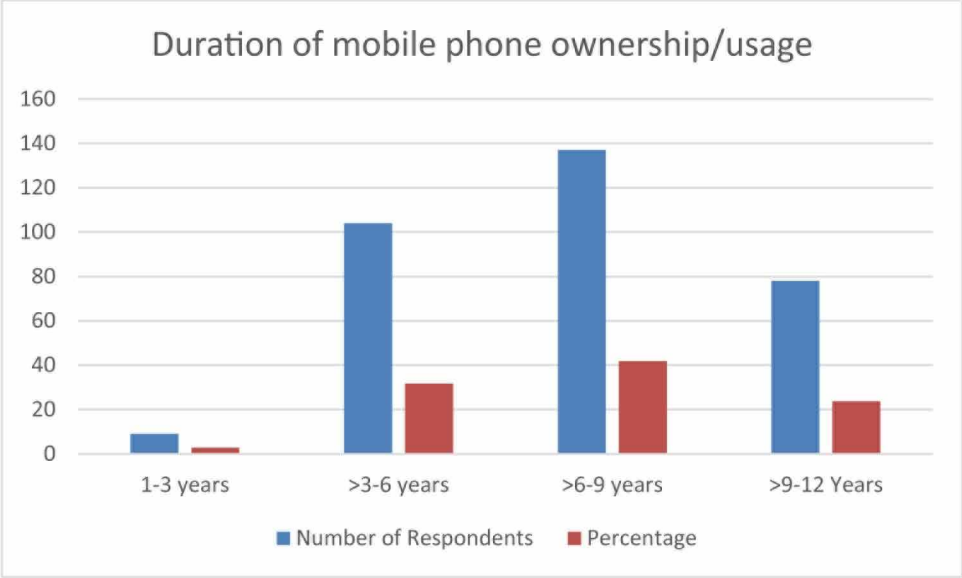
Table 1. Descriptive analysis of respondents. Sample size = 328

Variable	Variable characteristics	Frequency	Percentage of respondents
Gender	Male	248	75.610
	Female	80	24.390
Age Group	18 - 29 years	3	0.910
	30 - 39 years	112	34.150
	40 - 49 years	45	13.720
	50 - 59 years	45	13.720
	60 years and over	123	37.500
Educational qualification	First School leaving certificate	57	17.380
	Secondary School certificate	118	35.980
	OND/NCE	24	7.320
	Bachelor's degree/HND	114	34.760
	Higher degrees	12	3.660
	Others (Please specify)	3	0.910
Marital Status	Single	51	15.550
	Married	277	84.450

Note: OND/NCE = Ordinary National Diploma/National Certificate of Education; HND = Higher National Diploma

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Duration of mobile phone ownership/usage



Ownership is one of the major attempts toward the use of mobile phones. Ownership creates the willingness/power to explore the product and its functionalities, and increases the willingness/ability to use them for diverse situations. This 'use' process resulting from ownership increases the farmers' product knowledge. This long period of ownership/usage is also inferred to be predicated on the benefits accrued to the farmers not just in the economic sense alone, but also the cultural transformation of the business environment and the community's communication settings. Ownership of a mobile phone also symbolises high social status in the farming communities. It is not uncommon for people in the cities and major towns to buy a mobile phone for their parents to stand out among their contemporaries in the community. This social symbolism of the mobile phone is consistent with the studies by Martin and Abbott (2011), Okello et al. (2012), and GSMA (2013).

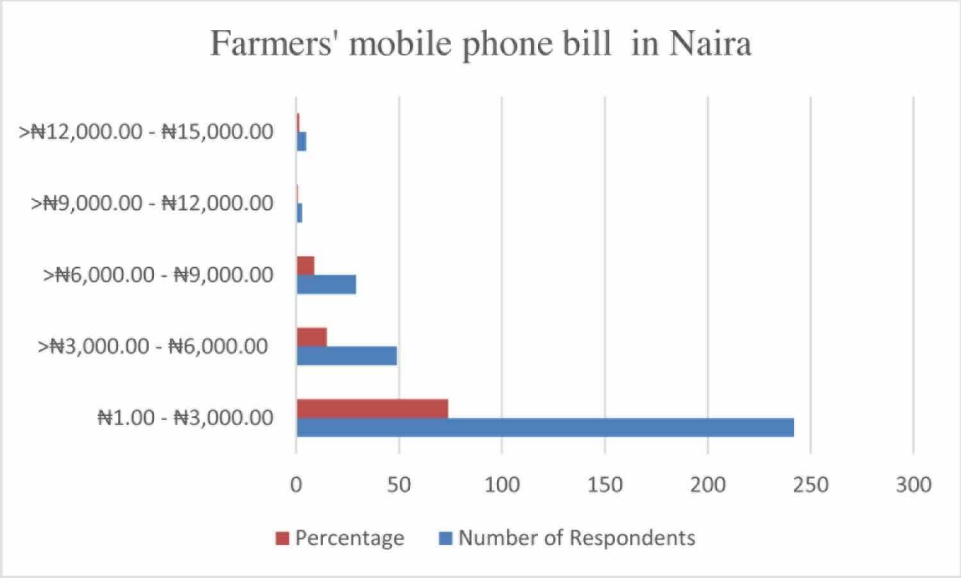
Farmers' Mobile Phone Bill and Use Pattern

While Figure 3 showed mobile phone ownership/usage, Figures 4 and 5 below show farmers mobile phone bill and the apportionment to activities consumed respectively.

More than 88% of the surveyed farmers spend a maximum ₦6,000.00 or less per month on a mobile phone bill. Despite this study not investigating the amount spent in relation to total income or cost, the mobile phone bill can be a measure of the farmers' need-to-call, network coverage, and projected amount to be spent on the service. The farmers' phone bills structure can also be influenced by the number of inbound calls received from farm business stakeholders like input suppliers, extension agents and customers. Competitive input suppliers are more likely to initiate contacts to farmers to market their products. Such contacts reduce the amount of outbound calls the farmers make.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Farmers' mobile phone bill. (₦1.00 = $0.007 USD)



Farmers' Mobile Phone Bill According to Use Pattern

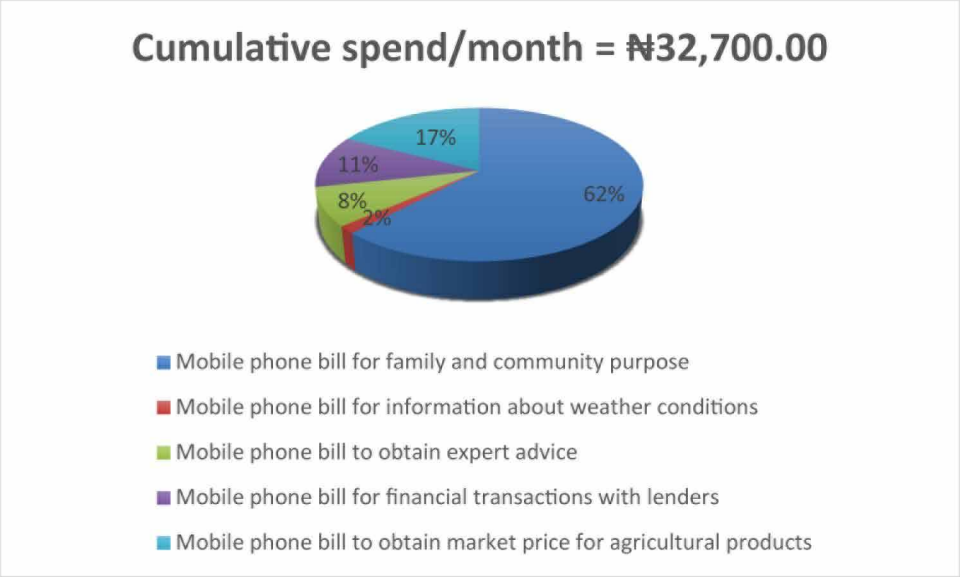
As interesting as the result is in Figure 4, more importantly are the components of the phone bill in Figure 5. Family and community uses accounted for about 62 percent of the phone bill. This indicates a higher usage compared to the farm related use. The high domestic usage is sequel to its capability to act as a tool to educate and gain knowledge as well as spreading viewpoints with family members and the rest of the larger community. Mobile phone interactions are cost effective ways to stay connected with others and provide the user with a sense of security and social value. The result was consistent with the findings of Okello et al. (2012) and GSMA (2013).

Despite the fact that approximately 62% of the surveyed farmers' mobile phone bills were incurred through family and other social interactions, the remaining part of the bill goes into several agriculture related activities. The farmers spent more than 17% of the mobile phone bill seeking market information about agricultural products. This represented the largest agriculture related component of the bill. The high percentage of farmers using mobile phone to source input and output markets was consistent with the result of Odhiambo (2014), Das, Basu, and Goswami (2012), and Ansari and Pandey (2013). This is an important result, considering the capability for mobile phones to bridge the wide divide that exists between the various players in the agricultural landscape. The input and output markets can be several kilometres apart and it can be time consuming and mentally draining for the smallholder farmers to make travel trips for every transaction.

Although the sourcing of inputs, outputs, and markets information represented the largest single agriculture related activity for which a mobile phone was utilized, this study found that farmers' phone bill on financial transactions with lenders represented almost 11% of the total mobile phone bill. Smallholder farmers require financing to purchase inputs and are known to have financial relationships with banks, particularly agricultural and community banks. Produce buyers also provide credit to smallholders to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Farmers' mobile phone bill according to use pattern



purchase inputs and to cover some operating cost in exchange for a promise to purchase the crops upon maturity or harvest. These kinds of transaction are enabled through mobile phone discussion without the farmers having to make physical presence.

The almost 11% of the total mobile bill spent on agricultural financial related interaction showed the reliance of the farmers on it as an effective way of business interaction and was consistent with Qiang, Kuek, Dymond, and Esselaar (2011), Martin and Abbott (2011), and Kirui, Okello, and Nyikal (2010). The percentage of mobile phone bill the smallholder farmers incurred on gathering weather information represented less than two percent of the total phone bill per month. The justification for the low spending will be revealed when the discussion on benefit of the use of the mobile phone by farmers is presented.

The Agricultural Uses of Mobile Phone

The various agricultural purposes to which smallholders use mobile phone were also tested. No specific research result exists for this test in the study area; a theoretical consideration was adopted that the t-test result for each variable will be the same as the assumed (hypothesised) mean value.

The t-test test statistics result is shown in Table 2. The result shows that for two variables – "Use of mobile phone to access market information", and "Use mobile phone for financial transactions" – the p-value associated with the t-test was 0.001 which is evidence that the mean of the two variables was different from the hypothesized value. For the variables "Use mobile phone to coordinate access to agricultural inputs", "Use mobile phone to seek agriculture emergency assistance", and "Use mobile phone to obtain expert advice", the p-value associated with their t-tests were 0.594, 1.000, and 0.512, respectively. Using the decision rule, "if the p-value associated with the t-test is not small ($p > 0.05$), then the null hypothesis is not rejected", it was concluded that the mean of each of these variables was not different from the hypothesized value.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. The agricultural uses to which mobile phone was put

Variable	mean	standard deviation	t - statistics	P-Value
Use mobile phone to coordinate access to agricultural inputs	17.384	8.783	16.430	0.594
Use mobile phone to access market information	30.036	5.063	29.485	0.001
Use mobile phone for financial transactions	22.292	7.375	21.487	0.001
Use mobile phone to seek agriculture emergency assistance	14.573	6.538	13.863	1.000
Use mobile phone to obtain expert advice	17.486	8.119	16.602	0.512

Sample size = 328

The result indicates the use of a mobile phone to access market information has increased and this emphasised how important access to market information is to farmers. Effective and efficient market information provision has benefits for smallholder farmers, inputs suppliers, and consumers. When farmers have up-to-date market information; are better able to negotiate with other stakeholders.

Relating the result from output sales perspective, the increased use of mobile phones for market information facilitates spatial distribution of products from production areas to consumer market with a clear price signals from the consumer market to farmers. With this information, farmers are able to adjust product quantity, quality, and variety as required according to their target markets. Furthermore, due to the increasing need for market intelligence, farmers use their mobile phones more often to obtain current relevant information and well-analysed historical market information to make production decisions, such that relate to what and when to plant or breed, at what stage should harvesting be done or what market should production be directed.

Considering the magnitude of the effort required to obtain market information across regional, national and at time international boundaries, mobile phone technology can be widely deployed by smallholder farmers in the study area to ensure they are current with market environments. The number of farmers that use mobile phone for financial transactions has also increased, as indicated in the result in Table 2. Governments, financial institutions, and other private lenders of fund are located often time remotely away from the smallholder farmers.

In some States in Nigeria, for example, some smallholder farmers obtain their loan through the ministry of Agriculture and the FADAMA program. They are able to use the phone to make quick calls to arrange loans and contracts that enable them to expand an existing farm enterprise or form new ones. Smallholder farmers can also explore the advantage mobile phone provides, to perform their social responsibility of paying the relevant taxes without making any travel to the Tax Office.

Benefits of Using Mobile Phone by Farmers

The surveyed farmers were presented with benefits options and were asked to agree or disagree with the options base on how these perceived benefits applied to them. Table 3 shows the result; a mean value that was “more than 4” indicated that more smallholders agreed the mobile phone provided the benefits for which investigation were made while a mean value of “less than 4 suggested otherwise.

Aside from the “Gets advance warning of weather risks” for which the surveyed farmers indicated no benefit, the farmers agreed to all the other benefits. The study does not explain why getting advance weather warning benefit was disagreed upon, despite it been one of the main benefits as shown in other

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Benefits of using mobile phone by farmers

Variable	Obs	Mean	Std. Dev.	Min	Max
Timely acquisition of price, market and farming practice information.	328	5.920	0.923	1	7
Facilitates access to technical and financial services	328	3.909	2.505	1	7
Easy to connect with other farmers for more effective collective action as producers, traders and buyers	328	5.979	1.277	1	7
Reduced cost of doing business	328	6.253	0.746	2	7
Reduced travel hours	328	6.289	0.707	1	7
Increased social networks	328	4.301	2.418	1	7
Empowers negotiations with wholesalers, traders and transport providers	328	5.526	1.786	1	7
Easier to link my products to distant markets and higher-end agricultural value chains	328	4.832	2.237	1	7
Gets advance warning of weather risks.	328	2.088	1.916	1	7
Enabled faster response to situational changes	328	5.655	1.246	1	7

studies such as Churi, Mlozi1, Tumbo, and Casmir (2012), Qiang, Kuek, Dymond, and Esselaar (2011), and Martin and Abbott (2011).

However, it can be inferred that in the study area, the meteorology services to farmers is still in its infancy. The weather information could be available yet not accessible to the farmers due to inability to gather, harmonise, and provide location specific information to the farmers. Effective weather services rely upon locally relevant data tailored to farmers' needs. When the meteorological service providers are deficient in capacity, they are not able to provide the relevant services to farmers as precisely and accurately to be useful for agricultural planning and operations. Another inference regarding the response to receiving advanced weather warning benefit is that over an extended period of time, farmers have used local knowledge and traditional coping strategies to adapt to changes in weather conditions. For instance, they can predict the arrival of the rainy season by a change in wind patterns and imminent rain fall event by changes in cloud colour.

Factors That Influence Mobile Phone Usage

This study also investigated the influencer of adoption of mobile phone usage. The education status of farmers, their gender, mobile phone ownership, and usage knowledge of the farmers were tested to determine their influence on the farmers' use of the phone for agricultural purposes (see Table 4).

The four predictors of mobile phone ownership, mobile phone usage knowledge, gender, and the educational status of farmers were statistically significant. This result indicates that the use of a mobile phone and its functionalities by farmers has been influenced by these variables. The farmers' knowledge of the use of the phone has increased enabling them to use the functionalities of the phone to meet agricultural purpose. One of the ways farmers acquired knowledge of how to the use mobile phone is through their children. Adult children teach their parents, particularly the less educated ones, how to make and receive calls, store and retrieve data, send, and receive MSM and MMS.

The gender of the farmer plays a part in the usage of a mobile phone for agriculture. Cultural issues, such as traditional roles of men and women in Nigeria affect, delay or even prevent women's acquisition

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Factors that influence mobile phone usage. N = 328

Variable	coefficient	P-Value
Mobile phone ownership	3.696117	0.001
Mobile phone usage knowledge	6.631437	0.001
Gender	16.40994	0.001
Educational status of farmers	5.047578	0.001

Note: 0.001 Indicates estimated coefficient is significant at the .01 level; coef. indicates coefficient.

of mobile phones. Agriculture is still a male-dominated sector in which the head of household often determines what goes on in the family and their means of livelihood. The relationship usually impacts women in many ways such that Martin and Abbott (2011) concluded that women are later adopters of technology than their male counterparts. The male dominance in the use of mobile phone also corresponds with the overall levels of economic development and women's role and participation in farming environment.

The level of educational attainment of the farmers had an effect on their ability to read, comprehend, and apply knowledge. The educational status of the farmers was instrumental to the adoption and use of mobile phone. As more and more educated smallholders are involved in agriculture, so will the use of mobile phone technology increase.

CONCLUSION

Nigeria has a larger rural population than the urban and is very agrarian. The agriculture is dominated by smallholder farmers who are positioned to become a key driver of future economic growth and prosperity if the confronting challenges are overcome. The spirit of this study looked into the contribution of mobile phone as an input-of-change for the country to achieve its agriculture and development potentials.

This study investigated the extent to which farmers have taken advantage of mobile phone technology and the benefits they have derived from it. In view of these objectives, the study sought and provided answers to the questions raised in the objectives. Mobile phone created many benefits for the smallholder farmers aside from its unique characteristics of being handy, customised content delivery and convenience. As mobile phone providers continue to penetrate their services into the rural communities where farming is predominant, the tendency is that there will be expansion in the adoption of mobile phone and increased use of the product to cover more aspects of agricultural activities.

The impact of geographic isolation, high transport costs, time lost to poor road networks and conditions, and the failure to deliver inputs on-time to farmers, or from the farmers to the market when prices are more favourable, can significantly impact revenue, profitability, and the overall social economic wellbeing of the rural communities.

Considering all these issues, the use of the mobile phone technology has reasonably reduced most of these problems. It has assisted farmers to gain easy and timely access to market, market information and financial institutions – formal or informal. However, the low use of mobile phones for obtaining weather information is worrying. Weather information is an important detail upon which modern agriculture relies. Apart from providing normal agricultural weather information, it is relied upon to provide sudden

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

extreme weather forecast that can be devastating. This study did not investigate the reason for the low mobile phone use to obtain this service; however, smallholder farmers generally are conservative and would often rely on tradition and local intuition to predict weather patterns. Moving forward, a review of the use of weather predicted data is first necessary to ascertain the availability of the data to farmers, secondly whether the farmers can access the data, and finally whether the data can be made available through mobile phone applications.

Cogitating the benefits farmers claimed to have obtained from the use of a mobile phone, the realisation of the full potential of mobile phones usage can be constrained by lack of social inclusion and physical infrastructure. Electricity is a critical infrastructure for this service for both the phone service providers and the user farmers. The farmers rely on electricity to charge their phones and often it is not available or epileptic in supply; however, farmers are excited about the benefits a mobile phone provides.

The role of the extension service/agents cannot be overstated; it often involves the visit to the farmers at home or on the farm by the extension agents. The discussions in such meetings often can be managed via mobile phone. Adoption of mobile phone for this purpose will save time and enable targeted messages to reach more farmers within the shortest possible time. The role of weather information in agriculture in modern time cannot be overestimated considering the volatility in the weather conditions due to the effects of climate change. It is important that every government should intensify effort to improve weather advice systems and to ensure the advice gets to the farmers. Governments in collaboration with mobile phone producers and network providers should develop applications that can provide weather information to farmers.

The study has limitations; despite the similarity generally in mobile phone adoption and use in the survey area, the information may not be sufficient to generalise. Therefore, caution should be taken when using the data. The depth of the agricultural activities for which the mobile phone is used could vary considerably within and between the States in Nigeria. This study presented results on female mobile phone users, thus it did not specifically examine the differences in adoption rate and ownership between men and women smallholder farmers. Furthermore, the study is a cross sectional one, so it may not be capable of providing consistent information about the study population over time. Future studies should be directed towards determining female farmers' adoption and use of mobile phone and a longitudinal survey should be conducted to confirm this study's outcomes.

Chapter 62
Farmer Suicides in India: A Case of Globalisation Compromising on Human Rights

Saloni Jain
National Law University Delhi, India

Khushboo Sukhwani
National Law University Delhi, India

ABSTRACT

Indian farmers are facing a crisis of their extinction caused by their suicides. A suicide, every thirty minutes, reflects towards a deeply rooted structural and policy defect in the country. A defect so extreme that many call the same to be state genocide. The State has several obligations towards its farmers, both nationally and internationally. However, the pressures of globalization combined with the influence of bodies like the WTO and IMF has managed to defeat these obligations. This has resulted in a state where ideas like profit, free trade and removal of barriers are being forced upon 'sovereign' States, who have allocated their power to decide on economic issues to supranational bodies due to their inability to operate in isolation like a Westphalian State. The aim of this chapter is to explore and elaborate upon the adverse consequences of globalization on the lives of farmers in India due to enhanced competition and policies which have been influenced by MNCs such as Monsanto and capitalist, north dominated supranational bodies like the WTO and World Bank.

I. INTRODUCTION

Indian farmers are facing a crisis, a crisis of their extinction caused by their suicides. The region of Vidharba in India is infamous for its suicide rate. In the two years preceding 2015, about three thousand farmers have committed suicide in the six districts of Vidharba itself (Purohit, 2015). Studies have found that over nine hundred, or nearly one in three farmers, had debts ranging between ten to fifteen thousand rupees. (Purohit, 2015). In the year 2009 itself, over seventeen thousand farmers had committed suicide (Ministry of Home Affairs, 2009). In other words, one famer died every thirty minutes.

A suicide, every thirty minutes, reflects towards a deeply rooted structural and policy defect in the country. A defect so extreme, whether by way of active acts or omissions, that many call the same to be State genocide. The State has several obligations towards its farmers, both under the Constitution of India and under international conventions like ICCPR and ICSCR, which it is deplorably deflecting.

However, busy with crafting a pleasant picture of "shining" India, the media too, barring a few rural journalists like P. Sainath, has neglected its duty to report on the lives and livelihoods of the largest group of working people in India, the farmers. Agriculture has transformed into a negative economy which is reflected in the rapid increase in indebtedness faced by the farmers (Katakam, 2009). Policies of trade liberalization and corporate globalization are at the root of the farmer distress.

The pressures of globalization combined with the influence of bodies like the WTO and IMF has managed to defeat the human right obligations. The influence of these bodies on national economies so extreme that a Mexican farmer had to stab himself to death to hinder the world trade talks in Cancun in September 2003 (Watts, 2003). The farmer was protesting against the north's efforts to open agricultural trade, whilst the global south wanted to deliberate on older issues that affected them the most, especially the impact of European and U.S. subsidies on their own agriculture and lack of access to those markets (Watts, 2003).

Globalization and liberalization has resulted in a state where ideas like profit, free trade and removal of barriers are being forced upon 'sovereign' States, who have allocated their power to decide on economic issues to supranational bodies due to the current trade scenario where a country cannot operate in isolation like a Westphalian State. The aim of this chapter is to explore and elaborate upon extensively the adverse consequences of liberalization and globalization on the lives of farmers in India due to enhanced competition and policies which have been influenced by MNCs such as Monsanto and capitalist, global north dominated supranational bodies like the WTO and World Bank.

II. BACKGROUND

Recently, a lot of reliable studies have reported the rate of farmer suicides in India. The rate of farmer suicides reported in the region of Vidarbha is alarming. The Indian Government compiled statistics for farmer suicides between 1995 and 2009 and according to the report, over two lakh forty five thousand farmers had committed suicide in that period of time (Ministry of Home Affairs, 2009). In the year 2009 itself, over seventeen thousand farmers had committed suicide (Ministry of Home Affairs, 2009). In other words, one famer died every thirty minutes. The hypothesis of this chapter is that the problem of farmer suicides in India is a result of the policy of the Indian state which is influenced by global pressure. The globalization of agriculture has resulted in this situation of producers of our food dying of hunger. The problem of farmer suicides in India can be addressed by way of states asserting their sovereignty, the developing and under-developing countries asserting and negotiating their rights and not succumb to the pressures of the international bodies like WTO, IMF, World Bank and the MNCs.

III: INDEBTEDNESS: THE ROOT CAUSE OF FARMER SUICIDE

There is no dispute to the fact agricultural growth is required for overall economic development in a country like India where 2/3rd of the people are involved in the agricultural sector (Singh, 2015). Agri-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

cultural growth depends upon the growth of productivity (Chand, 2005). Productivity in turn requires infusion of capital (Chand, 2005). Farmers in most developing countries require more capital than they can afford to generate through their savings (Chand, 2005).

Agricultural Credit Review Committee projected the demand for credit both for production and investments at Rs. 389990 million by 2000 (Reddy & Reddy, 2003). This demand has just been steeply increasing since. As can be seen, farmers require huge credit. A startling 48.6% of the farmer households are in debt according to the 66th NSSO survey (Indian Sociology Institute, 2009).

A farmer is unable to meet the exigencies of cash requirements due to several factors. Most of them are directly a result of globalization and active State policies influenced by supranational bodies, while some are omissions or failures on part of the State to adequately remedy this problem by provision of credit facilities which aren't exploitative in nature.

1. Factors Leading to Indebtedness

As stated in the previous head, globalization and supranational bodies are the main cause for the indebtedness leading to farmer suicides. The economic growth that India is witnessing is indeed a result of its supra-nationally influenced policies, but the very same policies have led to an uneven growth and pushed the farmers to a stage where they want to end their lives (Motlagh, 2008). The factors identified in this chapter are as follows,

2. Market Access

The Agreement on Agriculture under the WTO regime, aiming at liberalized trade in agriculture and for a 'fair' international market for agricultural products, is resulting into upheaval in the lives of farmers (Aksoy & Beghin, 2004). Market Access is an essential ingredient of the Agreement on Agriculture (Smith, 2009). The clauses on market access require that the countries open up their economies and allow a free flow of agricultural products. There are two basic elements attached to it:

1. The non- tariff barriers are to be replaced by tariffs. Non- tariff barriers are in the nature of quantitative restrictions, licensing etc (WTO Legal Affairs Division, 2011);
2. Maintaining a minimum level of imports (WTO Legal Affairs Division, 2011).

The implication of the Agreement on Agriculture is that India and other developing countries had to do away with the quantitative restrictions on market access (Order & Josling, 2011). This resulted in increasing the competition many fold, often to a level where domestic players could no longer compete, and the State couldn't implement protectionist strategies (Order & Josling, 2011). Most policies aimed at promoting the domestic sector were violative of the WTO regime. This also made farmers vulnerable to price volatility. India was undergoing a balance of payment crisis, which was worsening with increased imports into the country (McCalla & Nash, 2007). The exports weren't able to keep up due to decreased subsidies, and lack of the same amount to market access in other developed nations (Order & Josling, 2011). Also, the entrants to Indian markets were able to set the price of products artificially low due to subsidies available in their home country. (Chand, 2005).

These points will be elaborated upon in the next heading. Consequently, India attempted to continue some quotas and import restrictions which were challenged by the United States in the *India Quantitative*

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Restrictions on Imports of Agricultural, Textile and Industrial Products case. After failed consultations, a panel was set up by WTO to resolve the issue. India argued that the quantitative restrictions were to protect its balance of payment situation which was permitted under GATT Article XVIII (Westin, 2001).

The GATT Panel held that there is a general prohibition on quantitative restrictions under Article XI:1 and India's measures such as its import licensing system were quantitative restrictions which were inconsistent with Article XI:1 (Westin, 2001) . The panel concluded that the monetary reserves were adequate and there was no threat, or serious decline in reserves within the meaning of Article XVIII:11, to afford India its exception (Thomas, 2001).

Naturally, when these quantitative restrictions were abolished in 2001, a standing committee of group of concerned ministers was established to deal with the crisis that ensued (Stern & Mattoo, 2005). With phasing out of these restrictions, India had to re-negotiate tariff concession for several agricultural items. As many as 715 agricultural items were freed from quantitative restrictions in 2000 (Goldar, 2005). The result was that the aggregate of imports of such commodities increased by 70% in 2003-04 from the level of imports in 1999-2000 (Goldar, 2005). The Indian farmers all of a sudden were facing an exponentially high level of competition. Even if WTO didn't consider India's import licensing system as consistent with the GATT agreement, WTO could have allowed India some time to bring about changes so that the agricultural sector is not in a state of crisis post its finding. Certainly there is no room for socio-economic and human rights considerations under the WTO decision making framework.

An interesting pointer hinting towards WTOs bend towards the developed countries is its decision making process. In the above mentioned quantitative restrictions case, the dispute brought by the US against India, the panel had this to say: "Article 13.1 of the DSU entitles the panel to consult with the IMF in order to obtain any relevant information relating to India's monetary reserves and balance-of-payments situation *which would assist us in assessing the claims submitted to us.*"(Schott & Watal, 2000).

However, in the United States — Rules of Origin for Textiles and Apparel Products, the dispute was brought by India against USA's rules of origin on textiles and the panel held that India hasn't substantiated its claims while recognizing that the information was readily available with IMF and other international bodies (Schnitzer, 2007).

3. Fall in Prices of Produce, Subsidies, and Other Domestic Support

In order to industrialize more and comply with IMF and World Bank dictates, fiscal reforms took place in India which had an adverse consequence on public investment in critical areas like agriculture. The public expenditure on agriculture as a percentage of GDP fell significantly. There was decline in institutional credit to famers as a result of financial policies of the government (Reddy & Reddy, 2003). There was overall decline in expenditure on agriculture in the budget which was garbed in the name of fiscal constraint.

Similarly, opening up India's markets resulted in banks wanting to enhance their performance to compete globally. 4750 branches of rural schedules banks were closed (Chand, 2005). Loans given to the agricultural sector decreased from 18% to 12% almost immediately (Chand, 2005).

Another pressure Indian farmers started facing was the dramatic fall in prices of farm produce as a result of the WTO's free trade policies. The WTO rules for trade in agriculture are, in essence, rules for dumping. They have allowed wealthy countries to increase agribusiness subsidies while preventing other countries from protecting their farmers from artificially cheap imported produce. Four hundred billion dollars in subsidies combined with the forced removal of import restriction is a ready-made recipe for

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

farmer suicide. Global wheat prices have dropped from $216 a ton in 1995 to $133 a ton in 2001; cotton prices from $98.2 a ton in 1995 to $49.1 a ton in 2001; Soya bean prices from $273 a ton in 1995 to $178 a ton in 2001 (Diao & Somwaru, 2001). This reduction is due not to a change in productivity, but to an increase in subsidies and an increase in market monopolies controlled by a handful of agribusiness corporations.

Subsidies under the framework of agreement on Agriculture can be in the nature of subsidizing production as one the domestic support measure or can be in the nature of export subsidies (Orden & Josling, 2011). In fact, domestic support and export subsidies are two of the three pillars of the Agreement on Agriculture (the third being market access) (Smith, 2009). Under GATT 1947 -which governed the international trade in agriculture before Agreement on Agriculture came in force- the restrictions on subsidies on export of primary agricultural products were ineffective (Orden & Josling, 2011). The result was that quantum of export subsidies being offered by a country was dependent upon the money in the national treasury. The Agreement on Agriculture, which marked a shift, requires direct export subsidies to be reduced to a level of 36% of the 1986-1990 base year over a span of six years (Orden & Josling, 2011). The developing countries are subject to lesser reduction levels over a span of ten years and the least developed countries are not required to commit anything (Aksoy & Beghin, 2004). This appears good for the developing countries, but is again ineffective like GATT 1947. The exporters in India do not get any direct export subsidy (Chand, 2005). The national treasuries of India and many other developing and least developed countries can't afford subsidizing export marketing cost or transport charges.

The high level of subsidies given by developed countries to its agricultural products is one of the major problems in international trade in agricultural products. If the products are subsidized and consequently cheaper than the domestic products of the developing countries, the farmers in those countries can't compete. As is stated above, the agreement on agriculture, very good in its intentions, aims at resolving this problem by calling for commitments on reduction of domestic support. But at some level, the fairness of the agreement itself is questionable as well. Countries giving subsidies on their agricultural products have to reduce them over time while the countries not giving subsidies at all can't beyond the de-minimus limit (Rosset, 2008). There is no parity.

Cotton producers in the US are given a subsidy of $4 billion annually (Rosset, 2008). This has artificially brought down cotton prices, allowing the US to capture world markets previously accessible to poor African countries such as Burkina Faso, Benin, and Mali (Rosett, 2008). This subsidy of $230 per acre in the US is untenable for the African farmers. African cotton farmers are losing $250 million every year (Rosett, 2008). That is why small African countries walked out of the Cancun negotiations, leading to the collapse of the WTO ministerial conference in 2003 (Watts, 2003).

While MNCs like Monsanto pushes the costs of cultivation up, agribusiness subsidies drive down the price farmers get for their produce. The rigged prices of globally traded agriculture commodities steal from poor peasants of the South. A study carried out by the Research Foundation for Science, Technology and Ecology (RFSTE) shows that due to falling farm prices, Indian peasants are losing $26 billion annually (Reddy & Mishra, 2009). This is a burden their poverty does not allow them to bear. As debts increase — unpayable from farm proceeds — farmers are compelled to sell a kidney or commit suicide (Reddy & Mishra, 2009).

Further there is misclassification, underreporting and omission from notifications to WTO regarding the domestic support given by USA. Members of WTO have to notify the WTO about domestic support they give (Smith, 2009). The Domestic Support clauses in the Agreement for Agriculture are a guide to the quantum of domestic support that a country can give to its farmers. The method through which the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

quantum of domestic support is ascertained is by quantifying the total of the domestic support which is given by the country to a specific category of agricultural product (WTO Legal Affairs Division, 2011). Countries, based on whether they are developed or developing had committed reduction in the total Aggregate Measurement of Support (AMS), which is the quantity of support given by each country (WTO Legal Affairs Division, 2011). Domestic support under the Agreement on Agriculture is subject to three exceptions (Smith, 2009). These are:

1. **Green Box Measures:** These are measures which have a minimum impact on trade. These include measures like direct payment for relief from natural disasters (Smith, 2009);
2. **Special and Differential Treatment Box:** These are available to developing countries. Example of this is investment subsidies (Smith, 2009);
3. **Blue Box Measures:** They are relevant for developed countries only (Smith, 2009);

The domestic support in the nature of traditional price and income support programs (direct payments, countercyclical payments, and loan rate program benefits) (Hoekman & Olareagga, 2002). The US notifies various types of disaster payments in the green box as product specific support, and as non-product specific support (Orden & Josling, 2011). The Canadian request for establishment of a panel in the Total Agreegate Measure of Support case (TAMS) case (WTO 2007) case listed forty-eight separate disaster programs over the period 1999-2005 (Orden & Josling, 2011). Crop insurance and disaster relief payments in the green box range from a low of $100 million in 1995 to a high of $2.3 billion in 2008 (Orden & Josling, 2011). Important questions are whether all disaster programs have been included in the US notifications, whether those notified in the green box satisfied the relevant criteria and whether annual support through these programs has been measured correctly (Orden & Josling, 2011). Some disaster relief programs could be judged to provide product specific payments that do not qualify for the green box (Orden & Josling, 2011).

The EU has also provided the highest level of trade distorting domestic support among WTO members to its agricultural sector (Smith, 2009). The European Union has a Common Agricultural Policy (CAP) for its member states. The level of farm support in the EU has been historically high (Frandsen & Birgitte 2003). The Agreement on Agriculture was negotiated to bring restraints on policies as the EU's CAP (Frandsen & Birgitte 2003).

The EU notifications to the WTO about its domestic support reflect that the it has switched its support away from the trade distorting categories under the Agreement towards those deemed to be non or minimally distorting categories (Frandsen & Birgitte 2003). The notifications from 2008/09 to 2015/16 show that the payments have been decoupled from production and prices. There is clear manipulation of policy instruments to take advantage of the method of calculation. Further there is increased expenditure on initiatives such as rural infrastructure which falls outside the scope of Agreement on Agriculture (Orden & Josling, 2011). The net result is an increase in domestic support.

Subsidies and other domestic support given by US to its farmers is also the center of attention in the ongoing Doha negotiations (Anderson & Martin 2015). The US position has also been to acquire increased market access in the emerging markets (Anderson & Martin 2015). The problematic nature of the Domestic Support by US has emerged in the US-Cotton case (WTO 2005) and the Total Agreegate Measure of Support case (TAMS) case (WTO 2007) (Orden & Josling, 2011). In the US Cotton Case, the appellate body held that USA's measures were causing significant price suppression, violated Agreement on Agriculture and were causing serious prejudice to Brazil's interests (Orden & Josling, 2011).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the 9th conference of the WTO at Bali, India demanded that it should be allowed to extend its domestic agricultural subsidies (Food Security Schemes) indefinitely (Basu, 2013). The US opposed it, as they are trade distorting subsidies (Basu, 2013). They eventually reached a compromise that the subsidies will remain, but with future negotiations, and the developed nations will not complain on this issue for the next four years (Basu, 2013). This however, is not a permanent solution and till now there is no move by the WTO/Developed nations/US towards framing the guidelines for a permanent solution to subsidies issue. In the same Bali conference, Trade Facilitation Agreement (TFA) for an easy trade worldwide has also been declared (Jaipuria, 2015). India is aware that once it signs the Trade Facilitation Agreement (TFA) it will be obliged to ease its trade at any cost under which circumstances it will be forced to give up or reduce the minimal level subsidies that it has negotiated to give to its debt ridden farmers (Jaipuria, 2015).

4. Production of Cash Crops: Recolonization of India

From growing wheat and barley, farmers were forced to shift to growing cash crops like tobacco and cotton (Reddy & Reddy, 2003). When the Indian Rupee devalued due to sudden liberalization and opening up of the market, Indian goods became cheaper, which made products them appealable in the international market (Reddy & Reddy, 2003). The State trying to tap this revenue source profitably, urged the farmers to grow cash crops. When India was under the British colonial rule, farmers were forced to grow cash crops, for foreign nations (Reddy and Reddy, 2003). Again after more than fifty years of Independence of India, India returned to the same state of being subservient to the interests of others. So, farmers, at the behest of market demands, stopped producing for self-consumption.

What is important to note is that an average farmer holds approximately an acre of land, which makes profitable cultivation of cash crops and the like impossible (Indian Sociology Institute, 2009). Moreover, the cultivation of cash crops requires pesticides, fertilizers and other inputs much more than the traditional inputs (Indian Sociology Institute, 2009). The subsidies on pesticides was reduced dramatically when India liberalized in the 1990s due to pressure from IMF, as already discussed above (Deshmukh, 2010). Further, the inputs like fertilizers and pesticides were sold in the Indian market by the multinational corporations at costs which made cultivation unviable to farmers (Deshmukh, 2010). Thus the costs increased significantly and there was reduction in subsidies. This put the farmer in a debt trap.

5. Genetically Modified Crops

MNCs sought to benefit from India's structural adjustment policies and the LPG regime by assertively lobbying for the introduction of genetically modified seeds. Global corporations changed the input economy overnight.

In 1998, the World Bank's structural adjustment policies forced India to open up its seed sector to global corporations like Cargill, Monsanto and Syngenta (Sengupta, 2011). The farm saved seeds started getting replaced by corporate seeds, which need fertilizers and pesticides and cannot be saved (Sengupta, 2011). Corporations prevent seed savings through patents and by engineering seeds with non-renewable traits (Gilbert, 2013). As a result, poor peasants have to buy new seeds for every planting season and what was traditionally a free resource, available by putting aside a small portion of the crop, becomes a commodity. This new expense increases poverty and leads to indebtedness.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In early 2000s, Monsanto's Bt cotton and several other variants were approved by the Genetic Engineering Approval Committee (Indian GMO Research Information System, 2010). Bt cotton is a modified to produce the Bacillus Thuringiensis toxin, and the market cost of Bt cotton is at least double that of normal cotton seeds. Several reports indicate the market cost of these seeds to be much greater than five times (Qayum & Sakhari, 2005). Without availability of bank loans due to lack of collateral, farmers resorted to money lenders offering loans are exorbitant interest rates, which coupled with such high capital outlays put the farmers under severe pressure to generate high yields just to recover their costs of production (Gilbert, 2013). Bt cottonseeds also need a higher amount of water. What makes the situation worse is how the option to purchase non-Bt seeds is no longer available in some regions, nor in government seed banks. This forced farmers to get stuck in an endless debt cycle.

The Monsanto bt-cotton mayhem is perfectly captured by the region in India with the highest level of farmers suicides: the Vidharbha region in Maharashtra — 4000 suicides per year, 10 per day (Purohit, 2015). This is also the region with the highest acreage of Monsanto's GMO Bt cotton. Monsanto's GM seeds create a suicide economy by transforming seed from a renewable resource to a non-renewable input which must be bought every year at high prices. Cotton seed used to cost Rs 7/kg. Bt-cotton seeds were sold at Rs 17,000/kg (Indian GMO Research Information System, 2010). Indigenous cotton varieties can be intercropped with food crops (Qayum & Sakkhari, 2005). Bt-cotton can only be grown as a monoculture (Qayum & Sakkhari, 2005). Indigenous cotton is rain fed. Bt-cotton needs irrigation (Qayum & Sakkhari, 2005). Indigenous varieties are pest resistant (Qayum & Sakkhari, 2005). Bt-cotton, even though promoted as resistant to the boll worm, has created new pests, and to control these new pests, farmers are using 13 times more pesticides then they were using prior to introduction of Bt-cotton (Indian GMO Research Information System, 2010). And finally, Monsanto sells its GMO seeds on fraudulent claims of yields of 1500/kg/year when farmers harvest 300-400 kg/year on an average. High costs and unreliable output make for a debt trap, and a suicide economy (Sengupta, 2011).

6. Reduction of Biodiversity and Crop Failure

The shift from saved seed to corporate monopoly of the seeds also indicates a shift from biodiversity to monoculture in cultivation. The district of Warangal in the State of Andhra Pradesh used to grow diverse legumes, millets, and oilseeds (Shiva, 2004). The imposition of cotton monocultures has led to the loss of wealth of farmer's breeding and nature's evolution.

Monocultures and uniformity increase the risk of crop failure, as diverse seeds adapted to diverse to eco-systems are replaced by the sudden introduction of untested and uniform seeds into the market. When Monsanto first introduced Bt Cotton in 2002, the farmers lost 1 billion rupees due to crop failure. Instead of 1,500 kilos per acre as promised by the company, the harvest was as low as 200 kilos per acre. Instead of incomes of 10,000 rupees an acre, farmers ran into losses of 6,400 rupees an acre (Shiva, 2004). In the state of Bihar, when farm-saved corn seed was displaced by Monsanto's hybrid corn, the entire crop failed, creating 4 billion rupees in losses and increased poverty for desperately poor farmers (Shiva, 2004). Poor peasants of the South cannot survive seed monopolies. The crisis of suicides shows how the survival of small farmers is incompatible with the seed monopolies of global corporations.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

7. Spiral of Indebtedness: Credit Games

So while all the above discussed was taking place, and when effective credit was most needed, the State did not take any steps. It chose to neglect the needs and rights of the farmers. Government's inaction resulted in furthering of the agrarian crisis being faced by India.

Changes in the pace and composition of agricultural credit emerged as a significant issue in the context of farmers' distress in India.

The problem arose due to:

1. Lack of access to credit;
2. Inadequate supply of institutional credit particularly to small, marginal and semi-medium farmers.

This forces the farmers to rely on informal sources accompanied by hefty rates of interest. Prabhakara Reddy rightly noted the near absence of cheaper institutional credit and the rise of suicides in the regions in which input markets, output markets and credit markets are handled by the traders/moneylenders (Reddy, 2013).

Financial institutions do not necessarily prefer to lend to the agricultural sector as can be seen from the number of banks that have reached the stipulated 18% lending requirement to the agricultural sector (Deshpande & Shah, 2012). The total investment to the GDP ratio has declined from 1.6% to 1.3%. The supply of institutional credit works out to just 11%. Thus, of the total short-term credit requirement, nearly 90% of the same is being met by private moneylending (Jaipuria, 2015).

Farmers are unable to avail loans from the institutionalized sector because:

1. In the farm sector, the possibility of assured income is quite low- the banks refuse to give loans;
2. The poor farmers have no collateral to offer;
3. Absence of commercial banks;
4. Lengthy procedures to avail loans;
5. Lack of awareness on part of small, marginalized farmers.

The informal sector lenders exploit the farmer. Indebtedness is not an overnight phenomenon. It is nothing but the result of faulty credit policies followed over the years. Unlike industrialists, farmers do not have access to debt relief under any law. Being indebted to the private moneylenders, they cannot go to public authorities to declare themselves insolvent or to get any kind of debt relief.

With the tentacles of usurious moneylenders spreading fast, the absence of an effective and comprehensive law to curb harassment of borrowers seems to have emboldened the unscrupulous private financiers (Srivastava, 214). Exorbitant rates of interest, at times 10 per cent a day, harassment, threats and physical assault of borrowers for default in repayment to "discipline them" and to serve as a "lesson to others," have come to stay in the `trade', which strangely involves no paper work at all (Srivastava, 2014). As no worthwhile document is involved in the transaction and lenders' muscle power alone works, complaints by unsuspecting borrowers are far and few in between (Indian Sociology Institute 2009). Those who obtain money, who include the poor and the prominent in society, would have to suffer in silence to protect their honour.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In fact, according to a petition filed before the State Human Rights Commission, the producer, G. Venkateswaran, committed suicide because of the humiliation suffered by him at the hands of a Madurai-based moneylender (Indian Sociology Institute 2009). Informal sources of credit need to be substituted and the best alternative according to Ravikesh Srivastava is credit management through formation of Farmers' Groups or Farmers' Self-help Groups at the village level (Srivastava, 2014).

The government has failed in addressing the situation of such debt- ridden farmers. Though several debt waiver schemes have been launched by the Indian government, they have been ineffective. Moreover, the Governor of RBI, the Central Bank of India, at a conference of the Indian Economic Association questioned the effectiveness of the debt waiver schemes by stating, "In some states on certain occasions we have had debt waivers. How effective these debt waivers have been? In fact the studies that we have typically show that they have been ineffective. In fact they have constrained the credit flow post waiver to the farmers," Governmental steps to provide debt relief or compensation to farmers have not reached those in need and have seen very limited results (Press Trust of India, 2014). In 2008, the then government at Centre had come out with Agricultural Debt Waiver and Debt Relief Scheme (ADWDRS) 2008 under which 3.69 crore small and marginal farmers and 60 lakh other farmers were given debt relief to the extent of Rs 52,516 crore (Press Trust of India, 2014). Government auditor CAG had found in several cases that ineligible farmers were given benefit while deserving were left out, pointing to large-scale possibility of fraud (Press Trust of India, 2014). Complete waivers were available to small farmers, who were described as owning less than two hectares of land (Press Trust of India, 2014). Very little waiver was available to other farmers, who also suffered from extreme indebtedness. This two-hectare limit was arbitrarily fixed without any insight into the plight of the farmers. The other problem was that this scheme applied to bank loans only. Farmers who were indebted to money lenders, which comprised a majority of them, were excluded from any sort of governmental assistance. Further, while the State has introduced financial assistance schemes for the families of the farmers who commit suicide out of helplessness, such schemes have been intermittently and haphazardly implemented. They have served only as short-term solutions limited to very few affected families (Indian Sociology Institute, 2009).

8. State's Obligations Under the Indian Constitution

So far the chapter has discussed how the government's policies, which in turn have been influenced by international pressure for bodies like IMF and WTO, have been responsible for the condition of farmers in India. In this section, it is discussed how the government is not complying with its Constitutional Obligations which obligates it to address the distress of the farmers.

Article 21 of the Constitution of India states that no person shall be deprived of his life or personal liberty except according to procedure established by law. The Supreme Court i.e. the apex court in India, in numerous decisions has held that the right to life under Article 21 includes the right to livelihood. It includes the right to live with dignity. No person can live without means of subsistence and hence right to life would not make much sense if right to livelihood is not a part of it.

The plight of farmers in India is contrary to what is guaranteed under Article 21 of the Indian Constitution. In 2004 an Organic Farming association had written to Bombay High Court over the situation of farmers in the country (Katakam, 2006). The court treated this as a Public Interest Litigation and observed

The Constitution guarantees the right to life and to personal liberty. The values which underlie Article 21 of the Constitution are seriously eroded by deaths on such a systemic scale, as the facts before the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

court in relation to the State of Maharashtra demonstrate…. The suicides that have occurred are as much due to the failure of social and economic development to reach the poor, the landless and those on the margins of existence as it is due to natural calamities. (Katakam, 2006)

This was the first case in India against the plight of farmers. The court had also held that Article 21 is inviolable and the state is the bound to address the condition of farmers and ensure them their right to life enshrined under Article 21 (Katakam, 2006).

In 2006 another PIL was filed in the Supreme Court, the apex court of the country. The petition stated that in the last five years (2001-2006) 5910 farmers ended their life in Karnataka, 1835 in Andhra Pradesh, 981 in Maharashtra and 201 in Kerala (Saxena, 2006). The Supreme Court held that the suicide of farmers is a result of the structural deficiencies in the National Agricultural Policy.

In March 2015, a Public Interest Litigation petition was filed by the Punjab based NGO. The petition stated that the state has failed to address the issue of farmer suicides. Farmers are forced to buy seeds at high costs, every planting season which has resulted in a debt trap for them compelling them to commit suicides (Press Trust of India 2015). It also stated that state's inaction in implementing the recommendation of the National Commission on Farmers is responsible for non-alleviation of the farmers' distress (Press Trust of India 2015). On the filing of this petition, the court sought the government's response on why it has not made any amendments to the National Policy on Farmers which has structural deficiencies causing farmer suicides (Press Trust of India 2015). The government argued that there had been a decrease in farmers. Court though did not believe this assertion to be true, yet remarked, "Decrease in number (of suicides) is not enough, there should be no case of farmer suicide in the country." (Press Trust of India 2015). The court passed an order on October 30th, 2015 slapping fine on the government for not filling affidavit despite Court's direction (Press Trust of India 2015). The matter is now due to hearing on January 15. The laxity of state in the matter before the court reflects how much the government cares about farmers.

Besides Article 21, two more articles under the Indian Constitution impose an obligation on the Indian State to address the condition of Indian farmers. Article 47 of the Indian Constitution states that it's the duty of the State to raise the level of nutrition and the standard of living and to improve public health. The State shall regard the raising of the level of nutrition and the standard of living of its people and the improvement of public health as among its primary duties and, in particular, the State shall endeavour to bring about prohibition of the consumption except for medicinal purposes of intoxicating drinks and of drugs which are injurious to health.

Article 39 is of pertinence too. It states some principles of policy to be followed by the State. The State shall, in particular, direct its policy towards securing that the ownership and control of the material resources of the community are so distributed as best to subserve the common good;And that the operation of the economic system does not result in the concentration of wealth and means of production to the common detriment

IV. TIMES TO COME…

What would be WTO perspective on agriculture and farmers' distress be in future? Would it address the present concerns? The Doha Round is the latest round of trade negotiations among the WTO membership. The Round was officially launched at the WTO's Fourth Ministerial Conference in Doha, Qatar,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

in November 2001. The Doha Ministerial Declaration provided the mandate for the negotiations, including on agriculture. What does the WTO draft on agriculture in Doha Rounds mean for farmers? *I*n substance, the negotiations on agriculture focus on more market access, eliminating export subsidies, reducing distorting domestic support and sorting out a range of developing country issues (Anderson and Martin, 2015). To trade- offs being offered for more liberalized trade in agriculture are in the nature of supporting rural development.

Moreover, the draft on agriculture amongst other things states that wide range of support for agriculture as a whole would be allowed without limit under the "Green Box", ie, for development, infrastructure, research, agricultural extension, structural adjustment, etc. This in a way would mean that the developed countries can continue to manipulate the domestic protection to their farmers in the way they had been doing and a more liberalized trade in agriculture would worsen the situation of farmers in developing countries. The draft on key issues related to Blue Box, Green Box, Export Subsidies and Export Credit that continues to distort trade, manipulate price promote dumping is not very different from the text brought to Cancun which led to the collapse of the WTO Ministerial and suicide by the Korean farmer, Mr. Lee Kyung-hoe, the President of the Korean Advanced Farmers Federation.

At the domestic front, the Indian Government apathetic to the condition of farmers. An example of it is how it is trying to amend its land acquisition legislation which has been met by a lot of opposition by farmers. The land market in India is byzantine, with an absence of reliable official ownership records, competing claims for the same property and complicated government rules over who can buy land and how it can be used. To overcome these difficulties, MNCs and Indian businessmen grew dependent on the government, which used its powers to force compulsory sales by farmers, and then sold the land on to businesses. The presently in force land acquisition law limits the government's land acquisition powers by requiring that most of the affected population consent to any government acquisition of their land (Venkatesan, 2015). It also required a social impact assessment for any proposed project that would dispossess farmers. In August 2015, farmers from across India gathered in the capital city Delhi to protest against the land bill (Ghosh, 2015). Waving flags, and screaming anti-government slogans, they described the neo-liberal government policies as "pro-industrialist and anti-farmer." Farmers demanded proper compensation to farmers, if land is acquired; insurance against crop loss; minimum wage guarantee for the farmers; social security to landless farmers and agricultural labourers and right price for the produce. At the protest site, farmers pledged, "No to suicides; Onwards to united struggles" (Ghosh, 2015).

In light of all this, it doesn't seem that there is any genuine ongoing effort to address the issue of farmer distress.

V. SOLUTION AND RECOMMENDATIONS

The WTO perspective on agriculture and the international discipline that is evolving on agriculture is detrimental to the interest of the vast majority of small and marginal peasants, the agricultural workers, the rural and urban poor. The Government of India must recognize the crisis situation in agriculture and put an end to its anti-people policies. The Indian Government must strike a balance between its constitutional obligations and obligations under the other international covenants like ICCPR and ICESCR on one hand and the pressure of WTO, IMF and other such organizations on the other hand. India is party to a plethora of human right treaties including the ICCPR and ICESCR. Under Article 11 of the ICESCR, the Indian government is obligated to "recognize the right of everyone to an adequate standard of living

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

for himself and his family, including adequate food, clothing, housing, and to continuous improvement of living conditions," and to "take appropriate steps to ensure the realization of this right." The ICCPR recognizes that "every human being has the inherent right to life" and obligates States to ensure that "no one shall be arbitrarily deprived of his life".

WTO should allow India and other developing countries to protect its agricultural sector. Review of the Agreement on Agriculture requires reviewing the forced removal of quantitative restrictions (QR's) on agricultural commodities. Indian farmers are annually losing Rs. 100,000 crores due to falling prices. Bringing back QR's is the only real effective safeguard. Developing countries should firmly reclaim and assert their unqualified right to impose quantitative restrictions on imports to promote the development of our agriculture and to safeguard the livelihood of majority of their population, which is seventy percent in the case of India. Farmer suicide is a national security emergency and government must negotiate keeping farmer suicides in mind. The crisis and distress that countries like India are facing in agriculture is a national emergency. The suicides of thousands of farmers and the starvation deaths of thousands of tribals are the direct result of trade liberalization and the commoditization of food and agriculture. The government of India and other countries need to invoke Article 19 of the GATT on "Emergency action on imports of particular product" which states that, "If, as a result of unforeseen developments and of the effect of the obligations incurred by a contracting party under this Agreement, including tariff concessions, any product is being imported into the territory of that contracting party in such increased quantities and under such conditions as to cause or threaten serious injury to domestic producers in that territory of like or directly competitive products, the contracting party shall be free, in respect of such product, and to the extent and for such time as may be necessary to prevent or remedy such injury, to suspend the obligation in whole or in part or to withdraw or modify the concession."

Further, Article 20 on "*General Exceptions*" states that -

Subject to the requirement that such measures are not applied in a manner which would constitute a means of arbitrary or unjustifiable discrimination between countries where the same conditions prevail, or a disguised restriction on international trade, nothing in this Agreement shall be construed to prevent the adoption or enforcement by any contracting party of measure:

1. Necessary to protect public morals;
2. Necessary to protect human, animal or plant life or health;
3. Relating to the conservation of exhaustible natural resources if such measures are made effective in conjunction with restrictions on domestic production or consumption;

VI. FUTURE RESEARCH DIRECTIONS

There can be future research on how the international framework and policies of IMF, WTO and other bodies shape agricultural policies of countries other than India and how such policies are interlinked to the conditions of farmers in those countries. Future studies can also focus on the ongoing negotiations on agriculture in WTO and whether the demands of the developing and under-developed world would address the issues that farmers are facing.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

VII. CONCLUSION

The suicide economy of industrialized, globalised agriculture is suicidal at 3 levels — it is suicidal for farmers, it is suicidal for the poor who are deprived of food, and it is suicidal at the level of the human species as we destroy the natural capital of seed, biodiversity, soil and water on which our biological survival depends.

The country is preparing for a severe drought. The vulnerability to drought has increased as globalisation has replaced our drought resistant crops like millets, pulses and oils seeds with water intensive hybrid cotton and water intensive vegetables and fruits for exports.

Conservation of our water resources are soil and our biodiversity demands that we make a general exception to trade liberalization in agriculture using Rule 20. The protection of human life and the prevention of farm suicides is another reason to invoke this exception.

The globalization of agriculture has resulted in this situation of producers of our food dying of hunger. But states should assert their sovereignty, the developing and under-developing countries should assert and negotiate their rights and not succumb to pressures of the north coming to them via the international bodies like WTO, IMF and World Bank and the MNCs.

The WTO ministerial meeting in Nairobi in December 2015 is the litmus test of whether India will be able to make the lives of its farmers better or would succumb to the International pressure again. The tussle at Nairobi is between India and other developing and under-developing countries on one hand and the USA and the industrialized world on the other hand. India and other developing countries want to increase the subsidies that these countries can give to their farmers.

The suicide economy is definitely not an inevitability. The transformation from Seeds of Suicide to Seeds of Hope requires:

1. A shift from GM crops and non-renewable seeds to organic, open pollinated seed varieties which the agriculturists can save and share;
2. A shift from chemical farming to organic farming; and
3. A shift from unfair trade based on false prices to fair trade based on real and just prices.

India and other developing countries and under-developed countries need to ensure the seed of hope to their farmers in this globalized world by bargaining for these shifts in the WTO framework.

Chapter 63
Environmental Change and the Emergence of Infectious Diseases:
A Regional Perspective From South America

Ulisses Confalonieri

ABSTRACT

In South America in the past decades several infectious diseases have emerged or re-emerged either as part of larger pandemics or as local processes involving autochthonous pathogens. These included arthropod-borne viral diseases, such as Dengue Fever, Chikungunya and Zika as well as viral hemorrhagic fevers, such as Hantavirus Pulmonary Syndrome, Junin, Machupo and Guanarito viruses. Parasitic disease was also important such as Malaria, endemic in the northern part of the continent, Leishmaniasis and Chagas Disease. Carrion disease, a bacterial infection originally from the Andes region, also seems to be expanding geographically. Several social and environmental processes have contributed to the emergence of these pathogens, including human migration, deforestation, road and dam building and climate shifts. Due to its high biological diversity of wildlife, arthropods and virus species in still untouched natural ecosystems in the Amazon has the greatest regional potential for the emergence of new human infections.

INTRODUCTION

South America is at the Southern part of the America Continent (10ºN; 55ºS) spanning an area of 17,819,000 million km^2, which includes 12 countries and an independent territory (French Guyana). The regional climate is predominantly hot and humid, but subtropical climate is found in mountain regions (e.g. The Andes) and temperate and polar climates occur in the southern tip of the continent, in Chile and Argentina (Canziani & Dias, 1998).

There is a high diversity of ecological areas and ecosystems such as the desert areas in northern Chile; the large plains in Venezuela and Colombia and the vast Amazon forest, which is shared by eight countries. The region has the largest freshwater system in the world due to the network formed by the Prata, Orinoco and Amazon River basins (Comisión Económica para América Latina y el Caribe [CEPAL], 2014).

The regional population is about 410 million people with about 83% living in cities. The regional life expectancy reached 73 years in 2010 (Teixeira, Paixão, & Costa, 2013). According to the Pan-American Health Organization [PAHO] (2014), safe water access reaches 89% of people in the Andes. However, this is not consistent across the region. Bolivia has sewage collection and treatment covering only 46% of households. Gross income per capita ranged from US$12,470 for Chile and Argentina to US$7,784 in Andean countries. Between 1990 and 2010, regional infant mortality rates dropped by 50%; for Brazil it was 14,6/1000 and for Chile 7,8/1000, in 2012 (PAHO, 2014; Teixeira et al., 2013).

Several endemic infectious diseases occur in South America, some with high annual incidence such as Malaria and Dengue Fever; in 2013, Brazil alone reported a total of 1,470,487 cases of Dengue Fever (PAHO, 2014). Several other endemic infections are autochthonous to the region such as Carrion Disease in the Andes and different forms of hemorrhagic infections caused by Arenavirus, such as Junin, Machupo and Guanarito hemorrhagic fever.

South America is considered vulnerable to climatic conditions, especially when combined with land use and land cover changes (Caqui, Quispe, & Zegarra, 2013; Magrin et al.; 2014). The aim of this chapter is to show the impact of environmental change and human activities on the dynamics of some infectious diseases of major importance to public health in South America.

BACKGROUND

The emergence of infectious diseases was identified as a major global health threat in the last quarter of the 20th century. Zoonotic pathogens from wild animals formed the majority of newly emerged human pathogens in the past few decades (Jones et al., 2008). Several factors have been pointed as major contributors to human infectious disease emergence: new strains of the pathogens, increased resistance to antibiotics, reduced resistance of hosts (e.g. infection by HIV), variations in human populations densities, shifts in diversity of populations of vectors and hosts, hunting of wild animals for food, deforestation and loss of biodiversity and climatic anomalies (Jones et al. 2008; Keesing et al, 2010; Pongsiri et al, 2009; Wilcox & Gubler 2005).

In general, it is acknowledged that, for disease emergence to take place, an association of different drivers is necessary. In South America, since the middle of the last century, several diseases have emerged caused by different etiological agents, from Protozoa to viral infections. Some of these were part of larger epidemics/pandemics (e.g. Cholera; Dengue Fever) but other diseases have emerged as autochthonous

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

local processes and became endemic, such as viral haemorrhagic fevers caused by Junin and Guanarito Viruses. While some of those that have emerged or re-emerged became widely distributed (e.g. Dengue Fever), others occurred as local outbreaks with a small number of cases, restricted in time, and no more cases were reported (e.g. Sabiá Virus infections).

Field observations by scientists early in the 20th century in some regions of South America (associated with the expansion of economic activities) reported changes in the transmission of human tropical diseases as a consequence of human-induced changes to the natural environment. A classic example was the observations by Brumpt and Pedroso (1913) of outbreaks of Cutaneous Leishmaniasis in the state of São Paulo, Brazil, following the opening of a new railway to the centre of the country. The association between the natural environment and the - then poorly known- parasitic infection can be illustrated by the naming of the disease by these authors: "American Forest Leishmaniasis". These early authors have also observed that Cutaneous Leishmaniasis was more prevalent during the hottest period of the year, from November to April.

Another example of early observations of the linkage between tropical diseases and environmental factors in South America was given by Carlos Chagas, the discoverer of the American Trypanossomiasis. Also in the context of opening up of a new railway in Central Brazil, in 1905, he observed that the incidence of malaria among railroad workers was high during the summer and dropped to almost zero during the cold and dry winter (Chagas, 1907). Since these early observations, about a century ago, the environment in the South America region has undergone dramatic changes due to human encroachment on the natural ecosystems. Road buildings, deforestation for the expansion of agriculture, urban growth, and the building of dams have been the main drivers of environmental changes.

In the following section, representative groups of infectious diseases endemic to South America will be discussed in aspects of dynamic epidemiological shifts in relation to continuous changes in the physical and biological environments.

ENVIRONMENTAL CHANGES AND THEIR LINKAGES TO RELEVANT INFECTIOUS DISEASES IN SOUTH AMERICA

1. Malaria

Malaria is an endemic parasitic disease in the northern part of the South American continent, from where it extends up to the southern parts of Mexico. The disease occurs under two main forms in its various localities and sub-regions: stable transmission of endemic character and sporadic transmission of epidemic type (Cabral, Fé, Suarez-Mutis, Boia, & Carvalho-Costa, 2010).

Among the environmental changes usually associated with Malaria dynamics in South America, two process are considered most important: forest conversion due to deforestation and climatic variability in different scales such as seasonal or inter-annual, El Niño phenomenon, for example. El Niño corresponds to the warming phase of El Niño–Southern Oscillation (ENSO), an irregular and periodical variation in winds and sea surface temperatures over the tropical eastern Pacific Ocean. The cooling phase is known as La Niña. There has been some debate as to the relative importance of El Niño phenomenon in shaping the dynamics of this disease in specific areas of the Amazon. Several authors consider that changes in transmission patterns are more dependent on local aspects, such as failure of preventive measures or human population migration, than on large scale climatic phenomena (Cabral et al., 2010; Conn et al.,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2002). However, in Colombia and Venezuela, local studies were able to demonstrate a significant influence of the El Niño on the transmission of Malaria (Delgado-Petrocelli et al., 2012; Mantilla, Oliveros, & Barnston, 2009).

In Peru, the larvae of the main Malaria vector in the Amazon region, *Anopheles darlingi*, was shown to be associated with deforestation. Sites with *A. darlingi* larvae had an average of 24.1% of forest cover, compared with 41% for sites without *A. darlingi* (Vittor et. al., 2009). In the eastern part of the Brazilian Amazon region, culicid surveys performed in a pristine national forest revealed no species of Malaria vectors, among twenty-five thousand specimens collected (Confalonieri et al., 2013; Confalonieri & Costa-Neto, 2012).

Using a geospatial model to map Malaria hotspots in the Brazilian Amazon, Valle and Lima (2014) observed that, on a large scale, forest cover and the proximity to gold mining operations were important drivers of disease risk. They have also found that areas with a longer dry season and areas with higher average rural income tended to have highest Malaria risk. The former is related to the creation of water bodies suitable to *Anopheles* sp. breeding when the rivers recede in the dry season and the latter, may be due to greater access to health services available to the high income population, which potentially increases the reporting rate. In Western Brazilian Amazon, da Silva-Nunes et al. (2008) observed, in a frontier settlement, that Malaria morbidity was strongly associated with land clearing and farming and decreased after five years of residence in these areas due to the development of immunity. A spatial clustering of Malaria was observed in the area of most recent occupation, indicating that the influx of non-immune settlers to forest fringe areas perpetuates the cycle of environmental change that favors Malaria transmission. It was also shown that the place of residence – distance of the dwelling from the forest - was important in determining risk. Using a negative binomial model of Malaria for municipalities in the Brazilian Amazon – the model associated the number of cases of Malaria to covariates as sociodemographic characteristics of the population and land cover – researchers were able to show the influence of logging, road building and forest fires on the incidence of Malaria. The overall incidence rate of Malaria was higher in the states were logging is an important activity. The influence of unpaved roads was higher in the municipalities with rates of deforestation higher than 75% (Hahn, Gangnon, Barcellos, Asner, & Patz, 2014).

2. Chagas Disease

Chagas disease, discovered in 1909 in Brazil, has been extensively studied and the knowledge about the eco-epidemiology of this disease is vast (Teixeira et al., 2001). The adaptation of the different species of disease vectors to human dwellings and man=made environments is well known. In the Amazon region, different mechanisms play a role in the increased risk of Chagas disease infection: deforestation (causing the displacement of wild animal reservoirs of the infection), adaptation of wild species of triatomine vectors to man-made structures, and the migration of susceptible hosts, both humans and domestic animals (Coura & Junqueira, 2012).

Recent studies in Panamá (Central America) have shown that anthropogenic landscape disturbance – forest fragments and peridomiciliary sites - increased vector infection with the *Trypanosoma cruzi*, the etiological agent of Chagas disease. Vector infection rates were significantly greater in deforested habitats as compared to contiguous forests. This was due to a combination of factors: although the modified environments have a low diversity of vector species they have a high abundance of mammal reservoirs of the infection and suitable conditions for the reproduction of the insect vectors and, therefore,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of maintenance of the cycle of the parasite (Gottdenker, Calzada, Saldaña, & Carrol, 2011; Gottdenker, Chaves, Calzada, Saldaña, & Carrol, 2012).

Several decades ago, reports of the influence of temperature on the biology of a major Chagas disease vector – *Triatoma infestans* – found that for the same period of time, two generations of this species occurred in areas with high temperatures and only one generation in the cooler regions (Hack, 1955). Costa, Dornak, Almeida, and Peterson (2014) have modeled the distribution of *T. brasiliensis* complex of vector species according to projected temperatures and precipitation under conditions of climate change in Brazil, for the years 2020 and 2050. *Triatoma brasiliensis* is an important intra-domiciliary and peri-domiciliary transmitter of *T cruzi* in the semi-arid region of Brazil (Coura, 2015). Under scenarios of temperature increase of up to 1,72ºC and a precipitation decrease of 55,6mm, the overall distribution of the species was projected to remain stable. However, the model was able to indicate a great potential for the colonization of new areas by this vector species, a fact important for the planning of epidemiological surveillance.

In Venezuela and Argentina, the study of the future distribution of the species *Rhodnius prolixus* and *T. infestans* using the ecological niche approach, has indicated a possible reduction of the area of distribution of these species under a climatic scenario for 2050 (for future climate conditions, two scenarios were considered: the representative concentration pathways (RCPs) 4.5, 6.0 and 8.5 (hereafter scenarios), which were nested to HadGEM2-ES models and bioclimatic projections for 2050) (Medone, Ceccarelli, Parham, Figuera, & Rabinovich, 2015). Cordovez, Rendon, Gonzales, and Guhl 2014 obtained similar results in Colombia. These authors have concluded that, under scenarios of increased temperature for 2035, as a result of global climate change, a reduction of the area of transmission of Chagas disease currently known in Colombia would be observed.

3. Leishmaniasis

Leishmaniasis, specially the cutaneous forms of the disease, transmitted by vectors of the genus *Lutzomyia* in South America, are known to respond to different types of environmental changes. One aspect frequently reported is the impact of agricultural encroachment in natural forests on the formation of ecological niches for the sandfly vectors of the disease.

In Brazil, coffee plantations using traditional cultivation systems were reported to facilitate the transmission of cutaneous Leishmaniasis. This occurs because coffee trees provide shadow and the decaying leaves of these trees in the soil create adequate niches for the reproduction of sandfly vectors (Alexander et al., 2001, 2009). Other types of plantations such as sugar cane, bananas and cocoa were also reported to increase the risk of Leishmaniasis transmission (Azevedo et al., 1996; Azevedo & Rangel, 1991; da Silva et al., 1999). De Araújo Pedrosa and Alencar Ximenes (2009) and Membrive et al. (2012) reported the high risk of transmission to humans in banana plantations in Brazil due to the proximity of banana trees to the dwellings of peasants.

In French Guyana, Fouque et al. (2007) have reported an expansion of Leishmaniasis transmission into areas of environmental modifications linked to gold mining, agriculture and military training. Also in the Guyana region, an increased rate of cutaneous Leishmanasis transmission was associated with deforestation (Rotureau, 2006). Although in Colombia both the population density and the number of species of sandfly vector were higher in forested areas when compared to degraded areas, in the latter the risk of Leishmaniasis transmission to human and domestic animals was higher due to the adaptation of the most important vector species to the anthropic environment.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In Brazil, shifts in the epidemiology of cutaneous Leishmaniasis were associated with building of dams (Vilela, Azevedo, Carvalho, & Rangel, 2011) and also roads and railways (Gonçalves Neto et al., 2013). Factors influencing incidence increases and the spread of *Leishmania* spp. range from habitat changes for vectors (as they frequently adapt to man-made buildings) to human population displacements associated with infrastructure projects

Climatic variations have also been associated with epidemiological changes of Leishmaniasis in the Americas (Chaves & Pascual, 2006). In Colombia, associations of El Niño and La Niña climatic phenomena and the incidence of Leishmaniasis in endemic regions of the country showed variable linkages: in some areas El Niño has had a positive correlation with cases of the disease while in others, the cases were influenced by La Niña (Cárdenas, Sandoval, Rodriguez-Morales, & Vivas, 2008). The authors have stressed the need for further studies and emphasized the role of climatic factors in the dynamics of Leishmaniasis in different areas of Colombia.

4. Bartonellosis

American Bartonellosis, also named Carrión Disease, caused by the bacterium *Bartonella bacilliformis* and transmitted by the sandfly species *Lutzomyia verrucarum*, occurs in the region of the Andes, being endemic in altitudes between 800m and 3000m. Environmental factors were reported to influence the dynamics and the spatial distribution of this disease. Chinga-Alayo, Huarcaya, Nasarre, Del Aguila, and Llanos-Cuentas (2004) have reported a positive association between disease transmission and El Niño climatic phenomenon in endemic areas of Peru. The mechanism involved is the increase in vector populations influenced by higher temperatures. Also in Peru, Zhou et al. (2001) have observed a doubling in the number of new cases of the disease during the months of El Niño, in addition to an expansion of the disease to areas not previously affected. High correlations were observed between higher incidence and increased temperatures three months before the outbreaks (Zhou et al., 2001).

Recent reports of human cases of Carrión Disease outside the well-known endemic areas, such as cases in the forest areas and on the coast, indicate a trend of geographic expansion, probably influenced by both the adaptation of the vectors to new niches and human contact during population movements for commercial activities (Maco, Maguiña, Tirado, Maco, & Vidal, 2004).

5. Viral Diseases

In South America, two major groups of endemic viral diseases are reported to be influenced by climatic shifts and environmental changes: arboviral infections and viral haemorrhagic fevers. Some of these diseases have been established in this continent for several decades such as Yellow Fever and, more recently, Dengue Fever. Others seem to be autochthonous to the region, such as the Mayaro and Oropouche fever in the Amazon (Vasconcelos et al., 2001). In the past few years, new viral introductions were reported, such as the West Nile virus (Morales et al., 2006) and Chikungunya virus, which occurred either as isolated cases or slowly expanding to become endemic (Figueiredo & Figueiredo, 2014; Carbajo & Vezzani, 2015).

The emergence of the Hantavirus Pulmonary Syndrome virus in the Americas has been associated with human disturbances of the natural systems, affecting the composition of biodiversity. This is also true for infections caused by arenaviruses, which typically occur in South America: Junin, Machupo and Guanarito (Simpson, 1978; Mills, 2006). These infections have different species of wild rodent reservoirs

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and those considered to be opportunistic – more adaptable to peri-domiciliary environments and presenting high fecundity and shorter life cycles – tend to predominate in the anthropic environment (Mills, 2006). Most outbreaks have been reported in anthropic environments where these species predominate, in a context of reduced diversity of potential host species (Mills, 2006). In the years 1940-1960, the emergence of rodent-borne arenavirus infections causing hemorrhagic fevers in Argentina and Bolivia, have followed a similar mechanism. Agricultural encroachment to natural pastures used for livestock production have caused a change in the local dominant species of rodents: *Calomys musculinus* in the maize crops of Argentina and *Calomys callosus* in the subsistence crops near small forested areas in Bolivia. These two species had their populations numbers greatly increased as well as adapted to the human dwellings where they have shed the virus in the urine (Johnson, 1993). Consequently, outbreaks of Machupo's disease occurred in the northern part of Bolivia during 1960 and Junin viruses have been clinically described since 1953 in Argentina.

The population dynamics of the reservoir rodents also play a role in outbreaks and in the case of the Junin virus in Argentina (Simpson, 1978), it was observed that the clustering of human cases during the harvest of maize was linked to a peak in rodent abundance. In a study of wild reservoirs of hantavirus in Paraguay, a higher rate of infection of rodent species in anthropic landscapes (e.g. agriculture) was found. When compared with areas of low infection, this high infection rate seems to be linked to habitat fragmentation, which changes the mobility of the rodents and facilitates virus transmission due to increased encounters between different rodent species, capable of increasing the probability of virus transfer from an infected animal to an uninfected member of a host population (Goodin, et. al., 2006). The role of climatic change in modulating Hantavirus infection was modeled in Argentina in regard to spatial distribution of the main reservoir rodent species. Different results were obtained according to different climatic scenarios used and for different parts of the country, but the overall distribution of the host was projected to be reduced due to changes in precipitation and temperature (Carbajo, Vera, & Gonzalez, 2009).

6. Arboviruses

The most important arboviral diseases in South America are Dengue Fever and Yellow Fever, because of the high incidence of Dengue, and the high fatality rate of Yellow Fever (Cunha & Nogueira, 2005; Tauil, Santos & Morais, 2005). Both are influenced by climatic variability and change, and Yellow Fever, which is a focal disease rooted in natural ecosystems, is also influenced by changes in land use and land cover (e.g. deforestation) (Monath & Vasconcelos, 2015; Bryant et. al., 2003; Vasconcelos et. al., 2001). Several authors have reported the influence of climate, to variable degrees, on the epidemiology of Dengue Fever in tropical America (Chowell, Cazelles, Broutin, & Munayco, 2011; Herrera-Martinez & Rodriguez-Morales, 2010; Ibarra et al., 2013; Thai & Anders, 2011). Some of these are the higher Dengue incidence during El Niño periods in Venezuela, the rainfall and minimum temperature as a predictor of *Aedes aegypti* oviposition activity in Ecuador and the influence of seasonal temperature in Dengue epidemics in Peru. Reports were also made on the influence of specific types of natural ecosystems on the production of outbreaks of Yellow Fever (Degallier et. al., 1992) and of the micrometeorology of forest on the population dynamics of mosquito's vectors of this disease (Pinto, Confalonieri, & Mascarenhas, 2009).

In regard to Dengue Fever, models have pointed out that, although climate has a role in Dengue increase in the "Southern Cone" (Argentina), other geographic factors (e.g. distance to water bodies) and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

demographic variables have a stronger influence on the determination of disease incidence (Carbajo, Cardo, & Vezzani, 2012). The most critical factor in the emergence/re-emergence of Dengue fever in South America is considered to be the widespread adaptation of its main vector, the mosquito *Aedes aegypti*, to artificial containers in urban settings, a fact observed in most countries of the region. This vector could also pose a major threat for the transmission of urban yellow fever in major cities of the region, a situation reported for the last time more than half a century ago (Downs, 1981). In Brazil, for example, the disease has caused major urban epidemics from the colonial period to the first decades of the 20th century when it was recorded the last urban outbreak in Rio de Janeiro, 1929; sporadic cases appeared in Acre state, in 1942 (Ferreira, Rocha, Caputto, Fonseca, & Fonseca, 2011). Since then, the successful control of the urban form of Yellow Fever, both in Brazil and in the Americas, was made possible for two reasons: the eradication of *A.aegypti* vector and the widespread use of 17D vaccine. The former occurred through the Rockefeller Foundation and the Pan American/ World Health Organization initiative which, between the years 1930 and 1950, have implemented successful programs of eradication of the vector in the Americas (Braga & Valle, 2007). The vaccine appeared in 1937, also through the Rockefeller Foundation with the involvement of Oswaldo Cruz Institute (Ferreira, Rocha, Caputto, Fonseca, & Fonseca, 2011).

Two other frequently reported arboviral infections in the region are the Oropouche and the Mayaro fever viruses. Oropouche virus infections have been epidemic in the Amazon – Brazil, Peru, Colombia – and Panama and Trinidad. Its sylvatic cycle of transmission is poorly understood and involve multiple hosts and vectors, such as sloths, monkeys and birds (Pinheiro, Travassos da Rosa, & Vasconcelos, 1998). Still, epidemics of Oropouche as an anthroponosis are well characterized, with the involvement of a single species of vector – *Culicoides paraensis* (Carpenter, Groschup, Garros, Felippe-Bauer, & Pruse, 2013). Evidence points to an adaptation of the viruses to the peri-urban habitats since their midge vector species breed in holes thumbs and roots of planted trees, and they can bite inside houses. Outbreaks are associated with periods of high rainfall intensity and can reach thousands of cases in short periods of time in the Brazilian Amazon (Pinheiro et al., 1998). In the case of Mayaro fever, outbreaks were also reported from Amazonian countries, especially Brazil, Colombia, Venezuela and Bolivia. It is considered a forest disease similar to Yellow Fever, having the same mosquito species as vector – *Haemagogus janthinomys* - as well as primates as wild reservoirs, but cases transmitted in rural areas have been also reported (Travassos da Rosa et al., 1998). In the Amazon region, the main driver for Mayaro virus occurrence is deforestation, causing limited outbreaks (Vasconcelos et al. 2001). Although few studies have addressed the role of climatic variables in Oropouche and Mayaro fever epidemiology, Vasconcelos et al. (2001) observed that increased precipitation, especially in the first half of the year for the Amazon, seems to favor the reproduction of the vectors of both diseases. In fact, other environmental factors, such as temperature and humidity, play an important role influencing mosquito competence for arboviruses and its population abundance (Aybar, Juri, Santana, Grosso, & Spinelli, 2012; Tabachnick, 2013). Given the projections of temperature rise and reduced precipitation in the Amazon region, the distribution of cases of these two diseases can reduce or increase depending on the site studied.

In regard to other less important arboviral infections in South America, the detection of West Nile virus infections from horses in Argentina was probably associated with migratory birds (Morales et al., 2006). The same mechanism was proposed for a newly emerged infection in forests of Southern Brazil, the Rocio Virus, which was detected by immunological tests in sylvatic birds captured in São Paulo state, Brazil (Lopes, Coimbra, Sacchetta, & Calisher, 1978; Ferreira et al., 1994). The Rocio virus appeared in Ribeira Valley, São Paulo state, Brazil, causing encephalitis epidemics in 1975-1976 – around 1000

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

cases and 10% fatality rate (Monath, 1993). A newly emerged arboviral infection in South America is Chikungunya virus, an infection also transmitted by *Aedes* mosquitoes, mainly *A. aegypti*. It is believed to have originated in Africa, where it still circulates enzootically among nonhuman primates, whereas in the Americas it was reported for the first time in 2013 (Vega-Rúa, Zouache, Girod, Failloux, & Lourenço-de-Oliveira, 2014). As of the year 2015, the South American countries Colombia, Venezuela, Brazil, Ecuador and Paraguay have reported local transmission (Carbajo & Vezzani, 2015). Since it is a disease transmitted by urban vectors, its emergence has been associated to urbanization and human migration (Figueiredo & Figueiredo, 2014). Regarding West Nile Virus, the influence of climate on its occurrence is well stablished in temperate countries, where warm winters and spring droughts are pointed out as capable of amplifying the transmission (Epstein, 2001; Paz, 2006). For Chikungunya, as for other diseases transmitted by the *Aedes* genus of mosquitoes, models projecting the distribution of *A. aegypti* vector show a potential for its advance toward South America centre, colonizing areas where the vector is absent (Campbell et al., 2015).

7. Cholera

Cholera, a gastrointestinal infection caused by the bacterium *Vibrio cholera*, has re-emerged in Peru, South America, in 1990. Although strongly influenced by socioeconomic conditions, due to its marked seasonal occurrence in endemic regions, former studies have pointed out to the influence of climatic variability in the dynamics of this disease, especially in Asia (Pascual, Bouma, & Dobson, 2002). In Peru, its emergence has been associated with the 1991-1992 El Niño climatic phenomenon (Pascual et al., 2002). It seems that the bacterium has been present in the environment months before the beginning of the outbreak in Peru and marine ecosystem changes associated with El Niño led to the propagation of *V. cholera* along the coast (Seas et al. 2000).

Recent reassessment of cholera emergence in Peru has indicated that the epidemic may have been linked to ENSO through multiple pathways, including elevated temperatures, rainfall extremes, La Niña phenomenon (cold phase of the ENSO cycle) and social vulnerability (Ramírez, Grady, & Glantz, 2013). A local study in Piura, one of the most affected districts in Peru, showed significant cholera association with sea surface temperatures in the Central Pacific Ocean and on the coast, as well as with rainfall and minimum and maximum temperatures with varying lag times (0-5 months); the strongest consistent impact was with rainfall (Ramírez, 2015).

CLIMATE AND INFECTIOUS DISEASES: ADAPTATION OPTIONS

1. Infectious Disease Control

Regardless of what models project in terms of future infectious diseases profiles, as a consequence of climactic shifts, current actions targeted to the reduction of incidence and geographical expansion of endemic infectious diseases should be considered as part of the adaptation processes. This is particularly critical for those diseases known to be affected by climate variability, such as most vector-borne and water-borne infections (Smith et al., 2014).

These control strategies vary according to disease cycles and the available technologies for their control. The following are some examples of diseases endemic to the South American region:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Leptospirosis:** Usually associated to urban floods following tropical storms (Dutra et al., 2015). The control strategies focus on improvement of drainage of rain water as well as on the control of rodent populations (rats), which are the main reservoirs of the pathogen;
- **Dengue Fever:** A viral disease transmitted by the urban vector species *Aedes aegypti*, a mosquito which also transmits the Zika virus and the Chikunguya virus (Ibarra et al., 2013; Musso, Nilles, & Cao-Lormeau, 2014; Roth et al., 2014; Staples & Fischer, 2014). Since there are no vaccines against these viruses, the main strategy for their control depends on the reduction of the vector populations. This can be more effective through the reduction of the breeding sites for the vector: trash in backyards, discarded tires, flowers pots and other man-made structures that accumulate rain water (Tauil, 2002);
- **Malaria:** A vector-borne disease restricted to the natural environment. The main strategy for its control is the early treatment of the infected human hosts. A secondary strategy, at the local level, is the emergency spraying of insecticides to reduce the vector population (World Health Organization [WHO], 2014);
- **Yellow Fever:** A vector-borne disease known to be associated to climate variability and forest micrometeorology (Vasconcelos et al., 2001; Bryant et al., 2003; Pinto et al., 2009). Its control depends on the preventive vaccination of the population at risk in endemic areas (Ferreira, Rocha, Caputto, Fonseca, & Fonseca, 2011).

2. Healthcare, Education, and Adaptation

Future Public Health impacts of climate change on the epidemiology of infectious diseases and on health care systems are well acknowledged (Confalonieri, Menezes & Margonari de Souza, 2015; Costello et al., 2009; Pereira & Barata, 2014; WHO, 2009). However, current health policies and strategies do not address possible changes to the epidemiological profile of the populations to be affected by climatic change. Adaptation strategies should be focused on both populations currently under climatic stress as well as those expected to be affected by future shifts to the global climate system (Ebi, Lindgren, Suk, & Semenza, 2013). The first step towards this end would be strengthening of the health care systems in order to facilitate the development of adequate responses to climatic hazards (Costello et al.; 2009).

The promotion of secure infrastructure, not affected by extreme weather, is essential for the provision of health care services on a continuous basis. Several Latin American countries have built health care installations resilient to disasters such as Peru, Colombia, Equador, Chile and Costa Rica (WHO, 2009). In the urban environment in South America events like storms, floods and landslides are responsible for a high burden of morbidity and mortality. These require comprehensive preventive actions ranging from public health monitoring and disaster preparedness, in the context of community-based risk reduction strategies (Keim, 2008).

In the municipality of Nova Friburgo, Rio de Janeiro, Brazil, heavy rains (182.8 mm/24 hours) have killed 429 persons, mostly due to trauma, in January 2011. Despite the interruption of several basic services – energy, water, transportation – an efficient health surveillance intervention was able to prevent deaths after outbreaks of dengue fever, leptospirosis and waterborne diarrhea (Porto, 2012; Pereira & Barata, 2014). This can be considered as an example of successful intervention – or reactive adaptation – in the context of climate-associated disasters causing infectious disease epidemics.

Educational approaches are also an important part of the adaptation process. Lima and Layrargues (2014), have emphasized the need for a more comprehensive understanding of the impacts of climate,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

associating the knowledge of climatic hazards and risks to the daily life of the population and also the need for environmental conservation as part of the adaptation strategy.

Since risks associated to climate change are socially and spatially different, a revision of the practices of governance is needed. This entails both individual adaptation strategies that respect the social and economic characteristics of the affected people, especially those more directly dependent on natural resources (Adger, 2001) and an open and participatory decision making processes involving the actors concerned with the impacts, in order to complement the necessary technical knowledge (Jacobi, 2014).] Some local initiatives have demonstrated positive results in regard to public policies targeted to climate change. In the megacity of São Paulo, Brazil, Landin and Giatti (2014) have demonstrated the existence of a positive cross sectoral dialogue in the implementation of policies targeted to climate protection, in the context of a highly complex urban area.

A survey of the population of different countries has found that middle income countries tend to favor technological solutions while developed countries are more skeptical in this regard and people believe the solutions should come from changes in habits and individual behavior (Echegaray & Afonso, 2014).

Of great importance is the need to recognize that adaptation to climate change is also a social process, involving cultural aspects, beyond the economic strategies. Adger, Barnett, Brown, Marshall and O'Brien (2013) have demonstrated that the values adopted by the human groups can influence their interpretation of the problems, their motivation and their ways to respond and adapt to climatic risks; adaptation policies that ignore cultural aspects of the population affected by climate change can fail to increase the resilience of the targeted populations.

DISCUSSION

Infectious disease emergence in South America has been driven by different factors and these depend, in a large extent, on the life cycle of the causative pathogens, their arthropod vectors and animal hosts. Also important are the environmental settings where the infections develop: processes affecting strictly urban disease cycles (e.g. Dengue fever) are quite different from those found in foci historically rooted in pristine natural ecosystems. This is due to the epidemiological complexity of the latter, which can embrace a wider variety of competent hosts and vectors as well as be more influenced by environmental and climatic factors. On the other hand, in urban cycles new human infections usually depend on the massive exposure of the susceptible human population to a high burden of pathogens in the environment or to a high density of insect vectors (e.g. mosquitoes). In the case of vector-borne diseases, emergence is usually associated with environmental shifts, such as changes in temperature or rainfall, that create new ecological niches for both adults and immatures vector species. This applies to man-made environments, such as households and buildings (e.g. in Dengue fever) and also areas with natural vegetation, as in the case of Malaria (Travassos da Rosa, Pinheiro, & Vasconcelos, 2005; Vittor et al, 2009; Carbajo et al., 2012; Hahn et al., 2014).

Another important aspect is the biodiversity richness natural ecosystems. Pathogens circulating in wildlife, independent of the human host, can "spillover" and reach humans, following changes in the animal populations or encroachment of humans into natural systems, or both (Daszak, Cunningham, & Hyatt, 2000). Therefore, areas with rich assemblages of vectors and animal pathogens have a higher potential to support shifts in hosts and emergence of new human infections. In South America, one such region is the Amazon basin, which has the largest extension of tropical forests in the world and harbors

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a rich biological diversity. To date, more than 180 species of arboviruses were identified in animals and insects of the Amazon and around 30 of them infect humans (Gubler, 2002). A recent review has pointed out the role of changes of the Amazon environment, such as those linked to deforestation, road building and hydroelectric dams, in driving the emergence of parasitic infections in humans (Confalonieri, Margonari, & Quintão, 2014).

The Amazon region is one of the most vulnerable part of South America. Major projects in the area are impacting the natural ecosystems and causing alterations in land cover (e.g. forest conversion to pastures, dams), which present great opportunities for infectious disease emergence (Confalonieri et al., 2014). Encroachment to areas where endemic infections are present is also a cause of concern due to the risk of disease spread. For example, the construction of roads linking the Amazon to the Pacific Coast could facilitate the emergence of Bartonellosis – a disease originally restricted to the Andes Mountains – in lowland areas (Cesario & Cesario, 2005). International travel is thought to be the main mechanism involved in the most recently introduced viral infections in South America - Zika and Chikungunya viruses (Figueiredo & Figueiredo, 2014) - a mechanism already identified in other continents (Cordel, Quatresous, Paquet, & Couturier, 2006; Weaver & Reisen, 2010).

Specifically, in relation to disease emergence in the Amazon, monitoring and surveillance strategies necessary to tackle processes leading to regional disease emergence were discussed recently (Confalonieri et. al, 2014). An interdisciplinary approach comprising control measures and clinical management combined with an integrated international surveillance is needed to manage the environmentally driven changes in the disease dynamics in the Amazon in the near future. One important strategy would be to enhance regional epidemiological surveillance, especially to sub-regions where social-environmental modifications are occurring, as is mentioned in the "Amazon Malaria Initiative" (U.S. Agency for International Development [USAID], PAHO, 2010). The epidemiological impacts of environmental change in other parts of the South American continent could also be surveyed using the same association of interdisciplinary studies (parasitology, epidemiology, ecology, land use, climatology) and epidemiological surveillance in hotspot areas.

Further investigations in specific scientific areas - parasitology, epidemiology, climatology, geoprocessing, etc – should be pursued for a broader assessment of risks of infectious disease emergence in South America. Two topics deserve special attention. First, the role of cross-immunity of the population as a "barrier" to the introduction and persistence of new viruses to the region. Herd immunity for Dengue Fever viruses, endemic in this part of the world, could prevent taxonomically close viral species (e.g. West Nile Fever Virus) from becoming endemic in the human population. Cross immunity between different flaviviruses such as those causing dengue fever and the Zika virus is well known, a fact that makes the diagnosis of past infections with these pathogens using immunological tests more complex. Second, the significance of climate warming in the emergence of pathogens in the tropics. The potential to expand the distribution of vectors and enhance the transmission potential through alterations in the life cycle (e.g. shorter gonotrophic cycles and extrinsic incubation periods) of pathogens and vectors are likely to occur in temperate climates. However, in most of the tropics, suitable temperatures and humidity for endemic disease transmission are readily available and global warming may not be a critical factor in epidemiological shifts in this region.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

Infectious disease emergence in Latin America, as a consequence of environmental changes, is a complex issue. A high diversity of natural ecosystems and a vast extension of still pristine environments are important sources of microbes that circulate in wild animals and insect vectors and can potentially spill over to the human population due to encroachment of habitats following human activities to expand infrastructure and promote economic growth. Besides changes in land use practices and in land cover, climatic shifts are also expected to facilitate the emergence of pathogens in South America in the next few decades. A high degree of human population density in urban areas in this continent poses an additional risk factor for disease emergence in this region.

KEY TERMS AND DEFINITIONS

Anthropic Environment: New spaces formed by human actions that transforms the natural environment, such as large cities and agricultural fields.

Arboviruses: Viruses transmitted to humans by hematophagous insects and that are kept in natural or urban environment by vertebrate hosts.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Emerging Infectious Diseases: Diseases that had never been detected in humans before or which have affected a very small number of people in isolated places, such as Hantavirus Pulmonary Syndrome.

Epidemics: A higher than expected incidence of a given disease, when compared to the historical average, that occurs in a short period and in a specific geographic region.

Infectious Diseases: Diseases caused by pathogenic agents such as bacteria, protozoa and viruses that can spread from one individual to another, directly or indirectly.

Peridomiciliary: Spaces or environments surrounding human habitation, like backyard, henhouse, pigsty and barn.

Re-Emerging Infectious Diseases: Diseases that have affected large populations (worldwide or in specific countries) in the past, but were controlled and, at the present, they reappear as a major public health problem, such as Dengue Fever and Malaria.

Vector-Borne Diseases: Infections transmitted by the bite of blood-sucking arthropods such as mosquitoes, midges and bugs.

Chapter 64
Information Need and Seeking Behavior of Farmers in Laduba Community of Kwara State, Nigeria

Femi Titus Akande
Librarian, Nigeria

Akinade Adebowale Adewojo
Nigerian Stored Products Research Institute, Nigeria

ABSTRACT

The chapter present the report of a study that examined information needs and seeking haviour of farmers in Laduba community, Kwara State, Nigeria. This study adopted a survey research design using simple sampling technique to select 28 respondents from the population. Structured questionnaire was designed for the collection of data. It was discovered from the findings that majority of the farmers were illiterate of the middle aged group between 31-40. The farmers plant many crops, but it is noticeable that the farmers plant cassava mostly, the area which the farmers indicated they need information most is on agriculture, it was also observed that the farmers access information from colleagues (co-farmers), friends and relatives, agricultural extension workers. The information needs of the farmers in this study on agriculture includes how to prevent diseases for their crops on the farm and after harvesting, the farmers also stated that they need information on how to seek for loan, where to get the best market to sell their farm produce and how to get the best agro-chemical for effective use. In this study it was discovered that the challenges the farmers face in acquiring information includes, the inability to read and write in English language, lack of constant electricity supply, conflict among members of various associations and lack of access to agricultural extension workers. It is recommended that the farmers should be given effective adult education, provision of information centre with necessary personnel and information media to boost information accessibility. Also the government was encouraged to negotiate with mobile telecommunication operators to subsidize services so that the farmers who form majority in the rural areas can access information and communicate easily through their mobile phones.

INTRODUCTION

Information is quite indispensable to the progress of any business (Aziagba & Okede, 2011). The case of farmers is not an exceptional. Availability, accessibility of timely, concise and accurate information is a tool that has the capacity to reduce uncertainty. Hence it is an important resource in an economic planning and other life endeavor.

According to Swanson, (2008) information needs assessment give programme designers the ability to develop interventions that target users with specific information needs. (Swanson & Rajalahli, 2010) explained that the level and effort to search for information either local, national and global information depend on the aspiration of the searchers and the authors added that farmers' ability to search for information depends on the sources that are available to them. Hence, it is expected that local information needs of the farmers could be met by well-organized information acquisition and dissemination system that uses traditional and modern methods.

In Nigeria, according to (Okunade & Williams, 2014) quite a number of Nigerians are rural farmers living in small farming communities. In line with Okunade's view, Laduba is one of the Nigerian rural communities dominated by farmers. The community is subdivided into smaller clans and budoagun which has highest concentration of farmers in the community is one of them. The farmers' population in this community is about 500, it is located in Asa Local Government Area of Kwara State, Nigeria. The farmers in this community practice subsistence agriculture, which (Okunade & Williams, 2014) described as small scale farming using simple implements like hoes and cutlasses to meet the farmer's household needs and with very little for sale.

However, the advantage of availability of vast land in Laduba community and its nearness to Ilorin, the Kwara State capital made the community to attract different categories of elite who wants to engage in farming from Ilorin. In view of its strategic location, the community was selected as an adopted village by Nigerian Stored Products Research Institute (NSPRI), a Research Institute with the national mandate to research into post-harvest management of agricultural crops. Hence, the Research Institute do give her developed technologies through research to farmers at Laduba to use, while personnel from the Institute do regularly visit the farmers using the technologies to determine the efficiency of their research work. This further made Laduba community an attractive farming and research environment.

STATEMENT OF PROBLEM

Nigerian farmers are essentially rural dwellers; they live their lives based on their experiences and traditions that have been passed to them. However, the desire to increase productivity and make a better living through farming is making the scope and source of information required to extend beyond experience and tradition, so, it is observable that farmers now appreciate other sources to get information to improve their life, hence, there is a need to identify these sources and the type of information they get, so that their usage could be maximized or discouraged to enhance the productivity of farmers in Laduba and other similar communities, because without farming, man's existence on the earth would have been a mirage rather than reality (Okunade & Williams, 2014). This study therefore wishes to further support existence of farming and increase in productivity of farmers through determination of information required by them to enhance their productivity.

LITERATURE REVIEW

Effort had been made through different studies to determine information needs and information seeking behavior of different groups of people and professionals. Momoh, et al. (2015) conducted a study on information seeking behavior in central hospitals in Delta State, Nigeria. The study showed that nurses needed information to carry out their professional duties like health development and current approach to medical treatment. Friends, colleagues, libraries and internet were the identified sources where the nurses got their information.

(Aziagba & Okede, 2011) conducted a study on information seeking behavior of cassava farmers in Upata clan, Ekpeye community of Rivers State of Nigeria. The study confirmed that friends and colleagues are major sources of information for the cassava farmers. Discussion over the radio broadcast were equally strong source of information for the cassava farmers, most especially when it is broadcasted in their languages. The library, seminars, workshops and television broadcast, were revealed as sources where cassava farmers do not get needed information. The findings, equally established that these cassava farmers are still involved in sourcing for information mostly from friends and relatives within the locality.

In the study conducted by Babu, et al. (2012) on information needs and search behavior among farmers in Tamil Nadu, India, the authors grouped the different information sources accessed by farmers into four searching groups based on type of medium which include: print, broadcast, electronic and interpersonal. The findings showed how searchers relied on interpersonal sources such as imprint dealers, state department of agricultural extension workers, family and relatives. Semi medium searchers, according to the authors, accessed all media with most of them using electronic sources. High and medium searchers are revealed to also get information through print and broadcast media. Irrespective of the source used by farmers to obtain information, Babu, (2012) highlighted that the major constraints to information access were poor availability and unreliable information. Also, noticeable constraint that cut across was lack of awareness of information sources available and untimeliness of information the farmers do get. Saravan R. et al (2008) carried the study on information pattern and information need of the tribal farmers in Arunachal Pradesh, India indicated that most of the farmers need information on various topics such as pest management, disease management. Tologbonse D, et al. (2008) carried the study of information need of rice farmers' community in Niger state disclosed that majority of farmers need information about crop production. Meitei & Devi (2009) also conducted a study with farmer's community in Manipur, India to find out the information need of rural farmers' community in Manipur state. This result of the study shows that majority of the farmers did not get access to needed information for their activities. Hence, the farmers requested that ICT based agricultural information support systems should be developed for them. Byamugisha et al. (2009) conducted a study on information seeking and use of urban farmers in Uganda, the researchers found out from the study, that the information needs of the urban farmers in studied area seemed to be as varied as the farming activities and also appeared to vary from one urban farmer to another. Achugbue & Anie, 2011 carried the study in Delta State, Nigeria on Rural Female farmer's information need and importance of ICT in delivering information needs of female farmers. The findings from the research shows that the female farmers do not have enough skills to access information through ICT. Akanda & Roknuzzaman Md (2012) surveyed agricultural information literacy of 160 farmers in the northern region of Bangladesh. The survey shows that farmers need information for various purposes of agricultural activities, and they use different sources and media to access information. The researchers, therefore concluded that conceptualizing information need is a very difficult task. This is because the needs of individuals usually vary from time to time due to several factors.

UNDERSTANDING INFORMATION SEEKING BEHAVIOUR OF USERS

According to Wilson (1999, 2000), information-seeking behavior includes those activities a person may engage in when identifying his own information needs, searching for such information in any way, and using or transferring that information makes up the processes of information seeking behavior of an individual. Kakai, et al., (2004) have defined information-seeking behavior as an individual's way and manner of gathering and sourcing for information for personal use, knowledge updating, and development. This author explained further that information-seeking behavior of students, researchers, and professors has been the focus of enquiry for decades. He added further that initially, user studies were conducted in libraries and information centres primarily to evaluate library collections. These were said to be followed by studies of the research on habits of individuals or groups that would lead to the design of appropriate information systems and services. According to Kakai, et al., (2004) in mid 1980s, the focus of research shifted to holistic approaches to information-seeking behavior. However, Adereti, et al, (2006), and Aina, (2004) described information need as a piece of information, whether recorded or not, which an individual or a member of a group requires for effective functioning in their daily activities. Information needs can be seen as a set data which enables the user to make appropriate decisions on any related problem facing him or her at a particular time (Solomon, 2002).

In other words, information is needed because it enables individuals to make a decision that affects their living, just as Opeke, (2004) suggest that information represents an ordered reality about the nature of the world people live in. The need for information in any society is individualistic. Individuals need information depending on the motive for such information. Taking the right decisions depends on access to information on all the alternatives and their implications (Ajayi, 2003). Zhang (2001) is of the opinion that a thorough understanding of user information needs and information-seeking behavior is fundamental to the provision of successful information services. Anwar (2007) also reiterates that it is important to understand the information-seeking behaviours of different groups of people, as it helps in the planning, implementation, operation, designing of new information systems and the development of service programmes in the work environment for optimal performance. According to Line (2000), new studies of information users and their needs are even more necessary in the age of the Internet. Researchers such as (Callison, 1997, Devadason and Pratap, 1997, and Ellis, 1993) have explored quantitative and qualitative methodologies for user studies on how Information-seeking behavior differs among user groups. Librarians must understand the information needs of user in order to address those needs. This study explores the information-seeking behavior of farmers. Knowledge about the information-seeking behaviour and information use of individuals is crucial to effectively meet their information needs. The first basic user study in the broader sense was undertaken by Menzel in1966 and he defined information seeking behavior from three angles and they include; when approached from the point of view of the scientists or technologists, these are studies of scientists' communication behaviour; when approached from the point of view of any communication medium, they are user studies; and when approached from the science communication system, they are regarded as studies in the flow of information among scientists and technologists.

MODEL ON INFORMATION SEEKING

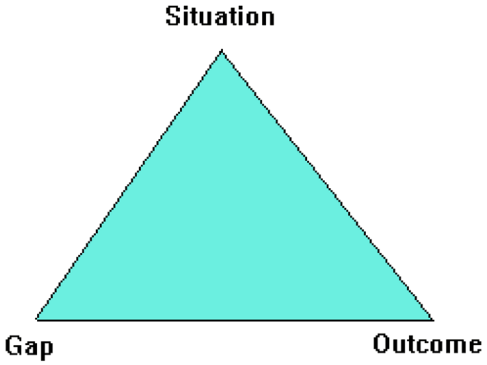
The Information seeking behavior is sub-discipline within the field of library and information science. It describes how people need, seek, manage, give and use information in different contexts. It may also be described as information-seeking behavior or human information behaviour. Information carriers may be in different forms based on the ISB and information-needs studies of various groups. The Information carriers may include a variety of channels, a variety of sources within the channels, and a variety of messages contained within these sources Johnson et al. (2006).

Wilson (1981) has noted that the information seeking results from the recognition of some need perceived by the user. The behavior may take several forms, such as demanding information from the library or from other people who know. The approach has however been criticized because of insufficient theories, concepts and research methods, and because it has not taken into consideration the needs of the information seekers (Dervin & Nilan, 1986; Wilson, 1994). Dervin illustrated information seeking behavior diagrammatically as shown below, illustrating it triangularly with situation for seeking for information at the peak, the base of the triangle has the gap and the outcome sections. The situation, is the information needed or being sought for, the gap is the challenge in retrieving or searching for the information and the outcome is the result of the whole process. However, Dervin explained this process further by using the illustration in Figure 2, according to him, it may be preferred to use the bridge metaphor more directly as presented in the model. The model revealed that the process of seeking for information has a bridge between the situation and outcome, which spans between time and space, which implies that the process of seeking for information has no time limit

Meho & Tibbo (2003) revise Ellis's study and give new model with more features. Among the researchers, Kuhlthau (1993) has conducted empirical research about students' information seeking behavior and developed a general model of the information search process (ISP). The ISP consists of 6 stages as: initiation stage, selection stage, exploration stage, formulation stage, collection stage and presentation stage.

Wilson (1999) believes in the strength of Ellis' and Kuhlthau's models as they are based on empirical research and have been tested in subsequent studies. Wilson, however reviewed Ellis model and created an illustration, it is diagrammatical explained in Figure 3.

Figure 1. Dervin's 'sense-making' triangle



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Dervin's 'sense-making' model re-drawn

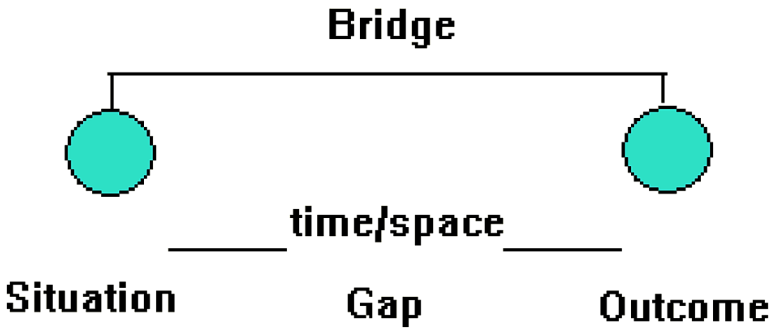


Figure 3. Wilson's information behaviour model

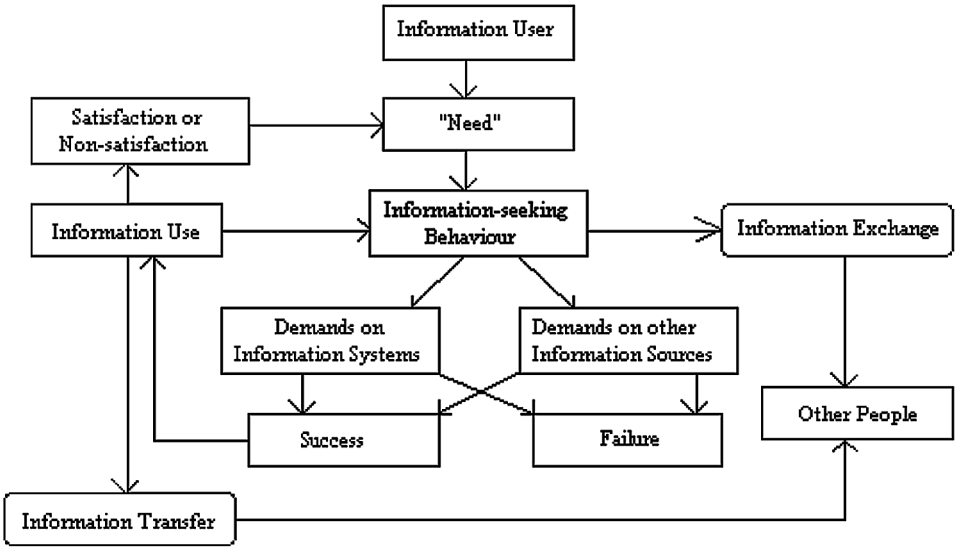
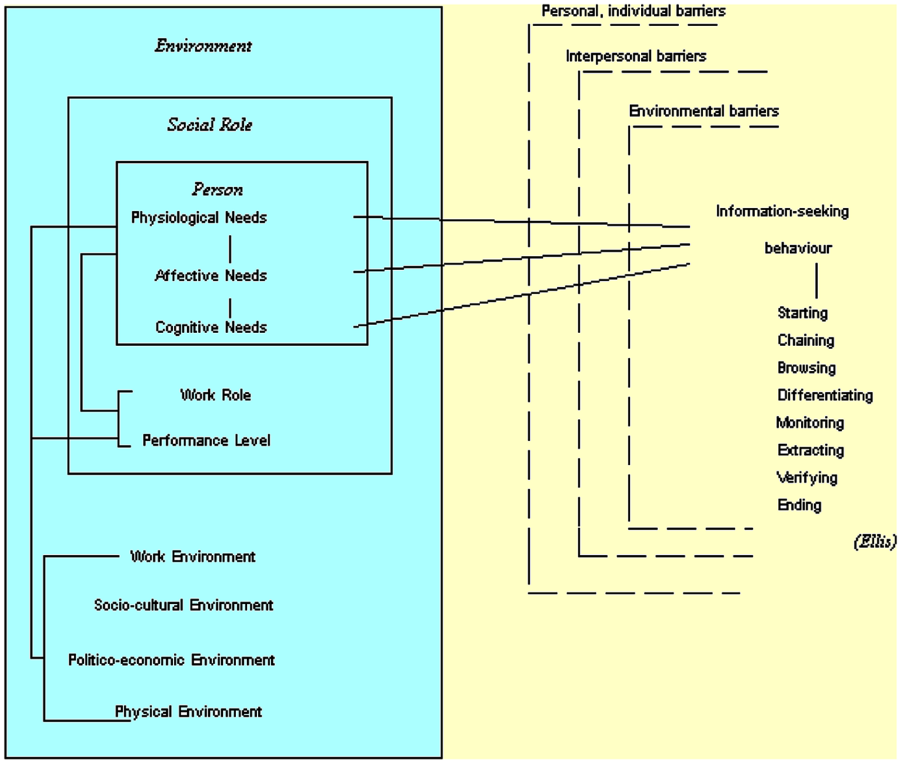


The aim of Wilson's model was to outline the various areas covered by what the writer proposed as information-seeking behaviour, as an alternative to the models indicated in Figures 1 and 2, but it is clear that the scope of the diagram is much greater and that it attempts to cover most of what is included here as information behaviour. The model also shows that part of the information-seeking behaviour may involve other people through information exchange and that information perceived as useful may be passed to other people, as well as being used (or instead of being used) by the person himself or herself. The limitation of this kind of model, however, is that it does little more than provide a map of the area and draw attention to gaps in research: it provides no suggestion of causative factors in information behaviour and, consequently, it does not directly suggest hypotheses to be tested (Figure 4).

Hayden (1999) has studied the different information seeking models like Wilson's model of 1981, Krikelas model of 1983, Kuhlthau model of 1992, Big Six Skills model of 1992 proposed by Eisenberg and Berkowitz. The author says that we need to question who the library community is; we also need to question how we can provide information skills that leads the students towards information literacy. Borgman (2000) defines information seeking as a continuous process, involving active and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Wilson's information-seeking behaviour model



passive behaviors, and formal and informal communication. She points out the cycle of creating, using and seeking information which can be viewed as series of stages which people move back and forth, and they may be actively, creating, using and seeking information concurrently. Therefore, information seeking behavior refers to the pattern of response to the information need by person or group of persons. (Jarvelin & Wilson, 2003) discuss the functions of conceptual models in scientific research, in IS&R research in particular. What kind of models are there and in what ways may they help the investigators? What kinds of models are needed for various?

Loeber and Cristea (2003) have made an attempt at investigating, analyzing and modelling the visitor and website. Weiler (2004) observes that the first model for study of information-seeking behavior in the general population was developed by James Krikelas in 1983. This model suggestes the steps of information seeking as follows:

1. Perceiving a need,
2. The search itself,
3. Finding the information, and
4. Using the information, which results in either satisfaction or dissatisfaction.

Based on Krikelas' model, people begin to seek for information when they perceive that the current state of knowledge is less than that needed to deal with some issue (or problem). Butterworth (2006) argues that typically Information seeking and retrieval behaviour is a strongly social, but weakly collab-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

orative leisure activity. He discusses how these assumptions fit with the existing information seeking and retrieval (IS&R) models and proposes path for future work. The author touches on the browsing behaviour and searching behaviour and has made a sketch of the characteristics of 'personal history' researchers.

Shah (2008) proposes a model that helps us to understand the requirements for a successful collaboration. The author attempts to formalize the notion of collaboration and proposes a model of Collaborative Information Seeking (CIS) that put collaboration in perspective. His model consists of four layers such as information, tools, user and results.

Of all the models, Ellis model is very much applicable to the 21st century mode of seeking for information, it is in this mode that we adopt the Ellis model on information seeking behavior. Ellis et al. (1993) model on information seeking behaviour includes six generic features. (Ellis & Haugan, 1997) have attempted to propose and describe the characteristics of a general model of information seeking behaviors based on the studies of the information seeking

patterns of social scientists, research physicists and chemists, engineers and research scientists in an industrial firm. Ellis's elaboration model describes the features of information seeking activities as generic. These features are: Starting, Chaining, Browsing, Differentiating, Monitoring, Extracting, Verifying, Ending.

- **Starting:** The means employed by the user to begin seeking information, for example, asking some knowledgeable colleague;
- **Chaining:** Following footnotes and citations in known material or 'forward' chaining from known items through citation indexes;
- **Browsing:** 'Semi-directed or semi-structured searching' (Ellis, 1989: 187);
- **Differentiating:** Using known differences in information sources as a way of filtering the amount of information obtained;
- **Monitoring:** Keeping up-to-date or current awareness searching;
- **Extracting:** Selectively identifying relevant material in an information source;
- **Verifying:** Checking the accuracy of information;
- **Ending:** Which may be defined as 'tying up loose ends' through a final search.

INFORMATION SEEKING IN DIGITAL LIBRARIES

Digital Information Resources

There are various researches have been conducted on information seeking of digital information resources by different researchers around the world. In 2013 Gakibayo et al. carried out a study at Mbrarar University Library Uganda regarding the use of digital information resources by university students. Results were tabularized and it shows that a large number of respondents were aware with the full use of technology in utilizing digital resources. Natarajan et al. (2008) revealed the users of Annamalai University library were aware of digital journals only among all the other digital resources and 50% of the users are fulfilled from digital resources and it was also observed that digital journals were only source used comprehensively by users and the digital dictionaries and digital encyclopedias were the digital resources with the least usage. The study tells that users are not well aware with the provided resources and they cannot identify their actual need properly because of which the satisfaction is below

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

average. The use of internet based digital resources at Manipur University, India. This study identified the utilization, rationale, difficulties and satisfaction level of users about internet based digital resources services provided by the library and they conclude that low speed internet, irregular power supply and lack of required full text journals. According to findings the use of internet based digital resources by the students of Manipur University is not found very significant. The reason might be those problems which they are facing while accessing these resources (Singh, et al., 2007). In 2008 a survey was completed by H.R. and Mudhol was completed a survey at College of Fisheries, India. The research study revealed that respondents were highly satisfied about the level of access for the use of digital information sources. The study confirmed that the digital information sources users are very satisfied with their retrieved results and as the sample is limited to faculty, research scholars and post graduate students to the main reason for using digital information sources is the research in which they are currently involved. It seems that they are well aware with the usage of such digital resources. Mostafa (2013) carried out a survey at some selected private universities of Bangladesh about the use and impact of digital resources. According to results, majority of the respondents gave preference to digital thesis among all other digital resources likewise digital books, digital newspapers and digital magazines. The study exposed the fact there are sufficient digital resources available in the campus and students use those digital resources frequently but is need to modify infrastructure and training courses as well. Okiki et al. (2011) had conducted a survey in Nigeria to determine the use of digital information sources by post graduate students in Nigeria. Results showed that a large number of respondents use digital information sources daily they are motivated to use digital information sources for their research projects. According to tabulated results show connection in a major problem faced by the respondents. The post graduate students in Nigeria are being motivated for the utilization of digital information resources because of which the use of digital information is found extraordinary among them. Information Needs: Fabritius (1997) investigated the information seeking behaviour of journalists. The main purpose of the study was to investigate the role of digital information in journalism, how journalists use latest information technology and how new digital technologies sustain news reporting. The journalists' information searching behaviour was examined by means of major hierarchical aspects. Fabritius places information seeking and salvage into a wider framework which have an effect on the loom to information sources and application of information.

Digital Information Seeking Behavior

Research in the domain of information needs, information seeking and information seeking behaviour started in early twentieth century. Whereas tracing the history of information seeking and behavioral studies, few studies were carried out in the early 1900s, Ayres and McKinnie in 1916 revealed the information seeking at the Cleveland Public Library. Tibbo informs that a distinguished production of studies on the subject take placed in the 1960s [e.g. a study by the American Psychological Association, 1963 -1969 and Earle and Vickery's study in 1969]. Wilson (2000) discovered an early importance on the use of information systems with a more person-oriented approach growing later in the 1980s. Although early user-centred research concerted on the scientific community, it rapidly expanded to integrate educational institutions to investigate students and staff's actions and inspirations when using the technology. According to Francis (2008), "Researchers and practitioners in the field of LIS have long held an importance in the information-seeking behaviour of diverse patron groups. Research in this part dates back to the 1940s and the deliberate was on scientists." Since then, studies rapidly improved, preliminary with those proposed to get better collection development, followed by folks that investigated

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the research behavior of individual's approach that observed the system as seen by the user Studies on web information seeking behaviour emerged afterward, and many pen down the mid-90s as the exact initial point. Jansen & Spink (2004) propose that the most primitive studies of web searching behaviour in the mid -90s occurred as web search engine and web browser use began to grow, mainly in academic environments. Author discovered the behavioral outline with special reference to electronic databases and the World Wide Web. Different models of information seeking behaviour were presented and the complexities in the procedure of searching were explored. These researches offer insight into the seeking behaviour in the course of electronic systems (Wilson, 2006). Asemi (2005) agreed to understand the information searching habits of internet users at the Medical University of Isfahan. The purpose of the study was to examine the position of information searching character of the users on internet. Data was collected using a questionnaire trailed by interview with users from five faculties. 188 users responded to the study. Study revealed that students use internet extensively, and it inhabits an important position with diverse sources. Study also revealed that electronic media has not substitutes print media. A study of Brazilian social sciences scholars found that, while print resources are still the most frequently used, electronic resources are becoming more and more accepted. Access to networked computers is the main barrier to the use of databases and other electronic resources. Francis (2005) focused on a study that explained the information seeking behavior of social sciences faculty at the University of the West Indies (UWI). One of this 2005 study's findings was that social scientists have a preference journal articles in electronic format over print. Wang (2007) wrote about disciplinary and cultural differences among information seekers in the Internet age, concluding that there are distinctions across disciplines and cultures in terms of how they rank the importance of these resources and how much they use them. Wang further discussed the information needs, information-seeking behaviors, and resource use of selected special interest groups. Electronic Information retrieval skills as noted by Tsakonas & Papatheodorou (2006), digital libraries, e-journal platforms, portals, e-prints and other web-based information systems provide services supporting users to perform intense work tasks that require complex interaction activities. This implies that users cannot access e-resources without adequate computer skills. According to Toner (2008), advances in technology have made possible virtual classrooms, online courses, and distance learning. This, coupled with the growth in society's access to information via ICT, has altered student perceptions of what the library has to offer. If libraries are to maintain their relevance in the cycle of student needs, then they must adapt and change (Toner 2008). MacWhinnie, (2003) and Thachill (2008), argue that students sometimes lack technical and research skills and so do not find the best and appropriate information, tempting them to use whatever information they can find first, fast and full text. More importantly, even with a good easy to use integrated system, students very often need the expertise of a librarian to apply search techniques and find the information they need (Thachill 2008). Tella et tal (2007) argued that the students' ability to find and retrieve information effectively is a transferable skill useful for their future life as well as enabling the positive and successful use of the electronic resources whilst at school. They noted that in this digital era any student at the higher level who intends to better achieve should have the ability to explore the digital environment. Students are increasingly expected to use electronic information resources whilst at the university. To make use of the growing range of electronic resources, students must acquire and practice the skills necessary to exploit them (Okello-Obura & Magara, 2008). Skills learning is essential in a technology driven environment but can be enhanced tremendously through the use of innovative learning strategies (Lawson 2005). Ray & Day (1998) suggested that the skills required to access the maximum potential of electronic resources are much greater than those required for searching printed sources. These skills include knowledge of the structure of the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

database and the instructions which must be input into the computer by the searcher – as well as an understanding of the ways in which the instructions are linked to one another. Okon (2005) asserts that the core skills traditionally associated with information professionals, which include information handling skills, training and facilitating skills, evaluation skills and concern for the customer, are all still relevant. The ability to find and retrieve information effectively is a transferable skill for enabling the positive and successful use of electronic resources by students while they are at university - as well as in their future lives. As Brophy (1993) argues, libraries must "reach a position where the acquisition of information skills is acknowledged as one of the key learning objectives for every student entering a university, so that no student leaves without being fully equipped to cope up with the information intensive world – the information society - as an end-user." The library has not only ready and free information highway, but also the adequate and efficient information transport means, which allows the readers to use the tools and obtain the information they need (Shuling, 2007). The literature highlights the advantages of electronic over printed sources of information, but also suggests the need for certain skills in order to access and use electronic resources effectively. Given their apparent lack of use of electronic resources, this study set out to determine if LIS postgraduate students at Makerere University have the required skills and ability to access and use electronic resources.

Why Electronic Information Resources?

Higher education is changing rapidly with the advent of technology. According to Shuling (2007), in recent years, electronic information has gradually become a major resource in every university library. The growth and diversity of electronic resources, especially e-journals, in the past few years has led many to predict the extinction of the printed journal (Okello-Obura & Magara, 2008). It has been suggested that a new paradigm is sweeping scholarship (Liew, Foo and Chennupati, 2000; Harper et al, 2006). Majid et al (1999) argue that technological advancements opened up new horizons for the creation, storage, access, distribution and presentation of information. In the global information communications technology (ICT)-dominated world, "place" is much less important (Ferguson, 2006). "The impact of moving from text-based to resource-based learning has involved heavier use of library materials and a demand for more and varied media sources" (Kinengyere, 2007). This makes the provision and use of Electronic Information Systems (EIS) in academic libraries a critical issue for those working in information and library services (Armstrong....et al, 2001; Elam, 2007). The pace at which information resources are being produced and converted into an electronic form is greater today than in previous years (Armstrong ... et al 2001). In today's information age it would seem that library users would not only be eager to take advantage of the convenience electronic resources have to offer, but would be fully immersed in the new technologies (Elam 2007). Electronic information resources offer today's students different opportunities compared to their predecessors. Liew, Foo and Chennupati (2000:302) argued that while reading an e-journal is not the same as reading a printed one, many are beginning to acknowledge the possibility that electronic documents (e-documents) offer users advanced features and novel forms of functionality beyond what is possible in printed form. Years ago Brophy (1993), noted that the advantages of electronic resources over print include speed, ease of use, ability to search multiple files at the same time, ability to save, print and repeat searches, more frequent updating and the ability to access from outside the library (a particular advantage for the distance learner). According to Dadzie (2005), electronic resources are invaluable research tools that complement print-based resources in any traditional library. Their advantages include access to information that might be restricted to the user

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

because of geographical location or finances, access to current information, and provision of extensive links to additional resources or related content (Dadzie 2005). E-resources could be stored electronically thereby saving space, the risk of lost, theft or damage is lessened and costs significantly reduced. Attitude towards e-resources Academic libraries now live in a superior new world. The rapid advancement of Information and Communication Technology (ICT) has brought a revolutionary change in the information scenario giving rise to a number of options to the users' community to handle varied information sources conveniently and effortlessly. As a result, e-resources have become the lively substance to the modern library's reserves in satisfying varied needs of students, teachers, and researchers with minimum risk and time (Swain and Panda, 2009). For better planning, it is vital to have knowledge on the attitudes of users towards e-resources. Swain and Panda (2009), say the library users' attitude to information is gradually shifting from the printed documents to electronic resources and thus, it has been their prerogative to know the details of the availability and organization of e-resources like online journals and databases, electronic theses and dissertations (ETDs), government publications, online newspapers, etc. in libraries. Given technology increased use, it is important to understand how technologically rich environments are influencing student attitudes toward e-resources access. Many factors influence attitudes. The introduction of open access journals and other resources for instance is creating another attitudinal tendency towards e-resources. Open access is one of the cheapest routes to electronic resources and over the last few years' open access resources have grown and provided an affordable way to provide access to some journal content (Price, 2009). Supporters of open access argue that, when academic articles, dissertations and theses are put online and open to all, it helps in fighting duplication and plagiarism of other people's intellectual works. Although the open access movement has brought access to many valuable resources, and provided libraries with an invaluable amount of resources, many open access projects still face an uncertain future (Price, 2009). Many critics are not sure that the open access model can survive because some are not considered "financially viable" or as high quality as traditionally purchased or subscribed content (Robinson 2006; Shao and Scherlen, 2007; Turk and Bjork 2008). Where do LIS postgraduate students fall in this case? What are their attitudes towards open access electronic resources? Attitudes towards e-resources access could be attributed to problems faced when accessing e-resources. For instance, in a situation where there are inadequate computer technologies to access e-resources or poor Internet connections, student's positive attitudes could be affected. That is why the problems that affect e-resources access are addressed in higher learning institutions libraries. The arguments for students using electronic resources are compelling. An adequate knowledge of computers and retrieval techniques is desirable to search these resources effectively. It is necessary to establish what computer skills students require to access electronic information resources in libraries. Amidst all the efforts to access e-resources, LIS postgraduate students face a number of challenges. These are reported in another paper by the same author.

SCOPE OF THE STUDY

The study is limited to farmers that cultivate land in Laduba community. Other inhabitants that engaged in other trades and other forms of farming apart from tilling ground were not included.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Objective of The Study

The specific objectives of the study are to:

1. Identify the information needs of farmers in Laduba community of Kwara State.
2. Determine the source of information and their preferences with regard to sources available to them.
3. Identify constraints the farmers face while searching for information.

Methodology

The Laduba Community is located in Kwara State of Nigeria. They have various occupations, but the main occupation of the natives is farming. This study adopted a survey sampling technique. Structured questionnaire was designed as the instrument for data collection and was supplemented by personal interview with the expertise of the extension personnel of Nigerian Stored Products Research Institute (NSPRI). The population of this study is about 500 farmers who dwells in Budoagun Clan of Laduba community of Kwara State, Nigeria. The Budoagun clan is where this study is based, because the clan is a section of the Laduba community where farmers that cultivates land settled. To obtain information from the respondents, 40 copies of questionnaire were administered to the respondents while 28 copies were recovered and used for analysis. Agricultural extension workers from the Nigerian Stored Products Research Institute (NSPRI) were used as the research assistants to administer the questionnaire. The questionnaire was administered to the respondents who are mostly illiterate on one- to -one basis. The research assistants read the content of the questionnaire and the options available to each of the respondent and the answers from the respondents were reflected on the questionnaire. The questionnaire was divided into two broad sections. Section one deals with the bio data of the respondents. The other section has other units that examined the information seeking behavior of the respondents. The unit in the second section of the questionnaires are five and the sub heading of the units are arranged as follows from B to F respectively; types of crops planted, area of information needs, information need of farmers, medium of accessing information and challenges faced while seeking for information. Also the head of the community, noticeable leaders among the farmers and some youths were interviewed to compliment information gathered from the respondent through the questionnaire. Data collected for the study were subjected to analysis using frequency count, simple percentage and bar charts.

RESULTS AND DISCUSSIONS

Bio Data of the Respondents

- **Age of the Farmers:** The age of the farmers in the community of Laduba shows that 42.9% are between 31-40 years of age, followed by 32.1% of the respondents which is between 41-50 years of age, the research shows that 7.1% of the farmers are between 20-30 (Table 1 and Figure 5).
- **Gender of the Farmers:** From the result shown, 60.7% of respondents were male and 39.3% were females (Table 2 and Figure 6).
- **Mode of Farming:** In response to the mode of farming, it was discovered that 75% of the respondents are into fulltime, while 25% of the respondents are part-time farming (Table 3 and Figure 7).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Level of Education:** The level of education of respondents was grouped into non formal, primary and secondary. The response obtained shows that 50% of the respondents belongs to non-formal, while 35.7% attained the level of primary education, and 14.3% being the least attained the level of secondary education (Table 4 and Figure 8).
- **Size of Farm:** Majority of the farmers' size of farm ranges from 1-2 acres (60.7%), the other size of farm used by other farmers include 2-4 and 4-6 acres with both with a percentage of 17.9% (Table 5 and Figure 9).
- **How Frequent Do You Go to the Farm:** Asked about how frequent they go to the farm, 92.9% of the respondents say they go to the farm every day, 3.6% of the respondents goes to the farm weekly and another 3.6% goes to the farm monthly (Table 6 and Figure 10).

Information on Other Types of Farming Apart from Tilling the Ground

- **Type of Livestock:** In response to types of livestock reared if any, 46.4% of the respondents engage in goat rearing, 39.3% of the respondents are into poultry farming, the percentage of those who are engaged in fish farming, pig rearing and cattle rearing is on the low side with 3.6%, 10.7% and 10.7% of the respondents respectively (Table 7 and Figure 11)
- **Type of Crops Planted:** Majority of the farmers' plants cassava (71.4%), they also plant grain crops and melon with results stating 67.9% and 57.1% respectively, other crops planted include vegetables (50%), yam (42.9%), fruits (42.9%) and groundnut (32.1%) the least crop planted is rice (3.6%) (Table 8 and Figure 12)

Table 1. Age of the farmers

Age Range	Frequency	Percent	Valid Percent	Cumulative Percent
20-30	2	7.1	7.1	7.1
31-40	12	42.9	42.9	50.0
41-50	9	32.1	32.1	82.1
51 and above	5	17.9	17.9	100.0
Total	28	100.0	100.0

Time	Frequency	Percent	Valid Percent	Cumulative Percent
Everyday	26	92.9	92.9	92.9
Weekly	1	3.6	3.6	96.4
Monthly	1	3.6	3.6	100.0
Total	28	100.0	100.0	

Areas of Information Needs

Majority of the farmers stated that the area they need information most is on agriculture, about 89% of the respondents stated they needed information on agriculture, followed by education where 75% of the respondents also stated they need information in that aspect, about 71% of the farmers also stated they need information on health, 32.1% of the respondents stated they need information about community and rural development, 25% of the farmers said they need information on politics (Table 9 and Figure 13).

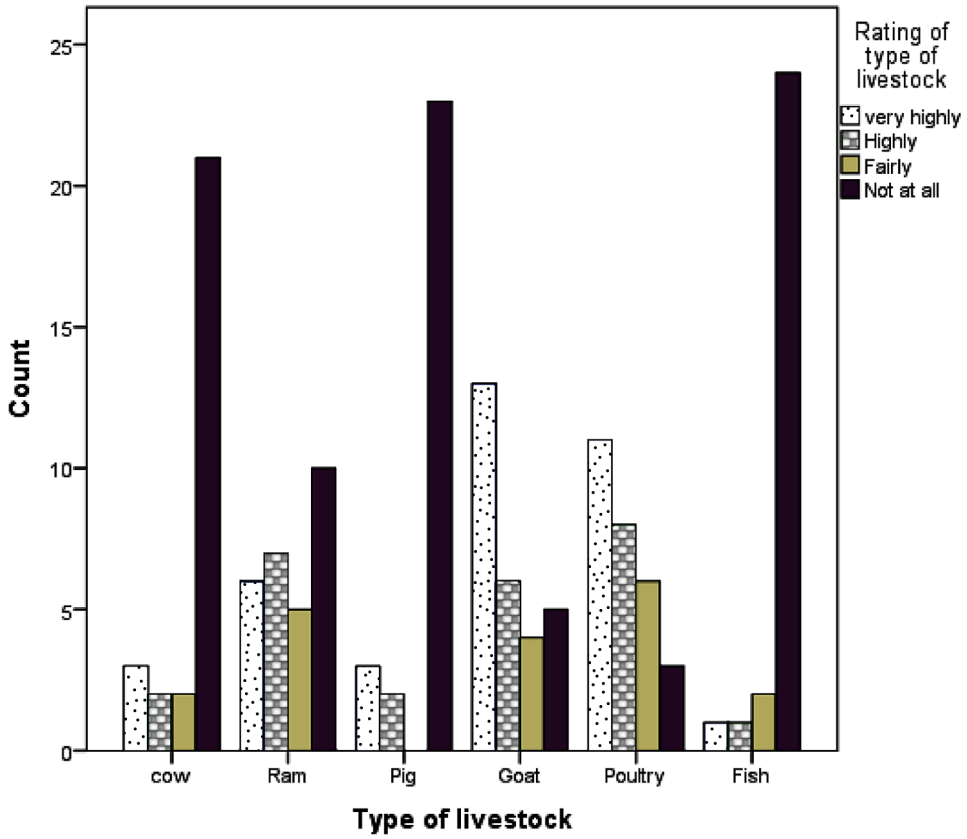
Information Need of Farmers on Agriculture

The information needs of the farmers on agriculture which is their major area of information needs are categorized into disease prevention, knowledge of price of farm produce in the market, source of loan for farming, how to obtain fertilizer, location of market to sell their agricultural produce, best mode of storage, labour cost and land maintenance (Table 10). 82.1% of the farmers agreed that they need to know how to prevent diseases affecting their farm produce. 64.3% of the respondents claimed they need information on how to get best price for their farm produce, 53.6% of the respondents indicated they need information on the best place to seek for loan. 71.4% of the respondents stated they need information on how to get effective agro-chemicals to apply on their farms. 64.3% of the respondents claimed they need information for more locations to sell their agricultural produce. 75% of the respondents indicated they need information on the best available mode of storage for their farm produce. 50% of the respondents indicated that they need information on how they can get labour to till the ground for them. 64.3% of the respondents claimed they need information on how to get tractors to clear their land for farming (Table 10 and Figure 14).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11.



Medium of Accessing Information

On the topic of accessing information, the farmers were asked orally whether they were aware of the presence of the information center and the library in their locality and if they used the places to seek information. The response from them shows that a majority are aware of the presence of the building but do not go there to seek for information. the response from the respondents from the questionnaire shows that, (see Table 11) 17.9% of these farmers' access information through the information center. 10.7% of the respondents were not aware of the information centre, 35.7% of the respondent who knew of the information centre occasionally use it. Another 35.7% said they don't use the centre at all. On information seeking behavior of the farmers, 57.1%, 60.7% and 60.7% of the respondents claim that they mostly collect information through their colleagues(co-farmers), friends and Association Members, respectively (Table 11). Further results showed that there are other sources where the respondents obtain information apart from the ones earlier stated. The usage of such other means like Radio, community heads, Extension Workers, Newspapers and Magazines by the respondents was 57.1%, 50%, 34.5% and 28.6% respectively. (Table 11). From the oral interview conducted with the respondents, it can be noted that the discussion over the radio broadcast was a strong information source. The respondents value radio broadcasts highly, especially when the broadcast is delivered in their local languages. As shown in (Table 11) seminars and workshop were not popular medium for gathering information by the

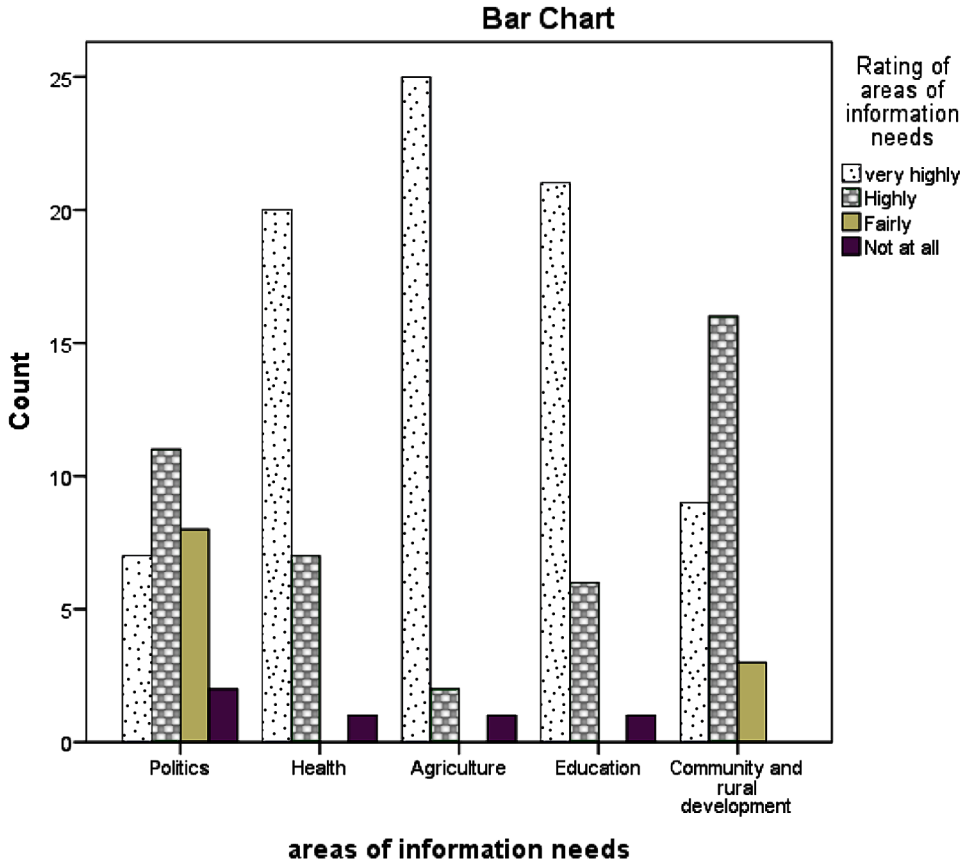
Figure 13.



respondents, only 25.9% of the respondents indicated that seminar and workshop had been a medium of getting information (Table 11 and Figure 15).

Challenges/Problems Highlighted by Respondents When Seeking Information

On challenges faced by the respondents when seeking for information (Table 12) shows that the most common problem the respondents experienced in getting information from other sources apart from their colleagues, friends and relatives is the inability to read and write, with 67.9% of the respondents indicating that they cannot read and write, hence they are constrained in using any information that is in English language. Availability of limited time after farm work is also seen as a constraint to farmers to seek for needed information 46.4% of the respondent agreed very highly to it, while 32.1% of the respondent also agreed highly to it, making a total of 78.5% of the respondents. also other challenges faced by the farmers; another noticeable constraint faced by the farmers is the lack of money to purchase airtime for their mobile phone to obtain information. 32.1% of the respondents agreed very highly to this problem, while 10.7% agreed to it highly and 32.1% said it is occasional and 25.0% of the respondents did not agree at all. Similarly, 39.3% of the respondents indicated that inability to use mobile phone is a challenge, with 14.3% of the respondents agreeing to it highly and 32.1% of the respondents agree-

Table 10. Information needs of farmers on agriculture

	Rating of Need of Farmers				Total
	Very Highly	Highly	Fairly	Not at All	
How to take care of livestock	57.1%	21.4%	7.1%	14.3%	100.0%
Best price available for my farm produce	64.3%	21.4%	10.7%	3.6%	100.0%
How to prevent diseases for my farm produce	82.1%	17.9%			100.0%
How to get loans	53.6%	28.6%	7.1%	10.7%	100.0%
Best fertilizer for my farm	64.3%	25.0%	10.7%		100.0%
how to marketing my farm product	64.3%	25.0%	10.7%		100.0%
how to store my farm produce	75.0%	14.3%	7.1%	3.6%	100.0%
Cost of labour in my farming	50.0%	32.1%	14.3%	3.6%	100.0%
How to get tractors to clear my land	64.3%	21.4%	3.6%	10.7%	100.0%
How to get agro chemicals	71.4%	21.4%	7.1%		100.0%
How to treat myself from ailments	64.3%	32.1%	3.6%		100.0%
Education of my children	57.1%	39.3%	3.6%		100.0%
Where to get good treatment for my health problem	57.1%	39.3%	3.6%		100.0%
Political situation of the local/ state/federal government	39.3%	42.9%	17.9%		100.0%
Available workshop and capacity building	50.0%	28.6%	21.4%		100.0%
Total	61.0%	27.4%	8.6%	3.1%	100.0%

ing to it fairly, we can say the inability to use mobile phones can be seen as a challenge to accessing information. Also, 32.1% of the respondents indicated that language barrier is a hindrance because from the oral interview, it is noticeable that most of the information available to the respondents from radio, newspapers and documents from government extension officers are written in English language. 39.3% of the respondents indicated very highly that lack of constant electricity is a challenge, while 32.1% of the respondents indicated highly, 25% of the respondents indicated fairly, 3.6% of the respondents did not see it as a challenge at all. From the oral interview, the constraint of electricity was attributed to contribute to their inability to charge their mobile phones, watch television and listen to radio broadcast, 42.9% of the respondents agreed very highly that the fear of going to urban areas to seek for information is a challenge, while 25% of the respondents agreed highly, 25% of the respondents agreed fairly, 7.1% of the respondents did not agree at all. 42.9% of the respondents claimed very highly that lack of reliable source of information in the community is a challenge to accessing information, 25% of the respondents agreed highly, while 21.4% of the respondents agreed to it fairly, while 10.7% of the respondents did not agree at all. The next variable is to confirm how satisfactory the respondents get access to government extension worker so as to get information on issues relating to their farm, the results shows that 17.9% of the respondents indicated very highly that they do not have access to extension workers, while 10.7%

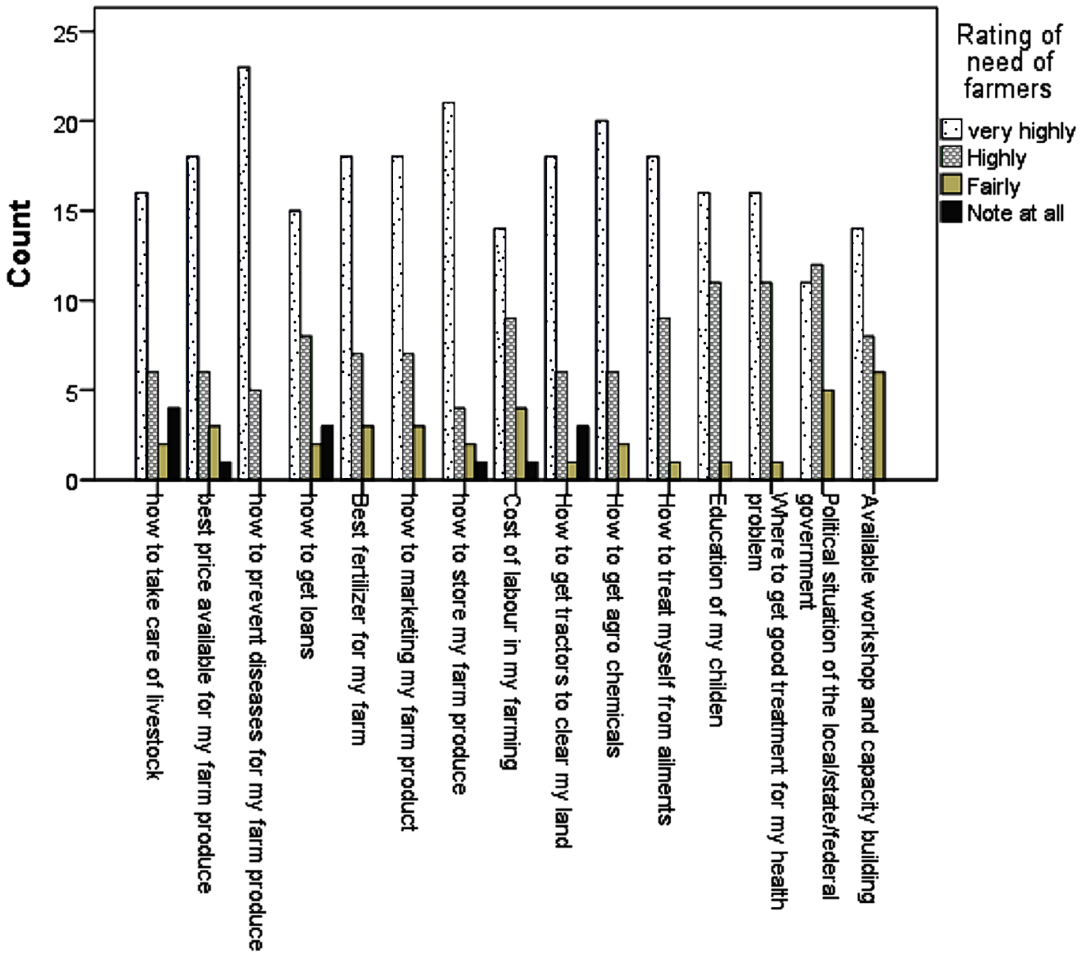
Figure 14.



of the respondents also agreed highly to it, 28.6% of the respondents also agreed fairly to it, while 42.9% of the respondents indicated that they have access to government extension workers. The study also tried to find out if conflict among various associations that exist in the community has ever been a hindrance to seeking information by the respondents, the findings in this case shows that 28.6% of the respondents indicated very highly that conflict among association of farmers can prevent information from getting to each other, 15.7% of the respondents agreed highly to it, 10.7% of the respondents agreed fairly to it, while 45% of the respondents did not agree at all. It could be observed that cumulatively, the conflict in association could be a hindrance to seeking and accessing information. However, despite all the identified problems, it is noticeable that about three of the variables does not constitute any hindrance to the process of accessing information to the respondents. For example, availability of network for mobile communication was not seen as a problem for getting information, only 25% of the respondents agreed very highly that lack of network for mobile communication is a challenge, while 10.7% of the respondents also agreed to it highly, 7.1% of the respondents agreed to it fairly, and 57.1% of the respondents did not agree to it at all. Similarly, body disability of any form was not accepted by the respondent as hindrance to seek information, from the analysis, 3.6% of the respondents indicated very highly that body

disability is a challenge, 10.7% of the respondents also agreed highly that it is a challenge, while 3.6% of the respondents agreed to it fairly. However, 82.1% did not agree at all that body disability hinders them from seeking information. The study also endeavored to find out if cultural difference among the farmers has been a hindrance to seek information, the respondents' response to this shows that 25% of the respondents indicated highly that cultural difference is a challenge faced by them in accessing information, 5.7% of the respondents also agreed highly, 15% of the respondents agreed fairly to it, however 54.3% of the respondents did not agree at all (Table 12 and Figure 16).

DISCUSSION OF FINDINGS

Information Needs of Respondents

Information on crops disease prevention, marketing agricultural products, agricultural loan and agro chemicals were the major information needs for farmers in the study area. This implies that farmers lack access to market information for their crops. This is consonance with Shepherd, (2000), who pointed out that information on, quantities traded, market prices and other marketing-related matters rarely reaches farmers in developing countries. Also, the study revealed that most farmers did not know where to get loans, similarly the study also indicated that the farmers need information on how to hire tractors to for land maintenance or purchase agricultural tools such as power tillers, which could be used to improve their agricultural productivity. Munyambonera et al., (2012) adds that availability and access to adequate,

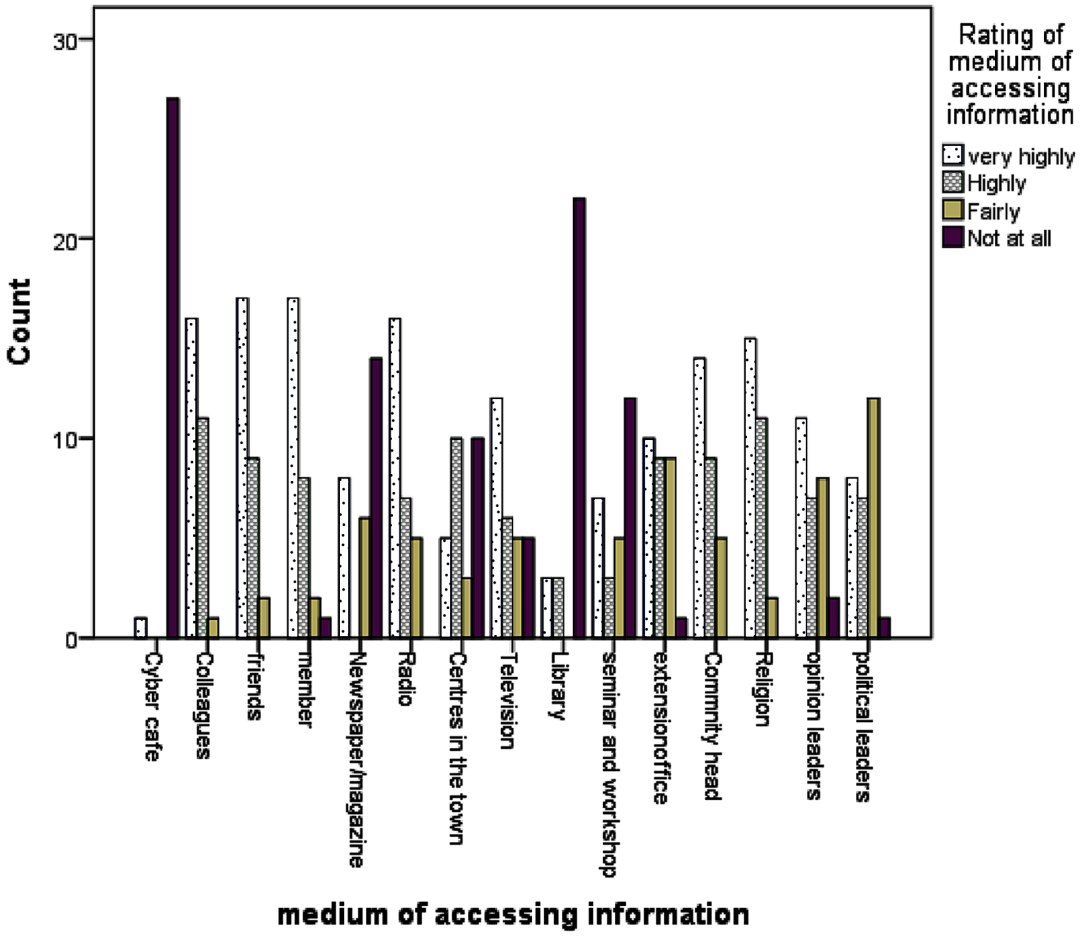
Figure 15.



timely and information on low cost credit from different institutional sources is of great importance especially to small and marginal farmers.

Medium of Accessing Information

Colleagues (co-farmers), personal experience, neighbors or friends and agricultural extension officers were the major sources of information used by the farmers in accessing agricultural information. The implication here is that most of the respondents relied on interpersonal sources in accessing agricultural information, probably because of their regularly availability and accessibility. Lwoga et al., (2011) for instance stressed that interpersonal sources such as friends, relatives and neighbours are all the time become the main providers of the agriculture information due to their credibility, reliability and most of all, they are trusted by the rural community. However, none of the respondents reported to use neither internet nor library and information centres in accessing agricultural information. This is probably because of low level of education, lack of electricity, lack of libraries or information centres in the rural areas, lack of of the role of internet in provision of agricultural information to farmers and lack of lack

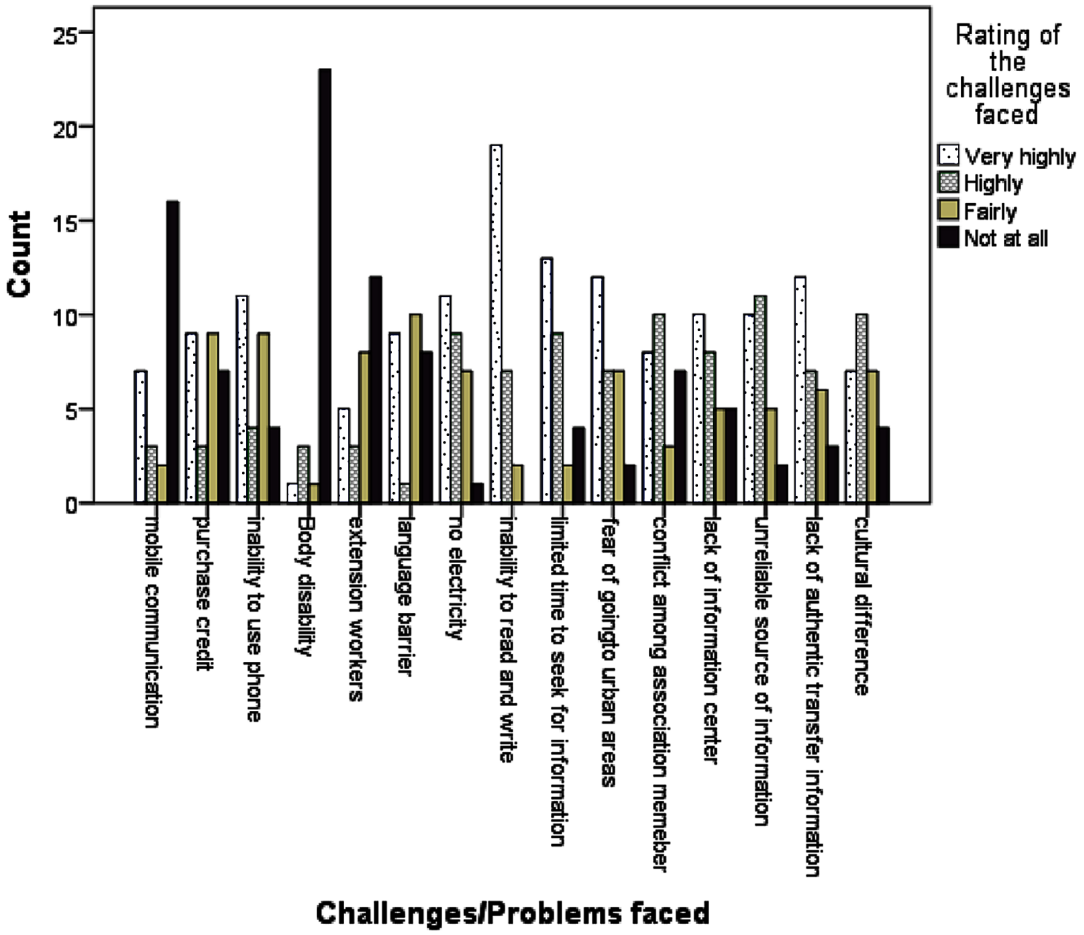
of ICTs infrastructure in rural areas. Finding of this study are not surprising as they are in line with what have been reported previously by Benard (2011), Mtega and Benard (2013); Shaffril et al. (2010) and Samah et al. (2011). For instance, have established a few reasons why farmers are reluctant to use advance technology in accessing agricultural information such as internet, and among the reasons are do not know the benefits of the advance technology; they are illiterates: do not have skills or expertise in using the advance technology; lack of time spent on ICT and difficulties in using ICT. This therefore, calls for the government to create enabling environment for the farmers to use this modern technology so as they can access timely and current agricultural information.

Challenges Faced by Respondents in Accessing Agricultural Information

The majority of the respondents cited inability to read and write in English language in the study area was one the challenges facing farmers in accessing information. Through the oral interview with the key informants and personal observation via the researcher it was noted that there were no information services available in the area of the study such as village/ward libraries and the information centre in the community is only present but it is not utilized by the farmers. This is a common problem in most rural farmers. Therefore, agricultural extension workers should regard it as a challenge and provide farmers with access to current and relevant agricultural information. The findings further revealed the inadequate numbers of extension agents as major challenges constraining farmers from accessing information. For instance, in the study, the farmers indicated that lack or non-availability of extension officers is a challenge. In view of this, they do not have enough information to access from the agricultural extension

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 16.



officers. This also is in line with what have been found by Aina's (2006) findings, which revealed that the ratio of agricultural extension workers to the population in Africa is low. Similarly, inadequate funds were another challenge hindering farmers from accessing agricultural information as it was pointed by majority of the respondents. Due to financial problems, some of the farmers cannot afford to buy airtime, also, due to lack of electricity, the farmers are usually unable to charge their mobile phones to access and communicate information. Therefore, agricultural information sources and services where they exist should be widely published and promoted, not only to create awareness but also to promote and encourage usage by farmers.

CONCLUSION

According to Sarah et al (2012) in recent decades the value of information has increased considerably as the agricultural systems in developing countries become knowledge intensive. Therefore, the need to determine how farmers access information, the medium they use and the constraint that hinders their free

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

access to required information is very important because like any other business farmers need concise, timely and comprehensive information to avoid loss of their farm produce, both on the farm and storage level, and also require appropriate environment to sell their produce for profit, all these and others are important factors to increase farmers productivity and consequently availability of food for citizens and sustenance of the nation. It is in this regard that this research is very important and findings can be of immense importance to guide research institute, state agricultural policy makers and international agencies who are also interested in the farming system in Nigeria.

RECOMMENDATIONS

It could be observed that from the age group, majority of farmers in laduba community are within the age range of 31-40, it is important that necessary incentives and encouragement is given to attract the youths of younger age to farming for availability of food for the nation.

It is noticeable that females form part of the farming population in Laduba, this is quite encouraging, for the population of the female to be improved, adequate access to information that will educate them and invoke their interest in farming is necessary.

The education status of farmers in in this study reveals that great percentage of them does not have formal education, only 14.3% of them had secondary education, this may hinder access to vital farming information from documentaries of national and international agricultural agencies. Hence, there is need for the farmers to be introduced to formal education through adult education programme on radio and television using the laduba information centre effectively.

From the study, the farmers significantly declared that information in agriculture is their major area of interest, therefore it is now important that all media that will assist the farmers to get concise, accurate and comprehensive information be made available to them. This may increase their interest in farming and consequently boost their economic level and consequently eradicate poverty among them and the nation in general.

Concerted effort should be made by government extension workers to provide the farmers information on how to prevent diseases on their crops on the field and also the best storage method for their farm produce, also they should be provided information on the best agro-chemicals to apply on their farm.

The information centre presently in the village should be improved for farmers to use it, human resource personnel that will promote its usage should be employed, the information center should have medium of disseminating information like radio and television and a well-stocked library could be developed in the centre, stocked with information materials to promote adult education programmes and enlightenment on different areas of farming. The documents acquired for these purpose should be in local languages and those written in simple understandable English language words.

The government should improve on the electricity in some of the rural areas including Laduba community and negotiate with operators of mobile communications, so that they can have subsidized airtime to communicate and receive information.

The group of extension workers like those from Kwara State Agricultural development project (ADP) and Nigerian Stored Products Research Institute (NSPRI) should interact effectively to give the farmers timely and necessary information they require and the extension workers should endeavor to sustain friendliness among the members of associations that exist in the community so that any conflict will not arise among them that will disrupt information sharing.

KEY TERMS AND DEFINITIONS

Community: A group sharing a common understanding and often of the same language, manners, tradition and law.

Farming: The act of cultivating land for the purpose of planting desired agricultural crops for sustenance of life and profit making.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Information: A processed data being searched for to use to enhance occupation and other things that sustains life.

Information Need: A piece of information, whether recorded or not, which an individual or a member of a group requires for effective functioning in their daily activities.

Information Seeking Behavior: An individual's way and manner of gathering and sourcing for information for personal use.

This research was previously published in Information Seeking Behavior and Challenges in Digital Libraries edited by Adeyinka Tella, pages 238-271, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 65
Congo Basin's Shrinking Watersheds:
Potential Consequences on Local Communities

Bila-Isia Inogwabini
Saint Pierre Canisius Institute of Agriculture and Veterinary Sciences (ISAV), Congo & Swedish University of Agricultural Sciences, Sweden

ABSTRACT

Rainfall time series data from three sites (Kinshasa, Luki, and Mabali) in the western Democratic Republic of Congo were analyzed using regression analysis; rainfall intensities decreased in all three sites. The Congo Basin waters will follow the equation $y = -20894x + 5483.16$; $R^2 = 0.7945$. The model suggests 18%-loss of the Congo Basin water volume and 7%-decrease for fish biomasses by 2025. Financial incomes generated by fishing will decrease by 11% by 2040 compared with 1998 levels. About 51% of women (N= 408,173) from the Lake Tumba Landscape fish; their revenues decreased by 11% between 2005 and 2010. If this trend continues, women's revenues will decrease by 59% by 2040. Decreased waters will severely impact women (e.g. increasing walking distances to clean waters). Increasing populations and decreasing waters will lead to immigrations to this region because water resources will remain available and highly likely ignite social conflicts over aquatic resources.

INTRODUCTION

Climate change is a scientifically established fact now (Walther et al., 2005), even though the magnitude of its multiple, diversified and multidimensional effects remain mostly in the domain of mathematical modeling. Discussions on the mitigation of climate change and adaptation processes (social, cultural and biological) remain at the core of scientific and political debates (Aiken et al. 1992; Fletcher, 1997; Fletcher, 2000; Hobbs & Knausenberger, 2003; Hughes, 1986; Inogwabini et al., 2006) because they are diversified and multidimensional, and will vary throughout the world (IPCC, 2007). The nature and the magnitude of these impacts have, however, yet to be described for different geographic environments

and locations. This is even more important for the tropical region of Central Africa where documented evidence is scanty (Halpin, 1998; Inogwabini et al., 2006; Sonwa et al., 2009). Informed guesses and mathematical projections convey the message that climate change's effects in Central Africa may range from drier conditions in areas adjacent to as deserts (Sahara and Kalahari) where water occurs in shortage to high floods in coastal habitats directly adjacent to oceans due to increased water levels as a result of the melting of polar ice (Halpin, 1998).

Unfortunately, however, long-term field data that can document changes which highlight the effects of climate changes over the past years are difficult to find for Central Africa (Edwards & White 2000; Pimm, 2007; Sonwa et al., 2009). Lack of data fosters the use of surrogate data that can predict the effects of climate variation in Central Africa. One of those surrogates has been the linking of phenological data to weather patterns (Tutin & White, 1998), direct measurements of water levels (Colombant, 2005), using direct meteorological data and looking at their trends (Inogwabini et al., 2006). The use of long time series meteorological data as a proper detector of the effects of the climate change is fully justified by the fact that if climate change will affect water level, then drier conditions in the terrestrial Central Africa region are, logically, linked to water cycles, especially rainfall regimes over the continent. However, continuous time series data on rainfalls are difficult to find in Central Africa to document the trends and extents of felt changes (Halpin, 1998). Furthermore, where there are continuous long time series data, the analytical capabilities have made it difficult to determine understandable trends that crude data can convey. Even less available are data on effects of climate change on local economies, health, security and biodiversity (Sonwa et al., 2009; Stern, 2007).

MAIN FOCUS OF THE CHAPTER

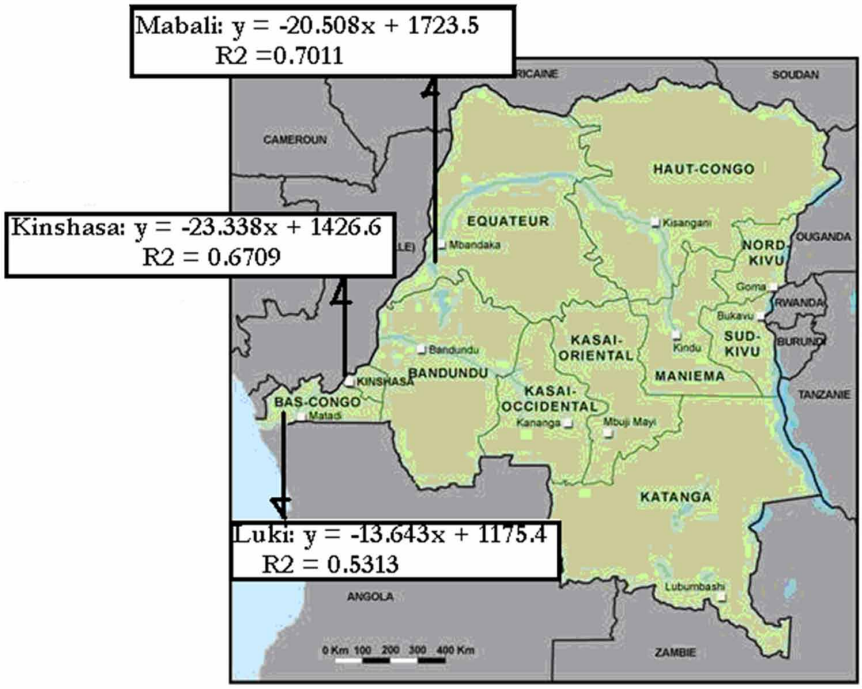
This chapter presents three long term data from three locations in the western Democratic Republic of Congo (Figure 1), with the aim of presenting these long time series data in a single analytical framework and discussing patterns that emerge from that analysis in the context of global climate change. The chapter links trends in rainfall and surface area Congo Basin watershed and projects potential effects of these trends to the level of the central Africa region. Combining these projected effects with field data freshwater resources, the paper discusses inferred effects on climate changes on local populations.

STUDY SITES

Rainfall data were collected from (1) Mabali, (2) Kinshasa and (3) Luki. Mabali is located near the equatorial line (Inogwabini et al., 2006). Located in the *Cuvette Central*, weather patterns are believed to be stable (Bultot & Griffiths, 1972). The Cuvette Central is a lowland, flat and heavily flooded equatorial region. It is characterized by *terra firma* forest (forest whose floor remains dry for most of the year), *swampy forest*, and diverse types of savannahs inundated and terra firma (Evrard, 1968; Leonard, 1951 & 1952; White, 1983). The *Cuvette Central* is the lowest point within the Congo Basin and once constituted a water retention point during the late Miocene when many African inland basins were still *endorheic* (Roberts, 1975; Thieme et al., 2005). Kinshasa is a town of nearly 9,000,000 people (Aveling et al., 2003) and located south-west of the Mabali. Adjacent habitats to this mega city are essentially composed of wooded savannas on a sandy soil. Kinshasa is located at Pool Malebo, an open water sur-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Locations from which weather data were collected



face leading to several multidirectional wind currents. These currents have an impact on rainfall regimes observed in Kinshasa.

Luki are located further south and closer to the Atlantic Ocean. With a population of 150, 4361 people (Iloweka, 2004), Luki is a forest island within a predominantly human landscape and degraded forests. Its position near the Atlantic Ocean implies that rainfall regime and other climatic events occurring in that region are potentially influenced by climatic events affecting the Atlantic Ocean.

The Congo Basin watershed covers 3,730,474 km^2, and is home to ~60 to 78 million people (Sonwa et al., 2009; WRI, 1998). About 62% (37 – 48 million people) of that population is still rural (Sonwa et al., 2009), even though the urban growth rate of the entire region is high and estimated at 5% per year (Atsimadja, 1992; WRI, 1998). This vast zone covers different habitat types, with tropical forest representing ~40% (14,920,190 km^2). The geography of the zone has an impressive biological diversity.

MATERIAL AND METHODS

Rainfall data from Mabali have been collected continuously from 1970 through 2004 (Inogwabini et al., 2006) while those from Luki were collected between 1958 and 2004. The data set from Kinshasa covers the period between 1971 and 2004. Total annual rainfall intensities (mm) of were plotted over time, i.e. 34 years for the Mabali data set, 46 years for Luki and 33 years for Kinshasa (Figure 1). To detect the trends in these data sets, the linear regression was used on annual rainfall intensities (mm). Those data, particularly on the Mabali Scientific Reserve, were published earlier (e.g. Inogwabini et al., 2006).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Other data came mainly from the search of existing literature. Human population data were gathered from Atsimadja (1992), Aveling et al. (2003), CEFDHAC (2001), and Sonwa et al. (2009), WRI (1998), Trends in populations were derived using the model presented by De Saint Moulin (1991 & 2003). Data on fish stocks were also gathered from different sources. Fish biomasses and estimated financial incomes generated from fishing were drawn from Bene (2005), CEFDHAC (2001), Corsi (1984a, b), Colom et al. (2006). Leonard (1987), and Data on the decline in fish stocks were those used by Inogwabini & Lingopa (2006).

These data indicated that over a 34 year period reported by Inogwabini et al., (2006), the water depth of Lake Tumba decreased from 8 m down to 6 m, which is a 25% decrease over 34 years, leading to a rate of decrease of 0.0074%/year. This rate was used in combination with regional elevation data to produce the map depicting the future water situation in the Congo Basin watershed. Also, repeating a survey conducted by the Food Aid Organization (FAO) in 1998, Inogwabini & Lingopa (2006) reported a fish stock decrease of 4.5% for the fish stocks of Lake Tumba over a period of 17 years, which equals a decrease rate of 0.25%/year. As suggested by Huggett (1993) and Hulme et al. (2001), these rates, maintaining each of them as constants and assuming that they would apply to the whole basin, were used in linear regression models to project decrease in watersheds and fish stocks. The financial incomes generated by fish production provided by Bene (2005) were used to determine the per-ton cost of fish. Maintaining the price constant over years, I simply multiplied projected fish stocks per year to obtain trends in incomes. The rate of production was calculated to measure the trend in how many tons of fish will remain available to the increasing rural populations of the region over the next 60 years if current conditions remain constant. This important measure was defined as a simple ratio of projected tons of fish over projected total populations.

Data on effects of shrinking waters in the study region on women were those that came from the socioeconomic study carried out by Colom et al. (2006). These included the gender-sorted fish market data, assessment of felt environmental threat disentangled between women and men, traditional work division, etc. They were collected through a variety of methods, including structured interviews, focus groups, and literature reviews Colom et al. (2006). These data are presented in this chapter as simple means and where projected, they were assumed to progress constantly over years. Data on health came from official reports of the provinces and particular health facilities (MSPPE, 2010; SS, 2007). To confirm that these data reflected the reality on ground, I have checked trends with medical doctors that worked in the health divisions of Bikoro, Ntondo and Mbandaka.

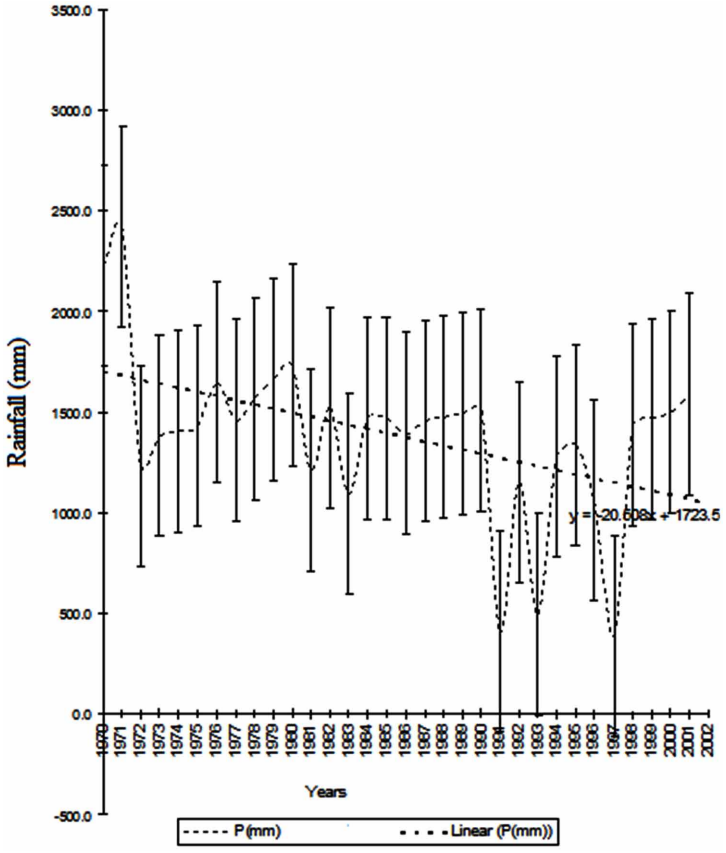
RESULTS

The rainfall intensities decreased in all three sites over time for each sites following the regression equation $y = -20.508x + 1723.5$ ($R^2 = 0.7011$), $y = -13.643x + 1175.4$ ($R^2 = 0.5313$) and $y = -23.338x + 1426.6$ ($R^2 = 0.6709$) respectively for Mabali (Figures 1 and 2), Luki (Figure 1 and 3) and Kinshasa (Figure 1 and 4). The rainfall for Luki and mean rainfall for Kinshasa in 2004 represented only 59% and 61% of its levels 33 years earlier, in 1971 following the drought of 1970 when Luki received only 327.8 mm of rain. The situation has been even more dramatic for Mabali where the maximum rainfall represents > 25% of its levels in 1970 or 34 years earlier.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

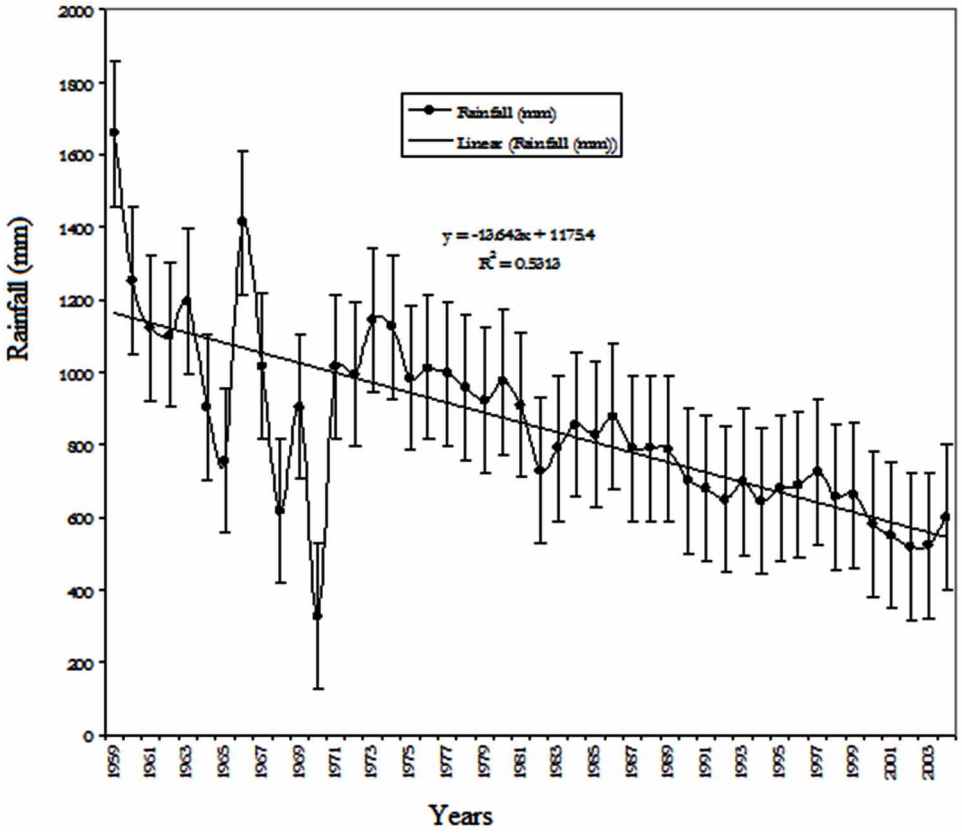
If the rate of water loss in Lake Tumba is applied for the entire region and remains constant, watershed will decrease following the regression equation y = -20894x + 5E+07 (R^2 = 0.7945). This model indicates that by 2025, the Congo Basin watershed will have lost 18% of its total water mass as compared with its 1998 levels. The loss will deepen to -26.6% by 2040, -39% by 2065 and then around -43% by 2070. Equally, if the loss in the fish biomasses in Lake Tumba are applied to the whole region and remain constant over years, the fish stock will decrease by 7% between 1998 and 2025. This decrease will deepen down to -11% by 2040, -16% by 2058 and by -20% in 2075. The same proportions will be observed if fish prices in the markets are constant, decreasing from 47.8 million American dollars/year in 2005 (Bene, 2005) down to ~42.5 million American dollars/year (~11%) by 2040. At the same time, the human population will grow from 60 – 78 million people to 109.6 million (or an increase of 40.5%) in 2025, then to 141.18 million in 2040 (an increase of 81.0%), 179.08 million in 2058 (129.6%) and 214.89 million (175.5%) in 2075. Combining trends in fish resources and human growth, these changes imply that there will be a decrease of ~70.1% of both tons/person/year, which parallels the projected magnitude of loss of income from 2009 through 2075.

Figure 2. Rainfall trends in the Mabali Region between 1970 and 2004



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Rainfall trends in the Luki Region between 1958 and 2004

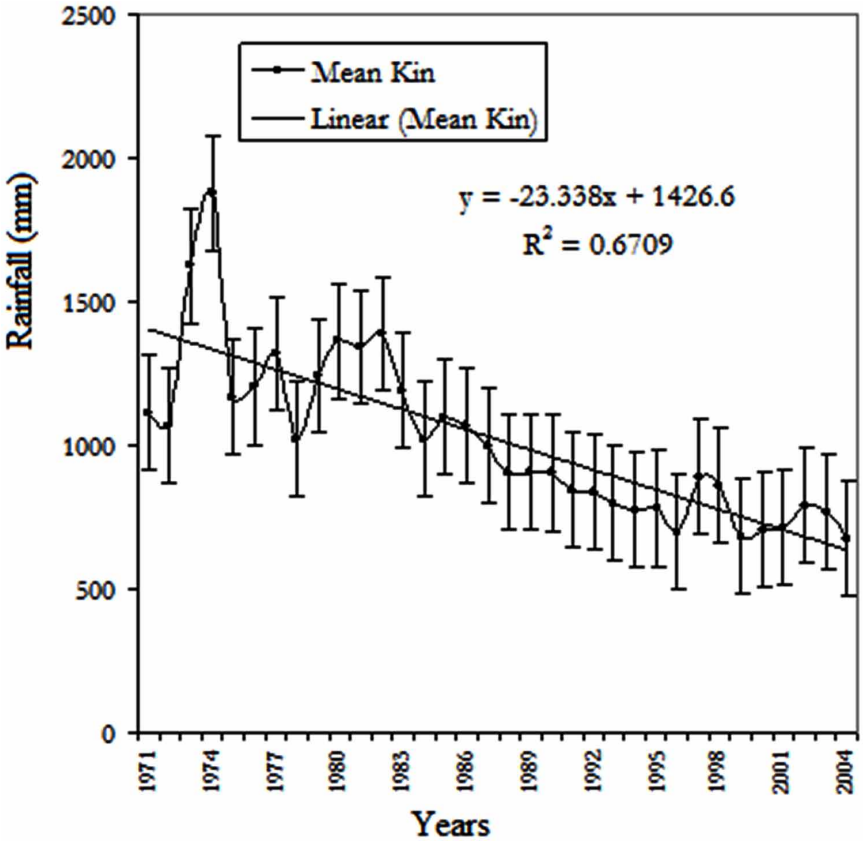


The 2005 socioeconomic data showed that 408,173 of ~1,012,000 all women (~51%) in the landscape were involved in fishing, and that each woman generated a mean annual income of ~2,100US$. This represented an overall income of 857,164,000 US$ annually; a significant % of the overall national budget for that year. In 2010, the fishing-generated financial income was estimated at ~ 1870 US$ per woman or a net decrease of 11%. If these trends are maintained constant, women generated income will decrease by 25% in 2020 and 59% in 2040 while the number depending on fishing for financial income will be 836,755 women, above the double of the women population in 2005.

Even though the region is a swamped zone, the data showed that more women (85%; N= 360) and girls (90%; N= 200) were involved in the activities of fetching water than men (25%; N = 140) and young boys (50%; N=140). The same socioeconomic data showed that that on average women walked ~ 6 km (round trip) to fetch drinkable water; this was done twice daily. This daily 12-km trip consumed 4 hours on average, representing 40% of a ten hour working day. Logically, three quarters of women reported that fetching water from long distances impeded their ability to conduct more lucrative activities such as commerce or even fishing, which are the most important economic activities in the region. More than three quarters of the interviewed women were afraid of fetching water from long distance sources because they feared being raped by former army soldiers. Interestingly, the same data set also showed reversed trends in girl education patterns; in areas where water sources were far away from the villages,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Rainfall trends in Kinshasa between 1971 and 2004



on average only 20% of girls had actually completed their secondary education while in towns where water sources are adjacent to houses, the figure increased to 45%.

Published reports (Secrétariat à la Santé 2007) from the study region indicated a global increase in diarrheas (globally 2.7% for the province of Equateur and 3% for that of Bandundu) and amoebic dysenteries (globally 8% for the province of Equateur and 7.2% for that of Bandundu) at the end of January through the end of February and from end of May through end of July. When looking at reports from Bikoro and Ntondo (near Lake Tumba) these figures are even higher for the same diseases. Diarrheas increase by 25% (Bikoro) and 30% (Ntondo) while amoebic dysenteries increase by 15% (Bikoro) and 24% (Ntondo). Health reports from Bikoro and Ntondo also show an increase in what they call skin itching (40% and 30% respectively for children under the age of 18); and 2007 health report from Ntondo also mentioned an increase in what they shyly called women specific genital ailments and infections by 23.6% during the same periods of the year. Periods from at the end of January through the end of February and from end of May through end of July are dry seasons when clean water is in shortage in the region.

DISCUSSION

General Foresighted Effects

The three data sets on rain intensities (Figures 1, 2 & 3) clearly indicate that there has been 'continuous' drying up of the zone over the last decades. The mean rainfalls for Luki and for Kinshasa in 2004 represented only 59% and 61% of its levels 33 years earlier while a more dramatic change was depicted for Mabali with the maximum rainfall in 2004 representing only $\geq$ 25% of its levels in 1970. These inter-site variations would be logically expected, given the fact that weather patterns are functions of multiple parameters, including micro climates, which are ecosystem-dependent themselves (Salati, 1987). Conditions, ecological and climatic, in those three sites are widely different and therefore account for those differences. In-site changes are rather difficult to explain, even though they may easily be linkable to major human activities in some cases.

Luki is an island of forest within the Bakongo Region, which is the most logged region of the Congo (Iloweka, 2004). With an estimated human density of 237 persons/km^2 (Iloweka, 2004), the population struggles to make a living through agriculture and woodcutting, which are fostered in response to high demands for foodstuffs and the high consumption of wood (for energy and construction) in Kinshasa and the expanding towns of Matadi and Boma. Most of the demand is met by products coming directly from the adjacent Province of Bas-Congo. All these activities increased the deforestation rate and unbalancing of forest ecosystems, which may be feeding the climate changes. Even though there is a need to deepen our knowledge on the correlation between forest cover and rainfall regime in this region, it is fairly logical to infer, based on studies undertaken in other regions of the world (Eltahir & Bras, 1993 Gash & Nobre, 1996; Lettau et al.1979,), that changes in the rainfall in this region may be a consequence of deforestation, which is feeding into global climate change and its effects.

The situation appears of Kinshasa seems to be similar to that of Luki. Kinshasa, with a currently estimated population of 9 million people, has seen its immediate environment stripped of all natural forests and bush due to the demand for land needed to accommodate a rapidly increasing population. Forested areas that were left to maintain a healthy urban environment have been either invaded by houses or have seen their trees cut down to provide charcoal for energy. Such is also the case for Luki and even though this question calls for more detailed information to help establish clear causation links, it remains reasonable, based on studies done elsewhere (Eltahir & Bras, 1993; Gash & Nobre, 1996; Lettau et al., 1979), to hypothesize that changes observed in rainfall patterns in Kinshasa may be subsequent to decreasing vegetation cover both within the town itself and its immediately adjacent areas.

The 34-year data set from Mabali intrigues common wisdom and can be fully understood only in parallel with the overall climate change paradigm (Inogwabini et al., 2006). Mabali (Figure 1) is located 75km straight south of the Equator. Within this strip, climatic metrics are constant (Bultot & Griffiths, 1972; Evrard, 1968) there are constant temperatures, stable rainfall regimes and regular seasonal cycles. A first look at the data from Mabali questions the rationality of the data because the site appears to be in an ideal environment for a rainfall pattern to remain constant over years. This remains the question even when you consider the fact that Mabali is also surrounded by active logging activities and many forest clearings due to high human concentration around Lake Tumba because the extent of vegetation clearing are far from being of the same magnitude as in Luki and Kinshasa. Deconstructing the puzzle posed by the Mabali situation, Inogwabini et al. (2006), found that while the most acknowledged consequence of the climate change was global warming (Houghton et al., 1990), the Mabali long-term data indicated a

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

local cooling phenomenon, which they attributed to longer dry seasons. Longer dry seasons mean less precipitation; therefore it is understandable that rainfall had decreased over the period covered by the study. Following Bultot & Griffiths (1972), Inogwabini et al. (2006), explained that in equatorial Africa dry seasons are cooler than normal temperatures due to over-evaporation, leading to persistent clouds. However, while tracking the explanations for longer dry seasons, they concluded that they could be logically explained only by inserting the global climate into the equation. Overall, decreased rainfall in the western Congo (in the three locations of Kinshasa, Luki and Mabali), regardless of reasons that may explain them, do agree with patterns in the other regions of Africa and have been documented previously (IRD, 2002; Mahe et al., 2001), albeit at localized scales.

In conclusion, these trends are clear and should ignite the will to establish causation links if they are to be managed appropriately. This is a call for appropriate research rather than depending on opportunistic data. There is also one precaution in trying to use these data sets and/or extrapolating them: decreased annual rainfall intensities may depict a phenomenon of a long term cyclical event whose frequencies may be difficult to decipher from such a short time-series data. Nevertheless, given the fact that human activities may have pushed natural environmental to the edges of irreversibility, the picture provided by these data series may convey an alarm signal given the fact that we may have gone beyond a certain resilience threshold. This is even more appealing when one considers that these climatic patterns agree with the overall picture of the Congo Basin and Africa, and may be attributable to the global climate change phenomenon (IRD, 2002; Inogwabini et al., 2006).

Previous studies (Hulme et al. 2001; Pearce & Turner, 1990; Sonwa et al., 2009; Stern, 2007) have described effects of climate changes to include economic aspects (decrease in financial incomes), health and sanitation (water quality and decrease in intake of fish proteins) and loss in biodiversity. Inogwabini et al. (2006) argued that the observed decrease in water depth of the Lake Tumba (from maximum depth of 8 m down to 6 m over 34 years) was essentially linked to the dramatic decline in rainfall. They also suggested that, apart from intensive fishing described by Inogwabini et al. (2009), observed decreases in fish stocks may also be linked to climatic conditions prevailing in the lake such as loss of reproduction sites, cooler temperatures and losses in some critical foods due to prolonged dry seasons, as fishes of the region adapted to different conditions and exhibit different requirements to reproduce and grow (Bailey, 1986; Banister, 1986; Chapman, 2001). They also indicated that if the weather change patterns they described remain constant, there would be numerous ecological consequences on forest ecosystems of the western Congo Basin (IRD, 2002; Inogwabini et al., 2006) in the long-term future. Evidence of such effects of climates on biodiversity have been described on several occasions (Fernández & Vrba, 2006; Lemoine & Böning-Gaese, 2003; Lemoine et al., 2007a & Lemoine et al., 2007b) and will likely occur in this region whose biodiversity is one of the most important on earth. To highlight the magnitude of the land affected by drying, a decrease in 18% of the size of the Congo watershed between 1998 and 2025 represents 673,968 km^2. This dried out area represents ~28% of the entire Democratic Republic of Congo and 23 times the size of Equatorial Guinea.

Beyond those consequences on biodiversity, the projected economic effects a drying watershed would also strike human economic activities, not only in terms of fish markets and protein intake but also in terms of agricultural productivity in the whole region. Increasing human populations will need more food and cultivatable land. Shortages in water will push people to find water sources for agriculture where this key resource will still is available, which is in the Central Congo Basin. That pattern would, most likely, lead to conflicts over water resources in the region. Lovett (2006) established that rainfall is one of the main determinants of ecological productivity, which in turn is the basis of agricultural economies.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Shortages of rainfall will, therefore, undermine the rich cultural diversity as well by forcing people to migrate to regions that offer better agricultural production and sufficient water sources. The destruction of the resources that support traditional culture is, by any measure, the most dramatic effect of climate change in this region. Climate change would certainly precipitate dramatic, permanent shifts in local cultures. For example, all people in the Lake Tumba region prefer fish as their most important food item. Decreasing fish stocks will most likely push them to adopt new life styles and other techniques to extract natural resources to live on. The introduction of new techniques will affect community views, relationship to the environment and overall stability.

SPECIFIC EFFECTS OF WATER DECREASE ON WOMEN IN THE REGION

Decreasing water levels would likely increase in walking distances to clean water sources, which will ipso facto increase time consumed to fetch water, reduce girls' chances to attend formal education, decrease women's economic powers and expose them to gender-based violence.

While there might be other factors affecting gender-education patterns described in this study, increased walking distances to clean water sources, at least contributed to that picture and will very likely continue to reduce girls' chances to attend formal education unless major cultural and social changes happen. This finding conforms to the results reported from Ethiopia, Ghana, Tanzania (Komba, 1995) and India (UN-DESA, 2005) and other areas across Africa (YPOW, 2006). As reported in many studies (Inter-Agency Commission, 1990; IIon, 1992; Kinyanjui, 1993), literacy of women is an important key to improving health, nutrition and education in the family and to empowering women to participate in decision-making in society. Naturally, according to the *Childhood Engenderment Theories* (Chafetz, 2006), impeded access to formal education will keep future women under the yoke of inequality and reduce their self-esteem, perpetuating the current imbalanced power toward women (Chafetz & Haggan, 1996).

Socioeconomic data indicate that decreasing water levels will have more severe impact on women commercial activities than compared to the global effect. That the numbers of women will double provides a prelude of heighten conflicts over fishing points resulting from increased competition of fishing points. This, combined with reduced access to education caused by water shortage, will therefore further hinder women's economic powers, limiting the contribution of more than 50% of the population to contribute to economic returns expected by their societies and impact on means of achieving sustainable development and economic growth, which agrees with findings by Hanjra and Qureshi (2010) who projected that climate change effects will hinder the contribution of women to the global development. Reduced economic power means, again, lost self-esteem and will keep the current paradigms of social inequalities between men and women. Ironically, this will happen though women will see their workload increased by doubling walking distances to fetch water. Indeed, the estimated workload for fetching drinking water was a daily 12-km trip, consuming 40% of women working day. This was higher than the average time spent by women across rural Africa (Blackden & Wodon, 2006), which had been estimated at 26% (Water Aid, 2012).

Water Aid (2012) had suggested a cohort of effects of reduced water availability on women in developing countries, principally on their health and that of their families in general. Both structured interviews and focus groups with local communities were not able to document feeling of worsening human health conditions in the region, though 21% of interviewed people talked about health increasing costs. However, official health reports indicated that there was an increase in some diseases during dry seasons, a period

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

when clean water is in shortage in the study region. Diarrheas, amoebic dysenteries, skin and itching in young people are water-borne diseases; and the fact that they increase during the period of clean water shortage indicate that should water decrease, the health conditions of the populations of this region would be affected directly. Diarrheas and amoebic dysenteries and other forms of diseases enumerated above have been reported to be directly linked to quality of water under other circumstances (Fewtrell et al. 2005; Gundry et al., 2004). Hence, the fact both structured interviews and focus groups with local communities were unable to document feeling of worsening human health conditions in the region may, most probably, be due to the sense of plenty of water and the fact that people had many other concerns that were priority to their livelihood than water-borne diseases. Of particular note here is that women specific genital ailments and infections increased by 23.6% during the dry seasons. Though there is no specific name on what these are, it would be sensible to think that decreasing water levels in the region would affect women's health conditions in a specific way. Aveling et al. (2003) and Inogwabini et al. (2009) documented the fact that people in the region of the study had no proper sewage treatment mechanisms and people have been used to dumping garbage into open water, which in turn they fetched for domestic needs. Decreasing water levels will reduce the potential that larger water masses have to dilute effects of dumped sewage and will, therefore, lead to unclean water, which will lead to unhygienic conditions.

It has been shown in the arid African regions (Manyanhaire et al., 2009), decreased water levels will reduce the spread of water-dependent human activities in a limited surface; limited spread zone for human activities alone will likely worsen health conditions. Major human settlements in areas of limited water supplies are always accompanied by worsening health conditions stemming from varied causes such as poor sewage and water treatment infrastructures, people sharing water sources with herds of cattle and other domestic animals. As indicated above, characteristics of this region are that there is no proper sewage treatment mechanisms, people dump garbage into open water, and defecate directly in open water (MSPPE, 2010). Decreasing water levels will reduce the potential that larger water masses have to dilute effects of dumped sewage and will, therefore, lead to unclean water. This will affect, in unforeseen degrees, both human populations and livestock who will be sharing the same water points.

It is worth repeating that in Central Africa, as most cultures, women and girls are primarily responsible for the use and management of water resources, sanitation and health at the household level (Seager et al., 2009; UN-DESA, 2005;); which facts will certainly expose them to gender-based violence. Water-driven conflicts would very likely results in similar impacts, including rape. An important result of this study is that women in this region already torn-apart by armed conflicts of different nature in the recent past have an acute perception of the risks of being raped while going for search of water.

Managing water at times of scarcity will bring women to the forefront of water-ignited conflicts. The recent history, with the Enyele Rebellion Movement on water pounds in the north-western part of the DRC provided proof to this situation (Guerra et al., 2010); decades-old suppressed conflict over fishing rights evolved into ethnic tussle for economic and political power in north-west. Some 200,000 refugees fled the fish-conflict violence since in 2009 (BBC, 2009) of whom 82% were women (IRIN, 2011). Unfortunately, the opportunity provided by the recent Conference of Parties to the Convention United Nations Framework Convention on Climate Change in Paris was not seized to discuss the implications of climate change on freshwater and its social consequences. The word water appears nowhere throughout the text of the Paris Agreement, the importance of water being inferred to only once in the preamble through the use of the word ocean, as a specific ecosystem. Without diminishing the value of other international mechanisms such as the International Water Management Institute and other conferences on the subject, this absence of water in the agreement shows how low the water issues are on the agenda of the global

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

decision-making processes and, hence, lack of global perspectives on how to handle potential conflicts over freshwater sources. Of course, it could easily be argued that water is inferred through article 1 (1) of the Paris Agreement, which refers to the 1992 New York Convention which, in its article 4(e), calls parties to cooperate in preparing for adaptation to the impacts of climate change develop and elaborate appropriate and integrated plans for coastal zone management, water resources and agriculture, and for the protection and rehabilitation of areas, particularly in Africa, affected by drought and desertification, as well as floods. However, this inference is no so obvious and would demand a more refined practitioner of natural resources management to dig it out and make connections. It is suggested here that the best way to account for water and consequences of lack of its proper management is to factor freshwater in the development of the nationally determined contributions (Paris Agreement, article 3). But that will need a much more developed advocacy on behalf of the practitioners of natural resources management toward political decision-makers.

ACKNOWLEDGMENT

I would like to thank Laurent Nsenga for allowing me to use data from Luki. Data from Kinshasa were gathered by students from Institut Bâtiments et Travaux Publics through the supervision of Alpha Egbango. Dr Mwanza Ndunda who co-authored the paper on Mabali shared the data from Mabali scientific Reserve.

Chapter 66
Nitrate, Total Ammonia, and Total Suspended Sediments Modeling for the Mobile River Watershed

Vladimir J. Alarcon
Universidad Diego Portales, Chile

Gretchen F. Sassenrath
Kansas State University, USA

ABSTRACT

This paper presents details of a water quality model of the Mobile River watershed that estimates total suspended sediments at the outlet of the watershed. The model is capable of simulating Nitrate (NO_3), Total Ammonia (TAM), and Total Suspended Sediments (TSS) for extended periods of time at a daily temporal resolution (1970-1995). The Hydrological Simulation Program Fortran is used for modeling the hydrological, nitrogenous constituents, and sediment processes. Based on the nutrient simulation and exploration of the effects of two management practices (filter strips and stream bank stabilization and fencing) on nutrient removal, the resulting sediment model is used to implement the most efficient nutrient management practice and explore its effects on TSS concentrations in the Mobile River. Results show that the implementation of the management practice "stream bank stabilization and fencing" to agricultural lands in sub-watersheds that had intense agricultural activities produced the highest reductions of NO_3 concentration (up to 14.06%) and TAM concentrations (8.01%). Based on the nutrient simulation and identification of "stream bank stabilization and fencing" as the most efficient BMP for nutrient concentration reduction, the sediment model was used to explore its effects on TSS concentrations in the Mobile River. Implementing "stream bank stabilization and fencing" produced monthly median TSS concentration reductions ranging from 3.6% to 10.6% in the Mobile River.

INTRODUCTION

The US Gulf Coast receives inputs of nutrients and sediments from intensive agricultural activities in upland watersheds (McPherson, et al., 2003). Seasonal hypoxia and high sediment load events have occurred in recent years. Continued land development and conversion of natural landscapes to urban development will exacerbate pollution (Vitousek et al., 1997; Wiener & Sassenrath, 2012). Moreover, nutrient and sediment contributions from upland watersheds where the main economic activity is agriculture play an important role (Harmel et al., 2007).

Nitrogenous constituents and sediments washed off by precipitation events from the croplands are loaded into streams (creeks, rivers) which take sediments and nutrients to coastal water bodies. Mobile Bay, an estuary located in the Alabama Gulf Coast, receives waters from one of the largest watershed in North America (Park et al., 2007): Mobile River Watershed. The estuary experiences regular hypoxic events during the summer (EPA, 2012). The Tombigbee watershed, one of the upland watersheds that drains into Mobile Bay via the Mobile River, has been identified as one of the sources of nutrient input due to its intensive agricultural activity (EPA, 2014). Increases in agricultural activities could potentially worsen the current situation. Alarcon & McAnally (2012) estimated that in a span of seventeen years some portions of the Tombigbee watershed underwent the following land-use/land-cover changes: 34% increase of agricultural lands, 263% increase of lands used for grazing or hunting animals (rangeland), and a 16% decrease of natural forest lands. With these significant changes in soil surface coverage, the transport of nutrient and sediments washed-off from this watershed to Mobile Bay and the Alabama Gulf Coast has increased proportionally. The increase of agricultural lands and agricultural intensification are anticipated to worsen the current situation (Matson et al., 1997; Harmel et al., 2006).

Conversion of forest land into crop or pasture can substantially increase the loss of sediments and nutrients from the land (Foley et al., 2005; Harmel et al., 2006). The rates of soil loss in particular will depend on management practices, especially the degree of tillage (no-tillage or conservation tillage versus conventional tillage) (Parajuli et al., 2013), and can also impact the loss of nutrients. While pastures may have reduced sediment losses, animal manures will increase the nutrient runoff from the field. A recent study at a small geographical scale (Kleinschmidt, 2005) postulated several management scenarios that may be used for reducing the effects of nutrient and sediment contamination to some of the Tombigbee streams. For cropland, filter strips, reduced tillage, stream bank stabilization and fencing, and terraces were identified as being the most useful in that order. For pasture land, stream bank stabilization and fencing, and terraces were the most useful.

The sources of nutrient and sediment loss in agricultural watersheds are mostly distributed in space (i.e., they are non-point sources). Non-point sources enhance the chances for complex physical and biochemical processes to occur during the transport of those contaminants through soil and water. Therefore, estimating the effects of nutrient and sediment wash-off from agricultural fields to streams and water bodies requires a complex quantitative approach. Watershed models are able to quantify those processes occurring either under natural conditions or due to anthropogenic activities. These models use mechanistic and empirical algorithms to calculate the hydrological processes within a watershed and also the migration of pollutants from point and non-point sources to water bodies. Previous research has shown the use of these types of models for quantification of processes in agricultural watersheds (Alarcon & Sassenrath, 2015). For the Mobile River watershed, an initial hydrological and nutrient model (Alarcon & Sassenrath, 2016) has been developed that covers all major streams in the watershed, including the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Tombigbee River and the Alabama River watersheds. A sediment transport model for the entire watershed, however, has yet to be developed.

In this research, an existing nutrient model of the Mobile River watershed (Alarcon & Sassenrath, 2016) is improved by including modeling of total suspended sediments. The Better Assessment Science Integrating Point & Nonpoint Sources, BASINS GIS system (EPA, 2008) and the Hydrological Simulation Program Fortran, HSPF (Bicknell et al., 2001) are used to geo-process the input data and water quality modeling respectively. Through nutrient modeling, the optimum Best Management Practice (BMP) for nutrient removal is identified and, subsequently, this BPM's efficiency in terms of TSS removal is tested via simulation.

METHODS

Watershed Under Study

The Mobile River is a typical coastal river with mild slopes and meandering course. The river is seventy-two kilometers long and is the main contributor of fresh water to Mobile Bay. It carries waters coming from two important rivers: Tombigbee and Alabama rivers. The Upper and Lower Tombigbee rivers, which watersheds are located in northwest Alabama and northeast Mississippi, drain a catchment area of approximately 59000 square kilometers between both states. Fifty six percent of the watershed is in Mississippi and the rest (44%) lies in Alabama. The Alabama River catchment covers approximately 56000 square kilometers draining most of eastern Alabama, and portions of northwest Georgia and southeast Tennessee (Figure 1).

The Mobile River has an average annual stream flow of 1840 m3/s. The Mobile River watershed (Figure 1) covers approximately 115,000 km^2, extending into four southeastern states: Alabama, Mississippi, Georgia, and Tennessee. This drainage basin is the fourth-largest in the United States and the sixth-largest in North America. The river and its contributors have historically provided the principal navigational access for Alabama.

Physical Geography Characterization

The topographical characterization of the study area was performed using National Elevation Data (NED) (30-m horizontal, 1-m vertical), and USGS DEM (300-m horizontal 1-m vertical) topographical datasets. The NED dataset provides a seamless mosaic elevation data having as the primary initial data source the 7.5-minute elevation data for the conterminous United States (Lent & McKee, 2011). NED has a consistent projection (geographic), resolution (1 arc second, approximately 30 m), and metric elevation units (Deliman et al., 1999). The land-use/land-cover within the Mobile River watershed was characterized using the USGS GIRAS digital map. The USGS-GIRAS is a set of maps of land use and land cover for the conterminous U.S. delineated with a minimum mapping unit of 4 hectares and a maximum of 16 hectares (equivalent to 400 m spatial resolution), generated using the Geographic Information Retrieval and Analysis System (GIRAS) software. Today, they are widely known as the USGS GIRAS land use data sets (Alarcon & O'Hara, 2010).

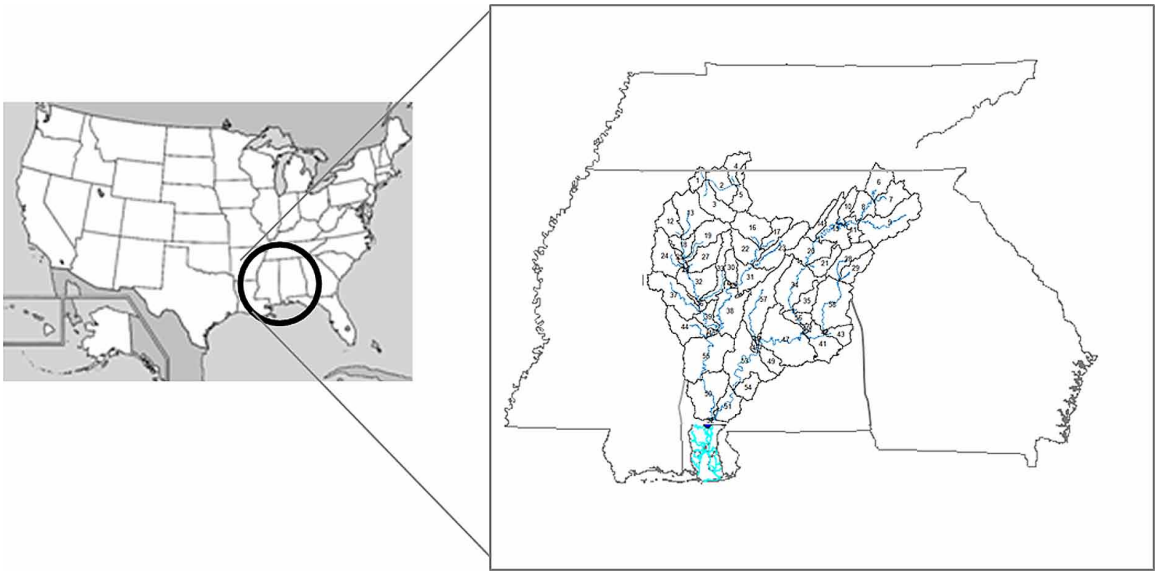
Figure 1. Mobile River watershed. The drainage basin (fourth-largest in the United States) drains streams located in Alabama, Mississippi, Georgia, and Tennessee.



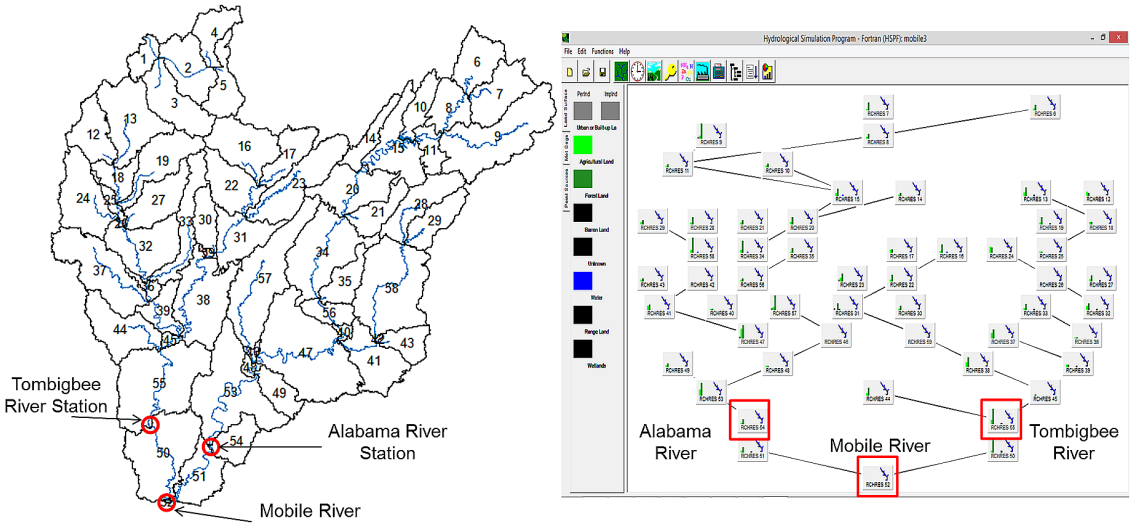
Modeling Tool

Hydrological, nutrient and sediment modeling of the Mobile River watershed was carried out using the Hydrological Simulation Program Fortran (HSPF). The HSPF software is designed for modeling and simulating non-point-source and point-source watershed hydrology and water quality. Time-series of meteorological/water-quality data, land use and topographical data are used to estimate stream flow hydrographs and pollutant-graphs. The model simulates interception, soil moisture, surface runoff, interflow, base flow, snowpack depth and water content, snowmelt, evapo-transpiration, and ground-water recharge. Simulation results are provided as time-series of runoff, sediment load, and nutrient and pesticide concentrations, along with time-series of water quantity and quality, at any point in a watershed. Additional software (WDMUtil and GenScn) is used for data pre-processing and post-processing, and for statistical and graphical analysis of input and output data (Alarcon & O´Hara, 2010). The BASINS 4.1 GIS system (EPA, 2008) was used for downloading basic data and delineating the watershed included in this study. The creation of the initial HSPF model was done using the WinHSPF interface included in BASINS 4.1.

Figure 2 shows the delineation of the Mobile River watershed and corresponding HSPF model, based on the watershed delineation. Locations of water quality stations (from McPherson et al., 2003) in Tombigbee and Alabama rivers are shown in both: the delineated watershed and the schematic HSPF representation of the watershed. Notice that the HSPF model schematic mirrors the arrangement of sub-watersheds. Water quality simulations were performed for the most downstream sub-watershed encompassing Mobile River.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Delineated Mobile River watershed and corresponding HSPF model. Locations of water quality stations (from McPherson et al., 2003) in Tombigbee and Alabama rivers are shown. The corresponding HSPF watershed mode for Mobile River is also shown. Notice that the HSPF interface mirrors the arrangement of sub-watersheds. Water quality simulations were performed for the most downstream sub-watershed encompassing Mobile River.



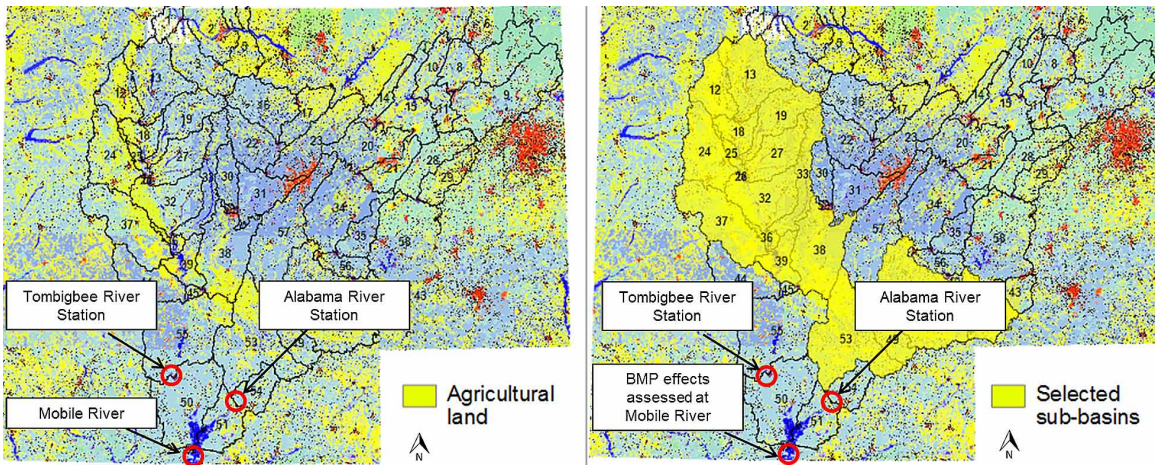
Water Quality Management

Modeling and simulation in this research was performed in two phases. First, to identify the best management practice in terms of nutrient removal, two types of BMPs were tested for reduction of Nitrate (NO_3) and Total Ammonia (TAM). The BMPs considered in this first phase were filter strips, and stream bank stabilization and fencing (based on Kleinschmidt, 2005). In order to carry out this first computational exploration, a selection of sub-watersheds was performed to reduce computer processing time of water quality simulations.

Figure 3 shows agricultural lands in the Mobile River watershed area (left). It is evident that most of the agricultural activity in the area is concentrated in an agricultural belt that originates in northeastern Mississippi, crosses mid-southern Alabama, and ends in southwestern Georgia. Therefore, the sub-watersheds to which these agricultural lands belong (right hand side of Figure 3) were selected for implementing the BMPs and their corresponding removal efficiency. Three levels of implementation (in terms of percent of agricultural acreage) were simulated: 25%, 50%, and 75%. Those percentages of BMP were selected for allowing comparison of HSPF-simulated results with results reported in Kleinschmidt (2005). Figure 3 shows locations where comparison of simulated and measured/reported concentration values was performed: most downstream outlet of Mobile River, and water quality stations at Tombigbee and Alabama rivers.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Distribution of agricultural lands in the Mobile River watershed and selected sub-basins for sediment and nutrient simulation. BMP effects were assessed at the Mobile River (watershed outlet).



The second phase of this research consisted on simulating a sediment management practice and assessing its effects in total suspended sediment concentrations in the Mobile River. The BMP for suspended sediments management was applied after the most efficient BMP for nutrient removal was identified. Therefore, the optimum BMP for nutrient removal was also assessed in its efficacy for TSS removal. The BMP was applied to the same sub-watersheds to which nutrient removal management practices were applied (i.e., sub-watersheds where agricultural activity was extensive).

RESULTS

Nutrient Modeling

Simulated nitrate concentrations from 1970 through 1995 are shown in Figure 4. Daily, monthly and annual mean concentration values achieved after the application of two types of BMPs: filter strips, and stream bank stabilization and fencing are shown. The charts show simulated results for application of those BPMs at 25%, 50% and 75% coverage of agricultural land areas.

As shown in Figure 4, most nitrate daily means range between 1 and 6 mg/L with seasonal peaks and minimums in summer and winter correspondingly. Monthly means follow the same seasonal pattern with concentration values ranging mostly between 1.3 and 5 mg/L. Daily and monthly means are mostly lower than the 10 mg/L criteria for nitrate in surface water bodies (EPA, 2016; Reilly et al., 1999). Spikes corresponding to summers of 1977, 1987 and 1988 coincide with low flow conditions reported by Alarcon et al. (2009). Annual mean concentrations range within 2.3 and 4.5 mg/L; 75% of the annual means are lower than 3 mg/L.

The assessment of the effects of the application of the BMPs at different percent coverages is shown in Table 1. Percent reductions in nitrate concentrations at Mobile River were calculated having as a baseline the model-estimated median concentration of nitrate when no BMP was applied.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Nitrate concentrations in the Mobile River. Reduction in Nitrate concentrations after application of filter strips (left) and stream bank stabilization (right) are also shown.

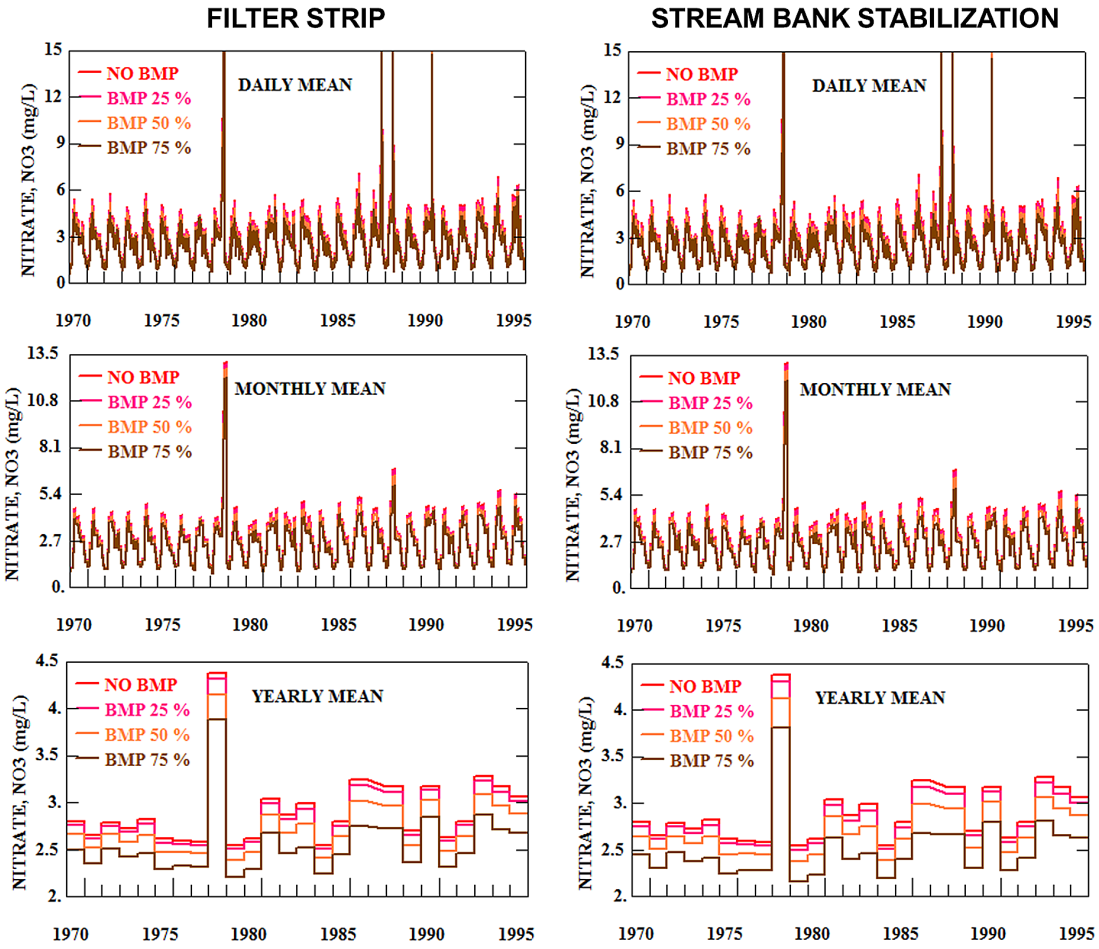


Table 1. Nitrate concentration reductions after implementation of a Filter Strip BMP or Stream Bank Stabilization and Fencing BMP to agricultural lands

NITRATE	Filter Strip		Stream Bank Stabilization	
	NO_3 mg/L	% NO_3 Reduction	NO_3 mg/L	% NO_3 Reduction
NO BMP	2.86	0.00	2.86	0.00
BMP 25%	2.82	1.48	2.81	1.82
BMP 50%	2.70	5.56	2.68	6.25
BMP 75%	2.52	12.24	2.46	14.06

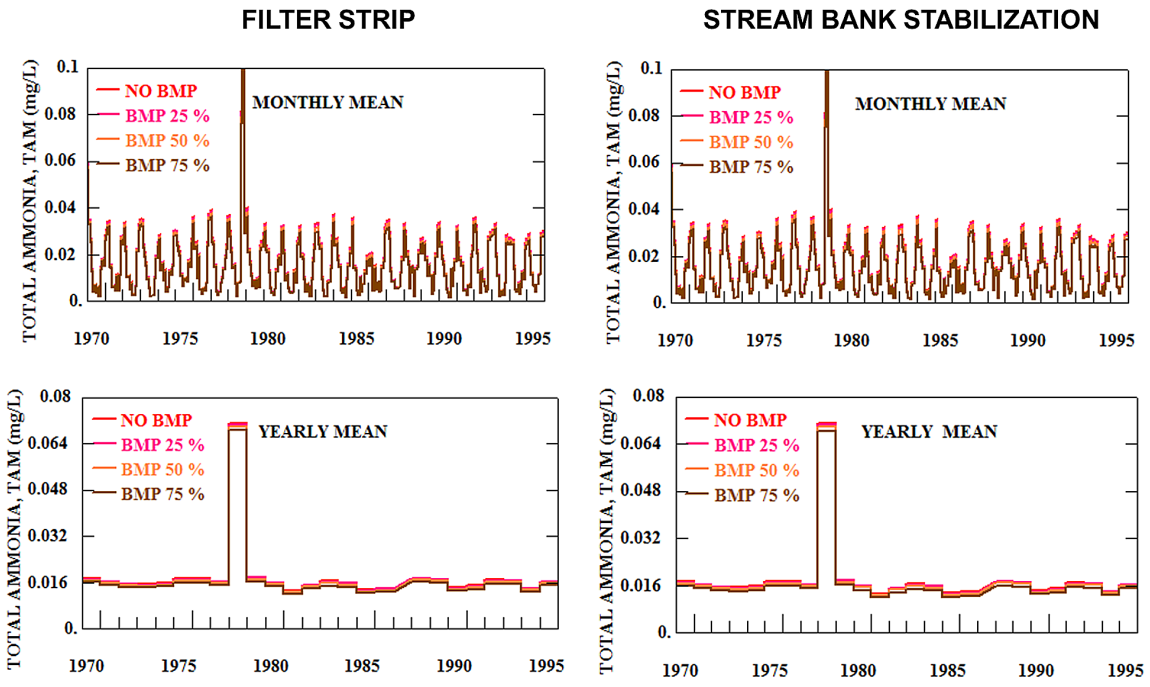
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

As shown in Table 1, stream bank stabilization and fencing is the BMP that shows better results in terms of nitrate concentration reductions in the Mobile River. Sequentially applying this BMP to 25%, 50% and 75% of agricultural acreage, produced NO_3 concentration reductions of 1.82%, 6.25%, and 14.06%, correspondingly.

Simulated total ammonia (TAM) concentrations for the simulation period 1970-1995 are shown in Figure 5. Simulated TAM monthly means range between 0.005 and 0.1 mg/L with summer peaks and winter lows as in the case of nitrate. Yearly mean concentration values cluster around 0.01 mg/L with the exception of 1978 when dry conditions were exacerbated by scarce precipitation (Alarcon et al., 2009). The figure also shows daily, monthly and annual mean concentrations for TAM after application of two BMPs (filter strip, and stream bank stabilization and fencing) are applied to increasing area coverages (25%, 50% and 75%). Table 2 compares the efficiency of those BMPs in terms of reduction of TAM concentrations in the most downstream point of the watershed. Stream bank stabilization is again shown to have a better efficacy in the reduction of TAM concentrations in the Mobile River.

Table 2 and Figure 5 show that stream bank stabilization and fencing is the BMP that is more efficient in terms of TAM concentration reductions in the Mobile River. Sequential application of this BMP produces 1.04%, 3.37%, and 8.01% reduction of TAM concentrations in the Mobile River, corresponding to 25%, 50% and 75% of this BMP application to agricultural lands.

Figure 5. Total Ammonia concentrations in the Mobile River. Reduction in TAM concentrations after application of filter strips (left) and stream bank stabilization (right) are also shown.



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

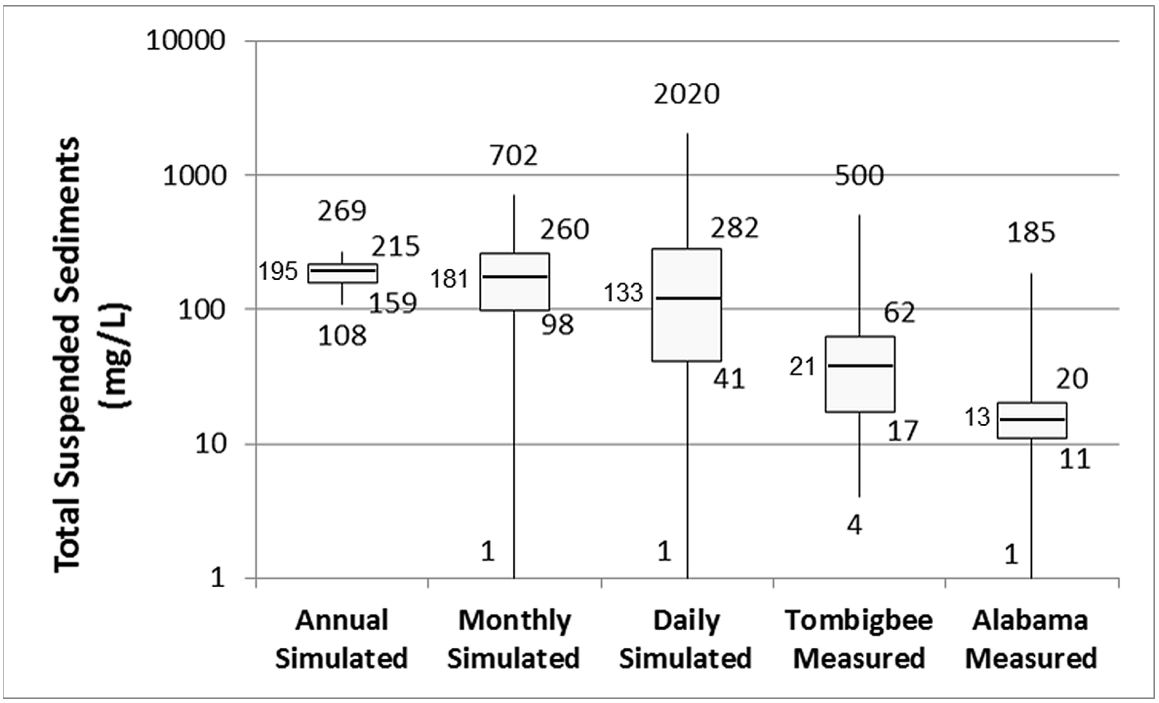
Table 2. TAM concentration reduction after implementation of a Filter Strip BMP or Stream Bank Stabilization and Fencing BMP to agricultural lands

TOTAL AMMONIA	Filter Strip		Stream Bank Stabilization	
	TAM mg/L	% TAM Reduction	TAM mg/L	% TAM Reduction
NO BMP	0.0240	0.00	0.0240	0.00
BMP 25%	0.0238	0.84	0.0237	1.04
BMP 50%	0.0230	3.16	0.0229	3.37
BMP 75%	0.0214	6.97	0.0212	8.01

Sediment Modeling

Since there were no water quality stations in the Mobile River it was not possible to proceed with a calibration of the model for total suspended sediments. However, McPherson et al. (2003) provide ranges of measured TSS concentrations at water quality stations located on the Tombigbee and Alabama rivers (shown in Figures 2 and 3). Those stations are located upstream from the Mobile River but their data could be used to assess the constancy of TSS estimations produced by the model. Figure 6 shows a comparison of TSS concentrations at the Mobile River against concentrations measured (McPherson et al., 2003) at Tombigbee and Alabama rivers. Minimum, first quartile, median, third quartile and maximum measured and simulated TSS concentrations are shown.

Figure 6. Comparison of total suspended solids (TSS) simulated and measured concentration. Measured concentrations at Tombigbee and Alabama Rivers were extracted from McPherson et al., 2003.



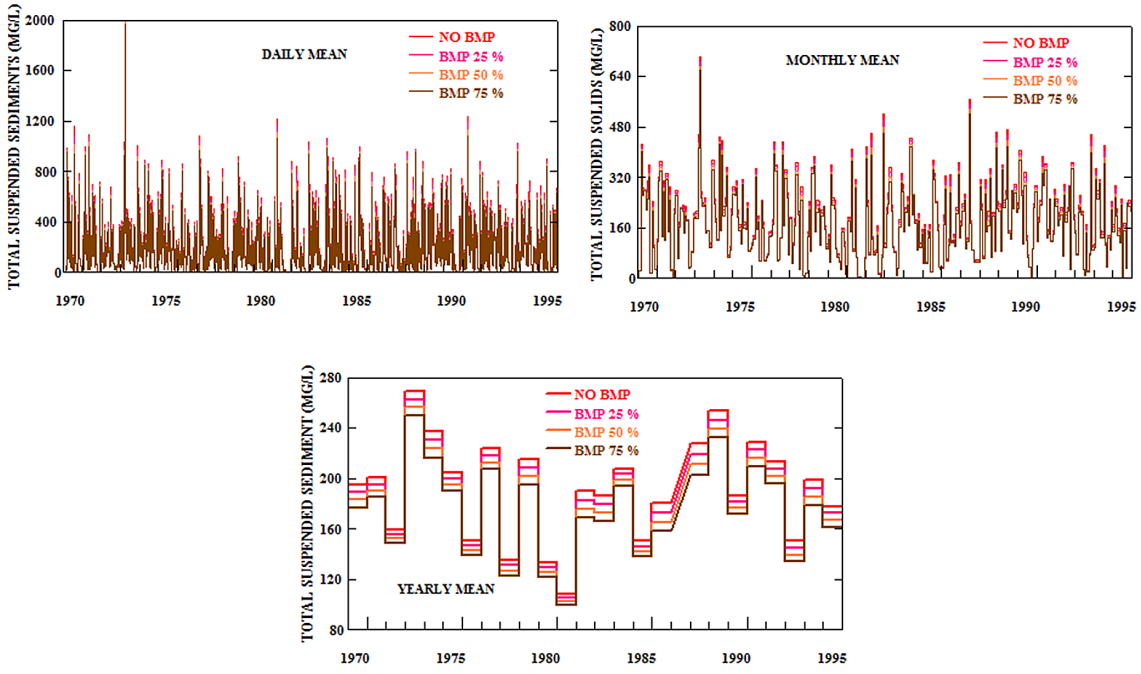
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

As shown in Figure 6 median simulated TSS concentrations range between 133 to 195 mg/L while median concentrations measured at Tombigbee and Alabama rivers range between 13 and 21 mg/L. Measured concentrations at those rivers reach 500 and 185 mg/L, respectively, while simulated concentrations for Mobile River reach 269 to 2020 mg/L. Simulated concentrations seem to be higher than measured concentrations. This is because statistics for Mobile River were calculated using daily mean concentrations for the 1970-1995 simulation period (more than 9000 daily values), while statistics for measured data were calculated with less than 35 data records. Therefore, simulated data captured a higher number of extreme events and this fact has shifted median and quartile values towards higher concentrations. Also, since the watershed areas draining to those stations are roughly half of the total area that drains to Mobile River, it is expected for measured concentrations at those locations to be smaller than concentrations at Mobile River.

The previous section identified stream bank stabilization and fencing as the most efficient BMP in terms of nitrate and TAM concentration reduction. The sediment model was set up such that it would test how efficient this BMP would be to reduce TSS concentrations in Mobile River. Figure 7 shows daily, monthly and annual average concentrations for the 1970-1995 simulation period. Table 3 summarizes monthly median TSS concentration reductions after the BMP application.

The application of stream bank stabilization to agricultural lands within Mobile River watershed results in TSS concentration reductions in the Mobile River comparable in percentage to those achieved for nutrients. Sequentially applying the BMP to 25%, 50% and 75% of agricultural acreage reduces TSS concentrations by 3.6%, 7.1%, and 10.6%, respectively (Table 3).

Figure 7. Total suspended sediments (TSS) concentrations in the Mobile River. Reduction in TSS concentrations after application of stream bank stabilization to agricultural sub-watersheds.



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Total suspended sediment (TSS) concentration reduction after implementation of Stream Bank Stabilization and Fencing BMP to agricultural lands

TOTAL SUSPENDED SOLIDS	Stream Bank Stabilization and Fencing	
	TSS mg/L	% TSS Reduction
NO BMP	180.5	0
BMP 25%	172.5	3.6
BMP 50%	168	7.1
BMP 75%	161.5	10.6

CONCLUSION

The nutrient model for the Mobile River Watershed estimates nitrate daily mean concentrations ranging primarily between 1 and 6 mg/L, with seasonal peaks and minimums in summer and winter, correspondingly. Monthly NO_3 mean concentrations follow the same seasonal pattern with most values ranging between 1.3 and 5 mg/L. Daily and monthly means are lower than the 10 mg/L criteria for nitrate in surface water bodies. Peak concentrations (15.1 mg/L and 13.2 mg/L, respectively) corresponding to summers of 1977, 1987 and 1988 coincide with low flow conditions. Annual mean concentrations range within 2.3 and 4.5 mg/L, with 75% of the annual means lower than 3 mg/L. Simulated Total Ammonia concentrations are lower than NO_3 concentrations as would be expected in surface waters. Simulated TAM monthly means range between 0.005 and 0.1 mg/L with summer peaks and winter lows as in the case of nitrate. Yearly mean concentration values are approximately 0.01 mg/L with the exception of 1978 where low flow conditions occurred and yearly mean concentration reaches 0.07 mg/L.

Nutrient modeling and simulation of the application of two management practices (filter strips, stream bank stabilization and fencing) for nutrient removal in the Mobile River revealed that stream bank stabilization and fencing had greater impact on reducing nitrate and TAM concentrations than the application of filter strips to agricultural lands. The water quality model for the Mobile River Watershed developed in this research estimates that consecutive application of this BMP to 25%, 50% and 75% of agricultural lands within the watershed, reduces NO_3 concentrations by 1.82%, 6.25%, and 14.06%, respectively. Similarly, TAM concentrations are decreased by 1.04%, 3.37%, and 8.01%.

Based on the nutrient simulation and exploration of the effects of those two management practices (filter strips, stream bank stabilization and fencing) on nutrient removal, the sediment modeling portion of the water quality model was used to implement the most efficient nutrient management practice (streambank stabilization and fencing) and explore its effects on TSS concentrations in the Mobile River. Implementing stream bank stabilization and fencing produced monthly median TSS concentration reductions ranging from 3.6% to 10.6% in the Mobile River.

Chapter 67
Impact of Climate Change on Potato Production in India

ABSTRACT

Potato is a temperate crop and higher day temperatures cause some areas to less suitable for potato production due to lower tuber yields and its quality. Tuber growth and yield can be severely reduced by temperature fluctuations outside 5-30 °C. The rate of warming in last 50 years is double than that for the last century. Increase in temperature and atmospheric CO2 are interlinked occurring simultaneously under future climate change and global warming scenarios. If CO2 is elevated to 550 ppm the temperature rise is likely to be 3 ºC with decline in potato production by 13.72% in the year 2050. The changing climate will affect the potato production adversely due to drought, salinity, frost, flooding, erratic unseasonal rains etc. It may reduce seed tuber production, impact storage facility and potato processing industries. Therefore, the quantification of regional vulnerability and impact assessment is very important for the development of early warning on disease forecasting systems, breeding of short duration and heat, drought, salinity tolerant and disease resistant cultivars.

INTRODUCTION

The book chapter "Sustainable Potato Production and the Impact of Climate Change" deals with the possible impact of global warming and elevated CO_2 on Potato production. The results presented in this chapter are summarized findings of the research conducted in India; its agricultural universities and Indian council of Agricultural Research (ICAR). The level of atmospheric temperature and carbon dioxide raised under controlled conditions to some possible changes in near future to assess the impact on climate change on potato production. Findings of various researchers of India are compiled in the form of book chapter for easy understanding and in line of future work. Mitigation of impact of climate change on potato is discussed in global context.

BACKGROUND

The bottom-line conclusion of the Third Assessment Report of the Intergovernmental Panel on Climate Change (IPCC, 2001) is that the average global surface temperature will increase by between 1.4°C and 3°C above 1990 levels by 2100 for low emission scenarios and between 2.5°C and 5.8°C for higher emission scenarios of greenhouse gases and aerosols in the atmosphere. The effect of increased temperatures on potato production in specific areas will vary depending partly on the current temperature of that area. Temperatures above 30 °C can have several negative impacts on potato production like: slowing tuber growth and initiation, less partitioning of starch to the tubers, physiological damage to tubers (e.g. brown spots), shortened/non-existent tuber dormancy, making tubers sprout too early. These effects can reduce crop yield and the number and weight of tubers. As a result, areas where current temperatures are near the limits of potatoes' temperature range will likely suffer large reductions in potato crop yields in the future.

Potato farming is the most important economic activity in some parts of India. Uttar Pradesh, Punjab and West Bengal are the major potato producing states. There is direct effect of global warming and serious risk to future crop production and food security in the country. At high altitudes, global warming will probably lead to changes in the time of planting, the planting of late-maturing cultivars, and a shift of the location of potato production. In many of these regions in India, changes in potato yield are likely to be relatively small in initial stage but expected to trigger in coming era of global warming. Shifting planting time or location is less feasible at lower altitudes, and in these regions global warming could have a strong negative effect on potato production. It is likely that the currently observed trend of global warming, which has been 0.6 ºC + 0.2 since 1900, will continue and that the average global temperature will increase by between 1.4 and 5.8 ºC over the period 1990 to 2100. It is shown that heat-tolerant potato cultivars could be used to mitigate effects of global warming in (sub) tropical regions. Climate change is now an acknowledged fact and reality. The evidence gathered world over using state-of-the-art technology by various national and international agencies is irrefutable. Human activities like rapid industrialization, intensive agriculture, and indiscriminate use of fertilizers, deforestation and increasing use of fossil fuels during past 150 years are the major contributing factors for climate change. The continued effect of these activities resulted in increasing emission of CO_2 and other greenhouse gases (GHG) leading to global warming as a '*greenhouse effect*' due to entrapment of back radiation from earth by these gases. The increase in temperature due to global warming is 0.76 ºC since 1850. The rate of warming in last 50 years is double than that for the last century. The rate of warming is increasing. The 20th century's last two decades were the hottest in 400 years and possibly the warmest for several millennia, according

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to a number of climate studies. And the United Nations' Intergovernmental Panel on Climate Change (IPCC) reports that 11 of the past 12 years are among the dozen warmest since 1850. The CO_2 concentration is projected to double from the current level of 360 ppm in the atmosphere. Global warming is occurring along with shifting pattern of rainfall and increasing incident of extreme weather events like floods, droughts and frosting. Concentration of greenhouse gases on time scale is presented in Figure 1.

Global annual average surface temperature in 2015 is looking set to reach 1°C above the pre-industrial average (as represented by the 1850-1900 reference period) for the first time, according to the HadCRUT4 dataset produced by the Met Office and the Climatic Research Unit at the University of East Anglia (Figure 2). This is based on the current January to September 2015 temperature anomaly, and is also expected to hold when the final full-year anomaly is calculated. The warmth of 2015 represents an important marker because it means we are reaching halfway to 2°C for the first time. In 2010, parties to the United Nations Framework Convention on Climate Change (UNFCCC) agreed warming should be limited to below 2°C to avoid dangerous climate change.

The growth of potato in India has been phenomenal since 1950 with increase in area production and productivity by 6, 15 and 3 times, respectively. Globally India stands at 4th and 3rd position now with respect to acreage and production, respectively. The crop is mainly confined to Indo-Gangetic plains in

mild and cool winters in India. The autumn/winter planted crop in northern plains of India comprising the states of Uttar Pradesh, West Bengal, Bihar, Punjab and Haryana contributes 84% of total potato production in India. Here, the crop is grown totally under irrigated conditions. It is also grown in small scattered areas as rainfed crop in hills during summers and as rainy (*kharif*) and winter seasons crop in plateau region. However, the climate change and global warming will have a profound effect on potato growth story in India impacting every aspect of not only production and profitability, but seed multiplication, storage, marketing and processing of this perishable vegetatively propagated crop. Under the impact of future scenarios of climate change, the growth projections of potato in India might be arrested or even reversed, unless effective adaptation measures are evolved for timely application.

IMPACT ANALYSIS

Increase in temperature and atmospheric CO_2 are interlinked occurring simultaneously under future climate change and global warming scenarios. Effect of their interaction on potato would be more relevant and of greater economic significance compared to their usually counteracting direct effects on crop growth, yield and quality. Potato is mostly grown in north India during winters usually receiving few scattered rains. Under future scenarios the global warming is projected to be more pronounced over land areas with maximum temperature increase over northern India. The winter and post monsoon seasons are likely to be more affected by warming. Therefore, potato in addition to direct effects on growth and yield may be subjected to indirect effects of warming. These are increasing drought due to reduction in precipitation accentuating salinity and unpredictable extreme events of erratic unseasonal rains, flooding and frosting *etc*.

Effect of Elevated CO_2 and Temperature

Productivity

Effect of Elevated CO2 and Rise in Temperature on Potato Production in India

All India estimates of potato production were made by INFOCROP-POTATO simulation model (Singh, 2005, 2008) without adaptations and assuming that area under the crop remains constant at current levels (1.2 m ha) in future climate scenarios (Table 1). Results showed that the potato production will increase by 11.12% at elevated CO_2 of 550 ppm and 1 ºC rise ºin temperature. However, the future climate scenarios for India indicates that at elevated CO_2 of 550 ppm the temperature rise is likely to be 3 ºC (IPCC, 2007), with decline in production by 13.72% in the year 2050. The 1 ºC rise in temperature is likely to be associated with only 400 ppm of CO_2 to be assumed in the year 2020 (IPCC, 2007), with a decline in potato production by 3.16% (Table 1).

Direct Effect of Elevated CO2

The effect of elevated CO_2 concentration in controlled experiments conducted in OTC (Open top chambers), FACE (Free air carbon enrichment) and growth chambers overwhelmingly suggests positive effect on growth and yield with only few negative influences.

The CO_2 concentration and assimilation are positively correlated. Doubling the CO_2 concentration from ambient level of 360 ppm to 720 ppm increased the total biomass by 27 to 66% (Collins, 1976; Heagle *et al*., 2003; Olivo *et al*., 2002; Donnelly *et al*., 2001; Miglietta *et al*., 1998; Van de Geijn & Dijkstra, 1995). The tuber yield increased from 32 to 85% (Collins, 1976; Wheeler *et al*., 1991; Heagle *et al*., 2003; Craigon *et al*., 2002; Olivo *et al*., 2002; Donnelly *et al*., 2001; Miglietta *et al*., 1998; Finnan *et al*., 2002). The increase in tuber yield is estimated to be approximately 10% for every 100 ppm increase in CO_2 concentration (Miglietta *et al*., 1998). These positive effects are attributed to increased photosynthesis from 10 to 40% (Collins, 1976; Katny *et al*., 2005; Olivo *et al*., 2002; Vandermeiren *et al*., 2002; Schapendonk *et al*., 2000). The increase in photosynthesis was most marked in young leaves (Katny *et al*., 2005; Vandermeiren *et al*., 2002). This is attributed to phenomenon of photosynthetic acclimation later in the growing season particularly in old leaves (Vandermeiren *et al*., 2002; Schapendonk *et al*., 2000; Lawson *et al*., 2001). Varietal differences in response to elevated CO_2 concentration exists (Olivo *et al*., 2002). Number of tubers remained unaffected under elevated $CO_{2,}$ but mean tuber weight

Table 1. Change (%) in potato production in India from current levels as affected by elevated CO2 and rise in temperature without adaptations

Atmospheric CO_2 conc. (ppm)	Rise in temperature (ºC)					
	Nil (current)	1 (2020)	2	3 (2050)	4	5 (2090)
369 (current)	0.0	-6.27	-17.09	-28.10	-42.55	-60.55
400 (2020)	3.40	-3.16	-14.57	-25.54	-58.63	-58.63
550 (2050)	18.65	11.12	-1.25	-13.72	-30.25	-49.94

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

increased mainly through increase in number of cells in tubers without influencing the cell volume (Collins, 1976; Chen and Setter, 2003; Donnelly *et al*., 2001). However, an increase in tuber number has been also observed (Miglietta *et al*., 1998; Craigon *et al*., 2002).

Elevated CO_2 concentration reduces evapotranspiration (ET) resulting in water saving to the extent of 12 to 14%(Magliulo *et al*., 2003; Olivo *et al*., 2002). Elevated CO_2 concentration advances the tuber initiation and flowering (Miglietta *et al*., 1998) but hastens senescence of leaves (Miglietta *et al*., 1998; Vaccari *et al*., 2001). The few negative effects of elevated CO_2 concentration include reduction in chlorophyll content in leaves particularly during later growing season after tuber initiation (Bindi *et al*., 2002; Lawson *et al*., 2001).

Direct Effect of Temperature

Growth and development is affected at high temperatures encountered in the tropics. No potato crop growth is possible below 2 ºC and above 30 ºC (Van Keulen & Stol, 1995). The minimum (0-7 ºC), optimum (16-25 ºC) and maximum (40 ºC) temperatures for net photosynthesis are reported (Kooman & Haverkort, 1995). Potato requires cool night temperature to induce tuberization (Burt, 1964; Ku *et al*., 1977; Cutter, 1992). Although photosynthesis in potato is suppressed by high temperature (Ku *et al*., 1977), it is not as sensitive to temperature as tuberization and partitioning of photosynthates to tuber (Reynolds *et al*., 1990; Midmore & Prange, 1992). The radiation use efficiency (RUE) is suppressed under high temperatures (Allen & Scott, 1992). High temperature reduces tuber number and size (Ewing, 1997).

High temperature brings about marked morphological changes like etiolated growth with smaller size of compound leaves and leaflets reducing the LAI (Ewing, 1997; Fleisher *et al*., 2006) in addition to reduction in tuber number and size (Peet & Wolfe, 2000; Khan *et al*., 2003). However, long day conditions and high temperature prevailing in spring season in Punjab state in plains of India favoured growth of foliage at the cost of tubers and improved processing quality of tubers (Marwaha & Sandhu, 2002).

Potato requires cool night temperature to induce tuberization, which is inhibited by even moderately high temperatures (Ku *et al*., 1977; Ewing, 1997). Tuber initiation was most affected by high temperature (Ghosh *et al*., 2000). High temperature reduces the gross photosynthetic rate (Fleisher *et al*., 2006). Although photosynthesis in potato is suppressed by high temperature (Ku *et al*., 1977), it is not as sensitive to temperature as tuberization and partitioning of photosynthates to tuber (Reynolds *et al*., 1990; Midmore and Prange, 1992). Therefore, even moderately high temperature drastically reduces tuber yield without much affecting the photosynthesis and total biomass production (Peet & Wolfe, 2000).

Interaction Effect of Temperature and CO_2

Potato tuber yield of plants exposed to high temperatures (35 ºC) were extremely low regardless of CO_2 treatment, while in a non-temperature stress treatment (25 ºC) doubling CO_2 increased tuber yield significantly by 71.5% (Peet & Wolfe, 2000). In another study potato was grown for 35 days under CO_2 concentrations (500, 1,000, 1,500 and 2,000 micromoles mol-1) at both 16 ºC and 20 ºC air temperature. The mean starch concentration increased with increasing CO_2 concentration at both 16 ºC and 20 ºC and was consistently higher at 16 ºC than at 20 ºC (Cao & Tibbitts, 1997). The SLW (g.m-2) was positively related to the foliar starch concentration on the basis of leaf area or dry weight (Cao & Tibbitts, 1997).

The CO_2 enrichment does not appear to compensate for the detrimental effects of higher temperature on tuber yield, while the quality of potato is likely to be impacted severely in terms of marketable grade of tubers and internal disorders.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Quality

Elevated CO_2 increased the amount of dry matter and starch with decrease in glycoalkaloid and nitrates improving the quality of tubers (Vorne *et al*., 2002; Schapendonk *et al*., 2000; Donnelly *et al*., 2001). Nearly all the nutrient elements tend to decrease in tubersunder elevated CO_2 (Cao and Tibbitts, 1997; Fangmeier *et al*., 2002) and the citric acid content decreases causing a higher risk of discoloration after cooking (Vorne *et al*., 2002).

High temperature is associated with tuber disorder of internal necrosis (Sterrett *et al*., 1991). In a pot experiment in naturally lit glass house and phytotron, the high temperature (30 ºC) decreased the total dry matter and tuber yield and degraded quality by reducing specific gravity of tubers (Ghosh *et al*., 2000). Nitrate reductase (NR) activity was also decreased by high temperature. The inhibition of tuber yield was due to limited translocation of carbohydrates from leaves to tubers following the reduction of NR activity and carbohydrate expense for dark respiration (Ghosh *et al*., 2000). It can also affect tuber quality by causing 'heat sprouting' which is premature growth of stolons from immature tubers (Wolfe *et al*., 1983; Struik *et al*., 1989) and internal necrosis (Sterrett *et al*., 1991). Potato processing requires large size tubers with high dry matter. Warming may reduce proportion of marketable and processing grade tubers for table and processing purposes, though dry matter may increase.

Indirect Effects of Climate Change and Global Warming

Draught

Optimal water supply is essential for potato, because of its shallow root system. The potato plant generally roots rather shallowly 40-50 cm (Beukema & Van der Zaag, 1990). Potato is extremely sensitive to drought particularly at tuber initiation with substantial loss in tuber yield. Dry matter partitioning to root, shoot, leaf and stem as a function of development stage (DS) and the root:shoot ratio is affected by drought stress. Drought, while reducing dry matter production increases the root:shoot ratio indicating a shift in the balance of growth in favour of roots. Roots of plants grown in drought conditions also tend to be thinner. Both responses enable drought plants to exploit the available soil moisture more effectively (Vos, 1995). Tuber initiation and maturity under drought stress conditions is hastened (Beukema & Van der Zaag, 1990).

1. **Salinity:** Potato is highly sensitive to salinity and irrigation with saline waters with even moderate residual sodium carbonate (RSC) values (Singh & Trehan, 1993).
2. **Frost:** Potato is extremely sensitive to frost. Complete loss of foliage is reported below 2 ºC of ambient temperatures for 2-3 consecutive nights. More than 4-5 hrs. duration of temperature below 1 ºC may result in foliage loss of 50% in even one night exposure. However, yield losses depend on crop growth stage at occurrence of frost. Frosting late in the season from 80-90 days after planting (DAP) results in yield loss of 10-15%, while that at 50-60 DAP may cause yield loss of 30-50%.
3. **Flooding:** Flooding for even short period of 2-3 days during active vegetative phase affects growth and yield. Flooding before emergence severely affects emergence due to rotting of seed tubers and soil crust formation, while that near harvesting results in rotting and rupture of tuber lenticels affecting physical appearance and marketable quality.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. **Erratic Unseasonal Rains:** Rains of even 10-15 mm during planting or immediately after planting affects emergence due to soil crust formation and delays planting operation with consequent loss in yield. Rains during active vegetative phase may promote incidence of late blight disease.
5. **Seed Tuber Production:** In vegetatively propagated potato crop, the disease free quality seed tubers as planting material has special and added significance. Tuber as seed material is the carrier of a host of fungal, bacterial and viral diseases, responsible for rapid and drastic reduction in yield in successive generations of clonal multiplication. Most importantly the seed tubers alone accounts for half of the cost of inputs in potato cultivation and the profitability of the cropping enterprise to a large extent depends on quality of seed used. Viral diseases transmitted by aphid and other vectors are mainly responsible for rapid degeneration of planting materials in potato crop. The technology of '*seed plot technique*' was developed on the sole premise of growing seed tubers in relatively aphid free periods in plains during winters and termination of vines by dehaulming before aphid population crosses a threshold to minimize infection of viral diseases. The appearance of potato peach aphid (*Myzus persicae*) is reported to advance by two weeks for every 1°C rise in mean temperature and population build up is positively correlated with maximum temperature and minimum relative humidity (Biswas *et al*. 2004; Dias *et al*., 1980). Thus, under the impact of climate change and global warming the earlier appearance and increase in aphid population is likely to limit the aphid free period to the detriment of seed tuber quality and quantity, which will ultimately affect potato production in India. In many regions warming may abolish seed tuber production altogether, while in others it will involve extra cost on chemicals and pesticides treatment with increased cost of seed resulting in decline in profitability.
6. **Storage:** The harvesting of potato in plains of India coincides with onset of hot summer season. Cold storage of tubers is recommended by the end of February to prevent heavy weight loss and rotting. It is cold stored up to the end of October till withdrawal for human consumption and planting is accomplished. In certain regions relatively cooler climate permits on farm storage of tubers for short period for 80-90 days in improvised country stores, heaps and pits with acceptable losses. However, warming during the period from March to June may preclude this practice with increased cost of storage in the cold stores. On the other hand earlier cold storage than the recommended by the end of February and prolonged storage beyond October till weather is favourable for planting, might become necessary under global warming scenarios. This will increase the operational cost and energy use in cold stores with implied increase in cost of cold storage and enhanced market price of potato for table and seed purpose. More number of strategically located cold stores near production and consumption centers would be needed to maintain the supply chain during hot summer months from March to October under global warming.
7. **Potato Processing Industry:** The potato tubers stored in cold stores at 4 ºC is not suitable for processing purposes due to increase in reducing sugar content imparting undesirable attributes in various processed products. Potato tubers kept in low temperature stores at 10 ºC or in on farm country stores are utilized for processing. However, tubers kept in these low temperature and country stores suffer from sprouting and weight loss once the dormancy is broken rendering it relatively unfit for processing. Global warming will reduce the 'time window' of availability of potato suitable for processing and will result in enhanced cost of chemical treatment of tubers to prevent sprouting. This has implication for viability of potato processing industry for supply of raw material for extended periods to be economical.

Regional Vulnerability to Climate Change in India

The entire Indo-Gangetic plains, where irrigated potato is mainly grown is vulnerable. However, the state of West Bengal with highest productivity and second largest potato producing state in India appears highly vulnerable. Winters are mild in West Bengal and 'window' of suitable growing period is small, any rise in temperature will severely impact productivity with associated problems of storage and post harvest handling of produce in warmer conditions. Other vulnerable states are Bihar and Uttar Pradesh, which contributes maximum in total potato production. The states of Punjab, Haryana, and adjoining areas in northern Rajasthan and western Uttar Pradesh, where winters are relatively severe experiencing occasional frost might benefit from global warming to certain extent. The rainfed crop in plateau regions and other areas in south India would be most vulnerable due to warming and associated drought conditions.

Observations on Aberrant Weather and Extreme Events

- Rains in winter season received at planting affects emergence and delays planting with reduction in tuber yield.
- Heavy showers during the crops season resulting in flooding affects tuber yield.
- Heavy rains at the time of harvesting induce rottage in field and in temporary heaps of harvested potato in the field.
- Overcast sky and rains early in the crop season invariably increases the attack of late blight disease with severe reduction in yield.
- Early frosting received in last fortnight of December and first week of January damages the crop in North-Western plains and western UP.
- Relatively warmer winters in the year 2008 reduced tuber yield in West Bengal, UP and Bihar.

Adaptation Measures for Climate Change and Global Warming

- Use of crop residue mulches for some time after planting.
- Using drip irrigation in place of furrow and basin methods.
- Alter cultural management in potato based cropping systems.
- Conservation tillage and on farm crop residue management.
- Improvement and augmentation of cold storage facilities and air conditioned transportation from producing to consumption centers.
- Subsidizing additional cost of pests and water management.
- Insurance against weather for the cash crop of potato with high cost of cultivation.
- Strengthen education, research and development in warm climate production technology for ware and seed potato crop.

Mitigation Measures to Reduce Emission of CO_2/ghg and Carbon Sequestration Potential of the Crop

Potato being a short duration annual crop with readily decomposable crop residues has very limited carbon sequestration potential. Other mitigation measures are as follows.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Resource conservation techniques
- Organic farming

FUTURE STRATEGIES FOR RESEARCH

- Quantification of regional vulnerability and impact assessment.
- Development of early warning disease forecasting systems.
- Breeding short duration and heat tolerant cultivars. Mining biodiversity to heat tolerance on priority.
- Breeding drought, salinity tolerant and disease resistant cultivars.
- Advance planning for possible relocation and identification of new areas for potato cultivation.
- Improved agronomic management for water and fertilizer use efficiency.
- Development of agro-techniques for warm weather cultivation and potato based cropping systems.

CONCLUSION

Potato a native of temperate region grown under long day conditions in mild and cool summer season in Europe and America was introduced and adapted to tropical short day conditions in India during the last century. The growth of potato in India has been phenomenal since 1950 with increase in area production and productivity by 6, 15 and 3 times, respectively. The crop is mainly confined to Indo-Gangetic plains in mild and cool winters in India. The autumn/winter planted crop in northern plains of India comprising the states of Uttar Pradesh, West Bengal, Bihar, Punjab and Haryana contributes 84% of total potato production in India, where the crop is grown totally under irrigated conditions. Growth and development is affected at high temperatures encountered in the tropics. No potato crop growth is possible below 2 ºC and above 30 ºC. The minimum (0-7 ºC), optimum (16-25 ºC) and maximum (40 ºC) temperatures for net photosynthesis are reported. Potato requires cool night temperature to induce tuberization. Although photosynthesis in potato is suppressed by high temperature, it is not as sensitive to temperature as tuberization and partitioning of photosynthates to tubers.

The climate change and global warming will have a profound effect on potato growth story in India impacting every aspect of not only production and profitability, but seed multiplication, storage, marketing and processing of this perishable vegetatively propagated crop. Under the impact of future scenarios of climate change the growth projections of potato in India might be arrested or even reversed, unless effective adaptation measures are evolved for timely application and implementation. Increase in temperature and atmospheric CO_2 are interlinked occurring simultaneously under future climate change and global warming scenarios. Effect of their interaction on potato would be more relevant and of greater economic significance compared to their usually counteracting direct effects on crop growth, yield and quality. It is estimated that due to global warming potato production in India may decline by 3.16 and 13.72% from current levels by the year 2020 and 2050, respectively. The potato production will be directly affected by climate change, while there would be several indirect effects on various facets of supply, storage, utilization and acreage of the crop in future climate scenarios.

Chapter 68
Rift Valley Fever and the Changing Environment:
A Case Study in East Africa

ABSTRACT

Rift Valley fever is a severe disease affecting both humans and animals. The Rift Valley fever virus can be transmitted by body fluids, and the most common way for humans to get infected is from animals. The virus is also vector-borne and can be transmitted by many species of mosquitoes. As with other vector-borne diseases, the epidemiology may vary in response to environmental changes. Here the effects of climate and land use changes on Rift Valley fever, as well as on other vector-borne diseases, are discussed. The effect of irrigation in East Africa on inter-epidemic transmission of RVF is discussed in greater detail, followed by recommendations for future research and actions.

INTRODUCTION

The last century has seen a period of ecological change, unprecedented in recent times, with dramatic reductions in pristine habitats, ecosystem services and biodiversity along with equally dramatic increases in numbers of people and of domestic animals. Most land use practices change the environment and are due to human influence, often related to feeding the growing population, such as increased irrigation

and land deforestation to allow crop cultivation. Environmental change is ubiquitous, and new diseases continue to emerge, while concerns about the impact of environmental change on human health grow. However, while it seems intuitive that degradation of ecosystems will increase the risk of disease, detailed knowledge on how specific environmental changes in a given context affect disease transmission is often lacking. As a consequence, decision makers may inadvertently increase health risks.

This chapter uses the example of Rift Valley fever (RVF) to explore relations between disease dynamics and environmental change. Two main drivers, climate and land use changes, can be identified. We focus on irrigation as a type of land use change. In addition, RVF is characterized, describing the knowns and unknowns about its epidemiology and recapitulating the history and impact of RVF outbreaks in east Africa. Next we discuss relations between RVF and climate and land use change. Findings from an ongoing study, which shows that an irrigated area can support endemic transmission of RVF, without any signs of outbreaks, are also presented and the relevance of this is discussed.

IMPORTANCE AND DRIVERS OF EMERGING DISEASE

Emerging infectious diseases in both animals and humans cause major economic and health burdens in every part of the world. On average, a new human disease appears every four months and around 75% of emerging diseases are zoonotic (Jones et al., 2008). Most originate from wildlife, and the study of disease emergence has a strong focus on wildlife. However, economically important emerging diseases often involve domestic animals. For example, between 1997 and 2009, six major emerging diseases have together cost at least 80 billion USD: the Nipah virus outbreak in Malaysia, West Nile fever in the USA, severe acute respiratory syndrome (SARS, starting in Asia), highly pathogenic avian influenza (HPAI, starting in Asia), bovine spongiform encephalopathy (BSE, starting in the UK) and RVF in East Africa (World Bank, 2012). In all of these, livestock or animals farmed for human consumption provided either a reservoir or a bridge to transmit the disease to people. Later outbreaks of emerging infectious diseases, such as Middle East respiratory syndrome (MERS) and the Ebola outbreak in West Africa, were also caused by viruses with an animal reservoir; in the case of MERS livestock (camels) are an amplifying host, and in the case of Ebola a livestock interface has been suspected (Atherstone, Smith, Ochungo, Roesel, & Grace, 2015; Wong et al., 2015; Yuen, 2015).

The burden of infectious diseases is not uniform, and in low-income countries a high proportion of disease stems from zoonotic diseases and diseases recently emerged from animals (Grace, Gilbert, Randolph, & Kang'ethe, 2012). In Africa, diseases affect poor people disproportionally and further contribute to their poverty in a vicious circle. In particular, zoonotic diseases have the potential to harm both the livelihoods and health of those depending on livestock. Africa is also the continent where more than half of all outbreaks of emerging infectious diseases verified by WHO between 1996 and 2009 occurred, and where the time lags between outbreak detection and public alerts are the longest (Chan et al., 2010).

Moreover, demographic growth is predicted to remain high in Africa, with the continent's population predicted to reach 4 billion in 2100 (from 1 billion in 2014) (Gerland et al., 2014). This rapid population growth is likely to drive equally rapid changes in ecosystems, including crop expansion into marginal areas, irrigation, deforestation, urban sprawl, road building, mining and bush meat harvesting (Grace & Bett, 2014). Depending on how these changes affect the number of susceptible animals and humans, their risks of exposure and the infectiousness of the infected individuals, they may either increase or decrease disease incidence (Lindahl & Grace, 2015). Land-use change often drives disease and has been

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

estimated to be responsible for more than 20% of disease emergence on the island continent of Australia (McFarlane, Sleigh, & McMichael, 2013). In addition, the risks of land use associated diseases are often exacerbated by change and variation in climate changes and the poor adaptive capabilities of communities.

Influence of Environmental Change on Arthropods and Arthropod-Borne Diseases

The dependence of arthropod vectors on the surrounding environment makes them susceptible to change. Arthropods are exothermic, and thus their life cycles, as well as possible pathogen replication within them, are strongly affected by temperature (Khasnis & Nettleman, 2005; Kramer & Ebel, 2003). Vectors are also dependent on suitable habitats for breeding, determined by factors such as soil, land cover and use, temperature, moisture, rainfall patterns and vegetation. When climate changes, the consequence may be that a vector changes its potential distribution and seasonal pattern of activity (Githeko, Lindsay, Confalonieri, & Patz, 2000; Patz, Campbell-Lendrum, Holloway, & Foley, 2005; Russell, 1998). Climate change may also result in changes in precipitation with varying effects on vectors (Githeko et al., 2000). For example, drastically increased precipitation may flush out larval habitats (Impoinvil et al., 2011; Khasnis & Nettleman, 2005; Murty, Rao, & Arunachalam, 2010), but the long term effect might be establishment of more breeding grounds.

The Effect of Climate and Indirect Consequences

Climate changes have direct and indirect impacts on vector-borne disease transmission. Changes in temperature can change vector competence, and thus cause mosquito species (that are minor or insignificant vectors) to become more important (Mellor & Leake, 2000; Tabachnick, 2013). Whether or not, and how efficiently, an arthropod can act as a vector depends on many factors. Temperature affects the longevity of the vector and the rate of virus multiplication within it (Kramer & Ebel, 2003; Tabachnick, 2013). In addition, humidity and wind could influence the longevity and dispersal of the vector, and precipitation may determine the spatial distribution and suitability of breeding grounds.

So how will vector-borne diseases be affected when climate changes? The complex nature of vector-borne disease transmission makes predictions difficult. It is important to understand the impact of climate change on environmental factors that may influence vector dynamics (Tabachnick, 2010), such as changes in land use, population movements and interactions. Increased temperatures may increase the need for irrigation or dams, thus creating vector habitats, and movement and interactions between humans and different animal species bring new vectors into contact with new hosts. The transmission from the vectors depends on the vector capacity (Cohuet, Harris, Robert, & Fontenille, 2010), defined as the number of potentially infective bites an individual is exposed to during one day from one particular vector species (Black & Moore, 2005).

Extrinsic and intrinsic factors needed to be estimated for the calculation of vector capacity:

- The probability that a vector feeds on a specific host, which depends on the feeding frequency and the proportion of meals taken from that host.
- The vector density in relation to the host density.
- The probability that the vector survives each day.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The vector competence, which is the proportion of vectors taking an infected meal that become infected and can transmit the infection to another host.
- The duration of the vector's life after the incubation period of the pathogen in the vector.

It is clearly an over-simplification, therefore, to equate increase in vector-borne transmission with increase in temperature. Temperature affects the intrinsic factors of the arthropods, such as development rate and longevity (and thus vector abundance), pathogen incubation period within the vector (extrinsic incubation period (EIP)), behaviour and reproduction. Increased temperatures speed processes up within the arthropods and thus decrease both the incubation period in the vectors and their longevity (Kramer & Ebel, 2003; Tabachnick, 2013). In general, all factors contributing to increased vector abundance, shorter incubation periods, and increased vector survival are likely to increase the disease transmission. However, factors contributing to an increased host density and proportion of suitable hosts could also result in increased disease transmission, and these factors may also be dependent on environmental changes, such as increased droughts making farmers keep more goats instead of relying on crop production.

The indirect effects of climate change on ecosystems are thus also important. Decreased surface water availability may cause large numbers of potential hosts to aggregate closer to the water sources which could intensify transmission, and reduced availability of water bodies could negatively impact the predators that feed on mosquito larvae (Epstein, 2001). In addition, even when an increase in disease incidence is observed after climate change, there are many possible confounding factors such as droughts reducing crop yield and impacting the nutritional status of a community, interrupted infrastructure, which may for example make vaccination campaigns or health care impossible, or decreased social and health services. All these events may contribute to the subsequent increase in disease incidence (Lindahl & Grace, 2015).

Due to these complexities, there are uncertainties as to how different vector-borne diseases may be affected by different aspects of climate change. Each vector-pathogen system has a different range of tolerated temperatures, with optimal transmission occurring within a tighter range (Mellor & Leake, 2000). Since minimum temperatures are predicted to change more than maximum temperatures, it has been suggested that the effects on vector-borne disease transmission are more likely to go from suboptimal to more optimal, than from optimal to temperatures higher than those ideal for transmission (Ostfeld, 2009). As an example, the lower temperature allowing malaria transmission is estimated to be around 14-18°C, whereas the upper limit is around 35-40°C. When changes occur, it is likely to affect disease transmission in borderline regions more than in areas of core suitability (Githeko, Lindsay et al. 2000), although temperature changes that could make transmission more optimal in the local setting are likely to have an impact. Cold temperatures affect the duration of the mosquito's breeding season and some species are able to continue breeding at lower temperatures (Mogi, 1996). Increases in temperature could lead to a life span shorter than the incubation period, or higher mosquito mortality, therefore, limiting disease transmission. However, the capacity of mosquitoes to find suitable microhabitats to avoid heat is an efficient adaptation strategy.

However, it is not certain that the increased potential for disease transmission caused by climate change will be observable. If the transmission of vector-borne diseases is already high, it may not be possible to observe small changes in transmission rates, and this could be the case especially in tropical low-income countries (Reiter, 2001). The opposite scenario may occur in developed countries, where socioeconomic factors may prohibit increased spread of diseases, in spite of climate becoming more permissive. Mosquitoes capable of transmitting malaria are present as far north as Scandinavia, but be-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

cause of improved living standards and healthcare, malaria disappeared from Europe in the 20th century (Hulden & Hulden, 2009), and is unlikely to return.

The Effect of Land Use Changes

Climate changes, though an important contributor to mosquito habitat suitability, is not the only factor responsible for distribution changes of vector-borne diseases. Indeed, most of the new introductions of invasive mosquito species have not been related directly to climate change (Gubler et al., 2001). Globalization, increased travels and trade provide excellent means for transportation of adult mosquitoes, as well as their eggs. In spite of these risks, travels and trade are highly promoted and unlikely to be reduced (Lindahl & Grace, 2015).

Vectors have different requirements for their breeding grounds, and these are often, but not always, dependent on meteorological factors. One of the major vectors for RVF in West Africa, *Aedes vexans*, breeds in seasonal ponds, which vary in size with the rainfall, since the mosquito eggs also require a period of draught before the rains in order to hatch (Vignolles et al., 2009). Some of the factors influencing the availability of suitable breeding grounds are, however, affected by anthropogenic activities, such as irrigation, agricultural intensification, urbanization, and deforestation. In addition, climate and land use changes interact with each other as well as other drivers. For example, climate induced deterioration of agricultural conditions may increase the rural-urban migration; it may initiate schemes for irrigation, or cause people to switch agricultural practices. Furthermore, large-scale changes in land use such as deforestation may contribute to climate change.

Irrigation may be an especially potent driver of vector-borne disease in Africa given current forecasts for large-scale expansion. Irrigation has been associated with a plethora of diseases including malaria, schistosomiasis, and RVF (Keiser et al., 2005; Steinmann, Keiser, Bos, Tanner, & Utzinger, 2006). Africa has an enormous potential for irrigation: just 4% of the total cultivated area is irrigated compared to 37% in Asia and 14% in Latin America (You, 2008). It is expected that heavy investments in irrigation are likely to occur over the coming decades and smallholder irrigation could cover 30-40 million ha, benefitting 400 million people (Keiser et al., 2005; Xie, You, Wielgosz, & Ringler, 2014). However, it is possible that this may expose them to additional health risks.

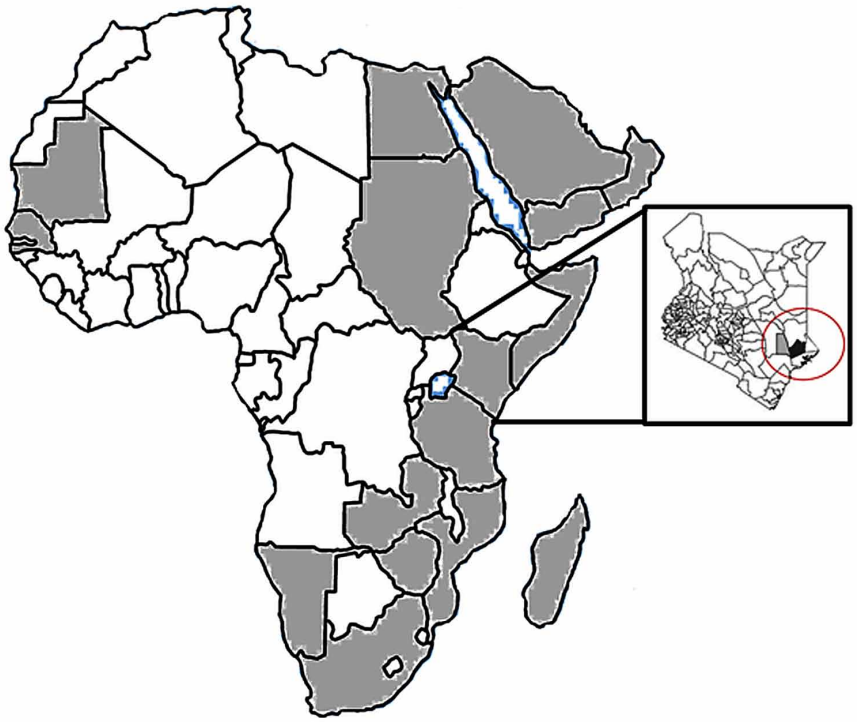
RIFT VALLEY FEVER: AN EMERGING DISEASE

Rift Valley fever (RVF) was identified in the 1930s in the Rift Valley region in Kenya, although probable outbreaks could be traced as far back as 1912 (Daubney, Hudson, & Garnham, 1931; Davies, 2010; Findlay, 1932). Analyses of the viral genome suggests that the original emergence of the virus, proposed to have evolved rather recently, might be due to early land use changes in the shape of colonial agricultural development with introduction of large scale ruminant farming (Pepin, Bouloy, Bird, Kemp, & Paweska, 2010).

The virus was not known to be zoonotic until human cases were described in the 1951 South African outbreak (Davies, 2010), and the full zoonotic potential was realized only in 1977 when an outbreak in Egypt resulted in about 600 human deaths, among some 200,000 human cases (Nanyingi et al., 2015; Soumaré et al., 2012). Rift Valley fever is considered one of the emerging infectious diseases that is having the most severe impacts in the African continent, and is present in most of sub-Saharan Africa,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Map over the countries in Africa which have experienced extensive outbreaks of Rift Valley fever (grey); the insert of Kenya shows the study areas for the case study on Rift Valley fever, with dark grey for the pastoral areas in Ijara district, and light grey for the areas close to the irrigation scheme in Tana River district.
Swanepoel & Coetzer, 2004.



with extensive outbreaks occurring in Kenya, Tanzania, Madagascar, Mauretania, Senegal, Namibia, Mozambique, South Africa, Zimbabwe, Zambia and Sudan (Figure 1), but additional countries have also experienced small outbreaks, or there has been evidence of virus circulation (Nanyingi et al., 2015; Swanepoel & Coetzer, 2004). With outbreaks extending outside sub-Saharan Africa and occurring as far north as Egypt and the Arabian Peninsula, it is feared that the virus has the potential to spread into Europe and to other parts of the world (Chevalier, Pépin, Plée, & Lancelot, 2010; Moutailler, Krida, Schaffner, Vazeille, & Failloux, 2008; Turell, Sardelis, O'Guinn, & Dohm, 2002; Turell et al., 2008). Within Africa, RVF strains seem to be circulating over large distances, with samples in Madagascar shown to be similar to both North and East African strains and to the strains causing outbreaks in the Arabian Peninsula (Sall et al., 1998; Shoemaker et al., 2002). Phylogenetic studies suggest that RVF virus has been introduced into West Africa from other parts of Africa on five different occasions (Soumaré et al., 2012). Trade and transport of infected animals has been suggested to be one of the mechanisms that allowed virus dispersal.

The RVF virus belongs to the *Bunyaviridae* family, in the genus Phlebovirus. This is a large viral family with more than 300 disease-causing viruses which have tripartite single-stranded RNA. Although the viruses often are transmitted by vectors such as mosquitoes or ticks, they may also be transmitted directly by body fluids, especially fetal materials that may carry high loads of virus. The RVF virus can

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

be transmitted by numerous mosquitoes from at least 6 genera and over 30 species (Pepin et al., 2010; Walter & Barr, 2011). However, even though many mosquitoes may harbour the virus, they may not all be important for the disease epidemiology, and different vectors are important in different parts of Africa. In East Africa, it is believed that the primary vectors maintaining the virus and starting outbreaks are floodwater breeding *Aedes* species, whereas secondary vectors fuelling the outbreak are likely to be *Culex* species (Anyamba et al., 2010; Sang et al., 2010; Vilaly et al., 2013).

The virus has a predilection for the liver but spreads to many parts of the body after a host is infected (Pepin, Bouloy, Bird, Kemp, & Paweska, 2010). Clinical cases in humans are usually characterized by hemorrhagic fever and encephalitis, whereas animals abort or have hemorrhages and necrotic hepatitis (Elliott, 1997). Case fatality in young livestock can be high, and although it is difficult to assess accurately how many humans were actually infected in an outbreak, as many as 47% of confirmed and probable cases may succumb to the disease (Mohamed et al., 2010). In addition, the virus frequently causes abortion storms (Pepin et al., 2010). In the earlier outbreaks, it was reported that indigenous livestock were unaffected (Davies & Martin, 2006); however, breed has not been reported as one of the risk factors for animal infection, summarized by recent reviews (Nanyingi et al., 2015; Nicholas, Jacobsen, & Waters, 2014). Moreover, if indigenous breeds are as likely as exotic breeds to be infected, but not to develop disease, seroprevalence studies are unable to detect such a trait.

Although much research has been conducted on RVF and its vectors, some uncertainties remain, especially as to how the virus is maintained during the periods between epidemics, which have been occurring every 5-15 years in East Africa. The vectors for RVF are divided into primary and secondary vectors, where the primary vectors are involved in the initial transmission of the virus to host animals, and the secondary vectors play a larger role later in the outbreak by propagating it. *Aedes* mosquitoes are believed to be most important for disease transmission, especially those breeding in flood water. In East Africa, these mosquitoes breed in depressions termed dambos, where the eggs diapause during the dry periods, and hatch during subsequent flooding that follows prolonged rain (Logan et al., 1991). Transovarial transmission has been shown in many mosquito species, and adult reared from larvae collected in naturally flooded dambos have been shown to contain the virus (Linthicum, Davies, Kairo, & Bailey, 1985). It is therefore believed that the virus may survive in the eggs for years while waiting to hatch, and that this could explain how the virus persists during the inter-epidemic periods. It is also possible that immature stages of mosquitoes can be infected by virus present in the breeding habitats, and it has been shown that larvae of *Culex pipiens*, *Aedes mcintoshi* and *A. circumluteolus* can become infected experimentally and subsequently transfer the virus when feeding as adults (Turell, Linthicum, & Beaman, 1990).

Another explanation is that wildlife reservoirs maintain the virus in an endemic sylvatic cycle. A number of studies have shown that wild animals naturally seroconvert to RVF (Britch et al., 2013; Evans et al., 2008; Olive, Goodman, & Reynes, 2012). Sudden increases in rainfall could lead to more mosquitoes hatching, and the increased number of vectors cause spillover onto livestock and humans. Secondary vectors, such as other *Culex* species also multiply after the rains, which promotes the outbreak. It is even possible that the virus is maintained by a low level circulation among domestic animals.

The epidemiology of RVF is further complicated because body fluids of infected animals (including fetal membranes) are infectious and this is the main cause of infection in humans, although they may still get infected from mosquitoes (Anyamba et al., 2009). Therefore, certain occupation groups such as herders, farmers, slaughterhouse workers and veterinarians are at greater risk of infection. Similar contacts may occur during care or slaughtering of infected animals or possibly from ingestion of raw milk.

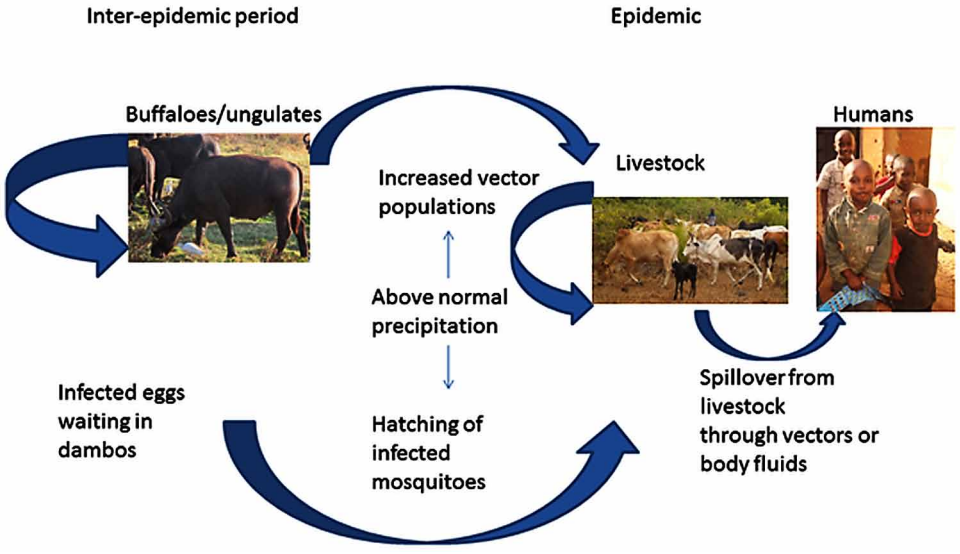
Whereas RVF is mostly known for the severe outbreaks, it is believed to be endemic and circulating between the outbreaks. Molecular epidemiological estimates suggest that the virus may not only persist but also expand undetected during these periods (Pepin et al., 2010). Possible ways in which RVF could be maintained during epidemiological cycles are shown in Figure 2.

Rift Valley Fever Outbreaks in East Africa and Their Impacts

Whereas RVF outbreaks have been associated with semi-arid or irrigated areas in West and North Africa, outbreaks in East Africa often occur in plateau grasslands (Martin et al., 2008). In 1997, Kenya experienced heavy rains, and this was followed by an outbreak of RVF, which may have infected as many as 27 000 humans (Woods et al., 2002). In this outbreak, the main risk factors for human infections were sheltering animals in the home and contact with sheep blood or body fluids. Farmers reported losing up to 70% of their sheep and goats, and as much as 95% of young lambs (Woods et al., 2002). The next major outbreak started in 2006 in Kenya and 2007 in Tanzania, continuing with Somalia and Sudan. While the Tanzania outbreak had a total number 511 suspected cases, it is unknown how many were really infected and it is believed that only severe cases were detected (Mohamed et al., 2010). For the outbreak in Sudan, up to 75,000 humans may have been exposed (Hassan, Ahlm, Sang, & Evander, 2011). It was estimated that more than 900 people died in the outbreak in the four countries affected (Nanyingi et al., 2015). Based on interviews, it was estimated that more than 400,000 livestock died in Kenya during the outbreak, with large economic consequences (Rich & Wanyoike, 2010). Also in Tanzania the economic consequences were severe, with exports of cattle decreased by more than 50% (Sindato, Karimuribo, & Mboera, 2012).

Livestock production is crucial for the livelihood in the arid and semi-arid areas of East Africa, where many are pastoralists, and an outbreak of a severe infectious disease such as RVF can be devastating for the individual livestock holders; however, it will also have an impact on national economy (Anyamba,

Figure 2. Epidemiology of Rift Valley fever



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Linthicum, & Tucker, 2001). After the 2006-2007 outbreak in Kenya, pastoralists ranked RVF as the disease with the highest impact on livestock-derived livelihoods (Jost et al., 2010). This outbreak was estimated to have caused large economic losses to the region. The World Bank (2012) estimated that the entire outbreak in East Africa caused losses of 30 million USD, similar to estimates by Rich and Wanyoike (2010).

Rift Valley Fever, Climate, and Land Use Change

RVF epidemics occur when environmental, ecological and climatic factors are conducive. Many studies have demonstrated the association with excessive rainfall, the El Nino Southern Oscillation (ENSO), changes in normalized difference vegetation index (NDVI) and presence of water bodies (Métras et al., 2011; Tourre, Lacaux, Vignolles, & Lafaye, 2009; Anyamba, Linthicum, & Tucker, 2001). However, the association with weather, which is very clear in East Africa where outbreaks occur after periods of above normal rainfall (in intervals of around 5-15 years) (Anyamba, Linthicum, & Tucker, 2001; Davies, Linthicum, & James, 1985), is not as evident in West Africa (Chevalier, Rocque, & Baldet, 2004).

There have been several attempts to model how climate change impacts RVF; either using knowledge-driven spatial models, or mathematical dynamic transmission models (Métras et al., 2011). The results of some models are being made available online, such as the model by the healthy future project and University of Liverpool (http://www.healthyfutures.eu/ (Morper-Busch, Kienberger, & Hagenlocher, 2015)). The modelling commonly takes into account mosquito vectorial capacity with biting frequencies and life cycle dependent on temperature, and breeding dependent on precipitation. However, there is a need to incorporate other environmental factors, such as land use, human and animal densities, water storage and irrigation, in such models so as to predict RVF transmission more accurately. Although climate is a very important driver of vector dynamics, more factors may be of importance and we lack a complete understanding of the life cycles of the vectors (Tabachnick, 2010). The consequences of this may be suboptimal prediction models and inaccurate decisions taken in the face of outbreaks.

Methods including remote-sensing have also proved very beneficial for studying spatial dynamics of RVF, and the influence of climate and environmental changes, and through this it has been possible to link the dynamics of *Aedes vexans* with rainfall and changes in water bodies (Tourre et al., 2009). Work in West Africa also shows the possibility of including these techniques in creating risk maps and early warning systems (Vignolles, Tourre, Mora, Imanache, & Lafaye, 2010).

Land use changes may have similar effects to climate change, by providing increased mosquito breeding grounds, and changing the availability and movements of different hosts. Increased water storage and utilization along rivers, as well as development of dams and irrigation systems, enlarge the areas that could be suitable for mosquito development, which can increase the risk of RVF transmission. A few outbreaks have been associated with anthropogenic changes to water bodies, such as the 2000-2001 outbreak in Yemen (Abdo-Salem et al., 2006), and the 1987 epidemic in the Senegal River basin (Thonnon et al., 1999). However, it must also be remembered that the purpose of providing a community with irrigation or water reservoirs often is to improve the livelihood of the inhabitants, which may lead to socioeconomic improvements, including increased living standards, improved nutritional status and access to health care and prophylactic measures. These socioeconomic factors may reduce the exposure of humans to pathogens, and make them more resistant to disease, which is likely to reduce the risks of disease spread (Lindahl & Grace, 2015). In addition, agriculture increase, following irrigation, makes

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

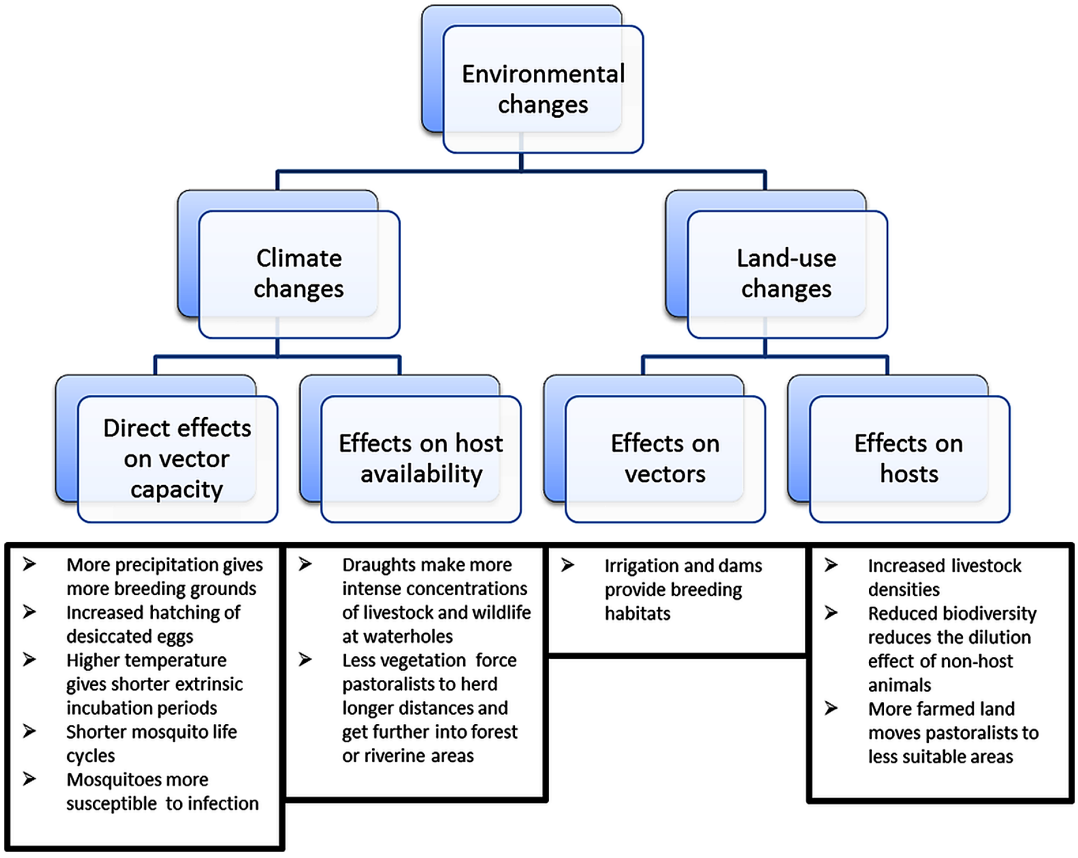
the communities more resilient to the devastating effect of a Rift Valley fever outbreak in cattle, by providing more diversified means of income and food sources (Figure 3).

Circulation of RVF Virus in Irrigated Areas During the Inter-Epidemic Period: A Case Study From Kenya

Kenya has considerable potential to increase irrigation (You, Xie, Wood-Sichra, Guo, & Wang, 2014) and there are many ongoing and planned irrigation schemes. The Northeast part of Kenya has been the focus of the last outbreaks of RVF, and the first case in the 2006 outbreak was detected in Garissa (Sang et al., 2010). The land bordering the Tana River is semi-arid with increasing irrigation. This area, including Garissa, and Tana River counties, is a hot spot for RVF outbreaks (Martin et al., 2008), and is also high in biodiversity with many endangered species threatened by land use change (Medley, 1993, 2009). Figure 1 is showing the location of the study areas within Kenya.

In this case study conducted in 2013-14, the aim was to study the circulation of RVF in an irrigated area by investigating seroprevalence of RVF in humans and animals; perform an entomological survey and interview actors in the animal value chains.

Figure 3. How environmental changes can affect Rift valley fever transmission



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Serum samples from humans, aged 5-90 years old, were collected in villages both from irrigated and non-irrigated, pastoral areas. In total, 303 people were sampled within the irrigation schemes in Bura and Hola in Tana River County, and 728 in the pastoral areas in Ijara district in Garissa County. Serum was tested using a commercial competitive enzyme-linked immunosorbent assay (ELISA) (Biological Diagnostic Supplies Limited, UK) according to manufacturer's instruction, but with a modified conjugate dilution (1:12 000) and adjusted incubation time. The original protocol was modified after consultation with the manufacturer to allow controls to fall within the fixed range before analyses. This ELISA does not differentiate IgG and IgM antibodies (Kortekaas et al., 2013), and therefore it is not possible to tell if infections causing the seropositivity are old or new. Overall 21.5% (95% confidence interval 19-24%) were seropositive, with no significant difference between the areas. Significantly more adults (over 18 years) were seropositive ($p<0.001$), and significantly more men than female ($p=0.04$).

Ruminants (sheep, goats, and cattle) were sampled in randomly selected villages within the two irrigation schemes located in Hola and Bura, in Tana River County. A total of 1997 animals were sampled, and tested with the same ELISA as the human samples. The overall seroprevalence was 25.6% (95% confidence interval 23.7-27.6%), with no difference between the two irrigation schemes, nor between the seroprevalences in goats, sheep and cattle. Juveniles had a significantly ($p<0.001$) lower seroprevalence rates than adults, 12.3% compared to 30.2%. The seroprevalence among adult ruminants may be confounded by previous vaccination campaigns in sheep and goats, campaigns were known to have taken place but there were no records of animals vaccinated. However, similar prevalence pattern was observed in unvaccinated cows: 36.4% in adults, significantly higher than in calves (19.1%, $p<0.001$). The last outbreak of RVF occurred in 2006-2007, therefore, juveniles could not have been infected during the outbreak. The level of prevalence detected is supportive of local endemic transmission (Table 1).

In the same study, entomological surveys were implemented with Kenyan Medical Research Institute (KEMRI) as has been described previously (Sang et al., 2010). Preliminary observations demonstrate that irrigated farms (specifically drainage canals) support the development of the primary vectors of RVF, mainly *Aedes mcintoshi* and *Aedes ochraceus*. These mosquitoes are believed to develop in floodwater after periods of prolonged heavy rainfall (Linthicum, Davies, Bailey, & Kairo, 1984) and it has been shown that they are infected with RVF in the same area (Sang et al., 2010). The irrigated areas had significantly higher numbers of both primary (*Aedes* spp) and secondary (*Culex* spp) vectors (Sang et al. unpublished data). This emerging evidence shows that irrigated fields can mimic breeding conditions established in flooded areas and there is a need to integrate vector management activities with irrigation, especially in areas that are conducive for RVF transmission.

Table 1. Rift Valley fever seroprevalence in humans and ruminants in Northeastern Kenya

	Humans	**Ruminants**
Overall seropositivity	21.48%	25.59%
Young*	3.71%	12.31%
Adults	30.69%	30.22%
Male	24.88%	14.81%
Female	19.22%	28.80%

*Young ruminants include weaners and younger animals. Young humans include people <18 years.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Interviews and focus groups discussions among livestock value chain actors in Tana River during the same time showed that knowledge about RVF was high in some groups, such as animal traders and slaughterhouse workers, where 88 and 90% respectively knew about the disease, whereas only 40% of milk traders knew about it. Out of 43 interviewed value chain actors, only two said they would report dead livestock to veterinarian, whereas nine reported that they would slaughter the animal. It was also common to slaughter sick animals, and the main reason for this was meat consumption (49%) (Nyokabi, 2015).

There was a higher seroprevalence rate in female animals, which may warrant further studies. Since RVF may cause reproductive failures and abortions in females, and aborted materials contain high viral loads (Pepin et al., 2010), this might indicate that the females are infected through contact with this infected material and not only through mosquito bites. This also indicates that even endemic RVF transmission could have economic impacts, and this might go undetected in an environment where there are many other pathogens causing abortions and reproductive failure. In humans, men are more exposed to infections. A higher prevalence in male herders has been observed in previous studies, and risk factors shown to increase the risk of seropositivity include contact with livestock, handling sick animals, fetal materials, or activities connected to slaughtering (Nanyingi et al., 2015).

It was observed that seroconversions must have occurred in the inter-epidemic period, since some positive animals were too young to have been infected in the last known outbreak 2006-07. Seroconversion in livestock during inter-epidemic periods has been observed before. Infected vectors have been encountered during inter-epidemic periods in Kenya, as well as seroconversions in both wildlife and livestock (Linthicum et al., 1985). This has also been found in other countries; in a recent study in Tanzania, 8% of the small ruminants were seropositive, including animals borne after the last outbreak (Wensman et al., 2015). Awareness is often decreasing in inter-epidemic periods (Martin et al., 2008), although we found varying levels of awareness among different risk categories.

Overall, this study showed that an irrigated area can have an endemic transmission of RVF, without any sign of outbreaks, but that seroprevalence is not necessarily higher in these areas compared to non-irrigated ones, in spite of significantly higher number of mosquitoes. This indicates that although it may be evident that irrigation increases the abundance of vectors, other factors also play a role in determining if infection will occur. Higher number of vectors are however likely to contribute to increased risk of outbreaks, but would need to be studied more intently during an epidemic period. Future work should include looking into how factors such as irrigation, agricultural and pastoral behaviour changes, animal and human densities, and socioeconomic parameters, including education and living standards impact on RVF disease transmission and outbreak occurrence.

SOLUTIONS AND RECOMMENDATIONS

As shown, both climate and land use changes can affect the epidemiology of RVF. The case of irrigation is particularly relevant in sub-Saharan Africa, which has low levels of irrigation and high levels of population growth, and many believe large investments in irrigation are necessary for sufficient food supply. Irrigation schemes are often constructed in dry/hot areas where rates of vector development are likely to be rapid, if water sources provide suitable breeding sites. This increased risk should be considered and monitored when designing new irrigation schemes or planning new dams. In addition, the effect of climate change on the introduction of new vectors and pathogens should also be considered in order to use the most suitable technologies and be prepared for public health consequences.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

There is no single optimal solution for dealing with the risk of RVF outbreaks. Depending on the risks in the region, vaccination campaigns before predicted outbreaks may be the most cost efficient option, but require good forecasting models, and for policy makers to be well informed about the disease. In addition, it is important that stakeholders and policy makers are informed about the risks of RVF transmission between epidemics and RVF emergence. Other strategies include better diagnostics, case management and farming practices to reduce RVF outbreak risks.

Importantly, there is a lack of reliable guidelines, tools or procedures to steer emergency response measures in the event of an outbreak. In the past, the losses associated with outbreaks have in part been a result of insufficient capacity offered by decision makers, who lacked accurate information about efficient preventive and response measures. More recently, there have been promising developments in planning for RVF control in East Africa. These include:

- **Risk Maps and Early Warning Systems:** Known disease hotspots have been geo-referenced and analysed together with detailed data on precipitation, rainfall, soil types, land use and vegetation to produce RVF risk maps (Martin et al., 2008; Sindato et al., 2014). These maps can be used to target surveillance efforts, and also in trade negotiations. This could put an end to the blanket trade bans and their disastrous effects on people's livelihoods. The maps have also been combined with socio-economic variables, which define vulnerability in order to determine how best to respond to an outbreak in local communities.
- **Contingency Plans and Standard Methods and Procedures:** These are key to mounting early, effective action in the face of an emergency. These are pre-prepared plans and operational protocols to create uniformity in animal disease detection, diagnostic and control procedure across a region. The Government of Kenya produced and endorsed a contingency plan for RVF in 2010 which was updated in 2014. In addition, a standards methods and procedures manual has been produced by AU-IBAR (2014).
- **Decision Support Tool:** Policy makers face a dilemma in responding to RVF. Too early response and they may cause unnecessary panic. Too late and impacts will be more severe. A decision support tool has been developed comprising a list of the sequence of events related to increasing and decreasing the risk of an RVF epizootic and the appropriate actions that should match these events (Consultative Group for RVF Decision Support, 2010).
- **Vaccination Guidance:** This is often lacking among policy makers. Model-based analyses can offer guidance on preventative action by indicating the proportion of animals that need to be vaccinated to prevent spread. In addition, model-based analyses demonstrate that vaccinating strategically over a five-year period could reduce the thresholds needed to stop an epidemic. Such periodic vaccinations could be done annually or biannually, depending on logistical/economic considerations and the type of vaccine available.
- **Impact Assessment Tools:** A system dynamics model that combines biological and socio-economic processes involved in Rift Valley fever transmission has been developed as an integrated framework for evaluating the impacts of the disease along livestock value chains in north eastern Kenya.
- **Disease Scenarios:** These are plausible stories, not projections, and illustrate what might happen, based on given assumptions in the chosen settings. They can be used to identify and discuss a range of possible futures and used to create action to build resilience. Scenarios have been developed for RVF along with some other emerging diseases in Africa (http://www.diseasescenarios.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

org/scenarios.html), and others have looked at how agriculture and disease risks in general will develop in different future scenarios (Oborn et al., 2013).

FUTURE RESEARCH DIRECTIONS

As mentioned above, there is a lack of evidence regarding RVF epidemiology and factors that maintain RVF between outbreaks. Such knowledge is necessary for efficient future interventions. Future research should focus on filling the gaps identified here and reported in the literature:

- The importance of different vectors, including their vector competencies, their breeding requirements and the risks of transovarial transmission.
- The inter-epidemic transmission, including the role of wildlife and domestic animals, and the risks for humans.
- The role of socioeconomic factors in improving resilience of vulnerable populations during outbreaks.
- The impacts of land use change and climate change on disease epidemiology.

CONCLUSION

It is difficult to predict exactly how environmental changes will affect the incidence of vector-borne diseases, and it must be remembered that other changes, not directly influencing the vectors directly, may play very substantial roles. RVF as a disease may be directly influenced by environmental and climatic changes, and increasing irrigation may be one cause of increased vector populations. However, this may not be directly translated into higher prevalence of disease, and it is important to further study the other factors that may contribute to this. In order to increase the preparedness for RVF outbreaks, it is important to bridge the knowledge gaps and to improve surveillance systems and decisions support tools that can aid stake holders.

Whereas social insecurity, political unrest and poverty may drive the emergence of disease, improved housing, education, nutrition and health care services will render people less exposed to mosquito bites and more resistant to disease. Increased irrigation and agricultural outputs may help in achieving this. Improving socio-economic conditions is therefore likely to increase people's resilience to the negative effects of environmental change with regard to vector-borne diseases.

Chapter 69
Impact of Overpopulation on Land Use Pattern

Shivani Garg
Kurukshetra University, India

ABSTRACT

Overpopulation does not depend only on the size or density of the population, but on the ratio of population to available sustainable resources. It also depends on how resources are managed and distributed throughout the population. Overpopulation is one of the hazards and serious problem, which creates a great obstacle in the way of national development. It is estimated that growth in human population affect the global land use pattern available for agriculture, forest land cover, nearby area of different type of water bodies. The rapid increase of human population is putting extraordinary pressure on our natural resources available e.g. land, water, ecosystem services etc. The purpose of this chapter is to highlight the various environmental implications of overpopulation and rural-urban migration which in turns affect the land use pattern of world. Deforestation and loss of ecosystems that sustain global atmospheric oxygen and carbon dioxide balance is also another implication.

INTRODUCTION

In past few years, cities grow due to the rapid increase in world population and the migration of people from villages to cities. In the developing countries, the population growth has been more unstable& some cities are facing unplanned and uncontrolled settlements (e.g. slums) at the densely populated areas. Human beings have maximum population on earth although it decreases with high death rate due to illnesses, infections, famines; accidents and war but comparatively fertility rates should be high for species survival. Many factors affect the rate of change of population. As number of individual increases, the problems related to it are also increased. The main reasons that affect growth of population are the natality, mortality, immigration and migration. The natality is the ratio between births and individuals in given population and time. The mortality is the ratio of number of deaths to individuals present in given area and time. Migration is the number of people enters in or out of an area. The rate of change of population size is affected by these factors in a particular region. Overpopulation has been initiated

due to the increase in birth rates and the decrease in death rates in present time due to better medical facilities and progresses in the field of medicine. Movement of people to developed countries for better job opportunities, war, and natural disasters like hurricanes, cyclones, earthquakes etc. There is great pressure on the natural resources (water, land) due to overpopulation. Among all the natural resources, Land is the most important one. All agriculture, animal and forestry productions depend on the land productivity. The entire land ecosystem, which composed of soil, water and plant, and soil biodiversity, is used to fulfil the community demand for food, energy, water requirement. The unmanageable use of land is the main reason for destruction of our environment. For the sustainable development of an area, regular monitoring of land cover/ land use changes is essential. Overpopulation, consumption, overuse, wastage and misuse of resources have strained the earth's carrying capacity. The demands that put pressure on our environment are also alter the future of sustainability on earth. Regular monitoring of urban land cover/ land use changes is necessary for sustainable development of an area. In India, increase in population size due to unplanned activities which leads to urbanization that reduces the agricultural land. This is also having serious impacts on the resources base of the region. The development of urban area takes place either in radial way nearby a developed city or linearly along the highways. Life of Indians depends on agriculture and similar activities in rural areas. As per Indian census during 2011, the population of country is 1,210,193,422 (Provisional Census, 2011). The Indian populations increased with a decadal growth of 17.64%. In this chapter, the impacts of increased population on land use types and availability of land for agriculture, industry, construction of dams, water bodies etc. and in turn their impact on environment will be discussed.

Population

Population is defined as the total individuals of a species in a given geographical area. While populations of a species acquire different areas are called sister populations in a geographical area, the population is further divisible into subgroups called demes. The population present in an area are capable of interbreeding among themselves. The chances of interbreeding are more between individuals of same deme than between different demes of that population which is further reduced between populations of sister populations. An individual usually interact with their closest neighbors, but if at some other point in the life cycle widespread movements occurs such as a dispersal stage, the deme is much larger than such neighbor interactions. The description of a population requires three parameters numbers and kinds of the species in an area or space and time. On Earth, various biotic interaction and effect of abiotic factors population can be dispersed:

1. Random dispersion.
2. Uniform or regular dispersion.
3. Clumped dispersion.

This dispersal of biotic community also occurs on the basis of availability of food and abiotic parts of environment interact with the biotic community. Habit of food and interaction between food chain also helps the population to survive in any area which is termed as food web; the individuals get more options of food than traditional way in its habitat.

Overpopulation

Overpopulation, an unwanted condition where the ever increasing human population exist affects the carrying capacity of Earth. Overpopulation is the difference between natality and mortality in populations. Environmental degradation occurs not only due to population growth but also on other impacts that contribute to environmental degradation. The results of such population growth for developing countries like India span three areas;

- Changes in land use,
- Disposal of harmful waste to the environment and
- Depletion of natural resources.

As growth of population occurs, this extended growth begins to alter our environment. This concept draws upon the idea that every individual has certain basic needs. As natural resources are used, wastes are generated and disposed of. Thus, the misuse of resources, generation of waste and environmental damage relies on that society's lifestyles and pattern of consumption. Population growth is determined by number of individuals added to the population by birth (natality) and immigration from other area and subtracted by the population decreases by death rate (mortality) and emigration to other area. It increases the size of population and population lost by deaths (mortality) and emigration, reduces the population size.

Population growth = (Natality + Immigration) - (Mortality + Emigration)

Human population size increases due to the following reasons:

- Change in population size: As discussed above growth of population is affected by the entry and exit of the people in given area.
- Population movement (emigration, immigration): Both these factors affect growth of population.
- Circumstances origin of a country that lead people to emigrate- As we all know people of particular area move in and out due the following reasons:
    - No job opportunities.
    - Poverty.
    - War.
    - Environmental disasters (flood, drought, famine, earthquake, etc.)
- Offers that attract people:
    - Economic opportunity (jobs, industries)
    - Political freedom.
    - More availability of resources (availability of better food, habitat, etc.)

As per Indian census 2011, the density of Indian population has increased from 325 persons per square kilometers in 2001 to 382 persons/square kilometers. It may occur by rural to urban migration. Environmental stress, biodiversity loss, change in climate and pressure on natural resources strongly distress the population of any area and various survey shows that the population of all countries in total is already overpopulated. But population of human are still increasing. World population counted 6.8 billion in

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2009, and are predictable to climb to 9.2 billion in 2050. According to Prospects of World Population, this growth will take place in the developing countries (United Nations, Department of Economic and Social Affairs, Population Division (2015). The ease of use of sustainable resources which is placing competitive stress on the basic resources support to biodiversity and reduces the way of life, do not affect the population growth. Overpopulation influences land use patterns with consumption behaviors and productive activities of people. "Consumption by human had far exceeded resources available for every individual on land and requires 1/3 of land more to complete their needs than mother earth provides (United Nations, 1992)."

Population Development and Environmental Exploitation

Below are listed a number of the effects of population development and environmental exploitation by human populations.

1. Loss of crop lands, forest lands, wetlands for industrial expansion and extraction of minerals use.
2. Fragmenting diversity and wildlife habitats.
3. Increasing impermeable surfaces means more flooding.
4. More resources extraction, manufacturing and consumption.
5. Destruction of habitat due to change of temperature and adaptation in food chain.
6. Extinction of different flora and fauna of different area and some species become endangered due to loss of habitat and disturbance in their food chain and environmental benefits like availability of medicinal plants, fire wood, sandal wood, etc.
    a. Economic loss.
    b. Health impacts.
    c. Social disruption.
7. Change in global climate leads to increase the temperature of earth which in turn leads to polar ice melting, rise in sea level, ice cap melting, decrease in biodiversity, change in temperature of earth, etc.
8. Burning of fossil fuel leads to air pollution and overexploitation of available resources.

Table 1. World Population Change in last few decades

Major Areas	Population (Millions)			
	1950	1975	2005	2011
World	2519	4074	6465	6987
More Developed Regions	813	1047	1211	1242
Less Developed Regions.	1707	3027	5253	5745

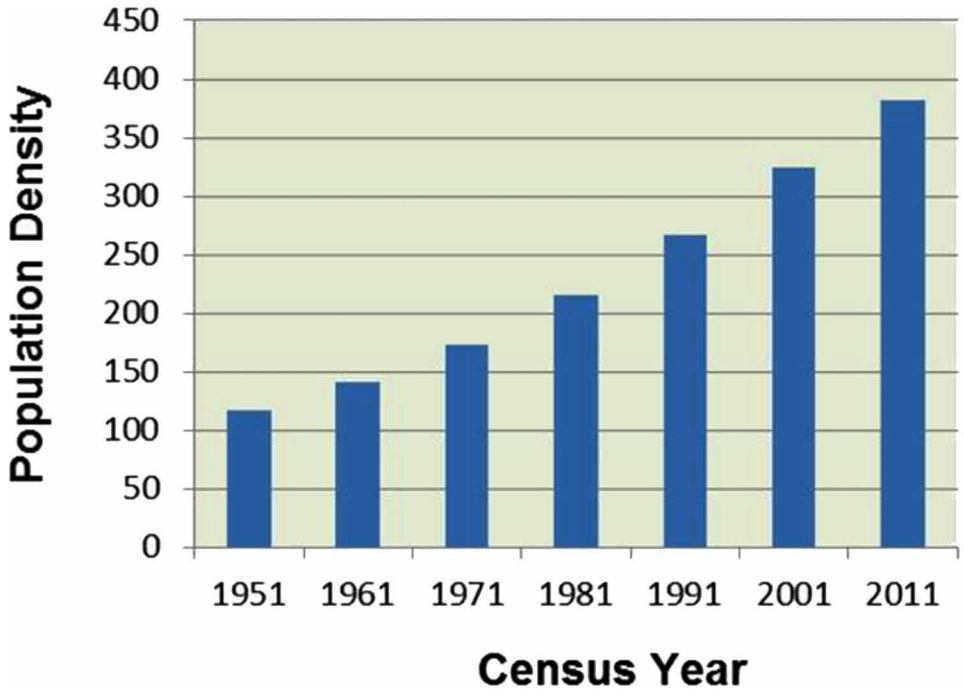
Figure 1. Population change in India during 1951-2011
Source: Indian Population Census (2011)



LAND USE AND OVERPOPULATION EFFECT ON LAND USE PATTERN

Use of land for different purposes of an area at a given time and space is land use. Land is used under different land use pattern like agricultural land, forest, fallow land etc. (Freeman, 1968). It is also used as cultivation of crops, building of houses, roads, railways, industries, grazing of animals, etc. The percentage of land used for various purposes differs from one region to another. The land use pattern is regulated by interaction of abiotic factors, such as relief, soil climatic conditions, minerals resources, etc. and the human density of population and the technological and social requirement of the people. Almost all human activities related to food, shelter and clothing takes place on land. Land use is categorized by, actions, the measures and contributions of people in a certain land cover type to cultivate change or maintain it. The availability of land on earth is limited. There is conflict over access and rights of these natural resources. It has also resulted in tough competition between the agriculture and other sectors over usage of land. Moreover, land also suffers from various problems such as soil erosion, degradation and deforestation. Worldwide changes to forests, farmlands, resources of water and air need to determine to provide, water, food, fiber and shelter for individuals present on earth. World's plantations, croplands, pastures and increase in urban area, associated with large increases in natural resources and fertilizer consumption, along with considerable biodiversity loss. Population increases in developing countries has produced stress on land, fragmentation of land holding, fisheries, forests, change in temperatures, biodiversity loss etc. Global warming due to increasing consumption of fossil fuels could have harmful impacts on the populous coastal regions in countries(developing). We face the challenge to make balance between instant needs of human and conserving the capability of the biosphere to provide goods and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

services for future. Practices for the food production, land use pattern change, over utilization of natural resources, development of urban area, industrial development, and change in methods of utilization are few reasons which make more complex relationship between population and land use.

Land on the basis of land use pattern are broadly categorized in following form:

1. Agricultural lands
2. Forests
3. Non- agricultural use of land
4. Barren and uncultivated lands
5. Permanent Pasture and other Grazing Land
6. Miscellaneous cash crops and groves
7. Cultivable wasteland
8. Fallow lands, other than current fallows
9. Current fallows
10. Roads, Dams, streams, lakes, building different infrastructure like schools, colleges, hospitals, government buildings, etc.

The global land area is 13.2 billion ha. Of this, 12% (1.6 billion ha) is currently in use for cultivation, 28% (3.7 billion ha) include in forest, and 35% (4.6 billion ha) includes grasslands and forest ecosystems and about 22% of land covered by low income countries (Fischer et al., 2010). As the population grows, the land use pattern also changes. There is transition of land use types to other type of land.

India is with a total geographical area of 328.37 million hectares of which 305.27 million hectares the reporting area. In the total geographic area, land covered by forest in absolute as well as relative terms has significantly increased from 14.2% to 22.80%. Area not available for cultivation has declined over the years indicating the spread of farm land while the pace of growth in land put in non-agricultural uses has outpaced the rate of growth in area available for cultivation.

Agriculture Land

The agricultural area is the sum of permanent crops, arable, permanent meadows and pastures land. Human is dependent on the nature for its needs. Agricultural lands provide open space and support habitat of wildlife, while the similarity between farmland to natural areas encounters management techniques that reduce the adverse effects of farming on sensitive areas. Agriculture has caused the greatest land transformations seen across the globe. The rapidly increasing population coupled with non-agricultural area uses available land will further shrink to very low level. The available land for agriculture also used for many purposes other than crop production like for establishment of animal husbandry to fulfil the need of milk and milk products of growing population (Ramankutty et al., 2006). Agricultural practices are also many types at different places for e.g. subsistence and commercial agriculture and both of these agriculture types further are of different types i.e. nomadic and shifting types in which people cultivate food crops for their livelihood only. Shifting cultivation is also called slash and burn agriculture i.e. clearance of forest or burn it for agricultural use. When the soil's fertility is lost, the land is neglected and the cultivators move to other available land. The method of cultivation is traditional and unscientific which reduce fertility power of land. Out of the total geographical area of India, 329 million hectares, area available for sowing is only 141 million hectares (i.e., 41%) (Table 2). the total cultivated

Forest	40.48	54.05	63.81	67.46	67.81	69.53	69.63
Not Available for Cultivation	47.52	50.75	44.61	39.55	40.48	41.48	43.22
(a)Area under non- agri use	9.36	14.84	16.48	19.66	21.09	22.97	26.17
(b)Barren & uncultivable land	38.16	35.91	28.16	19.66	19.39	17.59	17.29
Other uncultivated land excl. fallow land	49.45	37.64	35.13	32.31	30.22	27.74	26.82
(a)Pasture & other graining land	6.68	13.97	13.26	11.99	11.4	10.67	10.39
(b)Miscellaneous tree crops	19.83	4.46	4.37	3.58	3.82	3.44	3.31
(c)Cultivable waste land	22.94	19.21	17.50	16.74	15.00	13.63	13.12
Fallow lands	28.12	22.82	19.33	24.55	23.36	25.07	25.15
(a)Fallow land other than current fallow	17.45	11.18	8.73	9.72	9.66	10.29	10.34
(b)Current fallow	10.68	11.64	10.60	14.83	13.70	14.78	14.81

Source: (Indian Agricultural Statistics Research Institute, Data Book-2011, New Delhi)

land is 173 million hectares and net area sown is 141 million hectares and 37 million hectares of land used again and again. Population growth is also likely to promote agricultural intensification, shifting cultivation etc. Transformation of agricultural land into non-agricultural to support industries, housing, transport, irrigation, recreational facilities etc. It has been expected that during 1950-51 to 2009-10, the percentage of land not used for agricultural purposes over different area has change from 3.3 to 8.6%. Non-agricultural area has grown to 2.57 million ha i.e. by 11% (1999-2000 to 2009-10), Due to large demand for infrastructure, more and more fertile land is being diverted. (Statistical abstract of India, 2010)

Forest

Forest provided human being with employment and monetary income. The large-scale dependence exerts pressure on forests, leading to their unsustainable exploitation and eventual degradation. Unregulated exploitation of forest is a major cause of forest degradation and also for environmental pollution. Forests are exposed to overexploitation, encroachments, illegal cut down and so on, leading to their degradation. In 2007, the forest cover of world was observed under 4 billion ha, with the Asia-Pacific region accounting for around 20% (approx. 758 million ha) of area covered by forests (FAO, 2009). Global forest area tends to decline. The most considerable issues related to population distribution, pollution, and transport planning, infrastructure development and environment is reduction in forest land which reflect by following environmental problems.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Deforestation

The Amazon basin is the regions that have lost the largest area to deforestation, and where deforestation has the greatest impact on biodiversity and biomass loss (Houghton et al., 1991, Laurance, 1998, Lambin et al., 2003), but farming and pastures made by modification in agricultural land affect the environment of biomes. Agricultural lands deteriorate by different modern farming techniques or by slash-and-burn cultivation. When flora of forest area is transformed into grassland and burned, its production is lost in about three years. This causes deforestation of large areas, mostly in tropical regions. One of the reasons for deforestation is the use of wood as fuel for cooking and heating. Ghana lost almost a third of its dense forest due to this reason in between 1938 to 1980 (FAO, 1986b). The loss of primary forest is also caused by the building of roads and the expansion of residential areas in some areas. The changes in agricultural practices like shifting cultivation etc. are also increases desertification. Excess use of ground water by increasing population results in lower down ground water table leads to decrease in moisture of soil.

Destroying Diversity and Wildlife Habitats

Population increase alters the habitat of the migratory birds coming from different parts of the world. More people will demand more building sites, roads, schools, businesses, shopping, and enjoyable services by using resources from the national forests. In various parts of the world, wild animals are hunted for various purposes like meat, skin, horns, etc. This disturbs the ecological balance of the environment. Many birds have become extinct and many others are on the way of extinction. Our forests are treasure troves of biological diversity. They harbor millions of species of animals. Our wildlife suffers severely due to deforestation and urbanization. Many animals have become extinct because they have lost their natural habitation. Hence, there is greater need for the preservation of wildlife. The 2012 update of International Union for Conservation of Nature and Natural Resources (IUCN) and the Red List of Threatened Species shows that of the 63,837 species examined worldwide, 19,817 are threatened to extinction. It is found that 41% of amphibian species are threatened, as well as 33% of reef building corals and 25% of mammals (IUCN, 2013). If present trends continue, scientists warn, nearly half of all biodiversity will be vanished, because of acidifying oceans, climate change, invasive species, habitat loss, pollution and overexploitation of natural resources and increased human population. Overpopulation has changed some universal circumstances and parameters such as:

- Annual absorption of 42% terrestrial net primary productivity,
- 30% net primary productivity of marine,
- 50%fresh water,
- 40% land devoted to human food production and
- 50% land mass converted for human use. (Chadha et al., 2004).

Rainforests enclosed 14% land surface of the Earth, now they cover 6% of bare and researcher estimates that the last remain rainforests could be used up in, >40 years and indeed by the end of the century at the current rate of deforestation(FAO, 2011).Nearly 30% of the ocean's reefs since1980,due to mainly warming temperatures, acidifying oceans and pollution have disappeared, including 1/2 of the reefs in the Caribbean and 90% of Philippines' coral reefs, and experts observed that Australian Great

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Barrier Reef may be vanished by the year 2050 and coral reefs could be gone by the end of the century completely(FAO, 2011b).

Desertification

It appears an absolute evil, while an irrigation area faces the problem of salinization, while reversible, may be a greater loss than the washing off topsoil in a marginal area. "The reasons behind the destruction of ecosystems under the combined pressure of adverse climate & cultivation are desertification" (FAO, 1986). The area under irrigation faces the problems of water logging and salinization. According to FAO (1994), from total 240 million hectares currently irrigated land, about 30% are severely affected by salinity and another 60 – 80%isinfluenced to some degree. The largest irrigated areas affected by salinity are28% of the USA, 23% of China, 2% of Pakistan and 11% of India (Umale, 1993). India has observed huge increase in large projects from large dams and thermal power projects to massive industrial complexes and huge mines. About 92% regions in arid Rajasthan are affected by desertification (slightly 30%, moderately 41% and severely 21%). Area affected by desertification in the neighboring arid Gujarat is near about 93%. (ICARDA, 2006)

Non-Agricultural Use of Land

Population growth in world is now increases and its impact on land use trend is quite disturbing and shocking. The changes in land use posed pressure on land properties due to rising population. The problematic features are in the form of:

- Land used for non-agricultural purposes,
- Increase in fallow land,
- Decrease in area used for tree crops and
- Groves comes under categories miscellaneous.

Area under non-agricultural use is increasing rapidly but not at the cost of agricultural area. The effect of an increase in population density on change in cropping intensity is not significant statistically. Forest transition or more generally, ecological conversion arises as an economy change to non- farming production, agriculture emphases in the lands used for production, and agriculture at margin is abandoned, favouring the recovery of forests and other natural ecosystems. Although it is not as much of important as related to deforestation and much less observed by the general public and the scientific community, practices of ecosystem reclamation can be observed in many Latin American areas.

Barren and Uncultivated Lands

These areas include areas of bedrock coverage, path of desert, rock glaciers scraps, residues from volcanic eruption and other accumulations of rock without vegetative cover. Other types of barren and uncultivated lands include:

- Dry salt area,
- Beaches,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Sandbanks,
- Stripe mines, and
- Pebbles pits.

Mining of minerals sites displays such kind of problem in land use. As the top layers of the soil become harder to use site for other purposes, so that the land become barren land. Mining process increase as the demand increases which in turn increases wasted or infertile land. In this type of situation, an interaction of natural processes and human activities cause the land not to properly sustain its ecosystem services.

Permanent Pasture and Other Grazing Land

All grazing land like village common grazing land, permanent meadows/pasture or not included in this category. Population growth also affects the land used for grazing, as the animal's dependent on the grazing move from one place to another for fodder. Nomadic population take their animals with them and grow fodder for them nearby utilize available land or clear the forest area.

Miscellaneous Cash Crops and Groves

Land under dead trees, thatching grasses, bamboo, bushes and other groves for fuel, etc. which excluded under 'Orchards' are included in this category. As this area is not included in net area sown categories, cash crops are also grown in these areas for commercial purposes now a day. People alter practices of such land for their benefits.

Cultivable Wasteland

The land is not used for cultivation or left free past 4-5 years included in this category and left for succession for some reason or the other. Such lands are covered by the wild grasses or shrubs which have no economic value. They may be accessible or inaccessible or may lie in separate area. Agricultural lands, forests, grassland, sand metropolitan areas are part of the dry lands. A key role in biophysical practices by reflection and absorption of solar radiation and conserving the balance of atmospheric constituents is maintained by dry lands. The grain and livestock, fruity plants and micro-organisms, the habitat that supports many vegetable species of world is provided by them. Dryland regions faces occurrence of prolonged periods of drought because of high variation in both rainfall and intensities (FAO, 2004) as to affect the water and moisture balance and adversely affect services provided by ecosystem and the resident populations. Expansion of cropland area in these regions can fail owing to overexpansion of unsuitable technologies for production into the drylands environment. Increased population pressures and human expansion into drier areas during long wet periods leave an increasing in population vulnerable to drought. As the population grow rapidly in drylands due to improvements in health conditions and other factors has placed remarkable stress on the natural-resource base. The destruction of the fragile dryland ecosystem has also led to their impoverishment. An example of dryland agriculture in the Asia-Pacific region areas is land degradation defined as the productivity loss of the land (FAO, 2000).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Fallow Lands, Other Than Current Fallows

Fallow land and the cropland which are not seeded in one season; it may or may not be ploughed. For the control of weeds and pests, these lands are chemically treat or cultivated or left as it is. Crop rotation method is used to restore fallow lands. All land which was used for farming but currently is waste Landis placed in this category. There is need to decrease the extent and frequency of these lands in order to increase agricultural production. All these problems can be overcome by the use of fertilizers, providing irrigation facilities, crop rotation and several other similar modern farm techniques.

Current Fallow Lands

Current fallow lands are those lands which are leave as waste in current year but used for crop production in previous year.

Roads, Dams, Streams, Lakes, Buildings and Different Infrastructure Like Schools, Colleges, Hospitals, Government Buildings Etc.

Much type of renewable materials is derived from biomass. Sometimes lands available for different primary demands like food crops, fibre crops or as source of energy is also used at some time. As population grow and its needs increases, pressure on productive land and the water will certainly also increase, raise the problem of competition.

Roads

In order to further strengthen the network of road & making it more efficient to fulfil traffic rules; the key emphasis is on development of road network, building of roads, bye passes, bridges and road over bridges. A programme for improvement of roads widening, establishment, reconstruction, constructing of cement concrete pavements and blocks, premix carpet, building of cross hygiene and construction of pipes and retaining walls etc. need to be taken. Increases in human population and thickness often take place without sufficient investment in transport infrastructure. This raises time spent on driving vehicles, intervals and public transport systems faces the problem of overcrowd. Overloaded transport systems result in many adverse effects. The ratio of population in cities in developing countries has increased to nearly double since 1960 (from > 22%to < 40%), while in more developed regions the urban share has grown from 61%to 76%. The total length of roads in India increased more than 11 times during 1951 to 2011 i.e. 60 years. It has been increased from 3.99 lakh kilometer on March 31,1951, to 46.90 lakh kilometers as on March 31, 2011 (Ministry of Road Transport & Highways of India, 2012).

Rural – Urban Development

Urbanization is estimated to continue well into the next century. By 2030, it is expected that nearly 5 billion (61%) of 8.1 billion people of the world will stay in cities (FAO, 2000). The modern trend toward urbanization presumably brings with it, and is accelerated by, the economic advantages of division of labor, specialization of knowledge, skills and abilities, and multiplication of goods and services. As these advantages are realized, the requirement of moving persons, goods and ideas among establishments in-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

creases. Mobility becomes an index of progress and some of the limitations upon growth. India shares this global trend toward urbanization. Population growth of urban has gone beyond the development of:

- Basic services,
- Household services,
- Sewerage and solid waste disposal,
- Increasing waste generation at home,
- Water supply,
- Offices and industries, together with unplanned waste disposal facilities which consequence increased environmental deterioration.

There is increasing air pollution by automobiles. Ecology and health affected by this polluted environment. Poverty continues in metropolitan and peri-urban areas; awareness about the glaring inequities in close urban setting may lead to social unrest. Instead of harmful impact of urbanization on global warming, acid rain and ozone depletion, it has serious influence on the available arable land and subsequently leading to deforestation in maximum part of world. It is contended that decrease resources risks like water table lower down, soil nutrients declining etc. are also higher in the cities because of huge demand of food, water and fuel and disposal of municipal and other wastes are not only logistically difficult, however also a resource-consuming exercise. Although the efficiency of present agriculture and the connected reduce cost of foods are positive for consumers, farmers with small lands, mainly individuals on marginal lands, are frequently affected by large-scale agriculture. This is stimulating rural–urban migration. The modernization of agriculture and rural–urban migration increases the shift in the mode of production of food and the abandonment of agriculture at marginal land and land available for grazing that favour restoration of ecosystem with spontaneous processes and by enabling the construction of secure areas or conservation policies (Izquierdo and Grau, 2008; Grau and Aide, 2007; Aide and Grau, 2004; Mather, 2001; Mather and Needle, 1998).

REASONS BEHIND LAND DEGRADATION

As the demand of food and services provided by ecosystem increases, the production and cultivation of services also increases. The carrying capacity and land use pattern to provide services and goods ecosystem in given time for its beneficiaries is also reduced. The ecosystem services also exploit for the cost-effective growth and develop the livelihood of growing population. The farming system is largely subsistence based and not necessarily market-oriented. So, the land degradation is "the reduction or complete loss of the fertility of the soils for sustainable use."(FAO, 1980) These modifications occur due to soil erosion or by use excessive chemical in the fields. Here are few reasons of deterioration of land to overcome the scarcity of food and other ecosystem services:

Chemical Reduction

Chemical reduction may consist in:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The reduction of inorganic nutrients (mainly nitrogen, phosphorus and potassium) or organic matter like humus or fertile soil

For demand of irrigation, the river and stream water is used in certain regions of world. In some regions, nutrients concentration declined by water erosion: "several nutrients are percolated during the heavy rainfalls, in the humid tropics particularly on isolated land", in addition, these nutrients "can be exhausted due to cultivation of similar crops repeatedly in same area for many years" (FAO, 1983). Reduction is rigorous in the areas where "a poor or less fertile soil is used for agriculture, without the use of fertilizer or organic manure" (ISRIC/UNEP, 1991).

Salinization

The concentration of salts in the soil may changes due to:

Poor organisation of irrigation practices. Schemes high salt concentration of water used for irrigation or ignorance of drainage system of soil can increase the risk of soil salinization, especially at the regions with high evaporation rates e.g. in arid areas.

1. Sometimes salty water of sea mixed with groundwater by percolation and fresh water bodies generally used for irrigation;
2. Rapid loss of water due to evaporation in soils irrigated with salty water or saline water (ISRIC/UNEP, 1991).

The Decrease of soil fertility and the yield of crop are the damaging effect of Salinization. (FAO, 1994)

Acidification

Due to growth of population, industries are also growing now a day. These industries disposed excess of effluent in the nearby areas or in water bodies increases the acidity of land. Disproportionate use of acidifying fertilizer or drainage in specific types of soil is another reason of acidification. This type of soil is not good for agriculture or cultivable purposes so used for some other purposes like infrastructure of buildings, etc.

Pollution

As the number of individuals is increasing production of waste like solid, liquid and gaseous form. The growth of industries (waste addition, disproportionate use of pesticides, oil spills etc.) in different areas also pollutes the land and water bodies and it can strongly reduce the agricultural potential of lands. Soil pollution from heavy metals by inappropriate disposal of industrial discharges, along with the excessive use of pesticides and lack of management of municipal and domestic wastes, is becoming a key concern. Some commercial fertilizers also have high concentration of heavy metals that have negative impact on the environment. The indiscriminate use of agrochemicals (fertilizers and pesticides) is often responsible for land degradation. Soil texture, infiltration and permeability characteristics are affected adversely to a considerable extent due to excessive grazing, fire and unmanageable practices of cultivation in land.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Global Climate Change

India's urban population (1996) of about 240 million is one of the largest in the world. Increase in urban population is based on natural growth and migration from rural areas. The urban environmental issues arise from failure to provide the basic needs to urban population. Barely 50% of urban population have access to safe water supply and sanitation facilities. Intensification of agricultural is causing depletion of groundwater and serious soil degradation in some of the most agricultural intensive and significant areas of the planet. Land use for agriculture, urbanization and infrastructure (e.g. roads) continues to cause loss of habitat for much of the world's biodiversity. The terrestrial ecosystems as well as the world's marine ecosystems are being degraded and also intensive exploitation of marine flora, fauna, water, air & soil pollutions and chemical changes in ocean such as acidification, etc., is done regularly. The stress of increasing population on energy resources during the past decade has increased the concentration of atmospheric carbon dioxide. All this factors alter the whole earth environment and affect the biodiversity and global climate. The 21st Session of the Conference of the Parties to the United Nations Framework Convention on Climate Change (COP21) will be held in Paris in December 2015 with the objective to achieve, for the first time, a universal and binding agreement to efficiently combat climate change and stimulate and accelerate the transition towards resilient and low-carbon societies and economies. The anticipated new climate-related agreement in Paris in Dec.2015 is expected to result in more requirements, such as the reporting in the form of "intended nationally determined contributions (INDCs) i.e. towards achieving stabilization of GHG concentrations in the atmosphere (Kononov, 2015).

CONCLUSION

As we all know, the needs of every individual is dependent on the environment. For this we modify our environment and extract or destroy the resources. Land use pattern also changes with last few years of time period as the population increase. If these land use practices are well planned and sustainable, the problems related to land can be solved. Wasteland can be restored with afforestation and scientific techniques.

- By giving education, awareness to youngsters or teenager would create the required consciousness among them that small families are more efficient. It helps to enable them to attain considerable decline in the size of family, achieve their reproductive goals and improve quality of life.
- Agroforestry joins shrubs and trees with farming and forestry practices to produce more diverse profitable, healthy, fruitful, and conservation land use systems, to fulfil the needs of growing population. Itis mandatory to use the available agriculture land for great yield and better production of food. With two or more interacting plant species in a given area, it creates a more complex habitat that can support a wider variety of fauna and biodiversity. Apart from all these benefits, it is also reducing poverty by enhancing the production of timber, wood and other products for consumption and sale, contributing food security, cleaner water through reduced nutrient and soil runoff and also maintain ecological balance. But it uses more soil nutrient and need more attention for production. The Government of India initiated programme for agroforestry as a combined sustainable land management system on June 2, 1992. It announced the National Conservation Plan in order to tackle multidimensional agricultural problems facing the nation today.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The forest conserves the quality and quantity soil and water in many ways, leaves and branches decrease wind strength, after the absorbing solar radiation, decreases the surface area for evaporation. The canopy growth and the decomposition of plant organic matter like leaves, branches and fruits, etc., by soil fauna and microbes, modify soil quality and components, affect the water penetration and drainage and also increase the fertility of the soil. This process is cost affecting and meet the need of growing population. Water cycle and ecological system are conserved by increase in vegetation cover.
- A healthy ecosystem can mitigate change. With time, the composition of species may change but the ecosystem will still function to withstand life. New species moving into the environment, by increase or decrease in number of existing species, or by evolution over time may alter the ecological condition of the area. Natural resources are usually recycled within an ecosystem and progression can help the population to adapt the concern environment without collapse of the system. The more the biodiversity, more easily the system is able to adjust to changes.

Chapter 70
Characterization and Management Concerns of Water Resources Around Pallikaranai Marsh, South Chennai

Avantika Bhaskar
Care Earth Trust, India

G. Babu Rao
Care Earth Trust, India

Jayshree Vencatesan
Care Earth Trust, India

ABSTRACT

Pallikaranai is one of the last remaining natural wetlands of Chennai. This marsh collects floodwater and increases groundwater levels in the region. The present study characterizes the water sources available around Pallikaranai Marsh. Groundwater was found to be the main source of water in the study area, extracted through domestic wells as well as commercially through a large number of agricultural wells. Direct surface water extraction from wetlands by private tankers was also observed in some areas. Acute water shortage and inefficient water supply by the government has led to thriving of tanker market in this area. Shrinking of the marsh and surrounding water bodies owing to construction, dumping of waste and encroachment accompanied by over-extraction of groundwater is driving this area towards extreme water crisis especially in event of climate change. Conservation of wetlands and evolving norms for sustainable water extraction of groundwater especially by commercial entities is recommended.

BACKGROUND

Hydrological cycle forms an essential part of climate system (Askew, 1987) and change in climate is associated with changes in a number of components of hydrological cycle like altered precipitation pattern, intensity, etc. (Trenberth, 2011). Wetlands perform essential hydrological functions and are known to act as a sponge- 'soaking up water during wet periods and releasing it during dry periods'- signifying their importance as buffers against extreme climate change events that affect water availability (Bullock & Acreman, 2003; Maltby & Acreman, 2011). Some of the most important ecosystem services provided by wetlands are water supply and regulation, groundwater recharge and maintaining high water table, surface water storage, and removal of sediments, nutrients and other contaminants to improve water quality (Juliano & Simonovic, 1999; Zedler & Kercher, 2005). Apart from hydrological services, wetlands regulate global climate change through sequestration and long term storage of carbon dioxide from the atmosphere (Mitsch et al., 2013). Wetlands, mangroves and reefs also protect the coastal and inland communities from tropical storms and cyclones in events of extreme climate change (Turner, Oppenheimer, & Wilcove, 2009).

India sustains 16% of the world population with only 4% of the world's water resources (UNICEF, FAO and SaciWATERs, 2013). It is predicted that in future, the relative proportion of water used for irrigation will drop, whereas domestic and industrial use will increase. According to the National Water Policy, highest priority has been given to drinking water followed by irrigation, hydropower, ecology, etc. (Michael, 2009). However, with the rapid growth and expansion of metro cities, providing safe drinking water is one of the biggest challenges that the country faces today (Srinivasan, 2008).

Chennai, located on the east coast, is a water scarce city that has the lowest per capita availability of water amongst the four metro cities in India (Ruet, Saravanan, & Zerah, 2002). Although Chennai receives an average annual rainfall of 1200-1300 mm, only 5% of this actually seeps into the ground in urban areas (Janakarajan, Butterworth, Moriarty, & Batchelor, 2007). Traditionally a network of tanks (traditional rainwater storage reservoirs), ponds, temple tanks and wells formed the primary source of water in Chennai (Agarwal & Narain, 1997). Later due to increased inward migration and population pressure, these surface water sources had to be supplemented by groundwater pumped from wells in peri-urban areas (Janakarajan et al., 2007).

Chennai Metropolitan has 4 distinct systems of water supply-

1. Metro Water Board supply,
2. Municipal supply in towns adjoining Chennai city,
3. Domestic shallow wells or tube-wells, and
4. Private market including tanker trucks and retail distribution of bottled water (Anand, 2001).

Chennai Metropolitan Water Supply and Sewerage Board (also called 'Metro Water Board' or CMWSSB) obtains water from three interconnected rain-fed reservoirs, well fields and two inter basin projects (Srinivasan, 2008).

Despite the new projects, Chennai's reservoir storage capacity, mostly controlled by external agencies, remains very low (Srinivasan, 2015). As the gap between supply and demand is increasing by the day, the city is facing problems of low water supply, waste water management; fall in water table, salt water intrusion and flooding (Narain, Anand, & Banerjee, 2013).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

One important source of water in Chennai Metropolitan is a large number of wetlands located in and around the city. Care Earth's assessment of the wetlands of Greater Chennai, based on a study of Survey of India topo-sheets of 1971 and composite imageries for the period 2009-11, revealed that Greater Chennai has 474 wetlands organized as complexes (Care Earth Trust, 2012). These wetland complexes perform critical ecosystem services like providing fresh water and recharging groundwater aquifers. However it is estimated that more than half of these wetlands have been converted for various uses, encroached upon or used as dumping sites (Gupta & Nair, 2011).

Adding to the water woes is the changing climate which is one of the major factors that threatens water security (Schewe et al., 2014). The freshwater resources have been projected to be strongly affected by climate change (Bates, Kundzewicz, Wu, & Palutikof, 2008). The impact of climate change is expected to be more severe in developing countries and IPCC has predicted increased water stress in India (Mertz, Halsnæs, Olesen, & Rasmussen, 2009). Climate change can affect water resources in terms of changes in precipitation and runoff patterns, rise in sea level and subsequent altered land use and water demands (Frederick & Major, 1997). Projected impact of climate change on water resources suggest that water supply may either increase or decrease in water stressed countries in the near future. This can be accompanied by water quality degradation, increase in salt water intrusion into coastal aquifer, and an increase in flood and drought frequency (Erwin, 2009). Extreme and intense rainfall events associated with climate change resulting in increased runoff will not alleviate water stress but would rather lead to enhanced flooding if the excess water is not stored (Arnell, 2004).

Pallikaranai Marsh

Historically, a large part of South Chennai was a floodplain comprising of Pallikaranai Marsh, smaller satellite wetlands and tracts of pasture land (Vencatesan, 2007). Pallikaranai, one of the last remaining natural wetlands in the city collects flood water and increases ground water levels in this landscape (Care Earth, 2002, 2005; Drescher et al., 2007; Joshi & Kale, 2013). As Chennai is bound by Bay of Bengal in east and Andhra Pradesh in north, much of the recent expansion of the city has been towards south covering areas like Velachery, Madipakkam, Thoraipakkam, Pallikaranai, etc. swallowing several agricultural villages and wetlands. These areas constitute the peri-urban region of Chennai city. These transitional areas around the city not only provide land and water resources for urban expansion but also serve as a sink for urban wastes (Narain, 2010). Further, these areas in Chennai have been witnessing population escalation as well as rise in water demand (Appasamy, 1995). The recent expansion of the city with a spurt in Information Technology industry, residential complexes and large number of informal settlements has resulted in problems of encroachment of the land and wetlands, pollution and unsustainable groundwater abstraction. This has led to fall in water table, flooding, water contamination, salinity intrusion, health problems, etc. The present study focuses on characterizing and assessing the current status of the water resources located around Pallikaranai Marsh in South Chennai. This study was supported and funded by the Tamil Nadu Forest Department.

ASSESSMENT OF WATER RESOURCES

The study was conducted around Pallikaranai Marsh (12.949371°N latitude and 80.218184°E longitude) in Chennai Metropolitan Area. Pallikaranai is largely a freshwater marsh located nearly 20 km South of

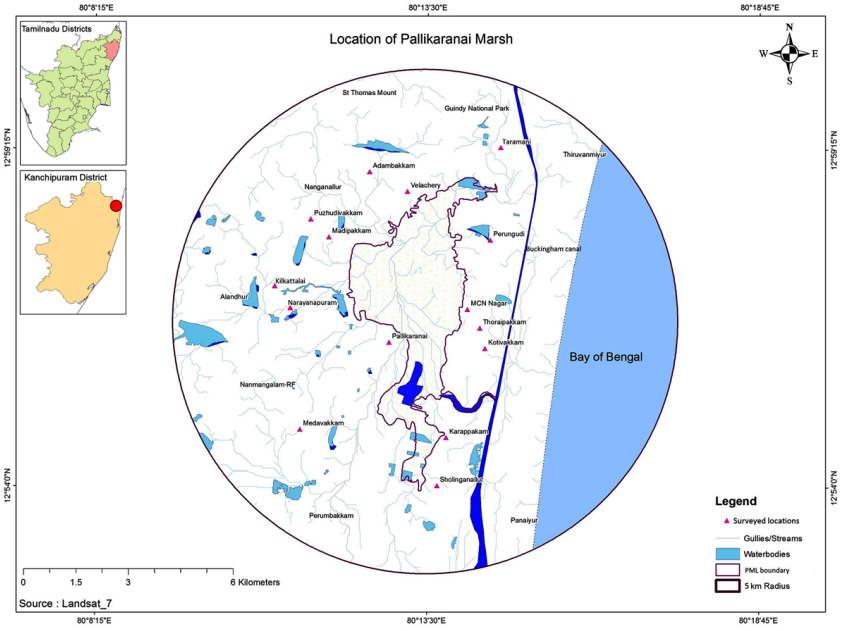
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chennai city. It drains an area of about 250 km^2 through two outlets - Okkium Maduvu and Kovalam creek and falls into Bay of Bengal (Vencatesan, Daniels, Jayaseelan, & Karthick, 2014). Over the years, the size of the marsh has reduced from 6000 ha in 1900s to the present 593 ha. Pallikaranai is one of the 94 wetlands identified under National Wetland Conservation and Management Programme of the Government of India.

A large part of South Chennai was historically a floodplain comprising of the Pallikaranai Marsh, smaller satellite wetlands and tracts of pasture land and forests. These small wetlands formed an important source of irrigation for the area. Presently, the occurrence of the freshwater aquifer running parallel to the coast has significantly contributed to the expansion of the city in this direction (Vencatesan et al., 2014). Over the past 50 years large parts of the marsh have been reclaimed into terrestrial habitats and converted to residential colonies. The assessment of water resources was carried out within 5 km radius from the centre of the marsh mainly covering residential areas of Perungudi, Thoraipakkam, Karapakkam, Velachery, Medavakkam, Madipakkam-Puzhudivakkam and Pallikaranai (Figure 1).

Systematic field surveys were carried out from January 2013-2014, in addition to the ongoing longitudinal surveys of Care Earth Trust on Pallikaranai Marsh for the past 13 years. The survey focused on the 5 km radius area from the center of the marsh to assess and characterize the water resources. Surveys were undertaken by walking along the highway roads, inside the colony streets and barren fields. Total area of 37.608 km^2 was covered within 5 km radius. Water sources were identified in the field and categorized on the basis of the nature of the source as surface and groundwater. These sources have been further classified as Primary and Secondary source. 'Primary source' defines the direct source of water for the consumer while 'Secondary source' are the sources that supply water to the consumer via a supply chain and storage structure. In this case the municipal water tanks and village tanks have been classified as secondary sources as they are filled by water tankers which draw water from groundwater sources.

Figure 1. Map showing the study area within the 5 km radius of Pallikaranai Marsh



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another secondary source is packaged drinking water plants which process groundwater to be supplied as water cans, packets, etc. to the consumer. However the actual number of groundwater sources has not been accounted for these two observations. All the shops selling water in the form of packets/cans/bottles have been classified as 'small scale water source' in the 'Others' secondary source category as the source (whether ground or surface) for these packaged units could not be ascertained in the present study. Accordingly, water sources are categorized as wetlands (including lakes), small ponds (relatively smaller water bodies), temple tanks, well sources (private dug well and agricultural wells), manmade water tanks (village tanks), and municipal water tanks (Sintex tanks erected by the government). The geographical position of source (latitude and longitude) was marked using GARMIN GPS. To quantify the fresh water usage around Pallikaranai Marsh, data was obtained by interviewing people at lorry tanker filling stations. Data collected included the number of water tankers being filled every day, cost of filling water tanker at filling stations and cost of delivery at final point.

On the basis of field survey, eleven water resources were identified around Pallikaranai Marsh. Table 1 classifies the water sources around Pallikaranai Marsh providing details about their location and their use. The important water sources in the region are described in the following section.

Table 1. Classification of water sources present around Pallikaranai Marsh, their number in each direction and use

Source	Primary Source	Secondary Source	No. of Sources in Each Direction Around Pallikaranai Marsh					% of Source	Use
			East	West	North	South	Total		
GW	Hand Pump				2		2	0.6	Domestic
		Manmade water tank (village tank)	16	15	5	8	44	14.2	Domestic
		Municipal water tank	33	20	52	16	121	39	Domestic
		Packaged drinking water plant	1	1			2	0.6	Drinking, cooking
	Pump set (Bore well)		2			1	3	1.0	Domestic
	Well (domestic)			5		1	6	1.9	Domestic
	Well (Agricultural or Private well)			19	1	10	30	9.7	Commercial (tanker)
SW	Small pond		1	6	4	2	13	4.2	Bathing, washing

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Groundwater

Groundwater is the dominant source of water in the study area available to the consumers through municipal water tanks and manmade/village tanks. Municipal tanks supply water to large slum areas located on the northern side of the Pallikaranai Marsh whereas private residential buildings, apartments and industries depend mainly on pump sets and private water tankers. More than hundred municipal water tanks were observed in all the areas around the marsh. Water supply to these tanks is under the control of CMWSSB. Maximum number of municipal tanks was observed on northern side of the marsh in areas like Velachery, Perungudi and Taramani followed by Thoraipakkam, and MCN Nagar located on the eastern side of the marsh. These tanks are filled by water tankers which extract water from agricultural and private wells present around Pallikaranai Marsh. Apart from this, nearly forty man-made water tanks/village tanks were observed mainly on eastern and western side, in Thoraipakkam, Kilkattalai, Puzhudivakkam and Madipakkam areas. These are tanks constructed in each village filled by groundwater extracted using pump sets. The water from these tanks is supplied through an underground pipeline system to the households.

Wells are one of the most important water sources in the area used for extraction of freshwater. About thirty agricultural wells located mainly on the western side of the marsh in Madipakkam, Kilkattalai and Narayanapuram were observed to be used for commercial extraction of water by both private and municipal tankers. The availability of well sources is higher in the west and south as some years back these areas were completely under agriculture, and the farming activities depended on seasonal wetlands and agricultural wells. However, as a result of commercial water extraction, farming activities in the area have almost discontinued. The area has given way to residential houses, commercial buildings and educational institutions. It was observed that these dug wells still have a remarkable storage of water possibly because of the presence of water bodies nearby and inflow of groundwater. Apart from this, the seasonal rainfall also safeguards these wells. As a household survey for water supply was not conducted, the extent of use of domestic wells could not be completely ascertained in the present study.

Surface Water

Nearly 30 wetlands, 4 temple ponds and 13 small ponds were observed around Pallikaranai Marsh. The wetlands are mainly concentrated in the western and northern side of the Marsh. The seasonally filled wetlands around the marsh include Lakes of Velachery, Adambakkam, Perungudi, Kilkattalai, Muvarasapattu, Madipakkam, Puzhudivakkam, Nesavallar Nagar and Narayanapuram. These water bodies are used to a small extent for domestic purposes like washing, bathing, cleaning of vehicles, by livestock, etc. Few tankers were also observed pumping surface water from Kilkattalai Lake nearly 3 km away from Pallikaranai Marsh. Narayanapuram Lake in the west has three open wells which supply fresh water to surrounding areas through underground pipeline system. The water in the lake was relatively clean and is used by local people for bathing, washing and fishing. However signs of pollution were also observed in different parts of this lake.

The number of small ponds is higher along the western side of the marsh. These water bodies are seasonally filled and provide fresh water, fodder, fuel, and fishery resources for local people. As a cultural tradition in Tamil Nadu, old temples generally house ponds in the vicinity, and 4 temple ponds (temple tank) were observed in the entire 5 km radius of the study site which serve as a vital habitat for aquatic flora and fauna, though not used for domestic purposes.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Tanker Market

The water vending by private tankers depends on groundwater drawn from agricultural and private wells situated in areas like Perungudi, Madipakkam, Medavakkam, Velachery and Thoraipakkam. Every day, on average 700-800 tankers are filled at source (Figure 2). The tankers with an average capacity of 9,000 liters per vehicle provide water every day to the low-income areas which are not connected with the piped supply system. These tankers transfer water to storage tanks made of concrete or plastic (Sintex tanks) installed by the CMWSSB. The cost of water tanker filling is ₹150-190 (USD 2-3) but the cost of delivery is ₹700-800 (USD 10-12), nearly 3-4 times the filling cost. The delivery cost varies depending upon the season and distance to the delivery point. The main consumers of water provided by tankers include domestic households, industries, hotels, academic institutions and offices across the city.

Two water processing plants were observed in the vicinity of the marsh in Medavakkam area. In addition, more than fifty shops selling packaged drinking water were recorded around the marsh. Though the actual source of this water supply could not be ascertained in the present study, the water processing plants generally draw groundwater.

Figure 3 shows the various sources of water available around Pallikaranai Marsh.

MAJOR CONCERNS

The expansion of Chennai city has led to growth of peri-urban areas. As a consequence, the water bodies in peri-urban areas are in the process of being reclaimed to build urban infrastructure in addition to extraction of water for supply to both urban and peri-urban areas (Narain et al., 2013). Flooding and

Figure 2. A long queue of water tankers at the periphery of Pallikaranai Marsh

Figure 3. Various sources of water around Pallikaranai Marsh, A. Piped water supply through village tanks, B. Tanker water supply, C. Wetlands, and D. Domestic wells

over-extraction of groundwater are known to affect the water security of urban and peri-urban areas (Janakarajan, 2009). The area around Pallikaranai Marsh which was originally a low lying floodplain is now a composite of industrial, residential, institutional and commercial establishments, and remnant natural habitats. In this peri-urban area, the water security is governed by the analogous processes of urbanization and climate change (Narain, 2010). On the basis of the present study, the following possible causes of water stress in the study area have been identified.

Over-Extraction of Groundwater

Chennai experiences acute water scarcity especially during low rainfall years. During these times groundwater plays an essential role in meeting the water demand (Janakarajan, Zehra, & Llorente, 2006). Growth of the city in the absence of adequate supply infrastructure has resulted in unsustainable extraction of groundwater (Srinivasan, Seto, Emerson, & Gorelick, 2013). The present study showed that nearly thirty agricultural wells located mainly on the western side of the marsh were used for extraction of groundwater by both private and municipal tankers. In addition to over-extraction, the increase in impervious surface owing to rapid urbanization has reduced the area for groundwater recharge. The impacts of groundwater depletion can be varied, the most direct and important being the loss of base-flow. This can further result in drying up of wells, increased cost of pumping and well infrastructure, salt-water intrusion, reduction in biodiversity, etc. (Ponce, 2006). Rapid urbanization together with disappearance of traditional network of tanks and ponds has resulted in over-exploitation of groundwater resources in Chennai. Chennai city during the past two decades has depended heavily on private and agricultural wells for water supply impacting groundwater table, changing the land-use pattern and affecting the livelihood of the farm-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ers (Ruet, Gambiez, & Lacour, 2007). According to Janakarajan et al. (2007) nearly 80% of Chennai groundwater has already depleted and further exploitation may result in enhanced sea water intrusion.

Degradation of Wetlands

Wetlands provide various ecosystem services of value to the society like preventing floods, filtering nutrients and pollutants thereby improving water quality, groundwater buffering, and serving as an important habitat for flora and fauna (Gren, Folke, Turner, & Batemen, 1994). Coastal cities similar to Chennai are one of the most rapidly urbanizing places and rapid urbanization affects the hydrology, geomorphology and ecology leading to drastic changes in the urban wetlands (Ehrenfeld, 2000). More than half of the wetlands in Chennai have already been converted to other uses (Chandramohan & Bharthi, 2009). A large part of South Chennai where the present study was conducted was historically a floodplain comprising of Pallikaranai Marsh and other smaller satellite wetlands. In our survey 29 large and 13 small water bodies were identified around the Pallikaranai Marsh. The historical images of Pallikaranai Marsh and surrounding areas show that a large number of water bodies drained into the marsh mainly during seasonal rains creating an effective drainage system (Care Earth, 2002 & 2005). However, over the years, in addition to Pallikaranai Marsh, the surrounding water bodies including Adambakkam, Kilkattalai, Narayanapuram Lake, Velachery Lake and other similar wetlands have shrunk drastically. This is attributed to rapid urban development, road laying and encroachment resulting in blocking of water channels in addition to draining of domestic sewage into the marsh. An inner ring road laid at the center of the Adambakkam Lake has completely separated it from the marsh while the Thoraipakkam radial road constructed in the center of the Kilkattalai Lake has divided the lake into two parts altering the water flow. As these wetlands belonging to a single system of water bodies, aid in crucial groundwater percolation, their disappearance will significantly impact water sustainability in this region (Chandramohan & Bharthi, 2009). Further, a large number of studies have shown that degradation of wetlands often results in loss of water retention and enhanced risk of flooding (Brody, Highfield, Ryu, & Spanel-Weber, 2007).

Informal and Unregulated Water Market

According to Janakarajan (2013) piped water supply accounts for only one fifth of the total water demand in Chennai while Ruet et al. (2002), state that at least 60% of water used in Chennai comes from sources other than public system. The limitations in groundwater availability and unreliable piped supply have led to an increase in demand for water tanker supply. This private water market is largely informal as it is not monitored by a regulatory agency in terms of quantity of water extracted, quality as well the economic value of water in the system. This informal commercial water sector consists of bulk suppliers like tankers and small scale suppliers including cans, bottles, sachets, etc. (Venkatachalam, 2012). Present study showed that an average of 700-800 private tankers extract groundwater from agricultural and private wells around Pallikaranai Marsh. Tanker water is nearly 3 to 50 times more expensive than municipal piped water supply (Srinivasan, Gorelick, & Goulder, 2010). Further these informal tanker markets have led to drastic decline in groundwater in peri-urban areas affecting agriculture and livelihood of farmers (Londhe et al., 2004). In order to regulate groundwater extraction and illegal transportation of water the Chennai Metropolitan Area Ground Water (Regulation) Act was enacted in 1987, foreseeing the registration of existing wells, regulations for sinking new wells, issuing licenses to extract water

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

for non-domestic use and issue of licenses for transportation through goods vehicle (Ruet et al., 2002). However this Act is grossly violated as both private companies and Metro Water Board are responsible for overexploitation of groundwater in many peri-urban areas apart from the private lorry and tankers that are operating in the Metropolitan Area without proper licenses (Janakarajan et al., 2006). In addition to water tankers, more than fifty shops were found to sell packaged drinking water in the study area. These small scale suppliers provide value added service in terms of treated water thereby setting up a strong consumer base and involving large money transactions. Studies have shown that informal water market serves both the high and low income groups in Chennai ensuring good quality water supply (Venkatachalam, 2012).

Anticipated Water Stress Due to Climate Change

Extreme and frequent weather events as a result of climate change are expected to alter the quantity as well as quality of available water resources in the future (Bahri, 2012). Water availability is the most critical and direct impacts of climate change in urban and peri-urban areas. As the population rises in these regions, the water demand goes up while the water becomes limiting as rainfall patterns and groundwater levels change (UN-Habitat, 2011). It has been projected that climate change will affect water supply primarily through flood damage and increased water treatment costs. On the other hand, prolonged periods of drought will affect surface water supply and enhance the vulnerability of groundwater systems (Bahri, 2012). It has been predicted that in India, climate change would affect water resources in terms of decline of the glaciers in the Himalayas, increase in both drought-like situations and flood events, change in groundwater quality and groundwater recharge, and increased saline intrusion of coastal and island aquifers due to rising sea levels (INCCA Report, 2010). In Chennai, a city located on the east coast, the future climate hazards include cyclones and floods resulting in drinking water shortage (Tanner, Mitchell, Polack, & Guenther, 2009). Further studies project occurrence of more extreme temperatures as well as rainfall events on the east coast of India (Dash & Hunt, 2007). An increase of flood risk has been observed across the last two decades over the eastern coast (Guhathakurta, Sreejith, & Menon, 2011).

Climate change affects precipitation variability, resulting in frequent floods and drought (Miller, Rhodes, & MacDonnell, 1997). These two major possible scenarios arising due to climate change affecting water resource availability are discussed below.

Flooding

Just as the government delegations from various countries including India were committing to limiting climate change at COP21, Paris; catastrophic flooding affected hundreds of people causing loss of life and property in and around Chennai. Even though such events are unpredictable and cannot be directly linked to climate change, climate change with its generally warmer sea water causes increase in number of storms and flooding, indicating that El Niño has a part to play in the sequence of extreme weather events (Gross, 2016). Climate change can affect the intensity and frequency of floods as a result of extreme rainfall events and such events are projected to become more frequent over a large number of regions (Bates et al., 2008). In addition to this, urbanization increases impervious surfaces and loss of natural drainage resulting in floods. Chennai receives an average annual rainfall of 1300 mm, most of which falls during North-East monsoon in the months of October through December (Figure 4). Meteorological data analyses shows that though there is a year-to-year variability, there are been no significant

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

upwards or downwards trend during the last 200 years. However, heavy precipitation events in the last few decades - 1985, 1996, 1998, 2005, 2008, 2010 and 2015 have resulted in catastrophic floods in Chennai ((Walsh, Glaser, & Militzer, 1999; Gupta & Nair, 2010). Pallikaranai Marsh in southern Chennai is an important area for the storage of storm water runoff from the surrounding areas, allowing the overflow to drain into the sea. Historically the seasonally flooded marsh was used for supporting agriculture as evidenced by the absence of dug out wells in the landscape until the last five decades. While agriculture declined over the years, the marsh continued to collect the overrun of the surrounding wetlands in south Chennai. The reason for rise in floods especially around the marsh is not only because of heavy rainfall events but also due to extensive urbanization of the surrounding areas which poses a physical obstruction to runoff to the marsh. Lack of adequate storm water drainage, garbage dumping in the marsh and encroachment of the wetlands also compound the problem. As a result, the natural drainage is highly obliterated leading to frequent floods in the area. Figure 5 shows one of the flooding events in an area surrounding Pallikaranai Marsh. A favorable microclimate and assured water availability has made the area prime spot for large scale real estate development. This however is adding to the water stress in the region. Figure 6 shows change in the extent of the Pallikaranai Marsh for the time period between 1970 and 2010. Degradation of the marsh over the years has severely curtailed its water holding capacity and studies have shown that events of above normal precipitation would cause flooding of the residential and commercial spaces within this landscape (Apfelbacher, 2008; Glaser et al., 2008; Vencatesan et al., 2014). More than 5,550 hectares of wetlands in the area has been developed into commercial real estate. Large scale encroachment of the wetlands around the marsh has also resulted in increased incidents of flooding. The density of habitation is maximum on the northern and north-western portions of the marsh which are impacted intensively during flooding (Vencatesan et al., 2014). Recent heavy rains in Chennai resulted in disastrous flood largely attributed to ignoring hydrological concerns during urban planning.

Wetlands are known to play a significant role in modifying the hydrological cycle and either reduce or delay floods (Bullock & Acreman, 2003). Nearly 80% of the studies suggest that floodplain wetlands reduce flooding by reducing both the magnitude and frequency of peak flow events (Acreman & Holden, 2013). Wetlands reduce the amount and speed of rainwater runoff and improve surface water quality in urban areas (Jha, Bloch, & Lamond, 2012). Alteration of wetlands is known to reduce the natural water retention and enhance flooding risk (Brody et al., 2007). Flooding can also contaminate water supplies in addition to rendering areas inhabitable and imposing additional costs on storm water drainage (Bahri, 2012). Worldwide, encroachment into of low lying areas closer to the water bodies has increased the damage potential due to floods. Further, globally, an increase in the number of inland flooding together with a rise in economic losses has been reported (Kron & Berz, 2007; Kundzewicz et al., 2014). Wetland restoration and conservation in Hubei Province, China and New Orleans, USA helped withstand storm surges and reduced the volume of rainwater runoff in these urban cities, resulting in improved resilience to flooding (Renaud, Sudmeier-Rieux, & Estrella, 2013). Further, a study by Walters & Babbar-Sebens (2016) in Midwestern United States, showed that presence of wetlands provided steady peak flow reductions across all climate change scenarios.

Drought

Decreased precipitation, enhanced evapotranspiration and reduced soil moisture have been defined as the main causes for drought. Climate change is predicted to impact water availability by altering both the frequency and severity of droughts (McDonald et al., 2011). According to IPCC Assessment Report (2007), the areas affected by drought are predicted to expand in addition to rising sea levels in the coastal areas. Growing demand from the expanding population and excessive withdrawals can thereby aggravate the problem of drought. Increase in vulnerability of shallow groundwater systems is also projected in case of extended dry periods (Bahri, 2012). The importance of groundwater as a perennial source of freshwater is projected to increase under more frequent and intense extreme climate events like drought. Wetlands have been reported to play an important role in groundwater recharge through both rain-fed discharge and focused recharge (Taylor et al., 2013).

A study by Dash and Hunt (2007) has shown that the maximum and minimum temperature have been increasing by 0.6°C and 0.4°C respectively on the eastern coast of India. Chennai city lying in this region faces acute water scarcity especially during low rainfall years. During such period groundwater plays an essential role in meeting the water demand and the south Chennai aquifer is an important source of groundwater during drought years. A study by Seifelislam (2013), analyzing the effective recharge amount over the period from 2001 to 2013 showed that there has been a decrease in the groundwater level of the aquifer recharged by Pallikaranai Marsh. The reduced recharge capacity is mainly attributed to decrease in the recharge area owing to large-sale construction.

Study by van der Kamp and Hayashi (1998) has shown that the wetlands in the semi-arid northern Prairie region are important sites of groundwater recharge. Their study also showed that drainage of wetland lowers the water table in the vicinity of the wetland thereby reducing the yield of surrounding shallow wells. Various other studies have recorded that the recharge rates of wetlands vary from 1 to 45 mm per year (Hayashi, van der Kamp, & Rudolph, 1998). Study by Acharya and Barbier (2000) showed that the Hadejia-Nguru wetlands in northern Nigeria formed by floodwaters of the region help in recharging of the aquifers which are used for domestic consumption and irrigation during the dry season.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another study in Okavango delta in northern Botswana showed that 80 to 90% of seasonal floodwater recharges the groundwater (McCarthy, 2006).

Events of low rainfall, drying up of reservoirs and reduced groundwater recharge makes Chennai highly vulnerable to multiyear drought (Srinivasan et al., 2013). The south Chennai aquifer is important, especially during the drought years for meeting the water requirements. However it is speculated that increasing urbanization of the area will lead to over-extraction of groundwater resulting in sea water intrusion.

CONCLUSION

Although climate change scenarios predict high risk to wetlands, intact wetlands would play a key role in climate change adaptation. Wetlands act as sinks for organic carbon in addition to storing water to buffer runoff and recharging groundwater table, thereby, positively impacting water availability (Junk et al., 2013). The water sources identified in the present study can suffice the supply of water to the area but not without proper maintenance and restoration. It was found that wells around the marsh retained water supply even during peak summer months owing to groundwater recharge by Pallikaranai and surrounding wetlands. The marsh also plays an effective role in collecting floodwaters and overflows from nearby wetlands in the surrounding area. Therefore Pallikaranai Marsh together with the surrounding wetlands is vital to Chennai city as a means of adapting to climate change. Hence it is imperative to maintain and restore these wetlands and tanks for ensuring sustainable supply of water to surrounding areas. It is suggested that institutions like CAP (Conservation Authority of Pallikaranai Marsh), CMWSSB, Central Groundwater Board, Tamil Nadu Pollution Control Board, etc. should undertake steps to conserve these wetlands, preventing further construction, reclamation, pollution and road laying. Further, in view of the rampant violation of the Groundwater Act, an attempt should be made to regularize the informal tanker market. Protocols for extraction of groundwater especially by commercial entities should be in place and unsustainable extraction of water from bore wells inside the wetlands should also be monitored. These few steps would be in line to facilitate the transformation of Chennai from water starved to a water sustainable city.

KEY TERMS AND DEFINITIONS

Aquifer: An underground layer of rock saturated with water through which water can be extracted.

Ecosystem Services: These are services provided by a particular ecosystem for the benefit of human beings.

Floodplain: It is a low lying area near a stream or river which is at a risk of flooding.

GW: Groundwater.

Marsh: Marsh is a type of wetland which is either frequently or continually inundated, dominated by emergent vegetation. It can range from freshwater to brackish to saltwater.

Peri-Urban Areas: Areas around urban centres having both urban and rural characteristics.

SW: Surface water.

Urbanization: It is the increase in population in urban areas resulting in social, economic and environmental transformations.

Wetland: Land which is either temporarily or permanently saturated with water, characterized by unique soil properties and vegetation.

Chapter 71
Managerial Reactions to Ambiguous Environmental Changes:
Attention, Reasoning, and Erratic Decisions

Wiboon Kittilaksanawong
Saitama University, Japan

ABSTRACT

Managers in organizations are typically faced with changing and ambiguous signals in their operating environment. Based on interpretation of these signals, managers react with appropriate strategies. This chapter presents critical organizational issues in decision making process and its outcomes, including the manager's selective attention, interpretation, and reasoning of uncertain operating environment. In particular, the chapter first discusses why individual managers in the same organization who are faced with same environmental changes may differently interpret threat and opportunity aspects of these changes. Second, the chapter links outcomes of such interpretation to investigate different types of organizational actions. Third, the chapter drives into a greater depth to explore how the manager's experience and characteristics of the environment affect forms of reasoning in interpretation process and performance of subsequent organizational actions.

1. INTRODUCTION

Organizations are required to adapt to environmental changes to survive and prosper. The adaptations are largely influenced by how managers interpret these environmental changes (Daft & Weick, 1984; Thomas, Clark, & Gioia, 1993). Managers in organizations are typically faced with challenges of interpreting changing and ambiguous signals in their operating environment. Based on their interpretation, managers formulate and implement appropriate strategies in response to these signals (Dutton, Fahey, & Narayanan, 1983). The effectiveness of these strategies on organizational performance is thus largely

determined by the extent to which the strategies are fit with the environment (Miles & Snow, 1978). Because signals in the environment are often complex and ambiguous, managers appear to simply categorize them into a salient form of either threats or opportunities (Dutton & Jackson, 1987). The importance of these categorizations lies in their link to strategic decision making process and subsequent organizational actions (Dutton & Jackson, 1987; Thomas et al., 1993). In addition to perceptions of the environment, actions of an organization are also influenced by its characteristics such as strategic orientations and resource slack (Chattopadhyay, Glick, & Huber, 2001).

Going more deeply into the decision making process, strategic decisions and organizational actions are often the result of the manager's attention, interpretation, and analogical reasoning (Dutton et al., 1983; Ocasio, 1997). Attention and interpretation are so intertwined that there is no meaningful distinction between them (Cho & Hambrick, 2006). Managerial attention to environmental changes strongly influences how firms behave (Ocasio, 1997). Attention refers to noticing and interpreting of various stimuli in the environment (Ocasio, 1997). Analogical reasoning is relevant when the present new situation that requires interpretation has both similarities and dissimilarities vis-à-vis the manager's prior experience. It builds on the manager's past experience in a similar circumstance to draw inferences about the present new and partially-known situation (Miller & Lin, 2015). In particular, managers focus on and respond to only certain aspects of their environment (Ocasio, 1997). Thereafter, they try to map their past similar experience onto the present partially-known situation to identify an appropriate analogy as a plausible inference for subsequent organizational actions.

High quality decision making and organizational actions via such attention and analogical reasoning processes are usually obtainable in stable and consistent environments (March, 1982). However, in reality, organizations seldom experience such environments as they usually have to adapt to ambiguous environmental changes. Strategic decision making, particularly in rapidly changing environments, can thus be highly unpredictable and, in response to these changes, is at times inconsistent. This inconsistency, at times even with limited new information, is simply because managers make erratic decisions (Mitchell, Shepherd, & Sharfman, 2011). These erratic decisions are influenced by cognitive and environmental factors.

This chapter presents critical organizational issues in the strategic decision making process and outcomes with respect to the manager's attention, interpretation, and reasoning of ambiguous environmental changes. In particular, we first discuss why managers in the same organization who are faced with same environmental changes may interpret threat and opportunity aspects of these changes differently, taking into account structural distance of the changes, perception of organizational capability, and domain-specific experience (Barreto & Patient, 2013). Second, we link outcomes of such interpretation to investigate organizational actions in terms of externally versus internally directed actions, taking into account organizational characteristics such as strategic orientation and resource slack (Chattopadhyay et al., 2001). Third, we drive into a greater depth to investigate how the manager's experience and environmental signals in terms of hostility and dynamism affect forms of reasoning in interpretation process and performance of subsequent organizational actions (Miller & Lin, 2015; Mitchell et al., 2011).

2. THEORETICAL BACKGROUND

According to attention-based view, firms can be viewed as systems of structurally distributed attention of individuals (Ocasio, 1997). Organizational behaviors are thus determined by how attention of decision

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

makers in the organization is channeled and distributed. In particular, strategic choices of these decision makers depend on issues and answers that they focus their attention on. Such attention is associated with biased interpretation where individual managers in an organization assign varying weights to contrasting aspects of the same stimuli (Cho & Hambrick, 2006). Therefore, individual managers in an organization may have different interpretations on the same stimuli. This interpretation is context-specific and it depends on characteristics of the stimuli and the individual who direct attention (Ocasio, 1997).

Managers interpret exogenous ambiguous signals by paying attention to their salient aspects in terms of an opportunity versus a threat (Dutton & Jackson, 1987; Ocasio, 1997). Which of these two salient aspects (e.g., threat and opportunity) of environmental signals individual managers are likely to pay more attention to depends on their attentional drivers (Ocasio, 1997). These drivers include social, economic, cultural, and cognitive factors that influence allocation of time, effort, and attentional focus of individual managers in an organization.

Based on strategic issue diagnosis theory (Dutton et al., 1983), individual managers' political interests and cause-effect beliefs can interact with characteristics of the environmental change to influence the interpretation. Managers are likely to pay more attention to particular aspects of such change when the change poses a potential threat to their political interests in terms of status, power, and control of resources. Cause-effect beliefs are understandings of effects of external environment and strategic inputs on organizational performance. Managers also use such beliefs to make sense of environmental changes and to selectively focus on certain aspects of these changes.

The assessment of future events, according to construal level theory, depends on individual considerations of desirability and feasibility of their outcomes (Liberman & Trope, 1998). Desirability refers to the degree of attraction or aversion that an individual attributes to outcomes of an event. Feasibility refers to the degree of ease with which an individual can reach outcomes of an event. For a given environmental change, a manager's political interests will therefore crate a more positive attitude toward that change when expected outcomes of that change satisfy those interests (Barreto & Patient, 2013). Likewise, a manager's cause-effect beliefs will therefore create a more positive belief toward that change when reaching expected outcomes of that change is feasible based on such beliefs (Barreto & Patient, 2013). Therefore, managers with political interests and cause-effects beliefs that create more positive attitudes and beliefs about an environmental change are likely to perceive opportunity aspects more salient while those with more of such negative attitudes and beliefs are likely to perceive threat aspects more salient (Barreto & Patient, 2013).

These perceived threats and opportunities are associated with urgency, difficulty, and high stakes (Dutton & Jackson, 1987). Threats are involved with an unfavorable circumstance where losses are likely and one has little control, and opportunities are associated with a favorable circumstance where gains are likely and one has a reasonable amount of control. To predict organizational responses to environmental threats and opportunities, the threat rigidity hypothesis (Staw, Sandelands, & Dutton, 1981) suggests that organizations appear to exhibit rigidity to act on something new, when faced with economic adversity or threats because of constraints in terms of information, control, and resources. Managers faced with threats are likely to perceive that they have little control over the circumstance that potentially yields a negative outcome. Threat perceptions can also heighten concerns about organizational efficiency. To mitigate such negative perceptions, managers are likely to respond to these threats by acting in less risky domains internal to organizations where they have a greater amount of control.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Prospect theory (Kahneman & Tversky, 1979), however, appears to contradict the explanation of such organizational responses. Actual decision making of individuals is not always rational as individuals are likely to frame decision alternatives as either gains or losses. However, their perception of losses from these alternatives tends to be more pronounced than gains. Importantly, individuals are likely to be risk averse when faced with gains and be risk seeking when faced with losses. In particular, managers in favorable or opportunity situations feel that they have more to lose than to gain, and thus are likely to be risk-averse. On the contrary, managers in unfavorable or threat circumstances feel that they have little to lose and thus are likely to be risk-seeking.

3. MANAGERIAL ATTENTION AND INTERPRETATION

Managers in organizations are usually overwhelmed with information that goes beyond their capability to attend to and to process all at once. They are faced with ongoing challenges of interpreting such information, which is changing in nature and coming from both inside and outside of their organization. Importantly, managers are able to attend to, interpret, and respond to only certain aspects of information in their organizational environment (Ocasio, 1997). Based on individual biases, they often assign varying weights to and interpret contradictory aspects of the same environmental signal. Managerial attention to a particular organizational issue is thus associated with context-specific and biased interpretation (Cho & Hambrick, 2006).

Environmental information is often ambiguous, containing both threat and opportunity aspects (Dutton & Jackson, 1987). Whether managers are more likely to attend to threat or opportunity aspects of the environment depends largely on social, economic, cultural, and cognitive factors. Particularly, these factors influence the extent to which managers allocate time, effort, and attentional focus to each of these two environmental aspects (Dutton & Jackson, 1987; Ocasio, 1997).

To understand why managers in the same organization who are faced with same environmental signals may interpret threat and opportunity aspects differently, we need to know characteristics of the focal organization and its environment. Such selective attention is influenced by individual managers' assessments of desirability and feasibility (Barreto & Patient, 2013; Liberman & Trope, 1998). The attentional drivers that capture variation in desirability and feasibility are structural distance of environmental signals and perception of organizational capability respectively.

3.1 Structural Distance From Environmental Change

Managers pay different levels of attention to aspects of an organization's environment because of their structural position within the organization (Ocasio, 1997). Different structural positions are associated with varying interests of stakeholders involved in these positions. Managers are therefore likely to give more weight to certain aspects of environmental changes at the expense of other aspects. Whether managers within a firm would assign more weight to threat aspects than to opportunity aspects of an environmental change or vice versa depends on the distance between their structural position and the locus of direct impact from that change (Barreto & Patient, 2013).

In the presence of an ambiguous environmental change, managers in a structurally shorter distance from the change are more likely to interpret such change as threat while those in a structurally longer distance from that change are more likely to interpret it as opportunity (Barreto & Patient, 2013). In

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

particular, when the distance is short, managers are likely to perceive that their interests are at a greater risk and possible losses are more salient. Therefore, they tend to focus more on what they currently have rather than look for what they could have in the future (Samuelson & Zeckhauser, 1988). When the distance is long, however, managers have more latitude to prepare and to draw on what they could have in the longer term to counter with such changes.

3.2 Perception of Organizational Capability

Firm resources and capabilities can direct managers to differently interpret aspects of an environmental change (Ocasio, 1997). Managers, however, have different perceptions of their organizational capability even if they belong to an organization that holds same resources and capabilities. This perceived capability is essentially determined by the extent to which each manager perceives their firm as holding the resources and capabilities that can sufficiently address requirements from the environmental changes (Dutton & Duncan, 1987).

In the presence of an ambiguous environmental change, managers with higher levels of perceived organizational capability are more likely to interpret such change as opportunity while those with lower levels of perceived organizational capability are more likely to interpret that change as threat (Barreto & Patient, 2013). In particular, when the perceived capability is high, managers are likely to form more positive early beliefs toward congruent opportunity aspects of the change. When the perceived capability is low, managers are likely to form more negative early beliefs toward incongruent threat aspects of that change.

Managers who possess greater and better-organized knowledge in a specific domain are likely to have more confidence in their beliefs related to that domain (Fischer & Budescu, 2005). Such domain-specific knowledge can indirectly affect the manager's attention toward threat and opportunity aspects of a given related environmental change. In particular, domain-specific knowledge tends to strengthen the positive effect of perceived capability on opportunity interpretation and also strengthen its negative effect on threat interpretation of an environmental change (Barreto & Patient, 2013).

These attentional drivers (e.g., structural distance from environmental change and perception of organizational capability) exert their pressure on managerial interpretation of environment in a hierarchical manner depending on the importance of events (Hubner, Steinhauser, & Lehle, 2010). Events are classified as superordinate when they are more central and essential and subordinate when they are peripheral and less essential to an organization (Barreto & Patient, 2013). Structural distance from environmental change is therefore superordinate because it directly affects the manager's interests, whereas perception of organizational capability is subordinate because it reflects the manager's beliefs about the firm's ability to address and handle the changes.

Accordingly, variations in the structural distance from environmental change have a priority and dominant effect on the interpretation of the change regardless of variations in the perceived capability (Barreto & Patient, 2013). In particular, a long structural distance to environmental changes tends to strengthen the manager's attention toward the opportunity aspects and weaken the attention toward the threat aspects regardless of the level of perceived capability. A high level of perceived capability may strengthen the manager's attention toward the opportunity aspects and weaken the attention toward the threat aspects only when the distance from the environmental changes is structurally short.

4. ORGANIZATIONAL ACTIONS AND MANAGERIAL INTERPRETATION

The simple categorizations of environmental information into either threat or opportunity aspects allow organizations to further process and respond to strategic issues related to environmental changes (Chattopadhyay et al., 2001; Dutton & Jackson, 1987). Because both threat and opportunity aspects of the environment are associated with urgency, difficulty, and high stakes, they are likely to evoke some organizational actions (Dutton & Jackson, 1987).

Organizational actions toward such environmental changes are broadly classified into whether they are directed externally or internally (Cook, Shortell, Conrad, & Morrisey, 1983; D'Aveni & MacMillan, 1990). Externally directed organizational actions are aimed at modifying the environment. Managers are often required to operate in new business domains where they have less control. These actions are generally riskier and more difficult to implement and control (Dutton & Jackson, 1987). On the contrary, internally directed organizational actions are aimed at adapting an organization to environmental changes. Managers are often required to operate in existing largely known business domains where they have a relatively larger amount of control. These actions are generally less risky and easier to implement and control (Cook et al., 1983; Dutton & Jackson, 1987).

4.1 Reduction or Enhancement of Control vs. Loss or Gain Situations

Organizational actions in response to either threat or opportunity interpretation are subject to characteristics of environmental events. These events are largely categorized as reduction or enhancement of control versus loss or gain situations (Chattopadhyay et al., 2001). In the events that are directly related to the reduction or enhancement of control, managers who interpret their environment as threats are likely to perceive that they have little control over the situation. This perception intensifies concerns about the organization's efficiency (Staw et al., 1981).

To mitigate such perceived control-reducing threats, managers are likely to respond to associated strategic issues in domains internal to their organization over which they have a greater amount of organizational control (Chattopadhyay et al., 2001; Thomas et al., 1993). This organizational response is usually done by initiating internally directed risk-averse actions (Dutton & Jackson, 1987). On the contrary, managers who interpret their environment as opportunities are likely to perceive that they have a greater sense of control over the situation with potential gains (Dutton & Jackson, 1987). Managers faced with such control-enhancing opportunities are likely to initiate externally directed actions, which might otherwise be perceived as too risky (Dutton & Jackson, 1987; Thomas et al., 1993).

In the events that are directly related to the loss or gain of tangible resources, mangers in favorable situations are likely to be risk-averse because they feel that they have more to lose than to gain from these situations (Kahneman & Tversky, 1979). On the contrary, managers who are in unfavorable circumstances are likely to be risk-seeking because they feel that they have less to lose than to gain from these situations. Thus, managers who interpret their environment as threats are likely to respond to associated strategic issues with externally directed risk-seeking actions (Chattopadhyay et al., 2001), while those who interpret their environment as opportunities are likely to respond with internally directed risk-averse actions (Fiegenbaum & Thomas, 1988; Wiseman & Gomez-Mejia, 1998).

The effects of threat and opportunity interpretation on externally or internally directed organizational actions are contingent upon organizational characteristics in terms of strategic orientation such as product-market development versus domain defense and organizational resource slack (Chattopadhyay

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2001). In particular, variations in an organization's adoption of such strategic orientation and use of resource slack are also shaped by the manager's perceptions of strategic issues in the environment.

4.2 Strategic Orientation

Organizations that focus on developing new products or markets are likely to pursue externally directed actions while those that emphasize on domain defense are likely to pursue internally directed actions (Chattopadhyay et al., 2001). The effectiveness of the former largely depends on the extent to which the organization can control or modify the external environment, whereas that of the latter relies on the extent to which the organization can increase its efficiency through standardization of internal organizational processes (Miles & Snow, 1978).

When faced with control-reducing threats, managers are likely to respond to the associated strategic issues with well-known and familiar organizational actions (Staw et al., 1981). However, for organizations that emphasize a product-market development, managers tend to pursue externally directed actions such as expanding in new markets or introducing new products to mitigate such control-reducing threats (Chattopadhyay et al., 2001). When faced with control-enhancing opportunities, managers are likely to go beyond their usual routines regardless of their organization's strategic orientation (Staw et al., 1981). Organizations that emphasize product-market development may, therefore, be even more likely to pursue such externally directed actions.

The effects of likely gain and loss situations are likely to be independent of organizational context such as strategic orientations (Fiegenbaum & Thomas, 1988; Kahneman & Tversky, 1979). In particular, managers who are faced with threats of likely losses are more likely to engage in externally directed risk-seeking actions. Such externally directed actions may be reinforced when the organization pursues product-market development strategy. Lacking such strategic orientation, the likelihood of externally directed actions may be reduced. Managers who are faced with opportunities of likely gains are likely to engage in internally directed risk-averse actions. Such internally directed actions are likely to be reinforced when the organization pursues domain defense strategy.

4.3 Organizational Resource Slack

Organizations holding more resource slack have greater flexibility to implement strategic actions in response to strategic issues in their environment (Cyert & March, 1963). Resource slack allows organizations to relax their internal control and to be more involved in externally directed actions that are otherwise considered highly uncertain and risky. When holding lower levels of resource slack, organizations are thus likely to pursue internally directed less risky actions, which require lower levels of resource slack.

When faced with control-reducing threats, organizations that possess higher levels of resource slack are likely to focus even more on internal processes to gain even more control over the situation by initiating internally directed actions (Chattopadhyay et al., 2001; Staw et al., 1981). Resource slack also provides the cushion for organizations to be able to spend time waiting until such threats are gone away or are at a manageable level (Dutton & Duncan, 1987). Without sufficient resource slack, organizations may be more sensitive to changing environment because of lacking resources to buffer the associated threats (D'Aveni & MacMillan, 1990). These organizations may have to engage in more externally directed problemistic search actions to adapt to the environment and survive from the threats (Cyert & March, 1963; Dutton & Duncan, 1987).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Opportunities often lead organizations to depart from their usual actions (Dutton & Jackson, 1987). With higher levels of resource slack, organizations may relax internal control and engage more in externally directed actions because resource slack buffers them from uncertainty and risk associated with these actions (Nohria & Gulati, 1996). In response to control-enhancing opportunities, organizations with higher levels of resource slack may therefore be more motivated to engage in even more risky externally directed actions to explore and exploit such opportunities in their environment. Without sufficient resource slack, organizations may engage in internally directed actions, which are mainly aimed at politically commanding a share of scarce resources to exploit such opportunities in the environment (Cyert & March, 1963).

When faced with likely loss situations, organizations are likely to take externally directed risky actions because they feel that they have less to lose than to gain from these situations (Kahneman & Tversky, 1979). With higher levels of resource slack, organizations may have even more latitude to pursue such risky actions (Chattopadhyay et al., 2001; Wiseman & Gomez-Mejia, 1998). Without sufficient resource slack, organizations are thus likely to pursue internally directed actions, which are less costly and less risky, aiming at tightening control in their existing business domains and improving efficiency (Cook et al., 1983).

When faced with likely gain situations, organizations are likely to be risk-averse and pursue internally directed actions because such opportunities are typically associated with a degree of uncertainty and risk (Kahneman & Tversky, 1979). Organizations are likely to feel that they have more to lose than to gain from these situations. Particularly, organizations with higher levels of resource slack may choose to forgo such external opportunities because the availability of resource slack allows them to sit back and afford to be risk-averse. Organizations without sufficient resource slack however may instead choose to take greater risk associated with externally directed actions and problemistic search to acquire additional resources (Cyert & March, 1963).

These organizational actions are the outcome of the manager's analogical reasoning processes (Miller & Lin, 2015). Along these processes, to facilitate organizational learning and effective actions, managers scan the environment to selectively collect relevant data and then interpret to give meaning to these data (Daft & Weick, 1984). Such interpretation transforms a variety of information associated with aspects of the environmental changes into an integrated and holistic understanding.

5. ANALOGICAL REASONING AND ERRATIC DECISIONS

The analogical reasoning processes of managers require that characteristics of the current situation be compared with those of past organized knowledge to arrive at classifications of the situation based on the degree to which they are matched (Dutton & Jackson, 1987; Markman & Moreau, 2001). This inference yields hypotheses that guide current organizational actions to exploit perceived opportunities or to mitigate threats in the changing environment (Dutton et al., 1983). The accuracy of such inference therefore critically influences strategic actions and organizational performance. Excessive optimism or pessimism about the organization's prospects may lead to inappropriate strategic actions and poor organizational performance.

Analogical reasoning has different forms including satisficing match, best available match, and exact match (Miller & Lin, 2015). The reasoning processes are involved with specifying possible analogies from past memories, comparing these analogies to the current problems, selecting an analogy, and deriv-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing inferences (Markman & Moreau, 2001). In dynamic environments, best available match and exact match as opposed to satisficing match are likely to improve the accuracy of interpretation over time (Miller & Lin, 2015). Past distant experiences through satisficing match may be useful in early periods when the complexity of environment is low. However, organizations should try to unlearn past distant experiences in favor of investing heavily in the learning of more recent dynamic environments through best available match or exact match.

For new entrants, investing heavily for learning in dynamic environments may lead to poor organizational outcomes in the short run. However, over time, they can attain better organizational performance derived from accumulated knowledge and experience in coping with dynamism in the environment (Miller & Lin, 2015). Decision makers with limited experience in their complex operating environment should employ the best of what they know, rather than wait for what they should ideally know to address the problems.

While in the short run, applying well known past experiences can reduce volatility of organizational outcomes relative to heavily investing for learning in the dynamic environment, this lower risk alternative also comes at the expense of organizational performance in the long run (Miller & Lin, 2015). Therefore, organizations in dynamic environments are required to tradeoff between their operating performance and risk when deploying past experiences and investing in learning to address problems in the short and long term, respectively.

5.1 Metacognition

The quality of analogical reasoning is associated with ability of managers to understand their own thinking. This ability is determined by the manager's metacognition. Metacognition refers to the ability to understand a given situation in relation to one's own cognitions (Haynie, Shepherd, Mosakowski, & Earley, 2010). A manager's inconsistent judgments for the same circumstance are erratic decisions which are the result of erroneous beliefs of one's own cognitions and lack of awareness in one's own decision-making processes. A person has a metacognitive experience if that person feels a particular task is difficult to understand and then draws on past experience to inform decision frameworks for present new, but related situations (Haynie et al., 2010). Therefore, managers with more metacognitive experiences are likely to better apply their previous decision-making processes to address the current decision tasks, thereby improving quality of their decision making.

Managers tend to use metacognitive experiences when the situations are complex and thus require careful consideration (Flavell, 1979). By using metacognitive experiences to address the current decision tasks, managers can verify the usefulness of their decision-making processes, thereby allowing them to improve quality of their thinking processes (Flavell, 1979). The use of metacognitive experiences, over time, allows managers to accumulate important knowledge and gain better control of their decision-making processes, thereby reducing the likelihood of making erratic decisions (Mitchell et al., 2011).

Managers possessing more metacognitive experiences are thus less likely to make erratic strategic decisions. Because thinking processes of individual managers are embedded in the broader external environment, quality of their judgments will rely not only on their metacognitive experiences and ability to understand their own thinking and decision making, but also on their perception of the environmental context.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

5.2 Hostile and Dynamic Environment

The extent to which managers make erratic strategic decisions is influenced by their perceived experience in hostile and dynamic environments (Dutton & Duncan, 1987). In hostile environments, decision makers may not be able to sufficiently carry out cognitive processes to arrive at a stable decision (Staal, Bolton, Yaroush, & Bourne, 2008). Managers may not be able to take sufficient past, present, and future alternatives into consideration. In particular, such a threatening environment worsens information processing ability of decision makers, thus leading to inconsistent decision outcomes (Staal et al., 2008). Managers are therefore likely to make more erratic strategic decisions in an environment with greater hostility (Mitchell et al., 2011).

Dynamic environments are highly unstable and unpredictable (Dutton & Duncan, 1987). In these environments, managers hardly comprehend the relationship between means and ends of the situation, so they are required to concurrently draw on multiple cognitive processes at a given time (Gilbert & Osborne, 1989). Managers may thus be less aware of their own inconsistencies between current and previously established preferences in decision making processes (March, 1982; Ocasio, 1997). In an environment with greater dynamism, managers are thus likely to make more erratic strategic decisions.

In an environment that is characterized by both hostility and dynamism, managers are likely to perceive a higher risk of failure and a greater uncertainty about sources of such failure. They tend to be anxious about highly uncertain threats (Freeman & Freeman, 2008). Because available data about environmental threats are not sufficient, managers are likely to utilize minimal data in their decision making processes (Freeman & Freeman, 2008). Such decision making processes are thus unlikely to yield thoroughly thoughtful and logical decision alternatives. The erratic strategic decisions due to hostile environments are thus likely to be more pronounced with a combination of high environmental dynamism.

6. DISCUSSION AND CONCLUSION

Managers play the critical role in diagnosis of strategic issues in their company's operating environment. This diagnosis is conducted through their attention and interpretation of organizational data and stimuli and their analogical reasoning (Barreto & Patient, 2013; Chattopadhyay et al., 2001; Miller & Lin, 2015). Because individual managers are different in their attention to opportunity versus threat aspects of the environment, managers within the same organization and environment may also differ in their interpretation of these two environmental aspects (Barreto & Patient, 2013). Such attention is shaped by individual managers' divergent desirability and feasibility considerations (Barreto & Patient, 2013; Miller & Lin, 2015). In particular, the results of such interpretation processes in terms of threat and opportunity are contingent upon structural distance of the manager from the environmental signals, perception of organizational capability, and characteristics of the organizational environment.

Organizational actions are largely influenced by such threat or opportunity interpretation. However, threat aspects of the environment are likely to be more pronounced than opportunity aspects in managerial decision making (Chattopadhyay et al., 2001). In particular, control-reducing threats lead to more conservative internally directed actions whereas likely losses lead to riskier externally directed actions. When faced with a control-reducing threat, managers are likely to act in domains in which their organization has the greatest control including implementation of well-known strategies (Staw et al., 1981). However, they will be risk-seeking when their organization is faced with a loss prospect (Kahneman &

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Tversky, 1979). Organizational actions in response to control-enhancing and likely gain opportunities are however rather equivocal (Chattopadhyay et al., 2001). When faced with opportunities, organizations may focus more on developing and exploiting new ideas and technologies rather than taking any actions in response to control-enhancing or likely gain opportunities (Dutton & Jackson, 1987).

Organizations are likely to pursue externally directed riskier actions when they are faced with external events that threaten their distinctive resources and capabilities. When managers place greater emphasis on product-market development instead of domain defense, organizational actions are likely to be externally rather than internally directed because their capabilities lie in gaining control over the external environment through building new products and markets (Chattopadhyay et al., 2001). These externally directed actions are likely to be more salient to deal with control-reducing threats which lower their control over the external environment.

Because threat aspects of the environment are likely to be more pronounced than opportunity aspects in managerial decision making, organizational resource slack appears to provide managers the resources necessary to respond to control-reducing threats and likely losses (Chattopadhyay et al., 2001). In particular, organizations with more resource slack are likely to respond to control-reducing threats with internally directed actions while respond to threats of likely losses with externally directed actions. Organizational resource slack however may not always influence organizational actions to respond to control-enhancing and likely gain opportunities. In such case, organizations may use resource slack to implement actions that are independent of the outcome of managerial interpretation.

In dynamic environments, managerial interpretations as discussed above are likely to be more accurate when organizations pursue analogical reasoning in the form of best available or exact match rather than satisficing match (Miller & Lin, 2015). While these forms of reasoning may worsen performance of organizational actions in the short run, they promote experiential learning and, over time, improve accuracy of the reasoning and thus organizational performance in the long run (Miller & Lin, 2015). Experiential learning is indeed fundamental to the accuracy of reasoning and interpretation of environmental signals. Therefore, organizations should unlearn past distant experiences, which often mislead them to pursue a satisficing form of reasoning for the sake of short-term organizational performance.

When environmental unpredictability is not very high, organizations should pursue reasoning in the form of best available match rather than exact match (Miller & Lin, 2015). In such circumstance, managers should deploy the best of what they know instead of waiting for all of what they should ideally know. Managers may pursue satisficing match only in early periods with low environmental volatility (Miller & Lin, 2015). In particular, satisficing form of reasoning, while stabilizing organizational performance in the short run relative to reasoning in the form of best available and exact match, comes at the expense to organizational performance in the long run.

Strategic decision making processes are critical to organizational outcomes. However, these processes are often inconsistent and thus erratic. Erratic decisions are engendered from the manager's lacking of metacognitive experiences in the decision domains and in the characteristics of environment (Mitchell et al., 2011). Such metacognitive experiences decrease the extent to which managers make erratic strategic decisions.

Environmental hostility increases the extent to which managers make erratic strategic decisions. However, in dynamic environments, managers may, over time, invest in learning to accumulate experience in these environments to the extent that such experience reduces erratic strategic decisions (Zollo & Winter, 2002). Environmental dynamism may thus provide organizations with learning opportunities that potentially mitigate such adverse effects of environmental hostility (Mitchell et al., 2011). In environ-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ments with greater hostility, managers may thus be able to reduce erratic strategic decisions when they have accumulated more experience through investing in learning from dynamic environments (Mitchell et al., 2011). However, without such learning opportunity (e.g., in low levels of environmental dynamism), the hostility aspects of environment are likely to exert a more salient negative effect on organizational decision making processes.

Managers should be aware that individuals in an organization may be unconsciously biased in strategic decision making. Managers may be able to reduce the biases by seeking more ideas from outside of their own organizations. Organizations often rely on their past experiences and apply these to current strategic decision making. Such local search may paralyze efforts of individuals and organizations to explore and develop new solutions for long-term performance. While recognizing the importance of past experience, managers should increase the number of alternatives, and utilize them to complement decision making.

However, managers should also be cautious that investing in new and unfamiliar alternatives may turn out to be not useable, excessively delaying responses and causing significant costs. In an uncertain organizational environment, managers should not forgo such opportunities but consider strengthening their capabilities by implementing experiments. Experiments allow an organization to learn and gain experience that potentially becomes alternatives and guidelines for encountering new challenges in the future.

Chapter 72
Assessing the Readiness of Farmers Towards Cold Chain Management: Evidences From India

Rohit Joshi
IIM Shillong, India

Sudhanshu Joshi
Doon University, India

ABSTRACT

The purpose of the paper is to gain an insight into the current status of farmers' awareness and practices towards maintaining the postharvest cold chain. The related hypotheses are developed and tested. The major findings include- marginalized and small farms, literacy and poor awareness level are the main causes for the backwardness of Indian farmers. Also, lack of funds forces farmers to ignore the use of cold storage. Further, multi-intermediaries and fluctuating consumer prices result farmers in not getting fair share of the consumer rupee. One of the major challenges in front of fresh food industry in India is to reduce postharvest losses across the chain through increasing awareness level of famers towards cold chain, building market information systems to assist farmers in decision-making and improving food safety and quality of farm produce available in the market.

INTRODUCTION

Given that most food, pharmaceutical, and chemical products get degraded by inappropriate exposure to temperature, humidity, light and certain contaminants (Smith, 2005), a consistent management of controlled environment all along the supply chain is a key in maintaining the quality of perishable products till the final delivery point. A 'Cold Chain' is a physical process that dominates the supply chain of perishable products. The cold chain includes a series of equipment and processes used to protect the perishables, by keeping them chilled and frozen, starting from the source of origin to the destination

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of consumption (Salin & Nayga, 2003). The perishable products can be categorized into two types viz, living products and non-living products. The living Products include fruits, vegetables, live seafood, flowers etc., where respiration is an on-going process, which uses up stored energy or food reserves by emitting heat and water vapors (Dahlenburg, 2001). Here, temperature is an imperative constraint, and the impact of non-optimal temperatures result into the loss of quality in form of earlier ageing and natural senescence. Too high temperature results in loss of quality, rapid deterioration and microbial spoilage whereas, in contrast, too low temperature shows early death, chilling injury, freezing destructions and death (Shewfelt et al., 2014; Ames, 2006).

Perishable products begin to loose quality as soon as they are harvested. Proper postharvest handling of fresh produce before and during their storage period is essential for maintaining the quality and increasing the shelf life of these produce. These fresh produce can become contaminated with human pathogens or spoilage bacteria at any point in the supply chain, i.e. from cultivation to consumption (James et al., 2008). As the consumption of fresh produce has increased significantly in the last decade (Rediers et al, 2009), with occurrence of series of food poisoning and related diseases, global consumers nowadays are more concerned about the safety of their food (Griffith, 2006). Cost reduction and quality improvement at the upstream side of the distribution center became the strategic attention points (Lemeilleur and Codron, 2011, Buurma & Saranark, 2006). The main sources of postharvest contamination are temperature abuse at farm level (Brackett, 1992), harvesting equipment, transport containers, processing equipment, and human handling (Beuchat & Ryu, 1997). Strict temperature control throughout the supply chain can minimize the risk of food-borne illnesses because cold storage drastically reduces the growth rate of most human pathogens (Ukuku & Sapers, 2007).

The sourcing of perishable products play an important role for food related business. It is a key factor for the production costs as well as for the quality of the food products, the social, sensorial or food safety aspects (Aidoo, 1993). Thus, it is important for any organization to have reliable sources. A farmer can be a reliable source if equipped with proper knowledge and skills. In a developing country like India, there is a need to strengthen the farmer link, which is a critical link of the cold chain.

A farmer plays an important role in cold chain. The farmer can be a reliable source if equipped with proper knowledge and skills. There is a need to strengthen the farmer link, which is a critical link of the cold chain. In this research, we intend to find the readiness of Indian farmers towards the cold chain practices. The main objective of the research is to gain an insight into the current status of farmers' awareness and practices towards maintaining the postharvest cold chain. For this, one sector from each living and non-living category of perishables is chosen. The sectors, Fruits and Vegetables (FV) and Milk and Milk Products (MMP) are chosen from the living products' and non-living products' categories respectively. The FV and MMP sectors include product handling at temperatures of -20^{o}C to +10^{o}C and that range covers handling temperatures of most of the perishable items.

LITERATURE REVIEW

Researchers (Tanksale & Jha, 2015; Narula, 2011; Allais & Letang, 2009; Ferna Andez-Trujillo et al., 2000; Srivastava, 2006; Jain, 2007; Singh, 2007) enumerated number of problems faced at farmers' end like, no transparency in pricing at farmer end, lack of awareness about the use of IT for being better informed, improper handling, loading and unloading of perishables, fragmented production, leading to fragmented chains, etc. One of the underlying reasons for such paradoxes is the lack of knowledge,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

skills and unawareness about the market information (Jarimopas et al., 2008). Small farmers are poverty stricken, illiterate and dependent on monsoon in India (Shukla & Jharkharia 2013; Sridhar & Ballabh, 2007). Poor market orientation and low value addition capacity, gives them low margins leading to low risk-taking abilities. Thus, small farmers enter a vicious circle and find it difficult to break. A little bargaining power and a heavy dependence on their farm produce for basic needs, add to their woes and they end up becoming victims to the exploitative market intermediaries who deny them a fair share of the consumer rupee (Sridhar & Ballabh, 2007).

India is world's largest producer of milk and second highest producer of fruits and (Planning Commission, 2013). But, unfortunately not a single Indian dairy company has featured in the list of global top 20. Also, around 30 to 40 percent of total production of fresh fruits and vegetables is wasted every year in India. One of the main reasons is inadequate knowledge, skills and awareness in the farmers about the postharvest losses. Most perishables are required to be cooled to a suitable temperature as early as possible after harvest. This is called pre-cooling. A delay of few hours between harvest and cooling can have significant effects on the degradation rate of many perishable products. Pre-cooling reduces their metabolic activity, reduces the growth of microorganisms and prevents other changes such as wilting, before the produce is placed in cold storage. It also reduces the load on the cold store refrigeration system.

Within this context, although India has been the world's largest milk producer since 1995, unfortunately not a single Indian dairy company featured in the list of global top 20 dairy companies (Banerjee, 2007). Moreover, estimates says around 30 percent to 40 percent of the total production of fresh fruits and vegetables, is wasted in India, which is tantamount to the total production of the United Kingdom (Khan, 2005). In most developed countries like the USA and the UK postharvest losses are below 15% of the production. Post-harvest losses (including storage) in Somalia are estimated at 20-30% of the production. If we glance upon the African countries; In Kenya post-harvest losses were estimated at 10-23%, in Malawi 6-14%, in Rwanda 10-20%, in Tanzania 20-60%, Uganda 4-17% and in Zambia 9-21%. For Sorghum post-harvest losses were estimated at 0-37% in Nigeria, 6-20% in Sudan, 0-10% in Zambia and 25% in Zimbabwe. In Ghana post-harvest losses were estimated at 20% (Manzini, 2014; Kader, 2008; Delken, 2008).

Most of the farmers are ignorant about the use of cooling activities, its usefulness and availability. The cold chain facilities usually do not reached them due to either poor extension services or high cost. Meenke (2006) attributed the reasons to the non-utilization of cold chain facilities as high cost of cold store space, cost of transportation and uncertainty of receiving proper return of the preserved value. Farmers are mostly ignorant of right stage of harvesting, proper cleaning, grading and packing of the produce, which results in low price for their produce (Sun & Zheng, 2006; Sridhar & Ballabh, 2006, Pai & Sastry, 1989). Sridhar & Ballabh (2006) emphasized that regulation and red tape is the key limitation why farmers are not getting a fair portion of consumer's money. Other hurdles are like inadequate support from government and a high unit refrigeration costs. Although Indian government has announced many subsidies to cold storage set up yet, many feel that it receives inadequate support from government. These observations lead to the formulation of hypotheses 1 and 2.

H1: Post harvest losses between farm and cold storage are positively influenced by (a) In adequate pre-cooling facilities, (b) Insufficient knowledge among farmers, (c) High cost of product refrigeration and (d) Inadequate support from government.

H2: There is a significant difference of perception between FV and MMP sector at farm level, regarding pre-cooling practices.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Related to Value of Perishable Produce: Procurement to Consumption

Perishable products begin to lose the value as soon as they are harvested (Bogataj et al., 2005). Proper post-harvest handling of fresh produce before and during their storage period is extremely essential for maintaining the quality and increasing the shelf life of these produce (Rediers et al., 2009). The main sources of these losses are temperature abuse at farm level (Brackett, 1992; Rosset et al., 2004), harvesting equipment, transport containers, processing equipment, and human handling (Beuchat & Ryu, 1997).

At farm level there are so many causes for losses in the value of product food chain like, microbiological, mechanical and physiological factors. To ensure that foods have a uniformly high quality for sale in the fresh market sector, it is necessary to clean, sort and grade the crop before cooling and cold storage. A few hours of delay between harvest and cooling can have measurable effects on the deterioration rate of many perishable products.

Temperature homogeneity in most cold storages is directly governed by the airflow patterns in the system (Duiven & Binard, 2002). Refrigeration systems with non-uniform airflow implicated as a major cause of temperature variability. For sensitive products, this level of temperature variability may have significant food quality and safety implications (Smale et al., 2006). The inefficient utilization of storage space within cold rooms has been identified and quantified accurately, whilst the quality control task has been recognized as the most time-consuming task and a critical cause for hindering product flow (Manikas & Terry, 2009, Joshi, et al. 2010). Zhang et al. (2003) stated that one of the particular attributes of the logistics systems for chilled and frozen goods is the maintenance of product quality, which is dependent on the duration of delivery time and variation of temperature in the cold chain. An effective logistics system not only delivers food products freshly and safely, but also on time, which is an important concern of customers (James et al., 2008). Tarantilis and Kiranoudis (2001) acknowledged that since long managing the perishability of foods is a difficult problem in distribution management. In context of developing countries it is observed that lack of adequate infrastructure (Salin & Nayga, 2003) along with high cost for installation and operation are the biggest bottleneck for strong and efficient cold chain. Operating costs for these cold chain facilities are about double as compared to developed countries (Joshi et al., 2009). These observations lead to the formulation of hypotheses 3 and 4.

H3: Loss in the product value with time is positively influenced by (a) Inadequate handling skills, (b) Improper use of cold storage, (c) Inadequate refrigerated transportation, and (d) High cost of cold chain facilities.

H4: There is a significant difference of perception between FV and MMP sector in assigning importance to quality and safety measures between farm and consumer.

METHODOLOGY

To address the issues related to cold chain practices of Indian industries and stakeholders, a questionnaire based survey is undertaken. The questionnaire is designed keeping in view the available literature and previous surveys. The practicing managers and academicians in the area of supply chain management of perishable items are also consulted during the development of questionnaire. In the questionnaire, farmer's survey is centered towards acquiring farmer's practices and awareness in handling farm produce (MMP and FV) within the framework of cold chain management.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The questionnaire is tested for two main types of validity, which are content validity, and construct validity. Content validity represents the adequacy with which a specific domain of content is sampled (Nunally, 1978) and that the instrument item has items that cover all aspects of variables being measured. Content validity cannot be determined numerically. Its determination is subjective and judgmental. It primarily depends on an appeal to proprietary of content and the way it is presented (Nunally, 1978).

The instrument developed in this study demonstrates the content validity as the selection of measurement items was based on both, an exhaustive literature review and evaluation by academicians and practicing managers during the pre-testing. The content validity was further tested during pilot survey as per the guidelines provided by Forza (2002). After a careful review of respondents' answers to questionnaire during the pilot survey, some questions were modified to convey their intended meaning, and some questions were deleted from the questionnaire as per the suggestion received from the respondents.

QUESTIONNAIRE ADMNISTRATION

Target Respondents

Maintaining the scope of the research, randomly (convenience random sampling) farmers are selected who are in the business of either milk or milk products or fruits and vegetables. Firstly, the purpose of the survey was made clear to them and then their consent for interview was asked for. Given the nature of the issues to be addressed in the farmer's questionnaire, it was decided to carry out the interviews on a face-to-face basis (rather than handing over questionnaire to them). This was felt to be particularly important as questions include few terms that are relatively unusual for farmers, and therefore the face-to-face context was considered more effective. In addition, the personal interview approach is one which is typically adopted for discussing issues of this nature within other comparable research (Skerratt & Midmore, 2000; Patton, 1990; Dey 1993).

A total of 120 farmer respondents (60 each from both the chosen sectors) were randomly selected. These farmers were resident of North India (Delhi, Rajasthan, Haryana and Uttrakhand) having their own farms and livestock.

FINDINGS

Related to Cold Chain Practices at Farm Level

Post-harvest losses of fresh produce are very serious in developing countries like India. It is a matter of worry that a farmer devotes so much time on to fresh produce, spends so much money on maintenance like irrigation, fertilization, animal vaccination and protection measures, but major share of the fresh produce is wasted about a week after harvest and that because of the ill practices and inadequate knowledge. Further, there are number of intermediaries and fluctuating consumer prices which finally result farmers not getting fair share of the consumer rupee. In this survey, the questionnaire administrated to farmers, contained issues related to farmer's practices and awareness towards maintaining cold chain at farm level for reducing postharvest losses.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

It was observed that literacy and poor awareness level are one of the main causes for the backwardness of Indian farmers. Literacy is the ability to read and write to a competent level which leads to awareness, which is knowledge of or competence in a subject or area of activity. Most of the respondents (92.33%) had low level of formal education (secondary or below). About 19% of respondents had no formal education background. However, despite low level of education all the farmer respondents were agreed, when asked if temperature abuse in any way can cause harm to their produce. Further when asked the time of a day to pick up crops, about 48% replied as 'early morning' and 22% agreed with 'as per the schedule of dispatch', only 7% of farmers insisted to pick up crops at night to benefit of low temperature at nights. This showed that farmers are not taking advantage of natural pre-cooling as they are not aware or influenced by the superstition that harvesting at night is an ill omen.

As observed in Figure 1, when farmers were asked about other practices (excluding yield) that are important after yield, for getting a good return, proper handling (Mean=4.2, SD=0.765) has emerged as the most influential practice for improving the value of produce, followed by sorting (Mean=3.87, SD=0.445) and cleanliness and hygiene (Mean=3.54, SD=0.654). Pre-cooling (Mean=3.46, SD=0.521) was given fourth rank. It was also observed that farmer respondents emphasized on temperature of commodity (Mean=4.16, SD=0.564), handling (Mean=3.12, SD=0.625) and relative humidity (Mean=3.26, SD=0.581), as the factors affecting the microorganism development. This showed that farmers are aware of the adverse consequences of poor temperature maintenance at farm level but they are not giving due importance to cold chain practices. In general, some of the reasons for this ignorance can be attributed to limited financial capacity and high cost associated with cold chain facilities.

As shown in Figure 2, when farmers were asked to assign weights to the reasons for wastages of their products at farm level, postharvest losses (Mean=4.05, SD=0.673) came into view as the most affecting reason followed by high cost of refrigeration of fresh produce (Mean=3.88, SD=0.672) and inadequate support from the Government (Mean=3.2, SD = 0.805).

From the literature and discussion with academics and practicing managers, factors identified that cause depletion (wastage) of fresh produce from a farm to till it reaches a consumer were, inadequate harvesting, packaging and handling skills, lack of pre-cooling facilities at farm level, lack of adequate containers for the handling of food, improper use of cold chain facilities, inadequate refrigerated vehicles to move the food to market before it spoils, high cost associated with cooling facilities, inadequate skills of staff (drivers, supervisors, managers), traditional processing and marketing systems, loss in product value with time, lack of communication link between producer and wholesaler, too lax or unduly strict legal standards, over purchase of cheap but highly perishable food products, lack of conscientious and knowledgeable management, and bumper crops that overload the post-harvest handling system. The response is in Figure 3.

A continuous loss in product value with time (Mean=4.125, SD=0.60) with High cost associated with cooling facilities (Mean=4, SD=0.614), and Inadequate harvesting, packaging and handling skills (Mean=3.18, SD=0.528) emerged as the top three reasons for the wastage of fresh produce from a farm to till it reaches a consumer. This can be easily visualized that all of these can be curbed properly if a due attention on cold chain practices is given.

Related to Education and Awareness Level of Farmers

Farmers generally lacks management skills, they are not fully acquitted with the new trends and innovations in agriculture sciences. They require extension education services to educate them on postharvest as well as marketing techniques. In this section of the survey, the farmers were asked about the information network they have, how much reliable it is and how far they have used it. Figure 4 shows the information sources used by farmers in India during the past one year to obtain information that can help them in increasing their returns.

It was observed that about 50 percent of the farmers had not used any sources for upgrading their knowledge. Out of those who did use sources, the most used source emerged as 'the other fellow farmers', who are doing well from past few years. Radio and the dealer who delivers seeds and fertilizers were the second-most used source. Television followed thereafter. The government extension workers ranked fifth, followed by the primary cooperative society and newspaper. Less than 1 percent of Indian farmers accessed NGOs, private sector extension, or para-technicians.

The respondents were also asked to rank the quality of information they received as good, satisfactory, or poor. Figure 5 shows the result. About 50% of the respondents ranked the quality of information received from most of the information sources as good. Most of the respondents suggested improvement in the quality, timeliness and reliability of the information provided.

Hypothesis Testing

In this section, the validity of hypotheses is tested. Multivariate regression analysis, correlation analysis and independent T-tests are used to test the hypotheses on SPSS. For the validity of multiple linear regres-

sion, it is essential that the independent variables in any regression equation are mutually independent and do not have strong dependence or correlation among themselves. According to George & Mallery (1999), a linear regression equation between the dependent and independent variables is possible if there is no linear dependency among the predictor (independent) variable. To compute correlations between predictor variables is always a wise step. Variable that correlated higher than 0.5 should be scrutinized carefully before such are included in a regression analysis. At the same time the Variance Inflation Factor (VIF) should also be considered to measures the impact of collinearity among the variables in a regression model. The regression model having VIF more than 10 Values are often regarded as indicating multi collinearity (Miles et al., 2001). We propose to conduct linear regression analysis for testing hypotheses. The Pearson correlation coefficients for independent variable are calculated before conducting the regression analysis. The low correlation coefficients indicate that there is no significant correlation among the independent variable and linear regression can be preceded. For quick reference each of the proposed hypotheses is reproduced before it is tested for its validity.

H1: Post harvest losses between farm and cold storage are positively influenced by (a) inadequate pre-cooling facilities, (b) insufficient knowledge among farmers, (c) high cost of product refrigeration and (d) inadequate support from government.

A multivariate regression analysis is carried out on SPSS to test this hypothesis. In this test the dependent variable is "Post harvest losses between farm and cold storage", and the independent variables are: "Inadequate pre-cooling facilities", "Insufficient knowledge among farmers", "High cost of product refrigeration" and "Inadequate support from government". The results of this analysis have been presented in Table 1.

The regression model derived from this analysis is:

Post-harvest losses = 0.729 + 0.363 (high cost of refrigeration) + 0.235 (inadequate pre-cooling practices at farm level) + 0.224 (inadequate support from the Govt.) + 0.172 (insufficient knowledge and skills).

As the independent variables in the model influence the dependent variable at a high significance level (p value are less than 0.05), the hypothesis is accepted.

Table 1. Multiple regression analysis for Hypothesis 1

	Regression Coefficients		t	Sig.
	B	Std. Error		
(Constant)	.729	.377	2.466	.016
Inadequate pre-cooling practices at farm level	.235	.062	3.767	.000
High cost of refrigeration	.363	.084	4.325	.000
Insufficient knowledge and skills	.172	.075	2.286	.025
Inadequate support from the Govt.	.224	.072	3.112	.003

$R^2 = 0.525$.

Dependent Variable: Post harvest losses.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

H2: There is a significant difference of perception between Milk and milk Product (MMP) and Fruits & Vegetables (FV) sector at farm level, regarding pre-cooling practices.

In question related to this hypothesis, respondents were asked to assign weights to 'pre-cooling practices' at farm level for not getting sufficient value for their products. On the five-point Likert scale, 1 and 5 correspond to very low weight to very high weight. The descriptive statistics of the responses for both the sectors are shown in Table 2

It is observed from the descriptive statistics that MMP sector is more concern about the pre-cooling practices. An independent sample t-test (Table 3) is conducted to test this hypothesis. In this test MMP sector is compared with FV sector.

The results of the test indicate that the MMP sector significantly differ (at p= 0.000) from FV sector in the pre-cooling practices at farm level. The result of the independent t-test is sufficient to accept the proposed hypothesis.

Hypothesis 3

H3: Loss in the product value with time is positively influenced by (a) inadequate handling skills, (b) improper use of cold storage, (c) inadequate refrigerated transportation, and (d) high cost of cold chain facilities.

In the testing of this hypothesis, "Loss in the product value with time" is taken as an independent variable. The dependent variables are: "Inadequate handling skills", "Improper use of cold storage", "Inadequate refrigerated-transportation", and "High cost of cold chain facilities".

The regression model derived from this analysis is:

Loss in the product value with time = 0.486 + 0.341 (inadequate handling skills) + 0.282 (improper use of cold chain facilities) + 0.269 (high cost associated with cooling facilities) + 0.128 (inadequate refrigerated transportation).

Table 2. Descriptive statistics related to Hypothesis 2

Issue for Comparison	Sector	Mean	N	Standard
Pre-cooling practices at farm level	MMP	3.26	40	0.834
	FV	2.13	40	0.552

Table 3. Independent sample t-test for pre-cooling practices at farm level (MMP verses FV)

Issue for Comparison	Mean Difference	Degree of Freedom	t Value	Sig. (2-Tailed)
Pre-cooling practices at farm level	1.1	78	6.957	0.000

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Regression analysis for Hypothesis 3

	Regression Coefficients		t	Sig.
	B	Std. Error		
(Constant)	.486	.262	2.154	.036
Inadequate handling skills	.341	.084	4.039	.000
Improper use of cold chain facilities	.282	.054	5.170	.000
Inadequate refrigerated transportation	.128	.061	2.108	.037
High cost associated with cooling facilities	.269	.058	4.628	.000

$R^2 = 0.651$.

Dependent Variable: Loss in product value with time.

From the above equation it is observed that the coefficient of "Inadequate harvesting, packaging and handling skills" is 0.341, which is higher than the coefficients of other variables. Therefore among all other variables it has maximum influence upon the losses in the product value with time. However, in order to assess the usefulness of each variable in the model, one cannot simply compare the coefficients to see the unique contribution of each variable. Beta coefficients are an attempt to make the regression coefficients more comparable as these coefficients indicate the relative importance of the variables without taking the constant into considerations.

For this model with four independent variables, the value of R^2 is 0.651. This value of explains 65.1% variability in the "loss in product value with time". As all the independent variables influence the "Loss in product value with time" at a high significance level (p value less than 0.037) the hypothesis is accepted.

Major Findings

1. Post-harvest losses of fresh produce at farm level are very serious in India. It was observed that literacy and poor awareness level are the main causes for the backwardness of Indian farmers.
2. It was observed that farmers are aware of the adverse consequences of poor temperature maintenance at farm level but they are not giving due importance to cold chain practices. It is the lack of funds that forces farmers to ignore the use of cold storage, even when available and effectively managed. Many farmers depend on almost daily sales for their income and hence may be forced to accept a lower price immediately, rather than to store their produce in the anticipation of a higher price.
3. It was also observed that small farmers do not have their own means of transport of their products. So they are dependent on intermediaries to get means of transportation. This again causes delay which means piling up of loss.
4. There are a number of intermediaries and fluctuating consumer prices which finally result farmers not getting fair share of the consumer rupee.
5. As observed 'proper handling' of perishables is considered as the most influential practice for improving the value of produce, followed by 'proper sorting' and *cleanliness*. *Pre-cooling* was given fourth rank.
6. Regarding the use of information sources by farmers that can help them in increasing their returns; it is observed that about 50 percent of the farmers had not used any sources for upgrading their knowledge. Out of those who did use sources, the most used source emerged as information from

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

'the other fellow farmers', who are doing well from past few years. *Radio, Television* and the *dealer* who delivers seeds and fertilizers were the next used source.

7. There is inefficient communication link between farmer members and company mangers. Losses will always occur in the absence of a dependable communication system.
8. In the absence of timely and correct information about prices, arrivals and market trends, compounded with the problems of low cash-at-hand and proper advice, farmers are forced to sell their produce at lower-than-expected rates.
9. Containerization is also, the weakest aspect in the procurement chain especially till it reaches company store room. In general, packaging materials of unsuitable quality, such as large sacks, rough wooden boxes, second-hand cartons, bamboo baskets, or rattan containers are liable to cause produce to suffer from bruising, crushing and puncturing.

DISCUSSION AND POLICY IMPLICATION

The present generation of farmers has lost much in terms of indigenous agricultural knowledge and skills and in the integrity of the social organization in which indigenous innovation capacity is embedded. Public policy in developing countries has failed to invest in educating farmers on how to deal with variable agro-ecosystems and a changing world (Van den Berg & Jiggins, 2008).

Post-harvest losses from physical and pathological (microorganism development) damage to perishables can be minimized by taking care while harvesting and by proper storage at conditioned environment, but limited economic background may obstruct farmer to take such care and treatment. A low-cost cooling system can help poor farmer for extending the life of perishables and can help in drastically changing traditional handling and storage limitations. New innovative measures can help in temperature reduction at low cost that could make a big difference. Usually the fruits and vegetables are picked manually by many inexperienced workers. Further bulk of these fresh produce are either undertaken various traditional methods of storage or to be sold to agents (intermediaries) at very low cost. A perception of immediate high cost of hiring cold storage space does not allow a farmer to perceive the justified advantage of the refrigerated storage. The observation also suggested that there are very less extension education program from the government.

There are manifold reasons which can reduce the value of product. Improper handling can result excessive exposure to rain, drought or fluctuating temperature. In correct stage of product maturity, contamination by micro-organism and physical damage can further reduce the value of fresh produce. It was also observed that small farmers do not have their own means of transport of their products. So they are dependent on intermediaries to get means of transportation. This again causes delay which means piling up of loss.

A farmer requires understanding the value of information especially about the new trends and cost effective innovations to preserve perishables. A well aware farmer can know about market prices, sellers, buyers, transporters, other intermediaries and relevant information. Now days with little communication cost accessing this information are easier than before. It is observed that still farmers stuck to agents (who exploit them) especially for sale of perishables. Using the communication devices there are many ways to find customers. A proper planning can always help farmers in getting right buyer. A proper awareness can always help farmers in getting profit and bargaining power while dealing with middle men.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

One of the underlying reasons for such problems is the lack of knowledge, skills and unawareness about the market information. Small Indian farmers are poverty stricken, illiterate and dependent on monsoon. The poor market information and low value addition capacity, gives them low margins and low risk-taking abilities (Bhalla, 2005). A little bargaining power and heavy dependence on their farm produce for basic needs pile up farmer's woes and compel them in becoming victims to the exploitative market intermediaries who deny them a fair share of the consumer rupee. Thus, small farmers enter a vicious circle and then find it difficult to come out (Sridhar & Ballabh, 2006).

Consistent temperature maintenance is an imperative constraint throughout the cold chain. The temperature of fresh produce should be maintained below 5^{o}C to reduce the proliferation of spoilage microorganisms and human pathogens. Quality loss at farm, which is the first link of the cold chain, drastically degrades the value of the produce in the subsequent links. Product condition at market reflects the cumulative quality losses at each link of the cold chain. At farm level there are few environmental conditions that can be managed to get good quality product to the next link. These are product temperature and humidity surrounding the product, ethylene gas concentration around ethylene sensitive products, and atmospheric composition (Smale et al., 2006).

From the farmers' perspective, the cold chain management is not easy even when operating in a developed economy such as the US and UK. It gets even more challenging in developing economy like India. In most developed economies, with affirm support from robust infrastructure, there is limited uncertainties in business process related to logistics. However, in developing economies logistics tends to poses several types of challenges due to unpredictable environment, weaker infrastructure and uncertainty in availability of basic necessities like water, power etc.

CONCLUSION

In this paper, the results of a questionnaire-based survey on the awareness and practices of Indian farmers towards the readiness as an active link in cold supply chain are reported. The two main objectives of the survey were firstly, to examine the current practices and issues related to Indian farmers preparedness towards cold chain and secondly, to test the validity of some hypotheses that have been formulated. The description of the methodology adopted to achieve the survey-oriented research objectives was also discussed. Subsequent to this, observations from the survey have been reported and discussed. It was observed from the survey findings that pre-cooling practices at farm level have significant influence on postharvest losses and value loss of perishables throughout the cold chain. Also, the practices of inadequate transparency in pricing at farmer end are also witnessed. Lack of awareness about the use of IT for better informed, Improper handling, loading and loading of products, Fragmented production, leading to fragmented chains, Traders dominate the chain are also major reasons for the poor stare of farmers and thus a farmer is totally a separated link. As per the study conducted under Government of India, the state of Indian farmers is characterized by prevalence of small and tiny holding that are financially non-viable. Discrimination between small farmers and big farmers by traders, extension service providers, government officials etc., were also mentioned by the farmers during the interview.

It was also observed that lack of knowledge and skills in staff involved in the cold chain has also significant influence on quality and safety measures. Traceability and service level improvement are important factors for any cold chain and requires sufficient attention. Between the MMP and FV sectors, it is observed that MMP sector is relatively more conscious about the cold chain practices at farm level.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The situation in most of the developing economies is by and large similar to Indian condition. These finding may help developing economies in policy level decision making. Finally, it can be concluded that these findings have apparently led to the focus of industry and academia to study the various issues, related to CCM in the companies who are in the business of perishables.

Chapter 73
The Loss and Damage of Environmental Ethics in the Threshold of African Culture:
Environmental Ethics and African Culture

Essien D. Essien
University of Uyo, Nigeria

ABSTRACT

It has been argued that human actions through pollution and other activities have imperil survival, harm health and dislocate the well-being of man on earth. This argument's corollary is that, given the curious datum that human beings are implicated in loss and damage of the environment, actions performed by individuals have aggregate negative consequences on the environment. Yet, what African culture is and how it matters in environmental ethics is regrettably unexplored and disproportionately contested. This study examines the contributions of culture toward the preservation and protection of the environment for future generation. The study adopts qualitative methodology and content analysis, as well as "relational theory" to respond to the thesis that African culture has a moral responsibility and an in-built mechanism to protect human interactions with nature and environment. The findings show that culture has the capacity to avert loss and damage of the African environment through African ethics.

INTRODUCTION

Regardless of all the distinctions that can be made on a theoretical level amongst ethicists and their different value positions in environmental ethics, there seems to be a growing need today in the world to articulate a pragmatic environmental ethics that can guide our actions, decisions and preferences in the individual, social, economic, corporate and public decision-making contexts (Pojman, 2001). This is why in Africa; environmental ethics is part of the larger issue of how to live an ethical life. This clearly manifest in the verity that harm to the natural environment though come in great measure from the collective detrimental actions and practices of the inhabitants constitutes the collective responsibility

of all. It is against this backdrop that it is proper to state that cultural and geographical contexts shape environmental orientations in all societies, Africa inclusive (Murove, 2004). This also explains why there exist interactions between the people and their environment which are as old as human civilization.

However, the problem of managing those interactions has today been transformed by unprecedented increases in the rate, scale, and complexity of crisis, degradation and other environmental challenges. In spite of this development, African societies, as organized and functioning human communities, have undeniably developed for itself ethical systems such as ethical values, principles, rules and norms intended not only to guide her social and moral behavior but protect her environment (Masaka & Chemhuru, 2010). This clearly depicts the sense in which human beings in Africa value nature as a vital component in the construction of their environmental ethics.

Nonetheless, the problems and crises afflicting the management and preservation of Africa's environment today are primarily the symptoms of the deep-rooted, long-term effects of centuries of neglect and insensitivity (Weberzik & Wilson, 2008). It is apparent that Africans have always been dependent on the natural resources in their environment for their livelihood. That is why about 70% of the people in Africa rely solely on forests for their food, shelter, energy and even medicine. This lends credence to the fact that the character of the environmental changes that today's lifestyle and technological advancement has produced and the increased public awareness of the importance of the natural environment connotes that we have entered a new age of environmental challenges (Omari, 1990). Across the world however, people are beginning to understand that part of what is needed to meet these challenges is the development of a new and more robust environmental ethics. This study therefore provides an overview of some of the environmental issues facing Africa and examines the role of African culture cooperation in meeting these challenges. An environmental performance analysis is used to identify the loss and damage of environmental challenges in Africa, as well as the significance of environment in African ethical life.

Conceptual Clarification

In order to commence an effective conversation on this paper, it is pertinent that we offer some clarification of notions that would facilitate effortless comprehension of the subject matter of our discussion. They include the following: environmental ethics, environment, African environment, deep ecology, and Humanistic ethics.

Environmental Ethics

Environmental ethics is a theory and practice about appropriate concern for, values in, and duties to the natural world. In this study, environmental ethics is understood as a research field and academic discipline, which focuses on principles and values regulating human relations towards nature, either as a whole or in its particular forms, the prerequisites and consequences of these relations, and theoretical, normative and practical issues related to them. Environmental ethics is deeply connected to the environmental sciences, on the one hand, and the humanities on the other hand (Guha, 2000). These are important epistemic resources for environmental ethics. Environmental ethicists need to understand environmental problems to be able to provide their ethical analyses. Environmental issues, like global climate change, air pollution, reduction of biodiversity and wilderness, desertification, etc., are practical issues and in so far as they have been produced mostly by un-precautious human activity, they cannot be solved by scientific and technological means only. Humans as individuals and communities should

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

recognize their responsibilities to solve such problems and this may be possible only on the basis of a fundamental shift in their outlook and value attitudes towards nature. Environmental Ethics aims to clarify these responsibilities, the condition of their possibility, their value foundations and behavioral implications (Harris, 2005).

The field of environmental ethics concerns human beings' ethical relationship with the natural environment. Although several philosophers have written on this topic throughout history, environmental ethics only developed into a specific philosophical discipline in the 1970s (Velasquez & Rostankowski, 1985). This emergence was no doubt due to the increasing awareness in the 1960s of the outcome and impact of technology, industry, economic expansion and population growth which were exerted on the environment. The development of such awareness was however aided by the publication of Rachel Carson's Silent Spring, in 1962, which alerted the public on the widespread use of chemical pesticides posing a serious threat to public health and leading to the destruction of wildlife. Of similar significance was Paul Ehrlich's 1968 book, "the Population Bomb", which warned of the devastating effects the spiraling human population had on the planet's resources (Velasquez and Rostankowski 1985). Of course, pollution and the depletion of natural resources have not been the only environmental concerns since that time. Others were the dwindling plant and animal biodiversity, the loss of wilderness, the degradation of ecosystems, and climate change were all issues that have implanted themselves into both public consciousness and public policy over subsequent years. In the light of this, the job of environmental ethics is to outline our moral obligations in the face of such concerns. In a nutshell, the two fundamental questions that environmental ethics must always strive to address are: what duties do humans have with respect to the environment, and why? The latter question usually needs to be considered prior to the former. In order to tackle just what our obligations are, it is usually thought necessary to consider first why we have them (Ojomo, 2011). For example, do we have environmental obligations for the sake of human beings living in the world today, for humans living in the future, or for the sake of entities within the environment itself, irrespective of any human benefits? Different philosophers have given quite different answers to this fundamental question which, as we shall see, has led to the emergence of quite different environmental ethics (Brechin & Kempton, 1994).

Environment

Environment is broadly defined as a community's natural surroundings (air, water and land) that contain natural resources (wood, herbs and medicine) for which the availability, accessibility and quality shape rural livelihoods and the overall health and wellbeing. Therefore, the local environment refers to the local setting within which proximate natural resources support rural livelihoods (Harris, 2005). The state of the local natural environment is central to the well-being of millions of rural households in developing countries. Environmental concern represents a specific component of broader environmental perceptions such as problem of resource availability, accessibility and quality. The moral values and cognitive beliefs of a culture play an important role in how well human beings adapt to their natural environment. Therefore, our approaches to environmental ethics should differ slightly depending on the cultural heritage and religious traditions through recognition of ecological knowledge, and an awareness of how modern cultural values have destroyed sustainable resource uses (Godofsky, 2010). We should appreciate the way in which moral ideals motivate persons to care for the world around them. It is through ethics that our roles are clarified through the value system in policy decisions and giving moral reasons for alternative course of action. By respecting nature, we can even achieve the ecological integrity towards the green

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

economy. Ethics helps in resolving some of the outstanding value conflicts that thwart conservation and development projects and even in defining a new social paradigm (Foltz, 2003).

African Environment

African environment is made up of Africa's terrain which includes lands, deserts, hills, mountains, rivers, lakes and coasts. These terrains have endured several millennia of modification caused by human activities. The forest mosaic, soils, vegetation and population settlements also encountered diverse transformations from time immemorial. Indigenous and exotic species, and new knowledge have contributed to the biodiversity in plants, animals and viruses on the continent. New crops like maize, cassava and cocoa have adapted to semi-arid savannah woodland, rainforests, coastal swamps and highland plateau (Ojomo, 2011). Africa's climate consisting of wet summers and dry winters dramatically changes life, vegetation and access to water on the continent. The animal kingdom in Africa comprises both diminutive and huge mammals. Fauna includes domesticated and wild, herbivorous and carnivorous species. Herbivores are in the majority and are sustained by vegetation; grasses, bush and trees, while carnivores – feline, canine, and avian – subsist on the herbivores. Omnivorous species live on different types of food including both plants and animals (Ojomo, 2011).

The African environment is also home to a range of benign and malignant disease agents, and some of them are protozoans, viruses, and nematodes which cause epidemic and endemic illnesses to both humans and animals. On the other hand, insects like lice, mosquitoes, locusts, tsetse fly, black, green flies and ticks are hosts or vectors of disease agents and make seasonal migrations following moist, vegetation and temperature influencing other fauna and flora in different ways. However, humans are probably the key determining factor in African environmental history (Callicott & Clare, 2005). Human actions, beliefs, notions, labor and tools have played a critical role in changing African environments. Central to environmental change in Africa are multi-layered interactions involving the physical world, flora, fauna and human activity (Hjort & Salin, 1980). These interactions also encompass tradition, beliefs, ideas, perceptions and prescriptions regarding habitats and inhabitants. Indeed, the African environment comprises both tangible and intangible, human and non-human activity, and the resulting phenomenon.

Theoretical Framework

This study is based on relational theory of corporate social responsibility taxonomy which has its root from the complex web of society-environment relationships. The theory emphasizes the role of social and cultural pressures imposed on institutions that can influence directorial practices and structures (Engel, 1990). Given that there is a great deal of heterogeneity of theories and approaches of moral responsibility, best practice and corporate social responsibility such as the utilitarian theory, managerial theory, and relational theory, social contract theory, etc, discussion in this paper is supported with a comprehensive analysis by Secchi (2007) and Maimunah (2003) compared with an analysis by Garriga & Mele (2006) objective responsibility.

For the purpose of this study, the stakeholder model and the social contract model have been adopted for the analysis of the interaction of environmental ethics with African culture. Stakeholder approach has been developed as one of the strategies in improving the management of the society. It is also said as a way to understand reality in order to manage the socially responsible behavior of societal institutions. The stakeholder approach further considers the society as an interconnected web of different interests where

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

self creation and community creation happen interdependently; and individuals behave altruistically. Based on Garriga and Mele's (2002) analysis, stakeholder approach is both within the integrative and ethical theories, where the former emphasizes the integration of social demands and moral responsibility, while the latter focuses on the right thing to do to achieve a good society. This is strongly supported by the standpoint that considers ethical duties towards stakeholders of the society and environment, respectively. In the same vein, corporate social responsibility is derived from the moral legitimacy the individual achieves in the society and the understanding about corporate social responsibility is contained in the justification of social actions that legitimize the behavior of the individual.

Against the backdrop of the underpinnings of this theory, it is imperative that an appreciation of the relational theory analysis is the most appropriate analytic paradigm for locating the loss and damage of environmental ethics in the midst of numerous environmental challenges in Africa. At the center of the adopted theory is an attempt at chronological scrutiny of the problems and demands of the environment aimed at revealing not only the patterns and regularities of the incidents, but also the impact and interrelationship it has had in the configurations of society. Using this framework therefore, this study will demonstrate that the environmental problem of many societies in Africa are as a result of individual and institutional failure in acquiescing to cultural prescriptions and best practices in the preservation of the environment in Africa. This study therefore is analyzed based on the stakeholder and social contract models of the relational theory principles.

Methodology and Data Presentation

The study employed the qualitative survey research design of an ex-post facto type. The independent variable in this study is African culture as it relates to its obligation for future generation, while the dependent variable is environmental ethics in the loss and damage of the African environment. The strategy adopted for this study involved a multiplicity of ethnographic methods such as individual in-depth interviews, focus group discussions and informal discussion sessions. The study population comprises of male and female who constitute community inhabitants of the study area, elders and traditional custodians of culture. Based on the principles of informed consent and confidentiality, information was voluntarily and successfully abstracted from a total of 348 respondents comprising of: 65 male, 157 females, 20 NGO activists, 45 traditional custodians of culture, 41 researchers, and environmental ethicists who are academics, and 20 religious leaders.

This was complemented with the examination of available secondary data from various sources such as educational institutions, government agencies, advocacy groups and different NGO offices. Field notes and tape recording went on simultaneously, while interviews were transcribed, anonymized and coded accordingly. Sample of 348 subjects were purposively selected from the population (Table 1). The population was divided into six clusters representing six countries: Nigeria, Ghana, Cameroon, Sierra Leone, Ethiopia, and Kenya. Each cluster consisted of 58 respondents. The respondents were selected accidentally from each cluster and target group. Data collection was entirely based on self-report and were collected from the respondents by six (three females and three males) research assistants. The interviewers were residents of the study area who knew the culture and language of the people.

The current study aims at studying the loss and damage of environmental ethics in the threshold of African culture amidst obligation for future generation and collecting data in a large quantity to examine the development, so it made use of qualitative methodology. In order to fulfill the goal of this study, a survey which embrace In-depth interview (IDI), was adopted to verify the findings of the survey method

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Sample and population of study

S/N	Location/Cluster	Sample	Classification	Percentage
1	Nigeria	58	Male and Female	16.5%
2	Ghana	58	Male and Female	16.5%
3	Cameroon	58	Male and Female	16.5%
4	Sierra Leone	58	Male and Female	16.5%

	Total	348		100% approx.

Sources: Field survey, 2015

with open questions administered. The open questions were asked in face-to-face interviews. Every individual was asked to answer the questions after contemplating about the contributions of culture toward environmental preservation. Another method utilized for the study is the Focus Group Discussion (FGD), which is also a qualitative technique adopted to verify the findings of the survey method. Six FGDs were conducted, each per a location and cluster. Each FGD comprised of eight participants from elderly male and female, activists, traditional custodians of culture, environmental ethicists, and religious leaders.

Table 2 above reveals that 111 respondents were males, representing 31.9%, while 237 representing 68.1% were females. This was contrary to a widely held belief that males are more involved in environmental issues and cultural matters than the female. Observations during the survey were that males were relatively unwilling to neither accept the survey instrument nor participate in the FGD, than female.

Table 3 above shows that majority of the respondents were literate and understood the socio-religious and cultural implications of protecting the environment as a status of communal rights to cultural and environmental self-determination for future generation. This is evident in 51.7% of the respondents in Nigeria, 51.7% in Ghana, 46.5% in Cameroon, 44.6% in Sierra Leone, 53.4%in Ethiopia, and 48.2% in Kenya who have acquired the first and the second level of education. They adhere strictly to the moral responsibility of African culture to the environment which constitutes a group value and a source of social identity. It also shows that members of this society approves of the people's sense of community in environmental issues. The data further show that the respondents were knowledgeable enough to understand the cultural context of the environment. Similarly, respondents based on their educational attainment were conversant with the instrument of data collection used for this study.

Table 4 above shows that participants in FGD and IDI were all knowledgeable about the subject matter and could discern the import of the questions asked. In the six FGD with 9 participants each, with a total of 54 participants in all, male were 16 (29.6) and female 38 (70.4). In the survey, it is apparent that

majority of the respondents that gave their responses were female signifying that they are more involved in the practice of taking care of the environment especially as it involved agriculture in the subsistent scale which they play prominent role.

Based on the findings of table 5 above, there are significant relationships among the different variables indicating that in many communities, human beings involve themselves in un-precautious human activities that destroy the environment. It is apparent therefore, that rooms for accommodation of views and obliteration of ignorance are not foreclosed. This is evident in the opinion of 244 respondents (70.1%) that African societies have developed ethical systems such as ethical values, principles, rules and norms intended to guide social and moral behaviour to protect her environment. Findings also show that moral

Table 5. Respondents' reactions about the role of culture in protecting and preserving the environment in Africa

S/No	Items for Respondents' Reaction	Percentage of Agreement		
		Agree	Disagree	Neutral
1	In Africa, is environmental ethics part of the larger issue of how to live an ethical live?	280 (80.4%)	61(17.4%)	7 (2.2%)
2	Is the cultural and geographical context a factor in environmental orientations in all societies in Africa?	275 (79.0%)	73(21.0%)	Nil
3	Are you of the opinion that African societies have developed for herself ethical systems such as ethical values, principles, rules and norms intended to guide her social and moral behaviour to protect her environment?	244 (70.1%)	131 (37.6%)	12(3.4%)
4.	Is it correct that Africa values nature as a vital component in the construction of their environmental ethics?	200 (57.4%)	148(42.6%)	Nil
5	Are you of the opinion that African environment should be preserve?	276(79.3%)	69(19.8%)	3(0.9%)
6	In your opinion, is there any functional conservation ethics embedded in the knowledge system of your community?	224(64.4%)	124(35.6%)	Nil
7	Does the reason for preserving the environment considered a valuable project to be pursued in your society?	212(60.9%)	136(39.1%)	Nil

values and cognitive beliefs of African culture play a great role on how the people preserve, protect and adapt to their natural environment. 55.5 percent of the respondents agreed that unprecedented misunderstanding of how African ethics help in resolving value conflicts oftentimes thwarts conservation and moral responsibility toward the environment. In fact, it can be argued that adherence to African culture does not only bequeath an environmental obligation to preserve and protect the society for the sake of humans living in the world today but also for the future generation.

Discussion of Finding

The study indicates a significant correlation between the cultural and geographical context of environment ethics and African societies. This study found out that in Africa, human actions, beliefs, notions, labour and tools, all play a critical role in changing African environment. The issues of environmental ethics are momentous and involve moral choices of enormous scale, which we must make. Our moral responsibility to nature and to the future is of unprecedented significance and a responsibility that we cannot escape. That is the essence of environmental ethics.

The study reveals that this effort have produced mixed results because of failure to take cognizance of the complex nature of the environmental issues involving politics, culture, rights and history of the people and institutions. This is in spite of the fact that several attempts made and facades as a rescue enterprise in many societies disregards the imperative of environmental ethics as challenging involving life-threatening concerns. This study further discovers that by failing to recognize the very dynamism of the concept of African environmental ethics, a dilemma is created by turning the campaign against African environmental crisis, based on the nature of the crisis which is anchored on poverty, industrialization and economic pressures. Therefore, the dichotomy and conflict between tradition and modernity represented in the prevailing social structures, constitutes a masks complex patterns of the nature of the environmental crisis seeking understanding and attention. However, evidence from the field further suggests that both traditional and modern social structures have led to environmental degradation, oppression and destruction. According to Mmama Bassey Antia, the high level inaction and lack of attention to environmental matters today are the reason why we have high numbers of death and ill-health in our society.

In sum, it is understandable to argue that in Africa, environmental ethics is a larger issue of how to live an ethical live. As a means of further justifying the practice of environmental ethics, Madam Nkoyo Owoanam avows that cultural and geographical factors of environmental orientations is crucial for all societies in Africa. This position explains why African societies have developed for herself ethical systems such as ethical values, principles, rules and norms intended to guide her social and moral behaviour to protect her environment. At this juncture, there is essentially the need to consider how individual choices and cultural self-determination play out in the justification for environmental protection.

Religiously speaking, the study also discovered that in Africa, the maintenance of certain tradition and, by extension, a specific cultural identity such as the traditional conservation practices manifest in sacred groves, shrines, spaces, trees, forest and natural features strictly adheres to religious beliefs, culture and tradition of the Africans regarding the obligation to the environment. This behaviour when critically evaluated suggests a link with the people's traditional religion. From the responses of most respondents, the study reveals that the standard African man and/or woman are the one with moral responsibility to the environment. In the FGD for instance, it was gathered that the moral values and cognitive beliefs of African culture play a central role on how well African people preserve, protect and adapt to their natural environment.

Moral Responsibility of African Culture to Environmental Ethics

The issues of environmental ethics are momentous and involve moral choices of enormous importance that we can make and even, which we must make. Moral responsibility normally implies knowledge, capacity, choice, and value significance (Agius & Chircop, 1998). Our moral responsibility to nature and to the future is of unprecedented significance and urgency, and it is a responsibility that we cannot escape. That is the essence of environmental ethics. Until fairly recently, human actions and effects on the environment were regarded as neutral simply because we assumed nature was both impersonal and too vast to be injured by our interference. Environmental ethics is concerned with the issue of responsible personal conduct with respect to natural landscapes, resources, species and non-human organisms (Bakut, 2006). In Africa, the African environment allows for a tripartite interaction of beings such as human beings, non-human animals and spiritual beings.

Consequently, Africans are obliged with a moral responsibility to show worth and value to their fellow human beings, non-human animals, as well as the spirit beings. Respect and gratitude to the ancestors as spirit beings is realised by continuing to care for nature in the present, and emulating the example of previous generations, by ensuring that the next generation also inherits an environment "in good shape" (Agius & Chircop, 2006). In this responsibility, a two-sided concept of stewardship in the management of the environment involving obligations to both ancestors and descendants which motivates environmental carefulness is required. Of all the duties owed to the ancestors, none is more imperious than that of husbanding the resources of the land so as to leave it in good shape for posterity (Ekeli, 2004).

African idea of environment has a deeper worth and weight against which it is considered immoral to abuse or misuse the environment. This explain why African worldview presents an environment as a background on which to measure and locate the significance and relevance of the human life and which spells out the danger of damaging the environment. Therefore, the environment in the African thought ought not be seen and understood as an economic item or a social space, but where to locate the significance and relevance of life (Lizanne, 2005). According to Iroegbu (2005), Africans have a deep reverential deference for life where its beginning, growth and end is elaborately celebrated. (Iroegbu, 2005). Life in Africa is held to be good because of its ability to regenerate perpetuity. By perpetuity is meant the ability to regenerate life itself. Thus the African thinking of celebration of life stems from a distinct framework that can be captured by the cult of perpetuity and ancestorship. The environment in Africa is thus seen as a metaphysical interpretation which provides a moral lens or duty that drives the Africa theory of life.

From this perspective, the environment is intended to serve as a moral support hence it should be treated fairly well since it will be wrong to expect a good thing from an environment that has been badly treated by its inhabitants. It is therefore, these elements of reciprocity that the African moral world demands. Consequently, it is then totally wrong and contrary to an African environmental world if the source of ill-will and discord finds its root in the resources of the environment because by doing so, the environment is negative or destructive moral agent (Ugwuanyi, 2011). This analysis of moral responsibility explains why environmental ethics has only recently attracted the attention and concern of environmentalists and the general public. Today, it is a common knowledge that humans know that they can cause massive and permanent damage to natural landscape, resources and ecosystems. Not only do humans know that they can cause these insults, they also know how they can cause them, and how they can prevent or remedy them. But the fact that knowing this exacts a moral obligation to act

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

with care, foresight and at times, with forbearance and constraint constitutes veritable operation space for environmental ethics.

Cultural Agents of Articulating Environmental Ethics in Africa

In African society, environmental activities are always linked with cultural and religious activities, with art and magic, if not with the realm of the mystical. African communities usually focus on the interrelatedness of all systems in the natural African world including the spiritual world (Adegoroye, 1997). When looking at the environmental ethics platform of African people, we can conclude that harmony with nature is the key concept. Man is not above nature, but the flourishing of both man and nature has value. This explains why in the traditional society, African people live in great harmony with the plants of the environment, excluding the wild animals. The traditional ecological knowledge goes beyond noting the interrelatedness of specific organisms. It embraces an all-encompassing world view of total relationship (Ojomo, 2011). This is where the sense of communality and oneness with the earth features very strongly in African societies (Mangena, 2013). This study is however, of the opinion that the attempts to find new solutions to the current environmental crisis in our contemporary societies can benefit immensely from looking back at the traditional ways as well as indigenous knowledge and culture of the people of Africa. Environmental ethics in Africa therefore, can best be articulated as found in the African folktales, riddles, taboos, sacred groves and spaces, trees, and features as well as rituals.

Taboos

The belief in the supernatural world is still prevalent among African communities. For this reason, Africans belief in certain avoidance rules has moral implications on the human person and how one has to relate with his surrounding environment. In Africa, taboos form an integral part and parcel of her morality (Essien, 2013). Among the people, environmental taboos have a pivotal moral role toward the ontological wellbeing of both the individual person and the environment at large. Prohibitions and restrictions through taboos on indefensible use of certain plant species, forests, mountains, rivers, pools and nonhuman animals, among other ecological species in the ecosystem, is not a new knowledge among many Africans, but reflects a long held African tradition and culture (Masaka & Chemhuru, 2010). This mentality is currently very lively and continues to shape the environmental ethics of several African societies. Although Africans have greatly felt the impact of the full weight of the domineering influence of western values, colonization and globalization, they have continued to cling on to some of their cherished values, including taboos.

With regard to the continued relevance of taboos in contemporary African societies, Gelfand (1973) rightly notes that "Africa possesses much that is worth retaining and the prospects are that they will save a good deal of it in succeeding generations." Despite the tide of modernity and cultural imports, contemporary African societies remain attached to some of their fundamental values, such as taboos. Whether, one has received a western education or has been imbued with a huge dosage of the western ways of life, unfailing adherence to certain aspects of African culture is an actuality as evident in taboos. Given that violation of African taboos are believed to invite an angry reaction at a supernatural level (Tangwa, 2011), fear of the unknown discourages the would-be offender of the African moral code to act in such ways that negates the moral code. One aspect of the African cosmology that has not succumbed to the weight of cultural globalization is the primacy of the spiritual world. Thus, since violation of

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

taboos is thought to invoke the anger of the spiritual world, no one is prepared to act in ways that anger the spiritual world even though one had no sufficient knowledge to validate such claims.

As a result of conceptualizing taboos not simply as avoidance rules that are merely observed by the Africans, but as a cultural agent of articulation of environmental ethics as well as an instructive tools aimed at inculcating desirable behavior, this study evaluates the extent to which taboos inform an 'environmental ethic' that emphasizes on deep ecological awareness even though they may appear, on the surface, to be simple prohibitions on unsustainable use of certain aspects of nature, such as sacred sites, mountains, rivers, pools, and some nonhuman animals (Essien, 2013. African environmental taboos consequently transcend simple prohibitions on certain sacred sites, plants and nonhuman animal species, pools, and rivers, among others, and enforce a desirable and sustainable use of the environment. In this regard, Gelfand (1973) argues, that "when a collection of African averting regulation is considered, it is evident that correct behavior is being emphasized." Thus taboo wisdom is examined as promoting desirable environmental ethics among the African people.

Cultural Folktales

By examining the folktales and riddles of the African people, it will be discovered that the people see many of the different occurrences and modes of expression in life as very much influencing others. But in order to understand the role and place of culture and oral traditions in the environmental ethics of African people, it is pertinent to situate the 'folktales and riddles of the people in its proper perspective (Lizanne, 2005). In Africa, oral traditions are one of the sources of social, economic, environmental and philosophical knowledge in non-literate cultures. It helps non-literate people to acquire a wide range of knowledge (Kelbessa, 2002). It seems that most African tribes use oral media like folktales, riddles, proverbs and songs to teach and entertain the young ones as well as the old. It is a way of sharing norms, beliefs and wisdom, and instructs the young as well as the rest of the society on acceptable and commendable behaviour. These oral media sources include the historical origins, migrations, war and settlement, records of land heritage, moral principles, social and political life, God, knowledge of birds, animals, plants, geologic features and the relationship between human beings and the natural environment which differs very much from general western norms and ways of living (Lizanne, 2005).

Because majority of African people are still very much dependent on natural resources for survival, and because they are living in and among nature and wild animals, environmental education begins in each and every family. Fathers and mothers teach their children how to behave and live with the natural environment. Understanding starts at an early age and develops gradually (Kelbessa, 2002). This wisdom and instruction regarding the relationship with the natural environment is thus transmitted since early childhood through the use of folktales and riddles containing some moral lesson. These moral lessons embody values, items of advice or warning, orders or prohibitions which are useful to develop environmental consciousness (Kelbessa, 2002). Although the African concept that harmony between man and the environment leads to the prospering of man, which is a valuable lesson to the west, the effects of such actions on environment, especially on animals, is better experienced than imagined. It is a veritable source of cultural diffusion and environmental ethics realization.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Cultural Riddles

Environmental ethics found in African riddles like folktales constitutes another source of knowledge in Africa toward protecting the environment. Riddles are characterized by question-and-answer form. However, in most cases, the question appears as a statement rather than as an interrogative in form. More generally, riddles are associated with children's amusement in contrast to the more serious use of proverbs by their elders (Essien, 2013). Riddles have the role of nourishing the intellect. However, the riddles in Africa elicit how the society sees themselves and their livestock mirrored in nature, as well as nature mirrored in the society. It is as if the patterns in nature find different forms in which to express itself and although its agent may differ, the expression stays very similar. This leads to the people learning lessons from occurrences in nature.

The Values of Plants

The African intimate knowledge of plants is another important aspect of their environmental ethics. This is manifested in the medicinal value of plants as herbal remedies as well as the role of spirituality regarding these remedies. Plants in African context play an important role in the people's protection of the natural environment (Taringa, 2006). In Africa, the natural vegetation has numerous uses in the daily life of the people including as firewood, building material, weapons, jewelry, household utensils for personal hygiene, and as food. The fact that the rural people in Africa live in close proximity with nature, and are therefore so very much dependent on their environment for survival, give them an advantage with regards to living in harmony with nature. A very good example is the fact that the traditional diet is much less damaging to the environment than that of the westerners (Omari, 1990).

Sacred Places

Sacred places are another concept among Africans which serves as a bridge between man and nature, and/or the physical and spiritual realms. It is not important whether a certain place or tree or river is really filled with spirit or whether it is the people's beliefs that make it sacred in their eyes. What is rather important is that the people see these places as worthy of respect (Boersema, 2001). It is as if the division between the spiritual and the physical are smaller in these places, almost non-existent. This concept is easily extended to a larger area and environment, even if not in the same intensity. The concept of increased spiritual value in certain places on earth is demonstrated by the words of John Mbiti (1970). They include rocks, trees, mountains, wells, and springs which are recognized as receptacles for spirits displaying in season their various properties, fertilizing, therapeutic and oracular. The earth as a living being has a far reaching impact for environment and conservation policies and attitudes. It is the opinion of this study that the most important aspect of sacred places is that of reverence for the earth environment which culminates into its protection and preservation.

CONCLUSION

This study emphasizes the importance of integrating cultural values, ideals and indigenous knowledge into contemporary management of the environment and natural resources as well as suggests for its use in planning and conservation of our environment. The paper has tried to establish a new foundation for a different approach toward environmental ethical hypothesis from African cultural perspective. The study demonstrates that humans are key determining factor in African environmental ethics and their actions, beliefs, notions, labor and tools have played a critical role in changing African environments. It was also discovered that central to environmental change in Africa are multi-layered interactions involving the physical world, flora, fauna and human activity which encompasses tradition, beliefs, ideas, perceptions and prescriptions regarding habitats and inhabitants. Given that the global community today is being confronted with diverse ethical issues which include, amongst others, the issue of ethics in the public as well as private spheres. Human beings were until recently, unable to see and foresee the harm done as a result of our interactions with nature (Weberzik & Wilson, 2008).

This study observes that in our dealings with the environment, we are in short, called upon to reflect, act, or perhaps to refrain from acting in a manner, which testifies to our worth as moral persons and as a moral culture. The caveat however is that we have an obligation to help ensure the existence of a clean environment and welfare of future generations through a functional environmental ethics. The most imperative question therefore is how to balance our obligations toward actual future people, that is, our future-directed obligations, with our obligations toward those presently existing, that is, our present-directed obligations. While it is sometimes claimed that we can have no idea what interests and concerns future people will have, this is without doubt exaggerated. Because future people will share roughly the same interests and needs that we already share with our contemporaries, our conditional moral duties toward them will resemble our present obligations toward each other: to not act in ways that could harm those people or their fundamental interests is a moral responsibility. It is ethically imperative that one should always live and behave in a way that maximizes harmonious existence in the present as well as in the future. In other words, our human behavior at present must take into account the concerns of the future generations which become an investment in the future.

Chapter 74
Understanding Glacial Retreat in the Indian Himalaya: Historical Trends and Field Studies From a Large Glacier

Rajesh Kumar
Sharda University, India

Prakash Rao
Symbiosis International University, India

G. Areendran
WWF, India

ABSTRACT

One of the most important and visible indicators of global climate change is the recession of glaciers in many parts of the world. The findings of the IPCC Assessment Report (2007) suggest that there has been a significant decline in mountain glaciers and snow cover, which has contributed to the increased sea levels and water flow changes in river basins. In the latter half of 20th century, an increase in the rate of retreat has been observed in Himalayan Glaciers since advent of industrialization. The paper attempts to present a critical review and understanding of the recent changes in retreat of selected Himalayan glaciers from potential climate change. The study explores scientific evidence and analysis of observed data from a large and a small glacier in the Indian Himalaya. This will help in understanding the vulnerability of retreat of the glaciers based on their size. The larger glaciers are unlikely to disappear in the near future, due to its large mass balance and large response time due to climatic changes. Future adaptation needs, research and action for downstream communities, ecosystems and impacts on power sector are discussed.

INTRODUCTION

The Cryosphere plays a major role in the Earth's climate system by impacting on the surface energy budget, the water cycle, sea level etc. and has control on the physical, biological and social environment over a major portion on the Earth. The cryosphere is most sensitive to temperature change hence capable of providing the most visible signatures of climate change. There are many indicators of climate change like changes in surface temperature, precipitation, extreme weather events, glaciers, ocean and land ice and sea level. Icesheets and glaciers changes are closely related with the global sea level changes impacting the global ocean circulation and marine ecosystems. The warming trend has been reported in the vertical profiles of temperature measured through the entire thickness of mountain glaciers, or through ice sheets climate over recent decades (Lüthi and Funk, 2001; Hoelzle *et al*., 2011). The loss of glaciers and snow cover near populated areas have direct impacts on the livelihood of the local communities in terms of water resources for drinking, agriculture, hydropower etc.

Over the last few decades, changes in climate and local weather conditions have impacted the world's glaciers both in terms of structure and characteristics, reflected in the form of advancement or retreat of glacial snouts (IPCC, 2007; UNEP, 2007). The changes in the length, width, area, volume and mass balance of the glaciers are among the most directly visible signals of global warming and these changes are the primary reasons why glacial observations have been used for climate system monitoring for many years (Haeberli, 1990; Wood, 1990), especially in areas where time series data on climate (mainly temperature and precipitation) is difficult to get and where climate change signals are not yet clear (Yadav et al., 2004; Roy and Balling, 2005). Thirty reference glaciers that have been studied in detail since 1975 show an average annual mass loss of 0.58 metres (m) water equivalent in the past decade, which is four times the rate for the period 1976-85 (UNEP, 2007).The IPCC, 2013 report (The physical science basis) clearly reflects the warming trend on the planet and state that "The last three decades has been successively warmer at the Earth's surface than any preceding decade since 1850 while in the Northern Hemisphere, 1983–2012 was likely the warmest 30-year period of the last 1400 years (medium confidence)". Unnatural rates of glacial melting, related to the changing climate, can have serious implications on the hydrology of the associated river systems and consequently on the livelihoods of millions of people who are dependent on these rivers and their ecosystems.(Stern,2007). Overexploitation of water resources and changes in hydrological cycle could be vital to future developmental strategies of the fertile belt of Northern India where agricultural productivity, irrigation etc.is to a large extent dependent on availability of freshwater resources (Mall et al, 2006).

The right approach, thus, in addressing these impacts is to have a better scientific understanding through long-term observations and analysis of the interactions of the different components of the mountain ecosystems with their climate. Then the lager data can be helpful in predicting the future scenarios and utilizing the information to formulate effective adaptation and management strategies. There is also a pressing need for disaster management and rehabilitation policies in areas affected by the glacial retreat, particularly focusing on agriculture, meadows and other livelihood support structures of the local people.

A growing body of scientific knowledge solidly indicates that carbon concentrations are changing the global climate and that there would still be significant changes to the global climate even if emissions would drastically reduce and fall to zero. The world is anticipating a 2°C warming above the pre-industrial level, and this will result in some unavoidable changes, the effects of which need to be understood, especially in fragile and endangered ecosystems. Generating a deeper understanding of the climate impacts on critical indicators such as glaciers are needed as there is inadequate documented scientific evidence

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

within India on the impact of climate change on the Himalayan ecosystems. This would help in developing regional climate projection models which are more accurate in providing information on future impacts. The recent observation of IPCC (2013) reveals that the globally average temperature show a warming of 0.85 (0.65 to 1.06)°C, over the period 1880 to 2012 as calculated on linear trend basis.

Glacial Retreat in the Himalayas

In the Himalayan region, glaciers and snow cover have been thinning since the end of 19th century in line with the global trends. With significant snout fluctuations, most of the glaciers in the Himalayan mountain ranges have been retreating and their rate of retreat is much faster than that of glaciers in other parts of the world (Cruz et al., 2007). These changes correspond to the rising surface temperature trends in the Himalayas which have been reported to be higher than the global average warming (UNESCO, 2007; Jianchu et al., 2007; Barnett et al., 2005). A study of the temperature trends in the North West Himalayan region (Bhutiyani et al., 2007) shows that a significant warming of 1.6°C has occurred over the last century with warming in winter taking place at a faster rate, with the highest warming rates recorded in the period 1991 -2002. Apart from warming, other factors like high human population density near these glaciers, deforestation and land use changes have also been responsible for the decline and shrinkage of glaciers (Cruz et al., 2007). At current rates of retreat, the smaller valley type glaciers are more likely to decline at a faster rate in the future, with uncertain impacts on the downstream areas.

The dynamics of a glacier are influenced by climatic factors including temperature, precipitation, amount of snowfall and wind. However, establishing firm linkages between climatic variability due to anthropogenic factors and glacier retreat requires long-term studies and monitoring. Mass balance and glacier snout monitoring have been important methods for the assessment of the volumetric and geometric changes in the glaciers brought about by advancement or recession (Dobhal et al., 2007).

In India, although high mountain glaciers occur across all the Himalayan range states of Jammu and Kashmir, Himachal Pradesh, Uttarakhand, Sikkim and Arunachal Pradesh, although only a few have been studied for long term monitoring or documented in terms of glacial retreat. Recent studies from 466 glaciers of the Indian Himalayas indicate that there has been a 21% reduction in the glaciered area from 2,077 square kilometers (sq km) in 1962 to 1,628 sq km in 2004 (Kulkarni et al., 2007). Smaller glaciers of less than one sq km have reduced in area by as much as 38% compared to a 12% retreat of the larger glaciers.

In the Indian Himalayas, studies on snout recession/mass balance measurements have been carried out on a few glaciers and some studies have been able to generate long-term monitoring data (Dobhal et al., 2007; Kumar et al., 2007; Wagnon et al, 2007). Studies by various institutions on the changing characteristics of glaciers in the Himalayas are limited (see box: Studies on some important glaciers in the Himalayas), generating an important debate on the role of climate change in the extent of glacier loss (Raina, 2009).

These glaciers have left behind imprints of their unnatural retreat, which is in tandem with the discrete but well defined phases of global warming. The melting process has two key adverse impacts on the environment. One is the loss in the reserve of freshwater and the other is a significant rise in sea levels (Kaser et al., 2006).

While the global view (IPCC, 2007) suggests that a large percentage of glaciers are declining worldwide, there are conflicting views also on the rate of retreat in the era of industrialization. Some

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

studies suggest that a few glaciers in the Himalayas may be showing reduced retreat patterns or actually increasing. e.g., the reduction in the retreat rate of Gangotri Glacier for 2004-05 (Kumar et al., 2007).

STUDY AREA

The Gangotri glacier, is one of the largest mass of ice and snow in the western Himalayan region of India and is located in District Uttarkashi in the state of Uttarakhand in India (Figure 1-2). The location derives considerable religious significance as an important sacred site as a source of the river Ganga which flows through several North Indian states before flowing into the Bay of Bengal. As such the region and the shrine at Gangotri, attracts thousands of pilgrims every year. The glacier along with other tributary glaciers (Figure 3) is a vital source of freshwater water supply, for much of the northern plains which has a large human population living downstream. The water discharge from the glacier flows initially as the river Bhagirathi before meeting the Alaknanda river at the confluence at Devprayag to form the river Ganga. Snow and glacial melt water contribute nearly 29% to the annual flows of the Ganga (up to Devprayag) and hence potential impacts on these glaciers due to various factors are likely to affect this large river system (Singh et al., 2009).

The north-west facing glacier is a typical valley type glacier originating in the Chaukhamba group of peaks in the Himalaya. Other smaller glaciers act as tributaries and join the main stem of the glacier to form the larger Gangotri group of glaciers. Including the tributaries, this covers an area of 210.60 sq. km(ETM+1999). The area and length of the main trunk of the glacier is 56.59 sq. km and 29.13 km respectively. The average width of the glacier is 1.85 km. The glacier, lies between 79°4' 46.13" E-79°16' 9.45" E and 30°43'47.00" N-30°55' 51.05" N (ETM+1999) with elevation ranging from 4,015–6,145 meters above sea level (SRTM data analysis).

The snout of the glacier occurs at an altitude of about 3,949 m above sea level, and from where the Bhagirathi originates (GPS observation, 2008). The snout position (2008) is at 73º4' 47.26" E and30º55' 36.45" N. Table 1 provides an overview of the characteristics of the glacier system.

Gangotri Glacier Retreat: A Historical Perspective

As one of the largest known glaciers in the Indian Himalayas, the Gangotri glacier often evokes considerable interest among glaciologists, geologists, water resource specialists, and mountaineers. It is said that the region has been frequented for at least hundred years by various groups in trying to understand the glacial system and process including reasons for retreat. Several workers have carried field studies on the snout and other sites on the glacier which has been receding since the last 'Little Ice Age', which ended in the 19th century. Interestingly, many of the tributary glaciers which source the river Ganga have also reduced with a few even being separated from the main trunk of the glacier. According to Srivastava (2001), this is evident by systematic studies since 1935 on the movement of the glacier snout, and by the presence of recessional evidences features such as terminal and lateral moraines. In the past century, the retreat rate of the glacier has shown a rising trend. It has been observed by glaciologists that the snout of the Gangotri glacier has retreated by about two km in the last 100 years. Both the snout retreat and area vacated by the Gangotri glacier has been documented by several scientists (see Table 2).

Local Climate Conditions Around the Gangotri Glacier

The combination of high altitude temperature and precipitation along with other climate factors like wind chill, humidity etc. often plays a key role in development of the state of glaciers and their associated hydrological features with impacts on water flow in the downstream region. Meteorological analysis of long-term data becomes a fundamental aspect in determining the structural changes taking place in glaciers. Various scientific institutions have been studying the Gangotri glacier for the past few years and have collected extensive data on the meteorological parameters (rainfall and temperature) through standard meteorological observatories installed near the glacier snout.

Rainfall

Precipitation is an important element in the evolution of a glacier worldwide and with reference to Gangotri past data suggests that the much of the region around Gangotri landscape receives less than 15 mm of daily rainfall during the summer season (Singh et al., 2005). A few exceptions in precipitation days in the form of extreme weather events like snow storms also occur. When studying precipitation trends on glaciers, it is noticed that August and September usually receive higher rainfall as compared to the other months. This is a continuous trend and even in recent years (2008-90 one can see higher precipitation patterns in those months from data obtained from weather stations installed at Bhojwasa. It has also been found that early morning and late evening are the most probable times for the occurrence of rainfall (Singh *et al*., 2005).

Temperature

Temperature in the ablation season increases for a few months after which it starts decreasing. July has been found to be the warmest month on the basis of the mean-maximum and minimum temperatures. Daily variations in temperature show that the maximum temperature is observed around 1400 hours, while the minimum is observed in the early morning hours (Singh *et al*., 2005). Changes in minimum

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

temperature have been seen to be more significant than those in the maximum temperature. It has also been found that the 'maximum diurnal temperature range' occurs in May and October while August shows the least variation in temperature range. This is probably due to the presence of a cloud cover during the rainy season.

Hydrology

The major sources of runoff at Gangotri are melting snow and ice. As a general assumption, since this area receives low rainfall, there is unlikely to be a heavy runoff from the region. Stream flow at the Gangotri glacier shows a wide variation depending on various factors. Early on and towards the end of the ablation season, day and night time flow volume show little variation ; however as the peak melting time approaches during the day, there is a comparative reduction in the nighttime flow. Despite this,it is also also observed that there is a continuous but low water flow pattern even when night temperatures are lower than normal. For large glacier this is a reflection of strong meltwater storage characteristics. Monthly variation of flow shows that the discharge starts rising from May and maintains a high flow during June to August with maximum average discharge in August. The discharge starts reducing from September onwards. Singh *et al.*, (2006) have also reported similar results in the discharge flows from the glacier.

METHODOLOGY

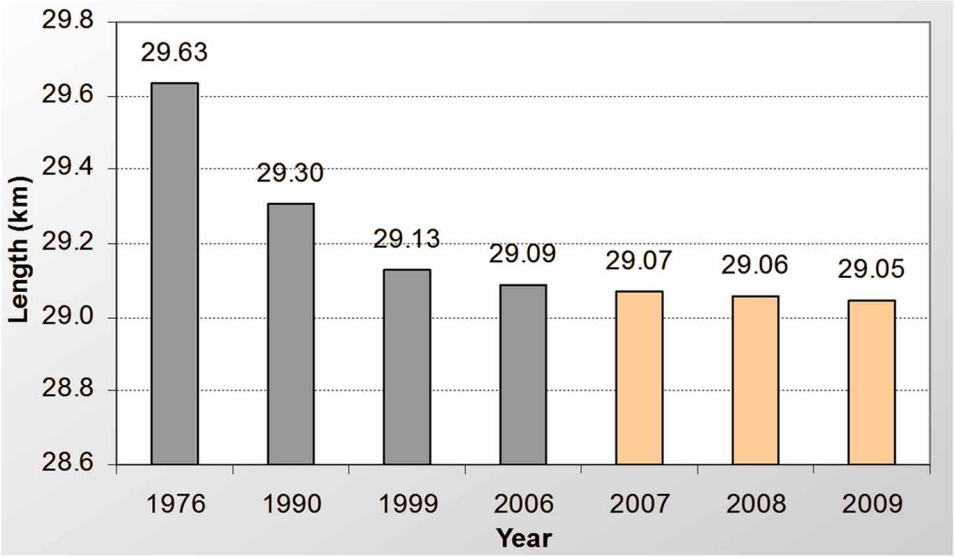
Field studies at Gangotri glacier for monitoring local climate and hydrological conditions involved using primary field data through the use of i) Differential Global Positioning System (DGPS) for assessment of snout positions at different time periods and ii) use of Remote Sensing satellite imagery along with iii) existing secondary data from earlier studies. DGPS measurements have been extensively used for locating the snout position in glaciological studies including at Gangotri during various field visits starting from 2006. While the task of long term data collections and observations is often tedious, due to inconsistency and access to field sites due to inclement weather conditions, it still remains an important factor for accuracy in any glacial research. In this context, it is important to note that due to variability in local climate, the snout position is quite dynamic and inter-seasonal changes are seen in the exact position of the snout. Primary data was collected on snout position during the months of September and October since 2006. This was supplemented by meteorological and local climate data through an automatic weather station (AWS) installed at Bhojwasa near the snout of the glacier. Apart from the glacial and meteorological monitoring, data was collected about the discharge patterns of the glacial meltwater. Remote sensing data was collected using satellite imageries of 1976, 1990, 1999 and 2006 by delineating the glacier boundary using ERDAS 9.0 and auto calculating the area using GIS methodology.

RESULTS AND DISCUSSION

A comparative analysis of the glacier's snout position was carried out using data from secondary sources and interpretations from various satellite imageries over the past three decades. Satellite imageries available since 1976 formed the baseline for the analysis of the fluctuations in snout position together with

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Length of Gangotri glacier in different years



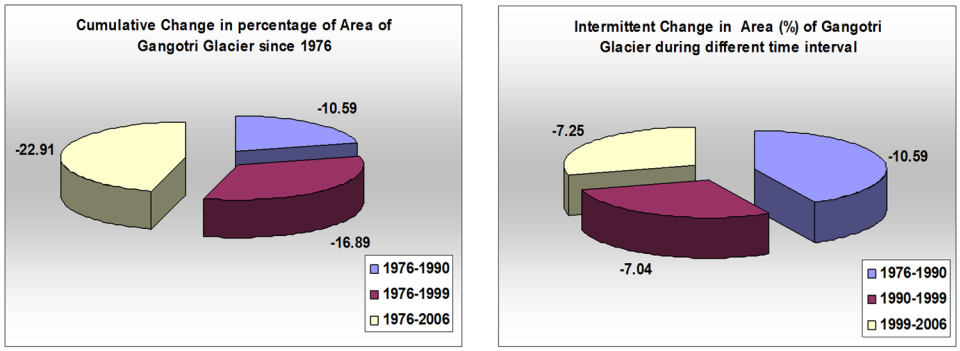
DGPS observations since 2006. A study of data from available sources suggests that the main trunk of the Gangotri glacier has been in a continuous state of recession and fragmentation during the past century. The length of the glacier has been computed for different years based on available data from various scientific agencies and workers. These trends show that the length of the glacier has reduced by about 0.59 km in 33 years, from 1976-2009, with an average retreat rate of 17.59 m/year (see Figure 4).

Based on the comparison of satellite imageries of the Gangotri glacier for the years 1976, 1990, 1999 and 2006, our analysis shows that the glacier is not only receding in length but also in terms of glaciated area from all the sides. The possible reasons behind this retreat may be linked with two main factors: (a) reduction in snowfall and (b) an increase in the temperature of the region. Cumulative analysis shows that between 1976 and 2006, the glacier area reduced by 15.5 sq.km, with an average loss of 0.51 sq.km per year. This reduction in glacier area is 22.9% over 1976 (see Figure 5). The glacier area reduced by 7.2 sq. km between 1976 and 1990, in fourteen years, with a 10.6% reduction in the glacial area. In nine years, between 1990 and 1999, the glacial area reduced by 4.3 sq.km and resulting in 7% reduction in area when compared to 1990. However, the rate has increased between 1999 and 2006, with glacial area reducing by 4.1 sq.km and a 7.25% reduction in area over 1999. This also indicates that in some years there is a reverse trend in the rate of retreat of the glacier as compared to preceding years. It is possible therefore that local climate conditions and fluctuations may be responsible for the reduced rate of retreat at different time intervals.

The calculation of the snout retreat using a DGPS based system involves assessment of point to point snout data that gives the straight line distance of the two points that may include the shift of the water outlet point (left/right) in the curvilinear shape of the larger snout. Traditional methods using a simple GPS methodology often assess the shift of the snout position in the glacier flow direction through measuring the perpendicular distance on the curvilinear shape of the snout. This measurement normally gives a lesser value if the snout point has moved either left or right rather than in the glacier flow direction as compared to the previous position.This can be critical since fluctuations are often noticed in the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. The cumulative and intermittent reduction in the area of Gangotri Glacier since 1976



snout positions for larger glaciers which have a significantly large area. Based on this measurement, we observed that the snout retreat during 2006-07 was 17.85 m when compared to snout position of 2006. In the subsequent years, the retreat rate has reduced 13.06 m in 2007-08 and 10.57 m in 2008-09. It can be inferred that retreat of the glacier between 2007 and 2009, is lower than the long term average. More importantly, while there is an overall average retreat noticed, fragmentation of the Gangotri glacier is likely to be of larger concern in the context of reduced water flows of the glacial system in the long term. The retreat of the Gangotri Glacier snout is shown by overlaying the glacier boundary on the Enhanced Thematic Mapper (ETM$^+$) 1999 imagery (see Figure 6).

Hydro-Meteorological Trends

Assessment of summer season discharge data at the snout in the past few years indicates that there are variations on a diurnal and monthly basis. Flows recorded at different times of the day were found to be highest during the evening hours (1700 hours) while discharge rates are lowest during the morning hours (see Figure 7). These results also corroborate earlier findings by Singh *et al*.,(2006) where high diurnal fluctuations in discharge rates during daytime and low rates at Bhojwasa were observed.

With the commencement of the summer season, increased water discharge reaches a peak during July and August due to the combined impact of more melting of ice, which is driven by higher average temperatures and rainfall in the catchments. The discharge starts reducing in September and reaches a very low level throughout the accumulation season. During winters, the flow is reduced and keeps almost at a constant value. The combined impact of low winter temperature (subzero) and higher albedo (90-95% for fresh snow) reduces the winter discharge rate to quite a low level.

The daily average temperature and average discharge for the ablation and accumulation season at Bhojwasa (Figure 8), is indicative of a positive correlation of 0.73 between the average temperature and average discharge during the ablation season. However, these parameters are negatively correlation (0.46) in the accumulation season, which shows a lower influence of temperature on melting because most of the solar radiation is reflected back to the atmosphere due to the snow covered valley that has a high albedo effect. The preliminary trends observed during the study in 2008 seemed to suggest that the volume of discharge and flow patterns is also being influenced by the temperature variations in the valley. This is in consonance with results obtained by other studies (Singh *et al*., 2006) over the past decade. However, it may be mentioned here that large glaciers like Gangotri need to be closely monitored for water discharge during both ablation and accumulation season and only long term trends can suggest any significant variations in retreat patterns. For smaller glaciers, which do not have a clearly

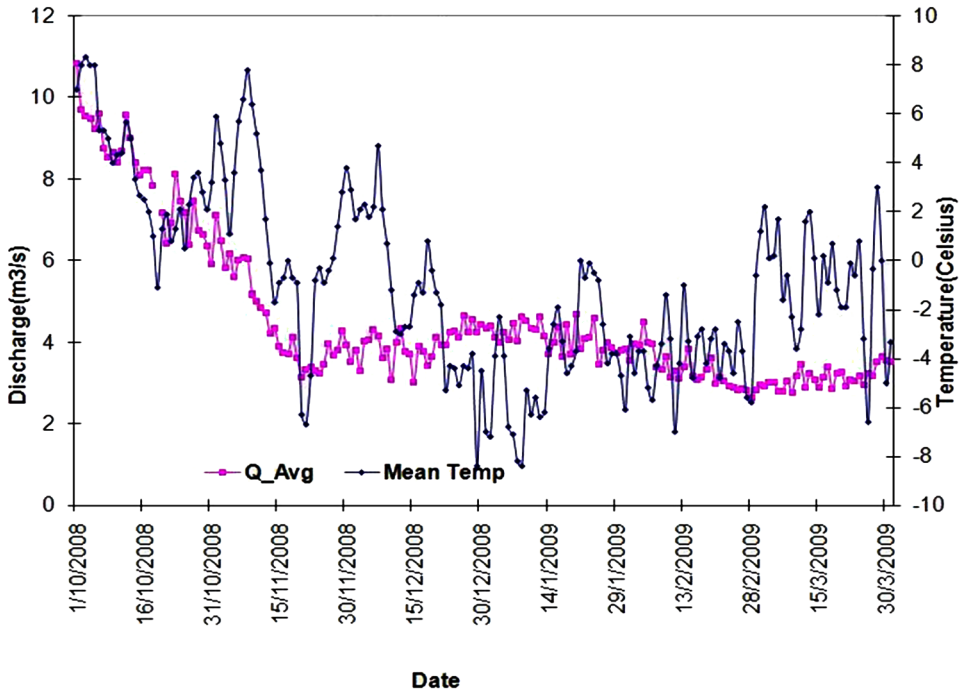
Figure 8. Average temperature and discharge during winter 2008-09 at Bhojwasa, Gangotri



**For a more accurate representation see the electronic version.*

demarcated ablation and accumulation zone, retreat rates may need to be monitored critically. While these results are specific to the snout at Gangotri, comparisons with similar studies indicate a consistent pattern in the rate of discharge and temperature increase for the region.

With regard the impact of mid-day temperature on evening discharge in the glaciated basin, a positive correlation of 0.63 between the 1200 hours temperature and the 1700 hours discharge at Bhojwasa (see Figure 9) is noticed. However, during October the discharge rate declines as the average temperature starts reducing (see Figure 9).

Trends in the Gangotri region (see Figure 9) reflect that temperatures start reducing from September. The maximum temperature reaches up to 18° C in June and July and remains mostly around 14°C during May to August. The early morning temperature (0800 hours) remains at around 9° C till August and falls to zero in mid-September. As winter advances, the intraday temperatures in December also show a variation with morning temperature at sub-zero levels and moving down to - 15°C. During peak winter months, the morning and evening temperature is subzero while noon temperatures may be above 0° C. During March, the morning temperature remains below zero, while the noon and evening temperature varies around 5°C .

CONCLUSION

The entire Himalayan region is known to have the largest concentration of glaciers in the world excluding the polar region. According to the WWF, the region is called the “Water Towers of Asia” as it

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

provides around nearly 86,000,000 cubic meters of water annually. These Himalayan glaciers feed seven of Asia's great rivers, namely the Ganga, Indus, Brahmaputra, Salween, Mekong, Yangtze and Huang Ho(WWF,2005).The current study has attempted to provide an understanding of the characteristics of large glacier like Gangotri, in the context of melting patterns and local hydrometeorological conditions. We also believe that the science of climate change is complex particularly while monitoring glaciated basins but also in studying large vs smaller glaciers. In long term, temperature variations may obviously be a key aspect to changes taking place in a glacier, but impacts of other climate/non climate stressors like local variability in monsoon, developmental concerns, industrial growth, tourism etc. may also play an equally critical role.

From a basin perspective, a combination of climate variability and non-climate stressors will have serious consequences for the freshwater ecosystems of the Ganga basin with long term impacts for eco-system, livelihoods, agricultural and industry in the catchment of the basin. As the Gangetic plains are considered a major food basket to the economy of the northern Indian plains, changes in environmental flows along the basin ecosystem may also affect region's agricultural productivity and industrial activity, but also have consequent impacts on future economic growth in terms of Gross Domestic Product (GDP). In a carbon constrained world, where greenhouse gas emissions are rising, beyond the level considered unsustainable, the economic costs of taking mitigation actions on limiting climate impacts now, would have far lesser implications than if actions were to be taken at a later stage. (Stern, 2007).

Larger vs. Smaller Glaciers

Field studies indicate that larger glaciers like Gangotri which occur a vast area are unlikely to show major declines in the near future, due to its relatively large mass balance. Although this study did not take into account changes occurring in a smaller valley type glaciers in the region, it may be worthwhile to mention that smaller glaciers with low mass balance and ice volume are likely to retreat at a faster rate. This could lead to increased losses in glaciated portion as well as their tributary glaciers,(see Figure 3) a trend which has been observed across the Himalayas for many other smaller glaciers (Dobhal *et al*, 2004). Regional climatic variations could threaten the fragile nature of these glaciers which are likely to disappear at a much faster rate or be considerably reduced in length as compared to the larger ice bodies. These glaciers are perhaps more vulnerable to local climate variations and hence long term and continuous assessment is required to monitor the hydro-meteorological parameters existing in their vicinity to develop predictive models for future water resource scenarios.

Larger glaciers like Gangotri show a continuous recessionary trend in recent years through this and other studies (Singh *et a*l., 2006). However, at present this trend may have a limited influence on the water flows downstream primarily due to the large extent of the glaciered area. The movement of larger glaciers is dynamic and snout retreat is a delayed response, but the fragmentation of the larger glaciers needs to be continuously monitored.

The Climate Change Angle

There is limited consensus and considerable degree of variations in studies on glaciers as reported amongst the scientific community and policy makers on the true extent of Himalayan glaciers retreating due to impacts of global climate change,(IPCC,2007,Raina,2009). The results of this study is a pointer to the fact that regional climatic variations along with changes in social and economic dimensions may also play a critical role in the behavior of these glaciers. Local communities living closer to Gangotri have indicated changes in snowfall levels in the winter months resulting in less soil moisture, which in turn is changing cropping patterns and availability of water.

Though glacial retreat is a natural phenomenon with the earth moving towards a warming phase, the accelerated rate of retreat could result from a combination of other impact factors also. Based on our study and past scientific data, it is clear that climate change has a visible impact on the status and condition of some of the glaciers as is evident through the increase in the net loss of ice mass year after year. Hence, it becomes difficult to predict the glacier retreat or advance scenarios with confidence. It is worthwhile to note that the phenomenon of global warming and climate change will impact not only temperature but also the other variables like intensity and quantity of precipitation, cloud cover, wind and radiation. The influence of other climate factors and stressors like precipitation, flooding and extreme weather events in the Himalayan region is well documented (Bhutiyani et al 2007, Raina, 2009, Mall, *et al*, 2006). However despite this the characteristics and nature of the Himalayan ecosystem and monsoonal effects remains less understood.

Since region specific climate models are limited, a long term monitoring of meteorological parameters is crucial before arriving at definitive conclusion regarding the impact of climate change.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Non-Climatic Stressors

Non-climatic stressors, such as rapid economic growth, including tourism and infrastructure development for industries like construction, large hydropower etc., are increasing pressure on the fragile Himalayan ecosystem. Unplanned development has already resulted in severe pressures on both local ecology and communities. The impacts of climate change and changes in climate variability would further create additional stress. This is exemplified by instances of extreme weather event in the region in the form of landslides, cloudburst, flooding etc. which has affected not only local communities, biodiversity but also industry. The decline in glacial area and variations in annual runoff patterns in the future gains importance in the context of hydro power planning and development of the Himalayan states. We propose that future studies should also focus on the impact of regional climate variables together with non- climatic stressors like local pollutants, changing urbanization trends, tourism etc. Implementing the Mission on Himalayan Ecosystem as part of the National Action Plan on Climate Change (NAPCC) of the Government of India would therefore be a key priority.

Way Forward

Continuing pursuits in scientific excellence has resulted in critical evidence of changes in the glaciers of the Himalayas by many workers, but probably not very accurately as there is inadequate record of organized, systematic and long term observed data monitoring. However, integrating the growing body of anecdotal evidence, observations of the local communities, policy directions along with the recent initiatives of the UNFCCC may provide the impetus to focusing on glaciological studies in the Himalayas.

The dynamics of the monsoon are influenced by Himalayan systems which act as a reservoir to sustaining agriculture, providing freshwater and groundwater recharge, and are home to a unique ecosystem with many endemic species (WWF, 2009). With the Himalayan region transcending geographical barriers glacier based studies may requires not just local action but also trans-boundary cooperative arrangements.

Future efforts in building the resilience of the local community and the ecosystems should take into account a concerted and integrated approach through local, regional and national policy. There is an urgent need by communities, scientists, industry groups and policymakers to take a closer look at the linkages between local impacts, scientific research, policy interventions and the larger understanding of using resource conservation technologies and practices for promoting societal benefits.

ACKNOWLEDGMENT

This study was conducted as part of a joint initiative between World Wide Fund for Nature (WWF) – India and the Birla Institute of Technology, Extension Centre (BITEC) and supported financially by WWF Netherlands as part of the Regional Programme on Himalayan glaciers. We are grateful to Mr. Ravi Singh, Secretary General & CEO, WWF- India and Dr. Sejal Worah, Programme Director, WWF- India for their kind encouragement and support for this study. Director, BITEC, Jaipur is acknowledged for support and facilities provided to carry out the field research. We gratefully acknowledge the contribution of several field assistants who provided the much needed logistical support at high altitude at Gangotri in difficult conditions for data collection and analysis.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

We thank Dr Pratap Singh and Ms Esther Blom, reviewers for providing objective inputs and suggestions to this study. We are thankful to the support and cooperation provided by the staff of Gangotri National park and the Forest Department, Government of Uttarakhand during the course of this study.

Chapter 75
Segmenting Paddy Farmer's Attitude and Behavior:
A Study Towards the Green Fertilizer Technology Adoption Among Malaysian Paddy Farmers – Adoption of GFT

Nadia Adnan

ABSTRACT

Agriculture is the major driving force of Malaysian economic. The aim of this research study is to segment the behavior of paddy farmers in Malaysia and understand how they influence adoption, a green fertilizer technology (GFT). The first objective of this chapter is to establish the thinking which enables a society to bridge the gap between embracing GFT among paddy farmer in Malaysia. Furthermore, the study builds the conceptual framework and examine the relationship among the relevant construct of this conceptual framework which was found by critically examining the different agricultural innovation literature. To make this conceptual framework robust it is found in the literature that theory of planned behavior and theory of reasoned action play a major role in segment farmer's behavior towards the adoption of GFT. Policy implications and/or suggestions for future research are deliberated for each issue and factor that affecting the adoption of GFT.

INTRODUCTION

The market of the 21st century is a giant network, which covers the whole globe. The market is divided into hundreds of domestic markets and international markets. There are thousands of organizations and millions of consumers, a wide range of products and services to be offered. A great skill is needed to be able to manage these markets. The marketing science studies show markets from bottom to top, develops techniques in managing consumers, competitors, partners, dealing with products and advertising strategies. Every single company has a marketing strategy. It might be well-structured or not thought through at all, but yet there is one in every company. One of the first steps on the way to a marketing strategy is completing market segmentation. Nowadays it is very important for a company to have a crystal clear understanding of its marketing strategy. Any attempts in doing marketing and product positioning won't work as they should unless a company has an understanding of its clients and develops a marketing strategy.

Market segmentation is one of the most basic and essential parts of developing a marketing strategy. During the past hundred years, the market has grown enormously: there are lots of new products and consumers' needs getting more and more twisted and complicated over time. Technology and innovations encourage farmers' wants and companies' imagination, which is why markets become more complicated. With continuous growth and development of different market segments, it is important for a company to have a deep knowledge of consumers and markets. This study concentrates on market research, specifically on market segmentation: what kind of information and advantages can be gained out of market segmentation. The purpose of this study is to provide to exemplifying that how market segmentation can determine the right target (paddy farmers) farmers for GFT which is name as One BAJA.

In the beginning of the study, the researcher will explain the segmentation process of marketing and after that, it will follow by the analysis as per the questionnaire led and using respectively the Minerva model and the Mosaic model. In the first part of the study, the market segmentation process will be defined later the different types of market segmentation and the variables will explain. These types are significant when identifying the right target customer's farmers to a product (One BAJA). There are four major types of segmentation first is the demographic segmentation, which is considered the most shared one that deals with basic demographic factors such as age, income, gender etc. and divides the target farmers into segments based on these variables. Whereas, the geographic segmentation divides the target farmers into segments based on geographical areas such as nations, regions, cities, etc. The psychographic segmentation divides the farmers into segments according to their values and lifestyle. Finally, the behavioral segmentation divides the target customer farmers into segments based on their attitude toward product.

On the basis of the description of the types, it will be concluded which of the types are best suited when identifying the target farmers of respectively the landline telephone and the mobile telephone, in this case, being the demographic and the behavioral segmentation. The second step for (One BAJA) team is the segmentation process which is a matter of right target marketing. After identifying the target customers (farmers), the fertilizer company essentially chooses which segment to target. Subsequently the fertilizer company then must decide which market strategy to choose i.e. undifferentiated marketing, where the fertilizer company does not consider differences between the segments and targets the market with one offer, differentiated marketing, where the company targets many market segments with offers specially designed for each segment or concentrated marketing, where the fertilizer company chooses one or few markets. Furthermore, the third and final step of the segmentation process is the matter of right positioning.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The fertilizer company (One BAJA) will have identified and evaluated the target customer it is then essential to choose what position the (One BAJA) wants to occupy in the chosen segments. In order for the One BAJA to achieve a successful positioning i.e. when the (farmers) find that the product satisfies their expectations and desires, there are steps the (One BAJA) must follow. These include amongst others; the fertilizer company (One Baja) must understand what the farmers expect and believe to be most important when deciding on a purchase, the fertilizer company (One Baja) must develop a product which caters specifically for the farmers' needs and expectations different analysis.

LITERATURE REVIEW

Segmentation

Segmentation involves finding out what kinds of consumers with different needs exist. In the auto market, for example, some consumers demand speed and performance, while others are much more concerned about roominess and safety (Kotler, 2012). In general, it holds true that "You can't be all things to all people," and experience has demonstrated that firms that specialize in meeting the needs of one group of consumers over another tend to be more profitable (Adnan, Nordin, & Redza, 2017). Whereas, Figure 1 states the different level of segmentation. However, in the line of this research our target consumer is paddy farmers in Malaysia.

Why Segmentation?

When it comes to marketing strategies, most people spontaneously think about the 4P (Product, Price, Place, Promotion) –maybe extended by three more Ps for marketing services (People, Processes, Physical Evidence) (Kotler, 2012; Kotler, Armstrong, Saunders, & Wong, 2003). Market segmentation and the identification of the target market are an important element of each marketing strategy? They are the basis for determining, any particular marketing mix (Kotler, 2012; Kotler et al., 2003). Literature of (Kotler, 2012; McDonald & Wilson, 2011) suggested that. Whereas, Figure 2 depicts the marketing segmentation process.

MAIN FOCUS OF THE CHAPTER

Segmentation and Marketing Planning

One of the essential issues in the marketing strategy of a company is marketing research. Marketing research gathers information about markets which concern the company as well as its potential farmers / current farmers (Wittman, Beckie, & Hergesheimer, 2012). The overall purpose is to get a clear picture of what is a current market, which market segments are related to a company, what are their needs and wants (Kotler, 2012). An outcome of a marketing research is a development of a strategy or improvements to it for reaching out to those market segments and satisfying their needs, or a strategy for a marketing company's specific product (McDonald & Wilson, 2011). Kristoferson and Bokalders

(2013) marketing research consists of information about actual and potential farmers, needs, products, technologies, and competitors.

To collect information about markets, either primary or secondary sources should be used in different type of marketing strategies. Furthermore, (Armstrong, Adam, Denize, & Kotler, 2014; McDonald & Wilson, 2011) highlighted the point that marketing research consists of information about actual and potential farmers, needs, products, technologies, and competitors. To collect information about markets, either primary or secondary sources should be used. Usually, it is way easier and faster to collect information from secondary sources, which are: published articles in journals, newspapers, commercially published market researchers, government statistics, yearbooks, Internet, and other published materials. Primary sources are the ones which are collected from the original source: with the help of questionnaires, interviews, experiments or product tests with consumers.

A combined way of the research process is quite often used by companies – when there is not enough information from secondary sources, information is collected directly from primary sources (Sacks et al., 1996). There are several types of marketing research that are carried out by marketers:

- Customer research
- Promotion research
- Distribution research
- Sales research
- Marketing environment research

THEORY OF MARKET SEGMENTATION

It all started from early economic theory, where it was discovered that demand is connected to the level of competition and pricing (McDonald, 2012). Based on the article of Croft (1994) "The international consumer market segmentation managerial decision process", lots of information about the theory of market segmentation were discovered. The market segmentation concept itself has its roots starting from the 1930s when Chamberlin and Robinson proposed their theories of imperfect competition. Only in 1950s marketing writer Wendell Smith stated his point that the recognition of diversity or heterogeneity in demand and supply proposed the existence of two quite different marketing strategies, which are in use even in our modern world– product differentiation and market segmentation.

Market Segmentation

The market segmentation is mentioned as being one of the key elements of modern marketing and is, as mentioned, the process of dividing the market into several groups and/or segment(s) based on factors such as demographic, geographic, psychological and behavioral factors. By doing so the marketers will have a better understanding of their target audience and thereby make their marketing more effective (Furnham & Gunter, 2015). This is due to the fact that by using the analytical process that puts farmers first, the marketer will get more satisfied farmers and thereby gain a great advantage over competitors (Kotler, 2012). There are four levels defined by (Kotler, 2012; Kotler & Caslione, 2009) are segments, niches, local areas, and individuals. Therefore, the following marketing strategies arise segment market-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing, niche marketing, local marketing and individual marketing, as well as mass marketing (Croft, 1994). Furthermore, in the line of this study, we segment the fertilizer industry in Malaysia.

- Mass marketing's advantage is that it has the biggest potential market, however, it becomes more difficult to practice mass marketing over time due to a huge range of products offered to consumers.
- Segment marketing isolates the broad market and adapts so that products match one or a few sectors' needs. Segment marketing's benefits are more efficient marketing and communications in terms of reaching out to consumers. It allows the company to create a more segment-adjusted product and price according to its audience. Also the ways of communicating to consumers and distributing products become easier.
- Niche marketing focuses on subgroups within segments of the market; the company knows its clients so well that it is able to offer very specific products to a consumer when other competitors cannot offer similar products. The client is ready to pay a premium price for that offer. Niche farmers usually have a very distinct set of wants and needs usually not satisfied. The niches of the market do not attract that many competitors due to their small size and specific expectations.
- Micromarketing is the practice of serving individual clients and their individual needs and wants, which goes beyond segment or niche marketing. Philip Kotler broadened this concept into a deeper one by dividing Micromarketing into local marketing and individual marketing.

MARKET SEGMENTATION BASES

According to M. Hutt and Speh (2012), two major categories for business to business market segmentation bases are a macro segmentation and micro-segmentation. Macro segmentation concentrates on the characteristics of an organization and its situation, such as size, geographic location, operating market, industry, etc. On the other hand, micro-segmentation requires a lot more detailed information and observations about companies, such as buying decision criteria, the importance of buying and attitudes within each macro segment defined. Philip Kotler and K. Keller ("Marketing Management", 2009 p. 355) on the other hand have their own vision on segmentation variables of business markets.

Even though it is pretty close to what has mentioned above, it just introduces a slightly different way of thinking. Kotler's and Keller's major segmentation variables are: demographic (industry, company size, location); operating variables (technology, user or nonuser status, customer capability); purchasing approaches (power structure, nature of existing relationships, general purchase policies, purchasing criteria); situational factors (urgency, specific application, size of order); personal characteristics (buyer-seller similarity, attitude towards risk, loyalty).Macro segmentation is a common choice of companies when doing market segmentation.

GEOGRAPHIC LOCATION

Geographic segmentation includes such variables as location, macro-economic factors, customer concentration, etc. It can be done by countries, states, towns or even continents such as,

- **Organization's Size:** The size of an organization can be measured by a few factors: the amount of employees or revenues. In different economies and different markets, there are different defini-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

tions for small to big companies, depending on the wealth of the economy, the size of the country and the size of the market.

- **Industry Classification:** Industry segmentation is a first one to do when dividing markets into groups. Moreover, it is one of the most complicated sub-variables due to a wide range of industries and sub-industries, and new ones appear with time and high technologies. One of complications related to industry segmentation is companies operating in many industries at the same time. Nowadays it is quite normal to operate in several industries and be successful in them.
- **Characteristics Relevant to the Organization:** In case a company finds some other factors related to the descriptive characteristics of its market, it can use those factors for the segmentation process. It can totally depend on the type of business, services and partnership history and other factors.
- **User/Nonuser Status:** It is important for a farming organization to know who its active users are, who are interested in its services and who are not. That will give useful insights on who was reached and who was not. Most of the companies keep track of their past activities and past results, that is where the information on segmentation upon user/nonuser can be received from.

IMPORTANCE AND BENEFITS OF MARKETING SEGMENTATION IN MALAYSIAN AGRI-INDUSTRY

Nowadays, the market segmentation concept is considered as a big and important part of marketing theory. Marketing is all about identifying and satisfying the needs of farmers, and the needs of possible farmers need to be identified as well as farmers need to be analysed. Market segmentation gives an agricultural industry a possibility to satisfy their farmers' needs in a smart way: to offer products

A STUDY ON AGRICULTURE INDUSTRY OF MALAYSIA

In history, Malaysia was an agricultural country, proceeding to its independence in 1957. The agriculture industry has been a backbone of the Malaysian economy (Hosseini & Wahid, 2013). Whereas, Dr. Mahathir Muhammad, the former prime minister of Malaysia with his Vision 2020, imagined Malaysia as an advanced industrialized country in the coming year of 2020 (Brooker,2012; Nagarajan, 2008). Furthermore, he mentioned in this vision that agriculture is the "sunset industry "for the nation (Bakar, 2009; Melchior, 2011). Moreover, agriculture remains an important part of the national budget in the new era for the gradually growing population with the challenge to deliver both food security and safety, and sustainable growth and wealth formation. As, (Ramli et al., 2013; M. Shaffril et al., 2010) describe the Malaysia's land area measures for agriculture is about 329,733 square km, most of the soil is acidic hence, infertile.

Additionally, the agriculture sector engaged as the backbone of the country's economy and had ominously contributed to the 11.6% GDP, till it remained outshined by contributions from the manufacturing sector as the country moves rapidly towards industrialization from the mid-1970's (Haris, Hamzah, Krauss, & Ismail, 2013). Therefore, the agriculture sector has persisted glumness previously, the government agencies focus on the manufacturing sector, but during the economic crisis in 1997, Malaysian

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

industrial sector faces the severe downfall. Whereas, in the agricultural industry has been proven as an effective medium to overcome self-sufficiency (Shaffril, Asmuni, & Ismail, 2010).

The country's agricultural sector has experienced various phases of transformation (Azadi, Ho, &Hasfiati, 2011). Now, after all, these phases of transformation, the agriculture sector contributes more to Gross Domestic product (GDP) increased from RM17.01 billion in 1995 to 18.22 billion in 2000 (8th Malaysian Plan). It also gained government attention in the 9th Malaysian Plan (2005-2010), agriculture is declared as the 3rd largest income generator for Malaysian. In the Malaysian agriculture sector, there are several commodities like palm oil, cocoa, livestock's fisheries and paddy. But, the government gives more emphasis more on the paddy industry because it is the basic good for the nation (FAO, 2012). Approximately, it is projected that around 300,000 farmers are involved in paddy cultivation (Moeskops et al., 2010).

Paddy is the staple food for more than three billion people all around the world. At least 114 countries grow rice and more than 50 have an annual production of 100,000 tonnes or more (Dastagiri, Gajula, & Patil; Edwards, 2015). Rice is the main food for most countries in Asia and, about 90% of the global rice area, production and consumption are concentrated on (Noppers, Keizer, Bolderdijk, & Steg, 2014). At this time, when the world's population is already reeling from higher food prices, many countries have already banned or restricted their rice exports, which pushes up the price of rice even higher (Edwards, 2015). Paddy yields have been increasing since the 1960s, but since the 1990s, the increase in rice production has been slower than population growth. Indeed, it is anticipated that rice production will need to increase by 30% by 2025 in order to cater for the world's growing population (Othman, 2012).

The current study is to look at Malaysia's paddy fertilizer sectors. Malaysia's paddy fertilizer sector is considered unique in several ways or elements. The government of Malaysia pays special attention to paddy farming. Therefore, the food crop has strategic value where rice is grown in both Peninsular and East Malaysia which is shown in Figure 3 (Haris, Hamzah, Krauss, & Ismail, 2013). About 300,500ha in peninsular Malaysia and 190,000 ha in East Malaysia are developed for rice production (Ahmad & Tahar, 2014).

There are eight granaries area in Malaysia named as MADA, Kedah, KADA, Kelantan, and Northwest Selangor project, SeberangPerai IADA, Penang, Perak and Ketara. IADA is the main paddy producer that meets seventy two percent (72%) of the demand of Malaysia stated by the Ministry of Agriculture and Agro-based Industry, (MARDI, 2010). Furthermore, it is predicted by the lawful agency that paddy will produce RM 988 million in 2010 (DOAStat, 2013). Nevertheless, if we relate paddy with other commodities of agriculture, there is still lot need to be done to strengthen paddy as the main agriculture sector in Malaysia. As per the report of (FAOstat, 2009a) the yearly production of rice stands at 2.51 million metric tons which is not sufficient. Stability of paddy plantation is essential in Malaysia as it is recognized as staple food for the majority of Malaysian.

Paddy is considered as important and essential food for both its citizen and the government, which is grown on 672,000 hectares (1.66 million acres) and the production is estimated at 3.66 metric tons per hectare which is not up to the consumption mark (Othman, 2012). Resolve this issue of low production with sustainable mean government has started providing all paddy farmers subsidized fertilizer since 1970 (Noh, 2012). On average, a Malaysian consumes around 300kg of rice per capita (FAOstat, 2012). There are many strategies to increase production in sustainable contexts. Recently, the government of Malaysia had allocated RM 100 million in the 2013 budget for the development and management of paddy industry including the subsidized fertilizer (Noh, 2013a). Furthermore, the government has taken various efforts to strengthen the paddy and rice industry like establishing many organizations.

Figure 3. Map of Peninsular Malaysia
Source:(Tey, 2013)

For instance, paddy marketing accountability was taken over by National paddy and rice board (NPRB) which was established in 1971. In the year of 1996, NPRB got privatized and changed to (Plan, 1996) PadiBerasNasionalBerhad, by having a mission to strengthen the paddy industry (Fahmi, Samah, & Abdullah, 2013). The Government's rigorous effort continues to be one of the big agendas. During the review (NinthMalaysianplans, 2006) 70% of 2.5 billion was allocated to national food security. But currently, the country produces only 60-65% of its requirement. It meets the remaining through imports, mostly from Thailand (Haris et al., 2013). Inasmuch, substantial progress has been made in the doubling of paddy production in the last 30 years (Grassini, Eskridge, & Cassman, 2013). However, there is still a need to increase the production to meet the need of the population without unsuitable practice (Adnan, Nordin, & Noor, 2017) It is mostly a farmer's effort that contributes in large measures to paddy production in the country. A multitude of factors could be relevant this disparity of production and sustainability (Nhamo, Rodenburg, Zenna, Makombe, &Luzi-Kihupi, 2014).

The paddy plantation needs to be cultivated by new ideas and methods. Farmers need to adopt One BAJA fertilizer to increase the production without damaging the environment. This contributes toward the sustainable environment (Unescap, 2011), because it increase the crop farm production system that avoids the use of synthetic fertilizers and pesticides, hormones, antibiotics and takes measures to protect

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the environment and increase the production (Othman, 2012). The annual growth rate of rice production from year 2000 to 2013 was about 1.47% and the production of rice increased from 2.14 million metric tons (MT) in 2000 to 2.63 million MT in 2013. However, the Self-Sufficiency Level (SSL) of rice in Malaysia was 70% in 2000, 72% in 2007 and it increased to 74% in 2013 (Lee, Kim, &Vohs, 2011). Consistent with the National Agriculture Policy (NAP), the Malaysian government wishes to escalate the SSL of paddy. The SSL of paddy production can be achieved by effective fertilizer application. Malaysia is a dynamic player as a consumer and producer of fertilizer. But most of the fertilizer used in Malaysia is produced out of the country. The total value of fertilizer imported into Malaysia has been on the rise from RM 1.47 billion in 2003 to RM 3.4 billion in 2007 and this has caused huge foreign exchange losses to the country (Nordin, Noor, & bin MdSaad, 2014). This indicates that there is a large market potential for locally produced fertilizers as import substitute as well as for local producers to move up the value chain.

To enhance the agriculture production and to get optimum plant growth, nutrients must be accessible in sufficient and balanced amount (Chen, 2006). Nevertheless, the traditional method of agricultural farming in which chemical-based fertilizers are heavily used has contributed to increased global warming and greenhouse effect. Moreover, increasing soil destruction and immense use of biochemical fertilizer, particularly the rice cultivation made the Malaysian government to introduce the 'National Green Technology Policy' (NGTP) in 2009. NGTP put emphasis on boosting and implementing the green technology in agriculture (Vlek& Byrnes, 1986).

GREEN FERTILIZER TECHNOLOGY DEVELOPMENT

The worldwide concerns about worsening environmental conditions necessitate the need for eco-friendly agriculture products (Hashim&Ho, 2011; Roopan et al., 2013). Green technology policy refers to the development and application of products, equipment, and systems used to converse the natural environment and resources which minimize and reduces the negative impact of human activities (Hashim&Ho, 2011; Roopan et al., 2013). The continual application of traditional fertilizers in Malaysian paddy production has been creating adverse environmental impact with negative social consequences. The development of an eco-friendly fertilizer is hence timely and appropriate. Green fertilizer technology in the form of control release fertilizer (CRF) has numerous advantages. These advantages are:

- It increases fertilizer efficiency and crop yield,
- It reduces losses of nutrients through leaching, runoff, volatilization, and denitrification,
- It saves time, cost, and labor in reducing the frequency required for fertilizer application compared to the conventional method,
- It synchronizes the release of all macro- and micro-nutrient in the soil necessary for crop plantation.

CONTROL RELEASE FERTILIZER "ONE BAJA" RESEARCH PROGRAM

A group of researchers from several public and private universities in Malaysia has embarked on a research program named as "One Baja". The primary objective of the One Baja research program is to develop a green fertilizer technology by featuring a green production of ammonia as well as a controlled-release

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

mechanism of urea for paddy farming fertilizer. This One Baja research program received a grant worth (Ringgit Malaysia) RM 12 million from the Ministry of Higher Education (MOHE) of Malaysia. The aims of this research program are:

- To model and synthesize ammonia and urea in a magnetic induction reaction zone with the presence of a catalyst and catalyst support;
- To design, multi-functional layers of biodegradable granulated urea and to develop a new coating formulation material to increase nutrient uptake;
- To systematically model the process design of Enhanced Efficiency Fertilizer (EEF) plant as well as to calculate the energy saving of the new system;
- To run efficacy test on the newly developed EEF products and to conduct some economic impact analysis via stakeholder communication.

NECESSITY OF THE STUDY FOR ONE BAJA

This remarkable achievement is a result of policy done by the Party and Government, which has paid attention to agricultural development. In addition, the agriculture has also applied the scientific and technical methods and effective usage of fertilizers in farming. In order to promote agriculture development, both in quantity and quality basis, the industry needs the support and contribution of all economic components, of which the important role of fertilizer production enterprises is undeniable. Fertilizers facilitate plants to have high productivity and quality products. Fertilizer companies must manufacture diversified and good products to meet the market needs. This would be a responsibility as well as a challenge for FELDA, RISDA, FELCRA and FOA when the firm provides urea and NPK fertilizers in the market. Before 2006, the production of fertilizer companies did not meet the need of the market; thus, the marketing activities were not paying enough attention and promoted by the fertilizer companies.

Background of Study

In average, Malaysia produces 2.67 ton of paddy each year (DOS, 2012). However, more than 60% of the production comes from the northern region where two of three largest granary areas in Malaysia are located. Furthermore, Muda Agriculture Development Authority (MADA) alone contains around 40,000 families who work as farmers (MADA, 2007). It makes the northern region of Malaysia as one of the main rice producers in Malaysia and contains the largest number of farmers compared to other regions. There are three major granary areas under MADA, IADA KADA. These regulatory bodies are responsible for managing farmers in terms of irrigation, planting, and technical advice. Under this management authority, there are several small groups of management team known as "Pertubuhan Peladang Kawasan" or PPK (Area Farmers Organization) which is the local union of farmers in the area. Their role is managing and planning for any errands for a single planting season. Furthermore, PPKs are also responsible for managing the purchase of non-subsidized fertilizer and storing the subsidized ones before the disbursement to the farmers. To this end, it is necessary for the company to carefully analyze the macro and industry environment and then map out the appropriate marketing solutions for NPK fertilizers of One BAJA. All the above-mentioned contents are covered in the specific study.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

DATA SOURCES AND RESEARCH METHODOLOGY

The research methodology is used in this study is a case study and this methodology meets the research's objective. Data used in the study were taken from both reliable secondary data about One BAJA operation collected in the process of working with One BAJA and primary data collected from interviewing agents and customers in target market about its products, prices, places and promotions and from author's observation. There are a number of techniques used to conduct a case study research will be:

- Interviewing staff and experts
- Economic statistic method
- Methods of description and comparison

This Project management all in all is a methodology and a discipline that intends to bring benefits to its One Baja fertilizer: managing complex change, using prudent resources on the right projects, using creativity and knowledge of specifically chosen team members, setting quality objectives. Its success is driven by the project 7 on schedule, expenses within budget, meeting predefined quality goals, meeting the expectations, objectives, goals and mission of the customers, effective teamwork, new business improvements and productive outcome. However, market segmentation is an important asset of the project planning phase, too. It does help managers to develop a proper set of projects (products/services), target it to the right people with the right strategy technique.

MARKETING MIX (4P)

Product is the most basic element in the marketing mix. The product can have tangible features including quality, design, function, package and brand. It can also have intangible features such as delivery service, warranty, training, etc. Price is a no less important element of market mix, which includes: whole sale and retail prices, discount, credit. Price must be in consistence with the value customers received and be competitive. Place is one of the major elements of marketing mix. This refers to how an organization will distribute the product or service they are offering to the end user. The company must understand the importance of distribution, and select the right intermediary for effective distribution. Promotion is all activities to communicate the product's advantages and convince target customer to buy that product. Promotion may include many actives to reach the target market. Company must set up activities such as, advertising, promotion, public relation, direct marketing. Thus, the research on the basic 4 p's of marketing mix is to check the market strategies of One BAJA such as positioning, product promotion and price

Positioning Strategies

Positioning of NPK fertilizer basing on the analysis of One BAJA comparative advantage and the result of interviews with customers in target markets, One BAJA can position its NPK products in the target market as follows: There are a lot of different kinds of Malaysia NPK Fertilizer of different brands namely: This data show the major player of manufacturers for compound fertilizer. Malaysian NPK Fertilizer (MNF) is the largest single factory manufacturer. (FPM got two factories at PasirGudang). There is compaction, granulated (method). If bio granulation it means during compaction process, they

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

put biofertilizer element during the compaction. We still import compound fertilizer, but the amount is not simply 3 million (requirement – manufactured) because some of the requirements involve straight fertilizer. MNF Sdn Bhd is major producers of paddy fertilizer. Table 1 highlights the Malaysian fertilizer producer. These brands have a remarkable reputation in the market, yet some companies own the backward technology, which makes poor product quality and unstable price. One BAJA is a new player with the advantage of modern technology in order to make products of superior quality. Also, the company considers the high quality product as the comparative advantage to penetrate and attract customers. The aim of market penetration is to offer diversified products and upgrade the product consumption. Whereas, Table 1 illustrated the Malaysian fertilizers producers.

Product Strategies

Product strategies study, design the suitable package for consumers and diversify the products with different types of packaging and weight, namely 10 kg, 25 kg, 50 kg, 100 kg, which will satisfy all demands of consumers. Frequently update and summarize the One BAJA market information, analyze

Table 1. List of Malaysian fertilizer producer

	Compound fertilizer manufacturer	Capacity (MT)	Type of process	Locations	
1	FPM Sdn Bhd	300,000	Liquified Urea	Pasir Gudang	Peninsula
2	Malaysian NPK Fertilizer Sdn Bhd	270,000	Liquified Urea	Gurun, Kedah	Peninsula
3	CCM Fertilizers Sdn Bhd	270,000	Liquified Ammonical	Shah Alam	Peninsula
4	CCM Fertilizers Sdn Bhd	230,000	Liquified Urea	Bintulu	Sarawak
5	Agromate Sdn Bhd	200,000	Liquified Urea	Lahad Datu	Sabah
6	Kemira-Kuok Fertilizers Sdn Bhd	120,000	Granulated	Port Klang	Peninsula
7	Narsco-Kuok Fertilizers Sdn Bhd (Agrifert / Kuok Brothers)	120,000	Granulated	Pasir Gudang	Peninsula
8	Agri-Bintulu Fertilizers Sdn Bhd (Agrifert / Kuok Brothers)	120,000	Granulated	Bintulu	Sarawak
9	United Compound Fertilizers Sdn Bhd	100,000	Compaction	Kuantan	Peninsula
10	All Cosmos Industries Sdn Bhd	80,000	Bio Compaction	Pasir Gudang	Peninsula
11	TM-Kay Fertilizers Sdn Bhd (Agrifert / Kuok Brothers)	80,000	Granulated	Port Klang	Peninsula
12	Agri-Sabah Fertilizers Sdn Bhd (Agrifert / Kuok Brothers)	50,000	Granulated	Sandakan	Sabah
13	PK Fertilizers Sdn Bhd	25,000	Granulated	Pasir Gudang	Peninsula
14	Twin Arrow Fertilizer Sdn Bhd	25,000	Granulated	Port Klang	Peninsula
15	Consolidated Fertiliser Corporation (CFC) Sdn Bhd	20,000	Granulated	Port Klang	Peninsula
16	Sasco Sdn Bhd	20,000	Granulated	Lahad Datu	Sabah
	Total MT	2,030,000			

Source:(Safitri&Andriyani, 2011)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and evaluate the information, identify the market trend, competitors' abilities, recommend solutions and strategies to bring into full play the products' competitive advantages. Frequently visit the primary consumers, farmers, who directly use the products, to **assess** their knowledge as well as the satisfaction from the products. For this reason, One BAJA should focus on high quality products, which have high demand, to convince the customers and distributors. One BAJA should invest in technology, which is more modern than that of other competitors, to create competitive advantages and superior products. One BAJA market is a fierce market; therefore, in order to survive and go far in the market, One BAJA need to invest in R&D activities in the long-term to differentiate their products with those of competitors.

Price Strategies

In terms of pricing a product, One BAJA is a newcomer; thus, the company needs a flexible pricing strategy, price determination must be taken into consideration of production costs, domestic and foreign prices and especially competitors' pricing. Being a fertilizer producer, the company deeply aware that its main customers are farmers, who are mostly living in poverty, underfunding and having a limited scientific understanding. To create favorable conditions for farmers to buy fertilizers on the installment plan, the company needs a late payment mechanism from 3 to 6 months so the farmers can purchase the fertilizer.

Promotion Strategies

Promotion strategy regarding the promotion and communication strategy, One BAJA should pay attention to, the following activities: The Company needs to hold seminars in the localities within the target market to introduce the product, which can help farmers and retailers aware of the products and the superior quality of NPK fertilizer against other competitors. In order to popularize as well as provide information about NPK products, the company needs to select media channels which are close to farmers such as agriculture programs broadcasted on radio and TV. The company should also take the agents in the urea nitrate market as a channel to introduce about NPK products. It is an important channel and popular with farmers. Besides that, One BAJA fertilizer awareness strategies through ICT should be proposed in the future as a promotional tool for the department of Agriculture, Malaysia organic farming.

The use of ICT can be used as a tool by the Department of Environment and the Ministry of Energy, Green Technology and Water for their sustainability promotion among Malaysian farmers. One Baja successful promotion with the help of ICT innovation will enhance the sustainability awareness through its recognition at the Malaysia Technology Expo (MTE) 2009. According to the National Green Technology Policy Malaysia, effective promotion and public awareness are two of the main factors that would affect the success of sustainable development among farmers through the adoption of One BAJA fertilizer. This is particularly significant as such adoption requires a change of mindset of the farmers through various approaches, including effective education and information dissemination to increase public awareness of sustainable agriculture and on ways to conserve the environment. This awareness of One BAJA fertilizer among paddy farmers in Malaysia with the help of ICT application with the element of captology, integrated into a persuasive learning environment can play an innovative role in promoting sustainable practices in agriculture. This research also aims to relate the issues of adoption of One BAJA fertilizer by using ICT in order to disseminate information about sustainable paddy farming practices in Malaysia. The government also plans to increase the usage of ICT in all sectors to increase productivity. Mastery of the use of information technologies will be emphasized to enhance the acquisi-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion and dissemination of new knowledge and technologies, and to motivate greater youth participation in technology development and transfer. Advances in "expert systems" or computer simulated scenario analysis will be exploited to enhance on-farm advice and information exchange to agriculture producers through extension. The most innovative approach is the development of a new product or process to solve a new problem or usage. An example is the Digital Video Disk (DVD), which illustrates an old process with a new usage. DVDs employ the same basic technology as CDs; however, the means for compression and reading hardware are more advanced.

Another example of product innovation is an electronic mail security that involves virus protection software (Othman et al., 2012). However, almost as quickly as new software and processes are developed for protecting a firm's information, new problems emerge. It is a constant war of innovation nowadays, in Malaysia there are many innovations in ICT in learning and promoting sustainability issues, including learning through VR, sustainable agriculture in multimedia and VR application, persuasive technology, educational games, serious games, criteria in choosing the learning games and positive impact of computer games on education and training. According to the Planning and Information Technology Department of MADA, the usage of ICT was existing in their daily operations. This is especially true when they convey information to the public through their website (http://www.mada.gov.my/). It is similar in Kajang, Bandar Baru Tunjong, Tanjung Karang and Sabak Bernam Agriculture Departments. They have all developed their own web-based information systems for the purpose of disseminating information about innovation in the fertilizer industry.

DIFFERENT TYPE OF FERTILIZER IN MALAYSIA

Mineral Fertilizers

Mineral fertilizers account for more than 90 percent of fertilizers used by all types of farming systems in Malaysia. The main fertilizers are urea, ammonium sulphate, calcium ammonium nitrate, phosphate rock, super phosphates, ammonium phosphate, potassium chloride, potassium sulphate and NPK, NP and PK compound fertilizers. Due to the rapid expansion in crop production, especially of plantation crops (rubber, oil-palm, cocoa, and paddy) there has been a corresponding increase in fertilizer use. Potassium fertilizers have shown the largest increase and very effective for the crops.

Organic Fertilizers

The government is promoting the use of organic fertilizers in Malaysia for two main reasons. Firstly, organic agriculture is seen as important for the sustainable use and management of natural resources. Secondly, in the NAP3, organic agriculture is identified as a niche market opportunity for fruits and vegetables. In an effort to reduce the dependence on mineral fertilizers and to move towards more natural and healthier methods of food production, the government is promoting programmers that encourage the recycling and use of agricultural waste.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Number and area of organic producers per State in 2001. Source: (Wai, 2001)

State	Number	Area(ha)
Selangor	4	10.8
Negri Sembilan	10	90
Melaka	2	1.1
Johor	2	3.5
Pahang	6	11.6
Sabah	2	12
Sarawak	1	2
Total	27	131

PRODUCTION AND MARKETING OF THAT FERTILIZER

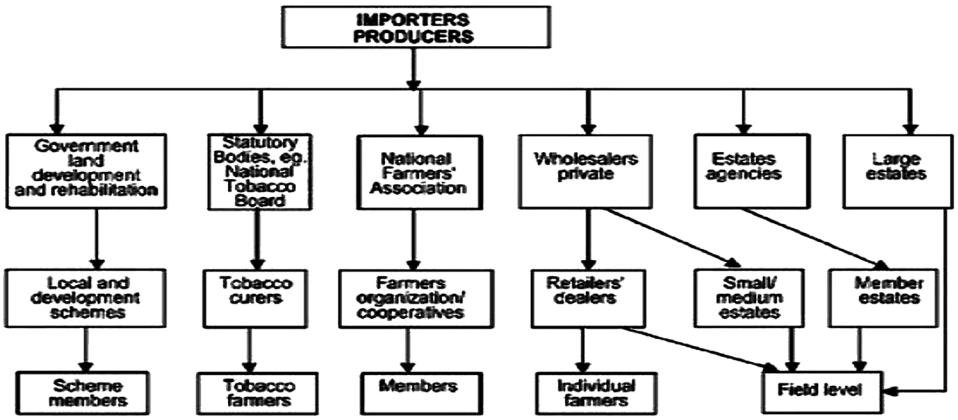
Most of the fertilizer used in Malaysia is produced abroad. Urea, ammonium based and organic fertilizers are produced in large amounts, but the urea used in Malaysia for agriculture is not locally produced material. This is because the prilled urea produced in Malaysia fetches a high price in the international market and is therefore exported. The parent fertilizer producing company has two subsidiaries involved in the production of urea. These are one subsidiary was incorporated in 1980 and located in Bintulu, Sarawak. The plant has a capacity to produce 600 000 tonnes of granular urea and 420 000 tons of prilled urea per annum.The other came into operation in 1999 and is located in Gurun, Kedah. It has an annual capacity of 650 000 tonnes granular urea. This second plant exports about 65 percent of its products to Australia, Thailand and other South East Asian agricultural countries. The remainder is sold to the National Farmers' Association, Malaysia's largest urea consumer, for distribution in Malaysia. Most of the companies involved in fertilizer production engage in the mixing of straight fertilizers to produce compound fertilizers. The fertilizer industry in Malaysia is efficient and highly competitive. There are over 50 companies involved in the branded fertilizer trade with over 350 brands of various forms of fertilizers (Malaysian Agriculture Directory and Index, 2004). The normal channels of distribution are shown in Figure 4. The Government, in its drive to help farmers, particularly smallholders, to procure fertilizers has: stimulated fertilizer consumption through subsidy and credit schemes; facilitated the supply and distribution of fertilizers through FELDA, RISDA, FELCRA and FOA; stimulated the establishment of a large number of distribution points through farmers' cooperatives improved the cost-value ratio between fertilizers and agricultural produce by providing price support; provided extension services, research on fertilizer use and quality control. The government has also encouraged suppliers to market fertilizers in packages smaller than 50-kg bags, to allow farmers who cannot afford 50-kg bags to purchase lesser quantities.

FERTILIZER USAGE IN PADDY INDUSTRY MALAYSIA

In the context of Malaysian paddy industry, reliance on fertilizer usage to increase yield requires a good relationship fostered between the farmers as consumers, generally represented by farmer organizations, and manufacturers or retailers as suppliers (Ismaila, 2008; Zainal, Shamsudin, Mohamed, Adam, &

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

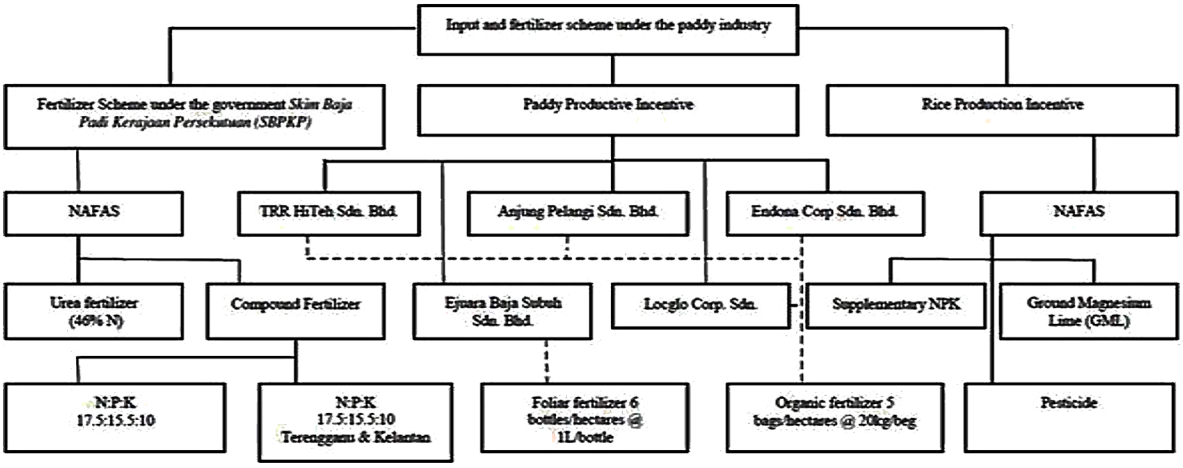
Figure 4. Marketing and distribution channel of fertilizers in Malaysia



Kaffashi, 2014). The relationship does not merely involve purchasing and selling products as it also requires professional advice to the farmers. For instance, in the case of introductions to new technology or products would require feedback from the consumers. The government's effort to strengthen the paddy and rice industry continues to be one of the main agenda. The Ninth Malaysia Plan saw 70% of RM 2.5 billion, and later RM 3 million during the mid-review, allocated to national food security. The paddy sector in Malaysia is a heavily subsidized industry, which the summary of the input and fertilizer subsidies is as follows:

Despite the rigorous efforts and initiatives by the Government, Fahmiet al. (2013) mentioned that Malaysia's rice production is considered inefficient in terms of cost and production. It has also been noted that there are also issues and challenges specifically on the supply of fertilizer that has an impact on the yield of paddy. Some of the challenges in fertilizer supply revolve around the following issues (reported in BeritaTransformasiPertanian: Lahir Peladang Progres if, 2012): Ensuring that fertilizer

Figure 5. Input and fertilizer subsidy in paddy agriculture
Source:(A. Rizal et al., 2014)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

is supplied only to eligible farmers, more frequent visits to meet the farmers for monitoring, timely distribution of fertilizer to farmers. Malaysian government spent about 30 million USD annually on chemical fertilizer. As illustrated in Figure 5 National Farmer Association (NAFAS) has been the sole distributor of the subsidized fertilizer to the paddy farmer's nationwide (A. R. A. Rizal, Nordin, Saad, & Ismail, 2012). Hence, there is a need to ensure that the subsidized fertilizer is supplied to and received only by eligible farmers which require efficient communication management, specifically between the suppliers and consumers. In of this research study One BAJA need proper segmentation in order to be successful in the market**.**

FUTURE RESEARCH DIRECTIONS

This paragraph summarizes the review results and suggests future directions of One Baja fertilizer and procedures. The specific research field is relatively new and possible future perspectives have to be emphasized so that new innovation can be effective in order to increase the production.

Investment positive:

- Rising population increased the demand of chemical fertilizer usage and changing diets, putting a heavy demand on higher crop yields. With limited available acreage for planting, fertilizers will be increasingly needed to produce strong yields.
- Crop prices have most likely hit with upward potential in the near future Increases in crop prices will directly result in higher sales of fertilizers.
- Using One BAJA fertilizer is a strong an opportunity exist for paddy farmers in Malaysia to increase the production without damaging the environment.

Investment negative:

- Most fertilizer companies specialize in a specific fertilizer type since fertilizers are dependent on various conditions, companies can experience cyclicality. Investing in the wrong fertilizer farmers in a downward cycle could result in heavy losses.

Key to monitor:

- Crop prices will have the most immediate effect on fertilizer consumption. Farmers will be more likely to purchase and utilize fertilizer when they experience high margin. One Baja fertilizer is also known as control released fertilizer

CONCLUSION

The study has met the goal of mapping out some marketing solutions that are suitable for the NPK target market of One BAJA. To this end, the author has logically revised the marketing literature, including concepts relating to marketing, models to analyze macro and industry environment and marketing mix. Based on the literature review, the author has analyzed the situation of One BAJA NPK fertilizer. The

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

study covers the macro and industry environment analysis of NPK fertilizer, major rivals' marketing mix. Then, the analysis of NPK market has laid the foundation of the marketing strategies to develop One BAJA NPK target market. With such a wide range of activities and a huge market to serve, it is important to have a structured marketing strategy and a marketing plan. In order to accomplish that, one needs to know the customers of the market. That is why market segmentation plays such a big role in marketing planning and marketing strategy. However, the results of One Baja research program validated that it is a value-added research program. Since the value of the obtained benefits is more than the funding devoted (RM12 million) on this particular research.

Overall, the marketing strategies of One Baja results indicated that the RM 12 million research program provided by the government can potentially generate benefits value of RM 1,824 million per year for the Malaysian fertilizer industry. In summary, the study concludes that the participants in research collaboration appear to get significant benefits and it also increase the paddy production. The most important benefit realized by the government is that the new green fertilizer technology in the form of CRF developed in this research program will have a high impact on the domestic paddy farming, the ecosystem as well as on the value proposition of the fertilizer industry. In a nutshell, this technology is economically efficient in the context of the fertilizer application frequency as compared to the conventional methods.

ACKNOWLEDGMENT

The authors would like to thank Universiti Teknologi PETRONAS (UTP) and the Ministry of Higher Education (MOHE), Malaysia, for the financial support under Long Research Grant Scheme (LRGS) and Management and Humanities to conduct this research.

KEY TERMS AND DEFINITIONS

Business-to-Business (B2B): Refers to a situation where one business makes a commercial transaction with another. This typically occurs when: A business is sourcing materials for their production process (e.g. a food manufacturer purchasing salt).

Market Segmentation: A marketing strategy which involves dividing a broad target market into subsets of consumers, businesses, or countries that have, or are perceived to have, common needs, interests, and priorities, and then designing and implementing strategies to target them.

Marketing Research: The process or set of processes that links the producers, customers, and end users to the marketer through information used to identify and define marketing opportunities and problems; generate, refine, and evaluate marketing actions; monitor marketing performance; and improve understanding of marketing as a process.

Chapter 76
Competitiveness of Turkey in the Sectoral Transformation Process:
A Comparative Analysis With the BRIC Countries

Sema Ay
Uludag University, Turkey

Hilal Yildirir Keser
Uludag University, Turkey

ABSTRACT

The aim of this study is to measure the competitiveness of Turkey by making a comparative analysis between the Turkish agricultural, industrial, and services sectors involved in foreign trade and the corresponding sectors of the BRIC (Brazil, Russia, India, China) nations. In addition to the determination of their relative competitiveness, assessments will be made about their competitiveness over time by analyzing the direction of the sectoral trends of the above-mentioned countries. In the study, after a brief theoretical overview, a summary of the literature related to the subject is provided, followed by a comparison of the competitiveness of the three sectors (agriculture, industry, and services) made by calculating the revealed comparative advantages (RCAs) of Turkey and the BRIC countries.

INTRODUCTION

In Turkey, as a consequence of the planned development period that started in 1963 following the implementation of the import substitution industrialization strategy, the share of agriculture has started to decrease while the share of industry has started to increase in terms of both production and employment. The increase of the share of industry in terms of Gross Domestic Product (GDP), an indicator of being a developed nation, has raised the share of the services and industrial sectors while reducing that of

agriculture. As a result of the outward industrialization model after 1980, this transformation evidenced in the main sectors has also emerged in the foreign trade structure. During the transformation process, the share of industrial production, especially for export, has rapidly risen while imports, and therefore the volume of foreign trade, have increased.

When the development of the sector shares in terms of global GDP is considered, the increasing global share of the services sector is highlighted. Within the framework of Turkey's import substitution industrialization strategy, the process by which the share of agriculture has begun to decrease and the share of industry has begun to increase, which develops the services sector, indicates a generally desirable economic development. This structural transformation trend, shifting emphasis from industry to services, is more evident in developed countries that have completed their industrialization. As the level of development of a country's economy increases, the shares of agriculture and industry decrease, while the share of the services sector increases.

Today, it is apparent that some countries with great industrialization potential other than Turkey have come to the forefront, and that Turkey is in fierce competition with these nations. According to the Global Competitiveness Index (GCI) developed by the World Economic Forum, Turkey is situated in the second group, in the classification of "the Attacking Countries." Also classified in this second group are the BRIC countries (Brazil, Russia, India, China), whose combined economy is expected to exceed that of any one of the current richest countries by 2050. During the process of sectoral transformation being experienced in Turkey, a comparative analysis with the BRIC countries in terms of international competitiveness is thought by economists to play a guiding role in determining policies for the future.

From this point of view, the aim of this study is to measure the competitiveness of the agriculture, industry, and services sectors in foreign trade for Turkey and the BRIC countries and to analyze the measurements comparatively. In addition to determining their relative competitiveness, assessments will be made about the direction of the sectoral trends over time for the countries in question. In the study, a brief theoretical introduction is followed by a review of literature related to the subject. Then, the competitiveness of foreign trade in the agriculture, industry, and services sectors will be compared by calculating the revealed comparative advantage (RCA) indexes for Turkey and the BRIC countries.

THE INDUSTRIAL TRANSFORMATION PROCESS AND COMPETITIVENESS

Technological advances, increased international competition, and the decline of transportation costs and tariffs creates the opportunity for different processes to be performed in different countries by dividing major production activities with different levels of intensity into smaller sub-processes. Global business division increases the export of industrial products of the developed countries and the leads them to use more imported capital and intermediate goods by integrating national economies into the world economy. Thus, while the comparative advantages of the developed countries have become great in terms of intermediate goods, the relative advantages of the developing countries have increased in terms of finished goods. With these increasing comparative advantages, the developing countries are able to allocate resources for infrastructure investments, follow technological improvements more closely, and begin to pay attention to the quality of labor power.

Therefore, new production techniques are being applied in the industrial sector by which costs are reduced and higher shares of international markets are obtained. Additionally, the advanced economies,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

while leaving the production and hence the trade of a number of industrial goods and turning to the services sector, are specializing in the technology, knowledge, and skilled-labor-intensive phases of the production processes (Rojec & Damijan, 2008).

The developing countries have more competitiveness in the agricultural sector in which they are able to leverage the natural resource and agricultural areas where qualified labor is not as essential as in other main sectors, such as the industrial and services sectors, since developing countries do not have access to sufficient resources for infrastructure investment from either public or private sectors. Therefore, geographical conditions and climatic features are considered to be one of the most important sources of competitiveness for the economies of developing countries. These countries have advantages in terms of geographic location, geographic characteristics, and climatic conditions that favor the competitiveness of their agricultural production and cause the share of agriculture in their total exports to remain high compared to their industrial and services sectors.

In the developed countries of today, the share of agriculture is less than 5%, the share of industry is 20% and the share of services is 70 percent. In comparison, in developing countries, the share of agriculture is between 15-20% and the share of services is less than 60%. Additionally, in the developing countries, the share of agriculture is more than 20% and the share of services is down to 50 percent (Kalkınma Bankası, 2014). The transitional trend from industrial production to the services sector has been more significantly observed in the developed countries, which have completed their industrialization. As the level of sophistication of a country's economy increases, the share of the services sector increases, while the shares of the agriculture and industry sectors decrease.

This transformation in the services sector, accompanied by economies gradually opening outward, reducing limitations on foreign capital investments, and expanding privatization, has also been observed in the sectoral distribution of foreign capital investments which have increased in recent years. While the share of primary production sectors and the manufacturing industry in total foreign investment has declined significantly, the share of the services sector has increased.

The sectoral trends in the economy of Turkey have been continuing for many years and have the characteristics of a process of structural transformation that developed countries have experienced much earlier. The increase in foreign investments in the services sector enables the services sectors in countries where such investments are made to advance their development around issues related to capital, technology, management, and the restructuring of companies (Türkiye Vakıflar Bankası T.A.O. Hazine Başkanlığı Ekonomik Araştırmalar Müdürlüğü, 2007). In Turkey, during the planned development period that started in 1963 and within the framework of the import substitution industrialization strategy, the share of agriculture in production and employment has started to decrease, and the share of industry has started to increase.

Turkey's pursuit of its import substitution development strategy in the 1970s, which paralleled the oil crises and the high worldwide inflation rates experienced in this period, was stymied by a foreign currency bottleneck that resulted in a situation in which investments and imports of required intermediate goods could not be executed; by the 1980s, it was clear that Turkey would no longer be able to continue to pursue this strategy. In 1980s, an export-oriented development model started to be implemented, and an intensive process of opening outward was experienced. In 1980, the share of agriculture of the Turkish GDP was 26%, the share of industry was 25% and the share of the services sector was 49%; in 2014, the share of agriculture had declined to 9%, and the shares of the industry and services sectors had increased to 27% and 64%, respectively (Kalkınma Bakanlığı, 2014).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In general, this process indicates a desirable development in terms of economic development. The increase of the volume of production of the services sector is primarily associated with production in the industrial sector. The forward and backward connections of the industrial sector and the expanding effect that they create in the economy stimulate the development of the services sector and become the basic dynamics driving economic growth. This structural transformation, at the same time, also has positive effects on the productivity of the Turkish economy. When the value added per employee between the sectors is compared, it is clear that industry is the most important sector of the economy and that the value added per person in the agricultural sector is at the level of one fourth that of the industrial sector. (Acar, 2008, pp. 32–33).

THE BRIC COUNTRIES AND COMPETITION

The rapidly growing economies of Brazil, Russia, India, and China were collected under the grouping acronym BRIC in 2001 by Jim O'Neill, chief economist of the giant U.S. investment bank, Goldman Sachs. O'Neill has advocated that a space should be opened in the platform directing the global economy for these countries and that they should have a larger say in the global economy since the BRIC economies have grown much faster than the original G-7 member countries. It is thought that if these four developing countries maintain their current economic growth, their combined economy will become the largest in the world by 2050, while the U.S. economy will drop to fifth place. Only 10 years since being labeled the BRIC countries, these nations have assumed their place among the largest economies of the world.

Today, the BRIC countries, which make up 40% of the world's population, cover more than 25% of the earth's surface and take in 15% of the world's income, are candidates to become the global economy's most powerful economic actors in the near future due to both their possession of the world's fastest growing markets and their accelerating production potential.

The BRIC countries do not have uniform structure in terms of competition. China, which is among the countries placed in this group, maintains the position of the group's relatively fastest growing country. However, in recent years, the real estate boom in China, the slowdown in the world trade, and fluctuating capital movements in economically advancing countries are contributing to the possibility of a long-term negative impact on the global economy by delaying the recovery process of China. In spite of this, China maintains its leading position among the BRIC countries by a substantial margin.

Following China, Brazil shows the most significant growth among the BRIC countries. India experienced an unexpected economic downturn in the last quarter of 2011. As a result, it has lagged behind Brazil, which it was formerly in front of, and its development gap with China has increased even more. Finally, Russia, just as with India, has been experiencing economic difficulties.

As an indication of the share that the global business divisions of these fast-growing economies have achieved, the sectoral distribution in their economies is seen in Table 1. In all of the BRIC countries and in Turkey, the share of agriculture is the lowest and the share of services is the highest in terms of GDP. India is the country with the highest agricultural share in terms of GDP with 17.39 percent. While the share of agriculture is around 10% in China and Turkey, this share in Brazil and Russia has remained around 5%. China is the country with the highest share of industry, followed by Russia. The share of industry of Turkey and BRIC countries, excluding China and Russia, are close to one another. Brazil is the country where the share of the services is the highest. Turkey follows Brazil. Although the share of agriculture in the developed countries is below 3%, the share of the services is above 70%;

Table 1. BRIC countries sectoral distribution of GDP (%)

	Agriculture	Industry	Services
China	10.05	43.89	46.09
Brazil	5.24	24.98	69.32
India	17.39	24.77	57.03
Russia	4.25	36.16	59.90
Turkey	9.14	27.06	64.41
Developed Countries	2.06	24.81	70.67

Source**:** Kalkınma Bakanlığı, Temel Ekonomik Göstergeler, 2014

the sectoral distribution of BRIC countries and Turkey as percentages of GDP is similar to the sectoral distribution of the developed countries in the respect that the share of agriculture is the lowest and the share of services is the highest.

The development of the agriculture, industry, and services sectors, which are three major sectors of the countries' economies, is affected by numerous conditions, primarily including globalization, economic and political development, technological change, consumption preferences, and climatic and geographical features. In recent years the global economy has experienced numerous crises in the developed nations. In contrast, the growth and competitiveness of the ascendant economies of the BRIC countries have generally continued on an upward trend. Turkey has also paralleled the improved economic performance of the BRIC countries during recent years, and global competition among the above-mentioned countries has increased. While the projections made for the coming years indicate that Turkey and the BRIC countries will receive a much larger share of the world's added value and will increase their global competitiveness, the BRIC countries' efforts to obtain the largest share of the pie in the international markets are escalating competition between them and Turkey.

COMPETITIVENESS: THEORETICAL FRAMEWORK

The increasingly global character of the world economy has led to the creation of different approaches and definitions related to competitiveness. In academic research, international competitiveness has been defined using two approaches. In the micro-level approach, competition between enterprises inside a given country and the effects of this competition in national/international markets are examined; in the macro-level approach, the focus has been the position of the country with regard to international competition. To include both approaches, competitiveness can be expressed as the offering of products and services produced under free market conditions to international markets and taking part in these markets while in the meantime increasing real incomes (Scoot & Lod, 1985).

From these and similar definitions related to competitiveness, it generally understood that competitiveness requires three essential features (Çivi et al., 2008):

1. The country should focus on its own unique features, capabilities, and potential in order to catch up with rival countries in the production and distribution of products and services.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. The main purpose of having competitiveness is to ensure the enhancement of living standards and the general welfare. These enhancements can be ensured by promoting harmonious arrangements among all of the specialized institutions in the country by paying adequate attention to activities such as trade, investment, and production.
3. Many indicators, including international market share, the trade balance of the country, production, and employment, are indicators used to measure competitiveness.

It can be concluded that the performance of countries in international trade is an important criterion for their international competitiveness. In addition, the above-mentioned indicators allow comparisons to be made at various levels in terms of competitiveness; for example, foreign trade performance indexes are used to empirically measure competitiveness pertaining to foreign trade. In studies within the framework of trade that apply approaches based on classical foreign trade theories, the Balassa index (Balassa, 1965), also known as the revealed comparative advantage (RCA) index, and its derivations are primarily used.

Measuring Competitiveness: The Revealed Comparative Advantage (RCA) Approach

Two of the most common methods for determining competitive advantage in foreign trade are the absolute advantage approach of Adam Smith and the comparative advantage approach of David Ricardo. For measuring competitiveness based on classical foreign trade theories, the revealed comparative advantage (RCA) approach was developed by Balassa (1965). This comparative advantage index is one of the criteria used to determine the goods and services for which a country has a competitive advantage or is at a competitive disadvantage.

The RCA index, proposed by Balassa (1965) and also referred to as the Balassa index, is formulated as follows:

$$RCAij = (Xij / Xit) / (Xwj / Xwt)$$

Xij represents the exports of country i in goods j; Xit represents the total exports of country i; Xwj represents the world's exports of goods j; and Xwt represents total world exports. Thus, the share of one type of goods in the total exports of the country is compared with the share of the same goods in the total exports of the world. If this proportion is greater than one for a given country, it means the share that country has of the export of goods j is greater than the export share of the rest of the world in goods j, and thus shows that this country has a comparative advantage in goods j. Conversely, if the proportion is smaller than one, it means that the country has a comparative disadvantage relative to goods j.

Literature Pertaining to Measuring Competitiveness

Regarding measuring competitiveness and the concept of competitiveness, numerous studies are available that measure competitiveness using the RCA developed by Balassa (1965) and similar indexes. In the literature, in almost all of the studies involving the RCA index, comparative competitiveness analyses are performed without using econometric methods. A large number of studies on Turkey that employed the RCA index are on the measurement and comparison of Turkey's competitiveness in EU markets.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

For example, Erlat and Erlat (2005), working with the RCA, measured the competitiveness of Turkey for the years 1990–2000 and compared it with the competitiveness of the EU-15 countries. According to the RCA index results obtained in the study, similarities were observed between Turkey and Belgium, Denmark, Finland, Greece and Spain. On the other hand, it was concluded that the competitiveness of Turkey has also risen in areas other than the traditional sectors while its competitiveness has declined in raw material-intensive goods.

Yılmaz (2003) compared the competitiveness of Turkey between the years1996–1999 with the competitiveness of Bulgaria, Romania, the Czech Republic, Poland, Hungary, and the EU. Among these countries and region, the competitiveness of Turkey and the Czech Republic were found to be the highest. Indeed, in the studies of Karakaya and Özgen (2002) along with the studies of Kösekahyaoğlu and Özdamar (2011), the conclusion that the competitiveness of Turkey is higher than the other countries was reached. This state of affairs has suggested to some that the EU membership of Turkey could harm the exports of Greece, Portugal, and Spain.

Turkey has been searching for ways to increase its volume of foreign trade, especially the volume of exports in line with expansion models put into practice after the industrial strategies of the 1980s for exports; similarly, it has been seeking foreign trade expansion in the customs union launched with the EU, the BSEC (Black Sea Economic Cooperation Region), which it has been trying to establish with its neighbors to the north, and the Economic Cooperation Organization which it has been trying establish with its neighbors to the east. In this context, Sandalcılar (2011) analyzed Turkey-Syria trade on the basis of commodity groups with the RCA index. The analysis concluded the rise in the foreign trade volume of Turkey has been reflected in its trade with its southern neighbor Syria, and it was determined that Turkey has a comparative advantage in the Syrian market. However, the civil war in Syria has terminated the increase in trade volume.

Some of the studies on Turkey using the RCA index are on the measurement and comparison of its competitiveness with countries such as China and India, which are the world's fastest developing countries whose international competitiveness is being increasingly scaled up and which, along with Turkey, have made a name for themselves on the global stage in recent years. Among these studies, Lohrman (2000) has evaluated Turkey's pre- and post-customs union competitiveness by measuring the country's RCA indexes for the 1994–1997 period. According to the RCA indexes, Lohrman (2000) has concluded that Turkey has started to gain competitiveness in some sectors that require intensive use of qualified labor, attributing this to the liberalization of countries having access to cheap labor, such as China and Malaysia, and their ability to rival Turkey in labor-intensive sectors.

Ferman et al. (2004), again using the RCA index, drew attention to the fact that China and India are the closest rivals of Turkey in EU markets. Similarly, Altay and Gacaner (2003), having investigated the competitive situation of China and Turkey in the textile and clothing sectors in EU and U.S. markets, stated that Turkey has a greater competitive advantage in U.S. markets in comparison with China.

In their study, Kösekahyaoğlu and Özdamar (2011) examined the competitiveness of China, India, and Turkey during the period 1990–2009 for five different commodity groups: "raw-material-intensive goods," "labor-intensive goods," "capital-intensive goods," "easily counterfeitable goods," and "hard-to counterfeit, research-based goods." The results have indicated the competitiveness of the three examined countries, as expected, depended for the most part on labor-intensive goods; however, recently and for India in particular, the importance of capital-intensive goods has further increased. Moreover, it was shown that Turkey is in a position of greater advantage regarding labor-intensive goods in particular and regarding easily counterfeitable goods with respect to China; with respect to India, Turkey's position is

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

less advantageous regarding raw-material-intensive goods and easily counterfeitable goods, but it has better export expertise regarding capital-intensive goods.

In summary, these and similar studies measuring competitiveness using the RCA index show that this index provides important information about competitiveness. In this regard, evaluations will be made according to the results of the RCA index pertaining to the measurement and comparative analysis of the competitiveness of the agriculture, industry, and services sectors in foreign trade for Turkey and the BRIC countries.

COMPARATIVE ANALYSIS OF THE COMPETITIVENESS OF TURKEY WITH THE BRIC COUNTRIES DURING THE SECTORAL TRANSFORMATION PROCESS

In the sectoral transformation process, the increasing share of the services sector is noteworthy. The fact that the share of agricultural production has started to diminish and the share of industrial production has started to increase and that this increase has benefitted the services sector is a desirable improvement in terms of economic development. This structural transformation trend of a shift from industry to services is much more obvious in the developed countries which have completed their industrialization. In this context, the observation of sectoral transformation trends and measurement of competitiveness are of importance for the BRIC countries and also for Turkey, which is classified with "the Attacking Countries" according to the Global Competitiveness Index.

Aim of the Study

The aim of the study is to measure the competitiveness of Turkey and the BRIC countries, whose agriculture and services sectors are rapidly growing as a component of foreign trade, and also to make a comparative analysis of their competitiveness. Assessments about the direction of sectoral trends of the mentioned countries will thereby be made possible, and similarities to Turkey can be highlighted.

Data and Method

In the study, the following RCA index has been used as a criterion for sectoral and overall competitiveness of Turkey and the BRIC countries in foreign trade assessments.

$$RCAij = (Xij / Xit) / (Xwj / Xwt)$$

In the case that $RCAij > 1$, the share of goods k (sector) of a country j during a period t is greater than its share in total global exports during the same period. The country has a revealed comparative advantage regarding the given product (sector) and has been specialized.

In the case that $RCAij < 1$, the share of goods k (sector) of a country j during a period t is smaller than its share in total global exports during the same period. The country has been specialized in the given product (sector) but does not have a revealed comparative advantage

In the case that $RCAij = 1$, the share of goods k (sector) of a country j during a period t is equal to its share in the total global exports during the same period. The level of specialization of the country is the same as that of the world (Hinloopen and Marrewijk, 2000).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hinloopen and Marrewijk (2000) have classified the RCA index into four separate categories in order to demonstrate the power of the comparative advantage between countries. These categories are shown in Table 2.

In the calculation of the RCA index, the total export figures and sectoral export figures for Turkey and the BRIC countries as well as total global exports and sectoral export figures between the period 1994 and 2013 have been used on annualized basis. The data related with foreign trade have been compiled from data of the World Trade Organization (WTO).

Application Findings

In the study, the RCA index findings are given first according to the order of the initial letters of the countries in the acronym *BRIC*, and finally for Turkey. Observations are made about competitiveness in accordance with the obtained results; finally, the comparative analysis is detailed.

Brazil

Figure 1 shows that Brazil further increased its existing advantage in the agricultural sector between 1994 and 2003. Hence, it can be stated the foreign trade competitiveness of Brazil in the agricultural sector is high. Brazil, which is an important producer of agricultural products, has two main agricultural regions. The region located in the southern part of the country receives much more precipitation. It has a half-temperate climate, more fertile land, more advanced technology and input utilization, sufficient infrastructure, and more qualified farmers. Most of the Brazilian grains, oilseeds, and exported products are produced in this region. The other agricultural region is located in the arid northeast and the Amazon basin. The distribution of precipitation in this region is not balanced. The region does not have fertile land, sufficient infrastructure, or capital for development. Though production there has been mostly dedicated to self-sufficiency, it has become increasingly important for the export of forestry products, cocoa, and tropical fruits. Among the products of Brazil that are exported the most are coffee, soybeans, sugarcane, cocoa, rice, meat, poultry, corn, oranges, cotton, wheat, and tobacco (Gitmez, 2013).

Industrial production in Brazil is concentrated in the following sectors: steel, metallurgical products, machinery, electrical and communications equipment, tools, chemicals / petrochemicals, food and beverages, textiles, clothing and footwear, cellulose and paper, and plastics (İTKİB, 2012). However, as these sectors require new technologies, sophisticated materials and biotechnology must be employed. As a result of the fact that these requirements have not yet been completely fulfilled, it is considered that Brazil's competitiveness in the industrial sector remains at a low level.

Table 2. RCA classification

Class	RCA Index Value	Situation
Class A	$0 < \text{RCA index} \leq 1$	Without Comparative Advantage
Class B	$1 < \text{RCA index} \leq 2$	Weak Comparative Advantage
Class C	$2 < \text{RCA index} \leq 4$	Medium Comparative Advantage
Class D	$4 < \text{RCA index}$	Strong Comparative Advantage

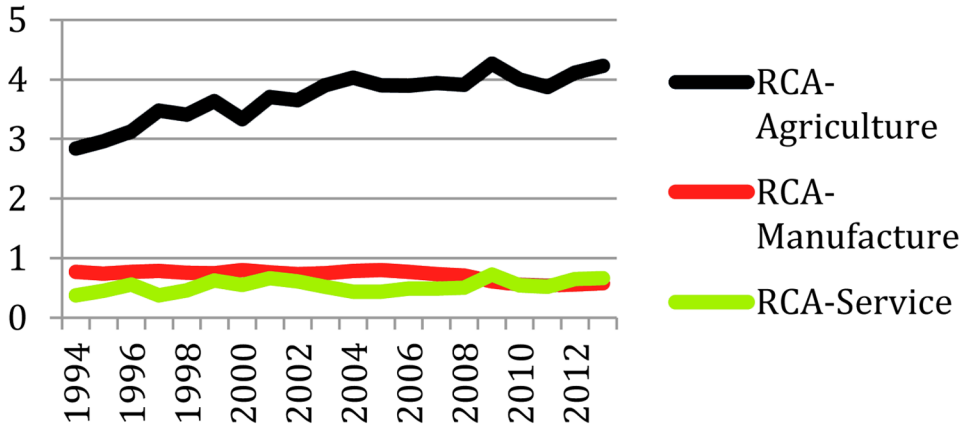
Figure 1. Comparative advantage of major sectors in Brazil



In Table 3, from the RCA index results, it is seen that Brazil, which does not have comparative advantage in industrial and services sectors, has reached a strong comparative advantage level of 4.22 in the agricultural sector.

The services sector is the sector in which competitiveness is the weakest in Brazil, despite having the largest share in the Brazilian economy. It is in the services sector that telecommunications, banking, trade, and data processing sectors have come into prominence; as a result, the services sector has gained more power in the domestic market. However, being an importer of services, just as many developing countries are in this sector, the foreign trade deficit of Brazil is increasing. This situation hinders the country from obtaining a higher level of competitiveness. Despite having experienced global crisis periods, the fact that Brazil has maintained its presence among the BRIC countries can be explained by its being a supplier country that is rich in natural resources.

Russia

In Figure 2, it is remarkable that while the comparative advantage of the Russian agricultural sector increased steadily until 1998, it started to decline after 1998. It is known that, despite Russia being a large country in terms of area, a significant portion of its land and the climate conditions are not suitable for agriculture. A similar decline, though not as steep as in the agricultural sector, has also been experienced in the industrial sector. It is thought that factors such as the decline in world prices of oil and minerals (which are main export products of Russia), the effects of the economic crisis experienced in Russia in

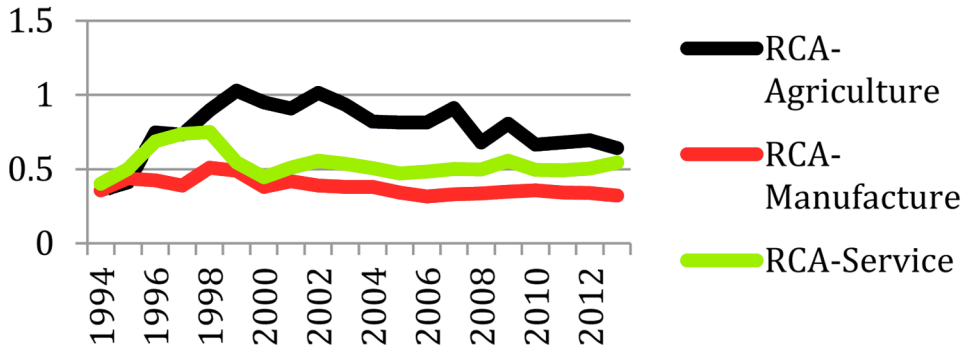
Figure 2. Comparative advantage of major sectors in Russia



1998, and disrupted investor confidence in developing markets due to crises in Asian have played a role in the decrease of Russia's comparative advantages (ISO-AIA, 2010).

In addition, Russia has a structure based on industrial infrastructure and energy, inherited from the USSR, which focuses primarily on the technologically underdeveloped and low-added-value defense and processing sectors. Even in fields such as aerospace and aviation, where Russia has competitive advantages in terms of technology, production rates have decreased due to lack of investment and loss of labor capital (DEİK, 2012). Moreover, it can be said the disappearance of the subsidies that remained from the Soviet era has further weakened the competitiveness of the manufacturers in the international arena.

With the impact of the 1998 crisis, significant declines have also been experienced in the comparative advantage of the services sector in Russia. The fact that the potential of areas such as tourism, transportation, telecommunications, and banking, which have an important place in the services sector, are not being completely utilized (e.g., inability to make the necessary presentations in tourism) hinders the export of services, which is kept at a low level and prevents the acquisition of comparative advantages. Table 4 shows that there is no comparative advantage in any of the major sectors in Russia and that its competitiveness in foreign trade is weak.

India

As seen in Figure 3, among the BRIC countries, the most distinguishable transformation of sectoral advantages has been experienced by India. Since 1994, while its comparative advantages supporting the competitiveness of its agricultural and manufacturing sectors in foreign trade have decreased, the service sector has increased its advantages. It is known that the Indian economy has two different structures. On one side, there is the service sector, which directs the most qualified labor of the middle class

Table 4. Competitiveness of Russia in major sectors

Sectors	Current RCA Index	Current Situation
Agriculture	0.64	Without
Manufacturing	0.32	Without
Services	0.54	Without

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and possesses global competitiveness based on knowledge; on the other side, there is the agricultural sector, which mostly employs less-educated labor, is affected by climatic situations, and is dependent on precipitation (Öz, 2007). Although the manufacturing sector is traditionally inadequate due to poor quality goods, this situation has begun to change in the recent years.

Unlike other East Asian countries, labor shifting from agriculture to other sectors is being experienced much more slowly in India. Since 2000, the annual growth of the agricultural sector has been realized at a rate as low as 2%. This was a period in which the competitiveness of the Indian agricultural sector had begun to decline. The increase in food prices in 2008 highlighted the necessity of making further investment in the sector in order to ensure food sufficiency. As a result of the investments made, a period of increased competitiveness in the agricultural sector has been entered.

The service sector that includes trade, tourism, banking, transport and communications activities has rapidly grown in India in recent years. The information technology sector, including telecommunications and software fields, is the sector that has shown the greatest development. India is one of the world's leading countries in the field of software. It is known that a total of 5,000 companies, a total of 60% of which are domestic ones, operate in the sector which has been structured as export-oriented. However, Table 4 shows that although the services sector has been sophisticated in India, it is apparent the highest competitiveness has already been reached in agriculture.

China

China is distinctly important, showing as it does the highest growth among the BRIC countries. Especially in the 1990s, with the emphasis placed on industry, the development of this sector has accelerated and

Figure 3. Comparative advantage of major sectors in India

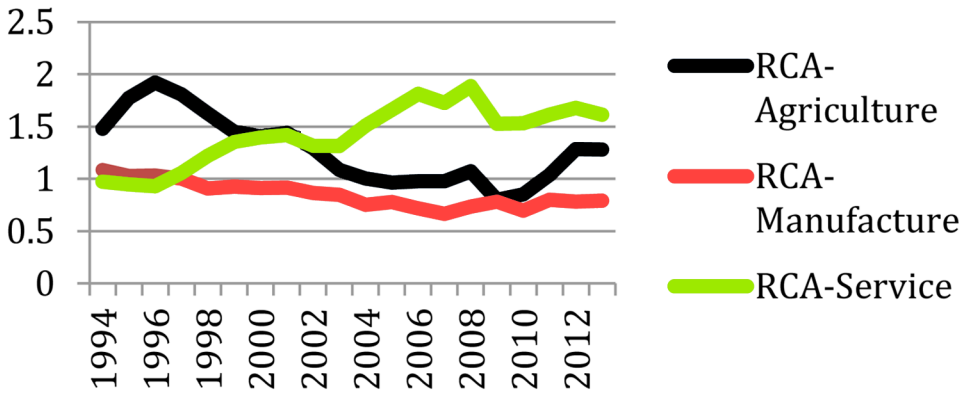


Table 5. Competitiveness of India in major sectors

Sectors	Current RCA Index	Current Situation
Agriculture	1.27	Weak
Manufacturing	0.79	Without
Services	1.61	Weak

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the Chinese economy has reached competence in many industrial fields. Modern metallurgy, mining and energy equipment, aircraft construction, automobile manufacturing, large machinery parts, castings, the aerospace industry, large energy circuits, electronics, communications equipment, and measuring tools are considered to be the major fields in which the Chinese economy has recently been operating (Öz, 2006).

These developments have been triggering the development of a comparative advantage for China in the industrial sector. The trend of the increasing comparative advantages of China in the manufacturing sector, as shown in Figure 4 and Table 6, can be accepted as a further indication of development in the manufacturing sector. However, the urbanization rate in the country has reached 52%, leading to suppressed income growth in rural areas as compared with the cities. As this is the case, comparative advantages in the agricultural sector and competitiveness there have been steadily declining.

However, while global economic integration and technological developments are causing an increase in the trade of services, the fact that international transactions, formerly impossible or prohibitively expensive, have become cheaper has provided possibilities for activities such as tourism, transportation, and banking, which are within the scope of the services sector, to be produced and sold by China as well. However, it is considered that that the infrastructure problems of the services sector and too much importance given to the industrial sector in the current situation represent obstacles to the achievement of competitiveness and the adequate utilization of the potential of the services sector.

Turkey

The state of Turkey's comparative advantage and competitiveness in the major sectors has shown a different development with regard to the BRIC countries. Today, the fact that the levels of competitiveness

Figure 4. Comparative advantage of major sectors in China

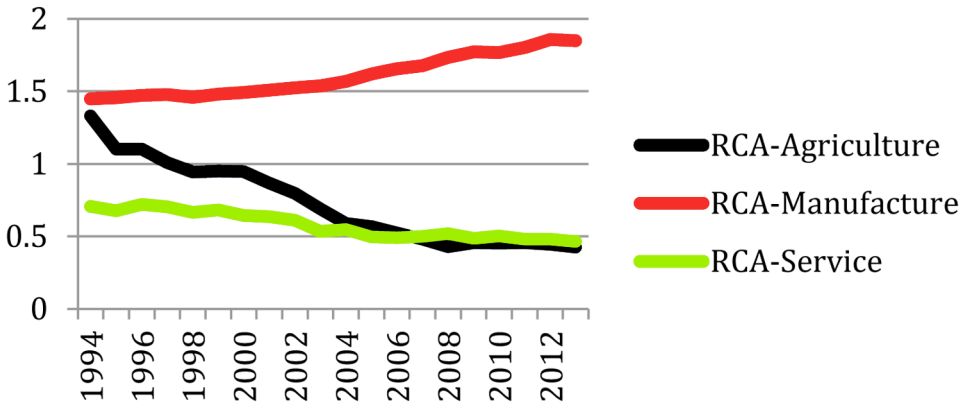

Table 6. Competitiveness of China in major sectors

Sectors	Current RCA Index	Current Situation
Agriculture	0.42	Without
Manufacturing	1.84	Weak
Services	0.46	Without

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of Turkey in the major sectors are quite similar is noteworthy. In Figure 5, while the services sector had the highest competitiveness at beginning of the 1990s, the agricultural and industrial sectors followed it. A process has occurred over the past twenty years in which the competitiveness of the services sector has been weakening and competitiveness of the agricultural and industrial sectors has been increasing, thereby closing the gaps among them, and the competitiveness levels of the three sectors have become too close to one another (Meçik & Afşar, 2014).

The agricultural sector in Turkey, which has great potential, has been making various contributions to the development of the country and to achieving competitiveness. Most important among those contributions are providing raw materials for industry, creating demand for industrial products, and contributing to GDP and exports. The agriculture-based industries in the manufacturing industry in Turkey hold a rather important position in the economy. The reason is that most of the raw material requirements of industrial enterprises based on agriculture are fulfilled from domestic resources. Indeed, the share of the agricultural industry in the number of workplaces in the manufacturing industry is around 50% (Demirbaş & Tosun, 2005). Thus, it can be stated that the agricultural sector has an important role in the development of the industrial sector.

However, technological developments and state subsidies have played an important role in development of industry and have been effective in obtaining competitiveness for that sector in the foreign markets. In addition, the development of the industrial sector has played a major role in the development of the services sector. Currently, the share of the services sector in Turkey is at the level of approximately 65%. However, when the competitiveness of the services sector is considered, a significant decline is evident after the first decade of the 2000s. Two of the biggest causes of this situation are that the supply of qualified labor has remained inadequate and that the number of enterprises in the services sector has increased.

In Table 7, it can be seen that Turkey's competitiveness in all major sectors is not very strong. The services sector, which was moderately competitive at the beginning of the 1990s, has begun to lose power due the effects of the labor in this sector shifting to the industrial sector. Additionally, the competitiveness of the industrial sector has increasingly scaled up and begun to take a significant share of foreign trade. The sectors which carry out the production of industrial products that are involved in trade in Turkey are the sectors that largely determine Turkey's role in the global economy.

While production grew in traditional sectors such as textiles, leather, tobacco, and food, Turkey had remained behind in sectors with higher technology levels, such as automotive, office machinery, and electrical machinery; however, Turkey has recently begun to establish competitive advantages in

Figure 5. Comparative advantage of major sectors in Turkey

Table 7. Competitiveness of Turkey in major sectors

Sectors	Current RCA Index	Current Situation
Agriculture	1.10	Weak
Manufacturing	1.07	Weak
Services	1.10	Weak

some of these sectors. (Acar, 2008, pp. 33–34). The inclusion of the East Asian countries in the global competitive race has complicated the situation of sectors which are both exporters and producers for the domestic market. The cheap labor advantage these nations possess often makes the situation of the labor-intensive sectors difficult.

Similar to the industrial sector, the services sector has also been experiencing a comprehensive transformation. In the transformation of the services sector, it is noteworthy that shops that conduct their activities without registrations are ceding their locations to organized retail stores which conduct all of their activities with registrations. This situation has significant ramifications for the logistics sector which is a sub-branch of the services sector.

The moderate competitiveness of the agricultural sector at the beginning of the 2000s has gapped down to a level of weak competitiveness over the past decade. When compared with the BRIC countries, Turkey is a developing country that has competitiveness at the same time, although it is low in all major sectors. However, the structural transformation process which Turkey is passing through carries with it a number of risks. It is thought that the country's inability to avoid an account deficit and unemployment problems is associated with this structural transformation. In this regard, strategies should be developed at the sector level to promote the continuation of the structural transformation without hindering economic development.

The Comparative Status of the Countries on the Basis of the Main Sectors

It has been determined that the BRIC countries and Turkey, which are evaluated as belonging to the same group of candidate countries with the potential to become the strongest actors in the world in the near future due to both their rapidly developing markets and increasingly growing production potential, do not have very similar structures in terms of competitiveness. This becomes clear when the competitiveness of the BRIC countries and Turkey is evaluated on the basis of major sectors. In the agricultural sector, Brazil, Turkey, and India have comparative advantage, but only Brazil has high competitiveness. The countries having comparative advantage in the industrial sector are China and Turkey. The comparative advantage of China and Turkey in the industrial sector is not supported by high competitiveness. If an assessment is made on the basis of the services sector, India and Turkey, from among the five countries subjected to investigation, are the two that have achieved comparative advantage. These countries are also the ones whose services sector comprises the largest share of GDP after Brazil. However, as observed in the other sectors, high competitiveness could not be achieved based on the comparative advantage of India and Turkey in the services sector.

When the transformations in the sectoral structure are examined, it must be stated that the most important transformations have been realized in the services sector. While global economic integration and technological developments have caused the trade of services to increase, the fact that international

transactions which were formerly impossible or expensive have become cheaper, in addition to the increase in population and the mobility of transactions, has enabled the activities covered by the services sector to be produced and sold by many companies.

The developing countries are trying to avoid the problem of instability in their export incomes by diversifying their goods and markets and by aiming for the export of goods having higher domestic added value and based on more advanced technology. An alternative way of increasing foreign currency incomes

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and stabilizing conditions is to increase the trade of services. However, this strategy is in the export of goods, as the developing countries do not have the power to compete with the developed countries in the trade of services as well (Değer, 2006). Nevertheless, developing countries such as Turkey and the BRIC countries, which have advantages in terms of historical and natural beauty, have an opportunity to mitigate the dimensions of the problem with the foreign currency incomes they obtain from tourism. Although tourism is not the only effective sector for achieving economic growth in developing countries, the developments experienced in this sector have been able to provide new economic opportunities for some countries.

CONCLUSION

According to the results of this study, which has attempted to measure the competitiveness of the agricultural, industrial, and services sectors in the foreign trade of Turkey and the BRIC countries as well as to make a comparative analysis, Turkey and the BRIC countries do not have very similar structures in terms of sectoral competitiveness. For example, although the countries have obtained comparative advantage in some sectors, Brazil does not have any significant competitiveness except for its high competitiveness in the agricultural sector.

Of all the economies subjected to analysis in this investigation, Turkey is in the position of being the only country that has achieved similar competitiveness in all sectors. The RCA index for Turkey was found to be at the same level in the three major sectors, each with a ratio of approximately 1.10. Turkey is expected to build on the competitiveness that it has achieved with new investments to reach higher competitiveness.

Brazil has high competitiveness only in the agricultural sector, in which its RCA index is 4.22. The natural resources and the fertile agricultural areas that Brazil possesses are considered to be effective in this.

Russia, possibly due both to the fact that it has not made adequate use of the industrial infrastructure left to it by the Soviet Union and that is has suffered the effects of an economic crisis, has not achieved competitiveness in the foreign trade of any sector. Russia should seek to regain its qualified labor pool and to recapture its competitiveness in foreign trade by encouraging investment in other sectors in addition to the defense sector.

India has competitiveness in the agricultural and services sectors. The competitiveness of these two sectors in foreign trade might be associated with two developments in that country. While on one side India has a modern and knowledge-based services sector that directs the most qualified labor of the middle class, on the other side, an agricultural sector that employs less-educated labor, is affected by the climatic conditions, and depends on precipitation has developed. These developments have facilitated the increase in the competitiveness of the two sectors.

China is of distinct importance because it is the country with the greatest economic growth. Especially in 1990s, the development of the industrial sector accelerated and the focus given to industry in China allowed the Chinese economy to achieve competence in many industrial fields. The development of the industrial sector can also be seen from the fact that the RCA index in the industrial sector of China is 1.84. According to its RCA indexes, industry is the only sector in which China is competitive. It should be immediately noted that China's competitiveness in that sector is not high. However, as the country

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

that has achieved the greatest economic growth, the competitiveness of the Chinese industrial sector in foreign trade is expected to be higher in the coming years.

Although Turkey and the BRIC countries do not have a similar structure in terms of sectoral competitiveness, when the transformations in the sectoral structure are examined, it is evident the most important transformations have occurred in the services sector. While global economic integration and technological developments have caused the trade of services to increase, the fact that international transactions that were formerly impossible or expensive have become cheaper along with the increase in population and in the mobility of transactions has enabled the activities covered by the services sector to be produced and sold by many companies.

While the welfare gain and high income levels associated with the development of the manufacturing industry in the developed countries have resulted in an increase in the importance of the services sector, the effects of activities such as banking, marketing, distribution, communications, and tourism, which are representative parts of the sector, have become much more obvious. Today, in many countries, the share of the services sector in national income and employment is more than the share of other sectors.

The services sector, the relative weight of which has clearly increased during the economic development process, has increased even more in significance and entered into a structural transformation process along with increasing globalization and in parallel with the developing technology of recent years. In this process, the increase of the share of sectors whose share in foreign trade was formerly scant, the emergence of new services sectors such as software, and the increase of the share that the services sector receives directly from foreign investments have been matters of concern. The fact that the developed countries have purposely shifted their investments in the services sector to developing countries, where educated and cheap labor is available, and that they have met their need for services through these countries has been the matter of discussion and debate.

Chapter 77
Sustainability, Environmental Sustainability, and Sustainable Tourism:
Advanced Issues and Implications

Kijpokin Kasemsap
Suan Sunandha Rajabhat University, Thailand

ABSTRACT

This chapter reveals the overview of sustainability; the overview of environmental sustainability; environmental sustainability and climate change; environmental sustainability, water resources, and energy consumption; and the overview of sustainable tourism. Sustainability is the important issue that attempts to bridge social science with civic engineering and environmental science with the technology of the future. Environmental sustainability is important because it ensures people have water and resources, and adopting its practices protects the environment and human health. Sustainable tourism is a growing segment of the global tourism industry that makes the positive contributions to the environmental, socio-cultural, and economic well-being of destinations and local communities around the world. Sustainability, environmental sustainability, and sustainable tourism are rooted in three issues that are considerably linked to fossil fuel depletion, climate change due to carbon dioxide emissions, and the increasing costs of energy and water.

INTRODUCTION

Sustainability is the business strategy that drives the long-term corporate growth and profitability by mandating the inclusion of environmental and social issues in the business model (Kasemsap, 2017a) and requires the transformation in the environmental inputs used for products and processes (da Ronch, di Maria, & Micelli, 2013). Sustainable consumption is an integral element of sustainable development and an issue of paramount importance, increasingly recognized by the international community (Kasemsap, 2017b). Sustainability integrates the environmental, economic, and societal aspects (Grigoroudis,

Kouikoglou, & Phillis, 2012) regarding the triple bottom line (TBL) (Tullberg, 2012). The topic of sustainability has moved from the borders of supply chain management (SCM) research to the mainstream and is an area of significant research activity (Pagell & Shevchenko, 2014).

Sustainability concerns may exist when current generations' preferences for environmental benefits occurring in the very long term are equal or higher with respect to those for benefits occurring in the long term (Faccioli, Hanley, Torres, & Font, 2016). Environmental sustainability is an important issue for many individuals, businesses, and governments (Shakir, 2011) and is the predominant prerequisite for social sustainability (Soliman, 2015). For all types of businesses, environmental sustainability is of great concern (Evangelista, Huge-Brodin, Isaksson, & Sweeney, 2014) and drives companies to extend their green effort across their supply chain (Wu, Wu, Chen, & Goh, 2014) toward green supply chain management (GSCM) and sustainable supply chain management (SSCM) (Seuring & Muller, 2008).

With the effects of climate change becoming an increasing concern, the tourism sector must urgently respond by mitigating its emissions and adapting tourism businesses to the changing climate conditions (Michailidou, Vlachokostas, & Moussiopoulos, 2016). Stakeholders' and customers' pressure on sustainability has pushed many companies to transform the environmental sustainability concepts into the business practices (Kumar, 2016). Stakeholders understand the stakes of sustainable tourism as either the lost opportunities for the environmental development due to the failed regulation of a natural resource, or as deteriorating the social relations due to the failed maintenance of socio-cultural values (Hultman & Sawe, 2016).

This chapter aims to bridge the gap in the literature on the thorough literature consolidation of sustainability, environmental sustainability, and sustainable tourism. The extensive literature provides a contribution to practitioners and researchers in order to maximize the business impact of sustainability, environmental sustainability, and sustainable tourism in sustainable settings.

Background

Mounting pressure for sustainable business practices has led to a greatly increased focus on highlighting sustainability drivers throughout the supply chain (Foerstl, Azadegan, Leppelt, & Hartmann, 2015). Due to the recognition of environmental issues in the traditional activities, organizations need to address the problem of sustainability in their operations (Ahi & Searcy, 2013). Sustainability has the unique issues related to market competition, global limitation of energy, availability of raw material, environmental protection crisis, and increased global population (Bajaj, Jha, & Aggarwal, 2013). Environmental sustainability is the foundation to sustainability in the sense that humanity needs the environment to continuously provide natural resources and to continuously deal with its wastes for humanity to sustain itself (Fitzpatrick, 2016).

Environmental issues attract the concern of global supply chain practitioners (Muduli, Govindan, Barve, & Geng, 2013). Current researchers and practitioners give special attention to environmental issues to achieve business needs (Caniato, Caridi, Crippa, & Moretto, 2011). Sustainability changes the existing practices and creates the management systems (Linton, Klassen, & Jayaraman, 2007). Companies can optimize their supply chains by integrating risk management and sustainability programs to improve the environmental sustainability (Kara & Fırat, 2016). The company's perceptions about factors affecting the decisions for the implementation of sustainable practices shares a relationship with the company's expectations while applying sustainable initiatives (Manikas, Ieromonachou, & Bochtis, 2014).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Tourism is the marketing of the enjoyable perspective and other features of a travel destination, and provision of facilities and services for the pleasure travelers (Kasemsap, 2015). Tourism and hospitality industry is one of the most important industries in the modern business world (Kasemsap, 2016a). Recent phenomena, such as climate change, a hypermobile society, and the shared economy (Dredge & Gyimothy, 2015), significantly add the new layers of complexity to the sustainable tourism. A number of recent discussions of tourism and sustainability have emphasized the problems, gaps, and deficiencies in sustainable tourism (Bramwell & Lane, 2013) and have addressed to a limited capability to find the suitable solutions which are acceptable to the commercial market and which adequately respond to sustainability challenges toward sustainable tourism.

ASPECTS OF SUSTAINABILITY, ENVIRONMENTAL SUSTAINABILITY, AND SUSTAINABLE TOURISM

This section emphasizes the overview of sustainability; the overview of environmental sustainability; environmental sustainability and climate change; environmental sustainability, water resources, and energy consumption; and the overview of sustainable tourism.

Overview of Sustainability

Sustainability is an evolutionary advancement of developing the management of systems through the enhanced knowledge (Faisal, 2010). Sustainability disclosure is greater for firms with a proactive communication strategy as manifested through press release activity (Herbohn, Walker, & Loo, 2014). Govindan et al. (2014) stated that manufacturing industries effectively implement environmental practices in their existing SCM. It is difficult for firms to achieve a balance between the traditional efficiency-based performance and environmental benefits, which influences green management at the business and functional levels (Mollenkopf, Stolze, Tate, & Ueltschy, 2010).

Lamming et al. (1999) discussed three dimensions of economic, environmental, and social perspectives as the broad elements of sustainable development. Sustainability incorporates the dimensions of corporate social responsibility (CSR) that include TBL factors (Seuring & Muller, 2008) and ethics (Vachon & Mao, 2008). Sustainable development is a major solution for reducing waste by effective resource utilization (Diabat, Kannan, & Mathiyazhagan, 2014). Sustainable development enterprise practically achieves the economic, environmental, and social benefits (Hart & Milstein, 2003). Sustainable development is interpreted to require the improvement in the areas of economic, environmental, and social performances (Searcy, Karapetrovic, & McCartney, 2008). Sustainable development improves industries' environmental performance (Diabat et al., 2014).

Schwarz et al. (2002) stated that putting the concept of sustainable development into operation requires the cost-effective ways to evaluate performance and measure improvement. Issues associated with supply chain governance, standards for sustainable SCM, collaboration with suppliers, performance measurement, and accountability within supply chain are explored in global business (Morali & Searcy, 2013). Proactive green initiatives yield competitiveness, economic benefits, better CSR, and sustainability (Molina-Azorin, Claver-Cortes, Lopez-Gamero, & Tari, 2009). Sustainability factors play the significant role in SCM (Wen, Xu, & Wang, 2013).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Businesses face the new challenges for adopting the good environmental practices (Sezen & Turkkantos, 2013). Hart and Milstein (2003) analyzed the global challenges associated with sustainable development, thus indicating strategies that contribute to a more sustainable world while driving shareholder values. Kuik et al. (2010) indicated that traditional supply chains should develop into SSCM regarding economic, environmental, and social benefits. SSCM can be defined as the integration of economic, environmental, and social practices within the global supply chain that provides green products, excellent services, and accurate information (Xie & Allen, 2013), thus sharing those benefits with all employees, shareholders, and business partners (Kuik et al., 2010).

Overview of Environmental Sustainability

Sustainability has become an important issue because of great concerns about the social, environmental, and economic effects of the increasing population and economic growth, as well as consumption of natural resources (Abereijo, 2016). Environmental sustainability has two major components to it: the sustainability of natural resource utilization and the impact on the environment due to wastes and land utilization (Fitzpatrick, 2016). Identifying the challenges of environmental sustainability in the form of environmental indicators, assessment, and strategies will be a good start for the organizations to be sustainable (Mukherjee, Kamarulzaman, Vijayan, & Vaiappuri, 2016).

Environmental concerns attract the increasing attention in the educational and scientific communities (Dogbey, Quigley, Che, & Hallo, 2014). Environmental collaboration with customers and suppliers based on knowledge sharing can reduce the total environmental impact (Aboelmaged, 2014). In order to enhance the environmental sustainability, organizations need to control their operations and link them with their environmental strategies (Sen, 2016). Sustainable manufacturing strives to produces the products by minimizing the negative environmental impact (Singh, Olugu, & Musa, 2016). Technological changes can be considered as a key driver to help knowledge acquisition on the environmentally sustainable use of information and communication technology (ICT) resources due to various innovations that have positively contributed in the learning process (Bekaroo, Bokhoree, & Pattinson, 2016).

Environmental reporting provides the comprehensive perspective to inform the target groups about the proper environmental strategies and to present the transparent profile (Akkaya, Wolf, & Krcmar, 2011). GSCM is the management that utilizes the green concept by coordinating and maintaining procurement and production process in order to produce, deliver, and reuse the products (Kasemsap, 2016b). Lean supply chain and green supply chain strategies help companies maximize the improvement of Lean Production in operations management regarding environmental sustainability (Kasemsap, 2016c). Green supply chain is capable of increasing corporate value while considering its impacts on all processes of physical distribution, production, and environment (Kasemsap, 2016d).

Environmental Sustainability and Climate Change

Many environmental policies typically relate to an increasing number of time-persistent environmental problems (e.g., climate change, nuclear waste, and groundwater pollution) which arise because of the accumulation in the environment of the long-lasting pollutants interacting in a complex way with ecosystem processes' dynamics (Underdal, 2010). The world's climate is changing, and the changes have an enormous impact on people, ecosystems, and energy use (Londhe, 2016). Climate change is one of the greatest threats to modern civilization and is a great challenge to economic development in the 21st

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

century (Dinda, 2016). Climate plays an important role in destination choice and the timing of travel (Scott & Lemieux, 2010). For example, ski tourism depends on snow conditions (Shih, Nicholls, & Holecek, 2009).

Understanding the climate change-human health interaction is imperative for following a pathway of sustainable development (Roy, Ghosh, Mukhopadhyay, & Ghosh, 2016). The effects of climate change increase the renewable projects developed by municipalities and public private sectors toward achieving environmental sustainability (Bostancı, 2015). Environmental vulnerability assessment studies increase in the field of climate change impact assessment and in the areas of hazard impact analysis, food insecurity, poverty, and development economics (Senapati & Gupta, 2016).

Environmental Sustainability, Water Resources, and Energy Consumption

Climate change poses the uncertainties to the management of water resources (Kumar, 2016). The impact on aquatic life due to the inadequate environmental flow, reduction in availability of water in the nearby natural water resources, and the increase in the rate of deforestation are the significant environmental impacts in the comparatively longer run (Kumar & Katoch, 2016). Because water is essential to life, addressing water pollution and environmental sustainability issues is of great concern to environmentalists and public health specialists (McKeown & Bugyi, 2016).

For decades, the issue of energy utilization has been a subject of global discourse because of its role in technology development and its negative impact on environment across countries (Fruergaard, Astrup, & Ekvall, 2009). Government needs to intensify the educational efforts toward enlightening people about the requirement for the sustainable utilization of energy resources (Ifegbesan, Rampedi, & Annegarn, 2016). In the context of current global energy supply, biofuels have the limited supply capability and cannot supply the major portion of current global energy demand, however they can replace the liquid fossil fuels with the second and the third-generation biofuels (Murphy, Woods, Black, & McManus, 2011).

Overview of Sustainable Tourism

Changes in sustainable tourism and the model of sustainable tourism, in the varying economic and political situations, have led to the appearance of new directions in sustainable tourism policy, which affect the entire sector (Torres-Delgado & Palomeque, 2012). Tourism is the climate-sensitive economic sector, considering that climate change affects a number of key factors in sustainable tourism (Michailidou et al., 2016). Sustainability is recognized as an important tool for handling the negative impacts of tourism and attaining its long-term environmental viability (Liu, 2003) and has become the important issue for tourism, environmental management, and environmental studies (Lee & Hsieh, 2016).

Sustainable tourism is the concept of visiting a place as a tourist and trying to make a positive impact on the environment, society, and economy (Kasemsap, 2016e). Sustainable tourism can be applied to all forms of tourism (Akrivos, Reklitis, & Theodoroyiani, 2014) and is highly dependent on the ability to increase the financial benefits, achieved by all participants in the tourism sector, including the ability to maintain the social, cultural, and environmental heritage (Janusz & Bajdor, 2013). Nature destruction is the important threat for sustainable tourism in a destination, therefore tourism development must include environment as part of tourism resources required to be developed in terms of quality and variety (Sutawa, 2012). Sustainable tourism requires a profitability trade-off where the additional costs related to sustainability do not result in the increased economic returns (Moeller, Dolnicar, & Leisch, 2011).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Tourism culture can be recognized as a precedent and antecedent of more sustainable tourism development (Canavan, 2016). Sustainable travelers are a travel market to be considered within the tourism marketing and business world (Nickerson, Jorgenson, & Boley, 2016). While the intrinsic benefits of sustainable tourism to the environment, culture, and residents of tourism destinations has been heavily researched (Boley & McGehee, 2014), the discussion of the economic benefits associated with sustainable tourism has been more conceptual in nature (Hassan, 2000). Most energy utilization in sustainable tourism is based on fossil fuels and the sector continues to emit the increasing levels of greenhouse gas (GHG) emissions (Hall, 2013). Current trends in tourism stand in contrast to a global policy momentum that aims for the long-term transformation of the economy to mitigate the GHG emissions and increase the resource efficiency (Lipman, de Lacy, Vorster, Hawkins, & Jiang, 2012).

The green economy paradigm presents the new situation of change for sustainable tourism (Law, de Lacy, Lipman, & Jiang, 2016). A community that utilizes tourism as an alternative method of strengthening its economic development must develop sustainable tourism to meet the demands of its residents (Puczkó & Rátz, 2000). The development of sustainable tourism is difficult without the participation of the community residents (Gursoy & Rutherford, 2004). Factors that influence the local community support for sustainable tourism development have been extensively studied by tourism scholars (Lee, 2013). These factors, such as attitudes (Lepp, 2008), perceived effects (Dyer, Gursoy, Sharma, & Carter, 2007), and perceived benefits (Nunkoo & Ramkissoon, 2011), may affect the residents' support for sustainable tourism development.

The expansion of the tourism industry encourages stakeholders to invest in the sector without considering the possible side-effects of such investments on the environment and on social development (Sorensson & von Friedrichs, 2013). The role of stakeholders in the implementation of sustainable tourism is becoming more prominent in both academia and industry (Waligo, Clarke, & Hawkins, 2013). Stakeholders have the potential impact on the sustainable tourism development initiatives (Hall, 2007) toward managing tourism more sustainably and considering different sustainable tourism perspectives (Dodds, 2007). Stakeholder collaboration represents the widely accepted approach to solving the problems associated with a lack of understanding and few shared common goals among many stakeholders involved in sustainable tourism development (Fyall & Garrod, 2005).

Questions of crisis, the environment, and tourism are connected to the wider discussion about sustainability and sustainable tourism (Ghaderi & Henderson, 2013). A common practice of sustainable tourism is to utilize an indicator system for designing and implementing tourism models that focuses on the sustainability approach (Lozano-Oyola, Blancas, González, & Caballero, 2012), toward managing crises (de Sausmarez, 2007), managing community tourism (Choi & Sirakaya, 2006), assessing tourism destinations (Pérez, Guerrero, González, Pérez, & Caballero, 2013), measuring tourism practices (Blackstock, White, McCrum, Scott, & Hunter, 2008), and selecting criteria for policy implementation and scientific recognition (Tanguay, Rajaonson, & Therrien, 2013).

Making tourism sustainable is not easy, mainly because the imprecise nature of the concept of sustainability makes it difficult to apply (Torres-Delgado & Palomeque, 2014). Regarding sustainable tourism, the scientific community has considered the impacts of climate change on tourism on global scale (Amelung, Nicholls, & Viner, 2007), country scale (Hamilton & Tol, 2007), and destination scale, such as coastal areas (Moreno & Becken, 2009), islands (Becken, 2005), ski areas (Scott, McBoyle, Minogue, & Mills, 2006), and parks (Jones & Scott, 2006).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of sustainability, environmental sustainability, and sustainable tourism will provide the potential opportunities for future research. Clean technology aims to reduce the reliance on the non-renewable resources and to enhance the environmental sustainability. The significant issues concerning clean technology include sourcing for the energy needed to maintain a hardware environment, including servers, workstations, and other integral parts of an organization's technological infrastructure. Green technology encompasses the evolving group of both methods and materials, from techniques for generating energy to non-toxic cleaning products. Green technology helps reduce the adverse effects on the environment toward improving productivity, efficiency, and operational performance of the technology itself. An examination of linkages among sustainability, environmental sustainability, sustainable tourism, clean technology, and green technology would seem to be viable for future research efforts.

CONCLUSION

This chapter highlighted the overview of sustainability; the overview of environmental sustainability; environmental sustainability and climate change; environmental sustainability, water resources, and energy consumption; and the overview of sustainable tourism. Sustainability is one the newest degree subjects that attempts to bridge social science with civic engineering and environmental science with the technology of the future. As a set of goals sustainability describes the desired conditions of the environment and the ability of humans to receive benefits directly and indirectly from it, in the present as well as in the future. As practices and behaviors, sustainability describes human actions that support and enhance the human well-being derived through interaction with the environment, and which support the ability of human society to interact with the environment in ways that discourage the reduced benefits.

Environmental sustainability is important because it ensures people have water and resources, and adopting its practices protects the environment and human health. The doctrine of sustainability aims to maintain the conditions in which nature and humans can survive by appropriately utilizing the natural components of the environment. Sustainability, environmental sustainability, and sustainable tourism are rooted in three issues that are considerably linked to fossil fuel depletion, climate change due to carbon dioxide emissions, and the increasing costs of energy and water.

Sustainable tourism is a growing segment of the global tourism industry that makes the positive contributions to the environmental, socio-cultural, and economic well-being of destinations and local communities around the world. Offering market-linked long-term solutions, ecotourism provides effective economic incentives for conserving and enhancing bio-cultural diversity and helps protect the natural and cultural heritage of the beautiful planet. The economic, social, and environmental aspects of sustainable tourism development must include the interests of all stakeholders including indigenous people, local communities, visitors, industry, and government.

KEY TERMS AND DEFINITIONS

Climate Change: The changes in the world's weather, in particular the fact that it is believed to be getting warmer as a result of human activity increasing the level of carbon dioxide in the atmosphere.

Energy Consumption: The amount of energy consumed in a process or by an organization.

Stakeholder: A person or group of people who own a share in a business.

Sustainability: The idea that products and services should be produced in ways that do not use resources that cannot be replaced and that do not damage the environment.

Sustainable Development: The economic development characterized by low growth rate, absence of pollution, and greatly diminished environmental impact.

Sustainable Tourism: The tourism committed to generating a low impact on the surrounding environment and community while generating income for the local economy and aiding social cohesion.

Triple Bottom Line: The economic, social, and environmental effects of a company's policies and actions that determine its viability as a sustainable organization.

Chapter 78
Are GM Crops the Answer to Africa's Critical Food Security Status?
Learning From the Experiences of Developing Countries

Nira Ramachandran
Independent Researcher, India

ABSTRACT

Despite unprecedented technological breakthroughs and rising incomes, the most basic human requirement–food security remains out of reach of many. The countries of Africa are the worst affected, and consistently score lowest on the Global Hunger Index. The downside of technological advance and increasing urbanisation is the decrease in cultivable land and water availability exacerbated by climatic unpredictability. While concerted efforts are on to control the crisis, it is time to take positive action and capture technology to boost food security. Genetically Modified (GM) crops engineered to be drought/flood resistant, reduce pesticide requirements or provide vitamins open up tremendous possibilities for enhancing food and nutrition security and counteracting negative environmental impacts. This paper reviews the current status of GM crops in Africa, the scope for expansion, possible impacts on food security and the validity of existing concerns about bio-safety and farmers' needs in the light of developing country experience.

INTRODUCTION

One of the major challenges that Africa faces today is that of ensuring food security for its population. Over the last few decades, the continent has witnessed severe food shortages, even starvation in one country or the other. This may be attributed to a variety of causes—environmental, economic, strife-related or as a result of pandemics like HIV/AIDS sweeping the continent. The continued heavy dependence on food-aid and cheap food imports also tend to undermine local agriculture and leaves the consumer

unprotected and completely vulnerable to global price fluctuations. Food Aid dates back to the late 1950s, but the number of food emergencies have tripled since the mid-1980s (MDG Report, 2013). Climate change which brings in its wake unpredictability of temperature and rainfall as well as an increase in severe climatic events is further exacerbating the situation. In this backdrop, it is encouraging to note that a number of countries in sub-Saharan Africa have improved their food security status in the new millennium. While the decade of the 1990s witnessed extremely slow progress in Africa as against South Asia, there has been more rapid improvement, from 2000 onwards. In fact, the Global Hunger Index (GHI) 2014 finds sub-Saharan Africa outpacing South Asia. The six countries which have made substantive progress reducing their GHI scores by over 50% since 1990 are Angola, Ethiopia, Ghana, Malawi, Niger and Rwanda. Yet even today, 12 countries have GHI scores in the "alarming" or "extremely alarming" categories: Central African Republic, Ethiopia, Comoros, Mozambique, Niger, Sudan, Zambia, Sierra Leone, Madagascar (GHI scores: 20-29.9), and Burundi and Eritrea (GHI scores: 30-39.9) (GHI, 2014). The Global Hunger Index is a composite of three hunger indicators: the proportion of undernourished population, the proportion of underweight children below the age of 5 years and the infant mortality rate, which effectively represent the food security status of a country. As the GHI scores in sub-Saharan Africa are heavily weighted by the proportion of undernourished population unlike in the case of South Asia, where underweight children tend to have more impact on the score, it is not surprising to find that in these countries (with alarming or extremely alarming scores), about one-third of the population does not consume the minimum calorie requirement. In Burundi and Comoros this proportion reaches as high as 65 and 67%, respectively.

The fact that Africa is endowed with vast and underutilised natural resources like huge tracts of cultivable land, water and temperatures suitable for cultivation, makes this chronic shortfall in food production a story of unused potential. With reference to potential land area alone, the FAO (2009) estimates that the unutilised rain-fed area suitable for cultivation could be as much as 700 million ha. It is widely accepted that food shortages in the African context result from the fact that 90% of the cultivators are small and marginal farmers, almost 60% of cultivated area is un-irrigated, and the practice of cultivating a large variety of crops on small farms does not lend itself to the adoption of green revolution technologies, which have been suggested as being more suited to large scale monocultures. In addition, poverty, illiteracy and weak infrastructure preclude access to markets or improved inputs. The Millennium Development Goals Report (2013) states:

In fact, the challenges of the past have grown and become more complex, exacerbating food insecurity. Africa's agriculture is underdeveloped, and people have begun abandoning it for better livelihoods. The effects of climate change are more pronounced and Africa's population is increasing so fast that countries might be unable to produce all the food they need.

An estimated 232 million undernourished people live in Africa (FAO, 2015) of whom almost 95% are in the sub-Saharan region alone. With the population of this region projected to reach 1.5–2 billion by 2050 (FAO, 2009), it becomes imperative to seek out viable solutions to the food security issue. This paper focuses on genetically modified crops and their potential to contribute to a food secure Africa.

Genetically Modified Crops: A Brief History

The selective breeding of plants dates back to the beginnings of settled agriculture. Improved varieties bred for higher yields, changes in colour or flavour or resistance to adverse climatic conditions underlie the development of agriculture in every country and form the basis of indigenous farming knowhow which is handed down through generations of farmers. Agricultural products most in demand in the global market like India's basmati rice, Ghana's cocoa or Hawaii's kona coffee are all the products of selective breeding practices over generations of farmers. Yet, when it comes to the question of genetic modification, there is instant alarm and stubborn resistance to such interventions, which could provide a relatively quicker avenue to improving food security and livelihoods in countries with low availability of food and high levels of malnutrition.

Genetic modification consists of the introduction of genes from a crop with the desired characteristics into the living DNA of another with a view to improving the latter variety. China was the first country to produce genetically modified (GM) crops for the market in the form of a virus resistant tobacco and a GM tomato somewhere in the late 1980s to the early 1990s. Better known is the case of the United States (US), where the first genetically modified food crop was brought into commercial use in 1994 with the *Flavrsavr* transgenic tomato being brought to supermarket shelves in the US. This variety of slow ripening tomato with a long-shelf-life received a positive response with consumers even paying a premium price for the product (Murnaghan, 2014). This breakthrough was quickly followed by the release of three more crops in 1995; The Bt potato, the first pesticide producing crop, Bt corn with insect resistant qualities and herbicide resistant Roundup Ready Soybeans. By 1996, all three crops were also approved in the UK and the European Union (GM Education, 2014).

In 1997, however, the European Commission EC novel Foods Regulation (258/97) came into effect mandating safety assessment for novel and GM foods before release into the market and by 1998 the first GM labelling rules were introduced so that consumers were informed about the use of GM ingredients in the food they were purchasing. These measures signalled the beginning of the disquiet with regard to the possible negative impacts of GM produce (GM Education, 2014).

Yet, the growth of GM crops during the same period was phenomenal. From 1.6 million hectares in 1996, these crops expanded to cover as much as 35 million hectares by 1999. The transfer of GM technology from the developed to the developing world was rapid and fifty two percent of the total area under GM crops is now in developing countries. GM crops cover a total of 148 million hectares (2010) in 29 countries across the world. This near doubling of growth makes GM the fastest crop technology to be adopted in the history of modern agriculture (Adenle, 2011). The largest producers in the developing world are Argentina, Brazil, China and India with Bt cotton dominating GM crop acreage in the Asian and African countries, and herbicide resistant soybean followed by insect resistant corn leading in the countries of Latin America (FAO, 2012).

Despite the growing unease with regard to the environmental impacts of GM crops and the intense debate on the unequal socio-economic benefits of this technology, which are likely to further accentuate the gaps between large and small farmers, as recently as 2010, the European Commission approved *Amflora*, a genetically modified potato for industrial use in paper making and adhesives in the European Union. The EC known for its strong resistance to GM crops also permits the import, but not the cultivation of GM maize for food and feed use (GM Education, 2014).

Do GM Crops Benefit the Small Farmer?

The main argument put forward by opponents of GM crops is that the technology was developed for large scale monocultures quite unsuited to developing countries where agriculture is dominated by small and marginal landholders. The pro-GM camp quotes significant increases in productivity, reduced pesticide costs and impressive growth of farm incomes in both developed and developing countries (Brookes and Barfoot, 2013; Bennett et al. 2004; Adenle, 2011; Morse, Bennet and Ismael, 2013; and Juma, 2014). The opponents, on the other hand, cite falling yields following the initial spurt, the emergence of new pests resistant to even the GM crops and rising costs of inputs for these crops making them unsustainable for the smallholder (Amir, 2014; Kuyek, 2002; Pschorn-Strauss, 2005; Witt, Patel and Schnurr, 2006; and Belay and Guri, 2013). This section aims to adopt an objective approach to the issue by basing its conclusions on available data, rather than rhetoric.

While it is difficult to obtain data on differential impacts of GM crops on large and small farmers, it is possible to compare variations in farm income from GM crops between developed and developing countries. Assuming that over two-thirds of farmers in developing countries have small holdings, this could provide a rough estimate of the extent to which small farmers can benefit from adopting GM technologies. Currently about 52% of the global area under GM crops lies in the developing countries of Asia, Africa and Latin America.

Comparing the economic benefits of GM crops to farmers in developed and developing countries in 2011 (Table 1), it is evident that a little over half (51.2%) of farm income benefits were earned by farmers in developing countries. The largest share of these income gains has been from GM IR (Insect Resistant) cotton and HT (Herbicide Tolerant) soybeans. In the fifteen year period since the introduction of GM crops (1996–2011), the cumulative farm income gain in developing countries was 50.5% of the global figure or USD $49.63 billion (Table 1).

In terms of costs incurred for accessing GM technology, farmers in developing countries incur a lower cost than their counterparts in developed countries (Table 2). For developing country farmers the total cost was equal to 14% of total technology gains as compared to 28% for farmers in developed countries. This difference perhaps reflects factors such as weaker provision and enforcement of intellectual property

Table 1. GM crop farm benefits 2011: developing vs. developed countries (million USD)

Crop	Developed Countries	Developing Countries
GM HT soybeans	1,794.2	2,085.0
GM IR maize	5,710.4	1,394.5
GM HT maize	897.1	643.1
GM IR cotton	650.7	5,908.9
GM HT cotton	80.7	86.2
GM HT canola	433.2	0
GM virus resistant papaya and squash and GM HT sugar beet	83.3	0
Total	9649.6	10,117.7

(Brookes and Barfoot, 2013)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

rights in developing countries and the higher average level of farm income gain on a per hectare basis derived by developing country farmers relative to developed country farmers (ISAAA, 2010).

Supporting these findings, the authors (Finger et al. 2011) of a meta-analytical study of 721 single study entries for GM crops derived from a review of 203 publications based on field trials and surveys, discuss the economic benefits of GM crops and conclude:

The results presented here do support the contention that the adoption of GM crops leads on average to a higher economic performance, i.e., benefits, for farmers than conventional (non-GM) crops. This is in agreement with other studies that analyze economic performance of GM crops and is also underlined by the high (and increasing) adoption rates for GM crops in a number of countries. An important finding of the analysis is that the kind and magnitude of benefits are heterogeneous across crops, traits, countries and regions. By and large, the results suggest that the adoption of Bt cotton is particularly (economically) beneficial for the farmers in developing countries while positive effects are present but less significant for developed countries.

COUNTRY EXPERIENCES

Analysing country specific experiences with important GM crops, makes it possible to compare yields, insecticide use and net incomes between farmers adopting GM crops and those cultivating traditional varieties. In India, for example cotton is a major crop accounting for 30% of the country's agricultural GDP. However, prior to the introduction of GM cotton, the country's average cotton yield was 48% lower than the world average with farmers losing 50–60% of their crop to the cotton bollworm (ISAAA,

Table 2. Cost of accessing GM technology (million $) relative to the total farm income benefits 2011

Crops	Cost of technology: all farmers	Farm income gain: all farmer	Total benefit of technology to farmers and seed supply chain	Cost of technology: developing countries	Farm income gain: developing countries	Total benefit of technology to farmers and seed supply chain: developing countries
GM HT soybeans	1,647.6	3,879.2	3,879.2	5,526.8	606.4	2,691.4
GM IR maize	1,686.6	1,540.2	1,540.2	3,226.8	433.3	1,827.8
GM HT maize	789.6	166.9	166.9	956.5	93.9	737.0
GM IR cotton	758.5	433.2	433.2	1,191.7	536.9	6,445.8
GM HT cotton	313.1	7,104.9	7,104.9	7,418.0	40.5	126.7
GM HT canola	140.2	6,559.6	6,559.6	6,699.8	N/a	0
Others	71.1	83.3	83.3	154.4	N/a	0
Total	5,406.7	19,767.3	19,767.3	25,174	1,711.0	11,828.7

N/a = not applicable. Cost of accessing technology based on the seed premia paid by farmers for using GM technology relative to its conventional equivalents

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2012). Bt cotton was introduced in 2002 with 3 hybrids in six states - Andhra Pradesh, Gujarat, Madhya Pradesh, Karnataka, Maharashtra and Tamil Nadu. By 2012, India became the world's largest producer of biotech cotton covering 10.8 million hectares compared to the next largest producer the USA with 4.4 million hectares. The country now has 1097 Bt cotton hybrids approved for planting.

Field studies (Bennet et al. 2004) in the cotton producing state of Maharashtra in India (2002–2003) revealed that:

- Bt cotton yield increased by 45% in 2002, and by 63% in 2003 compared to non-Bt cotton varieties
- Higher revenues were attained by Bt cotton farmers compared to those who planted conventional cotton. The average income difference for 2002 and 2003 were 43% and 63%, respectively.
- The average gross margin (difference of the revenue and variable costs which include seed and insecticide costs) is much higher for Bt growers compared to growers of non-Bt varieties.
- Less insecticide input against cotton bollworms resulted in an average reduction in expenditure per hectare of 72% and 83% in 2002 and 2003, respectively. Savings in spraying were around Rs 2,471 or $54 per hectare on average (at an exchange rate of 1 US Dollar = 46 Indian Rupee[1])

Table 3 compares cotton yields and revenues for farmers adopting Bt cotton and those planting non-Bt cotton.

Table 4 compares the number and cost of insecticide sprays between adopters and non-adopters.

In addition to farm level benefits, the adoption of GM varieties appears to have had a direct impact on household food security. A comparison of households growing GM cotton in India with those that did not do so found that those adopting GM varieties consumed significantly more calories. Juma (2014) stated that: "Each hectare of GM cotton increased total calorie consumption by 74 kcal per adult equivalent per day. Furthermore, a smaller proportion of households were food insecure (7.93% of adopting GM

cotton households compared to 19.94% of non-adopting households" The study also showed that GM cotton adoption led to consumption of more nutritious foods – such as fruits, vegetables and animal products. The authors estimate that if the households that do not currently grow GM cotton switched, "the proportion of food insecure households would drop by 15-20%".

Experiences of small farmers from China, South Africa, the Philippines and other developing countries using GM crops clearly show that small farmers can also benefit from the technology. The most consistent observation from these countries is that growing GM crops is a profitable farming endeavour.

A case similar to Bt cotton in India is that of Bt corn in the Philippines, where the Asiatic corn borer caused losses of up to 80% of production, and corn yield levels averaged only 2.8 tons per hectare. The commercial release of Bt corn in 2003 in the Philippines marked the first time that a GM food/feed crop was ever approved for planting in Asia. The initial area under Bt corn covered more than 10,000 hectares. By 2005, it had expanded to 52,000 hectares. Adoption of Bt corn in the Philippines provided small farmers with a 37% increase in yield, reduction in pesticide costs by as much as 60% and an incremental income of up to PhP 10 or USD $0.21, 132 per ha (Yorobe and Quicoy, 2006).

Table 5 compares economic differentials between Bt and non-Bt corn producers in the Philippines

In China, insect-resistant GM rice was approved for food, feed, and cultivation in 2009. Surveys of randomly selected farm households showed that small and poor farm households adopting GM insect-resistant rice obtained yields 6 to 9% higher than conventional varieties and reduced pesticide use by as much as 80% or 16.77 kg/ha, which also had positive health benefits (Huang et al. 2005). The same authors also claim an average reduction in pesticide sprayings for the Asian boll worm from 20 to 6 times per year with the introduction of Bt cotton in China and a fall in cost of production of a kilogram of cotton by 28% as compared the farmers growing non-Bt varieties (Huang, Pray and Rozelle 2002).

In Burkina Faso, almost 100,000 farmers cultivated GM cotton on 260,000 hectares in 2010 with 126 percent increase from 115,000 hectares planted in 2009. In terms of contribution to the economy of Burkina Faso, Adenle (2011) states that:

It was estimated that a benefit of over US$100 million per year could be generated based on almost 30% increase in yield. Additionally, close to a 50% reduction in insecticide sprays may be realised, thereby saving fossil fuels and lowering greenhouse gases emission, hence fighting against climate change.

Table 5. Economic indicators: Bt and non-Bt corn farms in the Philippines

Item	Wet Season 2003			Dry Season 2004		
	Bt	Non-Bt	% Diff	Bt	Non-Bt	% Diff

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

South Africa, the first and biggest producer of GM crops in Africa, has benefitted substantially from growing GM crops over the past decade. It is the only African country among the five principal countries (others include: India, Argentina, Brazil and China) producing GM crops, with 63 million hectares planted in 2010 alone. The economy of South Africa has benefited a great deal from the adoption of GM technology and it has been reported to have enhanced farm income from GM maize, GM soybean and GM cotton by USD $156 million in the period 1998 to 2006, with farm income in 2006 alone estimated to be USD $67 million (James, 2008).

The best known and most often cited case is, however, the success story of small farmers growing Bt cotton in the Mahkhatini flats of South Africa, which soon became a showpiece for Monsanto and paved the way for the widespread cultivation of Bt cotton in the country. The Mahkhatini Flats are the floodplains bordering the Pongola river stretching from just below the Jozini Dam to the confluence of the Pongola and Usuthu Rivers on the Mozambique border covering some13000 hectares to the east of the Umbobo mountains. The region is extremely poor with the majority of the farmers growing mixed crops on small holdings of 2.5–5 hectares; many farms are smaller than 1 hectare. Low incomes and falling employment levels characterised the economy prior to the introduction of Bt cotton.

As a departure from assessing farm level impacts, a study of Bt cotton growers was conducted over the seasons 2003–04 and 2004–05 to assess socio-economic impacts on the livelihoods of the farmers (Morse, Bennet, & Ismael, 2013). Questionnaire based interviews of 100 cotton growers revealed that 88% of the respondents reported higher income from Bt cotton as against conventional seeds and almost 90% increased their asset base, particularly in terms of cultivable land. In addition, some 88% reported a reduction in insecticide related health problems and labour with more time to spend with their families or on other farm activities as spraying was not required.

The study also sought to assess differential impacts on male and female farmers. Gender differentials in benefits from GM crops is particularly relevant in the African context as the region has one of the highest ratios of women to men farmers in the world- almost 50%. The analysis revealed that a larger number of female farmers perceive the beneficial impacts of GM crops in terms of increased income and reduced need to access credit.

A comparison of costs and benefits of GM cultivation for three groups of farmers- those with marginal holdings below 2 hectares, those with small holdings: farm size between 2–3.5 hectares, and larger farmers with holdings above 3.5 hectares reveals that there are no major differences between the three size classes. In fact, farmers with medium sized holdings appear to have the lowest costs and the best yields and revenues, though farmers with over 3.6 hectares have the highest profit margins (Table 6).

The authors conclude that overall the adoption of Bt cotton in Makhathini has not only increased incomes for resource-poor farmers but has also had a positive impact on the livelihoods of these farmers and their households.

On the other hand, the anti-GM group cites data on yields sourced from the South African Cotton Trade industry covering the pre-GM cotton cultivation period (1997 to 2005) when almost 100% of the farmers cultivated GM varieties (Witt, Patel & Schnurr, 2006). This data shows a substantive increase in cultivated area, but little improvement in cotton yields (Table 7). Un-irrigated crops stand more or less at the pre-GM cotton yield of 600 kg seed cotton per hectare as the authors point out, but yields on irrigated lands, though highly erratic do appear to have increased.

*Estimates
(Cotton SA cited in Witt, Patel and Schnurr, 2006)

The authors suggest that the large scale adoption of Bt cotton is more the result of a structured institutional framework which allows adopters access to seed, credit and support, than any increase in yields. They emphasize that technical interventions like Bt cotton are not inserted into a vacuum, but have to be assessed in the existing ecological, political and economic contexts. Yet on the balance they do find grounds for cautious optimism in the Makhatini area.

The African Experience

GM Crops in Africa: Current Status

The Green Revolution brought about the transformation of agriculture in Asia and Latin America from the late sixties onwards. India in the sixties for instance, was a country with 70% of its population of almost one1 billion living in rural areas and wholly dependent on agriculture for their livelihoods. The huge demand for food had to be met by low yielding traditional food crops and almost complete dependence on rainfed agriculture, the people hovering perpetually on the verge of hunger with food imports, the only insurance against famine. The almost miraculous transformation within a period of barely two decades into a country with massive food surpluses and now a leading exporter of food grain was brought about only through political commitment to ensuring food security and the courage to embark on an unfamiliar path to agricultural development. Admittedly, the negative impacts of green revolution techniques of mono-cropping, excessive use of water, fertilizer and pesticides are beginning to emerge in some areas. There is also evidence that this technological breakthrough benefitted more the large farmers, than their counterparts with small and marginal holdings. Yet the country overall experienced an amazing breakthrough in food production and the fear of hunger is consigned to the past.

The Green Revolution unfortunately bypassed the countries of Africa, perhaps because of unfavourable physical or socio economic conditions or lack of political commitment. There is once again an opportunity for agricultural transformation opening up with the Gene Revolution; can Africa afford to lose this opportunity too?

While in the countries adopting green revolution technology, agricultural growth outpaced population growth from the seventies onwards, in Africa, per capita agricultural output was almost 20% lower in 2005 than in 1970 (Cooke and Downie, 2010). Additionally, with over 70% of the African population engaged in agriculture, Africa still imports a quarter of its food (Paarlberg, 2010).

African interest in biotechnology is reflected in the fact that with the exception of Somalia, all countries in Sub Saharan Africa are signatories to the Convention on Biological Diversity which expressly recognizes the potential of modern biotechnology in the promotion of human well being, particularly in helping meet critical needs for food, agriculture and health care (SCBD, 1992) in addition to ensuring the development of appropriate safety procedures which minimize potential threats to biological diversity and risks to human health. Yet only three countries in the continent — South Africa, Egypt and Burkina Faso have adopted GM technology with the production of food crops being limited to Egypt and South Africa. Egypt was the first North African country to grow GM crops commercially in 2008 with 700 hectares of GM maize planted and the Egyptian government planning to increase the hectarage of GM crops in future (James, 2008).

As far as significant production of GM crops goes, South Africa stands alone. The diversity of environment and socio-economic conditions in Africa is reflected in the varying country responses. The oft cited landmark anti-GM stance of Zambia is contained in the response of President Levy Mwanawasa to the offer of milled GM grains from the US during the food crisis of 2002: "Simply because my people are hungry, that is no justification to give them poison". Three other countries –Zimbabwe, Malawi and Mozambique supported this stance refusing "contaminated food", but eventually accepted food assistance in the form of milled grains. Zambia, however, continued in its refusal and eventually obtained reprieve by the supply of certified non-GM grain from Europe.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The early acceptance and successful progress of GM crops in South Africa and Egypt can be traced to the well-established and adequately funded scientific organisations in both countries. Bt cotton, the largest GM crop in South Africa was approved for commercial release as early as 1997. South Africa is now the eighth-largest producer of biotech crops in the world, growing 2.3 million hectares of genetically modified maize, cotton, and soya in 2011 (ISAAA, 2012). Although GM technology has been in use in South Africa for nearly 17 years and is well accepted in medical applications, its use in agriculture is still a subject of intense debate. While the technology receives strong support from the scientific community, commercial farmers and the government, NGO opposition continues. However, as Cooke and Downie (2010) stated:

In many ways, the debate in South Africa reflects the reality that GMOs are a fact of life and have been for some time. Although opponents continue to question the safety of genetically modified crops and advocate the adoption of the precautionary principle, which argues for a 'when in doubt, don't' approach to GM food, most of them understand such crops are here to stay. Therefore, their efforts center on tightening the regulatory system and preventing the entry of new GMO products into the South African market.

Cooke and Downie (2010) also discuss the rejection of the USAID funded *SpuntaG2* application for a potato modified with a gene to protect against the potato tuber moth, a project given up by Egypt after eight years of field trials and one which would have made South Africa the world's first producer of GM potatoes. They emphasize the fact that the proposal was rejected on economic rather than safety grounds. The fear of losing the two main markets for potatoes and potato seed - Angola and Zambia, the first with no bio-safety laws in place and the second known for its strong anti- GM stance re-emphasizing the importance of trade as a controlling factor.

In the case of Egypt, the realisation of the country's inability to meet its growing demand for food led to an early endorsement of GM technology. Genetic engineering programmes started in 1990. The country has in place a full framework for biotechnology consisting of the Agricultural Research Center, the National Research Center, the Academy of Scientific Research and Technology, the Water Research Center, the Desert Research Center and the Universities and has been intensively researching a variety of GM food crops although none of them have reached the market (Abdallah, 2010). The Agricultural Research Center (ARC) was established as a part of the Ministry of Agriculture in 1983 and brings together 16 research institutes. The crops cover a wide range of foods including staples like salt and drought tolerant wheat, rice with improved protein content and rice varieties resistant to rice blight and stem borers, biotech maize saves on pesticide usage, gives almost 100% protection from stem borers and increases yield by 30–40% over the conventional maize varieties. In 2008, the first approved GM crop, AgeebYG a yellow hybrid maize resistant to three maize borers was launched. A range of vegetables including virus resistant melon, squash and tomatoes are awaiting approval for commercialisation (Abdallah, 2010).

Burkina Faso, the third African country with a significant production of GM crops has a very different history. One among the "Cotton 4" (C4) countries of West Africa (the other three being Mali, Chad and Benin) the country grows and exports a fine variety of cotton. Crop intensification boosted cotton yields from an average of 200 kg per ha in 1963 to a peak of 1400 kg per ha in the mid-eighties. As Vitale et al. (2008) write "Cotton quickly became the region's "white gold", one of the leading sources of export earnings and a major source of employment in rural areas where livelihoods center about cotton, accounting for 60% of household income." In Burkina Faso, over 2.2 million people derive their livelihoods from the cotton industry, with public services like schools, healthcare, roads and agricultural

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

extension being funded through cotton revenues (Vitale et al. 2008). However, the peak yields of the 80s began to decline and the search for a quick solution which would improve productivity in the short term, rather than the long term horizons of pest eradication programmes led to Bt cotton. Burkina Faso's national cotton company, Société Burkinabé des Fibres Textiles (SOFITEX), began a partnership with Monsanto in 2001 to introduce Bt cotton on a commercial basis. Since then the country has emerged as the most progressive in the West African region with reference to biotechnology. After the initial seven year period of field testing, monitoring, and development of bio-safety protocols, Burkina Faso commercially released Bt cotton in 2008. Expansion has been fast paced from an initial 12,000 ha in 2008 to slightly over 125,000 ha in 2009. In 2010, an estimated 400,000 ha of Bt cotton was planted in the country (Vitale et al. 2010).

Expansion of GM Cultivation

While the major GM crop producing countries in Africa have been discussed above, this does not imply that other countries are totally disassociated with bio-technology. Laboratory tests and field trials of a variety of GM crops, both food and non-food are in process across Africa (Tables 8 and 9).

Tables 9 and 10 provide ample evidence that despite opposition and misgivings among certain groups, Africa is well on the way to accepting bio-technology as an option to resolving hunger and malnutrition, particularly in the context of deteriorating environmental conditions.

DISCUSSION AND EXPERIENCES

Are GM Crops a Feasible Option in Africa?

We have discussed the status of GM crops in Africa and have also assessed whether transgenic crops benefit the small farmer in developing countries. There appears to be substantive evidence that gene technology does improve the livelihoods of small farmers as well as of those with large holdings. Apart from benefits at the farm level, visible improvements have been documented in household asset base

Table 8. Status of genetically modified (GM) crops in Africa

Application Stage	No. of Countries	Country Names
Commercial production	3	Burkina Faso; Egypt; South Africa
Confined field testing	7	Burkina Faso; Egypt; Kenya; South Africa; Uganda; Nigeria; Malawi
Contained research	At least 15	Burkina Faso; Cameroon; Egypt; Ghana; Kenya; Mali; Mauritius; Namibia; Nigeria; South Africa; Tanzania; Tunisia; Uganda; Zimbabwe; Malawi

Table 9. Range of GM crops being developed in Africa

Country	Crop
Kenya	Maize and cotton (insect resistant), cassava, sweet potato (virus resistant)
Uganda	Cotton (insect resistant and herbicide tolerant), banana (nutrient enhanced, fungal resistant), cassava (viral resistant), sweet potato (weevil resistant)
Nigeria	Cassava (nutrient enhanced)
Malawi	Cotton (insect resistant)
Nigeria, Burkina Faso, Ghana	Cow pea (insect resistant)
Kenya, Mozambique, Tanzania, South Africa, Uganda	Maize (drought tolerant)
Burkina Faso, Kenya, South Africa	Sorghum (nutrient enhanced)
South Africa	Maize (herbicide tolerant, insect resistant, virus resistant), Cassava (starch enhanced), Cotton (insect resistant, herbicide tolerant), Potato (insect resistant), sugarcane (alternative sugar)
Egypt	Maize (insect resistant), Cotton (salt tolerant, Wheat (drought tolerant, salt tolerant, fungal resistant), Potato, Banana, Cucumber, Melon, Squash, Tomato (all viral resistant)

(NEPAD, 2010)

and food security in developing countries, where GM crops have been cultivated over a number of seasons. It must be emphasised here that these positive impacts do not deny the emergence of setbacks in the form of lower than expected yields, higher input costs or unintended environmental impacts, which have also been witnessed in some areas and must be given due weight in the decision making process. As Finger et al. (2011) emphasized:

GM crops are designed with particular aims in mind such as insect and herbicide resistance, not with a view to increasing yields, except indirectly through the curtailing of losses. Thus other constraints like infertile soils or drought can only be addressed by varieties designed specifically to overcome these problems. In addition there are always socio-economic problems which GM crops cannot address. Hence, considering GM crops as a panacea for poverty and hunger is groundless.

South Africa and Burkina Faso, the only countries in the African continent where GM crops have been cultivated for over a decade have both registered success on all counts equal to their Asian and Latin American counterparts; yet the opponents of GM crops not only oppose their expansion in the African region on the basis of un-established but nevertheless very real fears of biotechnology, but cite as their explanation the contention that agriculture in Africa being distinct from agriculture in other developing regions is unsuitable for the introduction of advanced technology. In evidence, they emphasize the failure of the Green Revolution in the African context and predict a similar scenario in the case of the Gene Revolution.

Some Constraints to Agriculture

This section will inquire into the constraints that agriculture faces in Africa, why chronic food shortages persist despite abundant natural resources, the reasons behind the failure of the Green Revolution and whether the failure of one technological opportunity necessarily precludes the success of the next.

Africa is known for its diverse agro-ecological regions, abundance of water resources, though unevenly distributed, and almost unlimited land area which could be brought under cultivation — conditions which would be the envy of any agricultural country. Yet, agricultural growth has been slow and has even retrogressed leaving the region perennially short of food, open to droughts, erratic rainfall, attacks by insects and other pests, with survival being assured only by food imports or food assistance during emergencies. Over the past two decades an average of 32 countries in sub-Saharan Africa received emergency food aid each year. The numbers ranged from 22 countries in 1990 to 38 in 2009 (UNDP, 2012).

The issue is further compounded by trade barriers and poor transport systems, which leave food security, particularly in rural areas completely dependent on local production of food staples. It has been stated that "if the food available in sub-Saharan Africa were evenly distributed, all Africans could consume enough calories for their basic functioning" (UNDP, 2012). In fact 75% of the cereals and almost all the roots and tubers, the basic food crops, are grown locally.

In a bid to jump start the development process after gaining independence in the sixties, most African countries focussed on urbanization and industrialisation with the expectation of a trickledown effect to take care of the rest of the economy. The consequent neglect of the agricultural sector and the emerging policy bias, heavy taxation and government control of agriculture over the next two decades are some of the reasons for the stagnation in Africa's food production. At a time, when the developing countries of Asia set upon a trajectory to achieve self-sufficiency in food and free themselves from dependence on food imports, Africa was set on a contradictory mission. In this perhaps, lie the reasons behind the apparent failure of the Green Revolution in the region. With no political backing or supportive measures, technological revolutions are unlikely to succeed in any country and even less so in an agricultural economy characterised by small farmers.

The results of the post-independence policy framework were overvalued exchange rates supporting imports for domestic urban consumers and making agricultural exports less competitive in international markets (Binswanger and Deininger, 1997). Heavy direct and indirect taxes were also levied on agricultural activities. In effect:

these biased policies increased the combined effective tax rate on agriculture (from industrial protection, direct taxation and exchange rate policies) from 5% in the late 1950s to close to 25% in the late 1970s (UNDP, 2012).

Although most staples were unaffected by taxation or support, the food markets came under heavy control. The net outcome was to turn relative prices against farmers.

With the entry of structural adjustment policies, the bias against agriculture was lifted, but the UNDP (2012) states that:

The state retrenchment of the 1980s–1990s disabled the sector as an early driver of growth and retarded the kind of structural transformation needed to increase food security and reduce poverty. Rising population growth compounded the setback, as the need for food outpaced the continent's capacity to produce.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Although there has been a substantial reduction in agricultural tariffs, trade barriers still persist in sub-Saharan Africa slowing the growth of intra-regional trade in food, particularly staples. The 'border effect' or the additional costs of crossing the border between two countries is substantial, and is exacerbated by the price differentials between producing and consuming zones. For example, Brenton, Portugal-Perez and Regolo (2013) find that the effect on relative prices of crossing the Niger–Nigeria border is equivalent to adding an additional 594 km to the distance to markets.

Promoting inter-regional trade in food staples and reducing the costs of bringing food to the market could effectively reduce chronic food insecurity as well as vulnerability to risks. Engel, Jouanjean and Awal (2013) emphasize the importance of facilitating food trade and a more coherent trade policy in the arid and semi arid regions of the Sahel and the Horn of Africa, where the frequency of food shortages is making the population particularly vulnerable.

However, some positive developments are beginning to emerge:

Up until early 2000, the agriculture sector in Sub-Saharan Africa went through policy and budgetary neglect that led to growth stagnation but this has now changed: agricultural GDP in Sub-Saharan Africa as a whole grew by more than 3.5% in 2008, surpassing the population growth rate, and grain production growth rates have been kept above 3% (Ackello-Ogutu, Okoruwa, & Bahal, 2012).

Contrasting Experiences With Agricultural Technology in Africa and Asia

While both Africa and Asia faced severe food shortages and the recurring threat of hunger and starvation in the early sixties, development policies in the two regions, as mentioned above, were sharply divergent. Asian governments prioritised food security from the mid-1960s onwards by supporting the agricultural sector to adopt high yielding varieties of food staples known to be highly responsive to fertilizer, water and other inputs. Cereal production increased by 3.4 times during the period 1961– 2010, and per capita availability of cereals also rose sharply by as much as 44%. In Africa, on the other hand, development focussed on industry and export-based cash crops with the expected adverse impacts on food production and the livelihoods of small farmers. Although cereal production in sub-Saharan Africa has tripled over the same period, population growth has outpaced production with the result that per capita output has actually fallen by 13% (UNDP, 2012).

The basic difference between increased cereal production in Asia and Africa is that Asia owes about 44% of its increased production to higher yields, while in the case of Africa, the increase comes in area under cereals, and the exclusive contribution of higher yields is just about one-third of the increase in production. However, this must not be considered a negative factor. It only serves to underline the fact that there is much scope for improving yields in Africa, if the opportunity offered by currently available technologies is grasped. According to the UNDP African Human Development Report (2012):

African farming thus contrasts with the Asian norm of cultivating mainstream staples and cash crops, fertilized and often irrigated, unmixed in a single field on fully settled farms under individual tenure. In sub-Saharan Africa, reliance on many crops and traditional farming practices has resulted in less research and extension (per unit of output and per hectare) than in Asia. More fundamentally, sub-Saharan Africa has not benefited from the farm science–based, input-responsive boost in agricultural productivity that occurred in Asia.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Farming in Africa is characterised by smallholders typically growing a variety of crops, sometimes as many as ten including staples for the home and cash crops for sale. Cultivation is predominantly rain-fed and practised on weathered soils with low fertility and little mechanisation. Low population densities result in poor road network and restricted access to markets. The relative isolation of the African farmer also adversely impacts his access to modern inputs or extension services. "Only 30% of the rural population in sub-Saharan Africa lives within 2 km of an all season road in sharp contrast to South Asia's 58%" (Roberts, Shyam, & Rastogi, 2006).

Across the region (Sub Saharan Africa) just a little over 200 million hectares are cultivated, leaving four-fifths unused. "Excluding protected areas, land covered by forests and regions already settled, and limiting the definition of suitability to five crops, the balance of suitable unused agricultural land is about 200 million hectares, which, if brought into production, would double the amount of cultivated land in sub-Saharan Africa" (Berg and Ostry, 2011). Thus viewed from a different perspective, what appear to be Africa's disadvantages in agriculture, may well prove to be opportunities in the making in the form of unused and underused arable land and unused potential to boost agricultural productivity (UNDP, 2012).

While Africa's agro-ecological zones are more diverse than Asia's, this does not necessarily suggest an impediment to the introduction of improved technologies. The solution would lie in local- specific interventions tailored to meet specific needs and address problems specific to the region. Examples include among others, the development of drought-tolerant varieties of millet and sorghum for farmers in the Sahel and the Horn of Africa (Hunt and Lipton, 2011), GM bananas in Uganda and Bt black-eyed peas in Nigeria (Juma, 2014). Juma and Gordon (2014), while strongly endorsing the technological revolution in Africa, even go so far as to say:

Biotechnology is only a starting point. The introduction of Bt cotton, for example, requires system-wide investments along the entire cotton value chain. This means that the adoption of biotechnology can serve as a trigger for investing in R&D, rural infrastructure, technical training and entrepreneurship (and leapfrog agricultural development in the country.

As aptly summarised in the first African Human Development Report, (UNDP, 2012):

No lack of knowledge, ideas or vision stands between sub-Saharan Africa and this brighter future. And certainly no failure to commit to a new agricultural revolution, as evidenced in African leaders' affirmation of their commitment to agriculture in the Maputo Declaration and the Comprehensive Africa Agriculture Development Programme. But realizing the vision will require policies to increase yields up to the frontier of current science, through faster and wider adoption of better technology, and then policies to expand that frontier so that agricultural yields continue to rise. With rapid growth in agricultural productivity, anchored in rising yields of staple crops, sub-Saharan Africa can reduce mass poverty and ensure food security for most of its people.

CONCLUSION

On all issues discussed above, the evidence is in favour of GM crops, yet most African countries are reluctant to adopt GM technology. A major factor may be financial constraints. As Miller (2007) writes:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The high level of investment needed in GM research and its application has constrained African participation and has led to research that primarily focuses on developed country needs. Transgenic research is very expensive when compared to more traditional biotechnology techniques. For example, the IRMA project is estimated to have cost USD $6 million over 5 years and the transgenic sweet potato research USD $2 million, compared to the average funding of tissue culture and marker technology projects costing on average USD $300,000.

The lack of in-country research has prevented the dissemination of authentic information about GM crops, which would be readily acceptable to the local population. The reluctance to accept information from International Agencies, which are perceived as having their own agenda has created a climate conducive to anti-GM activists. Adenle (2011) writes:

Africa's relatively slow embrace of the "gene revolution", particularly GM technology, has, in part, stemmed from lack of access to GM crops available to beneficiaries such as farmers and scientists. This is partly due to international influence against GMOs.

The communication gap further fuels fears of being held to ransom by seed producing multinational companies, as the terminator gene precludes the traditional practices of seed saving and exchange. Juma (2014) however, adds a rider stating that:

The problem is not simply the presence of large corporations but the low level of the development of domestic seed firms. Such local firms can help focus on indigenous crops. They can also play key roles as business partners with foreign farms.

He further adds that new research shows that in Africa, local start-ups with local scientists are at the forefront of bio-technology research, not multi-nationals.

Yet another fear is that of losing the largest market for agricultural produce- the European Union, which is known to have stringent laws against the import of GM crops. This has led to the adoption of a Go Slow approach by the governments of many African countries (Adenle, 2011). A recent IFPRI (2013) research study concludes:

This European model does not correspond to African needs and realities, however. GM crops can aid farmers by reducing both losses from pests and the costs of weeding. For European countries, in which only a tiny percentage of the population grows crops such as maize, cotton, and soybeans, these advantages are negligible. In Africa, though, where 60% or more of the population depends directly on agriculture for income and subsistence, far more people could benefit directly from biotechnology that includes agricultural GMOs. ....Rather than imitate other regions' regulatory systems, African countries south of the Sahara need to consider and develop their own regulations for biotechnology development that balance risk avoidance (and the accompanying regulation costs) against such technology's net benefits for farmers.

A reasonable conclusion also, is that the fear of short term export losses is also unfounded as the major export crops from Africa are tea, coffee, vegetables and flowers, not staples, which are more likely to be genetically modified.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

It must be conceded that these fears are not totally unfounded, but they do not pose insurmountable obstacles to the adoption of this new technology. As Adenle (2011) writes:

Given both the lack of global consensus on GMOs and the growing need to regulate GMO products, the US may offer a good example for Africa and the rest of the world. It is one of the few developed countries to grow GM crops on a commercial basis (more than 70% of foods in the US contain GMOs) and is a leader in the safe application of GMO product.

It appears then, that Africa's path to enhanced food security through the adoption of GM technology is a viable one, given adequate political backing and wholehearted commitment to meeting the needs of the African people.

Chapter 79
Agricultural Growth Accounting and Total Factor Productivity in Jordan: Trends, Determinants, and Future Challenges

Samia Nadeem Akroush

Boubaker Dhehibi
International Center for Agricultural Research in Dry Area, Jordan

Aden Aw-Hassan
International Center for Agricultural Research in Dry Area, Jordan

ABSTRACT

This article develops new estimates of historical agricultural productivity growth in Jordan. It investigates how public policies such as agricultural research, investment in irrigation capital, and water pricing have contributed to agricultural productivity growth. The Food and Agriculture Organization (FAO) annual time series from 1961 to 2011 of all crops and livestock productions are the primary source for agricultural outputs and inputs used to construct the Törnqvist Index for the case of Jordan. The log-linear form of regression equation was used to examine the relationship between Total Factor Productivity (TFP) growth and different factors affecting TFP growth. The results showed that human capital has positive and direct significant impact on TFP implying that people with longer life expectancy has a significant impact on TFP growth. This article concludes that despite some recent improvement, agricultural productivity growth in Jordan continues to lag behind just about every other region of the world.

1. INTRODUCTION

Jordan has experienced spells of high growth, but the country has always faced the challenge of sustaining them. In the first half of the 1980s, Jordan's Gross Domestic Product (GDP) growth averaged 7.4 percent. Subsequently, as the regional economies entered into recession in the wake of a sharp fall in oil prices, the country's growth plummeted to -14 percent in 1988 and it took about 18 years for Jordan's GDP per capita to revert to its level of the late 1980s. Jordan posted an average 6.7 percent growth during 2000-2008, then the country's growth dropped sharply to 2-3 percent during the global financial crisis of 2009-2010. Jordan's resilience to exogenous shocks has remained extremely weak over the last 30 years.

The contribution of agriculture to the GDP in relative terms declined sharply from 40% in the 1950s to less than 4% in 2011 (Bahdousheh et al. 2010), while its contribution in absolute terms has increased from Jordan Dinar (JD) 32 million in 1964 to JD 560 million in 2010 (The Central Bank of Jordan, 2011). Despite the increase in absolute monetary terms, the contribution of agriculture to the national economic growth is very modest, reflected in the remarkable decline in the sector's share compared to other sectors.

The importance of the agricultural sector stems from the fact that it is not only the major source of food items especially dairy products, fruits and vegetables, but is also one of the sources of hard currencies originated from exports. About 25% of the total poor in Jordan live in the rural areas depending mostly on agriculture (e.g., livestock keepers, small holder farm households, and landless former agriculturalists), and in spite of poor motivation of the rural youth, agriculture is an important employer of the rural communities. Additionally, cultural, social, and environmental considerations and mainly because of its strong forward and backward linkages with other sectors and activities, agriculture remains a very important sector that must be considered in the rural development and poverty reduction plans. The sector employed about 124,000 people (a total of 2.1% of the entire population or about 7.7% of the active labor-force of 1.771 million), and contributed to 17% of total national exports (equivalent to JD 795 million) in 2011 (MOA, 2012).

A major weakness of the sector is caused by the scarcity of irrigation water and overexploitation of groundwater; use of poorly treated brackish and sewage water, land fragmentation and reduction in the size of agricultural holdings; weak extensions services; poor transportation, packaging and processing; infrastructure; unfavorable price policies, and low investment in marketing infrastructure, post-harvest and quality enhancing facilities (e.g., grading, packing, storage). The claim that agriculture consumes 62% of the Jordanian scarce water resources leaving scant reserves for domestic and industrial use is unrealistic and is yet to be proven. However, the claim generally reflects the extent of poor water use practices in agriculture, and indicates the need for adopting alternative and modern agricultural practices and techniques.

The agricultural output growth is usually due to three types of factors: area growth, yield growth, and prices change. Area growth is related to an increase in the quantities of inputs use in addition to land. However, yield growth is generated by both inputs use growth and total factor productivity (TFP) growth. Then, TFP growth is the result of both technical change and the efficiencies deployed to lead to increased output. Growth patterns could be then defined as a trade-off between these two sources which determines TFP growth. Although all choices of growth patterns can achieve the substantive growth of TFP, the distributions between both sources should be coordinated.

There have been virtually no sector-level studies on agricultural productivity in this region or on the role of public policies in improving productivity growth. This article develops new estimates of historical productivity growth and water use in Jordan. It investigates how public policies such as agricultural

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

research, investment in irrigation capital, water pricing, and others have contributed to agricultural productivity growth. The findings from this article will have important implications for agricultural development policy in the region.

The remainder of this article is divided into five sections. Section 2 provides a literature review on the empirical approaches used to measure the agricultural productivity in in Jordan and many other countries. Section 3 presents the methodologies used to measure TFP, and discusses the data used in Jordan to measure TFP growth. Section 4 presents results obtained from the analyses of outputs, inputs and TFP measurements, and then describes and summarizes the key findings of the TFP determinants. Finally, Section 5 presents the conclusions and policy implications.

2. BACKGROUND AND LITERATURE REVIEW

Agriculture productivity analyses performed to date show that most developing countries are experiencing relatively negative productivity growth with technical change being the main source of this regression. Kawagoe and Hayami (1985) showed agricultural productivity decrease in 22 Least Developed Countries (LDCs), but an increase in the 21 developed countries included in the sample. Kawagoe and Hayami (1985) found similar results for the same data set using an indirect production function approach that is similar to the indexing approach, except that input shares are estimated by using marginal productivities from an aggregate production function instead of prices. Lau and Yotopoulos (1989) also found in their analysis declining agricultural productivity for LDCs in the 1970s but an increase in the 1960s, although they used different functional forms.

In later research, Qualset, McQuire, and Warburton (1995) state that California's rich agricultural productivity is founded on its biological diversity, both native and exotic. Native species contribute genetic resources and play a vital part in preserving land, air, and water quality. Qualset et al. (1995) assert that exotic species introduced from around the globe provide the raw genetic material for nearly all of California's agricultural commodities. Through generations of selective breeding, native and exotic biodiversity have been used to solve agricultural problems. Such biodiversity — termed "agrobiodiversity" — includes not only crops, livestock and their wild relatives, but the species that interact with and support them: pollinators, symbionts, competitors, pests, parasites, predators, and biological control agents. Qualset et al. (1995) suggest that long-term security and flexibility of California agricultural production requires conservation of both exotic genetic resources and native California habitats.

Trying to explain measured productivity decline in developing countries, Fulginiti and Perrin (1993, 1998) related poor productivity performance to economic policy. They found that those countries with heavy agriculture taxes had the most negative rates of productivity change. They suggested that price policies or other interferences with the agricultural sector might stifle potential productivity gains. Fulginiti and Perrin also suggested, as an alternative explanation, that the methods and data used in these studies may have inaccurately measured technical regression. Arnade (1998) estimated agricultural efficiency change indices, technical change indices and productivity indices using nonparametric Malmquist indices for 70 developed and developing countries during 1961 - 1993.

A total of 36 of the 47 developing countries included in this sample showed negative rates of technical change, whereas most of the developed country indices rose or followed mixed paths. In contrast, recent studies of agricultural productivity growth in developing countries have showed positive and rapid growth. Coelli and Rao (2003) examined the growth in agricultural productivity in 93 countries during

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

1980 - 2000. Their results showed an annual growth in total factor productivity growth of 2.1%, with efficiency change contributing by 0.9% per year and technical change providing the other 1.2%. There is little evidence of technological regression found in the earlier studies. Those results are explained as a consequence of the use of a different sample period and an expanded group of countries.

Nin et al. (2003) re-examined the nonparametric procedure for estimating the Malmquist productivity index. They argued that the technical regression observed is principally the consequence of biased technical change together with the definition of technology used to estimate the Malmquist Index. They eliminated this effect by applying a broader cumulative definition of technology than is normally used to estimate the Malmquist Index. Their results using this new approach reversed the previous findings and showed that most countries in their sample of 20 developing countries experienced positive productivity growth with technical change being the main source of this growth.

Al-Karablieh (2004) in his study of analysis of the TFP in Jordanian agriculture, analyzed the agricultural outputs of Jordan during 1983 - 1997 using the Tornqvist quantity index. In this study, data on output produced, input used, and their respective prices for the period were obtained from the Jordanian Department of Statistics (DOS) and were supplemented with several other sources. Output growth, during the period under study, principally came from the growth of fruits, vegetables, and poultry. Growth rates for all other crops and livestock were unbalanced due to few research and development efforts on those relative to fruit and vegetables. The average growth rate of TFP was 3.9% during 1983 - 1997.

During 1983 - 1987, the average growth rate of TFP was 6.1%, but dropped later to an average of growth rate of only 0.7% during 1993 - 1997. Although land remained static, labor, fertilizers, pesticides and water increased. The increase in output during the whole period was mainly 70% due to the technological change, whereas 30% was due to the increase in the inputs used. Much of the additional productivity is expected to come from cereals and livestock products; therefore, policy prescriptions should be allocated to direct research and development efforts towards efficient production of those along with fruit and vegetables. Given land is considered the most limiting factor and labor is the most elastic factor, the shift towards production of high value crops will increase aggregate output growth and at the same time employment.

Belloumiet et al. (2009) investigates the patterns of agricultural productivity growth in 16 Middle East and North Africa (MENA) countries during 1970 - 2000 using a nonparametric, output-based Malmquist index to examine whether author estimates confirm or invalidate the previous studies results indicating the decrease of agricultural productivity in developing countries. They showed that, on average, agricultural productivity growth increased at an annual rate of 1% during the whole period. Their estimations show that technical change is the main source for this growth. Those results weaken as a whole the findings of the other studies; however, they find a decrease in agricultural productivity mainly for developing countries suffering from political conflicts and wars. This article fills the void of hardly any agricultural studies on MENA countries collectively, especially on productivity trends.

Telleria et al. (2011) used the Malmquist Index to measure agricultural productivity. It is a powerful tool providing insights into whether or not a country is approaching what may be termed as "best practices" by using and disseminating existing technology (efficiency change), and/or by innovating technology (technical change). Using the Malmquist Index on a sample of 12 countries within West Asia and North Africa (WANA) indicated that between 1961 and 1997, Turkey, Tunisia, Syria, and Algeria (in that order) were the "most productive" countries.

3. CONCEPTUAL FRAMEWORK

3.1. Methodological Approach

Productivity is defined as the efficiency of a production system, and as such would be a ratio of units of output per unit of input to the system (James & Carles, 1996). It is also defined as the production value (or quantity) divided by the amount of factors consumed in the production process. Generally, productivity is the relationship between the quantity of output and the quantity of input used to generate that output. It is a ratio of output to input (Productivity = Output/Input). The output used for productivity calculation could be of different forms such as produced goods or provided services. Outputs may be expressed in physical (quantities) or financial (value) terms. Inputs are resources used to produce outputs. Most common forms of inputs are labor, capital, and intermediate inputs.

Productivity has an effect on organizations/economies/sectors growth. In fact, higher productivity results in performances enhancement (production increases) and higher profits (e.g., minimal factors costs, better selling prices, marketing capacities). Enhanced skills in transforming inputs to outputs play critical role in enhancing productivity and competitiveness. In fact, with the same amount of inputs, some farmers can produce more than others depending on their skills, knowledge level, and cognitive capacities.

The two most commonly used measures of productivity are single (partial) factor productivity (SFP) and total (multifactor) factor productivity (TFP). When multiple inputs of heterogeneous nature are used in the production process, aggregation of these inputs may require the use of price indices. This implies that productivity can be affected by both changes in relative prices of inputs and by the input use per unit of output (Kathuria et al. 2013). Precise definitions of partial and TFP will be presented in this article. However, the main focus will be on the TFP since it is the method we are using in the APWEC-MENA project to account for agricultural sector growth in Tunisia, Jordan, and Egypt.

There are basically two approaches to measure TFP growth: the frontier and non-frontier approaches. Each of these approaches is further divided into parametric and non-parametric techniques. Non-frontier approaches include growth accounting methods (or non-parametric index-based methods/TFP index numbers) and econometric parametric approaches. Frontier approaches include the non-parametric Malmquist index methodology and the stochastic production frontier method; which is a parametric approach. A common feature of the TFP index number is that the empirical estimation of different TFP indexes is based on different weighting methods of inputs and outputs. In most empirical studies, the Divisia, Solow, and the Törnqvist Indexes are frequently used. Among index number methods, the Tornqvist-Theil Index, which is an approximation to the Divisia Index, was employed to construct the aggregate output index and aggregate input index.

In the literature on productivity measurement, the Törnqvist Index is the changing-weight index that has been most frequently examined and used. The Törnqvist Index, which was developed in the 1930s at the Bank of Finland (Törnqvist, 1936), makes use of logarithms for comparing two entities (e.g., two countries or two firms), or for comparing a variable pertaining to the same entity at two points in time. When used to compare inputs for two time periods within the context of productivity measurement, the Törnqvist Index employs an average of cost-share weights for the two periods being considered. The index number is computed after first determining a logarithmic change (or rate of proportional change). Explanation on theoretical properties and issues in measurement of the productivity through the Tornqvist Index can be found in Diewert (1978) and Coelli et al. (2005).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Tornqvist output, input, and TFP index in logarithm for can be expressed as follows:

$$\text{Output index: } \operatorname{Ln}\left(\frac{Q_t}{Q_{t-1}}\right) = \tfrac{1}{2}\sum_j \left(R_{j,t} + R_{j,t-1}\right)\operatorname{Ln}\left(\frac{Q_{j,t}}{Q_{j,t-1}}\right) \quad (1)$$

$$\text{Input index: } \operatorname{Ln}\left(\frac{X_t}{X_{t-1}}\right) = \tfrac{1}{2}\sum_i \left(S_{i,t} + S_{i,t-1}\right)\operatorname{Ln}\left(\frac{X_{i,t}}{X_{i,t-1}}\right) \quad (2)$$

$$\text{TFP index: } \operatorname{Ln}\left(\frac{TFP_t}{TFP_{t-1}}\right) = \operatorname{Ln}\left(\frac{Q_t}{Q_{t-1}}\right) - \operatorname{Ln}\left(\frac{X_t}{X_{t-1}}\right) \quad (3)$$

Where;

Rj,t is the share of output (j) in total revenue in time (t),
Qj,t is the output (j) in time (t),
Si,t is the share of input (i) in total input cost, and
Xi,t is the input (i) in time (t),

3.2. Data Sources and Data Collection Procedure

The Food and Agriculture Organization (FAO)'s annual time series from 1961 to 2011 of all crops and livestock productions, land areas, labor, machinery, animal capital, and fertilizer consumption are the primary source for agricultural outputs and inputs used to construct the Törnqvist Index for the case of Jordan. The FAO data is complemented, when needed, with data from national statistical agencies, especially when such alternative data is more accurate or up to date. Data from FAO was continuously cross checked with the available (sometimes limited) data from national sources in order to be sure of its reliability. Moreover, the TFP determinant variables where primarily collected from national sources, while some of them were also collected from international databases, as it is for the UNDP-human development index.

3.3. Hypothesis for Estimation of the Missing Data

As mentioned above, inputs and outputs data was mostly gathered from online FAO database. However, we faced some missing observations and were therefore obliged to use different assumptions to complete them. Below is a description of the different estimation procedures of these variables:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Total Agricultural Output

This variable was available in both FAO and the DOS. However, we considered the FAO values in our output index calculation since most of our inputs variables were also from the FAO source. The calculation of the agricultural output value from the FAO dataset was based on available information about different agricultural commodities production (in metric tons) and prices (FAO have a dataset of historical agricultural commodities prices). Multiplying produced quantities of each commodity by its unit price provide the overall annual value of that commodity. By summing up crops commodities and livestock commodities, we obtain the annual crops output values and annual livestock values (see Figure 1). For the missing commodity prices observations, we were simply applying different constant inflation rates for different commodities based on their current prices.

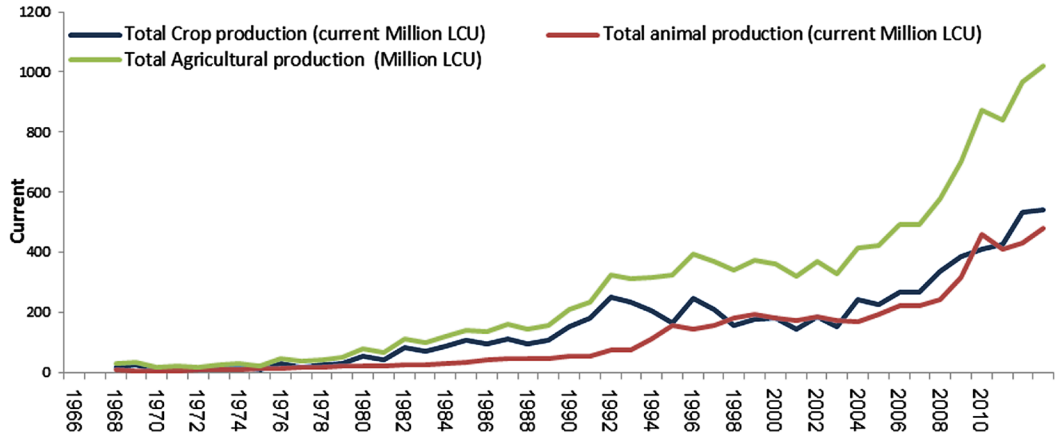
Total Agricultural Inputs

The FAO publishes data on cropland (rain-fed and irrigated), permanent pasture, labor employed in agriculture, animal stocks, the number of tractors in use, and inorganic fertilizer consumption. We supplement these data with better or more up-to-date data from national sources whenever available. For fertilizer consumption, the International Fertilizer Association has more up-to-date and more accurate statistics than does the FAO on fertilizer consumption by country, except for small countries.

Labor

this variable represents the annual volume of number (number of active persons) and value (in current JD) of the total labor mobilized in the agricultural sector. This variable was primarily collected from the DOS. The number of workers in the agricultural sector was not difficult to find as information, but the historical labor value was critical. We relayed on secondary data about daily wages in the agricultural sector to estimate this value. Secondary data about daily wages in the agricultural sector in Jordan were available from the DOS, but starting only from the 1990s. One observation of the wages in the 1960s

Figure 1. Crops and Livestock Output Values in Jordan (in current JD / from 1966 to 2011) Source: Own elaboration (2014)



**For a more accurate representation see the electronic version.*

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

was obtained from consulting experts, and then a constant inflation rate of this value was applied every five years until the 1990s.

Seeds

Seed quantity was available in FAO datasets, but the FAO did not provide any seeds pricing data. Because cereals are the most important component of the overall seeds quantity, we decided to use an average price of cereals as proxy of the cereal seeds.

Machinery

This variable is reflected by the annual number and value of tractors in use. Other types of machineries were not used to account for this vector. The unit prices of tractors (in current local currency) were calculated based on the annual machinery import value drawn from the FAO database. From this annual unit value, an annual cost of machinery services was derived by amortizing the price of machine over 15 years and assuming a fixed marketing margin.

Pesticides

It was not possible to find any pesticides quantities. Instead, we used the number of cropped hectares treated by different types of pesticides as a proxy. This latest variable was available at the DOS. It was also difficult to find the annual total value of pesticides used in the agricultural sector of Jordan. This latter value was, however, estimated from the annual value of pesticides importations (available in the FAO database) corrected by a marketing margin of 85%. This marketing margin was identified from some primary data about average farms expenditure in treatment products. The margin is high mainly because private companies import active ingredients and transform them locally, thus producing important quantities of treatment productions.

Fertilizers

Aggregated fertilizers quantities were available from FAO data, the DOS, and the International Fertilizer Association (IFA). However, values from the IFA and FAO sources were highly similar so we decided to use the FAO data. The aggregated fertilizers value was, however, calculated based on average unitary price which was estimated through: 1) the international fertilizers price index (IFA: international fertilizer industry association); and 2) the average unitary price of 1963 (from FAO source).

Animal Feed

Animal feed quantities were also estimated from FAO sources, more precisely from the annual "commodity balance sheets". These annual sheets provide the quantity (in tons) of each agricultural commodity allocated for animal feed. By summing up through all of these commodities, we obtained the total quantity of feed consumed by the livestock activity. It was remarkable that cereals usually constitute more than 85% of the total annual animal feed. Therefore, an annual average cereal unitary price was used to calcu-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

late the feed value in Jordan. For the remainder of the feed share (other than cereals), half of the annual average cereal unitary price was used since we supposed that cereals are the most expensive among feed.

Capital Stock

was also calculated based on the FAO data for the period 1975 - 2007. In the calculation, we were considering the following components: "land development", "livestock fixed assets", "plant crops", and "structures for livestock". Each of these values was amortized based on the following rates, successively: 99 years, 10 years, 20 years, and 25 years. These depreciation rates are in line with the accounting system in the respective countries. The final capital stock formula is then: CS ($year_t$) =sum ((land development/99) + (Livestock fixed assets/10) +(plant crops/20)+(structure for livestock/25)). The capital stock values are reported in the FAO data as '2005 Constant USD'. We first changed the values to current US Dollars (based on US inflation rates) and then we applied the exchange rates to obtain the current JD values. The period 1960 - 1970 corresponds to the period of complicated political situation for Jordan with neighboring countries. This was our interpretation of the declining TFP indexes between 1966 and 1974.

Natural Resources

includes land, rangelands, and water used for irrigation. The annual land area was available in the FAO dataset while the value of natural resources was calculated by the residual imputation method. It is, in fact, considered as being the residual difference between the overall agricultural output and the sum of all inputs values.

3.4. Data Limitations and Missing Values

Some limitations of these calculations should be noted given the nature of the data on which they are based. The first limitation is that revenue and cost shares are held constant over time. Some of the data variables were not available for the whole period 1961 - 2012 in the FAO STATA. For input data there were a missing data fertilizer inputs during 1961 - 1993 and values of labor also during 1991 - 1993 were also missing, in addition to labor numbers, mechanization values were also missing during 1961 - 1973. Water values and quantities were also missing during 1961 - 1990; national statistics from the ministry of water and irrigation were used to fill the missing data from the FAO STATA. Seeds data were also missing for the period 1961 - 1990, so data also from the DOS were collected to fill the data gap.

However, an examination of the output data shows that for major commodity categories (e.g., cereal crops, oil crops, fruits and vegetables, meat, milk). On the input side, there has been more movement in cost shares among the major categories, but these changes occur gradually over decades. Thus, the likelihood of major biases in productivity measurement over a decade or two is not large, although this does remain a potential source of bias for longer-term comparisons. The principal advantage of these TFP growth estimates, however, is that the calculations have a standardized quality.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. RESULTS AND DISCUSSION

The annual average growth rates in the total output index (TOI), total input index (TII) and total factor productivity index (TFPI) between 1966 and 2011 are shown in Figure 2 and Table 1. The results estimated for individual years appeared to vary widely because of fluctuations in the prices of inputs and outputs. The TFP index (Figure 2 and Table 1) shows an important fluctuation over the analysis period. This fluctuating trend is mainly due to the fluctuation of the Output index, which is explained by the variability of rain-fed agriculture in Jordan due to highly variable climate conditions.

Figure 2 and Table 1 show an increasing trend of the output, inputs, and TFP indexes in Jordan. However, these values should be further analyzed in order to investigate the components the TFP growth and attributes clear shares to the different growth sources.

Consequently, we conducted an econometric estimation of the relationship between TFP growth and different factors, including the most important factors that we consider crucial on the TFP determinants for the Jordanian case. In a stylized form, we used the following regression model (expected signs in parentheses):

$$TFP = f\ (HC, BTD, SRP, MC, RR, SIL, TO, INF, SM) \quad (4)$$

Where:

TFP = Total Factor Productivity in the Jordanian agricultural sector
HC (+) = Human Capital: Health status as measured by life expectance (Years)
BTD (+) = Balanced territorial development Indicators: Rural GDP per capita (US$/Capita)
SRP (+) = Share of the rural population (in %)
MC (+) = Main crop (Tomatoes in Jordan): Share of total cropland harvested (in %)
RR (+) = Resources reallocation: Agricultural employment share (in %)

Table 1. Normalized (base 100 for 1966) Values of Output, Input and TFP Indexes

Years	Normalized Output Index	Normalized Input Index	Normalized TFP Index
1966	100	100.00	100
1970	135.23	52.48	38.81
1975	169.87	61.82	36.39
1980	185.79	110.59	59.52
1985	219.66	147.19	67.01
1990	250.02	202.86	81.14
Years	Normalized Output Index	Normalized Input Index	Normalized TFP Index
1995	301.69	275.04	91.17
2000	291.92	281.24	96.34
2005	420.05	341.24	81.24
2010	326.82	426.51	130.50
2011	323.60	443.75	137.13
2012	323.22	443.75	137.29

Source: Own elaboration (2014)

SIL (+) =Share of irrigated land/total agriculture land (in %)
TO (+) = Trade Openness: (Import +export)/total production (in %)
INF (+) = Infrastructure: Road density (km /km2 agricultural land) - 1000 Km
SM (+) = Sustainable management: Share of agriculture in water use (in %)

The log-linear form of equation (4) allows for estimating coefficients that can be directly interpreted as elasticities. In addition, as highlighted in the pioneering work by Jud and Hyman (1974), equation (4) contains a weak residual variance relative to other functional forms for the same data set and adjusts the data better than the linear specification for both forecasted parameter signs and statistical significance. The standard Ordinary Linear Squared (OLS) method, if applied to non-stationary data series, can produce spurious regression. That is, the OLS regression can give high R2, low Durbin-Watson (DW) statistics, and significant t-values of the estimated coefficients, suggesting a significant relationship between dependent and explanatory variables, when in fact they are completely unrelated.

Conventionally, the factors explaining TFP have been studied by expressing variables in logarithmic form. This is similar to the first differencing of variables in time series analysis. Provided the original series are integrated of order 1, as is normally the case, expressing the variables in logarithmic terms ensures a stationary data series and means that the OLS method can safely and directly be used (Hendry, 1995).

The log-linear form of regression equation as indicated above was used to examine the relationship between TFP growth and different factors that affect TFP growth. While investments in agricultural research provide an obvious mechanism for TFP growth through technical change, the other variables (economic policy, human capital, infrastructure, and the absence of armed conflict) help to establish an enabling environment for economic growth. These factors enable farmers to access new technologies and markets, increase returns to savings and investments, and provide incentives for farmers to reallocate resources to the most profitable enterprises.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The results showed in Table 2 that human capital has a positive and direct significant impact on the TFP which implies that people with longer life expectancy have a significant impact on TFP growth. The other determinant which showed to have positive and significant impact on TFP is the share of the main crop which is tomato crop in Jordan as tomatoes are among the most important vegetables grown in the country. There are two areas where tomatoes are grown. The total area planted with tomatoes was 8,115 hectares in 2000 and increased to 12,954 hectares in 2011 which reflected positively on TFP growth.

The independent variable of share of irrigated land/total agriculture land (in %) has showed positive and significant impact on TFP as indicated by the result of regression analysis. The total area used under irrigation in Jordan is estimated at 76,911.62 hectares in 2000 for fruit trees, filed crops, and vegetables; this area is estimated at 95,653.84 hectares in 2012 with a 24% increase that explains the direct and significant impact on TFP. The investment in irrigation capital and the modern and efficient use of irrigation systems that been used for the cultivation in the irrigated area has posted the productivity of the agricultural sector significantly.

The independent variable Infrastructure expressed in road density (km /km2 agricultural land) - 1000 Km found to have positive but no significant impact on TFP, thus implying that government investments in agricultural roads will post the overall productivity of the agricultural sector and allows more access for farmers for local market and new markets. The independent variables of Balanced territorial development Indicators: Rural GDP per capita (US$/Capita), the share of the rural population (in %), and sustainable management expressed in share of agriculture in water use (in %) found to have negative and significant impact on TFP as shown in the regression analysis in Table 2. However, the agricultural employment share and trade openness: (Import +export)/total production (in %) variables showed negative relationship and has no and significant impact on TFP.

5. CONCLUSION AND POLICY IMPLICATIONS

This article has summarized the data collection and calculation procedures for the estimation of TFP of the Jordanian agricultural sector for the period 1961 - 2011. Data was collected from different sources and some missing values were estimated and/or approximated through some proxy variables and assumptions. The list of assumptions was discussed above.

The agricultural output growth is usually due to three types of factors: area growth, yield growth, and prices change. Area growth is related to an increase in the quantities of inputs use in addition to land. However, yield growth is generated by both inputs use growth and TFP growth. Then, the TFP growth is the result of both technical change and better allocative efficiency of the used factors. Growth patterns could be then defined as a trade-off between these two sources which determines TFP growth. Although all choices of growth patterns can achieve the substantive growth of TFP, the distributions between both sources should be coordinated.

Despite some recent improvement, agricultural productivity growth in Jordan continues to lag behind just about every other region of the world. While there are important data challenges in measuring trends in agricultural productivity, most studies agree that agricultural TFP in Jordan was stagnant or declining in the 1960s and 1970s, but turned positive around the mid-1980s. A number of factors appear to have contributed to the renewal of agricultural productivity growth observed in recent decades. One driver is human capital that shown to have positive and direct significant impact on the TFP and the share of the main crop which is tomato crop in Jordan and the share of irrigated land/total agriculture land.

Table 2. TFP Determinants in the Jordanian Agricultural Sector (1967–2011)

	Dependent Variable LnTFPt		
Parameters	**Estimated coefficients**	**t-ratios**	**p-value**
Constant	-6.38	-1.79	0.08
LHCt (Human Capital)	3.08	5.08	0.00
LBTDt (Balanced territorial development Indicators)	-2.68	-1.46	0.15
LSRPt (Share of the rural population)	-0.53	-1.79	0.08
Parameters	Dependent Variable LnTFPt		
	Estimated coefficients	t-ratios	p-value
LMCt (Share of the main crop – tomatoes - of total cropland harvested)	5.68	1.43	0.23
LRRt (Resources reallocation: Agricultural employment share)	-0.77	-0.51	0.62
LSILt (Share of irrigated land/total agriculture land)	0.57	2.96	0.01
LTOt (Trade Openness)	-0.34	-1.15	0.26
LINFt (Infrastructure)	0.70	0.53	0.60
LSMt (Sustainable management)	-6.38	-1.79	0.08
T	45		
R2	0.44		
F-statistic	3.66 (p<0.003215)		
Log likelihood	13.54		

Source: Author's calculation based on coefficient estimates of the linear regression model.

The Infrastructure expressed in road density (km /km2 agricultural land) - 1000 Km have positive but no significant impact on TFP, thus implying that government investments in agricultural roads will post the overall productivity of the agricultural sector and allows more access for farmers for local market and new markets. In addition to investing in agricultural research, strengthening the broader enabling environment for farmers to access technology, markets, and the necessary support services have helped raise agricultural productivity in Jordan. The main implication policy of this research is that estimating growth in TFP is difficult, but it is essential for assessing the country past and potential economic performance and the gains in TFP drive gains in income and growth.

ACKNOWLEDGMENT

The authors thank the 'Agricultural Productivity with an Emphasis on Water Constraints in the Middle East and North Africa (MENA)' project sponsored by the Economic Research Service (ERS) – United States Department of Agriculture (USDA) for funding this research.

ABSTRACT

Overpopulation has recognized as a global environmental problem since few decades, as it has caused a number of adverse effects on environment. Modern medical facilities and illiteracy in some interior regions of developing countries are the major reasons for development of this inverted pyramid demographic structure. Overpopulation has resulted in a series of catastrophic consequences by causing increased pressure on existing natural resources. Deforestation, effect on welfare, climate change, decline in biocapacity, urban sprawl, food security, increase in energy demand and effect on marine ecosystem are amongst most severe impacts of overpopulation. Concrete steps need to be taken on national and international level to combat the adverse effects of overpopulation, so that sustainability of natural resources can be ensured for future generations.

INTRODUCTION

The world's population has touched a mark of 7.3 billion in 2015 and could attain growth level of 9-12 billion before the year 2050 which suggest that the impact of overpopulation can increase the pace of ecological changes and impose a burden on biodiversity (Sala et al., 2000; UN, 2015). The 49 least developed countries have shown a growth rate of 2.3% annually, which was nearly twice as compared to the developing world i.e. 1.2% per year in the year 2009 (UN, 2009). Increases in human population

size have caused an increased risk of synergies among impacts with resultant accelerated environmental degradation (Harte, 2007). This increase in population size has fastened the agricultural activities and technological development up to the extent, which is catastrophic to environmental health. The negative effect of an agriculture or technological society on the abiotic and biotic components of the environment can be expressed in the simplest terms, by the relation,

$I = P.F$

where P and F denotes the population and function, respectively which measures impact per capita (Ehrlich and Holdren, 1971). Thus, to reduce environmental degradation and to ensure sustainability of natural resources, better understanding of potential impacts of overpopulation on environmental and human health are required.

BACKGROUND

An exponential growth of human population over the last few centuries has caused encroachment in the wild habitats and their consequent destruction, posing a potential threat to biodiversity components (Vinod, 2012). Growth rate of world population was approximately 2% per annum from 1960-2000, which indicted potential population doubling every 35 years thus could cause ecological unsustainability (Bloom, 2011). Projected world population growth for the major regions is presented in Table 1. Improved agriculture practices, modern medical facilities and illiteracy in rural regions caused demographic transition with more natality rate and decline in mortality rate. From 1980–81 until 1999–2000, agriculture showed a growth rate of 3.2% per annum, which exceeds the population growth rate of 2.0% annually over the period, while annual growth rate of per capita income was 3.1% between 1980 and 1991 and 4.3% since there forms of 1991 (Lal, 2006). According to the Inter Academy Panel Statement on Population Growth, several environmental concerns such as, elevated level of greenhouse gases, threat to biodiversity, climate change and environmental pollution are arisen as a result of rapid population growth (Coleman, 2011; Edet et al., 2014). This chapter reviews the impacts of overpopulation on environment, indicates future perspectives and provides some recommendation to combat the adverse impact of overpopulation.

IMPACTS OF OVERPOPULATION

Overpopulation has severe environmental implications. Although it has contributed in the nation's economy at global level, but has caused some adverse impacts on environment, which need to be addressed (Figure 1). Table 2 summarizes evolution of environmental concern, associated with population explosion.

Deforestation

Increasing urbanization has triggered deforestation at a very fast pace, in order to fulfill infrastructure demand of increasing population. Lands with high canopy covers are being subjected to deforestation and people are continuing to migrate from rural areas to urban areas. According to World Migration Report

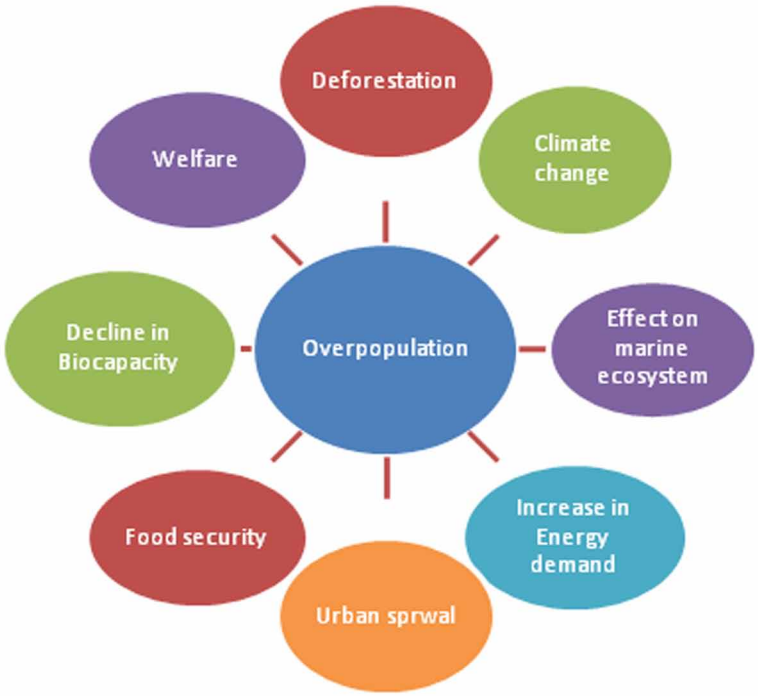
Figure 1. Effect of overpopulation on Environment



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(2015), net migration from rural to urban area during 1981–1991 was 11 million which has risen during 2001-2011 to 19 million, in India. Population growth caused an exponential increase in the alternation of the land utilization patterns to supplements economic needs in the form of agricultural products, fuel wood, timber etc. However, to control conversion of forest area to agricultural, industrial and residential area, Forest (Conservation) Act was enacted in the year 1980 in India as a result of which conversion of forest area to other land use practices was reduced with the annual diversion rate of 16,000 hectare (Economic Survey of India, 1998-99; Nagdeve, 2002).

Welfare

Overpopulation has severely affected the quality of life in recent years. Quality of life (QOL) of individuals is an approach used to determine their satisfaction in:

- Life,
- Financial status,
- Education,
- Social life,
- Family life,
- Health and
- Employment.

According to Quality-of-Life Index, 2005, Ireland ranks first in the quality of life, with comparatively low population in comparison with countries such as China and India which ranks 60 and 73, respectively. Increasing population has imposed a burden on existing recourses to fulfill the basic needs of such huge population, which resulted in elevated poverty percentage. According to Planning Commission, India, below poverty line population living in the rural area showed a sharp increase from 27.09% in 1999 to 41.79% in the year 2005. This increase is subsequently accelerating lack of education in a mass of poor population. It tends to increase fertility rate in illiterate and poor population, which is not much aware about degrading environmental quality due to increasing population. Table 3 represents general fertility rate of women by their education level in different states of India. Kerala showed lowest i.e. 1.3% of illiterate women, while Bihar represents highest illiteracy i.e. 51.1% of illiterate women. General fertility rate was found to be lower for literate women as compare to illiterate women in all states of India. However, states showed lower value of general fertility rate for illiterate population than the literate population which was ascribed to the fact that sample size in illiterate category was quite small as theses states have significantly high literacy level (Census of India, 2011). In addition, government of developing countries like India is not able to manage medical facilities to such huge amount of population.

Climate Change

Recent reports on climate change indicated more frequency and catastrophe in the weather extremes, leading to costly damage of infrastructure and loss of human life (Intergovernmental Panel on Climate Change, 2007). Increased use of fossil fuels since the mid-19th century in overpopulated regions around the globe caused release of over 1100Gt CO_2 into the atmosphere (IPCC, 2001). Furthermore, overpopulation accelerated agricultural practices, leading to enhanced emission of greenhouse gases. For

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

example, methane is produced from rice agriculture practices and livestock. For emission of greenhouse gases, agriculture sources in 2014 accounted for 24% of 2010 global emission (IPCC, 2014). Population reduction in high-income countries might act as a possible solution. Any reduction in population growth in high-income countries, even starting from zero or negative rates, will have much more impact on reducing climate change than the same size reduction in low-income countries, because of the much higher per capita consumption and emission of greenhouse gases in the high-income countries (Rosnick, 2014). In addition, switch to alternative energy options (solar energy, tidal energy, wind energy etc) and improved agricultural practices could help in combating the problem of climate change resulting from increased population.

Decline in Biocapacity

Increasing global population has accelerated resource consumption, which subsequently increased pressure on existing natural resources to unprecedented levels. Biocapacity is the area available as productive land and available water to produce resources or absorb carbon dioxide waste, given current management practices (Ecological Footprint Atlas, 2010). Biocapacity seems to decline sharply with increased pressure on ecological resources, as existing resources could not support consumption need of such a wide world population. Biocapacity per head decreased from 3.2 global hectares (gha) in 1961 to 1.8 gha per capita in 2008, even though total global biocapacity increased over this time (WWF Living Planet Report, 2012). The Ecological footprint denotes the land area required to meet the consumption and waste absorption needs of a population (Wackernagel & Rees, 1995). It can be used to track the availability and consumption of ecological resources and thus can aid in sustainable utilization of resources. According to Ecological Footprint accounts, demand for renewable resources has increased from 7.6 billion global hectares in 1961 to 18.1 billion global hectares in 2010. Similarly, global bioproductive area showed an increase from 9.9 billion global hectares in 1961 to 12 billion global hectares in 2010, indicating its unsustainable status (Global Footprint Network, 2015).

Urban Sprawl

Urban sprawl is one of the several consequences of rapid population growth. Sprawl is a large scale development process of real estate, producing low density, scattered, discontinuous car-dependent construction, usually on the periphery of the declining older suburbs and shrinking city centers (Hayden, 2004). Urban global population will grow to 4.9 billion by 2030, while, the global rural population is predicted to decline by approximately 28 million during 2005 to 2030 (Bhatta, 2010). In the United States, urban growth is expected to utilize about 19 million acres of farmland, environmentally sensitive and other lands during 2000–2025 (Burchell et al., 2005). Urban sprawl can be caused either by increased natality rate or by increased immigration. Better living facilities and need employment of employment are the major factors, which caused migration of population from rural area to urban area. Governmental organizations cannot deliver all basic services and quality life to huge urban population and thus, resulting massive sprawl may cause severe environmental degradation.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Food Security

Overpopulation has worsened the local and global food security by synergistic impacts of climate change. Emission from agriculture sources elevated from 4.7 billion tonnes to over 5.3 billion tonnes of carbon dioxide equivalents (CO_2 eq) during 2001-2011 (Food and Agriculture Organization, 2014). Climate change resulting from the enhanced emission of greenhouse gases has posed a severe threat on food security by affecting agricultural crop production and biodiversity. Food security is linked with food availability, accessibility and utilization. Increasing urbanization has limited the growth of agricultural sectors by encouraging industrial development in rural regions. Current food production is becoming limited along with the hasty growth in human population numbers. Technological development in the field of agriculture depends on availability of natural resources like water, land and energy. For instance, 1 kcal of food production requires about 10 kcal of fossil energy, which is present in limited amount and thus restrict the progress in agriculture production (Pimentel, 2011). Currently, agricultural land suitable for irrigation is 50% of the world's land. This land area is continuously being shrinking due to soil erosion, nutrient depletion, soil acidification and soil salination (Horizon, 2009).

Increase in Energy Demand

Growing global population has caused rapid inflation in energy requirement and consumption. According to Energy Information Administration (2001), use of energy, mostly for fossil fuels has boosted by nearly 85 percent globally during past 30 years, while for Asia, it is more than 300%. Sustainability for energy resources can be assured by the increased use of renewable resources, utilizing energy conserving devices for household purposes and development of advanced technologies for generating energy from biological sources.

Effect on Marine Ecosystem

Overpopulation in coastlines has mainly resulted from migration activities and caused severe environmental degradation. Mangroves, fisheries and beaches used commercially for tourism purposes are among the coastal resources, which are severely damaged by consumption practices (Naylor et al., 2002). Coral reefs are being rapidly degraded both due to direct impact of climate change and by human induced marine pollution, overfishing etc. Out of the 19,210 km^2 of coral reefs in South Asia, 45% of have been destroyed, while 10%, 25% and 20% are critically threatened, threatened and at low risk, respectively (Tun et al., 2004). In Mesoamerican Barrier Reef, coral cover is declining at an average rate of about 11% since 2004, with more than 50% cover loss for some reefs (Wilkinson, 2008). International agreements for conserving marine biodiversity have however caused a significant increase in several biodiversity rich marine regions but increasing population is still a hurdle for their successful implementations.

ISSUES, CONTROVERSIES, PROBLEMS

Several efforts are being taken to ensure reduction of adverse impacts of overpopulation on environment but these are associated with serious issues. For example, developing countries are being funded under clean development mechanism to increase plantation practices, but simultaneous deforestation, has

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

checked the advantages emerging out of the strategy. Huge population in rural regions is still dependent on fossil fuels for energy needs. Although renewable energy programmes are being initiated in rural regions by various governmental organizations but the success of these programmes always remains on question. No maintainers are provided for the solar panels after their installment. As a result, most of such renewable energy devices remain in non-working condition. Several schemes are being hurled by government of India to provide employment in the rural areas so that the massive urban sprawl can be checked. Government of India inducted a scheme for self-employment in 1980-81 namely, Integrated Rural Development Programme (IRDP), which was further remodeled as the Swarnjayanti Gram Swarozgar Yojana (SGSY). In 1989, Jawahar Rozgar Yojana (JRY) was initiated by amalgamating National Rural Employment Programme (NREP) and Rural Landless Employment Guarantee Programme (RLEGP). The main goal of the scheme was generating more employment opportunities for people living in rural areas, advancing rural infrastructure and quality of life (Planning Commission, Government of India). However, it turns out to be a very time consuming process for procuring actual financial gain by rural people due to red tapism involved in governmental procedures especially in developing nations. In addition, to ensure food security, use of enormous quantity of chemical fertilizers further worsened the environmental health by reducing soil fertility.

POSITIVE EFFECTS OF OVERPOPULATION

As a major problem many scientists agreed that human population may reach the point at which the earth will no more able to sustain life. However, many believe that ever increasing population have some advantages such as:

- Economic benefits,
- Increased human resources,
- Higher demand in industries,
- Innovative, cheaper and
- More readily available products etc.

A nation with high population and/or increasing number of youth can add more people to developmental activities. An increasing population can boost the economic growth of a country only if the demand for better services grows. Therefore, to yield positive effects from growing population a nation must have sound policies. Keeping the pace with population growth, countries that utilize their human resources efficiently in developing better health care and medicine, food production,

SOLUTIONS AND RECOMMENDATIONS

The impact of overpopulation on food security can be reduced by raising food production, improving food distribution and by increasing economic access to food (Gregory et al., 2005). Similarly, deforestation can be reduced by proper management of forest. For the management of forest, an effective strategy should be developed to harmonize conservation priorities and development goals i.e. by including native people in decision making procedures regarding utilization and conservation of forest resources

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Chakravarty et al., 2008). Similarly, for the efficient utilization of renewable energy, regular employment of maintainers and operators for each installed renewable energy plant should be ensured. In addition, Transparency in funding mechanisms of governmental procedures must be ensured, so that urban sprawl can be reduced. Population explosion awareness programs in developing nations need to be conducted, so that problem can be solved at grass root level. Some countries like China, had taken strong steps to combat problems of overpopulation but the scheme (One child policy) has failed due to several reasons. The scheme has encouraged people for increasing incidents of feticides, tending to gender inequality. A large mass of population is now entered in an old age and only a small proportion of young generation is there to support economic growth of country. Thus any scheme must be viewed with its possible pros and cons, before implementation.

FUTURE RESEARCH DIRECTIONS

Demographic structure of different countries needs to be evaluated and the reasons behind the inverted demographic pyramid should be assessed for each country. In addition, research needs to be conducted on the effective ways to maintain impartial sharing of resources, so that carrying capacity of ecosystem could be increased. Effective ways for awareness of people about programs related to family planning must be determined and implemented.

CONCLUSION

Overpopulation has posed severe threat to environment with regard to deforestation, ecosystem degradation, climate change and adverse impact of human welfare. Several measures were adopted by developed and developing nations in order to reduce the damage caused by overpopulation. These measures proved inefficient to curb population growth, as were associated with some serious drawbacks. Therefore, effective awareness programs about population control, education in rural regions and impartial sharing of resources must be ensured, so that population explosion could be controlled.

WWF/ZSL. (2012). *Living planet report.* WWF and the Zoological Society of London. Retrieved on December 23, 2015, from: wwf.panda.org/about_our_earth/all_publications/living_planet_report/2012_lpr/

KEY TERMS AND DEFINITIONS

Mortality Rate: It denotes the death of individuals per unit time.

Natality Rate: It represents the birth of individuals per female per unit time.

Red Tapism: It denotes the requirement of excessive paperwork for any work, that usually prevent or delay decision making process in bureaucracy.

This research was previously published in Environmental Issues Surrounding Human Overpopulation edited by Rajeev Pratap Singh, Anita Singh, and Vaibhav Srivastava, pages 1-11, copyright year 2017 by Information Science Reference (an imprint of IGI Global).

Mark to Market 1356
Marker Assisted Selection 1313, 1334
Market Information 188-189, 191, 207-208, 218, 220, 222, 467, 620, 671, 681, 832, 837, 844, 1066, 1358, 1362, 1364, 1368-1370, 1372, 1442, 1570, 1572, 1583, 1635
Market Orientation 1129, 1143, 1572
Market Segmentation 1624-1629, 1634, 1641, 1646
Marketing Mix 1335, 1348-1349, 1625, 1634, 1640-1641
Marketing Research 1625, 1627, 1646
Marsh 932, 940, 1536, 1538-1544, 1546-1549, 1555
Maximum Similarity based Region Merging 1078, 1081
McCain 274-276
Mechanical Innovation 316-318, 322, 324-325, 329
Medicine 210, 580, 630-631, 634-635, 637-638, 640, 644, 647, 649, 775, 1106, 1113, 1179, 1518, 1590-1591, 1731
Microcontroller 97, 99, 338, 406-407, 410
Micro-Financing 260, 268, 270, 275, 1070-1071
Microorganisms 80, 94-95, 100, 356, 564, 687-689, 695, 1572, 1583
Milk and Milk Products 1522, 1571
Mitigation 193, 263-264, 388, 564, 591, 907-908, 918, 921, 1181, 1258, 1260, 1270, 1278-1280, 1286, 1306-1307, 1321, 1333, 1452, 1483, 1490, 1617
Mobile Applications 519, 522, 524, 527, 529, 619, 778, 781
mobile based system 840
Mobile Cloud Computing 781
Mobile Phones 183, 202-203, 206-207, 224, 332, 337, 339, 342, 406, 408, 442, 464, 469, 473, 518-525, 527-528, 531, 618-625, 627, 640-641, 661-663, 665, 667-668, 671-672, 675-682, 716-718, 720-721, 726, 728-730, 773-774, 781, 838, 845-846, 1215, 1358-1360, 1362-1370, 1372-1373, 1418, 1439-1440, 1445
Mobile River 1469-1479
Mobile Robots 630-656
Modeling 93, 192, 319, 362, 395, 409, 738, 767, 805-807, 810-811, 813-815, 818-821, 1007, 1452, 1469, 1471-1474, 1477, 1479
Models 9, 38, 73-74, 81, 93, 171, 187, 202, 265, 284, 291, 326, 355, 358-359, 395, 481, 487, 491, 681, 717-718, 722, 726, 728-729, 738-740, 793, 805-811, 813-814, 816, 818-821, 840, 908, 920, 939, 953, 991-998, 1003, 1007, 1012, 1044-1045, 1053, 1083, 1088, 1179, 1203, 1212, 1249, 1253, 1265, 1269, 1276, 1288, 1291, 1295, 1320, 1399, 1401, 1403, 1422-1425, 1427, 1455, 1470, 1504, 1508, 1593, 1607, 1618, 1640, 1655, 1674
Molecular markers 1313
Monitoring 69, 74, 97, 219, 222-223, 261, 289, 334-335, 337-339, 353, 405-409, 440, 448, 517, 519, 523, 580, 634, 641-643, 653, 777, 781, 848, 860, 879, 940, 960, 1060, 1080-1081, 1083, 1207, 1276-1278, 1307, 1404, 1406, 1425, 1518, 1606-1607, 1612, 1617-1619, 1640, 1699
Moral Obligation 1598
Moral Responsibility 1589, 1592-1594, 1597-1598, 1602
Mortality Rate 1689, 1725, 1734
Mother Earth 48, 50-51, 54-56, 63, 1520
Mozambique 716-718, 724-728, 730, 1501, 1689, 1695, 1697
Multidisciplinary Approach 873
