Mobile robots are increasingly becoming the subject of research and a very important area of science, so that the 21st century will be named as the century of development of service robots. Mobile robots are an excellent "System Engineering" research example because it includes a lot of scientific research, namely in the area of mechanical engineering, electrical engineering, electronics, computer science, social science, and more. As mobile robots perform their tasks in the same environment as humans, mobile robots should have the abilities that people have. The mobile robots should be able to recognize faces, gestures, signs, objects, speech and atmosphere. Successful realization set of tasks results in bypassing obstacles without collision and destruction in the shortest possible time and distance. They should communicate with people on the basis of emotion. The range of mobile robots application is huge. Mobile robots have found application in many areas, but this chapter will cover the following distribution of mobile robots areas of application: medicine, agriculture, defense, logistics, construction, demolition, professional cleaning, space exploration, education and scientific research. The price of robots is declining steadily and they are coming into ever wider use. It is only a matter of time before robots become available to the population of today's high school students, just as it happened with computers and cell phones.

INTRODUCTION

In the early fifties, more precisely in 1951, Raymond Goertz made the first telecom operator – the hand that "dealt" with radioactive material and was developed for the Atomic Energy Commission. The first robot that could be programmed was also made in fifties – in 1954 – and its constructor was George Dovel, who had his methods patented. Two years later, George Dovel and Joseph F. Engelberg started Unimation Inc. company, which was the first company to deal with robots. In the sixties, precisely in 1962, the first robot was installed on the production line of the General Motors Company. The first robot arm controlled by computer was made a year later in the Los Amigos Hospital in California. Also, 1964

was a significant year when it comes to education in robotics. In fact, Artificial Intelligence (AI) research laboratories were opened at MIT, Stanford Research Institute, Stanford University, and the University of Edinburgh. Japan, which is among the leading countries engaged in robots manufacturing nowadays, imported its first robot from the United States. In 1968, Kawasaki Heavy Industries Company started production under the license of Unimation Company. At present, robots have a wide application – probably wider than it seems. They are used almost from the beginnings of space exploration (at the spacecrafts Viking 1 and 2, as we have seen) and, of course, to this day. NASA used robots to explore Mars. Similar vehicles were developed after the success of the Pathfinder mission, and those were able to travel 100 meters per day on each Martian day while carrying instruments used to explore the Red Planet. Robots are used a lot by different armies, but probably the biggest progress in this aspect was made by the United States army. Great number of robots is used in potentially dangerous situations. You can see on TV how robots manipulate with bombs or go through minefields. One of these is the Mini Andros, which has two "arms" and can climb and descend the stairs. It is equipped with three video cameras, and thus is useful in exploring new areas, such as large houses where there are dangerous people. Special versions of this robot are equipped with the radiation detector. Nowadays, robots are applied at home, for vacuuming, laundry, surveillance, etc. Lego Mindstorm robots are extremely popular. The project Lego Mindstrom itself was launched fifteen years ago by Lego and Massachusetts Institute of Technology. As the company Lego claims, a user who knows how to use a personal computer can make his first Lego robot up in an hour. Robots are also applied in sport: it is old news that some kind of RoboCup competition is organized every now and then. By 2050, RoboCup project aims to develop a complete humanoid soccer team, claiming it can certainly beat the current world champions. Nowadays, robots and artificial intelligence coexist and thus it is hard to imagine a present-day robot not being some kind of artificial intelligence. As with artificial intelligence, the question with robots, androids, as well as fusion of all three life forms is what if they get out of control? According to Hans Moravec, one of the robot/AI experts, robots will become as smart as a man by 2040, and we are sure they will be much smarter than many of the inhabitants. Despite pessimistic and paranoid predictions, Moravec is not worried. It is considered that robots and artificial intelligence will actually extend the life of man and improve the quality of life in general. As it seems, evolution has led man nearly to the degree that it can build a being as intelligent as himself! We live in a time that will in the distant future undoubtedly be remembered for many things, and it would be a shame we are not aware of it now as well. It is sufficient just to look around and realize that what we only used to read or watch is already around us. Mobile robots' application increases daily, so they are used in medicine, defense, agriculture, civil engineering, logistics, rescue and safety, professional cleaning, inspection and maintenance, space exploration, education, household, etc. It can be claimed there is no segment of a man's life in which mobile robots are not incorporated. With fast computerization of all forms of business and a vast expansion of the Internet, it is expected that there will be a big gap in the 21st century between those technologically advanced and those who have lost their connection with modern times. Most people are not aware of the extent to which robots are already represented within their lives. Their cars and computers are almost certainly partially assembled with the help of a robot. As it has been mentioned, the price of robots is steadily declining and mobile robots are increasingly coming into wide use (Chen, Chen, Chase, 2009; Karabegović, Doleček, 2012; Doleček, Karabegović, 2002; Angeles, 2007; Mulfer, 2010; Doleček, 2015; Teich, 2012; Steckelberg, 2007).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

THE DISTRIBUTION OF MOBILE ROBOTS

As a scientific discipline, mobile robotics is very attractive, challenging and imaginative. Mobile robotics aims to replace humans in performing dangerous, monotonous and heavy tasks, as well as to make human life more comfortable and enjoyable. The development and progress in new technologies, sensor technologies and information technologies has led to the development of hundreds of different types of service robots for non-productive applications. Service robots are designed to perform service tasks in civil engineering, maintenance, inspection, agriculture, therapy, rehabilitation, and fields of application in everyday life: at home, at work, in public environments, etc. It is estimated that today there are nearly 300 different types of service robots for performing all kinds of jobs, which is ensured by mobility, functionality and multimedia communications. Robotics aims at developing service robots that will help every person in everyday life. It is a relatively young technical branch, but already has a rich tradition. It turned out that robots, just like people, went through generational cycles. Each new generation of robots received the more advanced features than the previous one, which primarily relates to the actual degree of intelligence, supporting computing power, enhanced dynamic indicators and advanced control algorithms. The best example is shown in Figure 1.

As it has been mentioned and as it can bee seen from Figure 1, the characteristics of mobile robot are improving from year to year, which increases their application capacities. In order to perform the analysis of the mobile robots distribution in eight years, statistical data about mobile robots application have been retrieved from the International Federation of Robotics (IFR) (Karabegović, Doleček, 2012), as well as from the UN Economic Commission for Europe (UNECE) and the Organisation for Economic Co-operation and development (OECD), as shown in Figure 2. and Figure 3.

Based on Figure 2., it can be concluded that the trend of application (sale) of mobile robots for household and personal use is increasing at annual level from 2008 to 2014, so that it increased from 1.175.000 units of mobile robot in 2008 to 4.750.000 units of mobile robots in 2014. We can conclude that there is a growing trend in mobile robots application for household and personal use. Analysis of these trends yields a conclusion that the market for these robots is to increase constantly in the next 20 years.

World Robotics 2009-2015; Jason, 2014.

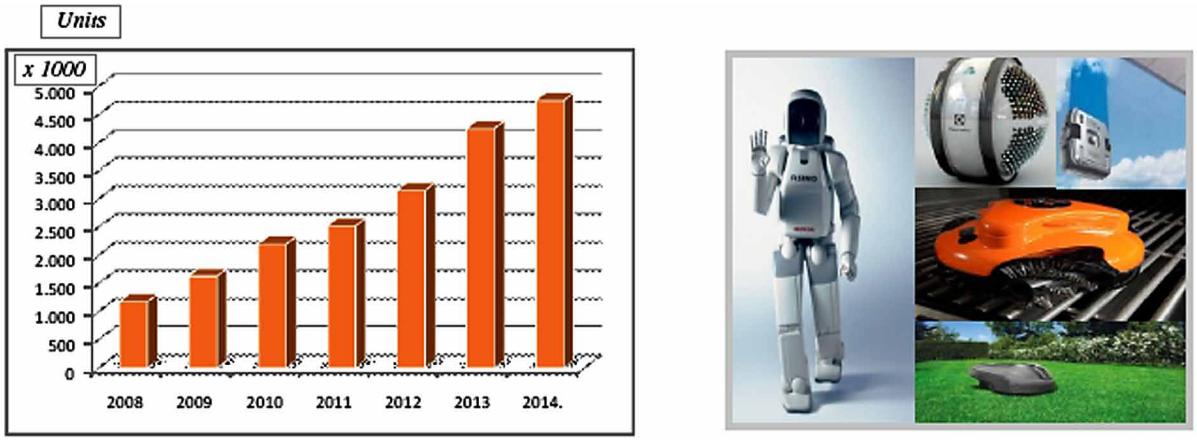

Figure 3. Mobile robots application at annual level for professional services from 2008-2014
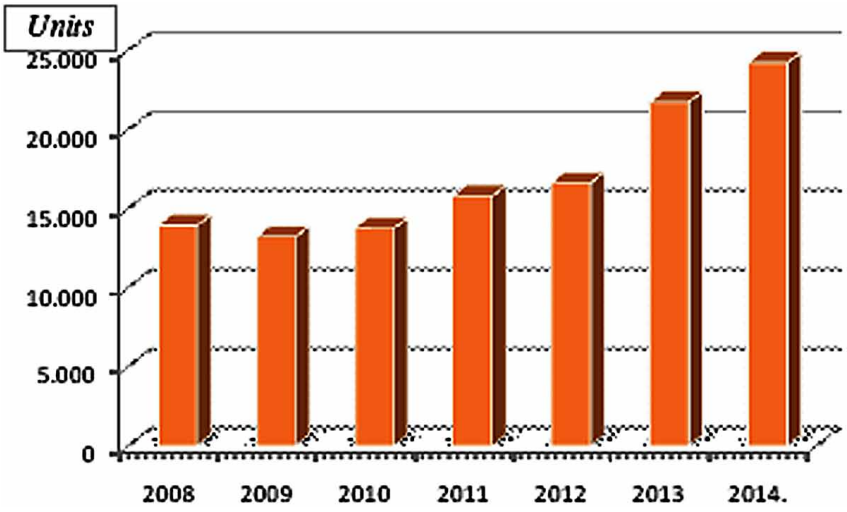
World Robotics 2009-2015.



Trend of mobile robots application for professional service increases each year from 2009 to 2014, where it reached the amount of 24.204 units of the robot in 2014. The mobile robots for professional services include the following: mobile robots for agriculture, mobile robots for professional cleaning, mobile robots for inspection and system maintenance, mobile robots for construction and demolition, mobile robots for logistics, mobile robots for medical services, mobile robots for security, mobile robots for defense (military), mobile robots for underwater systems, mobile platforms, mobile robots for public relations, and other mobile robots which are not counted here. It is predicted that the use of these mobile robots will increase from 2013-2016 to approximately 94.000 units, of which around 28.000 mobile robots for defense (military) and about 24.000 mobile robots for agriculture (milking) (World Robotics 2015).

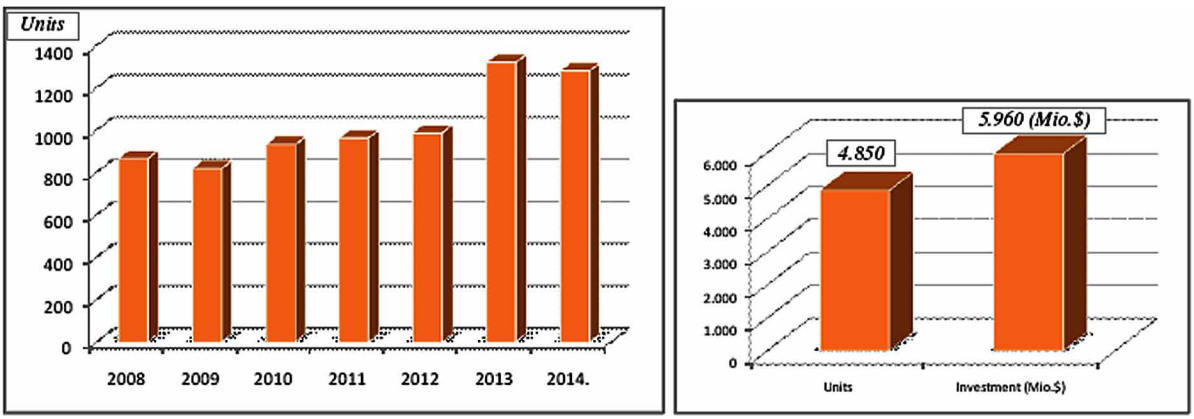
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

MOBILE ROBOTS APPLICATION IN MEDICINE

Mobile robots in medicine today, among others, have found application in many areas of medicine and some include: performing delicate surgical operation, replacing limbs that are lacking in people, rehabilitation therapy for patients who have had a stroke, visiting patients, serving patients with food and medicine, treating patients at a distance, monitoring operating procedures remotely in medical institutions, as well as carrying out a growing number of other similar tasks related to the health of patients in medical institutions. Mobile robotics can provide numerous benefits at present day. The development of new technologies, primarily sensor and information technologies that are much represented in robotic technologies resulted in the development of various robotic systems designed for different applications in medicine. In the field of medicine, there are potentially many applications of robots thanks to various ''features'' of those systems. One of them is the precision which robots have, where this feature is better than that of a skilled surgeon, e. g. when performing surgical procedures. Precision is very important in neurosurgery, and even orthopedics when e. g. drilling a bone to replace a hip. But these possibilities of robotic technology in medicine were developed only a few years back. The application of mobile robots in medicine is increasing from year to year, as it can be seen in Figure 4. (Meskoě, 2014; Carpanzano, Jovane, 2007).

Based on Figure 4, it can be concluded that the number of mobile robots increases continuously from year to year (886 units applied in medicine) so that it reached 1.280 units of mobile robots in medical institutions. We have to admit this is a very small number of applied mobile robots in medicine in the world, and such trend of application is due to very large investments, as shown in Figure 4 on the right. In the period from 2012-2015, over five million US dollars was invested in mobile robotics in medicine, which is quite a lot. The reason is that it is very sophisticated equipment and very expensive research. In relation to mobile robots used in other branches, the investments in mobile robots in medicine are the largest – as we shall see in continuation. Figure 5. shows in which medical branches mobile robots are used the most.

Figure 4. Mobile robots application at annual level in medicine from 2008-2014, the ratio of investment in medical robotics from 2012-2015 per unit of robot mobile
World Robotics 2009-2015.



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

As Figure 5 indicates, mobile robots in medicine are used in colonoscopy, endoscopy, dotted radiation, orthopedics, mini surgery, neurosurgery, etc. The biggest percentage of mobile robots is for mini surgical interventions (31%) and is followed by orthopedics (18%) and neurosurgery (15%) in 2014. The development of new applications of mobile robots in medicine will change this image from year to year. In order to better understand the mobile robots application in medicine, we will present only some applications of mobile robots in certain medical branches in the following figures.

Figure 6 shows the mobile robots application in determining diagnoses in radiology. Also, these are used when one needs to perform radiation on a patient with a certain diagnosis because point of radiation to the patient is precisely defined by mobile robot. The other two images provide an overview of patient services that can be provided by a mobile robot, e. g. measurement of pressure, serving medications or other things a patient needs (Karabegović, Felić, Đukanović, 2013; Karabegović, Karabegović, Husak, 2013; Karabegović, Karabegović, Husak, 2010)

Given that most mobile robots used for small surgical interventions, Figure 7 shows a surgical system for performing surgical operations. It has to be noted that several surgical systems have been developed to this date. The second image shows the mobile robot RP 7, which is used for treatment at distance. It is used in small rural places where it is not profitable to hire a doctor due to very small number of people. It is enough to have an ambulance and a nurse with this robot, while a doctor establishes an Internet connection to examine a patient, determine a diagnosis and recommend future treatment. With

Figure 7. Mobile robots application in surgery, distant treatment of patients, and rehabilitation of patients
Murrayon, 2013.

this robot, a doctor fully establishes communication with a patient. The last image shows a mobile robot for rehabilitation of patients. Many applications of mobile robots are developed for different types of rehabilitation.

Given that working staff of medical institutions loses a lot of time on serving patients and the very logistics required for the services that are necessary for normal functioning, various mobile robots have been developed depending on the services, and a small number is shown in Figure 8. Mobile robots for logistics in health care facilities are used for: serving patients food and medications, transporting materials to and from testing laboratories, transporting clean and dirty laundry to the laundry service where it is being prepared, etc.

MOBILE ROBOTS APPLICATION IN DEFENCE

World leaders' desire to lead wars of the future with as little human units is obvious, and thus defensive robotic systems play a major role. Robotic vehicles, i. e. service robots should reduce human involvement and the number of war casualties. Their mission is to find and destroy enemy vehicles and units, as well as to take strategic positions. Sensors with which mobile robots are equipped are able to identify armed and

Figure 8. Mobile robots application in logistics of patients and laboratories in medical institutions

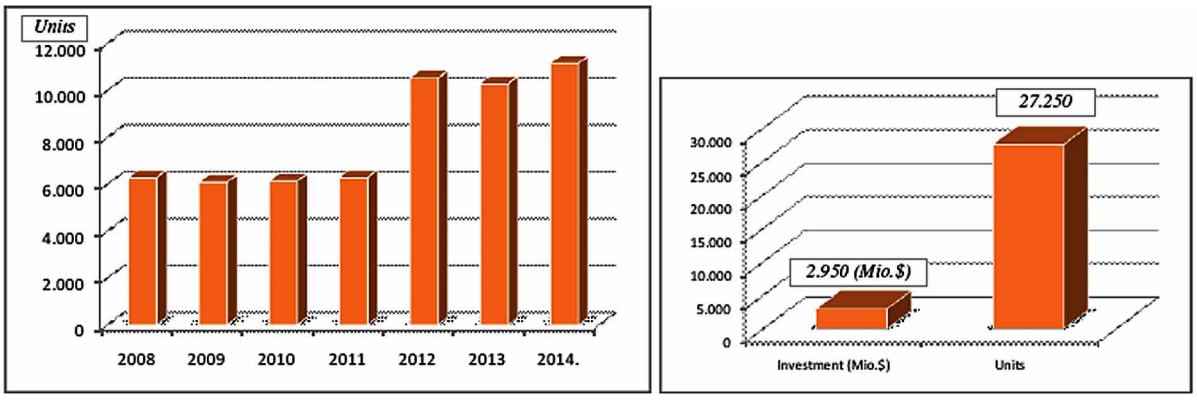
potentially dangerous targets, while a man who controls it via computer and videolink decides whether to act, open fire and destroy them. Unmanned platform should soon take over unconditional, dangerous and boring tasks. Great experience gained using a variety of remotely controlled devices and drones have led researchers to work in the direction of full autonomy. Military mobile robots are made in different shapes and sizes, from unmanned combat vehicles to groups of insect-like devices that will cooperate on specific assignments in not so distant future. Of course, the biggest part in their development takes place in the U.S., where defense community sponsored projects involving many different new technologies. In many cases, inspiration for these projects comes directly from nature, because what is actually being copied are the ways various living organisms perceive and feel their surroundings, determine the course of action, work together, move and perform some of their tasks. The U.S. military has introduced the use of mobile robots on the remote control. These are a transitional step on which to gather experience for the transition to a new generation of remotely controlled service robots. A remote operator only needs to manage a mobile robot on the remote control occasionally, while the service robot will be autonomous most of the time. The ultimate goal of development is one operator managing multiple remotely controlled mobile robots. Such service robots will be reprogrammable, retain a stable behavior even in complex, uncertain and changing conditions, as well as be able to learn. Also, it will be possible to use them safely and reliably in close proximity to people. Removing a crew (a man) from armed system reduces the need for armored protection. Robot's size is also reduced, and thus the conspicuousness of the system. This ultimately means greater flexibility and survivability, greater strategic and operational mobility and ease of logistical support. The most likely direction of development is a combination of unmanned and manned platforms, unmanned service robots being used in the most dangerous options. Number of mobile robots has a growing trend from year to year, as shown in Figure 9. New applications of mobile robots are being developed daily for use in defense purposes (Karabegović, Doleček, 2012).

On the basis of Figure 9, it can be concluded that the trend of application of mobile robots in defense was constant in the period 2008 to 2011 and it ranged around 6.000 units. This is followed by a sudden increase in applications in the period 2012-2014, ranging from 10.000 to 11.000 units of mobile robots. If one compares the application of mobile robots with application of mobile robots in medicine, it can be seen that it is almost ten times higher, which means that research in mobile robotics for defense have

Figure 9. Mobile robots application for defence on annual level from 2008-2014, the ratio of investment in the period 2012-2015 per unit of mobile robot
World Robotics 2009-2015.



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

been intensified leading to a number of new solutions in applications. Investments in mobile robotics in defense are significantly smaller – about two times smaller than investments in medicine – because they amounted to approximately 2.950 million U.S. dollars for 27.250 units in the period 2012- 2015. When it comes to defense, a vast number of applications has been developed – from mobile reconnaissance robots to those supplying the units on the ground with the necessary equipment. Because of the limitations of this chapter, we will show only some applications. The following figures show only parts of mobile robots applications in defense.

Figure 10 displays developed mobile robots used for defence purposes, and are equipped with a variety of weapons, camera sensors to heat and night surveillance. The platform of these mobile robots is such that their management and operation is performed from a safe position.

Mobile robots for defense that are used for reconnaissance have been developed and equipped with means for combat, as shown in Figure 11. Depending on the area in which they are used, these mobile robots can be driven by excavators and cranes. Apart from these, mobile robots for fast movement of units on a very rough terrain have also been developed.

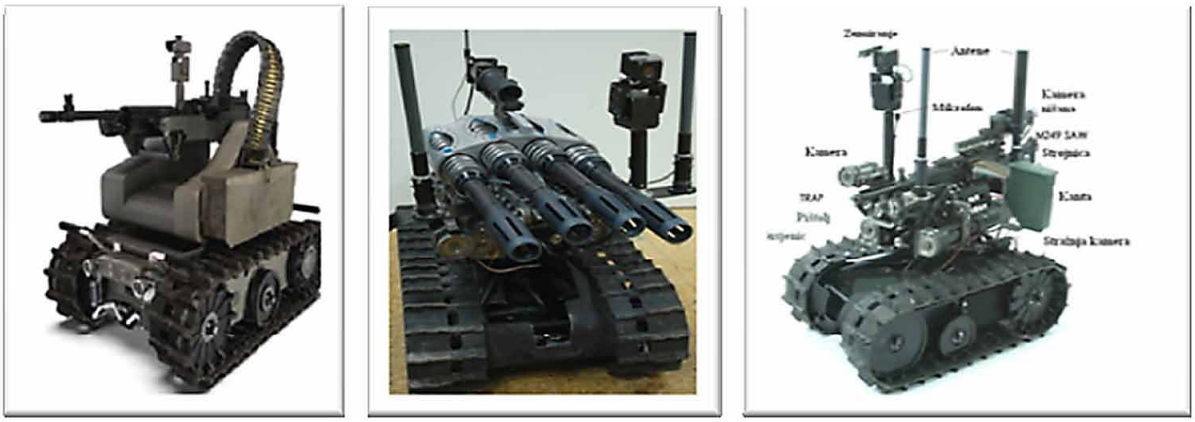

Figure 11. Mobile robots application in defence as combat vehicles Gladiator Tactical, Armed Robotic Vehicle (ARV) UGV and Black Knight
Robotic Armored Assault System –RAAS, 2016.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Numerous mobile robot applications have been developed for removing explosive devices lagging behind every war. Their development and application is very popular because it is otherwise performed by people, many of which die or become disabled. Figure 12 shows small mobile robots for removing explosives. However, large mobile robots that remove mines have been developed, so that the robot remains intact in case of an explosion and can continue performing its task.

UAV (*Unmanned Air Vehicles*) or automated aerial vehicles are commonly used in military and civil purposes for observation, research, mapping and inspection of areas, as well as for border patrol, the purposes of search and rescue, etc. But primarily, those are military devices used for reconnaissance and combat. These are unmanned aircrafts. See Figure 13. UAV look like small planes and range from small planes maintained and launched by man to large-size aircrafts to be managed remotely, as the RQ-4 Global Hawk. Thus, there are two variants of an unmanned aircraft, one controlled via "remote control" and the other pre-programmed in order to get to the finish line and complete the task. Drones, which have started off as platforms for reconnaissance, nowadays have increased capacities and thus serve as combat platforms. It should be noted that drones have the ability to perform certain actions with respect to pre-programmed procedures. What those procedures are depends from platform to platform and how many devices are capable of performing them.

U.S. Army sees mobile robots as an important, perhaps even a central part of its *Future Combat System* (*FCS*). Some elements of the FCS, including reconnaissance vehicles that monitor enemy's territory, could be unmanned. Removing a crew (a man) from armed system reduces the need for armored

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

protection. Robot's size is also reduced, and thus the conspicuousness of the system. This ultimately means greater flexibility and survivability, greater strategic and operational mobility and ease of logistical support. The most likely direction of development is a combination of unmanned and manned platforms, unmanned service robots being used in the most dangerous options. These two types of platforms should be similar to each other, so that the enemy is not able to identify mobile robots easily. Forms of service robots depend on the type of a task for which the service robot is developed. Mobile robots which have to go through difficult terrain use crawler belts. Flying service robots look similar to small planes. The American company "BOSTON DYNAMICS" develops robots that can replace a man in the danger zone. A part of the latest research is presented in Figure 14.

MOBILE ROBOTS APPLICATION IN AGRICULTURE

It used to be normal to use robots, namely industrial robots, in the manufacturing process, but today we can find a robot performing any task. Robots are designed to remove human factor from the working environment or places where it is dangerous to operate. The idea of applying mobile robots in agriculture is only a few years old. The main areas of service robots application in agriculture are the harvest, orchards, cow farms, floriculture, etc. There are various idea for mobile robots application in agriculture, such as: planting seeds, mowing, plowing, cultivating a particular culture, gathering the harvest, picking fruit, cultivation of vineyards, transplanting seedlings, flower production, work in greenhouses, as well as work on dairy farms, inspecting and cleaning cows, etc. Figure 15. shows statistical data about mobile robots application in agriculture, which International Federation of Robotics (IFR), the UN Economic Commission for Europe (UNECE) and the Organization for Economic Cooperation and Development (OECD) collected from mobile robots manufacturers (Karabegović, Doleček, 2012).

Trend of mobile robots application in agriculture is growing from year to year, and it was small only in 2009 and 2010 due to the economic and industrial crisis. Since 2010, the application of mobile robots is growing continuously, and it increased from 4.185 units up to 5.890 units in 2014. Investments in mobile robotics in agriculture amounted to $ 4.9 million for 24.950 units of mobile robots for agriculture from 2012-2015. When this is compared with investment in mobile robots in medicine, we conclude that investments are not great given the number of units. The very essence of mobile robots' work in agriculture is to specify, manage and give specific tasks to mobile robots using PCs and mobile phones

via server with a folder containing the processing area. The robots need to accomplish those tasks for a particular plant culture, as shown in Figure 16.

Communication, monitoring and control of mobile robots in agriculture are realized through server via a PC, a mobile phone, a GPS on the basis of which a processing plot is defined. Monitoring the

Figure 16. The manner of monitoring, management and communication with mobile robots when performing certain tasks in agriculture

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

performance of certain tasks with a mobile robot is made using "DRON", and all operations are performed from a center that may be located near the execution of tasks. For the types of mobile robots in agriculture, significant and useful factors are: high quality and productivity of work, reduced manual work and avoiding risks, i. e. increased safety, as shown in Table 1.

Table 1 shows the assessment of the relevance of factors for mobile robots in agriculture, with the degree of relevance marked from 0 (*not relevant*) to two points (*high relevance*). As a result of investments in mobile robotics in agriculture, many mobile robots applications were developed for this purpose, and a certain part of those is shown in the following figures.

Different applications of mobile robots in agriculture were developed, such as mowing lawns. The first robot presented in Figure 17 is used for smaller parcels, but a mobile robot has also been developed for mowing large plots with real mowers. The other two mobile robots are used for processing certain plant cultures and removal of harmful weeds from crops.

Given that a large work force is used for picking fruit, various applications of mobile robots have been developed for picking fruit – such as apples, pears, oranges, tangerines, grapefruit, etc. – in order to avoid physical work and reduce the time for harvest of a certain culture. See Figure 18. Mobile robots for grape vine pruning have been developed, as well as mobile robots to work in greenhouses for various types of vegetables.

Apart from working in the fields and greenhouses, mobile robots are used in livestock on farms. The largest number of mobile robots is used for milking cows on farms, monitoring and keeping cows, as well as for cleaning – as shown in Figure 19.

Table 1. Relevant factors and their estimation for mobile robots in agriculture

Figure 18. Mobile robots application for fruit picking, grape vines pruning and greenhouse work
Key, 2013.

Figure 19. Mobile robots application for cow milking, monitoring cows and cleaning cows on a farm
Amy, 2016; Edwards, 2016.

Automation of milking process is one of the most remarkable achievements in the modernization of farm work, as well as the process of milking cows. A robot for milking was first used in 1992 on a farm in the Netherlands. Already in 2001, automated milking systems (AMS) were used around the world on more than 1.100 farms. Nowadays, the number of AMS exceeds 10.000 at around 8.500 farms in the world. Most users are from the group of developed countries. The AMS should replace the work of employees in the milking process, i.e. to keep the necessary records of production and to be in operation 24 hours a day. The constant development of sensor technology, information technologies and new technologies leads to the development of mobile robotics, as well as the need for the rapid production in agriculture; improved quality of the product leads to the development of ever increasing number of mobile robots applications in agriculture and animal husbandry.

MOBILE ROBOTS APPLICATION IN LOGISTICS

Mobile service robots operate in diverse environments such as warehouses, manufacturing processes, airports, post offices, hospitals, transport networks, etc. For small proportions, logical mobile robots provide transport services in the offices (mail delivery and other services necessary for employees), hospitals and public institutions, and will largely be used to transport people and goods, which will in-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

crease the efficiency of road transport. In the future, the number of mobile robots applications in logistics will expand and grow, which will increase the efficiency and reduce the costs of logistics, because the logistics requirements will be processed more quickly with optimal routes. Mobile robots for logistics can perform the following tasks: delivery, transport, packaging, sorting and handling. Mobile robots in logistics can be classified into: courier systems (post offices, hospitals), logistics in factories, outdoor and field logistics, and other logistics. They are installed in offices, post offices, airports, hospitals and other public facilities for transport and delivery of a variety of goods, industrial production processes for the transfer of various items (pieces, boxes, toolbars, between machines, for transfer to a point or a warehouse) as well as indoor and outdoor warehouses, such as marine and water ports, airports, and transshipment centers for handling goods of any kind. Figure 20. shows the distribution of mobile robots for logistics, and statistical data retrieved from the International Federation of Robotics (IFR) and the UNECE are collected from manufacturers of mobile robots for logistics (Karabegović I. Doleček V., 2012).

Trend of mobile robots application for logistics is continuously increasing year by year. In 2008, 533 units of mobile robots were applied in logistics, whereas in 2014 the number amounted to 2.650 units. It can be said that the number of mobile robots units has increased five times in seven years. Investments in mobile robots in logistics amounted to $ 1.25 million for 10.500 mobile robot units from 2012-2015. It is a very small investment in comparison to investments in mobile robotics in medicine, agriculture and defense, but it is a significant increase in application of mobile robots for logistics. Many mobile robots applications in logistics have been developed so far, as it is shown in the figures that follow. But the work on the improvement of existing mobile robots and the development of others continues.

The structure of a robot itself depends on the institution in which mobile robot logistics is applied and the tasks which are performed. Figure 21. shows mobile robots for luggage transfer at airports, mobile robots to work in hospitals, as well as a mobile robot serving the personnel in offices (Bostelman, 2015; Karabegović, Husak, 2010).

In the manufacturing processes in industry, mobile robots (Figure 22) for logistics are developed for transporting a finished product to storage or supplying certain job posts with production material.

Figure 22. Mobile robots application for logistics in factories for finished products transport
Automated Guided Vehicles-AGV, 2016.

Figure 23 shows different applications of mobile robots for logistics in ports with heavy containers, unmanned guided trucks and transport of heavy items to warehouses. This shows only a small part of the application of mobile robots for logistics that have been developed and are already in use. But new mobile robots applications for logistics are being developed every day, and the most interesting are those for transportation of people. Certain applications of these robots have already been developed and are in the test phase of research.

In the future, it is expected to develop new applications of mobile robots for logistics in all segments of society. with the development of mechatronic systems, it can be said that cars are becoming mobile robots for logistics, because unmanned cars have already been developed to drive to the assigned destination.

MOBILE ROBOTS APPLICATION IN CONSTRUCTION, DEMOLITION

Mobile robots and their application in construction, demolition can be defined through several application areas at certain stages of the production of building materials, construction of certain parts of structures, installation of facilities, maintenance of finished facilities, etc. Their application in civil engineering

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 23. Mobile robots application for logistics in ports for container transport, unmanned guided truck for pallets transport and heavy trucks for steel coils transportation

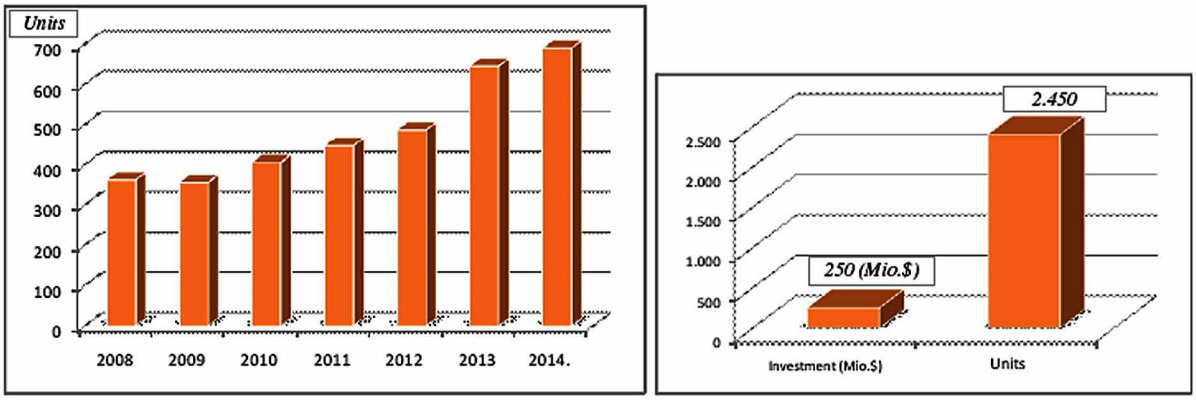
Figure 24. Application of mobile robots for logistics that are used in transportation of people
Theis, 2016.

can be roughly divided into four categories: transport of materials and servicing of machinery, assembly operations, processing operations, processes of maintenance and product control. Mobile robots in construction, demolition are the most applicable in the production of building materials, when and where robots themselves can be mass produced.

Today, the production processes of construction materials are technologically computerized to that extent that often one such factory is actually one automated production system. A classic industrial robot and mobile robots in the production of construction materials are used only in some phases of work or the production of certain materials in the brick industry, the production of plaster and glue, styrofoam production, the production of concrete structures, etc. Robots, i.e. automated structures in construction, can have a wide range of applications in situations in which the presence of people is dangerous or problematic. For instance, robots have already found application in the construction and testing on other planets, where the construction with human resources is disabled. They are applied in underwater research and construction in environments that prevent and hinder movement, in soil testing, in construction of underground installations and tunnels, in studying igneous changes in volcanoes, and the like. Figure 24 shows the distribution of mobile robotic systems in construction, demolition. Statistical data retrieved from the International Federation of Robotics (IFR) and the UNECE have been collected from the manufacturers of mobile robots (Karabegović, Doleček, 2012, Marques, Almeida, Armada, Fernández, Montes, González, Baudoin, 2016)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 25. Distribution of mobile robots in construction, demolition at annual level from 2008-2014 and investment ratio from 2012-2015 per unit of mobile robot in civil engineering
World Robotics 2009-2015.



As seen in Figure 25, the trend of mobile robots application in construction, demolition is growing, so that it amounted to 362 units in 2008, and 689 units of mobile robots in 2014. If we consider the investments in the development of these robots from 2012-2015, they are very small (only $ 250 million) in comparison to the investments in the development of mobile robots in medicine, agriculture, defense and logistics. We believe the time will come for the development of new mobile robot applications in construction, demolition and the increase in their use in the future. Let's present certain applications of mobile robots in construction, demolition that have been developed and are already being applied.

As it can be seen from Figure 26, mobile robots autonomously perform tasks which are programmed or that are managed by a server who provides commands to perform certain operations. In addition to these applications, many others have been developed.

The use of robotic systems in construction, demolition is still in its infancy and it needs to be said that robotics does not follow this branch of production at the same pace as other industrial manufacturing processes. See Figure 27. Certainly, the desire for greater capital gain will lead to a reduction of workers in civil engineering, which will definitely lead to larger robotization in this industry.

Figure 26. Mobile robots application in construction, demolition for drilling, placing panels for groundwork and masonry

Figure 27. Mobile robots application in construction, demolition for filling walls, flattening surface and drilling holes
Fleischer, 2014.

Glass facades on high buildings need to be cleaned every few months and considering that these are the objects that are most often located in the central city areas, where there is no access for potential robust cleaning cranes, the robotic systems for cleaning are used. Se Figure 28. These systems are remotely controlled or completely independent and connected to a movable base. A mobile unit of such robot either follows a conveyor belt or descends from the roof. Cleaning systems of high buildings usually cost a lot and in recent years, they are combined with the structural elements of a facade, while smaller buildings use standard systems with conveyor belts. Prices of these systems are declining and adapting to broader market, with the aim to enter into use in individual households. In the construction of these facilities, the process of introducing a mobile robot will be slower because it is a specific process. But surely, robots are already used for installing ceramic tiles, plastering, painting, etc., particularly when it comes to large surfaces. Given that the basic robotic applications can be traced through four basic categories of industrial robot applications, we look at the specific operations which robotic systems perform in certain phases of construction. The widest use of mobile robots is in the process of transferring materials and servicing of other machines, primarily in brick manufacturing, where robots serve for sorting, furnace servicing and palletizing. Similar jobs are also automated and robotized in the industrial production of powdery building materials. To a large extent, these jobs are similar to the tasks that robots perform in other industries, while the specifics of the work of robots applied in civil engineering can be seen

Figure 28. Mobile robots application in construction, demolition for cleaning glass facades, floors, as well as cleaning and control of brick facades
Zaragoza, 2009; FourAutomated Facade Cleaning System - GEKKO Facade cleaning capabilities, 2016.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the process of servicing operations such as mining and tunneling, where robots are used primarily due to the presence of hazardous substances and complex working conditions for men. The specifics can also be seen in the processing of glass and ceramic products, where there is a high concentration of toxic gases and high operating temperature. Robots also have a wide use in the processes of cleaning and maintenance of buildings and parts of buildings, mostly floors, tanks, pipelines, high facades, etc.. In this case, complex robotic systems are used to detect defects and contamination, as well as to remediate specific breakdowns that can not be repaired with the help of human labor. Robotic systems are often used for the removal of mines or demining areas. The development of robotic systems depends not only on the technical aspects and modular components, but also limitations of working conditions. In robotic systems used outdoors have to be taken into account following: protection from dust, protection against moisture and temperature, resistance to vibration, impact resistance, length of continuous operation (because power supply), the wireless communication range depending on demined location, etc.The civil engineering sector in which the most attention in the future will be devoted to the possible application of robotic systems is the area of construction and installation of elements on buildings, in order to speed up the construction process, avoid difficult and dangerous working conditions for people, and reduce labor costs.

MOBILE ROBOTS APPLICATION FOR PROFESSIONAL CLEANING

When it comes to cleaning mobile robots, we need to distinguish between mobile robots used for professional cleaning of facilities and those for home use. Professional mobile robots are commonly used for cleaning floors, tanks, windows, vehicles, pipes, pools, etc. Professional cleaning robots have a rising annual trend of usage. The largest application of cleaning mobile robots is for cleaning floors and swimming pools. Cleaning mobile robots are used in various fields, thus we will cover and analyze those areas, i.e. cleaning elements, where the use of service robots is the largest. International Federation of Robotics (IFR), the UN Economic Commission for Europe (UNECE) and the Organization for Economic Cooperation and Development (OECD) have adopted the introductory system for the classification of service robots for cleaning according to the categories and types of interaction, and thus service robots for cleaning have the following classification: floor cleaners, window and facade cleaners, tank and pipe cleaners, plane and car cleaners, and other cleaning robots. Annual application of mobile cleaning robots is shown at Figure 29. (Karabegović, Doleček, 2012).

Based on Figure 29, it can be concluded that the distribution of mobile robots for professional cleaning has a growing trend, so a continuous increase from 2008 to 2014 reached 360 units of robots. The investments in the development of mobile robots for professional cleaning in the period from 2012-2015 was $ 750 million, which is a very small amount considering the investments in the development of mobile robots in medicine, agriculture, defense and logistics. Let us show some of the developed applications of mobile robots for professional cleaning that are already being applied for various cleaning tasks (Dai, Taylor, Sanguanpiyapan, Lin, 2004; Karabegović, Kadić, Ujević, 2003)

Given the fact that labor costs of cleaning in large production systems are major issue, the increase in the number of cleaning robots is inevitable. In addition to cleaning floors, the robots are ever more applied in the so-called smart floors in order to reduce high price of robots. See Figure 30. Smart floors are equipped with RFID straps which enable simpler robotic navigation, and thus manage to reduce costs of the total cleaning process. Mobile robots for floor cleaning are standard cleaning machines equipped

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 29. Distribution of cleaning mobile robots at annual level from 2008-2014 and investment ratio from 2012-2015 per unit of a cleaning mobile robot
World Robotics 2009-2015.

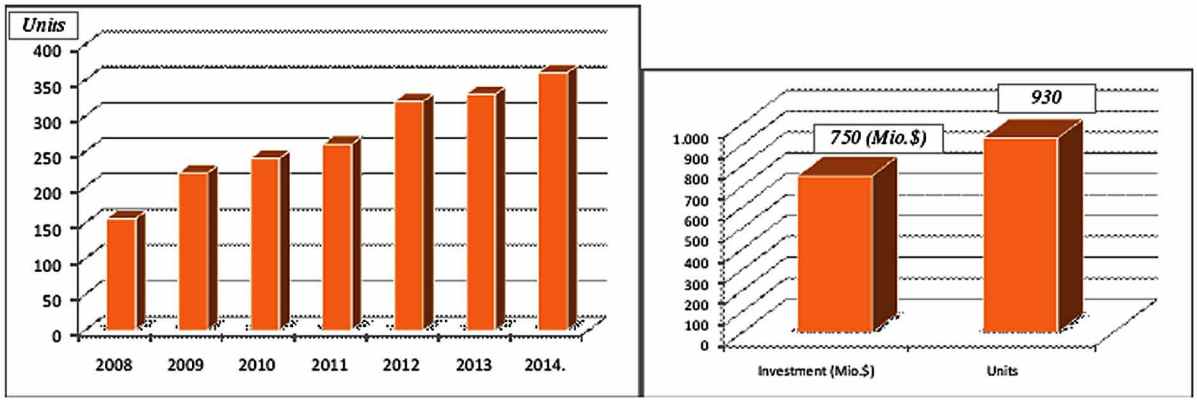

Figure 30. Certain applications of mobile robots for professional cleaning
iRobot Roomba 800 Robot Vacuums, 2016.

with the necessary robotic features that enable independent movement, navigation and control, as well as with sensors to determine distance and obstacles in order to avoid collisions with the elements of the environment. Navigation systems these robots range from those requiring cables and human management to very sophisticated ones, which clean the entire area automatically without human intervention. The most commonly used navigation system applies initial programming circuit to memorize the path at the area to be cleaned, and then controls the movements during the cleaning. Cleaning mobile robots are programmed to reach places that need cleaning, carry out the necessary cleaning operations (washing, scraping, drying), after which they return to the station to charge with detergents and water needed for cleaning. Many of them use their own elevators through radio connections, and thus fulfill their obligations on several floors of a building. They are the most effective on large areas, lobbies, airports, and railway stations. A large number of companies– both in Europe and in the world– is engaged in the production of these service robots. Mobile robots for cleaning glass windows and facades are of great interest nowadays, because large buildings are being built, containing glass facades that demand cleaning every few months. Mobile robots for window cleaning usually consist either of remote and controlled

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

cleaning units or fully automated cleaning units that can be mounted on a mobile base climbing. The climbing base mainly uses vacuum suction cups to fix to a wall. A mobile unit either follows the path or is suspended from the roof, moving freely across the facade. While a specific solution can be useful for large buildings, smaller buildings will rely on standard systems. Other efforts are directed to the window cleaning systems for the consumer market with a target sale price. Basic requirements are that these devices are easy to use, safe and maybe even useful for cleaning bathroom tiles. Let us show some of the constructions of mobile robots for cleaning glass facades (Siegwart, Nourbakhsh, Scaramuzza 2011; Iype, Porat,1989).

The characteristics of these mobile robots are: high quality of cleaning, automated operations of all systems, and a remote control. See Figure 31. A mobile robot is mounted on the crane, which goes towards a roof. It moves over the glass using very sensitive wheels or vacuum discs, in order not to damage the glass. The most famous robot for cleaning external airframe is Skywash robot, which integrates all the features of advanced robotic systems, pre-rendering movement programmed using CAD airplane model, while the location of an object is performed using a 3D sensor, i.e. 3D distance camera. Managing movement is performed using tactile sensors. A redundant arm is installed on the mobile platform, with security add-ons that provide maximum security. There are 5 major joints in his arms and an extra one for brush rotating. The robot contains a database about the geometry of a plane. Skywash is being supervised by man from the starting position so long as the robot does not come near the plane.

Cleaning mobile robots make cleaning and maintaining a pool easier. They act independently of a wastewater treatment device and at the same time, they help mixing the water in a pool by cleaning. There are different structural designs in this field of robotics too. Some of the service robots do not climb pool walls or have the option of disabling the climbing function, because most of the impurities are located at the bottom and climbing walls is more of an attraction than useful work. These service robots have telecontrol (remote control), which enables bringing the robot in the corners which it cannot reach on its own due to its mode of action. Indoor air control systems are inaccessible places for cleaning, so mobile robots of various structures have been developed for cleaning of these facilities, one of which is presented in Figure 32. Mobile robots for this use are simple in design, have four wheels, and can be rotated at an angle of 360 degrees in a very small space. They have cameras installed on both sides, so that a person operating with the robot can at any time see what needs to be cleaned. It is remotely controlled and capable of cleaning about 25 meters of a ventilation channel at once. A mobile robot is

Figure 31. Applications of mobile robots for cleaning glass facades

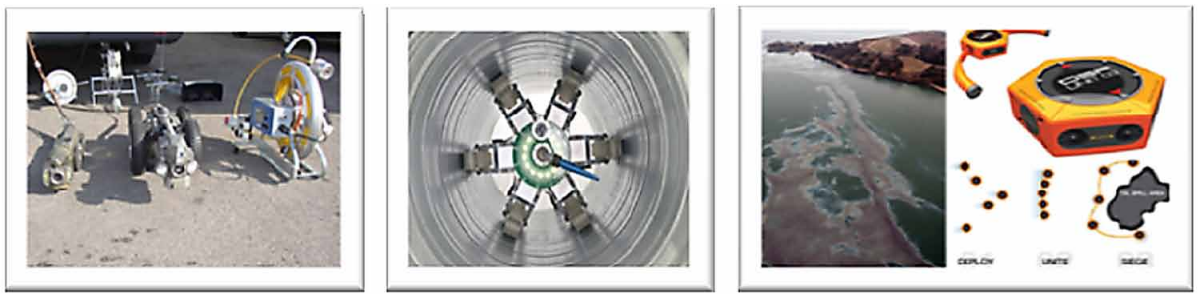
Figure 32. Application of mobile robots for a professional cleaning of airplanes, pools and ventilation shafts
Which NORDIC DINO is most suitable for your aircraft?.2013; Swimming Pool Chemicals and Equipment, 2013.

designed so that it is similar to a car, has a four-wheel drive and is very easy to operate on. There is a turbo rotary brush attached to it, which pushes all dirt to a vacuum cleaner installed on some of ventilation openings and collecting all the dirt accumulated in the channels. Nozzles are hooked up at the rear end of the robot, as well as a tank in which chemicals are poured to disinfect a cleaned area. Sewage is a basic infrastructure of every city, village or industrial plant. Although of a vital importance, sewage systems are usually worn and leaky, causing immense damage to the environment and posing a direct threat to drinking water sources, and thus human health. One of the parts of the entire cleaning system is the CCTV inspection of sewage, which enables persons controlling the sewage to get to know the real state of the facilities. This equipment includes digital service robots with cameras in the ex-performance that are able to capture the sewage pipes of all shapes and materials, with diameters from 100 to 1.500 mm. The result of such inspections contains comprehensive and detailed written and video documentation that reflects on the existing condition of examined pipes and can be used in the development of a digital cadastre (GIS) of the sewage system. Mobile robots for cleaning pipes and channels with larger diameter have been developed and are presented here at Figure 33. A mobile robot is equipped to use the high technology of cleaning with dry ice, but can also use other cleaning methods. It is designed with six legs which provide stability when cleaning and moving through pipes and channels during cleaning. The mobile robot can go through and clean circular, rectangular and square shaped channels

Figure 33. Application of mobile robots for professional cleaning and sewage structure inspection, large-diameter pipes and a mobile robot for cleaning oil spills
Cleaning and Inspection of Ducts, 2013; Brynn, 2011.



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

with maximum efficiency, because the rotation of a cleaning squirt and the speed of a cleaning rotor can be adjusted depending on the degree of contamination. The robot can clean the horizontal, sloping and vertical chanells, as well as channels in the form of the letter S. It is equipped with a camera. Monitoring of the control and cleaning processes is done using the display on a computer (Karabegović, Karabegović, Husak, 2012).

We are witnessing the disastrous consequences resulting from oil spills at sea. The sooner the oil slick is removed from the water surface, the lesser harmful effects on wildlife. Guided by this idea, the "JI HOON KIM" company came up with the idea to develop a set of modular mobile robot (Figure 33) called OSP robots– the cleaners of oil spills in seas or lakes, which can be quickly transported to the contaminated site by helicopter or boat and put into operation.

MOBILE ROBOT APPLICATION FOR SPACE EXPOLORATION

Mobile robots have a major role in space exploration. Various self-propelled robots are used for data collection from celestial bodies, for samples collection and analyzis, debris collection, photography, etc. Some of them are controlled by radio waves from the ground, while others have built-in electronic computers, so they move independently driven by a computer program. Self-propelled mobile robots have built-in sensors to receive data from the environment, a robotic arm to perform complex operations of samples collection, cameras and camcorders. Various remotely operated vehicles, so-called rovers, are used for different research of planet surfaces. One of them is a mobile robot named Viking, which has two automatic chemical laboratories, meteorological and seismological station, laboratory for photography, and two computers. A computer-guided hand digs and transmits soil samples in biological and chemical laboratory, where the samples are analyzed (Rita, Tyler, Kaczmarek, 2003). NASA has developed two most famous robotic vehicles (rovers) named "Spirit" and "Opportunity" intended for space exploration. Unlike the robots on Earth that act in a structured environment, robotic space vehicles operate in an unstructured and unfamiliar environment. Therefore, mobile robot explorers have to learn using their own sensors, including nine cameras located on each of them. The rovers have two navigation cameras for three-dimensional view of environment, two for view of the ground (to avoid collisions), and panoramic cameras to capture the planet's surface. The CPU in research devices is designed to withstand extreme cold and radiation on the planet Mars. During the night on Mars, when the robot is at rest, a team of experts from the Earth programmes its activities for the next day using very powerful computers, and then send him commands where to go or what actions to perform. When it comes to avoiding obstacles that mobile robotic rovers encounter during their research missions and that can not be predicted from the Earth, robots themselves make decisions how to avod them. Data from cameras for collision avoidance assist them to analyze the immediate environment in which they move at speed of a snail (the maximum speed is five centimeters per second), with regular stops for field observation. In addition to recording, robots examine the planet using several instruments on a mechanical arm. The arm has a shoulder, elbow and wrist in order to facilitate the movement and is equipped with four sensors, a microscopic camera to capture rocks from close up, as well as a spectrometer for measuring alpha-radiation to determine the mineral composition of the soil. The control of the arm is carried out using the prepared commands, while smaller movements are operated independently by a mobile robot itself. The following pictures show service robots – or we can say robotic vehicles – for testing the surface of a planet. Those are different variants, depending on the manufacturer (Karabegović, Doleček, 2012).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In addition to these vehicles, researchers have developed an SUV robot, named Athlete, for research on other planets, and it is shown in Figure 34. The Astrobotic Technology Inc., the USA, has developed a mobile robot Rover in cooperation with NASA, and it is shown in Figure 35. It is a lunar robot whose role at the surface of the Moon will be to make reception stations as close to the landing site of rockets as possible. At the reception stations, it is necessary to make levees around the landing site because stones and earth rise when rockets land and take-off due to the lack of oxygen. Thus, the levees should provide security for the facilities.

In addition to service robots, i.e. robotic vehicles and robotic platforms used for space exploration, there is another very important system – a mobile robotic arm of a spacecraft. In the last two Discovery's missions, the robotic arm is a key part of the new system of control of the thermal shield. It carries a camera that checks the state of the shield, and if necessary transfers an astronaut to the place where repairs need to be made.

Mobile robots for space exploration are analyzed as capable devices, which can perform manipulation, assembly and maintenance in orbit either independently or as assistants to astronauts, or serve as explorers at distant moons, planetoids and planets in the deep space. See Figure 36. Vehicles without a driver or automatically controlled vehicles used in space must be either telecontrolled from an extreme distance or automatically moved. The signals that take some time will be transferred and often all the

obstacles can be seen, the robot can change the "protection of teleoperation". Price of such mobile robots is very high. An additional price of mobile robot that was sent to explore space is another important factor. Therefore, the prices of such mobile robots belong to the overall mission of the prices, which include the development, production, launching, operation and postmission of data processing.

CONCLUSION

Nowadays, mobile robotics occupies an increasingly important place in the life and work of man. The beginning of the 21st century will be marked by a significant expansion in the practical applications of mobile robotics and intelligent machines in general. As new technologies are evolving and the end of further development and new knowledge is not known, it is certain that the mobile robotics will also develop to unimagined possibilities. Even now, the development and achievements in the field of mobile robotics reached such a level of development that a large part of humanity is not aware of how advanced robotics is. They are not aware that mobile robots do not serve as enemies of man i.e. humanity, as they are usually presented in science fiction movies. On the contrary, scientists from several disciplines strive to improve, facilitate, and beautify life for people and humanity. Generally speaking, the continuous improvement of mobile robot's quality is estimated, as well as the increase in its application, so that they will increasingly become systems that are easy to put into operation, to programme, to optimize and use to perform almost all the tasks currently performed by man. This will naturally lead to a large increase in their application, which is already evident from the annual statistical data on the use of mobile robots. Mobile robots are becoming ever more important for scientific research, as well as for the industry, because they are used and will be used in new areas of industrial branches. Nowadays, robots and artificial intelligence coexist and thus it is hard to imagine a present-day robot not being some kind of artificial intelligence. It is considered that robots and artificial intelligence will actually extend the life of man and improve the quality of life in general. For laymen, it is difficult to assess which of the scientists are right; the truth is that some of the possibilities and theories are concerning, but we have already realized that by reading some of the great works of science fiction. As it seems, evolution has led man nearly to the degree that it can build a being as intelligent as himself! The whole thing is now far advanced, and it is probably impossible to control them, but maybe just try to turn them in our favor.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In any case, the century in which we live has already brought us a good deal of scientific excitement, and those who do not find this outcome positive are actually rare. We live in a time that will in the distant future undoubtedly be remembered for many things, and it would be a shame we are not aware of it now as well. The ever increasing use of robots has its social consequences. With their introduction in factories, a large number of unskilled and semi-skilled workers who have been on simple, dangerous and boring jobs will remain jobless. They have no choice but to pre-qualify. An increase in the use of mobile robots entails an increase in their production, and thus a reduction in their prices, i.e. the accessibility of procurement of mobile robots and their use itself. The application of mobile robots is increasing from day to day; the development of new technologies is leading to the robots' higher functionality, and hence the increase in their applications.

ABSTRACT

This study sought to investigate on the access and use of mobile phones for improving the coverage of agricultural extension services among farmers in the pre-harvest stages of maize value chain in Kilosa district. The study examined the use of mobile phones as a means for improving the coverage of agricultural extension services. The study adapted a cross sectional study design and a multistage sampling technique. Data were mainly collected using structured questionnaires. The results revealed that majority of respondents used mobile phones and had a positive attitude on the contribution of mobile phone in their farming business. The study results also indicated that mobile phones offered an affordable solution to farmers' information needs and information requirements. The study concluded that the use of mobile phone to communicate agricultural information depends on information needs of farmers. The study recommended that farmers need to be encouraged and supported to access and use mobile phones in their farming business.

1. BACKGROUND INFORMATION

Agriculture is one of the major sectors of Tanzania's national economy which contributes about 24.0 percent to the Gross Domestic Product (GDP) in addition to the other sectors of mining, industry, and tourism (Osberg & Bandara, 2012). The agricultural sector employs over 75 percent of the population which constitute majority of the poor small-holder subsistence farmers who utilize about 85 percent of the land cultivating not more than 2.0 million ha (Sibuga, 2008).The agricultural sector in Tanzania has continued facing a number of challenges including poor agricultural extension services resulting in low performance, low levels of production, low output quality, and a low contribution of the sector to the national socio-economic goals, underutilization of available resources, poor quality food products that lead to weak competitiveness in the international market and poor implementation of legal and regulatory frameworks (POPC, n.d). The agricultural extension services mainly aim at providing knowledge; information and technology that farmers would require to improve their productivity and quality of their lives and livelihoods (UN, 2005). The agricultural extension services in Tanzania are mainly funded by the Government despite the presence of private sectors, Non-Governmental Organizations (NGOs), and farmer-led initiatives which have been supplementing extension service delivery of the public extension services through cost-sharing (Kapange, 2010).

Nonetheless, Rutatora and Mattee (2001) observe that these experiences have not improved the quality of extension services which have been considered to improve the agriculture sector in Tanzania. Because of financial difficulties faced by the Government, the allocated budgets for agricultural sector do not support sufficient visits by field extension staff to farmers. Consequently, the agricultural sector has continued to perform poorly leading to low yields which are insufficient to raise people's income and promote food security among the households in Tanzania (Kapange, 2010).

In an attempt to improve provision of agricultural extension service, some countries such as Pakistan, India, Brazil, and the United States of America have opted for the use of Information and Communication Technology (ICT) (Katz, 2002; Hassan & Semkwiji, 2011). It is observed the agricultural sector has improved in those countries through the introduction of ICT in the Agricultural Extension Services (Hassan & Semkwiji, 2011; Siani, 2012). Furthermore, it is reported that the introduction of mobile phones services in agricultural sector in Pakistan, India, Brazil, and the United States of America has enabled farmers and other actors in the different value chains to receive high amount and quality of the agricultural extension service. In addition, the speed of services delivery has been improved significantly as a result of mobile phone intervention (Thomson, 2006; Buys et al., 2009; Aker & Mbiti, 2010; Goggin, 2012; Acker, 2011; Etim, 2012a; Etim, 2012b; Etim, 2013c).

This phenomenon points to Sub-Saharan African countries such as Tanzania whose access and use of mobile phones has increased tremendously. For instance, it is reported the access and use of mobile telephone has increased ten times as many mobile phones as landlines whereby 60 percent of the population has mobile phone coverage (Aker & Mbiti, 2008). In Tanzania, the 2012 national population census indicated there were 46.9 million people of which 28 million people were mobile phone subscribers and spend an average of 56.7 minutes on domestic calls a month (TCRA, 2015). In addition, in Sub-Saharan African countries, entertainment applications (games), voice calls and text messaging have been noted to be dominant in the access and usage of mobile phone (Aker & Mbiti, 2008). With such a boom in access and usage of mobile phones in Sub-Saharan African countries, mobile phone technologies are not fully implemented in extension services in the agriculture sector where over 75 percent of the people

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

live in rural areas are highly engaged in agriculture for both as a source of food and income (Miller et al., 2013; ITU, 2014).

Therefore, this research sought to find how the access and use of mobile phone could help to improve the coverage of agricultural extension service among farmers in the pre-harvest stages of maize value chain. Cognizant of the role of mobile phones in achieving development goal, and given the recent nature of mobile phone in Tanzania, there are still concerns regarding the manner and the extent to which access and use of mobile phone improves the coverage of agricultural extension service in Tanzania. Previous research (e.g., Sife et al., 2010; Furuholt & Matotay, 2011) in the country has largely focused on how mobile phones contribute towards empowerment and improved rural livelihood and poverty reduction in general. Little (if any) has been documented with regards to how the access and use of mobile phones can improve the coverage of agricultural extension service in Tanzania from the user's perspective.

As presented earlier, the existing system of agricultural extension service provision faces a number of challenges including few extension officers and limited resources to serve many farmers (Due et al., 1997). There are few consultancies because extension officers and farmers often live in geographically dispersed areas (Anderson & Feder, 2007) and financial constraints which lead to irregular visits. For example, extension workers only wait until the budget supports them to visit farmers for extension service provision or re-visit farmers for feedback on the quality of the advice, new ideas and techniques rendered to farmers (Siani, 2012).

As Aker and Mbiti (2010) state, integrating mobile phones into the extension infrastructure will help to strengthen or develop an open system between farmers, extension agents, and other actors in the maize value chain to synergize the local and scientific knowledge so they do not only receive advice, but also give feedback hence creating a virtuous circle. In addition, the use of mobile phones in agricultural extension service has the potential to significantly reduce communication and information search costs whereby phone calls and Short Message Service (SMS) can replace the need for face-to-face interactions thereby reducing travel costs and saving time.

In addition, bringing mobile phone into use can also support the implementation of Tanzania's ICT Policy (2003) as it stands for efficiency, effectiveness, and sustainability in the provision of services and basic utilities by supporting the development and deployment of nationwide e-agriculture, e-health, e-tourism, e-education and e-commerce transactions (URT, 2003). Additionally, implementing the Agriculture Sector Development Strategy (ASDS) 2001 creates an enabling and conducive environment for improving profitability of the sector as the basis for improved farm incomes and rural poverty reduction in the medium and long-term plans (ASDS, 2001).

2. RESEARCH METHODOLOGY

2.1. Description of the Study Area

The research was conducted in the Kilosa District in Morogoro Region. Kilosa is located on the eastern part of Tanzania, and about 270 kilometers from Dar es Salaam and situated between 6 to 10S and 35E, with and altitude ranging between 300-600 meters above sea level. The District covers 14,918 square kilometers, and in 2002 had a population of more than 489,512 (NBS, 2012). The main ethnic groups in the District are the Sagara, Kaguru, Kwiva, Vidunda and some Gogo. The Kilosa District is comprised of nine Divisions, 36 Wards, and 132 Villages, with Kilosa town being its administrative headquarters.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The District is divided into three ecological and six agro-economic zones including the flood plain, the plateau, and the mountainous or upland zones.

2.2. Research Design

The study used a cross sectional design. The design allows data collection at a single point time and reasonable costs (Bryman, 2015).

2.3. Sampling Techniques and Sampling Procedures

A multistage sampling design was used to obtain the study sample. Multistage sampling is a technique which involves more than one stage to obtain the sample. The sampling techniques for this study included; cluster sampling and simple random sampling. In this study, the selection of study sample followed the existing administrative units such as division, wards, and villages. The clustering sampling was used to obtain the clusters or groups. One of the divisions was selected among division clusters. Then, six wards were selected randomly from the selected division. Thereafter, two villages were selected randomly from each of the selected wards hence forming 12 villages. The following were sampled villages and the respective number of respondents for this study (Table 1).

2.4. Data Collection

Both primary and secondary data were collected. Structured interviews and questionnaires were administered to 200 respondents (Table 1). Documentary review was employed to gather information about

Table 1. Sampled Villages and their respective number of respondents

Villages	Frequency	Percent
Batini	16	8.0
Mbuyuni	16	8.0

extension service in the district; specifically, reports from Kilosa agriculture and livestock development office, and agricultural extension officers were reviewed.

2.5. Data Processing and Data Analysis

Data collected were analyzed using the Statistical Package for Social Scientists (SPSS). Descriptive statistics analysis was conducted since it is mostly used in value chain analysis (Raikes et al., 2000; Kaplinsky & Morris, 2001) by computing frequencies/ percentages, measures of central tendency, measure of dispersion, and independent chi-square to show the association among variables.

2.6. Generalization of the study findings

The study was conducted in only 12 villages which were sampled from six wards of Kilosa district in the Morogoro region. However, the findings can be generalized beyond the 12 villages involved in the study provided there are similar situation to such selected study areas. It is therefore considered that the implication from the study will be applicable to other rural areas in the Kilosa district in the Morogoro region and elsewhere in Tanzania with a similar situation.

3. RESULTS AND DISCUSSION

3.1. Respondents' Social-economic Characteristics

In this aspect, the goal of the study is to establish the socio-economic characteristics of farmers. The sampled respondents are characterized by both male and female with the latter being in the majority (Table 2). A total of 72 percent of the respondents are married. Furthermore, a total of 89 percent of the respondents reported they had attained formal education while the remaining 11 percent reported not to have attained any formal education.

When asked to indicate their annual income, a total of 70 percent of respondents reported to have an annual profit which ranged from 500,000 to 1 million Tanzania Shillings (TAS). Further investigation revealed that respondents (50.5%) who did their transaction on maize production through mobile phones generated extra annual incomes ranging from 20,000 to 100,000 TAS.

3.2. Respondents' Other Factors Influencing Mobile Phone Ownership

Most of the respondents in Table 3 use electricity as a source of power to charge their mobile phones. When asked to indicate where they charge their phones, a total of 77.5 percent of the respondents do not charge their phone from their home as they depend on the neighborhood source of power. Furthermore, it was reported that because of many respondents charging their phones in the neighborhood which is a distance less than a kilometer, they prefer walking to and from charging their phones as compared to other means of transport.

3.3. Respondents' Socio-Economic Characteristics and the Amount of Money Spent on Voucher/ Airtime for the Mobile Phone

It was also important to examine the socio-economic characteristics of the respondents and the amount of money spent per day to buy voucher/ airtime for the mobile phone and try to gauge on the pattern of the money spent on the voucher. Table 4 illustrates that a total of 95(47.5%) were male of which 55 (57.8%) or more than half spend 500 TAS to purchase a voucher / airtime for the mobile phone. Mean-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

while, of the respondents interviewed, a total of 105(52.5%) were female of which 83(79.0%) spend more than 500 TAS to buy a voucher / airtime for the mobile phone. A chi-square test results revealed there was statistical significant influence on the gender of the respondents and the amount of the money spend per day to buy a voucher/ airtime for the mobile phone at $\chi^2 = 12\ .412$ and $\rho > 0.015$.

This is because with a minimum amount of 500 TAS an individual can connect to so-called Extreme (i.e., bonus promotion airtime) and obtain more airtime minutes unlike the usual airtime minutes given for the equivalent amount of money. Therefore, the results found similar to that of Souter et al. (2005), in his study whereby telecommunications were found to have a significant correlation with the socio-economic characteristics of individuals.

Furthermore, Table 4 shows that a total of 108 (54%) persons had a standard 7th Grade education level which is more than half of the sampled population spending 500 TAS to purchase voucher / airtime for the mobile phone. This was followed by a total of 16 (8%) respondents with no formal education who spend 500 TAS to buy voucher / airtime for the mobile phone. The chi-square test results revealed there was high statistical significant influence on the education level and the amount of the money spend per day to buy a voucher/ airtime for the mobile phone shown at $\chi^2 = 60.456$ and $\rho > 0.000$.

Table 4 also illustrates that a total of 144 (72.0%) persons were married of which a total of 95 (65.9%) persons spend 500 TAS to buy a voucher/ airtime for the mobile phone. A total of 30 (15.0%) of the respondents were single of which a total of 20 (66.65%) spend 500 TAS to purchase voucher / airtime for the mobile phone. A total of 10 (5.0%) of the respondents were divorced of which 8 (80%) spend 500 TAS to buy a voucher / airtime for the mobile phone. However, a chi-square test results revealed there was no statistical significant influence on the marital status of the respondents and the amount of the money spend per day to buy a voucher/ airtime for the mobile phone shown at $\chi^2 = 13.349$ and $\rho > 0.344$.

Furthermore, Table 4 and the chi-square test results indicate there was high statistical significant influence on the respondents' annual income and the amount of the money spend per day to buy a voucher/ airtime for the mobile phone shown at $\chi^2 = 64.999$ and $\rho > 0.000$.

3.4. Socio-Economic Characteristics of the Respondents and Perception on the Use of Mobile Phone for Communicating Agricultural Information

Table 5 shows that all 200 respondents interviewed confirmed owning mobile phones. This shows that mobile phone penetration is also far higher compared to that of the entire nation during the last quarter of 2009 as highlighted by Samuel et al. (2005) where the rate was only (39.0%). Table 5 indicates the perception on the use of mobile phone for communicating agricultural information by farmer's socio-economic characteristics such as sex, marital status, age, income, and education level attained.

Although 52.4 percent of female respondents agree that owning a mobile phone is a good thing for communicating agricultural related information as opposed to male respondents (Table 5), the chi-square test revealed the respondent's gender had no statistical significant influence on the use of mobile phone for communicating agricultural information at $\chi^2 = .035$ and $\rho > 0.05$. This insignificant influence on gender could be due to the reason that both men and women are conversant in the use of mobile phone.

Similarly, the findings on education levels and mobile phones usages concur with the observations by Bertolini (2002), Dunn and Dunn (2006); and Baumüller (2012) that primary education had a stronger influence on mobile phone ownership. This is because as presented in Table 5 the majority of those

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Socio-economic characteristics of the respondents and the amount of money spent per day to buy a voucher/ airtime for the mobile phone (n=200)

with a primary school education believe owning mobile phone is good for communicating agricultural information and a chi-square test revealed the respondents' education levels had no any statistical significant influence on the use of mobile phone for communicating agricultural related information at $\chi^2 = 2.916$ and $\rho > 0.572$.

This insignificance could be probably due to the basic knowledge required for one to make use of their mobile phone unlike other ICTs such as computers and other electronic devices. This agrees with the observations made by Khalil et al. (2009) that wireless technologies have reached rural populations because of the advantages such as mobility, ease of use, flexible deployment, and relatively low and declining cost.

Given the conclusion by Porter et al. (2012) and Brooks et al. (2013) that the majority of ICTs users tend to be young adults, an investigation on whether or not age was a factor for mobile phone usage in communicating agricultural information was conducted. The findings show that 47.8 percent who believe on communicating agricultural information through mobile phone were between the ages of 26 and 41. The chi-square test refutes Sounders et al.'s observation since it revealed that age of respondents had no any statistical significant influence on the use of mobile phone for communicating agricultural related information at $\chi^2 = 8.588$ and $\rho > 0$.

Additionally, the findings indicate that marital status has no influence on the use of mobile phone for communicating agricultural related information and a chi-square test shows there was no statistical significant difference at $\chi^2 = .950$ and $\rho > 0.813$ (Table 5). Lastly, a chi-square test results revealed that there was no statistical significant influence on the annual income obtained and the use of mobile phone for communicating agricultural information.

3.5. Benefits of Using Mobile Phone to Access Agricultural Extension Service

Khalil et al. (2009) observe that due to the many advantages such as mobility, ease of use, flexible deployment, and relatively low and declining cost, wireless technologies have reached rural populations, As it can be seen in Table 6, a total of 95.5 percent of the respondents believe that owning a mobile phone is advantageous for communicating maize related information, while only 4.5 percent do not agree. Furthermore, when asked on the areas where mobile strengthened their involvement in the maize value chain, more than half of the respondents (see Table 6) indicated to have been in the position of getting maize market information through their mobile phone. Approximately 25 percent of farmers use mobile phones to enquire input related information and a few respondents (10.5%) conduct the money transaction via their mobile phones. These findings are similarly to Kleih et al. (2004)'s study which found that cost savings, combined with quick access to information and instant communication with trade partners opens new market possibilities.

Apart from the areas in which mobile phone use has strengthened farmer's involvement in maize value chain, it was discovered there are other benefits on the use of mobile phone by farmers such as reducing risks and loss, increase of stable customers, etcetera. For example, looking at below listed different views and benefits on why farmers preferred using mobile phone in communicating maize related information:

N.L.M from Batini Village: I always use my mobile phone to communicate with retailers so to find out what is the current price for the maize when I want to sell my maize produce and this has helped to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Areas that mobile phone has strengthened farmer's involvement in maize value chain (n=200)

		Frequency	Percentage
mobile phone is used to communicate maize related information	Yes	191	95.5
	No	9	4.5
	Total	**200**	**100.0**
Areas mobile strengthened involvement in the maize value chain	Maize market related information	103	51.5
	Weather related information	6	3.0

reduce the risk of getting loss from selling the maize to brokers who come and persuade us to sell on their own price

A.R.M from Msowero Village: From mobile phone use, I have increased the number of potential buyers who normally call and enquire maize cargo available for market and sometimes the payments are made through M-PESA. I always don't prefer walking with huge amount of money I get from selling maize.

- Types of agricultural information communicated by farmers

3.6. Number of Calls Made by Famers Requesting for Land Preparation Information

The study also investigated on the consultancies made by farmers to different actors requesting land preparation related information and the frequency of contact. It was found that a majority of the respondents (see Table 7) call their fellow farmers requesting land preparation information during land preparation season. Additionally, a total of 48.5 percent of respondents were found to call their fellow farmers twice a day requesting for such information.

Interestingly, relatively few farmers (approximately 16 percent) contact the extension agent for agricultural information during land preparation. A total of131 farmers, more than half of the sampled population, call their fellow farmers requesting land preparation information during the land preparation season, whereas a total of 97 farmers contact their fellow farmers twice a day requesting for the land preparation information during land preparation season.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.7. Number of Calls Made by Farmers Requesting for Maize Planting Season Related Information

Table 8 shows the number of calls made by farmers to respective actors requesting maize planting season related information during the season. The data also indicates that many farmers (approximately 76 percent) contact their fellow farmers requesting for maize planting season related information during the season. Reviewing the number of calls per day indicates that 46.0 percent of the farmers call their fellow farmers twice a day requesting for maize planting season related information during the season.

Table 8. Number of calls made by farmers requesting for maize planting season related information (n=200)

		Number of calls made by farmers using mobile phone requesting for the maize planting season related information							Total

3.8. Number of Calls Made by Farmers Requesting for Herbicide Application Season Related Information

The study was further interested in investigating the number of calls made by farmers to respective actors requesting herbicide application season related information during the herbicide application. Table 9 shows that a total of 54 percent of the respondents seek herbicide application information from their fellow farmers as opposed to 24.5 of respondents who call the extension agents. On the rate of calls, the finding indicates that very few farmers have regular contact on the use of herbicides as only 22.5 percent of the farmers call their fellow farmers twice a day requesting for the herbicide application season related information during the herbicide application.

It was observed most of the calls made by farmers on the three types of agricultural related information (Table 7, Table 8, Table 9) on the pre harvest stages of maize value chain were direct to their fellow farmers. Furthermore, the findings indicate the planting season has the highest consultancy rate followed by land preparation season. The herbicide application season is the least consulted season. The study also discovered that farmers prefer calling their fellow farmers because of either lack of extension officers or poor cooperation shown by extension officers to farmers as it is clearly indicated in the below comments:

B.M. from Mkwajuni Village, I have remained calling my fellow farmer because the Agricultural Extension Officer (AEO) reported in our Ward and requested for the permission to go and collect his belongings he has never come back since then and we are told he has gone for further training.

S.R.A from Sikutari Village, There was one time in 2009 the all maize plants in one of my farm were invaded or affected by worms. I was given the Agricultural Extension Officer's number and called him for my surprise he promised to come but he did not come, I kept on calling but he never picked up. With that I got a huge loss and lost hope on the Agricultural Extension Officer's assistance. I just call my fellow farmers for any assistance needed.

Table 9. Number of calls made by farmers requesting for herbicide application season related information (n=200)

		Number of calls made using mobile phone requesting for the herbicide application season related information							Total
		twice in a day	Four times in a week	Once in a month	Once in two month time	Twice in two month time	Once in four month time	Once in six month time

3.9. Communication Channels used by Farmers to Get Maize Related Information

Investigating the other ways farmers employ to get maize related information shows that farmers also use other ways of communication used in the maize value chain to obtain information. Table 10 indicates that radio, newspaper, letters, television, leaflets, and face-to-face were found to be the common means of communication maize related information with the radio being the highly favored and leaflet being the least favored.

3.10. To Determine the Constraints in the use of Mobile Phones to Access Agricultural Extension Service among Actors in the Pre-Harvest Stages of Maize Value Chain

Although network problems were reported to be the major challenge that limits farmers to fully use their mobile phones to send and receive maize related information, the findings indicate a total of 89 percent of the farmers are constrained with mobile phone operating costs such as battery charging costs and recharging credits (Table 11). These findings concur with previous studies (Samuel et al*.,* 2005; URT, 2010) which suggest the improvement of the positive correlation between mobile phone ownership and access to electricity. Likewise, Gollakota (2008) observes that despite the positive effects associated with the use of ICT tools for enhancing livelihood opportunities, electric power and cost are hindering factors. Other challenges reported include unavailability of voucher and lack of mobile phone maize related contents. These limit farmers to fully utilize their mobile phone to send and receive maize related information.

3.11. Extension Agents' Views on the Use of Mobile Phones for Communicating Agricultural Related Information

The study findings indicated that most farmers seek agricultural related information from their fellow farmers much more than they request the same from extension agents. This drove an interest to gauge the extension agents' views on the interest of using mobile phones in communicating agricultural related

Table 10. Communication channels used by farmers to get maize related information (n=200)

Variables	Frequency	Percent
Radio	96	48.0
Newspapers	4	2.0
Letter writing	3	1.5

information. A total of10 extension agents were interviewed and all of them owned mobile phones. When asked whether they communicate with farmers about the maize related information using their mobile phone, they all agreed to do so; however, at a different rate. For example, only 40 percent reported to communicate with farmers about maize related information more than three times a week. Approximately 60 percent (see Table 12) called only twice a week and they had different views on it as follows:

J.M from Kimamba A ward. I have a positive hope in the use of mobile phone for communicating agricultural related information, for example and just from my ward, am the only agricultural extension officer, am to visit different villages within my ward for something which is always difficult during the agricultural season so needed by farmers in the different villages which is always difficult to divide myself for

G.M from Rudewa ward. YES that we are two agricultural extension officers in this ward but one may fall sick that can't be in the position to visit the villages but with a help of a mobile phone can just respond to the queries and give simple directives to farmers instead of leaving and making more matters worse

T.S from Msowero ward. I make calls but haven't officially acknowledged it that it would be, but if incorporated as a means or ways of agricultural extension provision will help the constrained budget received from the government that can't surfers the sufficient visit to farmers for agricultural extension provision

Furthermore, the following have been noted by extension agents as the most frequency of calls made by farmers inquiring about agricultural related information as follows:

Calls made during input application

When asked to what type of input application do farmers do frequently call, almost all the extension agents (see Table 13) reported that famers frequently call inquiring about the type of maize variety to plant, followed by the type of fertilizer to use. The least frequent calls that extension agents received were inquires on the type of insecticide to spray.

Calls made during farm operation activities

Furthermore, the findings presented in Table 14 on the frequency of calls made by famers to extension agents during farm operation activities indicate the most frequent calls received from farmers were during land preparation, followed by sowing periods with the least frequent calls made during weeding.

3.12. Challenges Facing Extension Agents on the Use of Mobile Phone

Apart from the various challenges noted in Table 15, the following were major challenges mentioned by extension agents in the use of mobile phone for communicating agricultural related information as follows:

J.M from Kimamba A ward. The most embarrassing thing in the use of mobile phone for communicating agricultural related information is that, majority of farmers do beep us instead of calling. They think that we always have enough credit hours or airtime to call them back for something not true

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 13. Frequency of calls made by farmers to Extension agents on maize input information (n=10)

		Frequency	Percentage

S.N from Mkwajuni ward. Just from mobile phone communication or conversation, it is sometimes difficult to know the real situation being conveyed of what is actually happening on the farm or ground and weather the description given back is appropriately

Additionally, extension agents mentioned network problems and mobile phone operating costs as the major challenges that limit them to fully use your mobile phones to send and receive maize related

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

information. In addition, many extension agents (see Table 15) noted the lack of mobile phone maize related contents, unavailability of vouchers, and awareness limit extension agents to fully use their mobile phone to send and receive maize related information.

3.13. Broader 'Community' Impacts on the Use of Mobile Phones for Agricultural Extension

The findings of this study indicate mobile phones are noted to be the most exciting forms of ICTs for agriculture particularly in the context of developing nations. They enhance ways in which communities acquire, exchange, and or manipulate information to maintain social networks or to provide access to information on socio-economic opportunities. For example, in the agriculture sector mobile phones farmers asserted to have had made informed decisions much more easily through the information communicated to respond to opportunities which have improved their agricultural productivity and bargaining power of farm produce.

The ownership of mobile phones by different agricultural stakeholders in the Kilosa District has widely spread and increasingly assisted to overcome isolation and make communication between rural farmers, extension officers, policy makers, transporters, traders, processors, input suppliers' and researchers from SUA easier. This concurs with what different researchers (Goodman, 2005; De Bruijn, 2009) who attempted establish the linkages between mobile phones, livelihoods and poverty reduction among communities.

Table 15. Challenges facing extension agents in communicating maize related information using mobile phones (n=12)

		Frequency	Percentage
mobile phone operating costs limit extension agent to fully use your mobile phones to send and receive maize related information	Yes	10	100.0
	Total	10	100.0
network problem limit extension agent to fully use your mobile phones to send and receive maize related information	Yes	10	100.0
	Total	10	100.0
unavailability of voucher limit extension agent to fully use your mobile phones to send and receive maize related information	Yes	8	80.0
	No	2	20.0

	Total	10	100.0

Source: Field data (2013).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

For example, Goodman (2005) reports that mobile phones have become increasingly important to agro-based entrepreneurs as it creates an infrastructure service to improve the efficiency of agriculture markets; hence, contributing to farmers' empowerment. Therefore, the economic and social returns of mobile phones are high to the communities which use it as communal tool.

In line with the above discussions, Table 6 shows that the information needs for the majority of the respondents' (51.5%) regards marketing information. This indicates the information seeking behavior is skewed towards marketing information rather than information related to farm productivity. Surprisingly, the main source of the marketing information for most of respondents is their fellow farmers and not the extension officers (Tables 6, 7, 8). The other source of communicating agricultural related information mentioned by many respondents is the radio (Table 9).

Table 3 shows that majority of respondents' (77.5%) charge their mobile phone in the neighborhood as opposed to those who charge them from their home. This implies that even though mobile phone is uplifting the well-being of rural farmers, there is a destructive phenomenon arising from it. Some philosophers have termed this emerging revolution of mobile phones to have brought a negative effect called possessive individualism[1]. In Kilosa, this negative effect has been addressed through the use of Kilosa Community radio which is used to communicate agriculture information for entire communities. Essentially, community radio is a means for "community" communication as it broadcasts different topics related to agricultural husbandry, marketing, and livestock keeping (Sanga et al., 2013).

Additionally, in Kilosa there is a private information centre called KIRSEC which works in collaboration with the Kilosa Community radio, the Kilosa District Council, and the Sokoine University of Agriculture. Through these different initiatives in Kilosa, the communication between rural farmers, extension officers, researchers, policy makers, producers, processors and traders have been strengthened using integration of multiple communication channels (Sanga et al., 2013).

These channels include web- based farmers' advisory information systems, mobile- based farmers' advisory information systems, community radio, and conventional face-to-face agriculture extension systems (Sanga et al., 2013). The application of the integrated system has helped to address the rise of possessive individualism brought by the mobile revolution. There remains much work to reap the wider impacts of mobile technology to different farming communities in developing world. The question forwarded by Toyama (2010) to whether technology can end poverty is still valid to different farming communities in Tanzania. Toyama recommended

…the value of a technology remains contingent on the motivations and abilities of organizations applying it—villagers must be organized, content must be produced, and instructors must be trained (Toyama, 2010: p.8)

Without observing the warning by Toyama (2010), we might experience the negative effects of mobile phones. Some communities have already started experiencing the negative effects of mobile phones. DeMaagd (2010) observe that there is a negative association between investment in mobiles and GDP in developing countries possibly because mobiles represent a diversion of resources away from other productive uses. Similarly, the study by Diga (2007) establishes that at the micro-level in some rural Ugandan households are sacrificing expenditure on purchasing food so that they can pay for mobile airtime. Additionally, some communities' members admitted that they don't go to social functions so that they can

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

save money for mobile phones and airtime. The findings by Diga (2007) is similar to that of Mpogele et al. (2008) who assert that respondents reported that they sometimes "substitute important needs (e.g. education, buying food, and clothes) for mobile phone ownership/usage" (Mpogole et al., 2008, p. 7).

Furthermore, Mpogole et al. (2008) noticed that respondents walk between 3 to 7 kilometers 2 to 3 times per week to recharge their mobile batteries. This is almost similar to this study which found most respondents walk less than 0.5 kilometers to charge their phones. Thus, for a single round trip the respondents travel almost one kilometer and for the whole week they might travels more than three round trips thus making more than three kilometers in total.

4. CONCLUSION AND RECOMMENDATIONS

This study found that mobile phones have provided rural farmers with a fast and easy mode of communication, thereby increasing famers' ability to access agricultural related information. In addition, mobile phones help rural farmers to secure better markets and price, save time and money, and promptly communicate their agricultural related information. Furthermore, the study found that mobile phone offers an attractive solution to many rural poor individuals and communities due to its general accessibility and collective ownership models.

The use of mobile phones have made market information available to farmers thus improving their position in the value chain by increasing their knowledge and ability to make better informed decisions which has increased their bargaining power with local middlemen. Mobile phones make a great contribution in reducing information costs, simply because as farmers communicate verbally with other actors in value chain, they do sharply, cheaply and without geographical limitation. The study findings again indicated that mobile phone technology is highly accessible to people in the study area.

In terms of access to agricultural information through mobile phones, it was evident that farmers in the study area took the advantage of increased numbers of mobile phone to access information related to their farming activities. This observation is similar to Sanga et al. (2013) who report that farmers used their mobile phones to contact different agricultural stakeholders to meet both technical and agricultural market information. In order to address the negative effect brought by the rise of mobile communication, which favors one to one communication sharing rather than networking communities or providing a shared public or community access point, we have developed an integrated system called 'Ushaurikilimo'. This system is found at http://www.ushaurikilimo.org.

4.1. What Is 'Ushaurikilimo'?

Sokoine University of agriculture in collaboration with a number of partners has developed Ushaurikilimo. 'Ushaurikilimo' is a Swahili word that stands for 'Agro-Advisory'.

'Ushaurikilimo.org' is an Agro-Advisory Service that allows any agriculture actors (e.g. farmer, extension officer, policy maker, trader, etc) to ask for advisory to agriculture extension officer using either web or mobile phone. This means the system is an integrated system which has modules for mobile based farmers' advisory information system (M-FAIS) and web based farmers' advisory information system (W-FAIS). M-FAIS & W-FAIS allows farmers to get advice in various agricultural issues such as agro-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

nomic practices, post-harvest operations, livestock husbandry, forestry, veterinary services, community development and market. A farmer can send a question to either 0688099408. After that the farmer is answered by agriculture experts via his or her mobile phone.

This system is developed by experts from Sokoine University of Agriculture under funding of EPINAV.

4.2. Recommendations

Based on the stated conclusion above, the recommendations from this study are as follows:

i. The Government, NGOs and other stakeholders should work together to help farmers own mobile phones, for instance through loans.
ii. Farmers should be provided with basic education on mobile phone usage, since views from Agricultural Extension Officers (AEO) and input suppliers reported that provision of education to farmers concerning mobile phones use could increase better use of mobile phones in communicating agricultural information to Tanzania farmers in particular.
iii. The Government should provide mobile phones to AEO and to some outstanding farmers to accelerate the adoption of new technologies.
iv. The use of mobile phone has a bright future to increase delivery of agricultural information; the Government should therefore reduce mobile phone tariffs, particularly through encouraging rigorous competition between mobile phone services providers.
v. The Government should introduce public phone booths for many farmers to be able to communicate agricultural information.
vi. Rural farmers need to be provided with education on the use, modes of application and benefits associated with mobile phones in the art of communicating agricultural information.
vii. Agricultural and Irrigation District Office should mount basic ICT courses for training farmers using their Agricultural Extension Staff in maize husbandry.
viii. Agricultural and Irrigation District Office should liaise with Kilosa District Council for lowering airtime charges so that many farmers can afford.
ix. Agricultural and Irrigation District Office should develop localized agricultural, and livestock contents and market information for web and mobile based famers' advisory information systems i.e. M-FAIS & W-FAIS.

Chapter 31
Biological Alchemy:
Gold From Garbage or Garbage Into Gold

ABSTRACT

The story of garbage processing is changing globally and is being considered as a potential option in the hierarchy of integrated solid waste management that involves stabilization of organic material by the joint action of earthworms and microorganisms. Vermicomposting is an economically viable technique in which the job is done by certain species of earthworms that enhances the process of waste conversion and produces a better end product vermicompost. Vermicompost is highly nutritive fertilizer and more powerful growth promoter over the conventional compost. It is rich in nitrogen, phosphorus and potassium commonly referred as NPK, micronutrients, growth hormones and enzymes. Its commercialization is a good business opportunity and is emerging as an industry itself. The farmers need to raise the crops by organic farming that will reduce the cost and will decrease the impact on environment. The present chapter is an attempt to highlight different approaches of converting waste into vermicompost and the importance of vermicomposting as compared to synthetic fertilizers.

INTRODUCTION

Different types of inorganic and organic waste is a worldwide menace and it is becoming more and more difficult to manage this problem day by day due to rapid increase in population and industrialization which leads to decrease in land space and as well as changes in our life style (Singh et al., 2011). Nowadays most of the waste generated is either disposed of in an open dump in developing countries

or in landfills in the developed ones. However, land filling and open dumping requires a lot of land and could also result in several environmental problems.

A sustainable approach to handle this will be to treat and reprocess organic waste on-site, and to produce useful products. Composting is the most economical and sustainable option for organic waste management as it is easy to operate and can be conducted in contained space provided it is managed properly to produce a good quality produce (Thyagarajan et al., 2010). Composting is a natural process of organic waste treatment which is currently practiced with various modifications (Nair, Vanja, & Anda, 2006).

The composting of waste by earthworms is a simple biotechnological process, in which certain local species of earthworms are used to enhance the process of waste conversion and produce vermicompost (Nagavallemma et al., 2004). Vermicomposting of different types of solid wastes, prior to land application may be a sustainable waste management technique, as the vermicast and vermiwash obtained at the end of vermicomposting process is rich in plant nutrients and is devoid of pathogenic organism. Utilization of vermicompost produced from urban/municipal solid waste in agriculture will facilitate in growth of organic farming and countries economy by lowering the consumption of inorganic fertilizer and avoiding land degradation and soil toxicity problem. Vermicomposting of urban/MSW can be an excellent and best sustainable practice, as it will be helpful in recycling valuable plant nutrients (Singh et al., 2011). Process of vermicomposting differs from composting in many ways (Gandhi, Sangwan, Kapoor, & Dilbaghi, 1997). It is a process in which earthworms and microorganism need moderate temperature 10-32°C (not atmospheric temperature but temperature within the pile of moist organic material) which is known as mesophilic process. Earthworms, through a unique type of biological process, are capable of transforming garbage into 'gold' (Vermi, 2001; Tara Crescent 2003).

Vermicomposting involves the stabilization of organic solid waste through earthworm consumption that converts the waste into earthworm castings. Vermicomposting is the method of combined activity of microorganisms and earthworms. Vermicompost is one of the richest soil conditioners there and improves soil structure and increases its water holding capacity. It brings beneficial microbial activity to plants and provides essential nutrients, available over a long period of time. Plants that receive vermicompost are more productive and resistant to parasites and disease (Singh, 2009). It is proving to be highly nutritive 'organic fertilizer' and more powerful 'growth promoter' over the conventional composts and a 'protective' farm input (increasing the physical, chemical & nutritive value of soil by improving its microbial content, which restore its natural fertility) against the 'destructive' chemical fertilizers which has destroyed the soil properties and decrease its natural fertility over the years. It is rich in NKP (nitrogen 2-3%, potassium 1.85-2.25% and phosphorus 1.55-2.25%), micronutrients, and beneficial soil microbes and also contains 'plant growth hormones and enzymes (Katiyar, Jat, & Singh, 2013).

The earthworm choice for vermicomposting is the key step as it affects the rate of waste stabilization. The different type of earthworms can be used for waste management and sludge stabilization all over the world. The earthworm's species having the capability to colonize organic throw away naturally, high rates of organic matter consumption, digestion and assimilation, able to tolerate a wide range of environmental stress, having high reproductive rates by producing large number of cocoons having short hatching time, rapid growth and maturation rate of hatchlings to adults (Domínguez & Edwards, 2004) are suitable to be used in vermicomposting process. Earthworms sustain aerobic conditions in the waste mixture, ingest solids, and convert a share of the organic matter into biomass and respiration products (Benitez, Nogales, Elvira, Masciandro, & Ceccanti, 1999). Earthworms expels the residual partially stabilized matter as discrete material commonly known as vermicasting (Benitez et al., 1999). The amount turned over by earthworm depends on the availability of total suitable organic waste. If the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

soil physical conditions like temperature and moisture content are suitable the number of earthworms increases in the piles, until the food becomes a limiting factor. The smaller earthworms feeding on the litter produces cast in form of almost entirely fragmented litter, whereas the larger earthworms consume large proportion of soil, and their casts have less organic matter.

Environmental degradation is a major threat confronting the world, and the violent use of chemical fertilizers contributes largely to the deterioration of the environment through depletion of fossil fuels, generation of carbon dioxide (CO_2) and contamination of water resources. It leads to the loss of soil fertility due to imbalanced use of fertilizers that has damaged agricultural productivity and causes soil microbial degradation. Now there is a growing realization that the adoption of ecological and sustainable farming practices can only reverse the declining trend in the global productivity and environmental protection (Wani & Lee, 1992; Wani, Rupela, & Lee, 1995; Aveyard 1988,).

Chemical fertilizers which ushered the 'green revolution' in the 1950-60's came as a 'mixed blessing' for mankind and soil health. It boosted food productivity, but at the cost of environment and society. It dramatically increased the 'quantity' of the food produced but decreased its 'nutritional quality' and also the 'soil fertility' over the years. It killed the native soil microorganisms which help in renewing natural fertility. Over the years it has worked like a 'slow poison' for the soil with serious 'withdrawal symptoms'. The excessive use of 'nitrogenous fertilizer' (urea) has also led to increase in the level of 'inorganic nitrogen' content in groundwater (through leaching effects) and in the human food with grave consequences for the human health.

In order to meet the needs of ever growing population widespread use of chemical pesticides became a necessity for the growth of high-yielding varieties of crops which was highly 'susceptible to pests and diseases'. Continued and long term application of chemical pesticides induced 'biological resistance' in crop pests and diseases and much higher doses are now required to eradicate them. Studies indicate that there is significant amount of 'residual pesticides' contaminating our food stuff long after they are taken away from farms for human consumption.

Adverse effects of agro-chemicals on the agricultural ecosystem (soil, flora, fauna & water bodies in farms) and also on the health of farmers using them and the society consuming the chemically grown food have now started to become more evident all over the world. According to World Health Organization (WHO) and United Nation Environment Program (UNEP) nearly 3 million people suffer from 'acute pesticide poisoning' and some 10 to 20 thousand people die every year from it in the developing countries (UNEP/GEMS, 1992). US scientists predict that up to 20,000 American people may die of cancer, each year, due to the low levels of 'residual pesticides' in the chemically grown food. Higher use of agro chemicals also adversely affecting their economy as the cost of agrochemicals has been rising all over the world. The only solution that may tackle the problem is organic farming.

Organic farming systems with the aid of various nutrients of biological origin such as compost are thought to be the answer for the 'food safety, farm security and environmental balance' in future. Among them 'composts' made from biodegradation of organics of MSW (municipal solid waste) which is being generated in huge amount every day all over the world are most important. The organic fraction of the MSW (about 70-80%) containing plenty of nitrogen (N), potash (K) and phosphorus (P) is a good source of macro and micronutrients for the soil. Composts also contain plenty of 'beneficial soil microbes' which help in 'soil regeneration' and 'fertility improvement' and protect them from degradation while also promoting growth in plants (De Brito Alvarez, Gagne, & Antoun, 1995; Weltzien, 1989). Composts also protect plants from pests and diseases.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The modern practice of agriculture and denudation of forests exert an impact on the soil as a habitat, affecting soil fauna and species diversity (Evans, Mc, & Guild, 1948). Earthworms, being one of the major inhabitants of the soil, are often exposed to these manmade hazards. The species that can tolerate repeated soil disturbances and relatively limited supply of organic material are favored at the expense of those that cannot. Although agricultural practices affect earthworm population in general, sometimes they also favor the growth of certain species (Edwards & Lofty, 1972). However, large populations are recorded from uncultivated areas (Edwards & Lofty, 1977). Despite such limitations, earthworms still exist in their variety and diversity in variety of soil types.

Because of the predominance of the earthworms in some tropical and temperate soils, they increase their ecological importance. Many workers have worked on the various aspects of the ecophysiology of earthworms inhabiting different ecosystems (Block & Banage, 1968; Abrahamsen, 1972; Dash & Patra, 1977; Kale & Krishnamoorthy, 1978, 1981a). Much more investigation are required with regards to qualitative and quantitative composition of earthworms, their seasonal variations in different soil conditions prevailing in India and to device and utilize earthworm based biotechnologies of welfare of human beings.

Composts are aerobically decomposed products of organic wastes such as the cattle dung and animal droppings, farm, agriculture and forest wastes and the municipal solid wastes (MSW). Bombatkar (1996), called them as 'miracle' for plant growth. They supply required macro and micro nutrients to plant roots and stimulate growth; increase organic matter content of the soil including the 'humic substances' that affect nutrient accumulation and promote root growth (Canellas, Olivares, Okorokova, & Facanha, 2000; Siminis, Loulakis, Kefakis, Manios, & Manios, 1998). They in fact improve the total physical and chemical properties of the soil. Vermicompost and vermiwash also add useful micro-organisms to the soil and provide food for the existing soil micro-organisms and thus increase their biological properties and capacity of self-renewal of soil fertility (Ouédraogo, Mando, & Zombre, 2001; Shiralipour, McConnell, & Smith, 1992). One ton of compost may contain 10 lbs of nitrogen (N), 5 lbs of phosphorus (P_2O_5) and 10 lbs of potash (K_2O). Compost made from poultry droppings contains highest nutrient level among all compost (Bombatkar, 1996).

Earthworms consume various organic wastes and reduce the volume by 40-60%. Each earthworm weighs about 0.5 to 0.6 gm, eats waste equivalent to its body weight and produces cast equivalent to about 50% of the waste it consumes in a day. These castings have been analyzed for chemical and biological properties. The moisture content of worm castings ranges between 32 and 66% and it is evident that vermicompost provides all nutrients in readily available form and also enhances uptake of nutrients by plants. Sreenivas, Muralidhar, & Rao (2000), studied the beneficial integrated effect of application of fertilizer and vermicompost on soil available Nitrogen (N) and uptake of ridge gourd (*Luffa acutangula*) at Rajendranagar, Andhra Pradesh, India. Soil nitrogen increased significantly with increasing levels of vermicompost and highest N uptake was obtained at 50% of the recommended fertilizer rate plus 10 t ha^{-1} vermicompost. Similarly, the uptake of N, phosphorus (P), potassium (K) and magnesium (Mg) by rice (*Oryza sativa*) plant was highest when fertilizer was applied in combination with vermicompost (Jadhav, Talashilkar, & Pawar, 1997).

Vermicompost is a nutritive 'organic fertilizer' rich in NKP (nitrogen 2-3%, potassium 1.85-2.25% and phosphorus 1.55-2.25%), micronutrients, and beneficial soil microbes like 'nitrogen-fixing bacteria' and 'mycorrhizal fungi' and are scientifically proving as 'miracle growth promoters and protectors'. Kale & Bano (1988) reported 7.37% nitrogen (N) and 19.58% phosphorus as P_2O_5 in vermicast. Moreover, Suhane, (2007) found that exchangeable potassium (K) was over 95% higher in vermicompost.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

A good amount of calcium (Ca), magnesium (Mg), zinc (Zn) and manganese (Mn) have also been reported. Additionally, vermicompost contain enzymes like amylase, lipase, cellulase and chitinase, which continuously break down organic matter in the soil (to release the nutrients and make it available to the plant roots) even after they have been excreted by the earthworms. Annual application of proper amount of vermicompost also lead to significant increase in soil enzyme activities such as 'urease', 'phosphomonoesterase', 'phosphodiesterase' and 'arylsulphatase'. The soil treated with vermicompost has significantly more electrical conductivity (EC) and near neutral pH. Vermicompost has very 'high porosity', 'aeration', 'water holding capacity'and 'moisture content'. Vermicasts have a vast surface area, for providing strong absorbability and retention of nutrients by the compost. They appear to retain more nutrients for longer period of time. Study showed that soil mixed with vermicompost had significantly greater 'soil bulk density' and hence porous, lighter and never show compactness. Increase in porosity has been attributed to increase in number of pores in the range of 30-50 μm and 50-500 and decrease in number of pores greater than 500 μm.

In tropical countries like India high temperature conditions result in nutrient deficient soil. High inputs of chemical fertilizers also decrease soil organic matter to a large extent. In both the cases, a series of chain reactions take place leading to biological degradation of the soil. For such soils, vermi-conservation technology using burrowing earthworms like *Polypheritima elongata* and *Lumbricus terrestries,* appears to be appropriate rather than vermicomposting worms (Bhawalkar, 1993, 1994, 1996). It combines soil processing with waste processing at the same time (Two-in-one Package). Reclamation of soil may be achieved using this technology.

WASTE INTO VERMICOMPOST

The various industrial wastes which have been already vermicomposted and turned into nutrient rich manure include paper waste (Elvira, Sampedro, Benitez, & Nogales, 1998; Kaur, Singh, Vig, Dhaliwal, & Rup, 2010), textile industry sludge (Garg & Kaushik, 2005), guar gum industrial waste (Suthar, 2006), sugar industry wastes (Sen & Chandra, 2007), distillery sludge (Suthar & Singh, 2008), leather industry (Ravindran, Dinesh, Kennedy & Sekaran, 2008) and beverage industry sludge (Singh, Kaur, Vig, & Rup, 2010), agroindustrial sludge (Suthar, 2010), primary sewage sludge (Hait & Tare, 2011), tannery industries (Ravindran & Sekaran, 2011). A number of workers have tried to process poultry manure through vermicompostiong. The manure from poultries has high nutritive value and is sometimes used in animal feeds, therefore, its use in the production of earthworms for preparation of worm meal. Despite the deleterious effect of poultry manure on the earthworm *Perionyx excavates* (Kale & Krishnamoorthy, 1981b), and its failure as feed in mass production of the earthworm *Eudrilus eugeniae* (Graff, 1981), six different dietary formulations with poultry manure as base were tried in an attempt to establish the feasibility of use of poultry manure in mass culturing of the earthworm *Eudrilus eugeniae*, a prolific breeder, for worm meal. Worm meal has been recognized as a valuable source of protein in animal diet (Sabine, 1978; Guerrero, 1983). The nutritive value of a variety of worm meals and their use as the pig's diet, poultry and fish food has been demonstrated by various workers (Sabine 1978; Graff, 1981). Earthworm species employed for vermicomposting of solid organic wastes is shown in Table 1.

Investigation by (Lowe & Butt, 2002) highlighted the ability of *E. eugeniae* to partially detoxify the wastes and convert the toxic cassava peels in to valuable vermicompost. In general, an organic C loss has been observed during the vermicomposting process (Kale, Bano, & Krishnamoorty, 1982; Garg &

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Earthworm species employed for vermicomposting of Solid Organic Wastes (SOW)

S.No.	Solid Organic Waste (SOW)	Species Employed	Reference
1	Potato peels	*Pheretima elongate*	(Munnoli, Arora & Sharma, 2000)
2	Press mud	*Pheretima elongate* *Eudrilus eugeniae, Eisenia fetida* *Megascolex megascolex*	(Singh, 1997) (Munnoli, 2007) (Munnoli and Bhosle, 2008)
3	Canteen waste	*Eisenia fetida*	(Kale, 1994)
4	Tomato skin seed	*Pheretima elongate*	(Singh, 1997)
5	Onion residue	*Eisenia fetida/Eudrilus eugeniae*	(White, 1996)
6	Sericulture waste	*Perionyx excavates*	(Gunthilingaraj and Ravignanam, 1996)
7	Sericulture waste	*Phanerochaete chrysosporium*	(Kallimani, 1998)
8	Board mill sludge	*Lumbricus terrestris*	(Butt, Nieminen, & Siren, 2005)
9	Sugar cane residues	*Pheretima elongate*	(Bhawalkar, 1995)
10	Gaur gum	*Eudrilus eugeniae*	(Bhawalkar,1995; Suthar 2006)
11	Agricultural residues	*Eudrilus eugeniae*	(Kale, 1994)
16	Sago waste	*Lampito mauritii*	(Rajesh, Yeom, Esakkiraj, Kumar, & Lee, 2008)
17	Sago waste	*Eisenia fetida*	(Subramanian, Sivrajan, & Sarvanapriya, 2010)
18	Onion waste	*Eudrilus eugeniae*	(Mishra, Singh, Upadhyay, & Singh, 2009)
19	Garlic waste	*Eisenia fetida*	(Mishra, et al., 2009)
20	Source separated from human feces	*Eisenia fetida*	(Yadav, Vinod, & Mansoor, 2010)
21	Paper mill sludge	*Eisenia fetida*	(Kaur et al., 2010)
22	Press mud, bagassi, sugar cane trash	*Drawida willsi*	(Kumar, Verma, Singh, Umesh, & Shweta, 2010)
23	Press mud	*Perionyx ceylanensis*	(Mani and Karmegam, 2010)
24	Kitchen waste, Garden waste, cow dung	*Eisenia fetida*	(Wani, et al., 2013)

Kaushik, 2005; Suthar, 2007). Earthworm transforms substrate conditions, which consequently affects the carbon losses from the substrates through microbial respiration in the form of CO_2 and even through mineralization of organic matter Table 2. The inoculation of worms in waste material considerably enhances the amount of nitrogen (N) due to earthworm mediated nitrogen mineralization of wastes. It also

Table 2. Rating of substrates for vermicomposting

S. No.	Types of Substrates	C:N Ratio	Suitability
1	Fish, scrap poultry manure, night soil, activated sludge, pig manure, sheep dropping, meat scraps, cotton seed meal and other oil seed residues	1-19	Most suitable due to high Nitrogen content
2	Garbage, sea weed, butter cup, amaranthus, lettuce, cabbage and vegetable waste which are fresh, green and succulent including wastes from food processing industries	19-27	Moderately suitable
3	Saw dust flax, waste straw, coir waste, etc. including all crop residues with high lignocelluloses content, high carbon and low moisture	27-208	Less suitable

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

observed by different researchers that the earthworm also enhances the nitrogen levels of the substrate by adding their excretory products, mucous, body fluid, enzymes and even through the decaying tissues of dead worms in vermicomposting sub-system (Suthar, 2007).

The earlier investigators proved that earthworms prefer food with higher quality of fungus and calcium (Cooke & Luxton, 1980; Parthasarathi & Ranganathan, 2000) and higher content of sugar and nitrogen (Lee, 1985; Edwards & Bohlen, 1996). Kurien & Ramasay (2006) used taro (*Colocasia esculenta*) as feeding material for *Eudrilus eugeniae* and *Eisenia foetida* and showed that vermicasts were produced with steadily increasing output in all the reactors.

Shweta, Kumar, Sharma, & Sonal, (2006), vermicomposted bagasse, rice bran, flower waste, leaf litter, banana leaf, fruit waste, kitchen waste and saw dust in combination with cow dung and mixed dung alone showed that mixed dung was best substrate to increase the biomass and cocoon production. Wani, Mamta, & Rao, (2013) indicated that vermicomposting of different organic waste like garden waste, kitchen waste and cow dung not only produces a value added product (vermicomposting) but at the same time reduce the quantity of waste (Table 3). The vermicompost of cow dung, garden waste and kitchen waste in combination were used with brinjal plants under field conditions. Different treatments affected significantly the seed germination of test crops. Plant height, number of leaves and fruit weight was higher in the vermicompost treated field as compared to control and no disease incidence was observed in the fruits of vermicompost treated plot. The study revealed that vermicompost amendments affected brinjal crop differently and we recommend that vermicompost should be used by farming community instead of synthetic fertilizers while raising brinjal crops Mamta, Wani, & Rao (2012).

Kostecka (1999) found that flax seeds are very attractive to *E. foetida* and can be useful for quick reproduction. The great attractiveness was confirmed by rapid vermicomposting and accumulation of 43 percent of *E. foetida* in the bed and a considerable increase of earthworm number and biomass. Dominguez, Edwards, & Webster (2000) reported that maximum weight and highest growth rate were attained in the mixture with food waste whereas; smallest size and lowest growth rate was achieved in the mixture of sewage sludge with sawdust. Earthworms showed much higher reproductive rates in the paper and cardboard mixtures compared to sewage sludge alone. Vermicomposting using *Lumbricus rubellus* for 49 days was conducted after 21 days of pre-composting. Three different combinations of treatments were prepared with eight replicates for each treatment (T1) namely cow dung: kitchen waste in 30:70 ratios, cow dung: coffee grounds in 30:70 ratio (T2), and cow dung: kitchen waste: coffee grounds in 30:35:35 ratio (T3). The multiplication of earthworms in terms of numbers and weight were measured at

Table 3. Nutrient content and different physico-chemical parameters in garden waste, kitchen waste and cow dung

Waste	pH	MC	TOC	Humus	Nitrogen	Phosphorus	Potassium
Garden waste	6.3 ± 0.06^{a}	2.7 ± 0.10^{a}	11.7 ± 0.24^{a}	68.7 ± 0.91^{a}	1.02 ± 0.07^{a}	0.37 ± 0.03^{a}	0.60 ± 0.02^{a}
Kitchen waste	7.2 ± 0.04^{b}	3.1 ± 0.08^{b}	13.3 ± 0.31^{b}	63.9 ± 1.99^{b}	1.30 ± 0.02^{b}	0.50 ± 0.02^{b}	1.01 ± 0.18^{b}
Cow dung	8.1 ± 0.06^{c}	2.6 ± 0.04^{b}	18.4 ± 1.16^{b}	64.1 ± 0.94^{c}	1.97 ± 0.07^{c}	0.62 ± 0.03^{c}	0.88 ± 0.18^{c}

All values are in mean ± 1 S.E. Values bearing different superscripted alphabets differ from each other at $P < 0.05$ (based on Duncan's multiple range test).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the end of vermicomposting. Consequently, only T2 showed significant increase (from its initial stage) compared to other treatments. The presence of coffee grounds in T2 and T3 showed higher percentage of nutrient elements in vermicasts produced. The data reveal that coffee grounds can be decomposed through vermicomposting and to help to enhance the quality of compost produced rather than sole use of kitchen waste in vermicomposting (Adi & Noor, 2009).

Experimental studies on the agronomic impacts of earthworms & its vermicompost on crop plants all over the world is conclusively proving that their application in farm soil over subsequent years can lead to enhanced production of 'safe food', both in 'quantity & quality' without recourse to agro-chemicals. Several scientists working on vermiculture throughout the world have confirmed the positive role of earthworms and its metabolic products (vermicast) on crop growth and development. Important among them are Alam, Jahan, Ali, Ashraf, & Islam, (2007); Ansari (2008); Atiyeh, Arancon, Edwards, & Metzger, (2000) Atiyeh et al. (2000); Arancon et al. (2003) Arancon, Edwards, Bierman, Welch, & Metzger, (2004) Arancon, Edwards, & Bierman, (2006); Bhat & Khambata (1994); Bhatia (2000); Bhatia, Sinha, & Sharma (2000); Baker & Barrett (1994); Garg & Bhardwaj (2000); Krishnamoorthy & Vajranabhaiah (1986); Palanisamy (1996); Reddy (1988); Scheu (1987); Sharma (2001); Suhane (2007); Spain, Lavelle, & Mariotti (1992); Tomar, Bhatnagar, & Palta (1998); Valani (2009); Wilson & Carlile (1989) ; Webster (2005).

Studies on vegetable and cereal crops done in India at University of Rajasthan (1997-2001) and at Bihar Agriculture University (2007-2009) and in Australia at Griffith University (2007-2009), has also testified and strengthened the views of other workers. Application of vermicompost in potted and field crops displayed excellent growth performances in terms of height of plants, number of leaves, color and texture of leaves, appearance of fruiting structures as compared to chemical fertilizers and the organic compost. There is also less incidences of pest and disease attack and reduced demand of water for irrigation.

The post-harvest residues of some local crops, e.g. wheat (*Triticum aestivum*), millets (*Penniseum typhoides* and *Sorghum vulgare*), and pulse (*Vigna radiata*) were subjected to recycle through vermi-composting by using the epigeic earthworm *Eudrilus eugeniae* Kinberg, under controlled conditions. The crop residues were amended with animal dung; and three types of vermibeds were prepared: (i) millet straw (S. *vulgare* + *Pennisenum typhoides* in equal quantity) + sheep manure (1:2 ratio) (MS), (ii) pulse bran (*Vigna radiata*) + wheat straw (*Triticum aestivum*) + cow dung (1:1:2 ratio) (PWC), and (iii) mixed crop residues (mixing of all types crop residues, used in this study)+cow dung in 1:1 ratio (MCR + CD). The fourth treatment was cattle shed manure (CSM). At the end, ready vermicompost showed lower organic C content and higher concentrations of other important plant nutrients. Organic carbon (C) content decreased in the order: MCR+CD (27.6%) > PWC (22.8%)>CMS (22.6%) >MS (19.4%). The ready vermicompost obtained from MCR+CD vermibed showed the maximum increase (% of initial level) in content of total N (143.4%), available P (111.1%) and exchangeable K (100.0%). The end product showed reduction in C:N ration between the ranges of 60.7% (CSM) and 70.3% (MCR + CD), at the end of the vermicomposting process. The composting earthworm *E. eugeniae* exhibited the highest values of biological parameters: maximum mean individual biomass (1261.25±7.0 mg), biomass gain (955.84±11.03 mg), growth rate (10.62±0.10mgwt.worm^{-1} day^{-1}), cocoon numbers (87.67±6.51), and reproduction rate (0.66±0.01 cocoonsworm^{-1} day^{-1}) in CSM container, while MS vermibeds showed the least values of these parameters. During tests, the maximum mortality for *E. eugeniae* was recorded in MS (16.67±7.63%) followed by CSM> PWC>MCR+CD. Results indicated that the C:N ratio of the substrate drastically influenced the growth characteristics of *E. eugeniae*, and it showed the close relations with maximum individual biomass gain (R2 = 0.96), individual growth rate (R2 = 0.82), and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

reproduction rate (cocoonworm^{-1} day^{-1}) (R2 = 0.72), in different treatments. This study clearly indicates that vermicomposting of crop residues and cattle shed wastes can not only produce a value added product (vermicomposting) but at the same time acts as best culture medium for large-scale production of earthworms.

A laboratory study was undertaken to examine the temporal changes in physico-chemical properties during vermicomposting of sago industry waste. The sago industry waste was mixed with cow dung, poultry manure at different proportions, and it kept for pre-treatment for 21 days and subsequently vermicomposted for a period of 45 days under shade. Earthworm species (*Eisenia foetida*) was introduced at the rate of 50 gm/kg of waste. The moisture content of substrate and temperature were monitored at regular intervals. The vermicomposts were sampled at the interval of every 15 days 0, 15, 30 and 45 days for the assessment of temporal changes in physicochemical properties. The data revealed that equal proportion of sago wastes; cow dung and poultry manure produced superior quality manure with desirable C: N ratio and higher nutritional status than other methods of composting. *E. foetida* is an earthworm suitable for composting organic wastes such as poultry manure with extreme pH and high temperature and sago waste with high organic carbon in a shorter period of time interval. This study suggests that the sago industry solid waste could be effectively converted into highly valuable manure that can be exploited to promote crop production.

Vermicomposting converts household waste into compost within the period of 30 days, reduces the C:N ratio and retains more N than the traditional methods of preparing composts (Gandhi et al., 1997). The C:N ratio of the raw olive cake, vermicomposted olive cake and manure were 42, 29 and 11, respectively. Both the raw olive cake and vermicomposted olive cake immobilized soil N.

ADVANTAGES OF VERMICOMPOST

High Levels of Bio-Available Nutrients for Plants

Vermicompost contains most nutrients in plant-available forms such as ‘nitrates’ (N), ‘phosphates’ (P), ‘soluble’ potassium (K), and magnesium (Mg) and ‘exchangeable’ phosphorus (P) and calcium’ (Ca) (Edwards, Domínguez, & Arancon, 2004; Edward & Burrows, 1988). Vermicomposts have large particulate surface areas that provide many micro-sites for microbial activities and for the strong retention of nutrients (Arancon et al., 2004; Arancon et al., 2006). Nutrient content and different physio-chemical parameters in garden waste, kitchen waste and cow dung as obtained by Wani et al., (2013) is shown in Table 3.

High Level of Beneficial Soil Microorganisms Promoting Plant Growth

Vermicompost are rich in ‘microbial populations & diversity’, particularly ‘fungi’, ‘bacteria’ and ‘actinomycetes’ (Brown, 1995; Chaoui, Zibilske, & Ohno, 2003; Scheu, 1987; Singh, 2009). Parle, 1963, reported bacterial count of 32 million per gram in fresh vermicast compared to 6-9 million per gram in the surrounding natural soil. Scheu, (1987) reported an increase of 90% in respiration rate in fresh vermicast indicating corresponding increase in the microbial population. Suhane, (2007) found that the total bacterial using Actinomycetes, Azotobacter using count was more than 1010 per gram of vermicompost.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Rich in Growth Hormones

Vermicompost further stimulates plant growth even when plants are already receiving 'optimal nutrition' as it has consistently improved seed germination, raise seedling growth and development and increased plant productivity much more than would be possible from the mere conversion of mineral nutrients into plant-available forms. Arancon, (2004) found that maximum benefit from vermicompost is obtained when it constitutes between 10 to 40% of the growing medium. Neilson, (1965); Tomati, Grappelli, & Galli (1988) have also reported that vermicompost contained growth promoting hormone 'auxins', 'cytokinins' and flowering hormone 'gibberellins' secreted by earthworms. Canellas et al., (2000) found that humic acids isolated from vermicompost enhanced root elongation and formation of lateral roots in maize roots. Pramanik, Ghosh, Ghosal, & Banik (2007) also reported that humic acids enhanced 'nutrient uptake' by the plants by increasing the permeability of root cell membrane, stimulating root growth and accelerating proliferation of 'root hairs'.

Vermicompost Is Free of Pathogens

Nair et al., (2006) indicated that vermicomposting leads to greater reduction of pathogens after 3 months of storage. Whereas, the samples which were subjected to only thermofilic composting, contained higher levels of pathogens even after 3 months.

Vermicompost Has No Toxic Chemicals

Several studies have found that earthworms effectively bioaccumulate or biodegrade several organic and inorganic chemicals including 'heavy metals', 'organochlorine pesticide' and 'polycyclic aromatic hydrocarbons' (PAHs) residues.

Vermicompost Protects Plants Against Various Pests and Diseases

There has been considerable evidence in recent years regarding the ability of vermicompost to protect plants against various pests and diseases either by suppressing or repelling them or by inducing biological resistance in plants to fight them or by killing them through pesticidal action (Anonymous, 2001; Al-Dahmani, Abbasi, Miller, & Hoitink, 2003).

Induce Biological Resistance in Plants

Vermicompost contains some antibiotics and actinomycetes which help in increasing the 'power of biological resistance' among the crop plants against pest and diseases. Pesticide use was significantly reduced where earthworms and vermicompost were used in agriculture (Singh, 1993; Suhane, 2007).

Repel Crop Pests

There seems to be strong evidence that worm's varmicastings sometimes repel hard-bodied pests (Anonymous, 2001; Arancon, 2004). Edwards & Arancon, (2004) reports statistically significant decrease in arthropods (aphids, buds, mealy bug, spider mite) populations and subsequent reduction in plant dam-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

age, of tomato, pepper and cabbage trials with 20% and 40% vermicompost additions. GEORG (2004), doing commercial vermicomposting in California, U.S., affirms that his product repels many different insects pests. There explanation is that this is due to production of enzymes 'chitinase' by worms which breaks down the chitin in the insect's exoskelton (Munroe, 2007).

Suppress Plant Disease

Edwards & Arancon (2004) found that use of vermicompost in crops inhibited the soil-born fungal diseases. They also found substantial suppression of plant-parasitic nematodes in field trials with pepper, tomatoes, strawberries and grapes. The high levels of agronomically beneficial microbial population in vermicompost protects plants by out-competing plant pathogens for available food resources, by starving them and also by blocking their access to plant roots by occupying all the available sites. Edwards & Arancon, (2004), reported the agronomic effects of small applications of commercially produced vermicompost, on attacks by fungus *Rhizoctonia* on radish and *Pythium* on cucumber, in the greenhouse, by *Verticillium* on strawberries and by *Phomposis* and *Sphaerotheca fulginae* on grapes at the field. In all these experiments vermicompost use suppressed the incidence of the disease significantly and also found that the ability of pathogen suppression disappeared when the vermicompost was disinfectd/sterilized, convincingly indicating that the biological mechanism of disease suppression involved was 'microbial antagonism. Szczech, Rondomanski, Brzeski, Smolinska, & Kotowski, (1993); Orlikowski, (1999); Rodriguez, Zavaleta, Sanchez, & Gonzalez, (2000); Zaller, (2006) also found that the aqueous extracts of vermicomposts depress soil-borne pathogens and pests, in their field experiment that only half as many plants of tomatoes sprayed with aqueous extract of vermicompost were infected with *Phytopthora infestans* (that cause 'late-blight' disease) as those of control ones.

NUTRITIONAL QUALITY OF VERMICOMPOST

The nutritional quality of vermicompost is determined primarily by the type of the substrate (raw materials) and species of earthworms used for composting, along with microbial inoculants, liming, aeration, humidity, pH and temperature. Cattle dung has been found to yield most nutritive vermicompost when composted by *Eisinea fetida*. Pramanik et al., (2007) found that application of lime at the rate of 5 gm/kg of substrate and 'microbial inoculation' by suitable 'cellulolytic', 'lignolytic' and 'N-fixing' strains of microbes not only enhance the rate of vermicomposting but also results into nutritionally better vermicompost with greater enzymatic (phosphatase and urease) activities. Kaushik & Garg (2004) found that inoculation with N-fixing bacteria significantly increased the 'nitrogen' (N) content of the vermicompost. Liming generally enhance earthworm activities as well as microbial population. Earthworms after ingesting microbes into its gut proliferate the population of microbes to several times in its excreta (vermicast). It is therefore advantageous to use beneficial microbial inoculants whose population is rapidly increased for rapid composting and also better compost quality. Pramanik et al., (2007) studied the vermicomposting of four substrates viz. cow dung, grass, aquatic weeds and municipal solid wastes (MSW) to know the 'nutritional status and enzymatic activities' of the resulting vermicomposts in terms of increase in total nitrogen (N), total phosphorus (P) and potassium (K), humic acid contents and phosphatase activity.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Total Nitrogen

Sinha, Sunil, Dalsukh, & Chauhan, (2009) found that cow dung recorded maximum increase in nitrogen (N) content (275%) followed by MSW (178%), grass (153%) and aquatic weed (146%) in their resulting vermicomposts over the initial values in their raw materials without liming and microbial inoculation. Application of lime without microbial inoculation, however, increased N content in the vermicompost from 3% to 12% over non-limed treatment, irrespective of substrates used.

Total Phosphorus and Potassium

Similarly, the vermicompost prepared from cow dung had the highest total phosphorus (12.70 mg/g) and total potassium (11.44 mg/g) over their initial substrate followed by those obtained from aquatic weeds, grasses and MSW. This was also irrespective of lime application and microbial inoculation. Among the microbes inoculated for vermicomposting, *Bacillus polymyxa* a free-living N-fixing bacterium was most effective in increasing total phosphorus (11-22%) in the vermicompost after liming.

Humic Acid

It was highest in vermicompost prepared from cow dung (0.7963 mg/g), followed by those from grasses (0.6147 mg/g), aquatic weeds (0.4724 mg/g) and MSW (0.3917 mg/g). And this was without liming and microbial inoculation. However, microbial inoculation again increased humic acid contents in vermicompost from 25% to 68% depending upon the substrate used. Inoculation by *Phanerochaete chrysoporium* recorded highest humic acid contents without liming as compared to other inoculants. But under limed condition, inoculation by *B. polymyxa* was most effective in increasing humic acid contents irrespective of substrates used for vermicomposting.

Phosphatase Activity

Vermicompost obtained from cow dung showed the highest 'acid phosphatase' (200.45 µg *p*-nitrophenol/g/h) activities followed by vermicompost from grasses (179.24 µg *p*-nitrophenol/g/h), aquatic weeds (174.27 µg *p*-nitrophenol/g/h) and MSW (64.38 µg *p*-nitrophenol/g/h). The 'alkaline phosphatase' activity was highest in vermicompost obtained from aquatic weeds (679.88 µg *p*-nitrophenol/g/h) followed by cow dung (658.03 µg *p*-nitrophenol/g/h), grasses (583.28 µg *p*-nitrophenol/g /h) and MSW (267.54 µg *p*nitrophenol/ g/h). This was irrespective of lime application and microbial inoculation. However, when inoculated by fungi all showed maximum phosphatase activities under both limed and non-limed conditions (Vinotha, Parthasarthi, & Rangnathan, 2000).

IMPROVED CROP GROWTH AND YIELD

Vermicompost plays a major role in improving growth and yield of different crops, vegetables, flower and fruit crops. The use of in soil vermicompost gave higher germination (93%) of mung bean (*Vigna radiata*) compared to the control (84%). Further, the growth and yield of mung bean was also significantly higher with vermicompost application. In the same way, in another pot experiment, fresh and dry

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

matter yields of cowpea (*Vigna unguiculata*) were higher when soil was amended with vermicompost than with biodigested slurry (Karmegam, Alagermalai, & Daniel, 1999; Karmegam & Daniel, 2000). The efficiency of vermicompost was evaluated in a field study by Desai, Sabale, & Raundal, (1999) and according to their application the vermicompost along with fertilizer N gave higher dry matter (16.2 g plant^{-1}) and grain yield (3.6 t ha^{-1}) of wheat (*Triticum aestivum*) and higher dry matter yield (0.66 g plant^{-1}) of the following coriander (*Coriandrum sativum*) crop in sequential cropping manner. Similarly, a positive response was obtained with the application of vermicompost to other field crops such as sorghum (*Sorghum bicolor*) (Patil & Sheelavantar 2000) and sunflower (*Helianthus annuus*) (Devi, Agarwal & Dayal, 1998; Devi and Agarwal, 1998).

Application of vermicompost at 5 t ha^{-1} significantly increased (5.8 t ha^{-1}) yield of tomato (*Lycopersicon esculentum*) in farmers' fields in Adarsha watershed, Kothapally, Andhra Pradesh in comparison to control (3.5 t ha^{-1}). Similarly, greenhouse studies at Ohio State University in Columbus, Ohio, USA have indicated that the vermicompost enhances transplant growth rate of vegetables. Application of vermicompost with a transplant grown without vermicompost had the highest amount of red marketable fruit at harvest and there were no symptoms of early blight lesions on the fruit at harvest. The yield of pea (*Pisum sativum*) was also higher with the application of vermicompost (10 t ha^{-1}) along with the recommended Nitrogen, Phosphorus and Potash than with these fertilizers alone (Reddy et al., 1998). Vadiraj, Siddagangaiah, & Potty, (1998) reported that application of vermicompost produced herbage yields of coriander cultivars that were comparable to those obtained with chemical fertilizers.

The fresh weight of flowers such as *Chrysanthemum chinensis* increased with the application of different levels of vermicompost. Also, the number of flowers per plant (26), flower diameter (6 cm) and yield (0.5 t ha^{-1}) were maximum with the application of 10 t ha^{-1} of vermicompost along with 50% of recommended dose of NPK fertilizer. However, the vase life of flowers (11 days) was high with the combined application of vermicompost at 15 t ha^{-1} and 50% of recommended dose of NPK fertilizer (Nethra, Jayaprasad & Kale, 1999).

ECONOMICALLY VIABLE TECHNIQUE

The new economic theory of development today is 'Environmental-Economics' which advocates for judicious balance between 'economy and ecology' in all developmental programs including agricultural development and amalgamation of 'economic development' programs with 'ecological conservation' strategies to usher in the era of sustainable development. The cost of production of vermicompost is simply insignificant as compared to chemical fertilizers. While vermicompost is produced from a 'cheap raw material' (community wastes including farm wastes) which is in plenty all over the world and is growing in quantity with the growing human population, the chemical fertilizers are obtained from 'petroleum products' which are not only very 'costly raw materials' but also a 'vanishing resource' on earth. While vermicompost can be produced 'on farms' by all farmers, big and small, the chemical fertilizers has to be produced in 'factories' at a high economic and environmental cost. This means vermicompost can be afforded by all farmers. The worms itself becomes an economically valuable products for the farmers to be sold to fishery, poultry, dairy and pharmaceutical industries.

Vermicompost production is also an 'economically productive' process as it 'reduces wastes' at source and consequently saves landfill space. Construction of engineered landfills incurs 20-25 million US dollars upfront before the first load of waste is dumped. Over the past 5 years the cost of landfill

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

disposal of waste has increased from $ 29 to $ 65 per ton of waste in Australia. Then, landfills have to be monitored for at least 30 years for emissions of GHG and toxic gases & leachate (Waste Juice) which also incur cost. During 2002-2003, waste management services within Australia cost $ 2458.2 million. Even in developing nations where there are no true landfills, dumping of wastes incurs high cost on local government.

Earthworms converts a product of 'negative' economic & environmental value i.e. 'waste' into a product of 'highly positive' economic and environmental values i.e. 'high nutrition content organic fertilizer' (brown gold) which improve soil fertility and enhance farm productivity to produce 'safe food' (green gold) in farms. Vermiculture can maintain the global 'human sustainability cycle-i.e. producing food in farms back from food & farm wastes. Vermicomposting is a self-regulated, self-improved and self-enhanced, very less or no-energy requiring zero-waste technology, easy to construct and maintain. It excels all other waste conversion technologies by the fact that it can utilize waste organics that otherwise cannot be utilized by others. It excels all other biological or mechanical technologies for production of 'bio-fertilizer' because it achieves 'greater utilization' than the rate of 'destruction' achieved by other technologies and the process becomes faster with time as the army of degrader worms and the decomposer microbes multiply in millions in short time (Sinha, Sunil, Agarwal, Asadi, & Carretero. 2002; Sinha, Nair, Bharambe, Swapnil, & Bapat, 2008). Earthworms involves about 100-1000 times higher 'value addition' in any medium (composting wastes or soil) wherever it is present (Appelhof, 1997; Appelhof, 2003).

Production of chemical fertilizers in industries is an 'environmentally damaging' process in its entire lifecycle, since harnessing of raw materials from the earth crust, to their processing in factories and their use in agriculture farms. It generates huge amount of toxic and hazardous wastes and pollutants at every stage of production and use. It also uses copious amount of energy in production process and emits huge volumes of greenhouse gases (GHG). It is an 'economically unproductive' process of development. Huge money has to be spent on infrastructure development for production of chemical fertilizers and in installations of equipments for pollution control, transport and then on safe disposal of hazardous waste in engineered landfills. Its application in farms pollutes the soil and water bodies and kills beneficial soil organisms with severe economic and environmental implications.

A matter of considerable economic and environmental significance is that the 'cost of food production' by vermiculture will be significantly low by more than 60-70% as compared to chemical fertilizers and the food produced will be a 'safe chemical-free food' for the society. It is a 'win-win' situation for both producers (farmers) and the consumers (feeders). The cost of production of vermicompost is simply insignificant as compared to chemical fertilizers. While the former is produced from 'human waste'-a raw material which is in plenty all over the world, the latter is obtained from 'petroleum products' which is a vanishing resource on earth. Vermicompost can be produced 'on-farm' at low-cost by simple devices, while the chemical fertilizers are high-tech & high-cost products made in factories (Munroe, 2007). As vermicompost also helps the crops to attain maturity and reproduce faster, it shortens the 'harvesting time' (Sinha, et al., 2009). This further cuts on the cost of production and also adds to the economy of farmers as they can grow more crops every year in the same farm plot.

Vermicompost Application Reduces Use of Chemical Pesticides and Cost

Continued application of chemical pesticides induced 'biological resistance' in crop pests and diseases and logrithamatically much higher doses are now required to eradicate them. There has been considerable evidence in recent years regarding the ability of vermicompost to protect plants against various pests

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and diseases either by suppressing or repelling them or by 'inducing biological resistance' in plants to fight them or by killing them through pesticidal action (Suhane, 2007).

Vermicompost Application Reduces Use of Water for Irrigation and Cost

Studies indicate that vermicompost is able to retain more soil moisture thus reducing the demand of water for irrigation by nearly 30-40%. (Sinha et al., 2009, Suhane, 2007; Suhane, Sinha, & Singh, 2008).

Better Growth and Higher Yield With Lower Amount of Vermicompost

Studies indicate that smaller amounts of vermicompost in fact promote better growth performances of crops. Subler, Clive, & Metzger, (1998) reported that in all growth trials the best growth responses were exhibited when the vermicompost constituted a relatively small proportion (10%-20%) of the total volume of the container medium. Valani, (2009) found that 200 gm of vermicompost applied in pot soils performed better growth in wheat crops than those with 400 gm & 500 gm of vermicompost. Singh, (1993) found that in the farm plots where vermicompost was applied in the 2nd, 3rd and 4th successive years, the growth & yield of wheat crops increased gradually over the years at the same rate of application of vermicompost i.e. at the rate of 20 Q/ha. In the 4th successive year the yield was 38.8 Q/ha which was very close to the yield (40.1 Q/ha) where vermicompost was applied at the rate of 25 Q/ha use of vermicompost in farm soil eventually leads to increase in the number of earthworm population in the farmland over a period of time as the baby worms grow out from their cocoons. It infers that slowly over the years, the earthworms build up the soil's physico-chemical and biological properties, the amount of vermicompost can be slowly reduced while maintaining the same yield. The yield per hectare may also increase further as the soil's natural fertility is restored and strengthened. In a study in Australia, Webster, (2005) found that vermicompost increased yield of 'cherries' for three years after 'single application'. Yield was much higher when the vermicompost was covered by 'mulch'. At the first harvest, trees with 5 and 20 mm vermicompost plus mulch yielded cherries of the value of $ 63.92 and $ 70.42 respectively. After three harvests, yield per tree were $ 110.73 and $ 142.21 respectively for the 5 mm and 20 mm vermicompost with mulch.

With vermicompost alone (without mulch), trees yielded cherries of $ 36.46 per tree with 20 mm vermicompost in the first harvest and after three harvest $ 40.48 per tree. Webster, (2005) also studied the agronomic impacts of compost in vineyards and found that the treated vines produced 23% more grapes due to 18% increase in number of bunch of grapes. The yield in grapes was worth additional $ 3,400/ha.

Chemical Fertilizers Are Needed to Maintain Growth and Yield

On the contrary, in chemical agriculture, the amount of chemicals used per hectare has been steadily increasing over the years to maintain the yield constant as the soil became 'addict'. Nearly 3- 4 times of agro-chemicals are now being used per hectare what was used in the 1960s. And the cost of chemical fertilizers has also been steadily increasing since then. There is also significant loss of chemical fertilizer from the farm soil due to oxidation in sunlight. Suhane, (2007) calculated that upon application of 100 kg urea (N) in farm soil, 40-50 kg gets oxidised and escapes as 'ammonia' (NH_3) into the atmosphere, about 20-25 kg leaches underground which pollutes groundwater, while only 20-25 kg is available to be used up by the plants.

COMMERCIAL VERMICULTURE

Vermiculture is a growing and developing industry not only for managing waste and land very economically but also for promoting 'sustainable agriculture' by enhancing crop productivity both in quantity & quality at significantly low economic cost than the costly agrochemicals (Bogdanov, 1996). Earthworms not only converts 'waste' into 'wealth' it itself becomes a valuable asset as worm biomass. Large-scale production of nutrient rich 'vermicompost' (especially from the municipal solid wastes) with potential to replace chemical fertilizers and protein rich 'earthworms' can be a good business opportunity today with awareness growing about use of these products in agriculture and other allied industries (GEORG, 2004). MSW is growing in huge quantities in every country with growing population and there will be no dearth of raw materials for production of vermicompost. Vermiculture have also enhanced the lives of poor in India and have generated self-employment opportunities for the unemployed. It has become good source of livelihood for many. In several Indian villages NGO's are freely distributing cement tanks and 1000 worms and encouraging men & women to collect waste from villages and farmers, vermicompost them and sell both worms and vermicompost to the farmers. People are earning from Rupees 5 to 6 lakhs (Approx. $ 15-20 thousands) every year from sale of both worms and their vermicompost to the farmers. Mostly they use farm waste and also municipal solid wastes (MSW) collected from streets and waste dumpsites. It is estimated that one ton of earthworm biomass on an average contain approximately one million worms (Anonymous, 1980). One million worms doubling every two months can become 64 million worms at the end of the year. Considering that each adult worm (particularly *E. fetida*) consume waste organics equivalent to its own body weight everyday, 64 million worms (weighing 64 tons) would consume 64 tons of waste everyday and produce 30-32 tons of vermicompost per day at 40-50% conversion rate (Visvanathan, Trankler, Joseph, & Nagendran, 2005). In any vermiculture practice, earthworms biomass comes as a valuable by-product and they are good source of nutritive 'worm meal'. They are rich in proteins (65%) with 70-80% high quality essential amino acids 'lysine' and 'methionine' and are being used as feed material to promote 'fishery', 'dairy' and 'poultry' industry. They are also finding new use as a source of 'collagen' in the manufacture of pharmaceuticals and in the making of 'antibiotics' from the ceolomic fluid as it has anti-pathogenic properties.

Nonetheless, the importance of local (native) species should not be ignored and due attention to them must be given. Kale et al., (1982) tried South Indian variety, Oriental worm, *Perionyx excavatus* for composting of animal wastes under laboratory conditions. Similarly *Perionyx sansibarious* in Kerala and *P. pallus* in Maharastra have been tested for organic waste degradation and they were found to be highly satisfactory. Agrawal, (2009) has also shown that the local variety, *Perionyx cressiseptatus* can be employed for vermicomposting, particularly of high moisture content waste. Kale and Bano (1988) recommended a mixed culture of exotic worms with local species. Many species of epigeic earthworms were tested for mass cultivation over different parts of the world, including the tropical and temperate regions. According to (Kale, 1993) three earthworm species, *Eisenia foetida, Edurilus eugeniae* and *Perionyx excavatus* come in the order of preference for their ability to degrade the wastes. They are very efficient and adaptable in cultures under semi natural conditions in India.

CONCLUSION

Although vermicomposting is being engineered into a novel and green technology, earthworms have been used routinely for the treatment and transformation of waste products for at least 100 years so far. The waste industry which is based on the exploitation of earthworms in now properly controlled and engineered systems also depends on the metabolic activities of earthworms which degrade the organic matter in vermicompost. Anthropogenic activities have caused widespread pollution of the natural environment. vermicomposting has grown into a green, attractive, highly beneficial and promising alternative to traditional physico-chemical techniques for the different types of wastes, as it can be more cost-effective and it can selectively degrade the wastes without damaging the site or its indigenous flora and fauna. However, vermicomposting technologies have had limited applications due to the constraints imposed by substrate and variability in environmental condition, and the limited biodegradative potential and viability of naturally occurring earthworms.

This review was not intended to address the much voluminous literature on vermicomposting, but rather to revisit the basic of vermicomposting and demonstrate that the application of vermicomposting in the fields of waste management. The application of diverse vermicomposting technologies must be based on sound and reliable scientific data obtained in both fundamental as well as research environmental laboratories. For the development of vermicomposting processes to succeed at commercial scale, it is necessary to link different disciplines such as microbial ecology, biochemistry and microbial physiology, organic farming together with biochemical and bioprocess engineering. In short, the key to successful vermicomposting resides in continuing to develop the scientific and engineering work that provides the real bases for both the vermicomposting and its evaluation; and simultaneously in explaining and justifying the valid reasons which allow scientists and engineers to actually use these technologies for the welfare and safety of a public which is more and more concerned about the environment and its protection.

ACKNOWLEDGMENT

The authors would like to acknowledge the support of the ITM University Gwalior and Jiwaji University, Gwalior for providing library and internet facilities throughout the study.

KEY TERMS AND DEFINITIONS

Anthropogenic: The term anthropogenic used by Russian geologist Alexey Pavlov denotes the influence of human beings on the environment However, the term was used in English by British ecologist Arthur Tansley in reference to human influences on climax plant communities.

Ecophysiology: The branch of physiology that deals with the physiological processes of organisms in relation to environment.

Garbage: All easily decomposable and putrefying organic (animal and vegetable) waste from preparation, handling, storage, and sale or serving of food refuse other than industrial-waste and effluents.

Organic Farming: Organic farming is a form of agriculture that relies on techniques such as crop rotation, green manure, compost, and biological pest control.

Vermiculite: Vermiculite is a hydrous, silicate mineral that is classified as a phyllosilicate and that expands greatly when heated. Exfoliation occurs when the mineral is heated sufficiently, and the effect is routinely produced in commercial furnaces. Vermiculite is formed by weathering or hydrothermal alteration of biotite or phlogopite.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Vermitea: Worm tea, usually referred to as vermicompost tea, or VCT, is a type of compost tea that is made by soaking vermicompost in oxygenated, de-chlorinated water. Worm leachate is the excess water that drips through the worm bin and picks up undigested material.

Vermiwash: Vermiwash is a liquid that is collected after the passage of water through a column of worm action and is very useful as a foliar spray. It is a collection of excretory products and mucus secretion of earthworms along with micronutrients from the soil organic molecules.

Waste: Waste and wastes implies unwanted or unusable materials. The term is often subjective (because waste to one person is not necessarily waste to another) and sometimes objectively inaccurate (for example, to send scrap metals to a landfill is to inaccurately classify them as waste, because they are recyclable.

Chapter 32
Making Agricultural Learning Accessible:
Examining Gender in the Use of Animations via Mobile Phones

ABSTRACT

Worldwide women play an important role in agriculture but they still are marginalized in extension education programs. Traditionally, male-dominated extension services may contribute to gender bias in terms of access to information, participation, implementation and innovation. Limitations women face in accessing extension programs are related to social and cultural constructions. Recently, mobile phone technology has facilitated the work of extension agents and has provided participants new resources to improve their yields; nevertheless, farmer productivity in Mozambique varies between genders. This paper illustrates how agricultural messages designed as animations, and delivered via smartphones result in learning for farmers better than traditional extension presentations. This chapter focuses on the creation of educational materials by Scientific Animations Without Borders (SAWBO), and then illuminates the gaps and solutions related to gender agricultural learning. Lastly, a case study of Mozambican gender agricultural learning using animations is presented.

BACKGROUND

The International Telecommunications Union (ITU) estimates Africa leads the world in the growth of mobile subscribers with a growth rate of over 40%, which is twice as high as the global average (ITU, 2015). Mobile phones have impacted various aspects of progress in developing countries; mobile phones allow people to communicate with others, access information, make decisions about buying and selling, and improve learning for those in rural areas. Sanya (2013) in her study of Kenyan rural women discovered that mobile phones empower women and democratize technology. Yet in most cases simply introducing mobile phones does not reduce the digital gap between men and women. This chapter focuses on one specific experiment designed to test whether rural Mozambican women could learn effectively using animations provided via smartphones.

This chapter is important because it attempts to discuss the following issues that face Mozambican agricultural learning: First, in the African agricultural sector there is a shortage of extension agents supporting local farmers linked to the Structural Adjustment Programs of the 1980s. Davis (2008; 2009) observed that only 13% of farmers in Mozambique were reached by extension agents in 1980. The Mozambican Ministry of Agriculture and Food Security (MASA, 2015) confirms that only 8.3% of farmers were reached by extension agents in 2014.

Mobile phones may provide option for reaching more farmers to increase these numbers. In agriculture learning, mobile phones and other new portable devices can provide a solution linking farmers to extension agents and providing other forms of support because mobile technologies are accessible in rural areas, can upload and store both audio and video materials asynchronously when farmers wish, and allow multiple plays in sharing agricultural information. Because of these advantages, mobile phones offer exciting delivery options. Mobile phones may particularly support women in agriculture who are more constrained than their male counterparts from attending trainings, meetings and other activities that involve agriculture learning.

Second, in addition to the shortage of extension agents, there is limited research on the specific extension needs of women farmers (FAO, 2006). Research shows female extension agents as central in reducing problems for female farmers in accessing agricultural extension services (Kondylis, Mueller, Sheriff & Zhu, 2015). Specifically, Kondylis and colleagues explore the impact a female messenger has in dissemination of information and whether this effect accrues to female farmers. Their results demonstrated how adding a female messenger addresses a gender bias in dissemination of sustainable land management (SLM) techniques in Mozambique. The reasons for this were listed as:

1. Increases in access to female farmers results through increases in the supply of extension services;
2. Inclusion of female messengers to the already existing male ones improves outreach farmers;
3. Adding female instructors encourages women to seek advice;
4. Female messengers help provide more relevant information to female farming practices; and
5. In male-headed households female messengers reinforce practices learned by female farmers from their husbands.

Third, the needs of women farmers are not yet fully understood (Trauger, Sachs, Barbercheck, Kiernan, Brasier & Findeis, 2008). Trauger, et al., found that women farmers require specialized kinds of knowledge and information within certain context and through certain means of communication. Additionally, extension models rely on teaching models where farmers' participation is limited. Instead the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

roles of creation of knowledge and experience sharing are still controlled by extension agents and may not include female perspectives. Scholars have long suggested the need to shift extension approaches towards including farmers' experiences and local knowledge (Kloppenburg 1991, Flora, 1992 and Lockie, 2006).

Fourth, patriarchal systems that privilege men also affect women as follows: Poor rural women farmers have other obligations, such as childcare, which may hinder their participation in trainings. In some parts of Mozambique women are not allowed to interact with men outside their culture, thus inhibiting their participation in the training (Bowen, 1989: Gallina & Chidiamassaba,2010). Also, patriarchy hinders women's access to land and thus relegates them to subsistence farming. Due to this method of farming female farmers are less likely to benefit from male dominated cash crops, agricultural learning, and training opportunities which may be the focus of extension service trainings.

SCIENTIFIC ANIMATIONS WITHOUT BORDERS (SAWBO)

Founded in 2011, Scientific Animations Without Borders (SAWBO) is a program with a mission of creating educational materials in the form of animations for low literacy learners in local languages. So far, SAWBO has more than 35 videos in more than 90 different languages. These videos span the sectors of agriculture, health, and empowerment for women. These videos can be accessed from a variety of SAWBO channels and used on mobile phones, tablets, televisions and overhead projectors. The program relies on volunteers from all over the world to translate, record, voice overlay, share, deploy and train others. SAWBO values indigenous knowledge with a goal of giving voice to the most impoverished communities, capturing their local knowledge and languages and sharing it globally. SAWBO has already established research on the impact of indigenous knowledge (Bello-Bravo & B. Pittendrigh; 2012).

SAWBO uses learner-centered, interactive ways of teaching which allow learners to draw on prior knowledge and bring the fore what they know in interacting with the presented content. Borrowing from adult learning theory, these video animations provide literacies to marginalized communities and empower community members by imparting knowledge and skills as well as raising awareness with the goal of transforming communities. SAWBO's approach is aligned with other similar initiatives and draws from established practices for serving these communities. For example, Van Mele (2011) found that 77% of organizations training rural farmers in the Democratic Republic of Congo are now using video as a part of their training.

SAWBO animation videos are developed for low literate learners. The short length of the videos allows for quick downloads of simple, concise otherwise complicated information, culturally appropriate visuals, and narration in local languages. The videos allow for diverse groups to use mobile phones without time and space limits.

Limitations include access to Wi-Fi, affordability and the cost of maintaining the mobile phone in addition to access to electricity for charging. In addition, techniques shown in the video animations may require new skills and need demonstrations supported by a facilitator. Follow-ups with end-users also may represent a challenge. Lastly, the content requires scientific peer reviewing, which is time consuming.

There are numerous models of agricultural learning based on the use of mobile devices. Trauger, Sachs, Barbercheck, Kiernan, Brasier and Findeis (2008) discussed these models as follows: First, the technology transfer model, which is based on persuasion by agricultural extension educators, faculty, or other agricultural professionals, delivers specific recommendations to farmers about the practices or technologies they should adopt. Secondly, the advisory approach is common in projects managed by

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

donor agencies and non-governmental organizations which use participatory approaches to promote predetermined packages of technology. A third model, the human resource development model, continues to be employed in the agricultural extension activities of land-grant universities in the United States. In this model, top-down teaching methods are used, but learners are expected to make their own decisions about how to use the knowledge they acquire.

The SAWBO animated videos model borrows from the second category and includes participatory methods for extension education based on adult learning principles that specifically take into account gender characteristics and needs of women farmers. The social reality of rural based women farmers is culturally constructed, and therefore, their knowledge about farming reflects this. Furthermore, Hassanein (1997) identified how the gendered social location of women farmers influences their information exchange and produces local knowledge that is easily transmitted and translated to other farmers, who were then able to adopt it for their own purposes.

ADULT LEARNING THEORY

Central to the description of this initiative is the theory of andragogy. Malcolm Knowles' definition of the theory of andragogy (1980) describes adult learning and provides a set of guidelines for practice. The main features of the theory are self-concept including self-directedness, focus on experiential learning, reliance on past experiences, readiness to learn, and an emphasis on problem-solving. Based on humanistic psychology, Knowles' concept of andragogy presents the individual learner as one who is autonomous, free, and growth-oriented.

The two dimensions of andragogy as elaborated by Knowles are its assumptions about the characteristics of adult learners and the process elements of adult education stemming from these characteristics. He initially described four basic assumptions and added a fifth and sixth in later publications as follows:

1. **Self-Concept:** As people mature, they move from having a dependent personality toward being more self-directed.
2. **Experience:** As people mature, they amass a growing set of experiences that provide a fertile resource for learning.
3. **Readiness to Learn:** As people mature, they are more interested in learning subjects that have immediate relevance to their jobs or personal lives
4. **Orientation to Learning:** As people mature, their time perspective changes from gathering knowledge for future use to immediate application of knowledge. As such, adult learners become more problem-centered rather than subject-centered (Knowles, 1980).
5. **Motivation to Learn:** As people mature, they become more motivated by various internal incentives, such as need for self-esteem, curiosity, desire to achieve, and satisfaction of accomplishment.
6. **Relevance:** As people mature, they need to know why they need to learn something (Knowles, 1984).

Knowles intended to separate the principles he defined for adults from those used in pedagogy – the teaching of children. In his book, *The Modern Practice of Adult Education: From Pedagogy to Andragogy*, Knowles (1980, p. 43) contrasts andragogy "the art and science of helping adults learn" with pedagogy,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

"the art and science of helping children learn". He contends that adults will learn faster if what they are studying has an immediate effect on their current situation in life. Figure 1 illustrates Knowles' adult learning theory.

The application of Knowles' theory in the SAWBO videos relies on the positioning of the adult learner as self-directed with a focus on relevant and experiential learning based on established prior knowledge and a predilection to solve problems. To this end, the videos focus on establishing the learners' prior knowledge and provide highly relevant information with a basis in directing the learners' involvement in experiential learning.

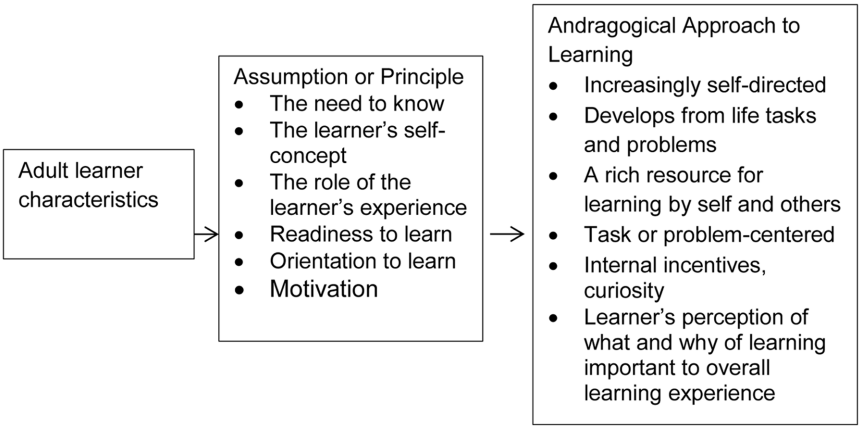
AGRICULTURAL LEARNING IN THE ERA OF MOBILE LEARNING

Recently, new participatory approaches in the context of agriculture have been facilitated with technology. Information and Communication Technology for Development (ICT4D) has been used to meet new needs in different contexts. Information and communication technologies for development (ICT4D) refers to using information and communication technologies to address social, economic, and political issues and promote social, economic and political development. The movement has an emphasis on helping poor and marginalized people and communities.

Mobile learning represents a new approach for extension agents and educators to encourage informal learning in rural areas. In addition to supporting learning, mobile phone usage can bring awareness of information and can allow for educators to respond directly to the demands and the needs of farmers in rural areas. In this way, mobile phones are a prime method for involving communities in the ideals espoused by ICT4D.

The availability and affordability of mobile phones for farmers in developing countries have led to a new paradigm in agricultural education known as mobile learning (Muyinda, 2007). The use of mobile phones has gone beyond traditional communication; farmers can use their mobile phones to check prices, to send money, to access videos, and to receive or send messages or receive information that it is relevant for them.

Figure 1. Model of Knowles's learning theory



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Advanced Distributed Learning (2013) defined mobile learning as "leveraging ubiquitous mobile technology for the adoption or augmentation of knowledge, behaviors, or skills through education, training, or performance support while the mobility of the learner may be independent of time, location, and space" (Advanced Distributed Learning, 2013, p.5). Pedagogically, the m-learning framework developed by Kearney, Schuch, Burden, and Aubusson (2012) identified three major affordances or capabilities of mobile devices for learning within sub-domains of activity: personalization (learner agency and customization), authenticity (contextual and situated relevance), and collaboration (conversation and data sharing).

Agriculture learning is germane to mobile informal learning. Proponents of informal learning, Watkins and Marsick (2001), explained that informal learning goes hand-in-hand with doing. Informal learning is not highly structured; it may be planned or not planned, but it is generally directed by the learner. Another characteristic of informal learning is that the learning process can unfold as opportunities arise allowing a serendipitous approach (Marsick & Volpe, 1999).

Mobile learning lends itself well with the serendipitous nature of informal learning because the mobile phone allows for information seeking and sharing in whatever context or setting the learner is in (Bell, 2015; Pachler, Bachmaire, & Cook, 2010; Sharples, Taylor, & Vavoula, 2007). The most significant outcome of m-learning is knowledge recall followed by learning satisfaction wherein learners report they enjoyed the experience. Technology acceptance or task performance was the next most frequently assessed outcome. Some of the benefits of mobile technologies include a natural ubiquity that supports situated learning and therefore gives users access and possibilities to share information, support, feedback and reinforcement (Naismith et al, 2004).

AFRICAN WOMEN AND TECHNOLOGY

On February 29th 2016, at the Mobile World Summit in Barcelona, the United Nations Secretary-General Adviser stated that:

The digital divide remains a yawning gulf that leaves the poor, those living in rural areas and a disproportionate number of women stranded on the wrong side. Mobiles do not merely contribute to development – they are an important dimension of development. (United Nations, 2016)

African women have long been active in using older communication technologies, such as the radio, to address their rights and inform their work in agriculture learning. Yet, the advent of Information and Communication Technology (ICTs) options has not fully reached this population leaving a gap between rich and poor countries as well as between rich and poor citizens, and particularly a gap between genders. This gap is often referred to as the digital divide. In order to fill this gap, programs have emerged with a focus on supporting populations disadvantaged by this divide. To involve women and bridge the digital gender divide means engaging in the construction of content with women's needs in mind as well as promoting, accessing, and participating in selecting technologies meaningful to women.

Recent proliferation of communication technologies has transformed communication and transformed how people learn. Current research on technology, especially mobile device usage in Africa, uses the modernization and 'leapfrogging' paradigm (Chiumbu, 2012; Sanya, 2013). The term "leapfrogging" was originally used to describe a phenomenon in economic development where technology was used

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to bypass some of the accumulated and enculturated processes that may perpetuate disparities between industrialized and developing countries.

Chiumbu (2008) wrote that the arrival of the digital era provides great opportunities for developing countries in accessing information and knowledge. The authors of this chapter agree with Chiumbu's assertion but posit that marginalized communities or groups should not be 'add ons' as this shift takes place. As opportunities for inclusion emerge, other considerations have to be kept in mind to center these populations as part of the conversation and not as an afterthought. For example, if women are to become users and producers of technologies, then previous existing problems resulting from gender inequity should be considered and surmounted, such as the lack of access to extension agriculture education due to time, distance and lack of female extension workers.

SAWBO AND MOBILE LEARNING EXPERIENCES

Globally, government-funded extension programs have often been the officially designated agencies for the transference and dissemination of information associated with agricultural production. They represent the local and country-wide source for the implementation of agricultural technologies in developing countries. However, there is an emerging potential for new partners to participate in the extension process and for global partners to be connected to local, in the field, partners in order to create and disseminate content. In today's global context, new opportunities exist to bring organizations, along with and/or beyond agricultural extension agencies, into these aforementioned roles (Cho & Bolan, 2002).

The old, highly structured, linear model of knowledge transfer (scientists → extension → users) is outdated and has the potential to be replaced by more interactive models based on networked systems, where such systems integrate producers of knowledge, adaptations to content, advice through diverse mechanisms, and the final educational product that may inform other components of this process (Murphy, 2012). Such models include a feedback loop from the end users via intermediary groups such as non-governmental organizations (NGOs), farmers associations and cooperatives to guide the development of new content. Additionally, as part of this feedback loop, expert knowledge can now be obtained through virtual Internet-based interactions and, in some cases, through crowdsourced feedback to improve on educational content being produced.

A significant number of development projects use live-action or animated videos, or both, as a component of their training programs and as supporting materials for their educational training (Bello-Bravo & Baoua, 2012; Bello-Bravo, Olana, Enyadne, & Pittendrigh, 2013; Bello-Bravo & Pittendrigh, 2012; Gandhi, Veeraghavan, Toyama, & Ramprasad, 2007; Ladeira & Cutrell, 2010; Medhi, Cutrell, & Toyama, 2012). Van Mele et al. (2010) found that approximately 78% of development organizations (e.g., universities, research institutes, and NGOs) use videos in their farmer-focused training programs.

Video-based educational content has multiple advantages, especially for agriculture training in developing countries (Van Mele, 2011). These videos can be shown almost anywhere at anytime and when as well as where the proper audio and visual equipment is in place (Coldevin,2003).

The continual increase in use of video capable cell phones, even in remote areas in developing nation countries, may ultimately result within the next decade in an almost ubiquitous access to a form of audio-visual viewing equipment. Even if target audiences do not own phones, an educator's phone can become a *de facto* portable video-viewing device for target audiences.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Visually based educational content has been shown to be an effective learning tool. Medhi, Prasad and Toyama (2007) demonstrated that live-action videos and static hand-drawn images were accurately understood by low-literate audiences. Further, Ladeira and Cutrell (2010) observed that participants were motivated to pay attention to live-action video resulting in enhanced learning. Videos have the capacity to explain complicated concepts as well as raise awareness and influence people's decisions (Lie & Mandler, 2009). Thus, there are precedents for combining visual and audio approaches for content development for educational programs.

Cognitive learning, as per information processing theory, involves the following: receiving, constructing, transforming, remembering, and storing information. Using visual and audio approaches, learners can connect existing knowledge with external stimulus in long-term memory. Live-action videos allow for easy local input into the content of the video. However, it is not practical when including cost- and time-effective feedback from global experts on any given topic. Additionally, unlike live action filming, animations can be created and adapted in a more culturally neutral manner.

Although there has been a rapid increase in the potential to view video-based educational content, there exist significant challenges as to how to systematically and cost effectively transfer knowledge from global experts to low literate learners in developing nation countries. With between 800 million and a billion low-literate learners globally, and very limited resources for creation of education materials for these groups, low-cost high throughput systems for creation and sharing of content for this incredibly diverse segment of the human population are needed.

Many low-literate learners live in rural areas, speak local language(s), and have extremely limited access to life improving knowledge. At the same time there is a considerable amount of explicit expert knowledge that exists in the global research and educational communities that does not make its way into educational material and language variants that would be appropriate for these low-literate learners. Experts in a given technique may be willing to contribute a small amount of their time to help create content that can be used by large numbers of people. However, a significant number of these people may not be in a position to disrupt their current life patterns in order to disseminate their knowledge more broadly. Conversely, educators of low-literate learners including, but not limited to, individuals, NGOs, government or inter-government organizations, may not have easy access to content for educational programs involving low-literate learners as the final target populations.

Scientific Animations Without Borders (SAWBO) has developed a methodology, described here, to achieve the goal of direct creation, with global expert knowledge, of educational content that can be placed into numerous languages and deployed directly to educators of low-literate learners, and in some cases directly to diverse language speakers across the globe, in a highly cost-effective and efficient manner. The process begins with (1) defining the topic area, (2) establishing contact with global experts through online searches and crowdsourcing, and (3) clearly defining and strictly adhering to a hyper-collaborator strategy with those global experts for the creation of accurate content, which involves goals, responsibilities, outcomes and attribution. Content is created with experts often working virtually with SAWBO. The SAWBO team produces the scripts, storyboards and final animations, with continual input from global experts, and the project is only complete once the expert and SAWBO team agree on the accuracy of all aspects of the content. Once released in English, a similar process is followed with language experts from around the globe to place content into a great diversity of languages. All animations are free and for educational purposes only. The goal of the methodology is to develop a standardized system to:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Work with global experts to create accurate content where small amounts of time (hours) from these experts is used and in a manner that is non-disruptive to their life-style or work life;
2. Obtain this expert knowledge as a volunteer activity;
3. Create content in a virtual manner, through online interactions, thereby minimizing production costs;
4. Create finalized content appropriate for low-literate learners that is both scientifically accurate, as culturally neutral as possible, and acceptable to low-literate learners;
5. Place finalized content into a great diversity of languages;
6. Make that content easily accessible to educators of low-literate learners; and
7. Where possible leave that content with the low-literate learners for their future reference or use.

The SAWBO systems approach entails the following:

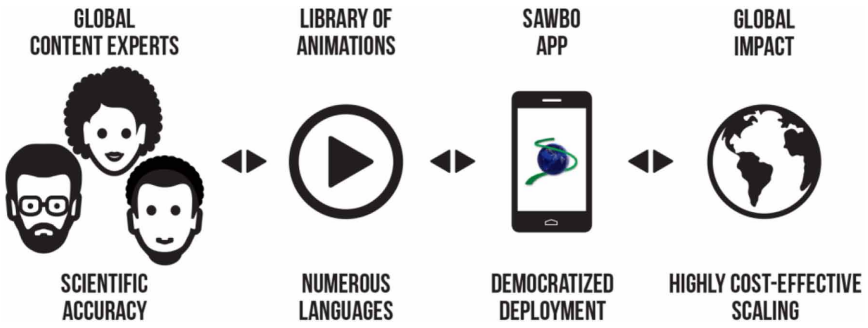
1. Continually create educational content with experts on diverse topics;
2. Place content into diverse local languages; and
3. Make it accessible to educators who can deploy such content in their communities as part of their own educational programs.

The material is defined by the funders after doing a feasibility study or when there is an urgent need, such as in the case of Ebola and Zika. While this model is prevalent, at other times the end-user approaches the SAWBO team to request an animation based on the needs of their community. NGOs also work collaboratively with SAWBO to create educational materials that are important for their mission. This approach allows organizations of any size, from small community-based organizations to large government and international organizations, to have access to education content in local languages that is scientifically accurate and accessible at no cost to these groups. Figure 2 illustrates this approach.

THE CASE OF MOZAMBICAN FARMERS LEARNING USING ANIMATIONS

Mozambique has a population of about 25 million people with approximately 18.4 million who own mobile cellular phones yielding a subscription of 75 per 100 inhabitants (The Central Intelligence

Figure 2. SAWBO systems approach



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Agency, 2016). According to The Central Intelligence Agency (2016), agriculture is the mainstay of Mozambique's economy and contributes to more than one quarter of the Gross Domestic Product (GDP) while employing 80% of the labor force consisting primarily of subsistence farmers. Regarding farming activities, 99.65% of farmers are smallholders with an average of 1.2 hectares (ha), 0.33% are medium sized farmers with 6.6 ha and 0.07% are large farmers with an average 282 ha (Mole, 2006). Small scale farmers grow food for their own consumption, especially grain and beans and/or peanuts. Approximately 400,000 commercial farmers earn their income from crop sales, and their yields per sector are double those of subsistence farmers.

Productivity levels are low because of a lack of modernization; after 30 years of independence, most peasant farms have not changed. Coughlin (2006) recognizes that only 3% of rural households have access to credit, less than 5% are part of a farmer association, and extension services reach only 13% of households. According to Walker et.al, (2015) the "Mozambique Agriculture Value Chain Analysis" reported that in Mozambique and due to the reduction in funding, farmer's access to public sector extension services declined from 13.5 percent in 2002 to 8.3 percent in 2014. For common beans producers Walker et al, (2015) recognized that about 15 to 20 percent receive extension service.

Rural men and women are said to allocate roughly equal amounts of time to crop production. Women spend more time fetching water, and men allocate more time to livestock production. Women also engage in other activities such as food processing, cooking, cleaning, other housekeeping, collection of firewood, and childcare leading to longer working hours and less participation in extension. Additionally, women are relegated to food crops production while both men and women are involved in the production activities for cash crops.

A World Bank study done in 2005 concludes that access to rural extension services increases farm production by about 8.4% in rural areas. Extension services have been very successful in promoting natural pesticides and improvement of soil conservation (World Bank, 2006). The number of government extension workers is around 7000 on the ground. In 2004, about 260 private extension agents worked for the cotton and tobacco companies, and 1300 worked for International and Governmental Organizations (INGOs), although many were organizing farmers' groups rather than doing agricultural extension.

Flaherty and Nhamusso (2014) noted that public spending on research and development in Mozambique has increased by 14% from 2008 to 2011. This increase is due to higher salaries and capital investment. At the same time the number of agricultural researchers has also been augmented. Agricultural research and development in Mozambique depends on ever-diminishing donor funding. Mozambique has created new policies, strategies, and initiatives to fortify its national research and technological innovation system. A recent policy development brings together international organizations and research centers. One outcome of this collaboration is the expansion of the national research, academic organizations, extension agencies and producers.

This case study is a summary of research conducted in Zambêzia Province, Mozambique by a team from two American-based universities. (Mocumbe, Abbott, Mazur, Bello-Bravo & Pittendrigh; 2016). The study was part of a multidisciplinary research project funded by USAID's Feed the Future initiative (Mazur et al. 2013). The project team plans to use the results of this research to engage farmers and other relevant stakeholders in a participatory process of considering a set of management practices and technologies that may help improve their farming activities.

A total of 314 bean-growing farmers from two different administrative posts in rural Zambézia province, Mozambique participated in the study. Farmers were assigned randomly by groups to one of three experimental treatments:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Message via extension demonstration only;
2. Message via smartphone animation only;
3. Messages by both extension demonstration and animation.

The topic of the experiment was use of a sealed container (jerrican) to safely store beans after harvest. Previous interviews had shown that farmers suffered serious bean losses due to weevil infestations after harvest, and that few farmers knew how to store beans in air-tight containers to avoid losses. It is important to note that the rural Mozambique farmers were involved in pre-testing the storyboards for the animation, although they did not produce the animation. Notably, even though they identified post-harvest storage as a serious problem, they did not approach SAWBO and ask for the animation to be produced. The decision was made in collaboration with the *Instituto de Investigação Agrária de Moçambique* (IIAM) an agricultural research institute based in Mozambique and a research project funded by USAID's Feed the Future initiative (Mazur et al. 2013).

Results showed that the three experiment treatment groups did not differ significantly from each other in knowledge about the jerrican storage method prior to the experiment. However, women knew significantly less than men prior to the experiment. After treatment, all three experimental groups increased their knowledge of the storage method significantly. Both men and women learned significantly from the animations delivered via mobile phones. However, the rate of learning from the extension only treatment was less than the rate that included animations (Mocumbe, 2016).

Comparison of post-test scores indicated that animation only and the animation plus extension treatment showed significantly higher learning than the extension only treatment. Women's knowledge of the jerrican method was still slightly less than that of the men after the treatment, but not significantly. Women, who knew significantly less than men at the beginning, were able to learn as much as men from the animations and in doing so narrowed the gap in knowledge to a statistically non-significant difference. Thus, even though they started at a lower level, they learned just as much as men from the animation. Women who received the animation treatment and the animation with demonstration treatment had higher scores than women who received the extension only treatment. The same was true for men, indicating that the animation seemed to work with equal effectiveness for both groups. Finally, 98% of farmers said that they intended to use this storage method in the future. So, ultimately the animation and animation plus extension models had good results indicating viability for future dissemination.

OBSERVATIONS

Data from these observations support the findings shared as a result of this study to explain the effects that were attained. As such, the observations served as a type of case study to deepen understanding of why and/or how the intervention treatment worked to create the impact measured in the study's quantitative data results.

Observations are not just about 'hanging out' but rather involve planning and self-awareness on the part of the observer (DeWalt & DeWalt, 2001). Observation entails the systematic noting and recording of events, behaviors, and artifacts (objects) in the social setting chosen for study. The observational record is frequently referred to as *field notes*—detailed, nonjudgmental, concrete descriptions of what has been observed. In this case study observations were made on how the farmers learned. The observations are

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

important in explaining how experience sharing and collective learning emerged and led to successful learning by these farmers.

The observations took place in Zambêzia (Mozambique) the summer of 2015 by one of the authors of this paper. There were two groups of 12 -15 farmers for each treatment, a morning and an early afternoon group. Both groups were involved in a treatment group of animation plus extension in order to assess the impact of the animation on the learners' experiences and specifically to examine how women engaged in the learning event. These groups were mixed gender, some with more men or women. Most of the participants, both men and women, had low levels of education. Men did not have more education than women.

Participants paid attention when watching the video, they were engaged. When they first watched the video they seemed to giggle at the animation. They were impressed that the video was in their local language. The first time, they seemed not to be paying attention to the content. The second time they paid more attention to the content than to the animation. Some requested to watch the video three times.

One group that watched the video three times volunteered to do the demonstration. A male and female participant got in the front of the crowd with the beans and the jerrican. They started performing what they had learned. As they did this, they interacted with the group in a playful manner. The other participants gave them suggestions as indicated in the instruction. It was a conversational activity where the whole group was engaged in the learning while the volunteers did the action. Sometimes a participant from the crowd came to check in order to confirm that the instructions had been carried out properly, for instance that the jerrican lid was sealed tightly.

During the process the women were not afraid of talking. At the beginning of the program, the women did not say much; however, during the demonstration they were involved in providing instruction. Their comments provided evidence that they knew what they were doing. On the other hand the men seemed to be more reserved than the women. It is plausible to say that this may have happened because women are more involved in the storage process than men. Figure 3 illustrates the research process.

Researchers, Mocumbe, Abbott, Mazur, Bello-Bravo and Pittendrigh (2016) indicated that the case study is not without its limitations. The gain in knowledge by these women could have been due in part to the 'novelty effect,' especially because these farmers were experiencing learning with animations for the first time. Therefore, this could have stimulated effective learning. Secondly, the women in the study generally do not attend extension service sessions as men do, and therefore their inclusion along with the 'novelty effect' might have positively influenced their learning.

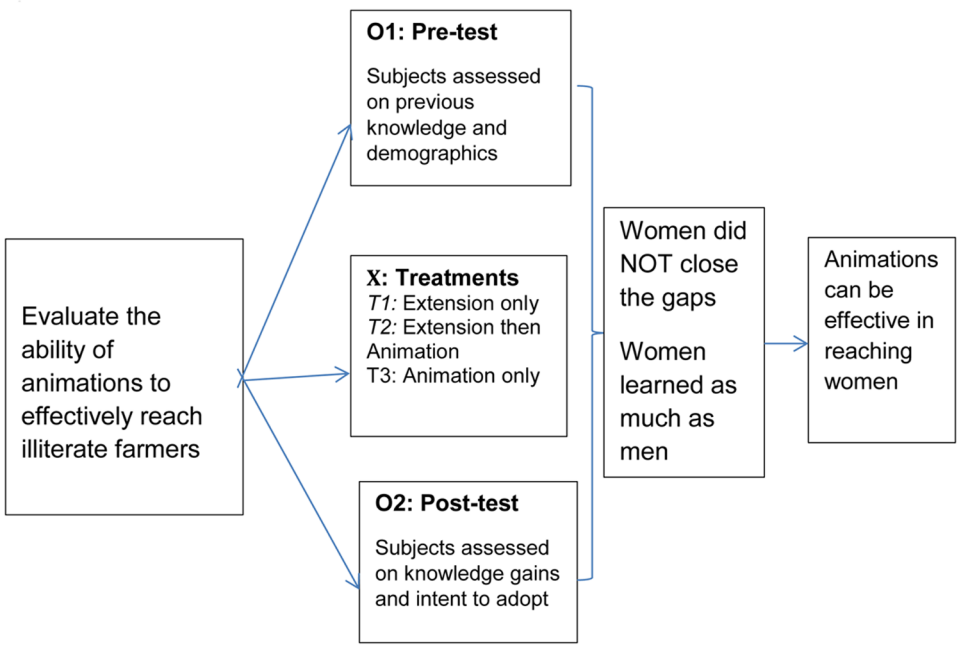
A limitation to the case study that should be noted is the size of the participant group. The training procedure focused on smaller groups of farmers; whereas typically extension training groups include 20-25 people. This use of small numbers within a group allowed for group learning and engagement, and the farmers were able to view the videos with limited distraction. Third, this group of farmers lived in the same community and had existing relationships that allowed them to participate and engage with each other openly. It would be interesting to find out what the results would be like if the farmers did not know each other.

SOLUTIONS AND RECOMMENDATIONS

Here, the authors of this chapter provide recommendations based on the study findings. First, the authors suggest that a central focus of agricultural learning should be women. Barriers that women face

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Illustration of the experiment



in agricultural education are based in stereotypes and social constructions based on gender identity and embodiment. Female farmers often are not visited by male extension providers because social customs do not allow communication between genders and husbands do not share the information they gain from extension visits with their wives. Additionally, agricultural learning in Mozambique may render women who actively participate in agricultural production invisible by introducing expert knowledge actors who are mostly trained males. These models position men as learners while women lose control of the technological process and the end product (Everts, 1998).

For these reasons, African rural smallholder farmers, particularly those involving women as primary players, have been generally marginalized in technical service and male dominated agricultural education. Training and employing female extension agents is thought to be one of the solutions to the seclusion of smallholder women farmers from extension services. The advent of mobile phones technology offers a direct way of connecting with the women, especially when the information is relevant and accessible to them. Additionally, providing information via animations allows for personalization for women by providing animated female actors in the role of service providers and sharers of information.

Secondly, the authors of this chapter assert that more innovative ways of agricultural learning that are culturally specific should be considered. To this end, learning could be offered in more formats than direct instruction including blended learning which combines online learning and/or resources with direct learning methods involving practical, face-to-face, problem-solving activities. Agricultural learning and extension training are good settings for teaching through these methods because the process of learning is anchored in an already formed community of farmers ready to use new acquired knowledge (Czarniawska, 1997). According to Mortera-Gutierrez (2005) blended learning includes a variety of approaches to learn through combining different delivery methods that can include technology-based

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and traditional face-to-face instructions where learning by doing, learning from experience, and learning by telling can take place.

A discussion of blended learning must take into consideration the digital divide. The digital divide is a major constraint in the use of technology in developing countries. Various local and international organizations are devising models of blended learning for agricultural learning to bridge the digital divide. For example, several centers of the Consultative Group for International Agricultural Research (CGIAR) are presently exploring approaches to address the increasing demand for learning in agriculture and natural resources management through e-learning.

Blended learning in rural agricultural setting will require flexibility and innovation. The use of animations offers an online platform that takes advantage of blended learning models and/or offers instructors using direct instruction additional resources to convey content to learners. With reference to the case study, the farmers were involved in an active dialogical process with the volunteers to confirm and elaborate on processes learned in the instructional event based on access to animations and guided demonstrations based on those animations. This event involved dialogue among all participants in the event. Greene (2001) maintains that dialogue is not just about talking, but it entails having a narrative process where people listen to each other, share experiences, and can inquire to find out meanings. Participants contribute and add other related experiences that they have while reflecting on the values and assumptions within. Dialogue, then, is characterized by respect, inclusion and engagement and is based in the blended learning environment.

FUTURE RESEARCH DIRECTIONS

Future research directions offered are three pronged:

1. Understanding various literacies that stem from mobile learning;
2. Examining the indigenization of content material for local access distributed via mobile learning; and
3. Strengthening of women's participation for intended and unintended outcomes via mobile learning platforms.

The outcomes of mobile phone learning are not entirely predictable; Sanya (2013) understood the multiple roles of the user as ranging from innovator to a creative user. To Sanya, mobile phones break down the top-down approach and allow individuals to share discuss and establish communities that are supportive. Sanya (2013) also saw the mobile phone as facilitating literacies where they were nonexistent before. As discussed earlier SAWBO has animations on health, agriculture and empowerment of women that can be accessed free of charge. Once the farmers know how to access one SAWBO animation, they can access the others and gain other knowledge.

The authors of this chapter see learning using animations as addressing two things. First, the farmer learns how to manipulate the cellphone, and second, the farmer can access additional animations. Therefore the farmers gain portable skills that they can use in other mobile related projects in the community. This dynamic exists for both male and female farmers and can be regarded as gender-neutral.

The type of literacy that the authors of this chapter see emanating from the mobile learning experience using animations is informed by discussions by Barro (2009) and Giroux (1993) of literacy as literacies;

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

that is, not only written forms which provide marginalized people with skills and knowledge that can empower them for better citizenship and participation in their communities. A significant proposal for future research is the follow-up of the farmers to not only understand how they are applying and transferring the knowledge they gained from the SAWBO resources but also scrutinizing the various forms of literacies gained from such trainings.

Second, Gakuru, Winters and Stepman (2009) recognized that information and communication technologies (ICT) provided the easiest way to disseminate information to farmers and also changed their agricultural learning. Traditional forms of ICTs are still relevant in providing advisory services. National ministries, NGOS and research organizations work together within information centers to facilitate technology transfers in the agricultural sector. E-agriculture is an emerging field that combines agricultural informatics, agricultural development and entrepreneurship through ICT and the internet. E-agriculture allows for integration of knowledge and information in order to reach various stakeholders at varying levels.

According to (Gakuru et al., 2009) there are challenges despite the widespread adoption of mobile phones. For example, farmers face issues of cost, the carrying capacity of the SMS, and the potential of the device to transmit the clarity of voice and pictorial illustration. Despite these challenges, voice solution, especially through animations, is considered to be a reliable platform for the farmers to access customized information.

Organizations such as SAWBO rely on the voice solution, specifically, voice overlay, to customize for language and therefore deliver the information in a natural and accessible manner to the farmers. We suggest that future research takes into account how farmers, especially women, are given voice and opportunities in the creation of the technologies and information. Locally informed projects have been known to have greater impact and to also gain ownership compared to impose ones (Chambers1983).

Lastly, from a gender perspective, some cultural traditions allow collective learning within cultural socializing and storytelling that is beneficial to women in agricultural learning. As noted in the case study, in Mozambique farmers were not passive consumers of information but contributors to their learning. Future research could benefit from considering unique regional and demographic factors that lead to women learning and learning more aligned with women's needs and learning preferences. Correspondingly, examining how project planning deliberately seeks to strengthen women's participation in agricultural programs and recognizing their ability to exercise leadership and collective learning is also necessary. Measures to support women in extension and agricultural learning will boost their participation in decision making and community engagement.

CONCLUSION

International development initiatives have included the use of mobile phones for training programs in developing countries. As discussed throughout this chapter, these efforts include those by SAWBO, especially because mobile phones are critical in Mozambican agricultural learning. As the authors of this paper have observed, the key rationale behind using mobile phones to provide agricultural content in local languages is situated in the opportunities that mobile learning offers to farmers in rural areas, such as individual access to animations after training sessions and collective participation in learning using local languages.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In sum, accounting for cultural variations may lead to studies within developing nations where innovative use of technology as it intersects with culture and gender can shape and inform learning to transform lives. The result may be a restoration of the balance between gender participation and an elimination of gendered inequalities in terms of access to agricultural learning and extension services perpetuated through cultural and external forms of patriarchy.

KEY TERMS AND DEFINITIONS

Agricultural Learning: Knowledge would be able to synthesize, analyze, and communicate basic information about agriculture.

Animations: Animation is a type of optical illusion; it is the process by which we see still pictures move. It involves the appearance of motion caused by displaying still images one after another at the rate of 24 pictures per second. The most common method of presenting animation is as a motion picture or video program, although several other forms of presenting animation also exist. There are 2D and 3D animations. The difference between 2D and 3D can be illustrated by drawing a rectangle and a cube. Rectangle is a 2D figure whereas cube is a 3D figure. 3D presents the object from every possible direction like in real life. 2D bitmap or vector graphics are used to create 2D animation figures.

Extension Services: The extended public education and information service operated by the government, NGOs and universities.

Gender: Refers to the attitudes, feelings, and behaviors that a given culture associates with a person's biological sex. Gender is a social construct that is different from the biological make up of a person.

Informal Learning: Learning that takes place in spaces surrounding people, activities and events. Planned and structured learning such as short courses organized in response to identified interests and needs but delivered in flexible and informal ways and in informal community settings. It can be considered as complementary to learning from everyday experience.

Learning: Learning is a change in an individual, due to the interaction of that individual, and his/her environment, which fills a need and makes him/her more capable of dealing adequately with his/her environment.

Patriarchy: Patriarchy is tethered to social and economic systems that secure women's subordination regardless of race, class, culture and ethnicity. Specifically, as an economic system of oppression, patriarchy marginalizes women from the access to property, forms of wealth accumulation, and production. As a social system, it privileges male social and economic organizing and therefore facilitates their access to roles of political leadership and enacting social mores.

SAWBO: Scientific Animations Without Borders™ (SAWBO) is a University of Illinois at Urbana Champaign based program. SAWBO transforms extension information on relevant topics such as agriculture, disease, and women's empowerment into 2D, 2.5D, and 3D animations, which are then voice overlaid into a diversity of languages from around the world.

Chapter 33
A Genetic Algorithm to Goal Programming Model for Crop Production With Interval Data Uncertainty

Bijay Baran Pal
University of Kalyani, India

Sankhajit Roy
Bidhan Chandra Krishi Viswavidyalaya, India

Mousumi Kumar
Aghorekamini Prakashchandra Mahavidyalaya, India

ABSTRACT

This chapter presents how Genetic Algorithm (GA) is effectively employed to Goal Programming (GP) formulation of an agricultural planning problem having interval model parameters and a set of chance constraints for optimal production of seasonal crops in uncertain environment. In model formulation, the planned-interval goals associated with objectives of the problem are converted into their equivalent two-objective deterministic goals. The chance constraints are also converted into their deterministic equivalents to solve the problem by using GP methodology. In goal achievement function, minimization of deviational variables associated with model goals is evaluated on the basis of priorities by employing a GA scheme to reach optimal decision. In the decision process, sensitivity analysis with variations of priority structure of goals is performed, and then the notion of Euclidean distance function is used to identify the priority structure under which optimal production of crops can be obtained in the decision environment. A case example is considered to demonstrate the approach.

INTRODUCTION

The history of human civilization shows that domestication of plants went on as far as 7800 B.C. and forest gardening for plant-based food production, world's oldest form of agriculture, was started as far back as 5200 B.C. Actually, development of agricultural production system is the root of starting human civilization. The rapid rise in human civilization due to technological innovations, significant improvements in agricultural techniques were taken place from the mid-12th century to 13th century and stayed steady until 18th century (Campbell, & Overton, 1993). However, owing to rapid rise of mechanization in the late 19th century and 20th century, farming tasks could be done with a tremendous speed and became more sustainable due to innovation of tillage tools. In reality, advancement of technology has led to enable to start the modern farming system on earth (Mazoyer, & Roudart, 2006). It is worthy to mention that crop production problem is actually a management science problem with multiplicity of objectives, where the objectives are to optimize production of crops and thereby to meet the need of agricultural products in society. The general mathematical programming (MP) model for allocation of cultivable land with regard to yielding of crops to optimal levels was first presented by Heady (1954). It may be mentioned that, although land utilization system for cultivation as well as water supply system for irrigation were improved a lot prior to middle of the last century, Green Revolution was actually taken place during 1960s due to the pioneer contributions of Nobel Laureate Norman Ernest Borlaug. The effective mathematical models were then developed to take measure for better water supply and land allocation decisions for crop production. A bibliography on the modeling of agriculture planning problems was first presented by Nix (1979). Then, study on implementation of management science models to farm planning problems were made deeply towards growth of agro-economic scenarios in the modern world.

Now, since agricultural planning problems are typically multiobjective problems in the premises of limited supply of farming resources and optimal of production of several crops to meet food products in society, goal programming (GP) method (Ignizio, 1976), that is based on satisficing philosophy (Simon, 1945), was introduced to a crop production planning problem by Wheeler, and Russell (1977). The survey on the study of agricultural planning models was further conducted by Norton, and Schiefer (1980), Glen (1987) among others.

However, in most of the cases of modeling the real-world multiobjective decision making (MODM) problems, it may be noted that decision makers (DMs) are faced with the problem of setting precise model parameters to the problems owing to inherent imprecise nature of parameters and ambiguity in human judgments. To cope with the situation, fuzzy programming (FP) (Zimmermann, 1987) approach based on the theory of fuzzy sets, initially proposed by Zadeh (1965), has been employed to farm planning problems with imprecisely defined model data by Slowinski (1986). Again, Fuzzy goal programming (FGP) (Pal, & Moitra, 2003) as an extension of FP within the framework of GP has been used to agricultural land allocation problem by Biswas and Pal (2005).

Further, in a farm planning environment, it is to be observed that some of model data, which are inherently associated with resource utilization constraints, are probabilistically uncertain (Liu, 2003) in nature. The stochastic programming (SP) (Charnes, & Cooper, 1959) method was studied (Kall, & Wallace, 1994; Sahinidis, 2004) extensively and implemented to practical problems (Bravo, & Ganzalez, 2009; Pal, Chakraborti, & Biswas, 2009). However, the use of such an approach to agricultural system is yet to be studied deeply in literature.

Again, in an uncertain environment, it may become difficulty to DMs to specifying fuzziness of model parameters as well as defining of probability distributions of them (Jiang, Han, Liu, & Liu,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2008). To overcome the situation, interval programming approach (Bitran, 1980) to MODM problems with interval parameters sets has been studied (Israel, & Robers, 1970), where an interval designates a bounded set of real numbers. Actually, seeds of interval programming could be traced in third century BC, when Archimedes (the father of mathematics) calculated the value of π (*pi*) with incorporation of certain lower and upper bounds ($223/71 < \pi < 22/7$) on it. A book on the modern interval arithmetic rules was first prepared by Moore (1966). The study on interval analysis and its crucial role to global optimization problems has also been well presented by Hansen (2003).

The GP (Ignizio, 1982) formulation of MODM problems with interval parameter sets, called interval-valued GP (IVGP), was introduced by Inuiguchi, and Kume (1991).The study on development of IVGP methodologies have been surveyed by Olivera, and Antunes (2007). The interval programming method to practical problems has also been well discussed in (Assavapokee, Realff, & Ammons, 2008; Jiang, Han, Liu, & Liu, 2008). The IVGP method to university resource planning problem has been demonstrated by Pal, Kumar, and Sen (2012). However, deep study on methodologies of interval programming along with implementation to MODM problems is yet to come widely in literature.

Again, it is to be noted that the different types of objectives involved in a decision making situation are generally incommensurable and conflicting in nature and also nonlinear characteristic are inherent to some of them in actual practice. To cope with such a situation, the conventional linearization technique (Ravindran, Ragsdell, & Reklaitis, 2007) in the framework of traditional single-objective optimization domain (Charnes, Cooper, & Ferguson, 1955) have been used to solve nonlinear MODM problems (Pal, & Moitra, 2003). But, computational load increases for use of such an approach and local optimal solution (Deb, 2002) is derived in most of the cases of practical problems.

To overcome the above difficulties, GA tools (Holland, 1973) in a paradigm of natural computing have appeared (Michalewicz, 1996) to solve MODM problems. The GAs to FGP models have been studied by Taguchi, Ida, and Gen (1998); Pal, Chakraborti, and Biswas (2009) and others. But, study on GAs as goal satisficers (Deb, 2002) is yet to be widely documented in literature. Further, use of bio-inspired computing to agricultural problems with inexact data is yet to be widely circulated in literature.

The objective of this chapter is to study a priority based extended goal programming (EGP) formulation of farm planning problem with interval data sets for production of seasonal crops with proper utilization of land and irrigable water as well as other productive resources. In the proposed approach, the objectives of utilization of total cultivable land, various farming resources and achievement of possible production of crops are described with interval data sets. The constraints on utilization of reserve water are crisply described, whereas total water utilization constraints for cultivation of seasonal crops are defined probabilistically owing to the stochastic nature of rainfall in a plan period. In the sequel of model formulation, planned-interval goals defined for interval goals are converted into standard form of goals by employing interval arithmetic rules(Moore, 1979) and introducing under- and over-deviational variables to them. Here, certain socio-economic goals in fractional form are transformed into their linear equivalents to employ linear IVGP methodology. The probabilistically defined resource utilization constraints are also converted into their deterministic equivalents to evaluate IVGP model of the problem. Then, from the optimistic point of view of DM, extended GP (EGP), which is convex combination of *minsum* GP (Ignizio, 1976) and *minmax* GP (Romero, 1991), are considered within the framework of standard EGP model to minimizing of total regret arising out of all possible deviations of planned values of goals in the decision environment. In model execution, GA scheme is employed in an iterative manner to achieve the goal levels according to priorities assigned to them. Again, sensitivity analysis is performed on the priorities of model goals to derive different possible solutions of the problem. Then,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Euclidean distance function (Yu, 1973) is used to obtain the best solution for crop production under a given priority structure of model goals of the problem.

An example of Hooghly District of West Bengal (WB) in the tropical country India is considered to illustrative the proposed method. To illustrate more the effective use of the approach, model solution is compared with solutions of EGP approach in a previous study (Inuiguchi, & Kume, 1991).

BACKGROUND

The constructive optimization models for optimal production of crops was deeply studied by Wheeler and Russell (1977), Nix (1979) and others in the past. Here, it is to be noted that irrigation water supply is a complicated issue (Molden, 2007; Chartres, & Varma, 2010) owing to its various needs in society, and it has now become a great challenge to obtain adequate irrigable water in cropping seasons in a planning period (Slowinski, Urbaniak, & Weglarz, 1983; Yeh, 1985; Slowinski, 1986). Although, water resource planning models were studied in the past, deep study in the area of irrigation water supply for farming in an uncertain environment is very thin in literature.

Now, concerning the use interval programming (Bitran, 1980) method to MODM problems, it may be mentioned that the values of model parameters are required in certain specified ranges and there is no need to know probability distributions or fuzziness of them in the domain of interest. Although, the potential use of interval programming approach has been implemented to robot path planning (Ida, 2000), portfolio selection (Ida, 2003), thermal power generation and despatch (Pal, & Kumar, 2003) and other problems, implementation of such an approach to crop production problems is yet appear widely in literature.

In this chapter, an EGP model for farming is considered, where interval data for measuring performances against crop production criteria and certain nonlinear probabilistic constraints against socio-economic objectives are taken into account in the formulated model.

Now, the general framework of IVGP problem is discussed in the following section.

CHANCE CONSTRAINED IVGP PROBLEM FORMULATION

In the field of IVGP, the objectives with interval parameters of a MODM problem are converted into interval goals by means of assigning target intervals, instead of fixed target values of achieving objectives, whereas the resource constraints and other structural constraints are considered inexact / crisp depending on the characteristics of model parameters of the problem.

The general structure of an IVGP problem having both linear and fractional objectives and a set of chance constraints can be presented as (Jiang et al., 2008):

Find $\boldsymbol{X}$ so as to:

$$\text{satisfy } Z_k : [c_k^L,\ c_k^U]\mathbf{X} + [\alpha_k^L,\ \alpha_k^U] = [t_k^L, t_k^U],\ k \in K_1 \tag{1}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\text{and } Z_k : \frac{[c_k^L, c_k^U]\,\mathbf{X} + [\mu_k^L, \mu_k^U]}{[b_k^L, b_k^U]\mathbf{X} + [\rho_k^L, \rho_k^U]} = [t_k^L, t_k^U],\ k \in K_2 \tag{2}$$

subject to,

$$\mathbf{X} \in S\{\mathbf{X} \in R^n \mid Pr[F(\mathbf{X}) \begin{pmatrix} \geq \\ \leq \end{pmatrix} b] \geq p,\ \ \mathbf{X} \geq 0\ ,\ \mathrm{b} \in \mathrm{R}^{\mathrm{m}}\}, \tag{3}$$

where Z_k represents *k-th* objective, *k=1, 2,..., K* and ***X*** designates the vector of decision variables, and where $[c_k^L, c_k^U], \forall k$, and $[b_k^L, b_k^U], k \in K_2,$ are the vectors of interval coefficients, $[t_k^L, t_k^U], \forall k$, denote target intervals. $[\alpha_k^L, \alpha_k^U], k \in K_1$, and $[\mu_k^L, \mu_k^U]$, $[\rho_k^L, \rho_k^U]$, $k \in K_2$, are constant intervals associated with the respective interval goals, where superscripts *L* and *U* indicate for lower- and upper-bounds, respectively.

It is assumed that the feasible region $S(\neq \varphi)$ is bounded, and $K_1 \cup K_2 = \{1, 2, ..., K\}$ with $K_1 \cap K_2 = \varphi$. Also, in case of the fractional goal expression in (2), $([b_k^L, b_k^U]\mathbf{X} + [\rho_k^L, \rho_k^U]) > 0$ is assumed to avoid any undefined situation and to preserve the feasibility of solution. '*Pr*' indicates probabilistic constraints, *F*(***X***) is (linear or nonlinear) function to represent constraints set, *b* is resource vector, and *p* (*0 < p <1*) is used to indicate probability levels for random model parameters. Here, if *p=1* is considered for a chance constraint, then that would be deterministic one as in the conventional case of optimization problems.

In the above formulation, the parameters with defined intervals represent the respective bounded regions within which the values they possibly take. In IVGP approach, goals in (1) and (2) are converted into planned-interval goals by expressing the objectives as planned value objectives by using interval arithmetic rules (Moore, 1979).

Now, basic operational rules in interval arithmetic are discussed as follows.

Basic Interval Arithmetic Operational Rules

Let *A* be a closed interval which is defined by an ordered pair of real numbers as

$$A = [a^L, a^U] = \{a : a^L \leq a \leq a^U;\ a \in \Re\}, \tag{4}$$

where a^L and a^U are left- and right-limits, respectively, of the real number *a* on the real line $\Re$.

Here, for a particular case, if $a^L = a^U = a$, then A = [*a, a*] represents a real number *a*.

Now, some useful arithmetic operations on interval numbers are discussed as follows:

- The midpoint *m*[*A*] and the width *w*[*A*] of an interval A can be defined as

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$m[A] = \frac{1}{2}(a^L + a^U) \text{ and } w[A] = (a^U - a^L), \text{ respectively.} \tag{5}$$

- The scalar multiplication of *A* is defined as

$$\lambda A = \begin{cases} [\lambda a^L, \lambda a^U], & \lambda \geq 0 \\ [\lambda a^U, \lambda a^L], & \lambda < 0 \end{cases} \tag{6}$$

The arithmetic operations, possible addition and possible subtraction, on intervals $A = [a^L, a^U]$ and $B = [b^L, b^U]$ are defined as

$$A(+)B = [a^L + b^L, a^U + b^U], \text{ and } A(-)B = [a^L - b^U, a^U - b^L] \tag{7}$$

- The multiplication between interval numbers is defined as

$$A.B = [min(a^L.b^L, a^L.b^U, a^U.b^L, a^U.b^U), max(a^L.b^L, a^L.b^U, a^U.b^L, a^U.b^U)] \tag{8}$$

- The variable multiplication of A is defined as

$$x[a^L, a^U] = [a^L x, a^U x], \text{ where } x \in \Re \text{ is a variable.} \tag{9}$$

If $\{A_j = [a_j^L, a_j^U],\ j = 1,2,...,n\}$ be a collection of intervals and $\{x_j(\geq 0);\ j = 1,2,...,n\}$ be a set of real variables, then the possible sum of *n* intervals is given by:

$$(\overset{n}{\underset{j=1}{+}})A_j x_j = [\sum_{j=1}^{n} a_j^L x_j, \sum_{j=1}^{n} a_j^U x_j] \tag{10}$$

Now, conversions of interval goals in (1) and (2) into planned-interval goals are discussed in the next section.

Planned-Interval Goals

The planned-interval actually signifies an interval planned for obtaining possible values of an objective, called planned values, in inexact environment.

Following operation rule on interval defined in (10), the planned-interval goals corresponding to goal expressions in (1) can be obtained as (Pal et al., 2012):

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\left[\sum_{j=1}^{n} c_{kj}^{L} x_j + \alpha_k^{L}, \sum_{j=1}^{n} c_{kj}^{U} x_j + \alpha_k^{U}\right] = \left[t_k^{L}, t_k^{U}\right],\ k \in K_1 \tag{11}$$

Again, the fractional interval goal expression in (2) takes the form:

$$\frac{\left[\sum_{j=1}^{n} c_{kj}^{L} x_j + \mu_k^{L}, \sum_{j=1}^{n} c_{kj}^{U} x_j + \mu_k^{U}\right]}{\left[\sum_{j=1}^{n} b_{kj}^{L} x_j + \rho_k^{L}, \sum_{j=1}^{n} b_{kj}^{U} x_j + \rho_k^{U}\right]} = \left[t_k^{L}, t_k^{U}\right], k \in K_2 \tag{12}$$

The expressions in (11) and (12) indicate the possible achievement of objective values within their respective planned regions.

Then, linear form of the expression in (12) can be obtained by using operational rules in interval arithmetic as follows:

$$\left[\sum_{j=1}^{n}\left(c_{kj}^{L} - t_k^{L} b_{kj}^{U}\right) x_j + \left(\mu_k^{L} - t_k^{U} \rho_k^{U}\right), \sum_{j=1}^{n}\left(c_{kj}^{U} - t_k^{U} b_{kj}^{L}\right) x_j + \left(\mu_k^{U} - t_k^{L} \rho_k^{U}\right)\right] = \left[0, 0\right], k \in K_2 \tag{13}$$

Then, in the sequel of model formulation, the defined goals in (11) and (13) are transformed into standard goals in an analogous to GP by using interval arithmetic technique and introducing under- and over-deviational variables to each of them.

Transformation of Planned-Interval Goals Into Standard Goals

It may be noted that, as in the case of conventional GP, deviations from planned values concerning achievement of objective values are inherent there owing to inexactness of setting parameter values of the problem.

The interval of possible deviation $D_k = [d_k^{L}, d_k^{U}]$ associated with *k-th* planned-interval goal can be represented as (Inuguchi, & Kume, 1991):

$$D_k = \left| \left[t_k^{L} - C_k^{U}(\mathbf{X}), t_k^{U} - C_k^{L}(\mathbf{X})\right] \right| , \tag{14}$$

where,

$$C_k^{U}(\mathbf{X}) = \begin{cases} \sum_{j=1}^{n} c_{kj}^{U} x_j + \alpha_k^{U}, & \text{for } k \in K_1 \\ \sum_{j=1}^{n}\left(c_{kj}^{U} - t_k^{U} b_{kj}^{L}\right) x_j + \left(\mu_k^{U} - t_k^{L} \rho_k^{U}\right), & \text{for } k \in K_2 \end{cases}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and

$$C_k^L(\mathbf{X}) = \begin{cases} \sum_{j=1}^{n} c_{kj}^L x_j + \alpha_k^L, & \text{for } k \in K_1 \\ \sum_{j=1}^{n} \left(c_{kj}^L - t_k^L b_{kj}^U\right) x_j + \left(\mu_k^L - t_k^U \rho_k^U\right), & \text{for } k \in K_2 \end{cases}$$

where $C_k^U(X)$ and $C_k^L(X)$ designate the upper- and lower-bounds of the planned-intervals in (11) and (13), respectively, defined for objective goals of the problem.

Now, it is worth mentioning that occurrence of zero deviational interval, i.e., $D_k = [0, 0]$, is a trivial case in actual practice, because goals are generally incommensurable and often conflict among themselves regarding achievement of values in a decision situation. Eventually, regret arising out of D_k need have to be minimized to the possible extent to obtain optimal solution.

In the above context, a regret function is designed to estimate actual goal achievements as well as occurrence of possible deviations of objective goals from the target intervals. In such a case, the planned-interval goals are to be converted into each of their equivalent two standard goals in executable model of the problem.

The standard goals of goal expressions in (11) and (13) are obtained as (Inuiguchi, & Kume, 1991):

$$\sum_{j=1}^{n} c_{kj}^U x_j + \alpha_k^U + d_{kL}^- - d_{kL}^+ = t_k^L, \tag{15}$$

$$\sum_{j=1}^{n} c_{kj}^L x_j + \alpha_k^L + d_{kU}^- - d_{kU}^+ = t_k^U; k \in K_1 \tag{16}$$

$$\sum_{j=1}^{n} \left(c_{kj}^U - t_k^U b_{kj}^L\right) x_j + \left(\mu_k^U - t_k^L \rho_k^U\right) + d_{kL}^- - d_{kL}^+ = 0, \tag{17}$$

$$\sum_{j=1}^{n} \left(c_{kj}^L - t_k^L b_{kj}^U\right) x_j + \left(\mu_k^L - t_k^U \rho_k^U\right) + d_{kU}^- - d_{kU}^+ = 0; k \in K_2 \tag{18}$$

where (d_{kL}^-, d_{kU}^-) and $(d_{kL}^+, d_{kU}^+) \geq 0$ with $d_{kL}^-.d_{kL}^+ = 0$ and $d_{kU}^-.d_{kU}^+ = 0$, $(k = 1, 2, \ldots, K)$, indicates under- and over-deviational variables, respectively.

Here, three possible cases arise concerning involvement of deviational variables to the goals in (15)-(18). Consequently, possible regret interval D_k takes the form (Inuiguchi, & Kume, 1991):

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$D_k = [d_{kL}^- + d_{kU}^+,\ d_{kL}^+ \vee d_{kU}^-]$ for both types of the defined goals, ($k \in K_1$ and K_2), where $\vee$ indicates *max* operator.

It is to be followed that there are two kinds of possible regrets, which are associated with lower- and upper bounds of D_k for involvement of two different types of possible deviational variables regarding achievement of goal values. In IVGP approach, the regret function is designed to minimizing either $(d_{kL}^- + d_{kU}^+)$ in optimistic decision system or $(d_{kL}^+ \vee d_{kU}^-)$ in pessimistic decision system in the decision search process.

However, from the optimistic point of DM, minimization of $(d_{kL}^- + d_{kU}^+)$ concerning achievement a planned value of the *k-th* goal is generally used MODM problems (Pal et al., 2012) in an inexact environment.

Then, deterministic equivalents (Blumenfeld, 2010) of chance constraints in (3) are obtained below.

Deterministic Equivalent of Chance Constraint

It is assumed that the probabilistic parameters in (3) follow independent normal distribution.

Then, the chance constraints in (3) with ≤ type restriction appear explicitly as:

$$Pr[\sum_{j=1}^{n} a_{ij} x_j \leq \ b_i] \geq p_i,\ \mathrm{i} = 1,2,...,m_1 \text{(say)} \tag{19}$$

where, a_{ij} and $b_i\,(i = 1,2,...,m_1\,; j = 1,2,...,n)$ are coefficient and resource parameters, respectively, and p_i is probability level of *i-th* constraint.

Using the standard probability rules, the deterministic equivalent of the expression in (19) appears as (Hulsurkar, Biswal, & Sinha, 1997):

$$E(v_i) + F_i^{-1}(1 - p_i)\sqrt{\{\mathrm{var}\ \ (v_i)\}} \leq 0,\ i = 1,2,...,m_1 \tag{20}$$

where $v_i = (\sum_{j=1}^{n} a_{ij} x_j - b_i)$ designates random variate and $F_i^{-1}(.)$ represents the inverse of the probability distribution function *F*(.), and where *E*(v_i) and *var*(v_i) represent mean and variance, respectively.

In an analogous way, the deterministic equivalents of constraints in (3) with ≥ type restriction are obtained as:

$$E(v_i) + F_i^{-1}(1 - p_i)\sqrt{\{\mathrm{var}\ \ (v_i)\}} \geq 0,\ i = m_1 + 1,\ m_1 + 2,...,m. \tag{21}$$

Then, formulation of EGP model is described in the following section.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

FORMULATION OF EGP MODEL

In conventional GP formulation, simultaneous minimization of under- and over-deviational variables of the defined model goals is considered for achievement of goal values. In GP, two widely used approaches are *minsum* GP (Ignozio, 1976) and *minmax* GP (Romero, 1991) In the former case, minimization of sum of weighted under- and over-deviational variables are considered in achievement function, whereas minimization of maximum of sum of under- and over-deviational variables associated with all goals is taken into account in later one. Here, an intuitive idea of taking the convex combination of both approaches (termed extended GP (EGP) (Romero, 2004)) is considered to make an aggregate achievement of possible goal values that arises in the decision-making horizon.

Then, the general structure of a regret function can be presented as (Iniguchi, & Kume, 1991):

$$\text{Minimize: } \{\lambda \sum_{k=1}^{K} w_k (d_{kL}^- + d_{kU}^+) + (1-\lambda)V\} \tag{22}$$

In a MODM environment, it is to be noted that the model goals are incommensurable in nature and they often conflict each other to achieve the individual goal values in the decision making situation. In such a situation, DM is often faced with the difficulty of using conventional GP approach to reach a proper decision for goal achievement on the basis of needs and desires in the decision making horizon. To overcome the difficulty, EGP model under a pre-emptive priority structure (Ogryczak, 1997) is considered with view to minimizing total possible regrets from the optimistic point of view of DM towards achieving the planned values of objectives within the respective target intervals.

The *priority based* EGP model can be stated as follows.

Find ***X*** so as to:

$$\text{Minimize } Z = [P_1(\bar{d}), P_2(\bar{d}), ..., P_r(\bar{d}), ..., P_R(\bar{d})],$$

and satisfy the goal expressions in (15-18), subject to the constraints in (21), and

$$d_{rkL}^- + d_{rkU}^+ - V_r \leq 0, \quad k \in I_r, r \in \{1, 2, ..., R\},$$

where

$$V_r = [\max_{k \in I_r}(d_{rkL}^- + d_{rkU}^+)], \; r \in \{1, 2, ..., R\} \tag{23}$$

In the model, Z is a vector of *R* priority achievement functions, *max* stands for maximum.

$P_r(\bar{d})$ represents the regret function for minimizing the vector $\bar{d}$ of under- and over-deviational variables of goals included at *r-th* priority level.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Again, $P_r(\bar{d})$ is of the form:

$$P_r(\bar{d}) = \{\sum_{k\in I_r} \lambda_r w_{rk}(d^-_{rkL} + d^+_{rkU}) + (1-\lambda_r)V_r\},\ 0 < \lambda_r < 1 \text{ with } \sum_{r\in I_r} \lambda_r = 1 \text{ and } \sum_{k\in I_r} w_{rk} = 1 \tag{24}$$

where I_r designates the set of model goals, *r = 1,2,...,R*, and where $\bigcup_{r=1}^{R} I_r = K$ and $I_q \cap I_s = \varphi$; *q* ≠ *s* and *q, s* ∈{*1,2,...,R*}. w_{rk} (>0), $k \in I_r$ represent numerical weights of achieving the goals, and where d^-_{rkL}, d^+_{rkU} are renamed for d^-_{kL}, d^+_{kU}, respectively, to represent them at *r-th* priority level.

The priority factors have the following relationship:

$$P_1 >>> P_2 >>> ... >>> P_r >>> ... >>> P_R,$$

which means that achievement of goals under the priority factor P_r is preferred most to the next priority factor P_{r+1}, $r = 1, 2, ..., R-1,$ where >>> stands for 'much greater than'.

Now, in actual practice, DM is confused in most of the times to assign proper priorities to goals with regard to their achievements. Therefore, sensitivity analysis of solutions with changes of priorities of model goals is made and *Euclidean distance function* is used to determine the optimal solution.

Use of Euclidean Distance Function for Priority Structure Selection

Let, *P* be the total number of possible priority structures with regard to generation of different solutions.

Then, let $\{x_j^p;\ j = 1,2,...,n\}$ be the optimal solution obtained with the selection of *p-th* priority structure, $p = 1, 2, ..., P$.

Consequently, the ideal solution can be recognized as $\{x_j^*;\ j = 1,2,...,n\}$, where $x_j^* = \max_{p=1}^{P} \{x_j^p\}$, *j=1,2,...,n*.

Using the *Euclidean distance function*, the distance of *p-th* solution from ideal point can be obtained as

$$D^{(p)} = [\sum_{j=1}^{n} (x_j^* - x_j^p)^2]^{1/2}, \tag{25}$$

where $D^{(p)}$ denotes distance function to measure distance between the solution achieved under *p*-th priority structure and ideal solution.

Now, from the viewpoint of closeness of a solution to ideal point, the minimum distance always provides optimal decision.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\text{Let, } D^{(t)} = min\{D^{(p)}; p = 1,2,...,P\}, \tag{26}$$

where, '*min*' stands for minimum.

Then, *t*-th priority structure is selected as appropriate one to obtain optimal solution in inexact environment.

Now, it is to be noted that computational complexity arises for solving MODM problems with nonlinear objectives with the use of traditional approximation techniques, and solution of a problem often leads to a local optimum rather than global one. Further, computational load due to linearization (Pal et al., 2003) as well as approximation error frequently occurs for use of traditional optimization methods.

To avoid the shortcomings, GA method (Michalewicz, 1996) is used to EGP model in (23) to obtain satisfactory solution.

GA SCHEME FOR EGP MODEL

In GA (Holland, 1973; Goldberg, 1989), generation of new population is made by adopting the operators, *selection*, *crossover* and *mutation.* The real value coded chromosomes are considered here in the evolutionary process of solving the problem. The simple roulette-wheel selection (Deb, 2002), arithmetic crossover (Hasan, & Saleh, 2011) for exploration of the promising regions of search space and uniform mutation (Craenen, Eiben, & Marchiori, 2001) for exploitation of best candidate solution in the domain of interest are considered in the process of executing the problem.

Now, the functions *Z* in (23) appears as evaluation function in the proposed genetic scheme.

The evaluation function is expressed as:

$$eval\left(E_v\right)_r = \left(Z_v\right)_r = \left\{\sum_{k=1}^{K} w_{rk}^{-} d_{rk}^{-}\right\}_v, \; v = 1,2,..., \text{ pop_size}, \tag{27}$$

where, $\left(Z_v\right)_r$ is actually renamed for *Z* in (23) to measure fitness value of *v-th* chromosome, when evaluation for achievement goals at *r-th* priority level $\left(P_r\right)$ is considered in execution process.

The best value (Z_k*) for fittest chromosome at a generation is determined as:

$$Z_k^* = min\ \{evel(E_v)_k \mid v = 1,2,..., \text{ pop_size}\},\ k = 1, 2, ..., K \tag{28}$$

The execution of the problem step-by-step for achievement of model goals has been well presented in (Pal, & Chakraborty, 2013).

Now, different types of decision variables and parameters involved in crop production planning are introduced below.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

DEFINITIONS OF VARIABLES AND PARAMETERS

1. Definition of Variables

Two types of variables, decision variables associated with arable land utilization for cultivation of seasonal crops and constrained variables associated with irrigation water supply system, are involved with the problem.

1. Decision variables:

x_{cs} = Allocation of land for cultivation of crop *c* during season *s*, $c = 1, 2, ..., C$; $s = 1, 2, ..., S$.

2.. Constrained variables:

CW_s = Supply of canal-water during season *s,* $s = 1, 2, ..., S$.

GW_s = Supply of groundwater during season *s,* $s = 1, 2, ..., S$.

2. Definition of Parameters

Two types of parameters, farm input and output parameters, are involved with the problem. The input parameters are associated with utilization of farming resources, and output parameters are associated with crop production and revenue achievement decisions in an agricultural planning system.

1. Farm input Parameters:
   a. Interval Coefficient.

$[mh_{cs}^L, mh_{cs}^U]$ = Interval of machine-hour (in hours (*hrs*)) requirement for tillage per hectare (*ha*) of land for cultivating crop *c* during season *s*.

$[md_{cs}^L, md_{cs}^U]$ = Interval of manpower (in days) requirement for cultivation of crop c during season *s*.

$[fr_{csf}^L, fr_{csf}^U]$ = Interval of fertilizer f $(f = 1, 2, ..., F)$ utilization per *ha* of land for cultivating crop *c* during season *s*.

$[P_{cs}^L, P_{cs}^U]$ = Interval of production of crop *c* during season *s*.

$[A_{cs}^L, A_{cs}^U]$ = Interval of cash requirement for purchase of various farming materials per *ha* of land for crop *c* cultivated during season *s*.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

b. Target Intervals.

$[D_s^L, D_s^U]$ = Interval of arable land (in *ha*) utilization for cultivating the crops in season *s*.

$[MH^L, MH^U]$ = Interval of total machine-hour (in *hrs*) required for all -seasons of a plan period.

$[MD^L, MD^U]$ = Interval of total manpower (in days) required for all seasons of plan a period.

$[FR_f^L, FR_f^U]$ = Interval of total amount of fertilizer f $(f = 1, 2, \ldots, F)$ (in quintals (*qtls*)) required for yielding all the crops in a plan period.

$[CR^L, CR^U]$ = Interval of budget allocation for purchase of different resources.

$[CW^L, CW^U]$ = Interval of the supply of canal-water (in million cubic meters (*MCM*)) for cultivation in a plan period.

$[GW^L, GW^U]$ = Interval of possible evacuation of groundwater (in *MCM*) for cultivation of all varieties of crops throughout the seasons in a plan period.

c. Random coefficient:

wu_{cs} = Estimated amount of water consumed (in cubic meter (*CM*)) per ha of land for cultivation of crop *c* during season *s*, *s= 1,2,…,S*.

d. Probabilistic parameter:

RW_s = Expected amount of rainwater (in millimeter (*mm*)) precipitated during season *s*,

s= 1,2,…,*S*.

2. Farm output parameters
   a. Interval coefficient

$[mp_{cs}^L, mp_{cs}^U]$ = Interval of possible market price (Rupees/quintal (*Rs./qtl*)) of yielding crop *c* cultivated during season *s*, *s= 1,2,…,S*.

b. Target intervals

$[AP_c^L, AP_c^U]$ = Interval of annual production (in qtls) of all varieties of crop *c* cultivated during all seasons of a plan period.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$[MP^L, MP^U]$ = Interval of market price of all the yielding crops cultivated in different seasons of a plan period.

$[FG^L, FG^U]$ = Interval of annual production of all major food-grain crops cultivated during all seasons of a plan period.

c. Farm output ratio interval

$[R^L_{yzs}, R^U_{yzs}]$ = Interval of production ratio of y-th and z-*th* crops cultivated in season s $(y, z = 1, 2, ..., C; y \neq z)$.

Now, following the expressions in (1) and (2), the algebraic structures of interval goals of the problem can easily be obtained. Then, the associated planed-interval goals can be determined by the expressions in (11) and (13).

PLANED-INTERVAL GOALS

The planed-interval goals are actually basic structural forms of objective goals to design the model of the problem. Planed-interval goals are discussed as follows.

1. *Land utilization goal.* The goals for utilization of total cultivable land for production of various seasons during a plan period take the form:

$$\sum_{c=1}^{C} x_{cs} = [D^L_s, D^U_s], \quad s = 1, 2, ..., S \tag{29}$$

2. Productive resource goals:
   2. a. *Machine-hour goal.* Total machine hour within a specified interval need be provided to tillage land in different seasons. The goal appears as:

$$\sum_{s=1}^{S}\sum_{c=1}^{C} [mh^L_{cs}.\ x_{cs}, mh^U_{cs}.\ x_{cs}] = [MH^L, MH^U] \tag{30}$$

   2. b. *Manpower requirement goal*. Requirement of manpower within a specified interval must be considered for smooth functioning of various activities throughout a plan period. The planned interval goal takes the form:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\sum_{s=1}^{S}\ \sum_{c=1}^{C}[md_{cs}^{L}.\ x_{cs},\ md_{cs}^{U}.\ x_{cs}]\ =[MD^{L},\ MD^{U}] \tag{31}$$

2. c. *Fertilizer requirement goal*. To maintain the fertility of soil, different types of fertilizers in essence are utilized to yield seasonal crops. The planned-interval goals for fertilizer requirement take the form:

$$\sum_{s=1}^{S}\ \sum_{c=1}^{C}[\ fr_{csf}^{L}.\ x_{cs},fr_{csf}^{U}.\ x_{cs}]\ =[FR_{f}^{L},\ FR_{f}^{U}],\ f=1,2,...,F \tag{32}$$

3. *Budget allocation goal.* An estimated budget for miscellaneous expenditure would have to be allocated for the purpose of purchase of seeds, fertilizers and other productive resources. The goal appears as:

$$\sum_{s=1}^{S}\ \sum_{c=1}^{C}[\ A_{cs}^{L}.\ x_{cs},A_{cs}^{U}.\ x_{cs}]\ =[CR^{L},CR^{U}] \tag{33}$$

4. Crop production goal.

4. a. *Total seasonal crop production goal.* To meet the demand of agricultural products in society, crop production within a specified interval is highly expected by farm manager. The goal expressions is stated as:

$$\sum_{s=1}^{S}[P_{cs}^{L}.x_{cs},P_{cs}^{U}.x_{cs}]\ =[P_{c}^{L},\ P_{c}^{U}],\ c=1,2,...,C \tag{34}$$

4. b. *Major food-grain crop production goal*. Some of the seasonal crops are taken in a group as main sources of major food-grains, where one of which can be consumed as an alternative to other ones in a same group to meet the need of main food products. Therefore, cultivation of major food-grain crops in different seasons would have to be considered as a convex combination of them in a plan period. The major food-grain crop production goal with target interval appears as:

$$\sum_{s=1}^{S}\sum_{g=1}^{C_{1}}\beta_{g}x_{gs}[P_{gs}^{L}.x_{gs},\ P_{gs}^{U}.x_{gs}]\ =\sum_{g=1}^{S}[FG^{L},\ FG^{U}], \tag{35}$$

where, $\sum_{g=1}^{C_{1}}\beta_{g}=1,\ 0<\beta_{g}<1,$ and where g is used as a rename of the crop c to indicate its inclusion in the set of major food-grain crops C_{1} ($C_{1}<C$).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

5. *Crop production ratio goal.* Since total arable land is limited, allocation of land (in *ha*) in certain seasons would have to be made in such a way that some principal crops could be yielded for civil utility purposes, beyond of satisficing different food-grain demands in society. In such a case, pair-wise ratio of production of crops cultivated during a season can reasonably be taken into account in a crop production decision situation. The planned-interval goal expression in linear form appears as:

$$\left[\sum_{s=1}^{S}\left(P_{ys}^{L}x_{ys}-R_{yz}^{U}\,P_{zs}^{U}.x_{zs}\right),\sum_{s=1}^{S}\left(P_{ys}^{U}x_{ys}-R_{yz}^{L}\,P_{zs}^{L}\right)\right] = \left[0,0\right],\quad y,z\in\{1,2,...,C\};\ y\neq z \tag{36}$$

6. *Annual profit goal.* The annual profit depends upon market price of individual yield crops. Therefore, planned-interval goal is considered for profit achievement.

The goal expression appears as:

$$\sum_{s=1}^{S}\ \sum_{c=1}^{C}[(P_{cs}^{\mathrm{L}}m\mathrm{p}_{cs}^{L}.x_{cs}-A_{cs}^{U}.x_{cs}),(P_{\mathrm{cs}}^{\mathrm{U}}m\mathrm{p}_{cs}^{U}.x_{cs}-A_{cs}^{L}.x_{cs})]\ =[MP^{\mathrm{L}},MP^{U}] \tag{37}$$

7. Water supply goals:
   a. *Canal-water supply goal.* The supply of canal-water from a River-barrage is the major source of irrigation water, which is inexact in nature owing to capacity limitation of barrage as well as constraints on the release of water up to a certain level to preserve ecosystem on earth. The planned-interval goal appears as:

$$\sum_{s=1}^{S}CW_{\mathrm{s}}=[CW^{\mathrm{L}},CW^{U}] \tag{38}$$

   b. *Groundwater supply goal.* Groundwater is always scarce in nature and abstraction of it cannot be made after a certain level to preserve biodiversity as well to make protection against water contamination with mixing of harmful minerals that lie in deep groundwater level. The planned- interval goal takes the form:

$$\sum_{\mathrm{s}=1}^{\mathrm{S}}GW_{\mathrm{s}}=[GW^{L},\ GW^{U}] \tag{39}$$

Now, the system constraints, which are inherently inflexible (rigid) in nature, are discussed in the following section.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

System Constraints

Water Supply Constraints

The adequate supply of water for cultivation is a major input in an agricultural production system. But, a water supply form reserve-water source is very limited owing to capacity limitations of them as well as to serve the other purposes in society including preservation of bio-diversity.

The two types of water utilization constraints are discussed as follows.

1. Water utilization constraints

The utilization of both the canal-water and groundwater need essentially be considered with great care, because they are always constrained for allocation to agricultural system.

The water utilization constraints can be deterministically obtained as:

$$CW_s \le y_s \sum_{s=1}^{S} CW_s, \quad s = 1,2,...,S; \qquad GW_s \le z_s \sum_{s=1}^{S} GW_s, \quad s = 1,2,...,S \tag{40}$$

where, y_s and z_s designate the percentages of utilizing the total allocation of canal-water and groundwater, respectively, to *s-th* cropping season of the plan period.

2. Total water utilization constraints.

A large part of the total demand of irrigation water depends solely on seasonal rainfall, which is highly uncertain as a natural phenomenon. As a matter of fact, adequacy of supplying total irrigation water in a cropping season is always probabilistic.

The seasonal water utilization constraints appear as:

$$Pr[\sum_{c=1}^{C} wu_{cs}.x_{cs} - (CW_s + GW_s) \le \ RW_s] \ge p_s, \ \ s = 1,2,...,S \tag{41}$$

Now, executable EGP model of the problem is demonstrated through a case example.

CASE EXAMPLE

The agricultural planning problem of Hooghly district in WB of the tropical country India is considered to demonstrate the proposed method. Hooghly district is typically known for its fertile soil to cultivate various season based principal crops throughout a planning year. Actually, the regional topography of Hooghly district is with average elevation of 19 meters from sea level and drained by the rivers, Hooghly river (i.e., the end part of Ganga river) and Damodar river. As such, it is an ideal landscape for agricultural industry in India.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Location Map of Hooghly District is presented in Figure 1.

The data were collected from various agricultural planning units: District Statistical Hand Book (2011), Economic Review (2011), Department of Agri-Irrigation of Hooghly District, Basak (2000).

Three prominent cropping seasons: Summer, Rainy and Winter, successively appear in WB in a planning year, and the patterns of seasonal crops cultivated in the sequential seasons are Pre-kharif, Kharif and Rabi, respectively. The major crops are: Jute, a variety of Paddy, Groundnut, Wheat, Mustard, Potato and Sesame. Again, season based cultivation of crops are: Jute and Aus-paddy in Summer, Aman-paddy and Groundnut in Rainy, and Boro-paddy, Wheat, Mustard, Potato and Sesame in Winter. In model formulation, the seasons are sequentially denoted as: 1, 2, 3, and crops are successively numbered: 1, 2, 3, 4, 5, 6, 7. Then, the decision variables to represent seasonal crops are defined as:

(Jute, Aus-paddy, Aman-paddy, Groundnut, Boro-paddy, wheat, Mustard, Potato, Sesame)

$$= (x_{11}, x_{21}, x_{22}, x_{32}, x_{23}, x_{43}, x_{53}, x_{63}, x_{73}).$$

In sequel of model formulation, five years' (2007-2011) rainfall data were taken into account to accommodate probabilistic constraints of the problem. The various types of data associated with objectives and constraints of the model are summarized in Table 1, Table 2, and Table 3, respectively.

Now, following the expressions in (15)-(18), the model goals are constructed by using data presented in Table 1 and Table 3.

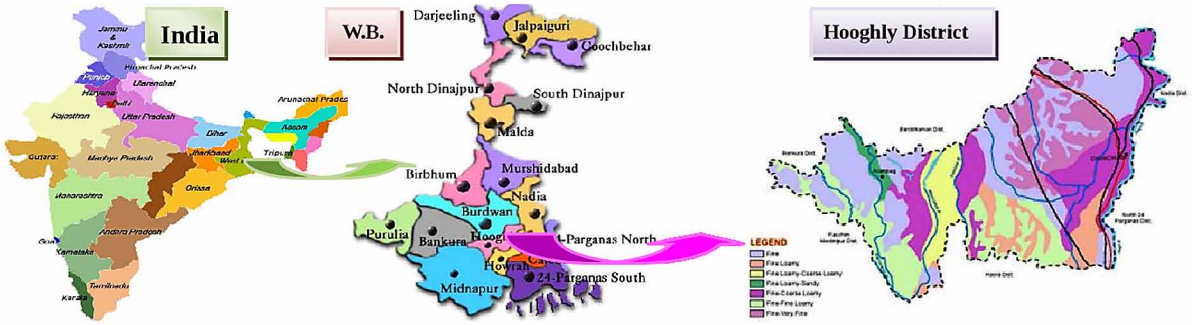
Construction of Model Goals

1. Land utilization goals:

$$x_{11} + x_{21} + d_{1L}^{-} - d_{1L}^{+} = 198650,\ x_{11} + x_{21} + d_{1U}^{-} - d_{1U}^{+} = 228776;\text{(Summer)}$$

$$x_{22} + x_{32} + d_{2L}^{-} - d_{2L}^{+} = 197550,\ x_{22} + x_{32} + d_{2U}^{-} - d_{2U}^{+} = 228776;\text{(Rainy)}$$

Figure 1. Location map of Hooghly district



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Data description of target intervals of goals

Goal	Target Interval
1. Land Utilization ('000 *ha*):	
(a) Pre-kharif	[198.650, 228.776]
(b) Kharif	[197.550, 228.776]
(c) Rabi	[197.950, 228.776]
2. Machine-hour requirement (in '000 *hrs*):	[48650, 49776]
3. Manpower requirement (in '000 *man-days*):	[86395, 90177]
4. Fertilizer requirement (in *metric ton*):	
(a) Nitrogen	[35.00, 38.59]
(b) Phosphate	[19.80, 20.67]
(c) Potash	[15.00, 16.56]
5. Budget allocation (in *Rs. Lac*)	[154550.30. 169784.54]
6. Crop production (in '000 *metric ton*):	
(a) Jute	[45.06, 46.12]
(b) Aus-paddy	[279.56, 300.25]
(c) Aman-paddy	[715.33, 735.45]
(d) Groundnut	[23.72, 25.76]
(e) Boro-paddy	[359.72, 372.67]
(f) Wheat	[6.14, 6.94]
(g)Mustard	[9.50, 10.17]
(h) Potato	[3218.73, 3247.50]
7. Total production (in '000 *metric ton*) of major food-grain crops (Paddy and Wheat):	[1356.814, 1377.140]
8. Annual profit (in *Rs. Lac*):	[145175.80, 145326.70]
9. Production ratio (Jute and Aus-paddy):	[1.20, 1.25]
10. Water supply (in *MCM)*:	
(a) Canal-water	[1555.5, 1635.37]
(b) Groundwater	[1355.45, 1443.33]

Note: Rs. = Rupees in Indian currency.

Table 2. Data description of rainfall

Year	Rainfall (RW_s) (in mm)		
	Pre-Kharif	Kharif	Rabi
2007	437	1264.11	58.8
2008	505.25	833.23	86.2
2009	273.94	855.67	25.4
2010	683.04	603.88	53.4
2011	375.75	930.34	44.4

Table 3. Data description of interval coefficients and random coefficients

Crop	$[mh_{cs}^L, mh_{cs}^U]$	$[md_{cs}^L, md_{cs}^U]$	$[fr_{csf}^L, fr_{csf}^U]$			$[P_{cs}^L, P_{cs}^U]$	$[A_{cs}^L, A_{cs}^U]$	$[mp_{cs}^L, mp_{cs}^U]$	wu_{cs}
			N	P	K				
Jute	[198, 210]	[86, 94]	[45, 56]	[19, 22]	[18, 20]	[2731, 2755]	[18655, 18845]	[870, 1050]	520
Aus-paddy	[420, 430]	[57, 64]	[58, 63]	[26, 33]	[22, 28]	[4324, 4401]	[21050, 21350]	[925, 1150]	864
Aman-paddy	[200, 210]	[56, 63]	[75, 85]	[30, 34]	[30, 34]	[4323, 4365]	[22250, 22750]	[920, 1000]	1270
Groundnut	[102, 119]	[28, 31]	[48, 52]	[24, 30]	[18, 24]	[2198, 2236]	[19250, 19750]	[720, 800]	255
Boro-paddy	[805, 822]	[55, 65]	[145, 155]	[78, 82]	[78, 82]	[5115, 5148]	[36430, 36970]	[950, 1105]	1787
Wheat	[200, 210]	[36, 43]	[105, 115]	[52, 58]	[47, 53]	[2380, 2432]	[24965, 25035]	[1350, 1475]	382
Mustard	[98, 105]	[27, 34]	[75, 85]	[35, 45]	[25, 35]	[1025, 1078]	[18520, 18786]	[2965, 3065]	255
Potato	[332, 345]	[66, 74]	[260, 290]	[165, 190]	[165, 190]	[27490, 27537]	[59245, 61390]	[500, 600]	457
Sesame	[95,105]	[26, 34]	[45, 55]	[22, 28]	[12, 18]	[813, 835]	[14170, 14595]	[2920, 3160]	286

Note: N = Nitrogen, P = Phosphate, K = Potash.

$$x_{23} + x_{43} + x_{53} + x_{63} + x_{73} + d_{3L}^- - d_{3L}^+ = 197950,$$

$$x_{23} + x_{43} + x_{53} + x_{63} + x_{73} + d_{3U}^- - d_{3U}^+ = 228776 \text{ (Winter)} \tag{43}$$

2. Productive resource goals:
   a. Machine-hour requirement goals:

$$210x_{11} + 430x_{21} + 210x_{22} + 119x_{32} + 822x_{23} + 210x_{43} + 105x_{53} + 345x_{63} + 105x_{73} + d_{4L}^- - d_{4L}^+ = 4865000,$$

$$198x_{11} + 420x_{21} + 200x_{22} + 102x_{32} + 805x_{23} + 200x_{43} + 98x_{53} + 332x_{63} + 95x_{73} + d_{4U}^- - d_{4U}^+ = 49776000 \tag{44}$$

   b. Man-power requirement goals

$$94x_{11} + 64x_{21} + 63x_{22} + 31x_{32} + 65x_{23} +$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$43x_{43} + 34x_{53} + 74x_{63} + 34x_{73} + d_{5L}^{-} - d_{5L}^{+} = 16395000,$$

$$86x_{11} + 57x_{21} + 56x_{22} + 28x_{32} + 55x_{23} + 36x_{43} + 27x_{53} + 66x_{63} + 26x_{73} + d_{5U}^{-} - d_{5U}^{+} = 17177000 \quad (45)$$

c. Fertilizer requirement goals:

$$56x_{11} + 63x_{21} + 85x_{22} + 52x_{32} + 155x_{23} + 115x_{43} + 85x_{53} + 290x_{63} + 55x_{73} + d_{6L}^{-} - d_{6L}^{+} = 35000000,$$

$$45x_{11} + 58x_{21} + 75x_{22} + 48x_{32} + 145x_{23} + 105x_{43} + 75x_{53} + 260x_{63} + 45x_{73} + d_{6U}^{-} - d_{6U}^{+} = 38590000 \text{ (Fertilizer } N\text{)}$$

$$22x_{11} + 33x_{21} + 34x_{22} + 30x_{32} + 82x_{23} + 58x_{43} + 45x_{53} + 190x_{63} + 28x_{73} + d_{7L}^{-} - d_{7L}^{+} = 19800000,$$

$$19x_{11} + 26x_{21} + 30x_{22} + 24x_{32} + 78x_{23} + 52x_{43} + 35x_{53} + 165x_{63} + 22x_{73} + d_{7U}^{-} - d_{7U}^{+} = 20670000 \text{ (Fertilizer P)}$$

$$20x_{11} + 28x_{21} + 34x_{22} + 24x_{32} + 82x_{23} + 53x_{43} + 35x_{53} + 190x_{63} + 18x_{73} + d_{8L}^{-} - d_{8L}^{+} = 18000000,$$

$$18x_{11} + 22x_{21} + 30x_{22} + 18x_{32} + 78x_{23} + 47x_{53} + 25x_{53} + 165x_{63} + 12x_{73} + d_{8U}^{-} - d_{8U}^{+} = 18980000 \text{ (Fertilizer } K\text{)} \quad (46)$$

3. Budget allocation goals:

$$18.85x_{11} + 21.35x_{21} + 22.75x_{22} + 19.75x_{32} + 36.97x_{23} + 25.04x_{43} + 18.79x_{53} + 61.39x_{63} + 14.59x_{73} + d_{9L}^{-} - d_{9L}^{+} = 15455030,$$

$$18.66x_{11} + 21.05x_{21} + 22.25x_{22} + 19.25x_{32} + 36.43x_{23} + 24.97x_{43} + 18.52x_{53} + 59.25x_{63} + 14.17x_{73} + d_{9U}^{-} - d_{9U}^{+} = 16978454 \quad (47)$$

4. Crop production goals
   a. *Total seasonal crop production goals.*

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$2755x_{11} + d_{10L}^{-} - d_{10L}^{+} = 45060000,\ 2731x_{11} + d_{10U}^{-} - d_{10U}^{+} = 46120000;\ \text{(Jute)}$$

$$4401x_{21} + d_{11L}^{-} - d_{11L}^{+} = 279560000,\ 4324x_{21} + d_{11U}^{-} - d_{11U}^{+} = 300250000;\ \text{(Aus-paddy)}$$

$$4365x_{22} + d_{12L}^{-} - d_{12L}^{+} = 710330000,\ 4323x_{22} + d_{12U}^{-} - d_{12U}^{+} = 735450000;\ \text{(Aman-paddy)}$$

$$2236x_{32} + d_{14L}^{-} - d_{14L}^{+} = 23720000,\ 2198x_{32} + d_{14U}^{-} - d_{14U}^{+} = 25760000;\ \text{(Groundnut)}$$

$$5148x_{23} + d_{13L}^{-} - d_{13L}^{+} = 357720000,\ 5115x_{23} + d_{13U}^{-} - d_{13U}^{+} = 372670000;\ \text{(Boro-paddy)}$$

$$2432x_{43} + d_{15L}^{-} - d_{15L}^{+} = 6140000,\ 2380x_{43} + d_{15U}^{-} - d_{15U}^{+} = 6940000;\ \text{(Wheat)}$$

$$1078x_{53} + d_{16L}^{-} - d_{16L}^{+} = 9500000,\ 1025x_{53} + d_{16U}^{-} - d_{16U}^{+} = 10170000;\ \text{(Mustard)}$$

$$27537x_{63} + d_{17L}^{-} - d_{17L}^{+} = 3218730000,\ 27490x_{63} + d_{17U}^{-} - d_{17U}^{+} = 32500000\ \text{(Potato)} \tag{48}$$

b. *Major food-grain crop production goals.* The crops Paddy and Wheat are the major food-grain sources across the countries. Therefore, a convex combination of annual production of Paddy and Wheat with certain target interval is considered to supply the demand of major food-grains. The model goals associated with the defined interval goals appear as:

$$\begin{aligned}&\beta_2(4.401.x_{21} + 4.365.x_{22} + 5.148x_{23}) + 2.432\beta_4 x_{43} + d_{19L}^{-} - d_{19L}^{+} = 1356.814,\\ &\beta_2(4.324.x_{21} + 4.323.x_{22} + 5.115x_{23}) + 2.380\beta_4.x_{43} + d_{19U}^{-} - d_{19U}^{+} = 1377.140\end{aligned} \tag{49}$$

5. *Crop production ratio goals.* In the crop production system, it is to be noted that Jute is a single season based crop and it is only used as raw material for textile product. Therefore, ratio of production of Pre-khariff crops, i.e., ratio of Jute and Aus-paddy would have to be maintained with a view to make adequate production of Jute depending on the needs in society. The model goals for the defined ratio appear as:

$$2.73x_{11} - 5.501x_{21} + d_{21L}^{-} - d_{21L}^{+} = 0,\ 2.755x_{11} - 5.189x_{21} + d_{21U}^{-} - d_{21U}^{+} = 0\ \text{(Jute and Aus Paddy)} \tag{50}$$

6. Annual profit goals:

$$\begin{aligned}&10272.50x_{11} + 29561.5x_{21} + 21400x_{22} + 8638x_{32} + 20455.40x_{23} +\\ &10970x_{43} + 14520.70x_{53} + 73832x_{63} + 12216x_{73} + d_{20L}^{-} - d_{20L}^{+} = 1451758000,\end{aligned}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$4914.7x_{11} + 18647x_{21} + 17021.60x_{22} + 6075x_{32} + 11525.50x_{23} + 7095x_{43} + 11513x_{53} + 48205x_{63} + 9569x_{73} + d^{-}_{20U} - d^{+}_{20U} = 1453267000 \tag{51}$$

7. Water supply goals:
   a. Canal-water supply goals

$$\sum_{s=1}^{3} CW_s + d^{-}_{22L} + d^{-}_{22L} = 1555.5, \sum_{s=1}^{3} CW_s + d^{-}_{22U} + d^{-}_{22U} = 1635.37 \tag{52}$$

   b. Groundwater supply goals

$$\sum_{s=1}^{3} GW_s + d^{-}_{23L} + d^{-}_{23L} = 1355.45, \sum_{s=1}^{3} GW_s + d^{-}_{23U} + d^{-}_{23U} = 1443.33 \tag{53}$$

Now, the constraints in crop production system are discussed as follows.

Construction of Constraints

Water Supply Constraints

1. Reserve-Water Utilization Constraints

It is to be noted that the chance of regular rainfall is very low during Summer season, and cultivation mainly depends on supply of water from reserve-water sources. Again, although Rainy and Winter are the major cropping seasons, the chance of precipitation in rainy season is very high and water consumption in winter is lower than the other two seasons. As such, utilization of cannel-water and groundwater for production of Pre-khariff crops are considered 60% and 50%, respectively, of their total amounts earmarked for supply to agriculture sector all over the seasons of the plan period.

Following the expression in (38), the affinity constraints can be presented as:

$$CW_1 \leq 0.60 \sum_{s=1}^{3} CW_s \, , \, GW_1 \leq 0.50 \sum_{s=1}^{3} GW_s \tag{54}$$

2. Total Water Utilization Constraints

The optimal yields of all the seasonal crops depend on how the probability levels of total water utilization constraints are satisfied during the cropping seasons. The satisficing levels of probabilities in the three successive cropping seasons, Pre-kharif, Kharif and Rabi, are considered 0.90, 0.85 and 0.65, respectively, which are depended on the needs of watering during the respective seasons.

Following the procedure and using the data in Table 2, the mean and variance pairs

$(E(RW_s), Var(RW_s))$, $s = 1, 2, 3,$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

associated with the successive seasons are obtained as (455.00, 18782.92), (897.45, 45514.89), (53.64, 393.94).

Then, following the expression in (39), the deterministic equivalents of probabilistic constraints for three cropping seasons are obtained as:

$$5.02x_{11} + 8.64x_{21} - (CW_1 + GW_1) \leq 331.65 \text{ (Summer)}$$

$$12.70x_{32} + 2.55x_{42} - (CW_2 + GW_2) \leq 715.66 \text{ (Rainy)}$$

$$17.87x_{53} + 3.82x_{63} + 2.55x_{73} + 4.57x_{83} + 2.86x_{93} - (CW_3 + GW_3) \leq 40.10 \text{ (Winter)} \quad (55)$$

Then, *priority based* EGP model can be constructed by using the expressions in (23) and (24).

In the execution process, five priority factors P_1, P_2, P_3, P_4 and P_5 are defined to include the model goals in (43)-(53). Three priority structures are considered to execute the problem under three successive Runs and then to perform sensitivity analysis on model solution.

Now, the general executable EGP model is obtained as follows.

Find $\{x_{11}, x_{21}, x_{22}, x_{32}, x_{23}, x_{43}, x_{53}, x_{63}, x_{73}\}$ so as to:

Minimize Z_p

and satisfy the goal expressions in (43) - (53), subject to the constraints in (54) and (55) with $0 < \beta_2, \beta_4 < 1,\ \beta_2 + \beta_4 = 1,$ and

$$d^-_{rkL} + d^+_{rkU} - V_r \leq 0,\ \ r \in \{1,2,3,4,5\};\ k \in \{1,2,\ldots,24\}$$

$$0 < \lambda_r < 1,\ r = 1,2,3,4,5. \quad (56)$$

where, β_2 and β_4 are associated with the goal expressions in (49).

The three priority achievement functions Z_p, $p = 1, 2, 3$, defined for the three successive Runs are presented in Table 4.

Now, for model simplification, $\lambda_r = 0.5, \forall r$, and $\beta_1 = \beta_2 = 0.5$ are taken into account for executions of problems under the three Runs, where equal weights are also given to goals included at the same priority level for achievement of their aspired levels.

Then, in course of solving the problem in (56), evaluation of the function $Z_p, (p = 1,2,3)$, is considered the fitness function in GA and execution is made step-by-step according to assigned priorities of model goals of the problem. Generation numbers = 300 is initially taken into account to conduct the experiment.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Priority achievement functions under the three Runs

Run	Priority Achievement Function (Z_p)
1	$Z_1 = \begin{bmatrix} P_1\left(\lambda_1 \sum_{k=18}^{20} w_{1k}(d_{1kL}^- + d_{1kU}^+) + (1-\lambda_1)V_1\right), P_2\left(\lambda_2 \sum_{k=10}^{16} w_{2k}(d_{2kL}^- + d_{2kU}^+) + (1-\lambda_2)V_2\right), \\ P_3\left(\lambda_3 \sum_{k=1}^{3} w_{3k}(d_{3kL}^- + d_{3kU}^+) + \lambda_3 \sum_{k=21}^{22} w_{3k}(d_{3kL}^- + d_{3kU}^+) + (1-\lambda_3)V_3\right), \\ P_4\left(\lambda_4(w_{49}(d_{49L}^- + d_{49U}^+) + \lambda_4 w_{4,17}(d_{4,17L}^- + d_{4,17U}^+)) + (1-\lambda_4)V_4\right), \\ P_5\left(\lambda_5 \sum_{k=4}^{8} w_{5k}(d_{5kL}^- + d_{5kU}^+) + (1-\lambda_5)V_5\right) \end{bmatrix}$
2	$Z_2 = \begin{bmatrix} P_1\left(\lambda_1 \sum_{k=1}^{3} w_{1k}(d_{1kL}^- + d_{1kU}^+) + \lambda_1 \sum_{k=21}^{22} w_{1k}(d_{1kL}^- + d_{1kU}^+) + (1-\lambda_1)V_1\right), \\ P_2\left(\lambda_2 \sum_{k=10}^{16} w_{2k}(d_{2kL}^- + d_{2kU}^+) + (1-\lambda_2)V_2\right), P_3\left(\lambda_3 \sum_{k=18}^{20} w_{3k}(d_{3kL}^- + d_{3kU}^+) + (1-\lambda_3)V_3\right), \\ P_4\left(\lambda_4(w_{49}(d_{49L}^- + d_{49U}^+) + \lambda_4 w_{4,17}(d_{4,17L}^- + d_{4,17U}^+)) + (1-\lambda_4)V_4\right), \\ P_5\left(\lambda_5 \sum_{k=4}^{8} w_{5k}(d_{5kL}^- + d_{5kU}^+) + (1-\lambda_5)V_5\right) \end{bmatrix}$
3	$Z_3 = \begin{bmatrix} P_1\left(\lambda_1 \sum_{k=10}^{16} w_{1k}(d_{1kL}^- + d_{1kU}^+) + (1-\lambda_1)V_1\right), P_2\left(\lambda_2 \sum_{k=18}^{20} w_{2k}(d_{2kL}^- + d_{2kU}^+) + (1-\lambda_2)V_2\right), \\ P_3\left(\lambda_3(w_{39}(d_{39L}^- + d_{39U}^+) + \lambda_3 w_{3,17}(d_{3,17L}^- + d_{3,17U}^+)) + (1-\lambda_3)V_3\right), \\ P_4\left(\lambda_4 \sum_{k=1}^{3} w_{4k}(d_{4kL}^- + d_{4kU}^+) + \lambda_4 \sum_{k=21}^{22} w_{4k}(d_{4kL}^- + d_{4kU}^+) + (1-\lambda_4)V_4\right), \\ P_5\left(\lambda_5 \sum_{k=4}^{8} w_{5k}(d_{5kL}^- + d_{5kU}^+) + (1-\lambda_5)V_5\right) \end{bmatrix}$

The genetic parameter values are considered as:

Probability of crossover $p_c = 0.8$

Probability of mutation $p_m = 0.08$

- Population size =100
- Chromosome length =150.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The GA is implemented using the GA-Toolbox under MATLAB Optimization Tool (MATLAB-Ver. R2010a) to execute the problem. The execution is performed in Intel Pentium IV with 2.66 GHz, Clock-pulse and 4 GB RAM.

The land utilization decisions under three Runs are displayed in Table 5.

From the results displayed in Table 5, the ideal solution point, the elements of which correspond to the maximum of individual variable values achieved under the three Runs, is found as:

$(x_{11}, x_{21}, x_{22}, x_{32}, x_{23}, x_{43}, x_{53}, x_{63}, x_{73})$

= (16.500, 62.621, 163.878, 11.179, 69.557, 2.936, 8.812, 116.911, 29.374).

Then, the *Euclidean distances* of individual solutions of the successive three Runs from ideal solution are determined as:

$$D^{(1)} = 0.963, \qquad D^{(2)} = 23.839, \qquad D^{(3)} = 0.961.$$

The result shows that the minimum distance corresponds to $D^{(3)} = 0.961$.

Thus, the priority structure under Run 3 is acceptable one for optimal land allocation decision in the farm management system.

The resulting land allocation (in '000 *ha*) decision is obtained as:

$(x_{11}, x_{21}, x_{22}, x_{32}, x_{23}, x_{43}, x_{53}, x_{63}, x_{73})$

= (16.500, 62.621, 163.878, 10.608, 69.557, 2.935, 8.812, 116.911, 28.611).

The production of crops (in '000 *metric ton*) in interval forms are found as:

Jute = [45.46, 45.95], Aus-paddy = [270.812, 275.453], Aman-paddy = [706.257, 715.027],

Groundnut = [23.816, 24.719], Boro-paddy = [365.784, 378.079], Wheat = [6.985, 7.138],

Mustard = [9.032, 9.500], Potato = [3211.883, 3219.378], Sesame = [23.219, 23.576].

Table 5. Land allocation decisions under the three Runs

Land Allocation ('000 ha) Run	x_{11}	x_{21}	x_{22}	x_{32}	x_{23}	x_{43}	x_{53}	x_{63}	x_{73}
1	16.500	62.621	163.878	10.608	69.557	2.936	8.812	116.818	28.611
2	16.500	62.621	163.878	11.179	54.399	2.936	8.812	98.427	29.374
3	16.500	62.621	163.878	10.608	69.557	2.936	8.812	116.911	28.611

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Here, using the additive rule of interval arithmetic, the production of total Paddy in interval form is obtained as [1342.853, 1368.559].

In the context of above crop production achievements, it is to be noted that the utilization of canal-water and groundwater during all the seasons are 97.96% and 75.23%, respectively.

The interval of profit achievement (in *Rs. Lac*) = [145115.331, 145338.432].

The result indicates that the obtained solution is most satisfactory for crop production decision in inexact environment.

To illustrate more the effectiveness of the proposed method, the modelling aspect without considering any priority structure is considered.

EGP Model Without Priority Structure

If priorities are not considered, the model would be the conventional EGP model proposed by Inuiguchi, & Kume (1991).

Here, the executable model appears as follows.

Find $\{x_{11}, x_{21}, x_{22}, x_{32}, x_{23}, x_{43}, x_{53}, x_{63}, x_{73}\}$ so as to:

$$\text{Minimize } Z' = \{\lambda \sum_{k=1}^{K} w_k (d_{kL}^- + d_{kU}^+) + (1-\lambda)V\}$$

and satisfy the goal expressions in (43) - (53), subject to the constraints in (54) and (55) with $0 < \beta_2, \beta_4 < 1,\ \beta_2 + \beta_4 = 1,$ and

$$d_{kL}^- + d_{kU}^+ - V \leq 0\,,\ k=1, 2,\ldots, K \tag{57}$$

where, $V = [\max_{k=1}^{K}(d_{kL}^- + d_{kU}^+)]$,

Here, equal weights are also given to the model goals, that is, $w_k = 1/23, \forall k$, and $\beta_1 = \beta_2 = 0.5$ are considered in the executable model of the problem.

Then, the achieved land allocation (in '000 *ha*) decision is

$$(x_{11}, x_{21}, x_{22}, x_{32}, x_{23}, x_{43}, x_{53}, x_{63}, x_{73})$$

= (16.500, 62.621, 163.878, 10.608, 69.557, 2.936, 8.812, 116.911, 10.107)

The production of crops (in '000 *metric ton*) in interval form are obtained as:

Jute = [45.46, 45.95], Aus-paddy = [270.812, 275.453], Aman-paddy = [706.257, 715.027],

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Groundnut = [23.816, 24.719], Boro-paddy = [365.784, 378.079], Wheat = [6.985, 7.138],

Mustard = [9.032, 9.500], Potato = [3211.883, 3219.378], Sesame = [8.217, 8.492].

Here, the interval of total production of Paddy is found [1342.853, 1368.559].

The result shows that production achievement of Sesame is quite dissatisfactory in terms of the specified interval of demand, where the intervals for achievement of other crops are found acceptable with regard to meeting the need in society. Here, utilization of groundwater is found 8.32% more than that of the result obtained under the proposed method.

The interval of profit achievement (in *Rs. Lac*) = [145101.023, 145237.453], which is an inferior one in contrast to the result achieved by employing the *priority-based* IVGP method.

Therefore, it may be said that the EGP method is better than that of conventional IVGP method studied previously concerning achievement of pragmatic solution in inexact environment. However, to make a precise interpretation of using the proposed method, a performance comparison is made with possible crisp solutions of the results discussed under the above two approaches along with existing cropping plan of Hooghly district in the next section.

Illustration for Solution Comparison

The crisp version of the solutions for crop production and profit achievement obtained under the different approaches are presented as follows.

- Using the midpoint arithmetic rule of interval analysis, the achievement levels of production (in ’000 *metric ton*) of crops obtained under the proposed approach are as follows.

(Jute, paddy, Groundnut, Wheat, Mustard, Potato, Sesame)

= (45.705, 1355.706, 24.267, 7.062, 9.266, 3215.604, 23.60).

The achievement profit = *Rs.* 145226.283 *Lac.*

- If the crisp definitions of model parameters are considered by using the midpoint arithmetic rule, then the production levels (in ’000 *metric ton*) of crops are found as:

(Jute, paddy, Groundnut, Wheat, Mustard, Potato, Sesame)

= (45.705, 1355.706, 24.267, 7.062, 9.266, 3215.604, 8.354).

The achievement of profit = Rs. 145169.238 *Lac.*

- In a precise decision environment, the existing land utilization (in ’000 *ha*) decision for seasonal crops in the planning year (2011-2012) is

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Jute, paddy, Groundnut, Wheat, Mustard, Potato, Sesame)

= (9.12, 203.42, 2.87, 1.96, 7.68, 72.45, 16.18).

The crop production (in '000 *metric ton*) decision is

(Jute, paddy, Groundnut, Wheat, Mustard, Potato, Sesame)

= (25.89, 879.24, 7.09, 3.42, 15.97, 1960.34, 15.56).

The achieved profit = *Rs*. 98673.59 *Lac*.

It may be mentioned here that the existing land allocation pattern for cropping plan is mostly adopted on the general prediction of demands of crops in society and not based on any planning model.

Now, the graphical representations of the above crisply defined solutions against crop production decision are displayed in Figure 2.

Similarly, the schematic presentations of crisply defined solutions against profit achievement decision are displayed in Figure 3.

Figure 2. Comparison of crop production under the two approaches and existing plan

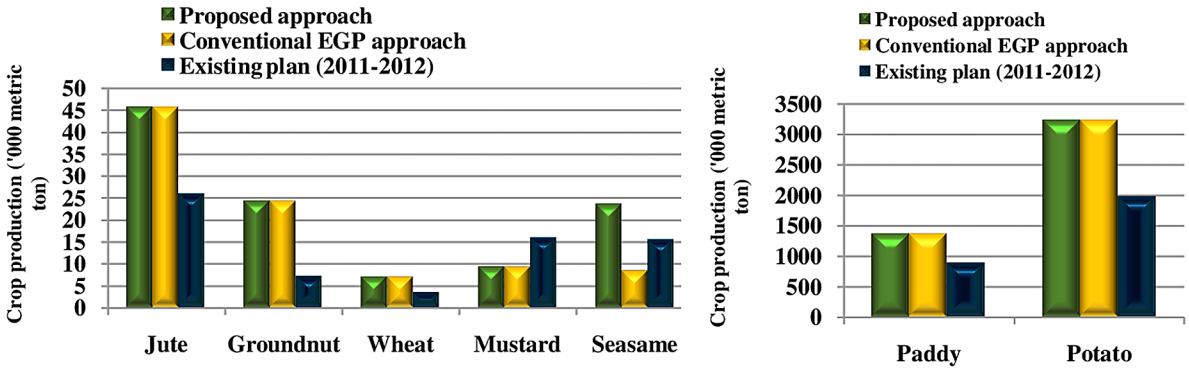

Figure 3. Comparison of profit achievement under the two approaches and existing plan

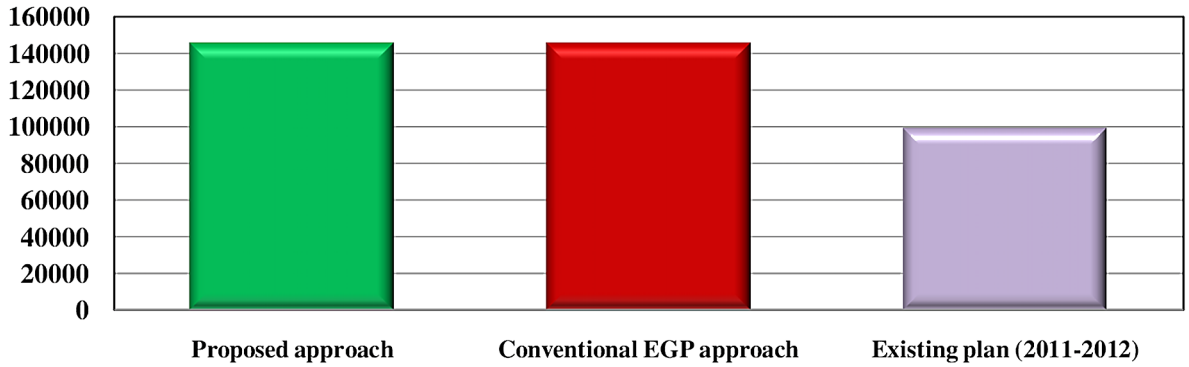

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The graphical comparisons indicate that the proposed approach is superior over other ones with regard to acceptable crop production decision.

Remark 1: It may be mentioned that, if any change of decision with regard to resource utilization as well as crop production is needed there in inexact environment, then that can be considered in the model with possible changes of interval parameters as well rearrangement of priorities of model goals of the problem.

Remark 2: With regard to implementation of the proposed model, the problem with involvement of computational load with rearrangement of priorities in different ways in solution search process may generally be raised in the context of management of farm. Because, if R be the total number of priorities, $R!$ priority structures may have to be considered there to search optimal solution. But, it is worth mentioning here that at most 'five' priority levels are typically involved (Ignizio, 1976) and the conflict to assign priorities occurs up to 'three' priority levels in actual practice in a decision environment.

FUTURE RESEARCH DIRECTIONS

In future study, the proposed approach can be extended to cropping plan for fuzzy description on bounds of interval data of model parameters with a view to further relaxation on resource utilization plan towards arriving at more effective crop production decision. Again, the possible extension of land under cultivation along with investment in rain-fed agriculture to improve environmental sustainability, agricultural waste-water management and other crop yielding criteria may be introduced in the model presented here, that are the emerging research problems with regard to take challenges for elimination of hunger and poverty in society. However, may be said that the study made in this chapter leads to open up new avenues to modeling agricultural problems in the current scenario of increasing demands of food grains in society.

CONCLUSION

In this chapter, a GA based EGP formulation of agricultural problems with interval model data under a set of chance constraints is presented. The study provides a new way of modeling and solving farm management problems in uncertain environment. Further, other different types of parameters and environmental constraints can be accommodated in the proposed model to make cropping plan towards meeting the demand of various food products in modern society.

ACKNOWLEDGMENT

The authors would like to thank the Editors, Handbook of Research on Natural Computing for Optimization Problems, and anonymous Reviewers for their valuable comments to improve the presentation of the chapter.

KEY TERMS AND DEFINITIONS

Farm Planning: Proper allocation of cultivable land for optimal production of several seasonal crops by utilizing different productive resources.

Fractional Programming: Special field of study in the area of mathematical programming, where certain objective functions appear in the form of ratios for optimizing them in the decision environment.

Genetic Algorithm: Genetic algorithm is an adaptive heuristic search algorithm based on the evolutionary ideas of natural selection and genetics in living system.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Goal Programming: Goal programming is a goal-oriented optimization technique to solve decision problems with multiplicity of objectives in crisp environment.

Interval Programming: Interval programming is the modelling aspects of optimization problems in which model parameters are defined in the form of bounded intervals.

Stochastic Programming: Stochastic programming is an optimization technique for solving problems with probabilistically defined data in uncertain environment.

Chapter 34
Mobile Vision for Plant Biometric System

Shitala Prasad
GREYC – Imaging Lab, CNRS, France

ABSTRACT

In human's life plant plays an important part to balance the nature and supply food-&-medicine. The traditional manual plant species identification method is tedious and time-consuming process and requires expert knowledge. The rapid developments of mobile and ubiquitous computing make automated plant biometric system really feasible and accessible for anyone-anywhere-anytime. More and more research are ongoing to make it a more realistic tool for common man to access the agro-information by just a click. Based on this, the chapter highlights the significant growth of plant identification and leaf disease recognition over past few years. A wide range of research analysis is shown in this chapter in this context. Finally, the chapter showed the future scope and applications of AaaS and similar systems in agro-field.

INTRODUCTION[1]

At the beginning of this century, there was a tremendous technological revolution in the field of wireless communication and mobile technology. Mobile and ubiquitous computers are increasing their magnitude in every small, portable, wireless computing and communication fields. The technological omnipresence of ubiquitous devices invisibly activates the world by providing accessibility *anywhere-anytime* computing. However, this revolution is still slow in the agricultural sphere, despite the advancements in technologies making it possible to build and deploy wireless sensor networks (WSN) in fields that would radically improves the farming efficiencies. This is because the current wireless technologies are too expensive and complicated for farmers to use especially in the developing countries like India. Two-way radios have long been used by farmers in many such developed countries with large farmlands to contact their employees, farm suppliers, equipment dealers, agents, buyers and farm awareness. Today, world-wide availability of smartphones and cellular networks, the use of mobile phones in agricultural sector is popularly, replacing the use of two-way radios (Wang, Li, Zhu, & Xu, 2016). The advantage of using two-way radios and mobile phones is that these wireless tools are relatively cheap and very simple

to use. Additionally, smartphones have several important advantages such as all the brands of mobile phones are generally compatible for running various types of application software, and are equipped with Wi-Fi, Bluetooth, camera(s) and GPS capabilities.

In Asia-Pacific region, India has outscored the other nations in terms of the number of mobile users. With such rapidly increasing tele-density, mobile penetration in rural areas is also growing strongly. These days, mobile phones are available to people even in rural India, especially among the agrarian community. Motivated by the advancement in mobile technology and the wide-spread use of phones in India, as discussed above, researchers are aiming to help the illiterate agrarian community to improve their agricultural activities through the use of mobile phones. Thus, a new agro-information technology needs to be introduced in order to bridge the gaps between the real and digital objects via mobile computing (MC) and augmented reality (AR).

Agricultural Scenario

In developing countries, agriculture accounts the major role of rural employment and holds the promise for socio-economic growth. In fact, agro-community is roughly five-times more effective in raising the income of poor farmers compared to any other sector. Agricultural improvement also directly impacts on the hunger and malnutrition and thus plays a significant role in decreasing the occurrences of famine. However, the growing global population has heightened the demand for foods. Due to the lack of infrastructure in rural areas, raising the food prices and the climatic change and the real effective and "smart" agriculture is essential. Together with geographic information systems (GIS) and virtual reality (VR) smartphones can play an important role in precision agriculture environment (Bakhsh, Colvin, Jaynes, Kanwar, & Tim, 2000; Jain, Tim, & Jolly, 1995; Tim, 1995). Some of the uses of on-farm wireless network technologies in improving the agricultural productions are discussed in (Vellidis et al. 2007; Izzat, Ismail, Mehat, & Haroon, 2009; Revenaz, Ruggeri, & Martelli, 2010).

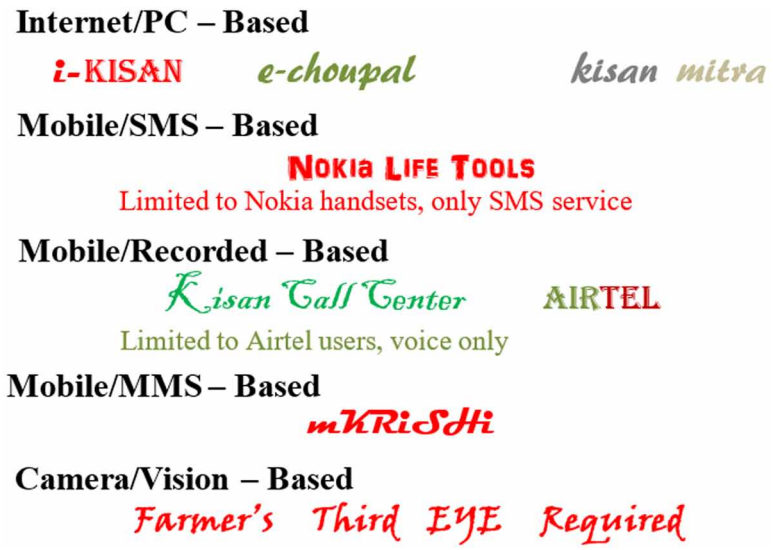
Mobile-Based Agriculture

Information and Communication Technology (ICT), particularly mobile technologies, are often seen as the 'game changer' in agro-community. The already existing *m*-Agricultural information system provides a giant leap in agriculture that offers a plethora of services, serving as a tool for information dissemination (Brugger, 2011). Various mobile-based services such as Internet-based, SMS-based information services (Gore, Lobo, & Doke, 2012), voice-based agro-advisory services like mKRISHI -(Shinde et al. 2014), and videos over mobile networks (Pande, Jagyasi, & Choudhuri, 2009) are utilized for transferring general knowledge about the farming techniques and trends, information of the plants and their varieties regarding how to keep them disease free. The general awareness in India by using *m*-Agriculture techniques since last decade are listed in Figure 1. But due to the limited and disconnected services they did not server the real needy.

Specifically, *m*-Agriculture refers to the delivery of agriculture-related services via mobile communication technology (Brugger, 2011). In order to make decisions on agricultural measures, it provides an individual decision support systems and services. These decision are based on the local contextual information, *i.e.*, delivering location-specific information like climatic patterns, soil and water conditions. Here, *m*-Agricultural termed to involve gathering of related information through mobile technologies like automated weather stations or sensors used in mobile. Thus, *m*-Agriculture involves a two-way advisory

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Mobile-based ICT agro-services launched in India



systems that provides individual feedbacks and advices like remote diagnosis of diseases by experts using some fertilizers/chemicals. These advisory systems typically include smartphones and intermediaries for wireless communication with the farmers and require remote sensing instruments like GIS.

m-Agriculture projects are built on the opportunities to increase the use of mobile/ubiquitous devices by farmers in the developing countries. Therefore, the primary objective of this chapter is to project such mobile-based vision systems for plant species identification and disease diagnosis using plant leaf imaging. Why an agro-vision system? Because famers or the other illiterate (non-botanical) person may not be able to explain the exact visual symptoms occurred on the crop to the expert to get a proper solution for the problem(s).

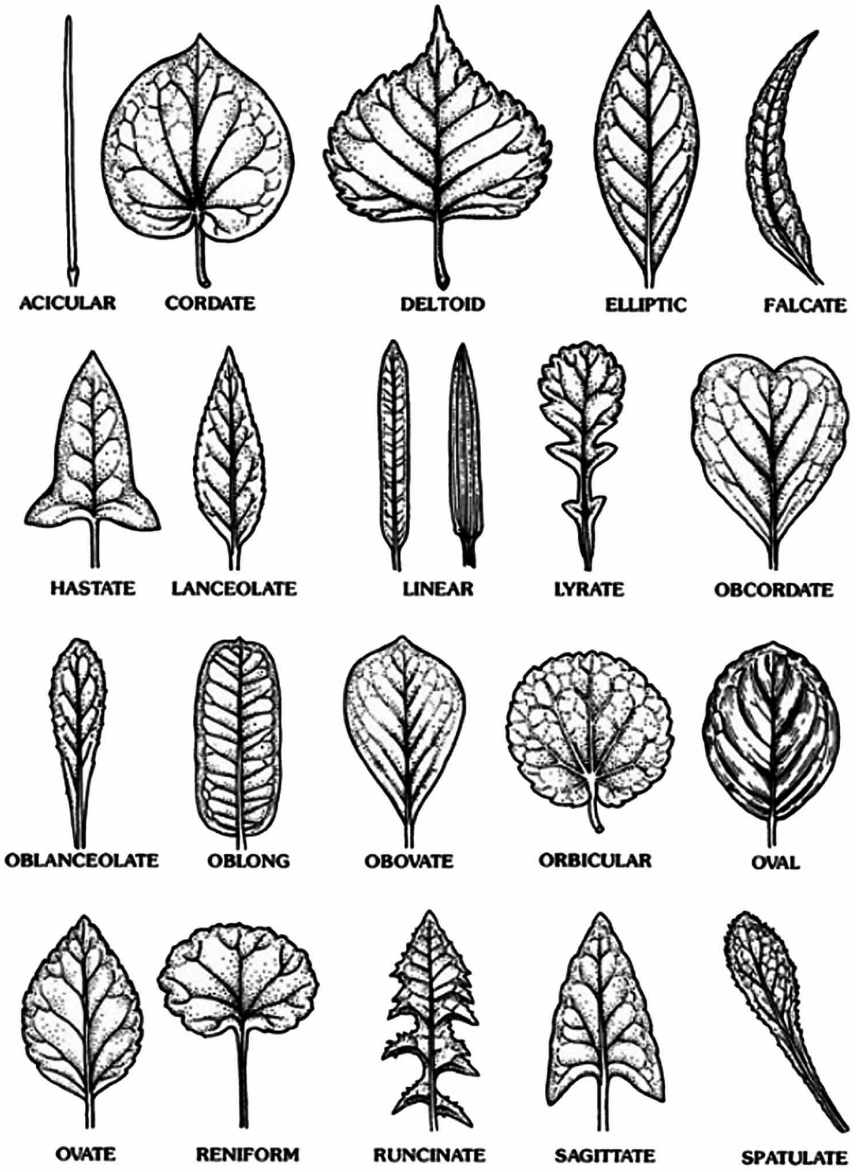
Motivation

The biodiversity is rapidly disappearing and we are losing the opportunities to know and understand the complexity of our mother-nature. Smart technologies are indispensable in order to rapidly identify the species and access the biodiversity information. If possible, it also develops the eco-informatics expert systems. Thus, mobile-based automated plant biometric system to automatically segment leaf from a complex background, followed by leaf analysis to identify the plant species, and diagnose the diseases on the leaf, is a need.

Currently, there are several plant classification methods such as plant genetics method, cytotaxonomy method and chemotaxonomy method. Plant species classification is not only botanic, but also is the foundation of ecology, medicine and life science (Wang, Li, Zhu, & Xu, 2016). According to a survey conducted in 2003, botanists claimed that to identify more than 3,15,000 plant species the key features used are fruits, flowers, stems, roots and leaves (Scotland & Wortley, 2003). Different types of plant leaves are shown in Figure 2. However, fruits and flowers are seasonal and may not be available throughout a year for identification purpose, while roots and stems are difficult to analyze. This is not the case with a plant leaf. It is available throughout the year and can easily be photographed; containing

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. The common shapes of simple leaves (Plant Glossary, 2009)



sufficient information for species analysis. As a result, majority of the existing techniques are based on plant leaf features such as leaf shape, leaf margin, leaf vein and leaf texture (Cope, Corney, Clark, Remagnino, & Wilkin, 2012).

Some of the basic plant leaf shapes with their venation details are shown in Figure 2. These features are well explanatory in real world but for virtual or digital world they are mathematically represented using various transforms in both spatial and frequency domain (Cope et al., 2012). In this chapter, both spatial and frequency domain representations of plant leaf features are highlighted for further analysis (specie or disease recognition).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The chapter, especially focus on the novel techniques used for plant identification and disease diagnosis. The graphical abstract of the proposed system is shown in Figure 3 where the crop leaf (object) is photographed via mobile/ubiquitous device, and subsequently represented mathematically in feature space which is then projected for classification using an optimal classifier.

The next few sections describe the existing automated plant biometric systems and their limits with their comparison and results.

BACKGROUND

As discussed, the manual monitoring and experimenting involves human expertise which is a tedious, time consuming, brittle and frustrating practice. Users need to traverse a decision tree manually to make a decision related to species, as shown in Figure 4(a). Botanists collect the specimens and preserve them in herbaria like Royal Botanical Gardens, Kew in London[2] (Kumar et al. 2012), as shown in Figure 4(b). The herbarium can be seen as a major collection of experts' knowledge in form of a structured repository and thus, to facilitate the access they are being digitized with images of species, dates, locations and so on.

In computer vision (CV) and pattern recognition (PR), feature representation and feature selection are the most important aspect of research since many decades. Various image processing and machine learning algorithms such as neural network (NN), support vector machine (SVM), and *k*-nearest neighbor (*k*-NN)

Figure 3. The graphical abstract of the proposed system

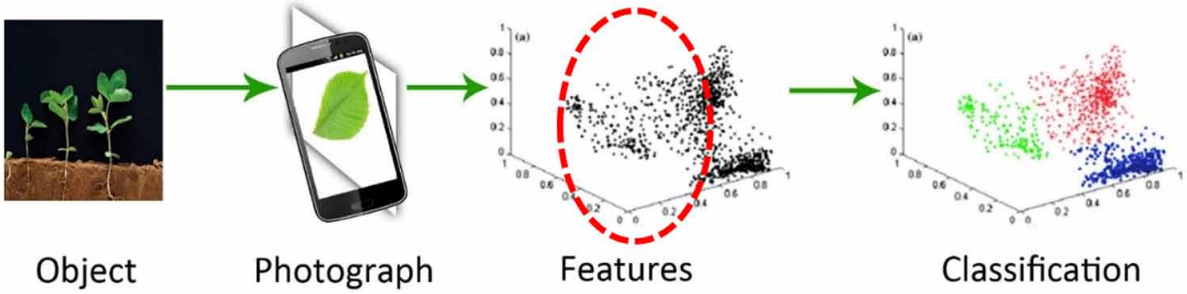


Figure 4. (a) Hierarchy of biodiversity classification and (b) bio-specimens herbaria

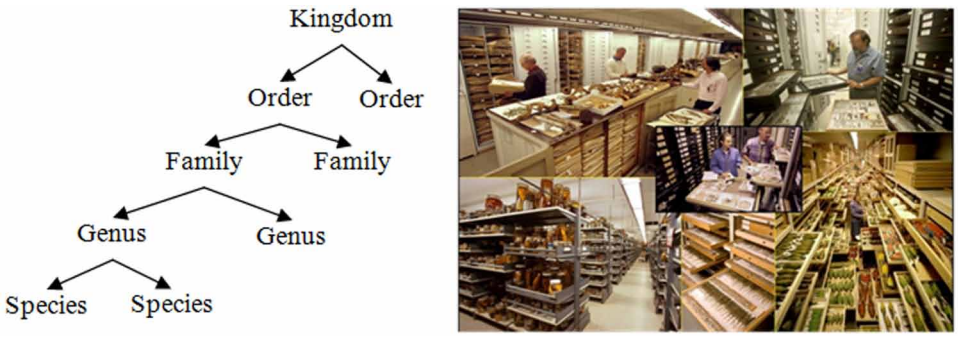

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

are used in different domains like medical imaging (Orr, Peersson, Marquand, Sartori, & Mechelli, 2012), surveillance (Pogorelc, Bosni, & Gams, 2012), object recognition, species identification (Kumar et al. 2012) and designing automated defence systems (Heinze, Goss, & Pearce, 1999). The development and ubiquity of technologies like mobile cameras and mobile processors in related fields have brought such ideas close to the reality (MacLeod, Benfield, & Culverhouse, 2010). Therefore, various CV systems have been proposed for plant identification using their fruits, flowers or leaves[3], especially morphological studies, e.g., Tilia (Schneider, 1912), Ulmus (Melville, 1937), Betula (Natho, 1959) and many more.

There are many aspects of plants that are used by botanists in identification such as the 2-dimensional outlines of leaf, veins of leaf, margin of leaf and texture of leaf. Among these, leaf shape information is the mostly exposed and popular method among CV researchers. The two well know mobile applications launched in market for species identification are *LeafSnap* and *Leafview*. Both uses the leaf shape information for plant leaf identification via iPhone, as shown in Figure 5(a-b). *LeafZone*[4] (Figure 5c) is another app that not only identifies the plant species but also provides information about the effect of ozone on them making it more exciting for people to know their nature.

Leaf-Shape-Based Identification

Leaf shape has the maximum discriminative power among all the other parts of a plant. At the same time, leaves of the same plant may have different shapes and size. Over it, leaves of different species may have similar characteristic shape. As discussed above, the existing algorithms used to extract shape information in the frequency domain from a leaf I^3_{leaf} are Fourier analysis (McLellan & Endler, 1998), elliptic Fourier descriptors (EFDs) (Neto, Meyer, Jones, & Samal, 2006) and Fourier harmonics (Hearn, 2009). Following this, Principal Component Analysis (PCA) was also applied to reduce the dimensionality of the feature-space for efficient classification. The advantage of using such methods is that the shape can be reconstructed from its descriptors and are rotation invariant. Recently, EFDs was also used by different authors for leaf shape analysis (Andrade, Mayo, Kirkup, & Van-Den-Berg, 2008; Lexer et al. 2009; Neto et al. 2006). Next, a number of approach uses contour signatures for leaf shape classifica-

Figure 5. (a) LeafSnap, (b) LeafView, and (c) Leafzone are the popular electronic plant information systems

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion such as the morphological description (Cope et al. 2012) and the centroid-contour distance (CCD) (Wang, Chi, & Feng, 2003). CCD is a sequence of distances between the center pixel to the contour of the object and hence, suffers from orientation problem. The other signatures include centroid-angle and tangents of the leaf outline. Meade and Parnell (2003) and Wang, Chi, and Feng (2003) attempted to increase the CCD accuracy when applied on leaf shape identification. A new time-series shapelets approach to calculate local features was proposed by Ye and Keogh (2009) and Prasad, Kumar, and Ghosh (2016). But a major difficulty with these contour based signatures is that they are sensitive to self-intersection which occurs quite often with multiple lobe leaves and in compound leaves. Prasad, Kumar, and Ghosh (2016) overcomes with this limitation to some extent. Another common approach for shape extraction is the use of movement invariant (MI) features (Zulkifli, Saad, & Mohtar, 2011), region-based features (Lee & Chen, 2006), and others. Warren (1997) proposed an automated system to recognize plant genus "Chrysanthemum" with thirty species. In Warren (1997), three basic mathematical descriptors such as the shape, color and size of leaf, flower and petal were used to identify the species. Similarly, authors (White, Marino, & Feiner, 2006 & 2007; White, Feiner, & Kopylec, 2007), used a morphological descriptor for shape information extraction from a complete leaf image. They designed a mobile vision Tablet-PC-based electronic field guide to identify plant leaves for the use of botanists and others to make their work much easier. Since *LeafSnap* is designed for iOS, Zhao et al. (2015), proposed *ApLeaf*, an Android based replica of *LeafSnap* with few pros-and-cons. Thus, Multiscale-ARCH-height (MARCH) a shape-based algorithm for mobile devices to retrieve plant leaf image was introduced in Wang, Brown, Gao, and Salle (2015).

In Prasad, Kumar, and Ghosh (2013b), the authors proposed a mobile plant identification system with a statistical leaf shape information. Here, they used the reduced shape and color mean information where the leaf image was down sampled to an acceptable and feasible limit which is optimal for mobile-level computing. The first step in this was to capture an isolated constant background plant leaf image I^3_{leaf} using mobile camera. The pre-processing step is minimal or negligible due to the above pre-segmented input leaf. The shape and color features are extracted and used for classification after limiting I^3_{leaf} to a fixed window size to make the approach translation and scale invariant.

Since shape or color cannot be used individually for a reliable leaf classification, as they may vary with different conditions and locations, researchers applied a decision level fusion to avoid such problem(s). The first level decision is based on shape information which is subsequently verified in the second level using color features (Prasad, Kumar, & Ghosh, 2013b). For the purpose of shape feature extraction, geometric features (elongation, roundness, circularity and porosity) and polar Fourier transform features were used. On the other hand, for color features, the mean, standard deviation, skewness and kurtosis were derived (Prasad, Kumar, & Ghosh, 2013b). To test the functionality two different datasets were used: Flavia dataset[5] and a set of hundred plant species dataset (Wu et al. 2007) with an accuracy of 91.34% and 76.21%, respectively. Other than this, few other authors have used some very specific leaf features to identify plant species, such as the leaf lobedness (Pauwels, Zeeuw, & Ranguelova, 2009) and fractal combined with Linear Discriminant Analysis (LDA) (Bruno, deOliveira Plotze, Falvo, & deCastro, 2008). It is found that fractal features are significant only if used with the combination of other features. In 2006, Du, Huang, Wang, and Gu proposed a polygonal representation of plant leaves for comparison limiting the method to a more generic tasks.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Leaf Veins and Margin-Based Identification

The second commonly used leaf information is its vein pattern. The common leaf vein structure are shown in Figure 2. The veins provides structure to a leaf and thus, the vein pattern of a leaf can serve as a measure for its identification. The algorithms proposed in these are Independent Component Analysis (ICA) (Li, Chi, & Feng, 2006) and Artificial Ant Swarm Intelligence (AASI) (Mullen, Monekosso, Barman, Remagnino, & Wilkin, 2008) to extract leaf edge and leaf vein patterns for species recognition. Cope, Remagnino, Barman, and Wilkin (2010) used Genetic Algorithm (GA) to identify vein pixels and non-vein pixels. Whereas, vein extraction is best achieved by using threshold and neural network approach, as claimed by Fu and Chi (2006). Some other similar methods are discussed by Nam, Hwang, and Kim (2008) and Park, Hwang, and Nam (2008).

The third information used to classify a plant species is by its leaf margin. However, it is not a perfect feature and, therefore, generally used only in combination with other features. The leaf margin often consists of teeth pattern, as shown in Figure 1, which offers a small contribution in automated plant species recognition. Clark (2004) used multi-layer perceptron for identifying species and in Clark (2009), he used a hair descriptor as one of the features in self-organizing map (SOM) for Tilia classification. Rumpunen and Bartish (2002) used a manual measure to calculate the angle and length of the leaf tooth. If undamaged leaves are available, then leaf margin may be a good option for the purpose. On the other hand, leaf vein combined with leaf margin may perform well in damaged leaf cases. But for taxa that do not have teeth, it may fail.

Leaf-Texture-Based Identification

Last but the most important information of a plant leaf is its texture and so many novel techniques have been proposed using it. The size and color of plant leaf varies arbitrarily and even in a single plant two leaves may have different sizes. Thus, the algorithm needs to be translation, scale and rotational invariant, as in case of Curvelet transform (CT) (Prasad, Kumar, & Tripathi, 2011). Image texture quantifies the perceived texture of an image and can be calculated using either structural approach or statistical approach. Backes, Gonalves, Martinez, and Bruno (2010) proposed multi-scale fractal approach to represent the texture of leaf and used neural network for classification. Other methods based on Gabor transform (GT) (Casanova, de Mesquita, & Brun, 2009; Cope et al. 2010, 2012), wavelet transform (Liu et al., 2009) and Relative sub-Image Coefficient (RSC) feature (Prasad, Kundiri, & Tripathi, 2011a) were proposed to extract leaf texture for species recognition.

In 2014, Yanikoglu, Aptoula, and Tirkaz used shape-texture-color features to identify plant species from photographed images with a maximum accuracy of 81% in various lighting, poses, and orientation conditions. Finally, each method has its own pros and cons. It is conjectured that texture combined with contour-based shape analysis may be the best solution in the present context.

The plant biometric also entered into the deep learning and come up with several convolutional approaches for plant leaf species classification (Lee, Chan, Wilkin, & Remagnino, 2015; Sünderhauf, McCool, Upcroft, & Perez, 2014; Reyes, Caicedo, & Camargo, 2015; Jassmann, 2015).

Based on Flowers and Other Parts of Plants

In the literature, there is a dearth of research done on leaf lamina feature extraction using wavelet and Gaussian interpolation (Gu, Du, & Wang, 2005). To other extent, 3D image processing has also been proposed for leaf feature extraction (Ma et al. 2008). They combined 2D leaf images to extract 3D leaf structure and together with 2D and 3D information, leaf boundary segmentation is achieved by applying normalized-cuts. They applied CCD for classifying leaf into palmate and cordate. Similarly, Teng, Kuo, and Chen (2009) used stereo imaging and stereo matching for the same purpose.

A number of approaches have also been proposed that use flower as a key to identify plant[6]. In case of flower, color is the most common and significant feature. Nilsback & Zisserman, (2010) combined petal shape and color information to design flower segmentation algorithm. Hong, Gang, Jun-li, Chi, and Zhang (2004) used the same color-histogram with CCD and angle-code histogram to classify a set of fourteen species. Yoshioka, Iwata, Ohsawa, and Ninomiya (2004) used Elliptic Fourier Analysis (EFA) for shape analysis of petals in case of Primula sieboldii while Gage and Wilkin (2008) used EFA for outline analysis of tepals (such as petals and sepals) of three species of Sternbergia to validate whether they actually have distinct morphology. Huang, Huang, Du, Quan, and Gua (2006) used Gabor transform (GT) and radial Probabilistic Neural Network (PNN) for bark texture analysis. Lastly, few of the researchers used digital imaging on plant root to analyze root shapes and structures via polynomial curve fitting (Huang, Jain, Stockman, & Smucker, 1992; Zeng, Birchfield, & Wells, 2010). Recently, Mzoughi, Yahiaoui, Boujemaa, and Zagrouba (2015) proposed a hybrid approach for plant species identification. They used leaf arrangement, leaf lobation and leaf partition information to form the feature space necessary for classification. But again, this novel retrieval strategy lacks proper feature representation and selection for ImageCLEF 2011 leaf dataset[7]. Majority of them are content-based image retrieval which needs to be replaced by semantic and cognition based resulting higher level of accuracy in very small time of response (Candan, Kim, Nagarkar, Nagendra, & Yu, 2011; Li et al., 1997, 1998).

Mobile-Based Plant Species Identification System

On the other side of the coin, MC can aid timely access to agriculture related information such as production monitoring, bank policies, *m*-agriculture commerce, and so on, as claimed by Prasad, Kumar, and Ghosh (2013a). Other than Kumar et al. (2012), White et al. (2006), Zhao et al. (2015), Prasad, Kumar, and Ghosh (2013b), Prasad, Kumar, and Ghosh (2015) presented an *Agriculture-as-a-Service* (*AaaS*) framework combining MC, AR and wireless communication technologies with cloud computing (CC) to better serve the agricultural community (agro-community). As the *third eye* of farmer, *AaaS* automatically assists in monitoring their crop fields by a smart remote expert's eye. As discussed above, majority of works were desktop driven and limited to laboratory only. Few approaches are executed on mobile device as an interface such as the *LeafSnap*, *Apleaf,* and *AgroMobile*. Nonetheless, the mobile applications are very popular among the mass communities compared to other desktop-based systems. In addition to this, Mobile Cloud Computing (MC2) manages the energy consumption of a mobile phone supporting an off-line accessibility of plant information and pathological data, as shown in Figure 6. Accordingly, Kim et al. (2013) proposed a self-growing agriculture knowledge using CC services assisting farmers to make smart decisions. The detailed MC2 in agriculture is discussed in Prasad, Kumar, and Ghosh (2013a, 2015).

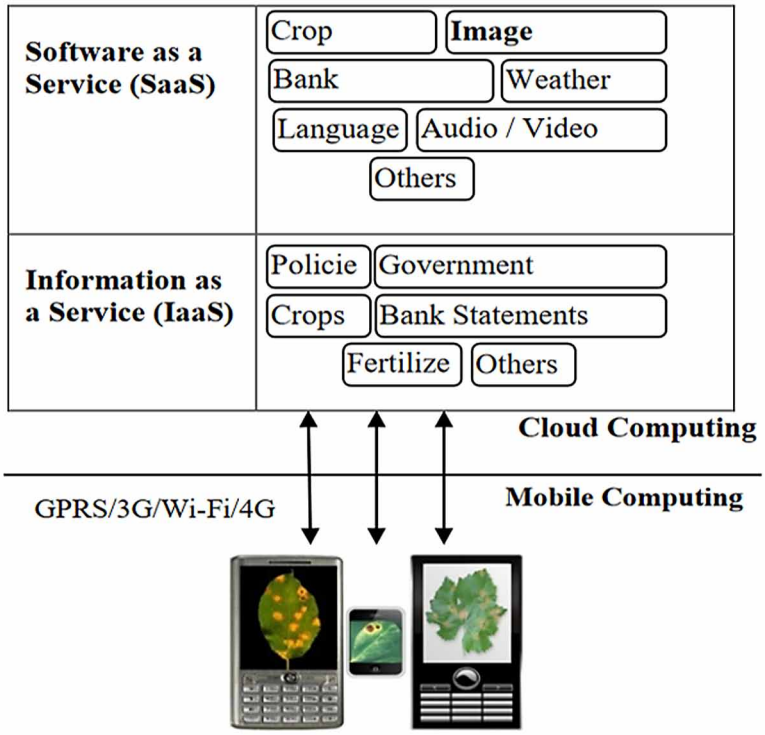
Figure 6. AgroMobile framework (Prasad, Kumar, & Ghosh, 2013a)



Disease

With recent advances in technology, Prasad, Kumar, and Ghosh (2016a) proposed a system that can recognize plant leaf disease using efficient CV algorithms. The author used Gabor Wavelet transform (GWT) over GLCM for disease patch pattern computation which is further used for classification using *k*-NN. The dataset used was a diseased leaf dataset with 5 different pathogen attacks on 4 different species. The system proposed is an Android-based mobile client-server architecture which even an illiterate farmer can operate. The server performs feature extraction followed by classification of the disease and inform the farmer in the field via a fax-back system. The accuracy reported by the author is 93% for diseased identification. In this paper, author have also mentioned an unsupervised leaf diseased patch segmentation in *L*a*b** color space which is quite acceptable (Prasad, Kumar, & Ghosh, 2016a). Such system in future may be used to monitor, control and manage the agricultural productions automatically without any manual expert via MC2 (Prasad, Kumar, & Ghosh, 2013a, 2015). The tremendous growth in MC2 and its rising popularity among people all over the globe have motivated researchers to develop ubiquitous plant disease diagnosis system.

DATASETS

For plant biometric system, several plant leaf datasets are introduces with different challenges like the first dataset which is mostly used by researchers is the Flavia Leaf dataset (Wu et al. 2007) having 32

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

different species and 1900+ high quality image samples. Secondly, ICL (Intelligent Computing Laboratory) Leaf dataset (ICL) with 220 species, third is 100 plant leaf dataset (Mallah, Cope, & Orwell, 2013), and fourth is Swedish leaf dataset 11 (Sderkvist, 2001). All these leaf datasets are semi-segmented and so pre-processing is reduced. While there is another big dataset called PlantCLEF 2015 dataset[8] which is composed of 113,205 plant images of 1000 different species (trees, herbs and ferns) in Western European regions (Goeau, 2015). A diseased leaf dataset collected from Indian Institute of Technology (IIT) Roorkee and Forest Research Institute (FIR) Dehradun campuses (Prasad, Kumar, & Ghosh, 2014, 2016a) is also available for plant leaf disease identification. More details related plant leaf datasets and research papers can be found on http://www.visionbib.com/bibliography/applicat842l1.html.

COMPARISON EVALUATION

The contribution of automated plant biometric system since 2000 is shown using a graph (Figure 7), where y-axis shows the number of good related articles published in respective year on current topic (Wang et al., 2016). The increasing number shows the dedication of CV researchers in agriculture field. For comparison, several datasets are compared with different approaches proposed, as mentioned in this chapter, is shown in Table 1. The first column is for Flavia dataset and second for ICL leaf dataset. The third column is a mixed dataset highlighted only to compare the highest accuracy achieved by various researchers in recent years in plant species identification. From Table 1, it is seen that CNN is currently the best feature map to represent plant leaves for accurate classification. The problem with CNN is it needs a proper training with large datasets which requires huge number of resources.

AaaS framework in reality may server agro-community in all sectors with high accuracy assisting famers when, what and how to plant with what fertility rate and chemical/natural controls. It even aware one remote farmer working in other end of world with the situations of other farmer's failures while cultivation.

CONCLUSION

In this chapter, a brief survey of automated plant biometric systems since decades is presented highlighting the current state-of-the-art. According to several authors, plant leaf patterns are represented mathemati-

cally using various transforms including both spatial and frequency domain. More than fifty feature spaces for ten different plant datasets are discussed using different classifiers. Based on this survey, we find out the pros and cons of different feature spaces and classifiers. The future scopes and applications of such systems in agro-communities also motivate researchers to work in this field.

Chapter 35
Demand for Food Diversity in Romania

Lucian Luca
Institute of Agricultural Economics, Romania

Bianca Păuna
National Institute of Economic Research, Romania

ABSTRACT

The present research work applied a food diversity measurement tool (Transformed Berry Index) on the 2011 Household Budget Surveys data. The investigation was performed on household purchased based TBI measure and on actual consumption TBI, in order to highlight the errors that one would make if one fails to take into account the production of goods by the household. There are some important differences in the food diversity of the actual food consumption in comparison to the purchased food quantities, the number of food items being higher in the case of actual consumption. However, food diversity does not seem to be influenced by the residence area (urban vs. rural) in any of the two approaches.

INTRODUCTION

In Romania, the transition period was associated to a massive reduction in the population's real incomes, this leading to the increase in the consumption of products considered inferior from a nutritional point of view, such as potatoes and cereal-based products, together with the decrease in consumption of the products that are more valuable in nutritional terms, such as meat and dairy products. Food substitutions took place not only inside certain groups of products, but also between groups of products (meat with cereals, for instance), out of the households' need to adjust their food expenditures in the situation of real incomes diminution (Petrovici and Ritson, 2000).

Subsequently, in the period of accession preparation to the European Union, and in the post-accession period, meat and dairy consumption increased, but the still low incomes resulted in a very high share of food expenditures in the household budget, in parallel with the relatively low dietary diversity, low consumption of fresh fruit and vegetables and high consumption of animal fat. An important part of the food consumed by households comes from the own produced food and this is especially true for rural households. The difficult situation from an household economic point of view due to the severe reduction in incomes, led to the increase in the share of consumption from own resources. The transfers of products from the rural to the urban households from the same family continue to represent a cultural pattern, and in the situations of crisis even a survival strategy for extended families.

Due to this reason, the investigation of food diversity in Romania cannot be made by exclusively applying the methodology specific to the developed countries, where most food products are bought, as this would exclude the food consumption from own resources, the contribution of which is quite significant for certain households. The present research work applied food diversity measurement tools for a data set obtained from the Household Budget Surveys for the first quarter of the year 2011, both for the amount of products bought by the households and separately for the amount of products effectively consumed on the households, in order to highlight the differences between the results of the two approaches.

Numerous approaches link dietary diversity to the level of incomes (Jackson, 1984). Thus, in the situation when the level of incomes is low, only a subset of available foodstuffs is bought. This pattern is known as the hierarchic demand system. The higher the level of consumption, the larger the number of products that go to the consumer's basket.Most studies dedicated to the developed countries reveal the positive correlation between diversity (measured by the Herfindahlindex or the entropy index) and the level of incomes, measured by the real income per capita. One of these studies (Lee and Brown, 1989), where consumer demand for food diversity is measured by the entropy and Simpson indices for budget share, show that consumer demand for food diversity is related to total food expenditures and household size and composition.

The econometric models by which the dietary diversity in the developed countries was investigated, for instance in Germany (Thiele and Weiss, 2003), reveal that dietary diversity is influenced by the household socio-economic characteristics, by income in the first place, then by the household size and composition, mainly the number of children 7 – 17 years old, the residence area and the size of the locality where the household is located. Dietary diversity decreases with the age of household members (up to 46 years), to moderately increase afterwards, in general the relationship being non-linear. The farmer households feature lower diversity for the purchased products, as certain foodstuffs are produced on their own households.

While in the consumption pattern of developed countries, in nutritional terms, it is not the variety between the groups of products that is mostly important, but rather the variety between the individual products, in the less developed countries the diversity between groups of food products can be more important than the diversity of products as such, which could belong to the same group (Swindale and Bilinsky, 2006). At the same time, in the case of subsistence economies, a positive influence upon food diversity on the rural households is brought by the household's access to the agricultural resources (Taruvinga et al., 2013).

Recent studies in the New Member States of EU, including Romania, dedicated to dietary diversity, measured by the Count Measure and the Transformed Berry Index, indicates that food diversity is income elastic (Cockx et al., 2015; Cupak et al., 2014; Alexandri and Pauna, 2015, Alexandri and Kevorchian, 2015). The gender and occupational status of the household head play an important role, as female-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

headed households have significantly higher levels of food diversity and self-employment in agriculture decreases diversity measured by food expenditures. The results further indicate a significantly positive effect for the presence of young children.

METHODOLOGY

Romania has some particularities in terms of consumption when compared to other similar countries. Almost half of the population live in rural areas, and a large percentage of them are self-employed in subsistence agriculture. Besides the obvious poverty aspects of this occupation, it means that a large share of the households' food consumption is not transacted on the market but is produced in-house. The effect of self-consumption on diversity is not very easy to assess, households might use the additional resources available to them for buying other food products (ambiguous effect on diversity), but they could equally buy non-food products (diversity decreases). This is why authors are interested to see how the determinants of diversity vary when the purchased food quantities are considered and when the actual food consumption are considered, and in order to do so, it was estimated the same diversity function for both data sets.

The diversity measure that we have used in the paper is the Transformed Berry Index (TBI) which is computed using the share of expenditure for all purchased food products. We have computed two indices one based on the actual food purchased by the household and the second based on the actual household consumption. In the case of actual consumption, for each food product which originates from own production a price was imputed, equal tothe price of the purchased product in the same household if available, or the average sample price for that product if that food item was not purchased by the household.

The Berry Index (BI) is constructed by adding the square of the share of expenditure for all food products:

$$BI = 1 - \sum_{i=1}^{n} \left(\frac{x_i}{X} \right)^2$$

where: x_i is the expenditure on the i product and X is the total food expenditure. Typically, the dependent variable in a regression is the transformed Berry Index (TBI) which is computed from the BI as follows:

$$TBI = \ln \left(\frac{BI}{1 - BI} \right)$$

DATA AND ESTIMATION RESULTS

We use the Household Budget Survey for first quarter of the 2011 (7843 households). The survey contains detailed information on the composition of the household like the age of the members, education level, occupational status, etc. as well as information on the consumption and income in the month of the interview. The survey includes 106 records for food expenditure/consumption, and this is the information

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

that is used for computing the diversity measures described above. Table 1 presents the values of TBI for the two approaches, purchased quantities and actual consumption.

The importance of taking into consideration the consumption of food coming from own resources of the household is revealed by the higher diversity in the case of estimating the demand on the basis of actual food consumption compared to the results for the purchased food quantities. Thus, the average number of effectively consumed food items is 36.2, while the number of purchased food items is 22.5. There are also relevant differences in the case of BI (0.93 versus 0.88) and TBI (2.72 versus 2.22), with higher values for actual food consumption compared to purchased food quantities.

The graphs in Appendix A plot the relationship between TBI and the age of the household head in the case of the expenditure based TBI (Figure 1) and actual consumption based TBI (Figure 2). The graphs indicate the importance of selecting the appropriate measure of diversity. Since the importance of own produced goods in total consumption differs from urban to rural households, the diversity gap between urban and rural households is greatly diminished when appropriately defining the household consumption. On the other hand, it does not appear that the age of the household is an important determinant of the food diversity for a given household.

The other graphs in the same Appendix A present the dependence of the expenditure based TBI (Figure 3) and actual consumption based TBI (Figure 4) as a function of the total household income. The graphs use nonparametric methods and their shortcomings are evident on the graph, due to the scarcity of the data, the method is not very reliable at both ends of the data. As expected there is some increase in diversity due to the increase in household income both in the case of urban and rural households. Again, the gap between the rural and urban household diversity diminishes significantly when the diversity measure based on actual consumption is employed. There seems that the relationship between income and food diversity is less elastic when using actual consumption measures in comparison to expenditure measures.

The equations estimated have as dependent variable the Transformed Berry Index (TBI) measured based on the purchased goods and on the effective consumption. The explanatory variables used are: the logarithm of the household income, in order to assess the elasticity of the diversity with respect to income, information on the household composition, the characteristics of the household head, and information on the residence area. The household composition variables are the number of household members and the number of children. The household characteristics that are included in the equation are age, education, occupational status. In terms of residence, we have included a dummy for the urban households, the county of residence. In addition, the education of the household head was interacted with the residence area (urban/rural) in order to assess whether the educated/uneducated urban households made different choices in terms of diversity in comparison to the educated/ uneducated rural households.

Table 1. Statistics of the Transformed Berry Index

Variable	Obs.	Mean	Std. Dev.	Min	Max
Actual food consumption					
TBI	7843	2.724478	0.38573	0.09713	3.708334
Purchased food quantities					
TBI	7835	2.2217	0.607214	-1.17966	3.531456

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

By estimating the two regressions the goal was to understand how distorted the results would be if one fail to take into account the fact that numerous households are able to consumed foods which are produced internally. The output results for the two TBI computed as explained above are presented in Appendix B (see Table 2).

REGRESSION ON TRANSFORMED BERRY INDEX

A very important determinant of diversity is household income. As expected, in both regressions the food diversity increases with the increase in income, but the TBI based on actual food consumption is less elastic than the TBI based on purchased food quantities, indicating that one might arrive to misleading results if one does not take into account the actual food consumption and looks only at the purchased food consumption.

The education level in the case of the urban households is important in the determination of TBI diversity. In both regressions, any education means higher diversity in comparison to the omitted category which is no education, but again the importance of education on diversity is misleading if one analysis the diversity computed based on the purchased foods. This time the coefficients are five times as big as the correct ones, falsely indicating that higher educated urban households are opting for a more diverse diet. The rural education level is not significantly affecting the diversity level of the household. It appears that no education for the household heads means less diversity. There are certain levels of education that seem to be associated with higher TBI diversity (before university studies).

As regards the occupational status of the household head, housewives are associated with lower diversity of food. The age of the household head does not appear to have a significant effect on the food diversity of the household, ceteris paribus. A female household head has a positive influence on the TBI measure, both in the case of purchases and of actual consumption.

Household composition greatly affects the TBI diversity, the increase in the number of members decreases diversity, but if the household has children the diversity is increased. As before, the effect on diversity of household size is overvalued by the TBI based on purchased goods.

There is some indication that cultural differences may affect the food diversity of households. There are some counties which appear to be associated with higher or lower food diversity. TBI measure of diversity is higher for the households located in developed counties and lower in less developed counties.

CONCLUSION

Romania has some particularities in terms of consumption when compared to other similar countries. A large percentage of rural population are self-employed in subsistence agriculture. The investigation of food diversity in Romania cannot be made by exclusively applying the methodology specific to the developed countries, where most food products are bought, as this would exclude the food consumption from own resources, the contribution of which is quite significant for certain households.

The present research work applied a food diversity measurement tool, Transformed Berry Index (TBI), on a Household Budget Surveys data set for the first quarter of the year 2011. TBI was computed for the amount of products bought by the households and separately for the amount of products effectively consumed on the households, in order to highlight the differences between the results of the two approaches.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

There are some important differences in the food diversity of the actual food consumption in comparison to the purchased food quantities. The TBI diversity is more elastic with respect to income in the case of purchased food quantities than in the case of actual food consumption, indicating that one obtains misleading results if one is not careful in the definition of the diversity. A female household head has a positive influence on the TBI measure, both in the case of purchases and of consumption. The education level seems to be important in the determination of TBI diversity only in the case of the urban households. Household composition greatly affects the TBI diversity, the increase in the number of members decreases diversity (both for purchases and consumption) but if the members are children, diversity increase. Food diversity does not seem to be influenced by the residence area (urban vs. rural) in any of the two approaches. Yet TBI measure of diversity is higher for the households located in developed counties and lower in less developed counties.

ACKNOWLEDGMENT

The research leading to these results has received funding from the European Union's Seventh Framework Program under Grant Agreement no. 290693 (FoodSecure) and from UEFISCDI (Romania) under contract 198/EU/2012.

Chapter 36
Simulation-Based Approaches for Ecological Niche Modelling: A Geospatial Reference

Anusheema Chakraborty
TERI University, India

P K Joshi
Jawaharlal Nehru University, India

ABSTRACT

Over recent years, many modelling approaches have been used to map and monitor both present and potential distribution of species in the context of ecological niche-based conservation, especially in the face of global environmental change. Using different statistical techniques in a built-in geographic information system (GIS), the development of predictive species distribution models has extensively increased. This chapter introduces a geospatial reference to simulation-based approaches of ecological niche models. The chapter discusses various environmental modeling tools and simulation models available in open source domain used by scientific communities. As an effort of this chapter, we focus on the potential of using such experimental models for large-scale ecosystem modelling studies, highlighting opportunities of research, for a variety of bio-geographical applications. It would serve as a basis for beginners in ecology exploring this field of research, who can further contribute and develop such models to better understand the complex field of ecosystem studies.

INTRODUCTION

The knowledge of spatial distribution of species is essential, especially to investigate the species' realized and fundamental niches. The understanding of this species-environment relationship is central for many current research programmes in ecology and conservation under global change (climatic and environmental) and it is of great scientific and societal relevance. This realization of the importance of predictive modelling of species is crucial in the field of both conventional as well as applied ecological research. Over past few years, species distribution models have seen an impressive growth in its mod-

elling approaches in studies of biogeography, conservation biology, ecology, palaeo-ecology, wildlife management, and more recently, studying the effects of climate change (Table 1). Such an experimental modeling approach allows us to estimate species' ecological requirements (Araújo and Guisan, 2006), generally based on various hypothesis (Guisan and Zimmermann, 2000). The idea is to quantify correlation between known occurrence of species and features of the ecological and environmental landscape (Miller, 2010). These models are often termed as *species distribution models*, *climatic envelope models*, or, most commonly known as, *ecological niche-based models*. The aim of such models is to reconstruct empirically derived 'environmental profile' which can be used to estimate the *ecological space* of species and/or predict the geographical distribution of species (Peterson, 2006). This sort of useful predictive modelling technique has had overwhelming success in the recent past (Austin, 2007, 2002; Elith et al., 2006, 2002; Guisan and Thuiller, 2005; Guisan and Zimmermann, 2000; Peterson, 2006; Sinclair et al., 2010). However, despite widespread use of these models, conceptual ambiguities and the biotic as well as abiotic limiting constraints need to be clearly addressed before any practical application of these modeling results are made available (Araújo and Guisan, 2006; Dormann, 2007).

The predictive modelling of species is one of the vital components of applied research (geography and ecology). With the advancement in geographic information system (GIS) and other related technologies, increased availability of satellite-based remotely sensed data and myriad number of open source tools that have developed; this enables scientists to employ powerful and sophisticated means of species' distribution modelling. As a result of simultaneous development of parallel applications with considerably different objectives, this process referred here as 'ecological niche-based modelling' has been previously described as 'predictive vegetation mapping' (Franklin, 1995; Miller et al., 2007), 'predictive habitat distribution modeling' (Guisan and Zimmermann, 2000), 'bioclimatic envelope modeling' (Heikkinen et al., 2006; Pearson and Dawson, 2003), 'habitat suitability index mapping' (Brown et al., 2000; Roloff and Kernohan, 1999), 'habitat suitability modeling' (Hirzel et al., 2006, 2002), and 'niche modeling'

Table 1. Some of the uses of ecological niche-based models

Quantifying the environmental niche of species	Austin et al., 1990; Vetaas, 2002
Testing biogeographical, ecological and evolutionary hypotheses	Anderson et al., 2002; Graham et al., 2004; Leathwick, 1998

(Peterson, 2006; Stockwell, 2006), among other terms. The ecological niche-based models, for instance, have been used to study relationships between environmental factors and species richness (Nally and Fleishman, 2004), presence of species in landscape influenced by characteristics and spatial configuration of habitats (Araújo and Williams, 2000; Dormann et al., 2007; Ferrier et al., 2002b; Scotts and Drielsma, 2002), potential of invasive non-native species (Peterson, 2003), historical species' distributions (Hugall et al., 2002; Peterson et al., 2004) or species' distributions in future climates (Araújo et al., 2004; Bakkenes et al., 2002; Thomas et al., 2004; Thuiller et al., 2005; Woodin et al., 2013), and ecological and geographic differentiation of the distributions of closely-related species (Graham et al., 2004).

Another controversial usage of terms relates the concepts of 'habitat' and 'niche', which needs to be clarified by scientific researchers while conducting any predictive modelling studies on spatial distribution of species (Miller, 2010). Hence, what needs to be addressed is the urgency in rigorous assessments in this field of science to move forward with much transparency in the usage of terms (Kearney, 2006). Unambiguous interpretation of the aforementioned concepts requires explicit chosen assumptions and hypothesis about the spatial extent and spatial resolution of the areas that are measured; the types, mechanisms and effects of the biotic and abiotic interactions that may affect the distributions; the different roles that environmental and climate variables that can influence the presence and absence of species, and also the anthropogenic disturbances should be accounted in the niche definitions; and the scope of spatial displacements in ecological and evolutionary time frames.

The correlative ecological niche-based models often require little knowledge of the mechanistic links between species and its surrounding environment, which acts as an advantage for poorly studied taxa (Kearney and Porter, 2009). In many circumstances, this can be proven beneficial given the paucity in the amount of data available (Barbet–Massin et al., 2012), but otherwise, scientists employing ecological niche-based models should reflect more on their limitation of these approaches. The key issue in species distribution modeling is the selection of the explanatory variables to create species-environment profile that supposedly predicts the distribution and abundance of organisms (Dormann, 2007). Since the causal mechanism of species distribution is not readily quantifiable, we often resort to substitute and proxies (Minor and Urban, 2007). Table 2 summarizes the shortcomings of ecological niche-based models and species distribution projections. The most basic and fundamental constraint of the usage of such models is the understanding of physiological limitations of the species. Although, the field of physiological ecology is developing ever so quickly (Buckley et al., 2010; Helmuth et al., 2004), much still needs to be done to overcome the barrier of limiting behavioral, morphological, and physiological traits of species with GIS datasets (Kearney and Porter, 2009). In correlative modelling approaches, species occurrences information is linked with GIS built-in environment through different statistical techniques. In mechanistic modeling approaches, information on the functional traits of species is linked with GIS built-in environment through different models that explicitly capture key processes by which traits and habitat features interact to determine species-environment relationship.

In this chapter, we aim to review the various steps involved in predictive modeling of species, from the conceptual model formulation to species prediction and its application. After highlighting the major concerns on using such predictive models, we provide a basis for further developing the current existing ecological niche-based models. This state of the art technology, even though has been used considerably, with spectacular progress in dealing with the challenge of impacts of climate change; a better integration of these models with ecological theory can help to avoid the precluding use of these models in many theoretical and practical applications. We first define the concept of the term used from here on, *ecological niche-based models*, and provide an overview of the basic ecological theory and major assumptions

Table 2. Overview of problems associated with ecological niche-based models

General Species Distribution Model Issues
Causal drivers are rarely quantifiable.
Species may not be at equilibrium with environmental drivers
Limiting factors may differ throughout a species' range
Distribution patterns are governed by processes at multiple spatial scales
Extrapolation Issues
Identity of limiting factors may change with environmental change
Biotic interactions are probably affected by environmental changes
Genetic structure of species is likely to be affected by environmental changes
Trends may not be valid beyond the range of present data
Environmental change scenarios are spatially uncertain
Statistical Issues
Drivers have non-linear effects on species distribution patterns
Drivers interact in their effects
Causal drivers may be correlated with each other
Data points in space are non-independent (spatial autocorrelation)
Presence-absence data have low information content
Low sample size and parsimony may lead to inadequately simple models

Source: Dormann (2007).

used in the predictive modelling process. We outline the steps involved in making a niche-based model used in the field of applied ecology, and we identify issues and applications associated with new developments in this field. We then discuss some methodological issues involved, and the decisions that are made during the process of developing a model and its calibration, and the implications of such results in ecological conservation and management. We summarize this chapter by addressing the challenges that should be overcome keeping in mind the limitations of these models. To add to this, we also discuss niche conservatism across different time scales and spatial scales in order to suggest future direction of species distribution modelling.

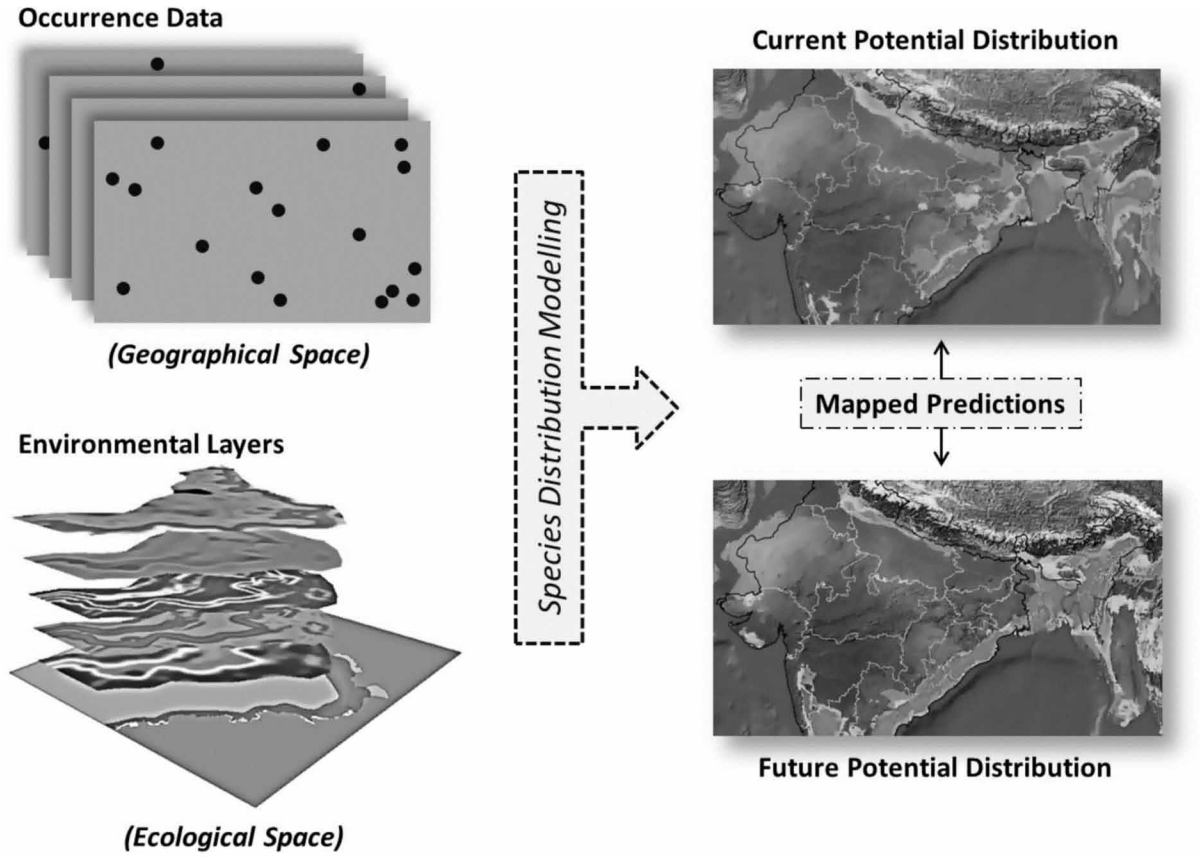
BACKGROUND

The ecological niche-based models attempts to provide detailed prediction of the distribution of species which is trained on its presence or abundance or absence or may be both, by relating it to environmental variables. For instance, the major concept central to predictive modelling is the distinction between geographic and ecological space, where geographic space is defined by either two-dimensional or three-dimensional space having information on species (such as occurrence records), and ecological space is a hypothetical multi-dimensional space which can be defined by sets of environmental layers (Figure 1).

In the field of ecology, any framework will have three basic major components for the statistical modelling process; namely,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. An example showing relationship between species and environmental data, and predictive modelling (current and future) of species using any set environmental variables



1. Ecological model,
2. Data model, and
3. Statistical model (Austin, 2002).

The ecological information to be used or tested in the study would be comprised in the ecological model. The data model would consist of the information regarding data collection and its pre- and post-processing. The statistical model would involve the choices of statistical method being employed, the error basis function and other significant tests to be conducted. The models interact with each other and determine the success or failure of any statistical predictive species distribution modelling process.

The ecological niche-based models are empirical models which mainly relate field observations with environmental variables; based on statistical or theoretical surfaces (Guisan and Zimmermann, 2000). The information about species data can simply be the presence, presence-absence, absence or abundance observations based on either random or stratified field sampling, or historical observations (Guisan and Thuiller, 2005). The environmental variables, however, can have direct or indirect influence on the species, optimally chosen to reflect the three foremost types of influences on the species, such as,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Limiting factors (or regulators),
2. Disturbances, and
3. Resources.

These relationships between the species in study and its overall environment can cause different geographical distribution patterns that needs to be observed at different temporal and spatial scales (Figure 1), often in a hierarchical manner (Pearson et al., 2004) (Figure 2).

For robust prediction of distribution of species, the understanding of the elements that can limit geographical range of species is crucial. The different statistical techniques used in the ecological niche-based models analyze organisms and its spatial existence in the ecosystems. These models vary significantly in scope and complexity. The distribution of species is intertwined with myriad number of climatic and environmental factors, which lead to the presence of a species at a particular geographical location. The niche-based modeling involves two fundamental steps; *first*, estimate the relationship among species in a particular area with respect to its biotic and abiotic conditions and *second*, forecast changes in the spe-

cies' distribution in response to any environmental change. Some species distribution models strategies predict changes in the geographical distribution of species by combining factors that relate to niches and suitable environmental surroundings with the presence and abundance of species in a single modeling framework. In contrast to this archetype, a pure niche-based model will first estimate suitability on the basis of current environmental information. This kind of niche model is then applied to predict future conditions to estimate the potential areas suitable for that particular species' growth, which can serve as a critical input for a spatially explicit simulations (Anderson, 2013). The distribution and abundance of any species', however, can be influenced by many ecological and evolutionary processes, which may or may not be limited to a species' niche (Figure 3).

The niche of any species' can be predicted through either correlative or mechanistic models (Table 3); lately, efforts have been attempted to successfully link them (Kearney and Porter, 2009). Mechanistic models are directly on physiological and behavioral tolerances. However, these models can be quite dif-

Figure 3. Major ecological processes can be captured by niche-based models. These processes may or may not include biotic interactions (realized niche vs. fundamental niche).

Table 3. A comparison of mechanistic and correlative approaches to species distribution modelling

	Mechanistic (Physiological) Approaches	Correlative (Statistical) Approaches	Advantages of Mechanistic Approaches	Advantages of Correlative Approaches
Conceptualization				
Theoretical basis	Energy-mass balance, climate space, mechanistic conceptualization of the Hutchinsonian niche	Probability, statistical theory, pattern recognition, often considered in the context of the Hutchinsonian niche or habitat concepts	Grounded in physico-chemical principles, provides mechanistic understanding of underlying processes	Can implicitly incorporate any process, biotic or abiotic, statistically associated with the independent variables, can be used to develop hypotheses about underlying processes
Model selection	Prescribed (variants of an energy balance equation)	Flexible (numerous algorithms and variable selection procedures, e.g. regression, maximum entropy, polynomial ⁄linear terms)	Energy⁄mass balance equation provides a common frame of reference	Can be more easily tailored to fit available data
Generality (transferability) and precision	High generality across environments but potentially low precision	Local analysis often with high precision, although choice of variables and fitting strategy can be tailored for emphasizing generality or precision	Scope of applications extends to non-equilibrium/novel circumstances	More likely to capture a limiting processes, less likely to overestimate potential range
Data Requirements				
Species data	Functional traits, (morphology physiological and behavioural responses)	Occurrence data (presence only, presence⁄absence or abundance records)	Directly applies physiological understanding to range prediction. Can be applied when occurrence data is limited or in non-equilibrium⁄novel circumstances	Exploits a more commonly available data source
Spatial data	Prescribed – energy balance equations demand specific independent variables	Flexible	Less subjectivity in variable selection	While directly related (proximal) environmental variables are preferable, can exploit a wider range of proxy spatial data types
Scale	Prescribed – highly proximal (scale of an individual organism)	Flexible	Less subjectivity in variable selection	Can use data sets of a wider range of scales, can capture processes at different scales within a single model
Model Fitting				
Parameters	Trait values, enegry/mass transfer coefficients, physiological response curves (may themselves be parameterized statistically)	Dimensionless coefficients	Robust because parameters are estimated independently of the (geographical range⁄abundance) data	Pragmatic because parameters are estimated from a single dataset within a single analytical framework
Geographical variation (plastic and genetic)	Explicit	Implicit	Permits assessments of the degree of geographical variation and inference on its adaptive significance	Easier to incorporate geographical variation because it is indirectly represented in the occurrence data
Evolutionary change	Explicit	Implicit	Permits explicit consideration of evolution, avoids confounding with other processes that may alter environmental associations through time	Can exploit readily available datasets to set up testable hypotheses about the past evolution of traits
Inference				
Output	Fitness components (survival, performance, development, growth and reproductive capacity)	Dimensionless habitat suitability indices or estimates of probability of occurrence or abundance	Highly interpretable ecologically, may serve as input into other process models (e.g. dispersal)	Provides a simple output indirectly representing many different processes
Validation and evaluation	Validation through independent empirical studies (field and laboratory), e.g. of behaviour, body temperature, energy and water turnover, evaluation against independently observed occurrence	Fit evaluated against original occurrence input data, subsets of original data left aside for validation, or (rarely) independent data on distribution and abundance	Biologically grounded and independent of the data used to derive the model	Often easier because model construction and validation⁄evaluation uses a single, readily available dataset and analytical framework

ficult to be implemented give the amount of extensive data it requires, along with cost factors. Hence, for most studies related to distribution mapping of species, correlative approaches are used. This can be conducted due to relatively easily available and accessible online and offline data sources regarding species occurrences and environmental conditions. Nonetheless, the challenges for building an ecological niche-based model differ substantially between mechanistic and correlative approaches; however, many relevant principles hold true for both the approaches (Anderson, 2013).

In this chapter, we aim to sketch a conceptual overview of niche and niche-based models in the field of ecological modelling. In order to do so, the theoretical paradigm of the selection criteria of the niche-based models while considering the methodological constraints is highlighted in the upcoming sections.

Niche Concept and Niche-Based Models

The notion of 'ecological niche' is central to ecology of an organism, where the ecological properties of species and area of geographical distribution is related (Grinnell, 1917; James et al., 1984). Over the years, scientists are trying to estimate distributional area of species, by calculating 'environmental' or 'ecological' niches (Guisan and Zimmermann, 2000; Peterson, 2006). The foundation of niche modeling may vary depending on the application of niche concept being applied, namely, Grinnellian concept, Eltonian concept and Hutchinsonian concept of ecological niches (Table 4).

The term 'niche' is used interchangeably by the modelers; although, much has been written about its different interpretations, both in general (Chase and Leibold, 2003; Pulliam, 2000) and as applied to ecological niche-based models in particular (Araújo and Guisan, 2006; Austin, 2002; Franklin, 2010; Guisan and Zimmermann, 2000; Kearney, 2006; Soberón and Peterson, 2005). It is, therefore, important to clarify which ecological niche concepts are being translated in the species distribution modeling process.

Model Selection and Methodological Considerations

There can be many modeling approaches, consequently, resulting in different outputs, depending upon the selection of the constructed ecological niche-based model. These modeling approaches could vary

Table 4. Summary of division of niche concepts

Niche Perspective	Relevant Environmental Variables	Generalities Regarding Scale	Nature of Driving Factors	Relationship to Population Growth Rate	Relevant Modeling Approach
Grinnellian niche	Variables not affected by the presence of the focal species	Coarser grains; geographic extents	Density-independent	Related to intrinsic population growth rate	Static models
Eltonian niche	Variables affected by the presence of the focal species	Finer grains; local extents	Density-dependent	Related to instantaneous population growth rate	Dynamic models
Hutchinsonian niche	Variables affected by the presence of the focal species	Spatial grains; regional to continental extents	Density-dependent	Related to instantaneous population growth rate	Static models

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

from the input sources itself, depending on the amount of data available. For instance, the model may be constructed from species occurrence points (presence; or presence/absence information) which acts as the dependent variable, and along with the required available environmental data of the same or approximately same region, which act as the independent variables. This kind of approach will lead to two types of common outputs: binary classification of geographical region as being within or outside the species distribution, and continuous or probabilistic distribution of species. The parameters can be further projected using future climate scenarios to develop and map the predicted future distribution of the species.

Predicting the distribution of species has gone through different phases in history:

1. Based on empirical data, non-spatial statistical quantification of the species–environment relationship,
2. Expert-based spatial modelling of distribution of species (non-statistical, non-empirical), and
3. Modelling of distribution of species through spatially explicit statistical and empirical models (Guisan and Thuiller, 2005).

With the evolvement of this field, it can be seen that there is little agreement on appropriate data, methodology or even interpretation, and mostly, there is little discussion behind the conceptual framework on which the predictive ecological niche-based model is based.

Even for comparison, the different methods of modeling approaches rarely use the same type of data (whether it is the abundance or presence/absence information), or type of the regression method being applied (for example, multiple linear versus curvi-linear), or even the usage of common set of predictor variables. Most of the evaluation of comparisons among the different set of modeling approaches by scientists lies in how the methods are being applied, i.e. model parameterization (Austin, 2007). Although, the basic paradigm for any modelling approach consists of commonly agreed set of evidences (that is, presence or absence data on species), a conceptual framework (viz. the niche theory to be considered), set number of variable that can be considered (climate and environmental condition of species distribution) and method of modeling the distribution (for example, logistic regression) (Guisan and Zimmermann, 2000).

Nonetheless, the ecological niche-based models, even with different levels of complexity fit within a basic framework. For instance, it either is using only climate as independent variables or/along with the usage of biophysical variables. The least common used models generally include the models that are constructed from physiological needs of different species (Kearney and Porter, 2009), rather than more commonly used species–climate models that are based on the distributional data.

Selecting the model best or most appropriate using the most influential predictors is crucial. Shortcomings in the selection procedure have been recognized and in response, newer approaches have been implemented to better predict species distributions (Guisan and Thuiller, 2005). These ecological niche-based distribution models can be developed using a variety of algorithms, including heuristic models (for example, BIOCLIM—Busby, 1991), statistical models (such as, generalized additive models, i.e., GAMs—Guisan et al., 2002), combinatorial optimization (e.g., genetic algorithm for rule set production, i.e., GARP—Stockwell, 1999) and machine learning (for instance, artificial neural network, ANN—Hilbert and Ostendorf, 2001; or, maximum entropy, MAXENT—Phillips et al., 2006). Studies have used multiple models to extrapolate global extinction rates from climate change (Thomas et al., 2004; Woodin et al., 2013). Table 5 lists the most of different published predictive models for studying species-specific information. One can conclude that each modeling approach has its own merits and demerits,

P – Presence; A – Absence.

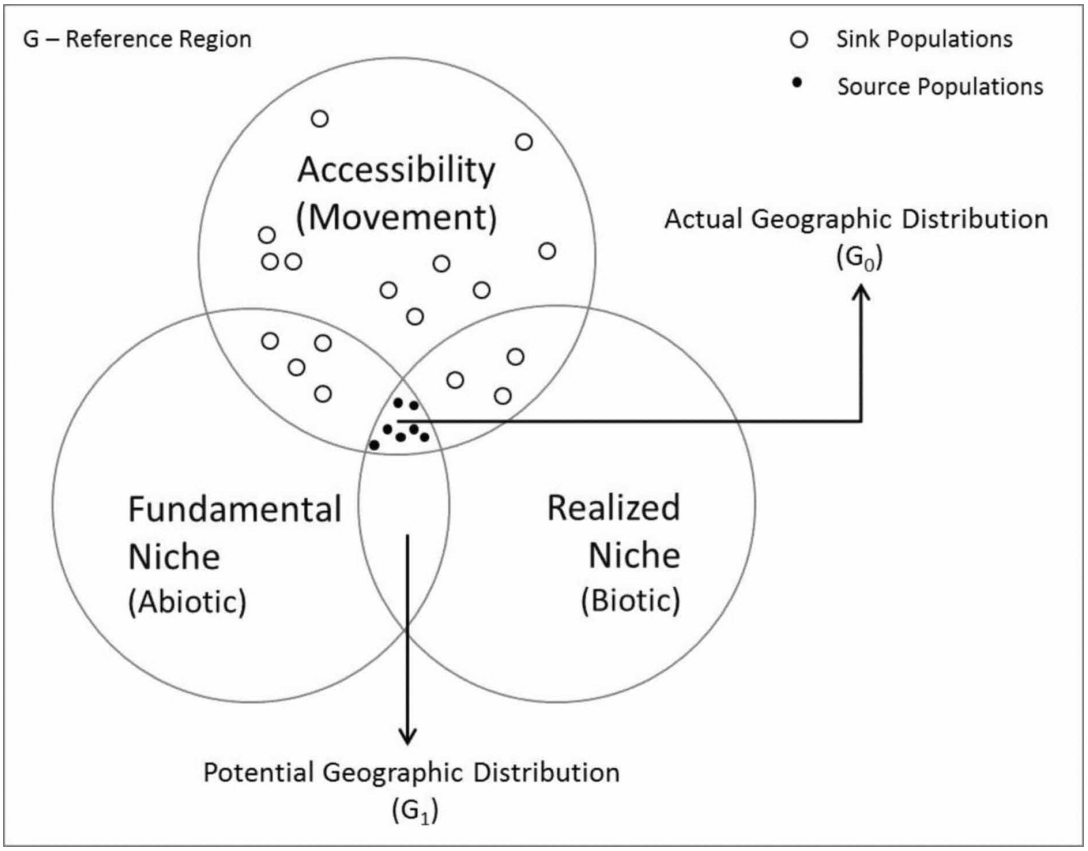
and accordingly has its own important strengths and weaknesses. In order to test the performance of any modeling approach, it can be generally evaluated using a test or validation datasets (Elith et al., 2006; Hijmans, 2012; Wisz et al., 2008). What can be achieved, or hoped to be achieved, is the use of different set of modelling approaches, and identification of significant interactions among the species and the environment to better understand the complexity in nature.

Functionalities and Possibilities

At times, bearing in mind the availability of data and the landscape constraints, as researchers we also need to delimit the scope and extent of our analysis. While doing so, one needs to also consider the abiotic, biotic and movement factors (‘the BAM diagram’) that may or may not limit the distributions of species in geographical space (Figure 4). This kind of illustration of the scale-dependent relationship is critical for identifying the nature of differences in predicting the distribution of species. These three interacting set of factors,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. A simplified version of the BAM diagram; the distribution of species corresponds to three sets of factors: abiotic niche (A), biotic niche (B), and, accessibility or movement (M). A and B roughly correspond to the fundamental ecological niche (A) and the realized ecological niche (A ∩ B, here termed the potential geographic distribution). The area corresponding involvement of all the three set of factors (A ∩ B ∩ M) is the actual geographic distribution of species. [Note: The absence of species can be due to incorrect environment, lack of dispersal capacity; and also due to both incorrect conditions and limited dispersal (it can be present anywhere, depending on the condition)].
Source: Adapted from Soberón and Peterson (2005).



1. Abiotic,
2. Biotic, and
3. Movement factors, help us in anticipating the geographical distributions of organisms.

The basic requirements of most of the ecological-niche based models are the same. The set of applications that they have been used for have are summarized in Table 6. The first and foremost step is to understand the ecological requirements of the species by understanding its ecological dimensions relevant to the geographical distribution (Peterson, 2006). The second most important criteria is the knowledge on limiting factors that constitute the geographical space of any species should be clearly understood and categorized before applying any niche-based model for ecological studies. Depending on the availability of the data required, one can then select the appropriate best model for selecting the

Table 6. Summary of different uses of ecological niche-based models, and their requirements in terms of output and information

Quality of Interest	Understand Ecological Requirements of Species	Understand Biogeography and Dispersal Barriers	Find Unknown Populations	Find New Species	Identify Sites for Translocations and Reintroductions	Conservation Planning and Reserve System Design	Predict Effects of Habitat Loss	Predict Species' Invasions	Predict Climate Change Effects
Form of prediction (e.g., binary, ranked, absolute)	Any	Any	Any	Any	Absolute	Absolute	Any	Any	Any
Grain required	Any	Any	Population	Any	Individual-population	Individual-population	Any	Any	Any, but may be limited by resolution of climate change data sets
Causal variables needed, or surrogates OK?	Causal	Causal	Surrogates	Surrogates OK if within range; causal necessary if extrapolating	Surrogates OK if within range; causal necessary if extrapolating	Surrogates	Causal	Causal	Causal
Need model response curve or parameter retrieval	Yes	Yes	No	No	Useful, to avoid error	Useful, to avoid error	No	No	No
Error needs	Overall low error needed	Overall low error needed	Low omission (don't mind searching extra localities, but don't want to leave anything out)	Low omission (don't mind searching extra localities, but don't want to leave anything out)	Low commission (very high cost of errors)	Low commission (very high cost of errors)	Overall	Overall	Overall
Potential distributional model *versus* realized distribution?	Potential	Potential	Realized	Potential	Realized	Realized	Realized	Potential	Both
Uncertainty estimates needed?	No	No	No	No	Yes	Yes	No	No	No

Source: Peterson (2006).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

distribution model for predictive studies. The third basic requirement of any models would lie in the known and unknown population of species.

The in depth understanding of the ecological niche-based models functions and further possibilities will help in prioritizing areas based on the patterns of species' occurrences. This can help in establishing conservation sites accordingly to the most likely suitable or unsuitable sites for the species in study, depending on the case of management strategy that may be. The relatively easier applicability of the ecological niche-based models helps in identifying the framework that can be applied for conservation of the threatened or likely to be the threatened species in present as well as in future.

Assumptions and Statistical Stumbling Stones

Since the information on both species' occurrences and the environmental as well as climatic data is limited to either time or space, the species-environment relationship that is generated through these ecological niche-based models, it can only provide us a overview of the expected relationship. One of the convenient ways of working around such predictive modelling approaches is to assume that the species modeled would attain if not any complete but partial pseudo-equilibrium with its environment (Guisan and Thuiller, 2005).

The appropriate selection of the models for correlative niche modeling, both regarding records of the species' presence or absence, along with environmental variables assumes certain hypothesis. Much of the information regarding the environment and climatic parameters at the predictive species' site, show disagreement with the correlative niche modelling techniques found at presence records datasets (Anderson, 2013). To add to this, several statistical obstacles are also there when it comes to interpretation of these modelling results. The first and foremost factor that needs to be looked in details is the availability of data. The collection of data at different resolutions, during different time periods, along with collection under different taxonomic concepts and ecological hierarchies creates difficulty, depending on the purpose of niche modeling exercise. To integrate all the data available in one platform itself, is a big challenge and requires more specific dedicated analysis, unlike done otherwise.

The first challenge and the major assumption that is considered in most studies are the linear predictors used for species distribution (Dormann, 2007). For most ecological studies, one can safely accept non-linear effect of species abundance or performance to environmental variables (Austin, 2002). Likewise, few analysis attempt to investigate of species distributions with interactions among environmental drivers (Thuiller et al., 2003). The second most important assumption is disregarding the commonalities among interrelated drivers (Anderson, 2013; Dormann, 2007). Many a times, the predictive modelling approach fails to detect the species in the geographical space (whether or not it occupies those regions). The abiotic conditions that can be found in the species' occupied areas correspond to the species' occupied niche space, which is termed the *realized niche* in the analysis. Even if we assume that all occurrences of species represent demographic sources and the sampling was unbiased, the presence-only records may provide inadequate and/or inaccurate classifications of the species' *fundamental niche* for the examined abiotic variables. Therefore, we can conclude two major issues that contribute to the performance of ecological niche-based models:

1. The limited range of environmental conditions that exist in a study site; and
2. Non-equilibrium distributions of species (Anderson, 2013).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another ambiguity that may arise is the purpose of the modeling approach, where the estimates of the fundamental niche require clarity in the niche space assumption, that is, whether it is applicable to the study region (correlative niche modelling) or experiments (mechanistic niche modelling). Moreover, correlative niche models assume that presence records constitute unbiased samples, unlike mechanistic niche models. Table 7 summarizes these assumptions regarding occurrence data as the dispersal/demographic noise assumption, the biotic noise assumption, and the human noise assumption. Each assumption relates to the condition for a particular species in any given study site.

These descriptions clearly leave us a bleak impression on the current state of the art modelling approaches. However, it is known that species' distribution modelling has both potential for science and social science. Since the assumptions lead us to principally selecting the ecological niche-based model to be applied, one must acknowledge them clearly before concluding any solutions. If any such assumption is not clarified in a study, the niche model will automatically start accounting for incomplete or distorted predictive estimate of specie's geographical distribution. Despite the drawbacks, many insightful studies have been attempted to solve the above mentioned problems. Realizing these caveats is essential, as one may take up the endeavor to solve such ecological riddles.

FUTURE RESEARCH DIRECTIONS

Given the current need to improve our knowledge on the distribution of species in the era of global change, we need to address the issues in our modelling approaches. Consideration of few steps is crucial to successfully apply the practical solutions of such predictive modeling experiments. To further develop

Table 7. Four assumptions associated with data used in niche models estimating abiotic suitability for a species, with recommendations for correlative models of Grinnellian niches

Name of Assumption	Assumption	Consequences of Violation	Recommendations
Niche space assumption	The study contains the full range of conditions that the species can inhabit (for the examined abiotic variables)	The existing fundamental niche is smaller than the fundamental niche; the species' response is truncated for one or more abiotic variables	Use presence records from many portions of the species' range and over multiple time periods; examine response curves and detect truncations in calibration region
Dispersal/ demographic noise assumption	Factors related to dispersal, establishment, and persistence do not cause the species to occupy an environmentally biased subset of the abiotically suitable areas	The occupied niche space is smaller than the existing fundamental niche; the species' response is truncated and/or distorted for one or more abiotic variables	Use occurrence data (presence records and comparison data) only from regions where the species is at equilibrium with abiotic variables or where limitations caused by dispersal/ demography, biotic interactions, or human modifications do not cause the species to occupy an environmentally biased subset of the abiotically suitable areas
Biotic noise assumption	Biotic interactions do not cause the species to occupy an environmentally biased subset of the abiotically suitable areas	Same as above	
Human noise assumption	Human modifications of the environment do not cause the species to occupy an environmentally biased subset of the abiotically suitable areas	Same as above	

Source: Anderson (2013).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

these ecological niche-based models, few recommendations should be considered in such experiments and their projections. The first critical step would imply to understand the uncertainties involved with the outputs of predictive modeling of the distribution of species. The identification of the flaws causing major variability should be noted and accepted in the models. These assumptions include the quality of primary and secondary data being collected, the choice and collinearity of explanatory predictor variables, and type of statistical modelling approach considered (Dormann, 2007). The next step would involve efforts to compare the differences in outputs of the distribution models. Consideration of maximum possible abiotic and biotic factors accounting for the ecological processes is also important. Given the data availability, such factors can determine the performance of the niche models. And lastly, the validation of such predictive modeling exercise should be thoroughly conducted before jumping to conclusion on the geographical range of species distribution.

Although many studies have been using predictive ecological niche-based models for impacts studies on climate change and species conservation, recent studies suggest that their uses is in now resurfacing in theoretical ecology and evolution. However, given the pitfalls in this field of study, we need to be reasonable and therefore, further improve the methods. Species which require general environment to survive are preferably better candidates for such modeling studies. While species which require more specific explicit environment of survival, may not be best modeled with such species distribution models.

The future of this field of science lies in further developing the basic biological and ecological research tools. If our understanding and knowledge of the target species' ecology is clear, such predictive models can be very well utilized. We need to improve our modelling algorithms and try to use the best available method. Systematic collection of species distribution records is essential as it represents the basic requirement of any model. Even the collection of absences is valuable, because many modeling routines may require both absence and presence data information about the species. Both the geographic and environmental space should be well-sampled and surveyed for these niche models. The outputs of such studies should be regularly monitored especially while predicting future distribution of species. In this way, the models can be further validated and improved. While addressing the uncertainties explicitly, it should be communicated with other researchers, along with managers and policy makers, so as to put these models to better use. Whether it is the migration process, or the dynamics of species, or the incorporation of biotic interactions while modelling the functional traits and communities, it should be explored more in this field (Guisan and Thuiller, 2005). It would be interesting to see such efforts which can drastically influence the outputs and reliability of such modelling approaches.

CONCLUSION

Although there has been tremendous development that has been made on many aspects related to the building and evaluation of ecological niche-based models, focused future efforts should be considered for developing and standardized more robust modelling frameworks. This chapter points out the critical, but obvious issues that need to addressed. It may be pointed out that, although it may seem obvious, it has been neglected in the past. However, recent efforts have been made to improve such modelling frameworks, while keeping mind the uncertainties.

Many important basic concepts require deeper dwelling and understanding. Some of them are as follows:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. To explore the relationship between niche concepts and species distribution;
2. To assess the equilibrium or pseudo-equilibrium stages of modelled species; and
3. To investigate the degree to which competition among species can limit their geographical ranges along environmental gradients (Guisan and Thuiller, 2005).

Both information of time scale and spatial scale should be further enhanced to decrease the errors and uncertainties in ecological niche-based models.

Sources of biological data continue to expand, particularly for presence-only observations; environmental data are available at even finer spatial resolutions; and more complex modeling algorithms are being developed or becoming accessible to the SDM community. Each step taken in the species distribution modeling process involves a combination of assumptions and subjective decisions that propagate to affect the product, which is increasingly used to inform policy decisions. Given their current and potential use in a wide range of applications, these conceptual issues associated with the data and methods used need further study.

With this chapter, we try to highlight issues that can be identified in such simulation experiments of ecological niche-based models, in a geographic built-in environment. Whether it is the spatial autocorrelation, or paucity in the availability of data, there is still considerable debate that needs to be addressed. Although, we try to model scenarios of species' distribution based on simulated data, it can be proven most useful if the assumptions of niche concept and the environmental profile can be further elucidated. If the ecological niche-based models are used in forecasting studies, issues of ecological equilibrium theory and ecological niche conservatism should be answered prior to such exploration.

In conclusion, with this chapter, we critically assess different ecological modeling approaches. We focused on the potential of using such experimental models for large-scale ecosystem modeling studies. This can serve as a basis for the scientist and researcher interested ecological modeling, who can further contribute and develop such models to better understand the complex field of ecosystem studies. We urge the ecologists, geographers, bio-geographers, modelers, and biologists to work in unison and contribute in a much concentrated manner to further develop this field of scientific research. Along with this we also need initiatives to develop interfaces between the scientific interpretation and required generalization for policy analysis.

Chapter 37
Information Societies to Interactive Societies:
ICT Adoptions in the Agriculture Sector in Sri Lanka

Uvasara Dissanayeke
University of Peradeniya, Sri Lanka

H.V.A. Wickramasuriya
University of Peradeniya, Sri Lanka

ABSTRACT

Information is crucial for the development of any sector, including agriculture where information needs to be exchanged with farmers and other stakeholders quickly. Thus, efficient linkages for information sharing are essential. ICT innovations enable the shaping and reshaping of communication and interaction. Many of the technology driven information dissemination methods have been initiated by government, private, non-profit making bodies and independent research groups. This chapter explains the integration of ICT within Sri Lankan agriculture communities and how the focus is changing from information dissemination towards facilitating interactions among the stakeholders. The present status of agriculture information dissemination, including the ICT interventions is given. Prevailing issues and limitations in these ICT-based information dissemination approaches initiated by the different entities is explained, giving due recognition to various factors that have contributed to the adoption of ICT initiatives. The chapter ends outlining the possibilities for future focus on ICT activities in an agriculture information society.

AGRICULTURE INFORMATION SOCIETY

Agriculture plays an important role in the Sri Lankan economy. Agriculture provides a direct source of income for around 31% of the population (Central Bank of Sri Lanka, 2013b). The rural population in Sri Lanka is around 85% (World Bank, 2014), and agriculture is both a direct and indirect source of living for about 65% of the population who live in these rural areas. The contribution of agriculture to the country's gross domestic production is about 10.8% (Central Bank of Sri Lanka, 2013a).

Right information delivered at the right time is vital for successful farming. Farmers need information regarding crop growth, pest and disease problems, and marketing. A study conducted by De Silva and Ratnadiwakara (2008) reports that information search cost accounts for 11% of the total cost, and nearly 70% of the transaction cost. Information search costs arises from the need to obtain information related to decisions such as the crops to plant, agronomic practices, pest and disease identification and management, harvesting, storage and post-harvest practices. Information systems which provide the required information are described in Table 1. Transaction costs are incurred in transactions related to the purchase of inputs such as seed, fertilizer, and pesticides, and also in the sale of produce. Additional transaction costs are seen when farmers deal with external agents indirectly through Farmer Organizations. In such instances transaction costs arise between farmers and the Farmer Organizations, and also between the Farmer Organizations and the external agencies such as input suppliers or buyers. Appropriate information systems can reduce the transaction costs incurred in such situations.

At present most of the information obtained, and transactions conducted are through traditional mechanisms. Generally in Sri Lanka farmers have been obtaining information through the farm visits of, or the office visits to, extension agents. Thus, if the time spent by the farmers for this activity is taken also into account appropriately the information cost is bound to increase. Furthermore, it is noted that this cost analysis is from the perspective of the farmer. When the time and other associated cost, such as the transport cost, of the extension agent is also taken into account the actual cost of such information would vastly increase. Hence mechanisms which obviate the need for such meetings could reduce the associated information costs. ICT mechanisms are very well positioned for this, thus being able to reduce this information costs. It is not argued that ICT mechanisms are appropriate for all situations. Rather, that it would be appropriate in many situations. The reasons for such an assertion are as follows. Unlike in mass communication, or even group communication methods adopted in agricultural extension, the information provided through ICT mechanisms could be tailored to the particular requirements of the specific farmer, as in the traditional individual extension methods. For example, the requirements for a particular crop, or variety, could be provided. The needed information could be obtained irrespective of the location of the farmer. Transport and time costs too would be almost eliminated. Interactivity, which is not generally used or possible through many other information providing channels, could also be used. For example, Smartphones could be used to take photographs of field problems such as pests or diseases which are sent for possible identification, after which requests for further information, or recommendations for the management of such problems, or the links to the appropriate information which is already available could be sent back to the farmer. The added advantage of this mechanism lies in the fact that if the first level of personnel handling such requests are unable to provide the information that they can channel it to increasingly higher levels of experts, according to the nature of the question, and then respond to the information seeker. Access to such higher levels of expertise would not normally be possible for most information seekers. Even in instances where such access may be possible, the time taken for access to personnel and awaiting their response could possibly lead to a situation where the response is of lesser value due to the associated delays. For example, measures against a pest or disease attack should be taken as quickly as possible. Even a delay of a few days could lead to substantial losses. A further advantage lies in the fact that the proficiency of the limited experts could be more widely utilized to service a larger group of people. Thus, the expertise of officers based in central stations could be utilized from almost any area of the country.

There are many traditional sources of agricultural information as seen in Table 1. Technical advice was traditionally provided by extension agents, including subject matter specialists, attached to various

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Agriculture information sources which cater for farmers information needs

Sources of Information	Information Needs
Input suppliers (Agro chemical merchants)	• Seeds and planting materials • Agro chemicals: fertilizers, pesticides, herbicides • Agriculture equipment, machinery
Markets /buyers	• Market prices • Places
Extension agents	• Technical advice • Training opportunities, demonstrations, plant Clinic • Government subsidy schemes, loans
Subject matter experts and researchers	• Solutions for farm management practices • Latest innovations
Mass media	• Weather information • Market prices
Farmer organization	• Cultivation plans • Water availability
1920 Agri advisory service	• Technical information related to farming • Purchasing inputs • Marketing

Sources (Dissanayeke & Wanigasundera, 2014; Wijerathna, 2011; Dissanayake, Wijekoon, Madana, & Wickramasinghe, 2009)

government departments and institutions. For example, the Department of Agriculture had a vast network of field level extension agents who catered to the needs of farmers in the food crop sector. However, it is noted that this coverage has been greatly diminished due to the transfer of the field level extension agents to another department. Technical advice on crops such as tea, rubber and coconut, as well as information on subsidy schemes are provided by different agencies related to these crops. Whilst these agencies use mass media too, the 1920 Agri-Advisory Service is a telephone based service introduced by the Dept. of Agriculture. However, as seen in Table 1, apart from these sources there are numerous other information providers too. Though information suppliers like input suppliers are likely to be biased, farmers obtain information from them due to the relative convenience. Whilst physical markets also provide marketing information, its range and accuracy is certainly limited. Accordingly, most of the traditional information sources could be vastly improved as seen by the steps already taken, as given in this chapter, and also by initiatives that could be taken in the future.

Information Needs of the Farmers

As mentioned previously, farmers need information throughout the cultivation process until they harvest and sell the products. De Silva and Ratnadiwakara (2008) proposed a six stage value chain for agriculture information starting from the decision on which crop to cultivate until selling the harvest. During the first stage the farmers have to decide on several aspects such as which crop to cultivate, the extent of land to be allocated for a particular crop, when to start cultivation, and making arrangements for working capital. Selecting a suitable crop would be depending on many factors such as climatic conditions, season of the year, availability of seed and other raw materials including labour and, fertilizer.

The second stage is where they purchase or use their own seeds saved from previous cultivations. Land preparation and planting is regarded as the third stage in which plant beds are prepared and sub-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

sequently planting seeds. During this stage the farmers have to decide on labour; whether to hire or use family labour, and use of machinery in land preparation.

Growing is the fourth stage in the agriculture value chain, where farmers are faced with issues such as managing pest attacks, diseases, irrigation, fertilizer, weeding. During this stage, the farmers look for fertilizer and subsidy programmes. In the next stage farmers engage in harvesting, sorting and packing. During this period they have to find labour for harvesting, storing spaces. They would also look up to information on post-harvest management and value addition too. Selling represents the last stage of the value chain in which farmers have to make decisions on market prices, places to sell the produce and transport arrangements. Accordingly a farmer has to take numerous decisions regarding the cultivation of crops. Thus, a farmer is basically a manager who has to make numerous decisions from selection of crop to ultimate sale of produce. Thus, decisions support systems, which go beyond just the provision of generalized technical information, are needed for commercial farmers. A pilot product for such a decision support systems for the vegetable sector has been developed by one of the co-authors with the collaboration of many other technical personnel. It provides information to help decide what vegetable to grow, seed requirements, cultivation practices, input requirements including labour for specific growing areas, pest and disease control measures, harvesting and post-harvesting practices. The costs and returns of all these practices, as well as the cash flows and the overall income and expenditure are provided to facilitate farmers to take decisions.

In certain areas of the country farmers make collective decisions at the Farmer Organization level with respect to field and irrigation channel maintenance activities, as well as cultivation aspects such as cultivation dates and crops. Collective decisions are especially important when dealing with external agencies as in agreements related to Forward Sales Contracts, where Farmer Organizations could agree to provide a crop to a particular purchaser at agreed upon prices. In such instance access to market information to negotiate prices would help in reducing associated transaction costs. Furthermore, such systems should facilitate communication between the Farmer Organizations, or network/s of Farmer organizations, and the produce buyers. As Farmer Organizations make collective purchases of inputs, such as fertilizer, these information systems should enable the aforementioned communication abilities with potential suppliers of agricultural inputs too.

As indicated the need for information in agriculture is very wide. This need is further expanded as it includes a very large number of entities requiring widely differing types of information. In terms of sectors it needs to cater to the sectors such as crop, animal husbandry, and fisheries. Within a sector such as the crop sector it needs to cater to differing segments such as the food crop sector, the plantation sector, the protected agriculture sector, the floriculture sector, and the food processing sector. Within each segment it needs to provide information on crop and variety selection, cultivation practices, pest and disease management, harvesting and post-harvest practices as well as marketing information. Due to this diversity it is essential that an overall strategy to provide agricultural information take cognizance of this fact. Accordingly, multiple initiatives, rather than just a few, are needed by different players to provide the information requirements in agriculture. Institutions, which have developed strong ICT capabilities and initiatives, such as the Department of Agriculture, could be supported to provide advice and training to other agriculture organizations to develop their own information services. Such a mechanism should provide for new initiatives from the different organizations, to enable adaptation and innovation to develop and deliver products most suited for their clientele.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Arising from the diversity of requirements noted above, another perspective is possible in terms of Agricultural Information Systems. Roling (1988) in his work on Agricultural Knowledge Systems identified many sub-systems such as the research, dissemination (or extension), user (or farmer), training, input supply/ marketing, policy, and NGO sub-systems. This view broadens the scope of agricultural information systems, indicating user needs beyond that of the farmer. An overall information strategy for the agricultural sector certainly needs to take account of all these needs. Clearly priority areas of importance, and possibility, need to be the initial initiatives. However, an overall strategy should not get bogged down only with the initial initiatives, and their maintenance, but also forge ahead to meet the other information requirements too.

Traditional Systems of Agriculture Extension

Traditionally, the scientific research and new knowledge related to agricultural practices were delivered to farmers through a process of farmer education, aiming to increase produce and productivity of agriculture. Provision of such information can lead to improved yields (Rosegrant & Cline, 2003). This process of disseminating agriculture information is known as *agricultural extension* whilst a village bound extension agents typically play the main role in bridging the gap between research and practice. A variety of teaching methods, such as individual methods e.g farm visits, group methods e.g. demonstrations, and mass methods e.g. television and radio programmes are used to educate the beneficiaries.

In a given agriculture education system, learning could take place along four paradigms; technology transfer, advisory work, human resource development, and facilitation and empowerment (National Agricultural and Forestry Extension Service [NAFES], 2005). Technology transfer involves a top-down approach to deliver specific recommendations related to cultivation practices the farmers need to adopt, while advisory services help farmers in clarifying problems, by responding to their queries with technical prescriptions. Facilitation for empowerment involves facilitating experiential learning and farmer to farmer exchanges. Farmers are encouraged to make their own choices, by interacting with each other.

However, it is seen that the traditional methods of information dissemination have become less successful and less cost effective due to various reasons. The average number of farm families to be served by a single extension officer has exceeded 4000, which is an extremely hard target to achieve. The withdrawing of grass root extension workers from extension activities and overburdening of extension workers with duties other than provision of extension services are two of the other constraints that affected the agriculture extension system in Sri Lanka. Decentralization of the extension services to provincial government has weakened the extension service seriously affecting the research –extension linkage, and the efficiency of the national agriculture extension system. Weak knowledge management systems especially in the areas of information sharing, dissemination of information, and agricultural extension is being regarded as one of the major challenges ahead of agriculture research and extension today.

Given the fact that many farmers are literate, and the growth of ICTs in the recent years, integration of ICT is seen as one of the promising solutions, which can be used to provide up-to date information to the agriculture sector. The efforts to harness ICTs in reaching agricultural communities were evident during last decade, when looking at the investments made by the agriculture organizations, including major projects such as the cyber extension project, which will be discussed later in this chapter. A number of agriculture based organizations have started websites and have started offering web based services.

Access to ICTs

Compared to other low income countries Sri Lanka performs exceptionally well in its affordable ICT services, as it has remarkably lower mobile broad band prices (International Telecommunication Union [ITU], 2012). The ICT development index (IDI) ranks Sri Lanka in 105th position in year 2011, out of 155 countries. The same index places Sri Lanka at 50th position in terms of ICT prices. Table 2 shows the sub-indices used to calculate the IDI, and the rank of Sri Lanka based on the sub indices. Sri Lanka provides one of the lowest mobile –cellular prices thus being ranked in the 14th position in the mobile–cellular price category of the IDI. Mobile subscriptions per 100 people is as high as 99.2 at the end of year 2013 (TRCSL, 2013). It is noted that this value does not indicate the percentage of subscribers as it is fairly a common practice in Sri Lanka to have multiple subscriptions, probably due to the fairly low cost, and in some cases, free availability of such mobile subscriptions.

Internet

Sri Lanka has a well developed broadband infrastructure; however the penetration is relatively low. Fixed line penetration is 2.35%, while mobile broadband subscriptions are around 5.9% (Telecommunications Regulatory Commission of Sri Lanka [TRCSL], 2013). At present there is a well developed broadband market, with different fixed and mobile operators providing broadband services through different technologies. There is a potential to increase the broadband use in the future. Both the TRCSL and the Information and Communication Technology Agency of Sri Lanka (ICTA) have made broadband access a policy focus. Examples of recent ICT development projects include the setting up of over 500 rural tele-centers, a subsidy scheme to build and operate a fiber backbone in rural areas, and the development of e-government applications (ITU, 2014).

Literacy

The adult literacy rate in Sri Lanka is around 91% (Central Bank of Sri Lanka, 2013b) which indicates that the majority of the population, including the farmers, can read and write. High literacy levels give a definite advantage in using various ICT resources, and it is an important factor to be considered in planning for information and communication interactions.

Table 2. IDI sub indices and rank of Sri Lanka (Source ITU, 2012)

Index	Sub-Indices	Rank 2011	
ICT access/ readiness infrastructure	fixed-telephony mobile telephony international Internet bandwidth households with computers households with Internet	103rd	3.3
ICT intensity/ Usage	Internet users fixed (wired)-broadband mobile broadband	112th	0.67
ICT capability or skills	adult literacy gross secondary enrolment gross tertiary enrolment	98th	6.45

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ICT INTERVENTIONS

There are many ICT based interventions to serve the agriculture society in its various stages of the production process. Some projects stand out due to its coverage of population, publicity and investments: Among these are, the government initiated a cyber extension project, agri-advisory service, and other collaborated projects on SMS based market price dissemination systems. Websites are the most commonly adopted web technology by most of these organizations, which is similar to the observations reported by Rhoades and Aue (2010) who studied the use of social media in agriculture information dissemination. Use of social network sites like Facebook or micro blogging sites such as Twitter is not commonly seen at the organizational level. Interactive Voice Response (IVR) methods are still at research level and are successfully tried out with smaller communities. This section discusses some of the important ICT interventions that attempted to use ICTs in reaching various levels and categories of the farming community.

Cyber Extension Project

The DOA initiated a cyber extension project way back in 2004 as an "appropriate information exchange mechanism which seems affordable and convenient for rural farmers in satisfying their information needs" (Wijekoon, Emitiyagoda, Rizwan, Rathnayaka, & Rajapaksha, 2014). This was established in two phases; as a wireless extension strategy at first and as a real cyber extension mechanism with internet and telecommunication facilities as the second phase. It was felt necessary and important that farmers were provided with necessary information needed in the various stages of the farm decision making process and the extension system was facing criticisms that it was not being able to satisfy the information demands from the farmers. The Department of Agriculture was thus looking for alternative methods powered by the latest ICTs and their solutions is to introduce computer based learning to the farmer community.

Forty five agrarian service centers, out of the 550 centers, were selected to establish cyber extension units (CEU). A cyber unit was provided with a computer, digital camera, internet facility, telephone, printer and a scanner, similar to a rural information center with the aim of supporting the agriculture community in the area. Thus, a set of Interactive Multimedia CDs (IMMCDs) were designed as an offline cyber extension strategy to provide crop related information to the farmer community. Typically a CD contained information on various aspects of the growth of a particular crop including cultivation and management aspects of crops such as chili, big onion etc. There are also a few CDs which present information on more general topics such as 'integrated pest management', home gardening, and micro irrigation, which discuss important management practices that are common for a group of crops. The learning contents in the CDs were developed with the assistance of Research Officers who verified the technical information. These IMMCDs included video clips, audio narrations, graphics, images and text based illustrations.

The extension agent is to act as the officer in charge of the cyber unit while farmers can use the CDs when they visit the extension agents' office and learn the technical information provided in the CDs. The extension officer may also use the CDs in farmer training classes to design training aids. A list of IMMCDs that have been produced by the Department of Agriculture and is available in the sales outlets is presented in Table 3. These CDs are available mostly in Sinhala, some in Tamil, and a few in English.

Lack of awareness of the cyber mechanism was seen as one of the major problems according to (Wijekoon et al., 2014). Later the DOA had taken steps to popularize the CEUs among farmers. However

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

there are other problems such as poor computer skills by the farmers to use CDs on their own (Dissanayeke, Wickramasuriya, & Wijekoon, 2009). Certain farmer groups are seen more confident in using CDs to obtain information. These are the well-educated and mostly part time farmers who have a main source of income other than agriculture. Some of them even had computer facilities in the home and they made copies of these CDs for later reference. However the majority of the famers had to mainly depend on the cyber extension unit to use these CDs, while they need the extension agent's assistance to select the relevant pieces of information. This interferes with the schedule of the extension agent because he is pre-occupied with other major responsibilities, rather than only managing the CEU. Considering this difficulty, the DOA is planning to appoint a separate officer to manage the CEU and help with farmers to find the necessary information.

The IMM CDs have an interactive user interface where the users have some control in selecting what information to be viewed and when. This can be considered as a positive development because farmers, being adult learners, need to have some control over what they want to view. However the best uses of these could not be harnessed by many farmers mainly due to the poor computer skills and less access to computer facilities.

A substantial amount of resources has been expended to develop good ICT material such as the IMM CDs for the food crop sector in Sri Lanka as mentioned above. However, as with any other information source, it is important to continuously update such material. While updating may not be as glamorous and rewarding as the initial development of a product, it is very important to ensure that the information seekers are provided with current information. Apart from the greater fulfillment of the information needs leading to greater customer satisfaction, it will also enhance the trust and credibility of these sources of information. This is especially so when such material becomes available online. To facilitate such updating and appropriate technical system, key responsible persons whose work will be appropriately recognized, adequate support staff and financial allocations are important.

Another important consideration of the cyber extension project is to link farmers with the other major agriculture stakeholders such as, wholesale traders, researchers and policy makers. It is considered necessary and important to regulate the information flow between stakeholders i.e. researchers and farmers, farmers and policy makers, farmers and traders. It is expected that this would enable farmers to make email queries to researchers seeking technical assistance to solve field problems. However this objective is achieved to a lesser extent so far due to limitations such as low computer literacy of farmers, Extension officers are overburdened with responsibilities other than managing the cyber unit and assisting farmers to send emails will add to their already heavy workload.

Marketing Information Systems

According to Dharmaratne (2013), Sri Lanka had commenced an Agriculture Market Information System (AMIS) as early as 1980s. Market data had been collected, analysed and finally disseminated to interested parties. The main purpose of the system was to measure food security and provide price signals to agriculture marketing stakeholders including the small farmers, traders and policy makers. AMIS had been initiated as two bulletins; a weekly publication that included information on wholesale and retail market prices of nine food items, including price comparisons with the previous week, producer price, statistical indicators such as range and average price. The bulletin was made available for policy makers, general public, and media agencies. The second publication was a monthly information system, which provided key indicators of prices, production, crop situation and food stocks.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Some of the major problems with the initial years of implementing AMIS were poor understanding of the purpose of data and information collection, underutilization of data and information, ineffective communication and presentation, lack of internationally comparable and compatible methodologies for data and information handling and limited capacity of national programs. Farmers were also unable to use the system as the information provided by the system was limited to a few crop types. These were hardly enough to make right decisions. In addition the small farmers and traders were not skilled enough to interpret some of the data presented in the bulletin. It is also noted that these earlier systems did not meet the actual needs of farmers for real time information. Whilst this information is certainly useful for academic studies and policy decision makers, its utility to farmers is limited. However, present data collection, analysis, and dissemination possibilities have enabled the rapid collection and provision of user required specific information almost in real time. Thus, the use of present day Agricultural Marketing Systems by farmers too is bound to increase. However other stakeholders such as policy makers, scientists, and academics are also able to use the system in a useful way.

Agriculture Advisory Service

A call centre solution known as Agriculture Advisory Service is implemented by the DOA as a supplementary service to the present extension system in the country. This is foreseen as a quick mechanism of disseminating agriculture information to strengthen the linkages between research, extension, training, and farmers. This type of a system helps to facilitate a demand driven extension service, as the farmer initiates the communication process.

The extension officers, working in the call center, assist farmers in solving their various problems such as agriculture related technical matters, inputs and marketing problems. The service, which is available in the local languages, receives nearly 100 to 250 calls from the agriculture community every day and is regarded as one of the most wide spread ICT related agriculture activites in Sri Lanka (Dissanayake et al., 2009; DOA, 2010; Wijerathna, 2011). A study conducted by Dissanayake et al. (2009) reports that the farmer community is satisfied with the information provided, while the field extension staff regards the service as an effective solution which eases their work at the field level.

Mobile Based Information Services

Mobile based information dissemination methods recieved wide attention in the recent years mainly due to the availability of mobile phones among people in Sri Lanka, including the farmers. A recent study shows that about 73% of the rural farmers have access to a mobile phone while some extended farm families had access to more than one mobile phone at a time (Dissanayeke & Wanigasundera, 2014) making it a common household item. When compared with the use of computers with internet facilities, the mobile phone was found to be the most common ICT facility among the farmers. Wide usage and accessibility to mobile phones has given opportunities to see how to use mobile based information systems in reaching the farming community. Short message service (SMS) based systems to send market prices, toll free call line facilities to inquire about agriculture based queries, and interactive voice response systems have been experimented with, and later some used by government, private sector, non-government based organizations as well as by independent research groups. Some of the important mobile based initiations are discussed later in this chapter.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Use of mobile SMSs to deliver important pieces of information has become popular worldwide due to the simplicity, effectiveness and low cost (Dhaliwal & Joshi, 2010; Fafchamps & Minten, 2012). Information related to commodity prices, market opportunities, crop advisory, and weather information are the main types of information that are sent to farmers using SMSs in the above studies. Many farmers preferred to have these informative SMSs as it is an inexpensive way to get access to important information. Given this fact that the present access and use of mobile devices is very high, and also that it could be expected to grow even further, this should be seriously considered as a tool that would have even more importance in the future. Initiatives should not be limited to basic cell phones but should cover applications for Smartphone too. While the majority of the present farming population may not own Smartphone yet, their prices will undoubtedly come down making them more affordable. Further, given the large number of migrant workers who have gone overseas from rural areas, the want for communicating with them will propel more people to purchase Smartphone even as prices come down as well. Thus ownership per se of Smartphone in the rural areas is bound to increase. Even if people may not have their own Smartphone, they are bound to have access to them through other rural people who own them. If the information is valuable enough farmers will probably be willing to pay enterprising people who could look up the information on behalf of the farmers for a small reasonable charge. Owners of communication centres that are spread all over the country could be one group that might show interest in such an enterprise.

Mobile SMS Based Price Information Dissemination Services

"Govi Gnana Seva"

The Govi Gnana Seva (GGS) project started as an independent price collection and dissemination service to help farmers get the best possible prices for their produce. This is one of the pioneer projects to initiate sending vegetable market prices to farmers in Sri Lanka (De Silva, 2008). The project operated from the Dambulla Dedicated Economic Center from where vegetable spot prices are collected and then sent by SMSs to the farmers who are registered with the system. Traditionally low farm-gate prices, especially for perishable crops such as vegetables, have been reported even when consumer prices for the same products are relatively much higher. Whilst the low bargaining power of individual small scale farmers is one factor, another factor is their lack of knowledge regarding the prevailing wholesale prices in major agricultural markets closer to the urban areas. Hence, the attempts to fill the information gap between farmers and markets became significantly important.

Later the GGS project started a partnership with a leading mobile company and continued to offer the service on a Tradenet platform (Dialog Axiata PLC, 2009). They have also expanded the service to collect price information from 2 other dedicated economic centers. The system can match the buyers with possible sellers and send alerts to both parties with their respective contact details (de Soyza, 2014). The buyer and seller can negotiate and proceed with the transactions. Buyers and sellers can upload posts to the Tradenet using web, WAP, call centre and IVR, SMS and USSD access technologies using English language or the two local languages.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Interactive Voice Response (IVR) Systems

IVR System for Mushroom Farmers

The Ruhunu University together with a private mobile service provider developed an Interactive Voice Response (IVR) system to educate small-scale mushroom farmers. This is implemented as a technology dissemination programme under the Life Long Learning for Farmers (L3F) employing ICT for one of its components. The IVR system embedded pre-recorded messages of two minutes duration for six months to guide listeners on how to establish, and manage a mushroom shed. Business planning and financial management lessons are also included (Wijeratne & Silva, 2013). About 5000 farmers have taken part in the programme. Farmers are able to obtain needed information quickly and accurately using ICTs. The study reports that the majority have accessed the knowledge system, which can be considered as a positive development. They have listened to the voice mail during their free time. Poor feedback from farmers is seen as one of the limitations by the researchers. The L3F have recently started a similar programme in collaboration with the Open University of Sri Lanka (OUSL) and the same mobile service provider to offer financial management lessons to rural women using IVR systems.

Agricultural Price Information Index

In the recent years a government based agricultural research institutions have started offering daily whole sale vegetable price information, collected from eight markets Island wide with the assistance of a private mobile service provider, one of the leading mobile service providers in the country (Hector Kobbekaduwa Agrarian Research and Training Institute [HARTI], 2014; Mobitel Pvt Ltd, 2014). The service is made available in the two local languages using an Interactive Voice Response System (IVR) to the customers of the same mobile service provider. The callers have to bear the cost for using the IVR system.

Decision Support Systems

Social Life Network

Social Life Network (SLN) is an attempt in developing a holistic mobile based system to aid farmer information needs, throughout the farming life cycle (De Silva, Goonetillake, & Wikramanayake, 2012). The SLN will address issues such as 'how to strengthen the linkages among various agriculture stakeholders using mobile based systems', and 'how to capitalize on the latest mobile technologies such as inbuilt sensors and processing capabilities'. As implied in its name, this system intends to create a network of the users, who would generate real time information, through their participation in the SLN, which will eventually be accessible for the same user community in return. It is assumed that such systems would eventually help the stakeholders to make informed decisions by opening up opportunities for predictive models to strengthen the decision making process. Mobile interfaces of the SLN have been continuously tested with the stakeholders, using action research approaches, to assure user-friendly and usable designs

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Websites

The Internet and websites play a major role in today's information culture. A website can be used to post important information that could make the farming community instantaneously aware of relevant information (Reddy & Ankaiah, 2005). Websites can further act as an important medium to ensure the dissemination and sharing of essential agriculture information that fits the agriculture community's interests and needs. A content analysis study, which evaluated 27 agriculture related websites in Malaysia, concludes three important categories of information that should be there in agriculture websites namely technical information with regard to crops, fisheries, and livestock, training opportunities offered by the institutions, and the financial aspects related to capital, loan facilities and interest rates (Ramli, Hassan, Samah, Sham, & Ali, 2013).

A number of agriculture related organizations in Sri Lanka have marked their web presence (Table 4) providing useful information for the visitors. In fact reports do indicate a high impact on the agriculture sector, next to the telecommunications sector (Jayathilake, Jayaweera, & Waidyasekera, 2010). The types of information and services available through these websites include; technical information related to crop and livestock, marketing information, online services, training opportunities, organizational structure and administrative divisions, vision and mission, news briefs, and contact information.

Almost all the websites are available in English, while the majority has accommodated Sinhalese language as well. Only a few websites have the complete Tamil translations, while this facility is under construction on many sites. For systems where the target group is the farmers, in most instances the content material will have to be in both local languages which are Sinhala and Tamil. As the availability of the same content in both languages is not seen on all sites, this needs to be done. Hence efforts for automatic translation from one language to another needs to be enhanced. Such a facility, together with verification by experts, should be used to enhance the efficiency and reliability of having the content in both languages. To the extent possible, English versions are to be made available to meet requirements of multi-lingual companies and NGOs, as well as other users such as students.

The Department of Agriculture (DOA) website has been recognized both locally and internationally for its pioneer work in using ICTs for agriculture information dissemination in Sri Lanka. According to the website statistics, the number of hits exceeded 3 million as of 2014 whilst thousands of online users visit the website every day. This website has been recognized as the best website among the government websites over several years and provides an example for the other websites which followed. Thus we discuss some of the important features in the DOA website, which is of prime importance to understand the agriculture information culture in the country.

Technical Information Dissemination

Most of the websites presented in Table 4 have made efforts to share technical information related to cultivation aspects in their websites. Online learning resources, including pdf versions of printed publications, and video documentaries are most commonly used to achieve this objective.

The DOA website publishes technical information related to important crop varieties that are grown in the country under the crop recommendation section. These crops belong to the food crop sector including rice, vegetables, fruits, grains, tubers, oilseed crops and condiments. Specific information

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

related to the nutritious value of the produce, recommended varieties, suitable climatic conditions, and crop management practices such as propagation, pest and diseases, fertilizer application, post-harvest handling, and value addition are presented in English and one other local language (Sinhalese). This technical information is presented in the format of online learning resources, using interactive menus to locate learning contents. Text based illustrations were the most commonly used medium, while graphics and photographs are also used appropriately to illustrate facts. Similar efforts have been made by several other organizations to disseminate technical information.

It is a positive trend to observe that many of these organizations have shared their printed publications on the website as a portable document format (pdf) files, giving an opportunity for online users to download them easily without any cost. These publications otherwise have to be purchased from selected sales outlets. Sales outlets sometimes face problems when certain publications are sold out, and when the farmers who are coming for the particular publication has to wait for the next print. Some other organizations have displayed the list of publications in the webpage with the respective prices, directing farmers to the sales centers where a copy can be obtained. Publications include books, leaflets, agriculture magazines, advisory circulars, and other agro-technology based reports that are originally designed to be in the printed format.

Video is a very powerful source to provide information, compared to other mediums as it can combine several media at the same time. It is seen that only a very few agricultural organizations other than the DOA is utilizing online videos to reach agriculture audiences. This situation is similar to the observations made elsewhere (Goodwin & Rhoades, 2009; Rhoades & Aue, 2010). The Department of Agriculture has a repository of video documentaries produced for national television that is made available for the online users. The DOA has its own video production unit at the Audio Visual Center where these documentaries have been produced. Thus a rich collection of more than 300 video documentaries are now available in the DOA website. The Department of Export Agriculture and the Coconut Research Institute are two other organizations that have made good use of online videos in agriculture related technical information dissemination. Both these organizations have shared these videos on YouTube, which is an important step in reaching non-agriculture audiences and especially young farmers. In fact it is important to get more agriculture related videos on such common platforms to reach a majority of the community.

Agriculture Information Management Systems

The Agriculture Information Management System (AgMIS) is developed by the DOA to share information related to food crops such as cultivation extents, production or yield forecast, and contact details of the farmers and officers involved. This is an interactive system which is developed to minimize marketing problems, while it is also expected that it would provide a comprehensive database for policy makers to help in planning and decision making (Food and Agriculture Organization of the United Nations [FAO], 2014). Latest news updates related to the food crop sector is displayed in the website for the frequent visitors in English and the two local languages. Only a few organizations are seen supporting online databases to manage information on buyers and sellers. The Coconut Development Authority maintains an online directory to provide information on manufacturers and importers for interested parties. Users can search a manufacturer based on the district, product and product type using an interactive menu in this website which help stakeholders to access important information easily.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Agricultural Price Information

Use of websites to display market information is seen as one of the recent developments. As seen in Table 4, several organizations have started publishing market prices of the relevant crops as well as related products on their websites so that online users can glance through these prices before making important decisions. Some organizations are using multiple methods such as publishing on the website using interactive menus, mobile IVR based systems, and publishing as PDF documents. For instance the Hector Kobbekaduwa Agrarian Research Training Institute started publishing the daily and weekly food prices on their website for easy access. This is an interesting difference from the earlier system they had, which was available on printed format only. Wholesale, retail and farm gate prices of more than 100 commodities can be obtained through the web site in the two local languages and also in English. Interactive menu items help the users to locate and view a specific category of product easily, and this saves time as otherwise time has to be spent on browsing a long list of items. The same information available in the website is accessible using a mobile based IVR system too, as discussed under mobile based systems.

Farm gate prices for all the export agriculture crops, collected weekly by the Economic Research Unit of the Department of Export Agriculture, are displayed on their website. A mobile version of the website is also available, making it easier for the export agricultural crops stakeholders to view information using a Smartphone. Information for the past few years have been saved on the website that helps users to compare prices in different years and different seasons of the year, thus making it easier in taking important decisions such as selling the produce. The Rubber Development Department is yet another organization that uses their website to publish price information. The latest information is published on the home page itself, making it much easier for the users to have a quick glance over the prices. Detailed information related to a specific year or month or a date can be obtained easily using the interactive menus.

Agriculture Related Services

A comprehensive list of services offered by a particular organization is available on many of the web sites. These services include training opportunities, credit and loan facilities, subsidy programmes, provision of export /import permission, agriculture inputs, certifications and some analytical services such as soil testing. In most of these cases, the website is simply being used to create an awareness in the public of the types of services, posting a brief description of the services. A few organizations such as CCD and RRI have moved a step forward by enabling the download of a copy of an application form through the website. DAPH has an online application portal, which can be used to submit applications and track the progress of the application to obtain import and export permits, which is an interesting development.

Extension and training opportunities were displayed on most of the websites mainly to make the public aware about these programmes. Furthermore, information related to credit facilities and subsidy schemes are also seen, along with facilities to download application forms from the website, as in the case of the Coconut Cultivation Board.

Information and Communication Technology Agency (ICTA) of Sri Lanka

Most of the websites and the features discussed in the section above are funded by the ICTA, which is the single apex body, owned by the government, involved in ICT policy and direction in the country.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Its work includes improving technological capacity of the country, such as building ICT infrastructure, and the ICT readiness of its people, through education and human resources development. ICTA has provided financial support to a number of agriculture based organizations to establish interactive information services that are directly related to agriculture information dissemination. A complete list of these organizations and types of services financially supported are presented in Table 5.

ICTA has also supported disseminating agricultural best practices through e-Learning by funding two important projects namely Wikigoviya by the Department of Agriculture, and Navagoviya by a private organization. Wikigovia consists of an e-learning system, agri-forum to discuss agricultural issues of importance, and an agriculture Wikipedia that can be edited by users ("Wikigoviya," 2014). The Navagoviya website is an initiation from a leading private sector company to develop and deploy e -earning and digital content to build awareness of new techniques and technologies in the agricultural sector. Most of these websites are published in English and two other local languages.

Rural resource centers, with internet facilities have been established to disseminate information at the village level. These centers are referred to as "*Nenasala* Centers" and currently there are 667 such centers. *Nenasala* centers provide a range of services including high speed internet access, e-mail, telephone, computer training classes and other ICT related services. The content essential to the rural community is available to all users in the Sinhala and Tamil languages. *Nenasalas* also caters to the diverse needs of the village community including agriculture, fisheries, and trade, which make it an important landmark in agriculture and related information culture in Sri Lanka.

ICTA has also funded a SMS enabled platform to exchange dairy product information among a small community of farmers. The system helped farmers to access a database to obtain necessary information, connect with the extension officer, the veterinarian, and other service providers. In addition a network of computers with touch screens were set up in public places for the easy access by farmers who does not have mobile phones (Mubarak, 2009).

Table 5. Interactive information services funded by ICTA (source Information and Communication Technology Agency [ICTA], 2013)

Organization	E-Service Offered by the Website
Rubber Development Department of Sri Lanka (RDD)	Provide Rubber Prices
Department of Animal Production and Health (DAPH)	• Online Application Submission portal • DAPH Application Manager
Department of Export Agriculture (DEA)	Market Information
Department of Agriculture (DOA)	• Farmer Database • Classifieds - Advertising platform for farmers to sell their products • Agriculturists – to get contact information of agriculture specialists and their publications
Hector Kobbekaduwa Agrarian Research and Training Institute (HARTI)	• Weekly food prices • Daily food prices
Tea Small Holdings Development Authority (TSHDA)	Subsidy Information
Sri Lanka Tea Board	• Tea Price • Tea Directory

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

PROBLEMS AND LIMITATIONS

ICT adoption is seen to be moderate among the farmer community, and a large part of this success can be attributed to the growth of the telecommunication sector in the recent years. The latest ICT based inventions in the agriculture sector can be seen as more of an effort to harness the best uses of ICTs in the agriculture information dissemination process. In this context, it is more likely to expect the emergence of information dissemination systems that are more of a technology driven nature than that of user driven nature, which could be a major drawback. In the future it is more important to see how to develop systems that would cater to actual information needs of the farmer community, by getting their involvement in the design process.

On the other hand we can see reasons such as cost of technology, lack of ICT proficiency, and inability to cater for the actual user needs slowing down the adoption and use of ICTs in agriculture. According to Jayathilake et al. (2010) the cost of technology can be seen as the main drawback that limit ICT adoption among farmer. Farmers' reluctance to invest on ICT based services could be due to a low awareness of the benefits of such services, less trust on the return of the investment, and high initial cost. This especially affects small farmers who practice subsistence agriculture, who see spending on ICTs as a waste of money, and who do not see the benefits of investing on them. During the inception of ICT projects, we can see more farmers using the systems when the services are offered free of charge, and there is no financial cost to the farmer. Latterly the farmer has to bear at least a very small part of the cost such as the cost of the telephone call, which was toll free at the inception.

Lack of ICT proficiency is seen as another important reason that affects the use of ICT in agriculture. For instance the unfamiliarity with mobile based technologies may lead to poor adoption of mobile SMS based price information systems. The majority of the farmers would be more conversant with the voice based services, while only a few are comfortable with SMS due to various reasons such as lack of technical know-how, and language proficiency (Wijerathna, 2011). Poor language proficiency is mainly due to the inability in using the English alphabet in sending and receiving text messages, rather than their literacy levels. Sri Lanka enjoys fairly high literacy rates due to the free education system thus there is a high potential to impart technology based education. As most of the mobile phones used in the country have English language inbuilt, it is necessary to come up with solutions to have phones with local language facilities and information systems. Interestingly the young and progressive farmers are seen mostly using these ICT based systems, and generally, low income, elderly farmers lag behind being unable to use the SMS facility.

Little or no emphasis has been given on linking farmers with the other important stakeholders such as extension agents, researchers, subject matter experts, traders, and input suppliers. Even though the present ICTs can be successfully used in strengthening the existing networks, and can be used to facilitate interaction among stakeholders very little attention is paid in this regard. This does not encourage interaction between the various stakeholders and the farmer is generally unaware of who else will be there in the network. This might be one of the reasons for the poor adoption of such technologies. The other possible reasons may be lack of awareness, negative attitude of some individuals at senior management levels, and administration problems, as with the case of cyber extension project (DOA, 2010)

It is seen that most of the attention is presently devoted to developing websites however the power of other web technologies such as social media, video sharing, and micro blogging has not yet being

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

recognized. Rhoades and Aue (2010) noted similar observations with a group of agriculture journalists from the United States. Accordingly, most participants have seen the benefits of such tools, but some are still doubtful to adopt them because of the fear of time and resources needed.

FUTURE FOCUS

The landscape of agriculture information systems is changing. Commercialization, intensification and a greater involvement of the private sector is seen. Furthermore an expansion of the food processing sector is also seen. Thus, the need for agriculture related information has changed and grown in terms of the end users as well as the need for specialized information as in the case of protected agriculture. With the drastic reduction of the field extension workers in the 1980's, the agricultural extension role of the Department of Agriculture too has changed. The private sector and the NGO sector have undertaken the provision of agricultural extension, or information, services. However, these are but limited initiatives. The varying ICT initiatives already undertaken have tried to address this gap between the need for enhanced information and the reduction in the traditional extension services provided. There certainly is the need for more initiatives, some, if not many, of which should be from the ICT sector.

An apex body, such as a joint one between the Council for Agricultural Research Policy (CARP) and the Information and Communication Technology Agency (ICTA) which are the main respective government bodes at the national level, together with representation from the private agricultural companies, the plantation companies, and representatives of the farming communities should be formed. Such a body should map out the overall policy and strategy for agricultural related ICT initiatives. Seed funding should be provided for initiatives. Funding could be under different categories serving different purposes. It could also be under different scopes to include small short term projects, as well as more complex and longer term projects. Joint proposals by a technical agricultural agency and ICT competent personnel should be encouraged. The technical agency should prove its commitment and capability to maintain such a system once developed. The rationale for the above are elaborated upon below.

Whilst efforts of individual agencies and personnel do contribute to the availability of agricultural information, those would be dependent on their priorities, capabilities, and interests. When uncoordinated, such efforts may be duplicated, not completed due to the lack of competence or funds, and not adequately maintained over time. Furthermore, important areas may not be addressed. Hence, the coordination of information systems in the agricultural sector is important. The strategy for such coordination should be done by a representative body. Thus for Sri Lanka, representatives keen and committed to this initiative, from the following organizations could be considered for such a body. The Sri Lanka Council for Agricultural Research Policy (CARP) is the main body for agricultural related activities, whilst the Information and Technology Agency (ICTA) is the main organization involved in public funded ICT initiatives and thus, is in a good position to play a key role. Representation from the Ministry of Agriculture would be required to align initiatives to related policy, and also to influence the formulation of such policy. The Department of Agriculture, whilst being the main organization for the food crop sector, is also the organization that has been innovative and done the largest amount of work in agricultural ICT sector, as indicated before, and thus should continue to play a leading role in this sector. It would also be important to obtain representation from other agriculture related Departments, and the plantation

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

crop sector as well, as they generate the technology and information for such sectors as well as providing the agricultural extension services. Another sector to be included would be representation from the Universities, with Faculties of Agriculture, as they represent another important source of knowledge and research in agriculture. Whilst the organizations identified above are mainly the information providers, it would be important to include the actual users of such information too to make such initiatives more demand driven. Hence the importance of key farmer representatives who are in a position to understand the possibilities and requirements from anticipated information systems. These could be from different categories identified to be important. The consideration of the needs of larger entities such as the Regional Plantation Companies, which are responsible for the management of the private plantation estates, as well as the requirements of the small-holders in these sectors too need to be ensured through appropriate participation. Similarly the requirements of the private sector agricultural organizations that are playing an increasing role, especially in catering to the more commercialized agricultural ventures need to be ensured. The requirement of NGOs for reliable agricultural information is also high since many have agricultural components in their projects, and hence their needs also should be considered. A committee comprising all those identified might be too large. However, their representation and input would certainly add value to future efforts. Hence, one way to balance these competing requirements of wider representation and a leaner committee could be to have a committee with permanent representation from the relatively more important organizations, and rotating membership of the other segments. Wide representation of this nature would enable clearer identification of key ICT initiatives that need to be focused on, coverage of a wider area in terms of both technical areas and information requirements, and better maintenance and future enhancements to the products. This forum would also enable the determination of possible lead-roles, such as the Department of Agriculture providing leadership and support to other organizations in their areas of ICT development. It could also determine those with multiplier effects, such as a base ICT system that is developed for the technical content only to be included by the different agencies. Since many agricultural organizations could lack personnel competent to develop full information systems, systems such as these would enable those organizations, normally unable to do so, to provide information to their clients through these 'pre-written shells' of ICT systems.

The role of a committee, such as the one proposed above, should be mainly to determine overall policy, priorities, strategy, and funding mechanisms. Deliberations of such a committee should be infrequent, but well planned and prepared for, and of high intensity, whereby substantial objectives are accomplished. If implementation is to be handed over to such a committee, apart from the need for frequent meetings of the main personnel, it would also need additional support staff and other resources. Thus, a more feasible alternative for implementation of the coordination of initiatives would be the handling of such activities by an existing national level organization, such as the ICTA in Sri Lanka. Such an agency could call for proposals according to the guidelines determined by the main committee, and coordinate the selection of projects, fund disbursement, and the progress monitoring and evaluation of agricultural ICT projects, which would be then and addition to the nature of activities already undertaken by them. An agency such as this could be involved in ensuring the maintenance and thus the longer term sustainability and continued utility of these ICT initiatives.

Clearly, a mechanism to propel activities towards desired goals, as determined by a representative committee as outlined above, would be to provide funding for the determined areas. Given the fact that most ICT information system initiatives are of relatively lower cost in comparison to infrastructure projects or organizational expansion, and also the relative availability of funds as countries strive to become

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

more knowledge based economies and allocate funds accordingly, the availability of funds for these purposes is probably not a constraint. Funds could be provided mainly for the development of products. This funding should cover the period beyond the testing and prototype stages to actual initial use by the end users. This funding would act as an incentive for innovative ideas and possibilities. It would also enable those agencies lacking the needed ICT personnel for product development to hire them for the period needed. Whilst the major portion of the available funding could be for new initiatives, it would also be prudent to allocate funds for enhancement of previous products. In any field, and especially in ICT products, continuous improvements are almost essential. Hence, whilst the agency undertaking the initiative should be able to fund and undertake normal maintenance of the product, periodic major revisions could be supported as in its initial development.

The allocation of available funds should be pre-determined based on the needs and priorities identified for ICT activities in agriculture. For example allocations could be done proportionate to both the relative importance and need of different sectors such as the crop, animal husbandry, fisheries, and food processing sectors. Even though important, the funding for an area could be curtailed if suitable ICT applications already exist for that area. Within a sector, such as the crop sector, a similar pre-determination of the allocation of funds could be done for the food crop and plantation sectors. This process could be continued to a reasonable level to ensure that adequate coverage is provided. Such pre-determination of allocations should allow for reasonable margins of cross over, whereby provisions for certain areas are increased above the pre-determined allocation, and another/others reduced correspondingly. This would minimize the acceptance of a weak proposal purely because of it falling within a given area of allocation, and also increase the acceptability of a good proposal which might not have been funded due to other better proposals being allocated the available funds for that particular area.

In the allocation of funding for different areas it would be beneficial to strategically allocate funds based on short term, and probably smaller and simpler systems, as well as more long term, and probably larger information systems. Whilst many ideas for the short term could be projects with a relatively limited scope the longer term projects could be more complex and of greater scope. A mix of both would be needed. Smaller applications could be completed quicker and show results fast, thus giving a quick return on investment, as well as being a motivating factor for further work by the basically non-ICT personnel who probably would be a major group desiring to develop such systems. The areas considered could either be technical areas of importance, or areas of information systems which are complex systems akin to Enterprise Resource Planning systems of other sectors. Thus, the need for more complex systems to cater for more integrated information requirements should not be overlooked. Especially in such instances the involvement of ICT professionals should be ensured.

In general the strength of a technical agency would be its personnel, knowledge base and research output in the crops or areas related to the agency. In terms of ICT initiatives a weakness in many of these agencies, especially the smaller ones, would be the lack of personnel competent enough to develop and continuously maintain information systems. Hence, it would be beneficial to promote collaboration between personnel in these organizations and ICT competent technical organizations or personnel. This could be accomplished through the specific indication of such a requirement for funding purposes. The evaluation of proposals could be based on the agricultural competence and accomplishments, as well as the ICT competence and accomplishments of the personnel involved.

In an era of knowledge explosion, updating data to minimize obsolete information is essential. Furthermore, maintenance of an information system by rectifying bugs, or errors in the system, and also

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

minor modifications and upgrading of the system has to be done. Thus, to enhance the continued utility, and thus the use, of the information systems developed, the capacity and commitment of an organization desiring to develop a new system, to maintain such a system in the future should be determined. Possibilities for an external agency, or agencies, to provide such backup if needed should be determined. A network of practitioners could also be promoted to help both in the initial development, as well as this latter aspect of maintenance.

Facilitation of the Interaction among Agriculture Stakeholders

Use of ICT based information exchange systems is most commonly seen among young and progressive farmers. Thus, future ICT based agricultural information systems need to be able to cater to their information needs, by identifying these farmers as special target communities. While doing so it is vital to move toward more interactive systems and building communities of stakeholders those who would interact and learn from each other's. Facilitation of interactions is important for two reasons. Firstly, farmers are likely to learn more from their colleagues than the extension agent or other authorities, as the problems they experience in the field are similar to the other farmers. They are much more likely to follow the footsteps of a successful farmer from the same community as the results are proven readily. Farmers, in general, are knowledgeable on whom to go for advice, while they relate to their own community and colleagues first when they have a problem. Secondly, the farmers would like to discuss and share what they found as a useful piece of information with their colleagues. The farmers prefer to see the opinion of the others in the community before adopting agricultural practices even when the information is passed down by the extension agent or any other important source. Thus it is necessary to create ICT based systems that can be used to facilitate interaction and information sharing among the agricultural communities. Participation of agricultural extension officers and other subject matter experts in such systems is crucial for successful functioning of such systems. These officers can initiate interactions, aware farmers on latest technologies and practices, and various other opportunities available for their training and development. Using the traditional system of extension to give away such information would be more time consuming when compared to an ICT based system.

When implementing such ICT based mechanisms, we need to pay attention to three important aspects; use of existing technologies when and where applicable in order to minimize the cost, go for participatory methods in developing and implementing ICT based agriculture information systems, and providing training for target communities.

Ideally we can develop applications and software to facilitate farmer collaboration using ICTs. However this could take a long time, and may involve substantial costs for development and maintenance of such systems. One alternative is to choose from the existing web based technologies, namely social networking, blogging, sending and receiving SMSs and IVR services, that are freely available with minimum or no maintenance cost. Some of these technologies have been tested out with smaller communities and has given promising results. Being in the category of a middle income country, it would be useful for Sri Lanka to explore existing and emerging technologies and modify them based on the specific requirements of the target groups.

Adoption of such ICT based information systems by the agriculture community depends on a number of aspects. One important question is 'how a given farmer community choose a suitable web based

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

technology for collaboration?' This could be made possible in a number of ways. Ideally the community could make use of web technology, including social media, which the members are already familiar with. There are farmers and other stakeholders, those who already use web based technologies for interactions. Especially, the young farmers today are well aware of social networks and they can be encouraged to use such networks to link with other farmers. Another option would be an outside facilitator, such as the extension agent or any other authoritative person, introducing farmers to networking using social media. With a little help from the government or another organization in training these officers, they can easily initiate these networks at village level.

Use of participatory and interactive project designs when implementing ICT interventions with agricultural communities would improve the chances of sustainable impacts on target communities (Donovan, 2011). Accordingly future projects can adopt design research approaches, while ensuring stakeholder participation throughout the design process. This would lead to higher participation, easy adoption and sustainability, as farmers would get a sense of ownership for the outcome.

In many instances the average farmers may not have the necessary skills and attitudes to use a given ICTs although they are willing to do so. Thus, it is important to provide necessary training for them. The farmers who are conversant in using such technology could be identified and they could be assigned to help the other farmers.

There are informal leaders and followers in the community. We need to identify these groups and help them identify suitable ICT based communication systems to facilitate collaboration. It is important to identify the existing means of communication (such as face-to-face gatherings) that can be enhanced, or replaced, with modern ICTs, to strengthen the networks that are already present in the community. This would give recognition to each stakeholder in the system and users would be more comfortable in interacting with people who are already known to them.

CONCLUSION

Information and communication technologies have revolutionized the traditional systems of information exchange mechanisms, while opening up number of gateways to integrate ICTs in the development process. The agricultural information society has been significantly affected by these latest ICTs. A number of interventions made to harness best use of ICTs in agriculture information dissemination. Computer based learning methods, mobile based information dissemination systems and websites are the most common.

The major challenges ahead of the agriculture information society are less emphasis on networking stakeholders, duplication of work due to poor coordination, cost for developing and maintenance of ICT based systems, lack of ICT proficiency among farmers, and inability to cater to the actual user needs by the existing systems The possibility of using existing web based technologies, which are freely available, have not been adequately explored.

Addressing the above limitations is going to be very challenging. However, some of them can be addressed by ensuring proper coordination among the organizations, developing suitable ICT based agriculture information systems by following participatory research approaches, choosing from the existing web based technologies such as social media and modify them to suit local situations, and provide support for target communities by providing necessary training.

Chapter 38
A Case Study of Innovation Platforms for Agricultural Research, Extension, and Development:
Implications for Non-Formal Leadership and Adult Learning

Matthew L. S. Gboku
Sierra Leone Agricultural Research Institute, Sierra Leone

Oitshepile M. Modise
University of Botswana, Botswana

Jenneh F. Bebeley
Sierra Leone Agricultural Research Institute, Sierra Leone

ABSTRACT

Stakeholder organizations clearly need to have more than a symbolic role in IAR4D decision making. They are currently hindered by their lack of knowledge of leadership roles and capacity to implement the IAR4D. In this chapter, the authors have presented the use of the IAR4D in Sierra Leone with clear justification of how it fits into contemporary approaches and interventions at the national, regional and global levels. The chapter focuses on the "Dissemination of New Agricultural Technologies in Africa (DONATA)" project in Sierra Leone as a shining example of leadership development and adult learning in both formal and non-formal settings. The authors highlight current challenges of the use of innovation platforms through IARD and articulate implications of the case study for adult education, agricultural extension and non-formal training in agricultural research institutions. The chapter ends with recommendations for surmounting the current challenges of the case described.

INTRODUCTION

This case is taken from the Sierra Leone Agricultural Research Institute (SLARI) using the success story of the Dissemination of New Agricultural Technologies in Africa (DONATA) project. The project was implemented by the Njala Agricultural Research Centre (NARC), which is one of the seven constituent centres of (SLARI). The case is developed from the reports covering the work of Sahr Fomba, Lansana Sesay, and Alhaji Massaquoi between 2008 and 2014. As Projects Development and Management Officer at one time and now Research Coordinator of SLARI, the lead author of this article participated in several of the activities of DONATA Project but he takes no responsibility for the reports from which the case is developed. Rather credit is fully given to the authors of those reports from which excerpts are taken.

The Authors' understanding of the aim of the publication for which this chapter is meant is the following:

1. Selection of a leadership case
2. Demonstration of why the selected case qualifies to be a shining example of leadership within the context of adult education (e.g. Agricultural extension, or other non-formal education projects)
3. Highlights of current challenges facing the case of leadership described.
4. Recommendations for surmounting the current challenges of the case described.

Within the above framework, we have structured the chapter into six sections as follows. The first section is the introduction which provides the reason for this chapter, what the chapter entails and the manner in which it is structured. The second section provides the historical perspectives of research in Sierra Leone including the various institutions conducting research, the approaches used and a clear differentiation of efforts before the IAR4D approach and what pertains presently. In the third section of the article, the authors specifically present the use of the IAR4D in Sierra Leone with clear justification of how it fits into contemporary approaches and interventions at the national, regional and global levels. The fourth section is about the case study on the "Dissemination of New Agricultural Technologies in Africa (DONATA)" as a shining example of leadership development and adult learning in both formal and non-formal settings. Following the case presentation, the authors focused discussion on the implications of the case for adult education, agricultural extension and non-formal training on innovation platforms. The sixth section of the article addresses the challenges facing the use of Innovation Platforms (IPs) which is presented in the case study as model example for the promotion, dissemination and adoption of agricultural technologies. Finally, the article ends with a discussion of the implications of the case study for leadership development in adult education settings.

HISTORY OF RESEARCH IN SIERRA LEONE

In this section, the authors looked at the institutional arrangements involved in conducting research from pre-colonial to the present time and also the approaches used for conducting research from independence (1961) to the present era of the Integrated Agricultural Research for Development (IAR4D).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Institutional Setting

Sierra Leone has had a long history of agricultural research, spanning almost 100 years. Up to the early 1980s research efforts in Sierra Leone were fragmented and uncoordinated, with research programs controlled by separate institutions with the mandate confined to annual crops. In 1985, the National Agricultural Research Coordinating Council (NARCC) was established to coordinate research and harmonize research activities. The Mission of NARCC was to support the promotion of pro-poor sustainable growth for food security and job creation as part of Sierra Leone's Poverty Reduction Strategy Paper. The two constituent institutes of NARCC at the time were the Rice Research Institute dealing with rice, millet, sorghum, banana, plantain and vegetables, and the Institute of Agricultural Research dealing with cassava, sweet potato, yam, maize, cowpea, groundnut, soybean and sesame. In addition to the research institutes, Njala University and the University of Sierra Leone also carried out agricultural research. The devastation of research infrastructure during the ten year civil war (1992 – 2002) and the departure of well-trained scientists during this period brought agricultural research to a halt. Since 2001, many of the scientists have however returned and there is goodwill from the Government and partners to resuscitate the research establishment.

After a period of coordination of agricultural research under NARCC, the Government of Sierra Leone (GoSL) established the Sierra Leone Agricultural Research Institute (SLARI) through the SLARI Act of Parliament of 2007. SLARI is now the agricultural research and agricultural technology generating body for the benefit of the farming, fishing and forestry sectors and to provide for other related matters. As a major role player in addressing the many challenges facing the agriculture, fishery and forestry sub sectors in Sierra Leone, SLARI is expected to conduct research to obtain knowledge, information and technologies needed for sustainable development of the country's agricultural sector.

In order to position itself strategically as a key driver in the transformation of the agricultural sector from subsistence to a commercial and profitable business enterprise, SLARI has adopted the Agricultural Product Value Chain (APVC) approach to research for development within the framework of Integrated Agricultural Research for Development (IAR4D). The adoption of this approach to research requires SLARI to shift focus from production of commodities to differentiated agricultural products including increased value-addition to commodities within the rural areas and development and promotion of new products that fit the demands of the target market (SLARI, 2011a).

The adoption of the APVC approach to research for development has been necessitated by the renewed focus on agriculture and agribusiness as priority sectors for spurring economic growth in Africa with calls for development of APVCs that integrate producers and markets to make the agricultural sector more responsive to consumer demands. An important feature of the APVC approach according to Hawkins, Heemskerk, Booth, Daane, Maatman, and Adekunle, (2009) is that it permits analysis of the whole product system leading to the identification and prioritization of opportunities and problems throughout the system which facilitates the development of more realistic research and development intervention projects.

In addition to this, the APVC approach to research for development implies expansion of the research portfolio to components such as post-harvest processing, marketing and internalization of consumer needs. The approach involves working with all players along the different APVCs from resources, production, processing, marketing to consumption. The APVC approach is characterized by increased vertical coordination of many actors along the commodity chain including research, extension, farmers, policy, processors, input and output market, transporters, and agricultural financing agencies (FARA,2007), and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

would be expected to demand for more integration and coordination of all different service providers around priority APVCs.

Research Approaches

The history of research in Sierra Leone is tied to the use of a number of approaches which span from colonial to the present era. During the colonial era (1950 – 1960), the traditional approach to agricultural research was mainly supply-driven, in which researchers set the research agenda without consulting clients and other stakeholders. Up to the late 1960s, most research efforts tended to be largely commodity and factor oriented. The underlying paradigm is that understanding of the whole comes from understanding of the parts and their interactions. This paradigm works well especially where interactions among the parts are not important, that is, where the whole is essentially the sum of the parts. However, work done with farmers in many parts of the world has shown that they operate complex farming systems and they have to make difficult decisions about adoption of technologies (Bigs & Clay, 1981; Chanbers et al, 1989; Okali, Sumberg & Farrington, 1994). Because if this complexity of the farming systems, the traditional approach, often referred to as the top-down approach, to agricultural research and development was not having an impact on small-scale agriculture. Chambers et al. (1989) further observed that the way agricultural research and extension organized itself was a major reason why science was failing to improve the livelihood of the poor. Consequently, the linear research-extension-farmer linkage and technology transfer championed by the public extension service in 1960s and 1970s are no longer suited to agricultural research for development.

During the early 1970s and early 1980s following Independence of most African countries, there was a start in history with the formation and consolidation of the National Agricultural Research System (NARS) supported by International Agricultural Research Centres. During this era, we experienced disjointed disciplinary on-station research, and cultivar development. Towards the late 1980s, the need to strengthen the NARS was realized. This was also the advent of extension services as link to farmers. Linear technology transfer model was dominant. Emphasis was placed on improved management of NARS for program relevance to client. Analysis of complex farming systems under which farmers operate led to the conclusion that appropriate technology could only be developed if it was based on full knowledge of the existing farming system, and that technologies should be evaluated not only in terms of their technical performance in specific environments, but also in terms of their conformity with the objectives, capabilities and socioeconomic conditions of clients. As a result, research and development practitioners looked for alternative approaches to agricultural research and development.

Between the mid to late 1990s, the farming systems research approach became very popular with emphasis on adaptive on-farm research, sustainable agriculture, multi-disciplinary research approach, pluralistic participation, grassroots emphasis, information system and long term innovation development. From the definition, FSA is holistic and participatory, multi- and -interdisciplinary, demand-driven and problem-solving. It promotes partnerships and linkages, as well as synergies and cost-effectiveness in research and development. While FSA transformed the way research was conducted, its participatory nature was limited to incorporation of farmers and did not permeate research institutions that continued to operate singly. In the mid to late 1990s there was popularization of the farming systems research approach involving adaptive on-farm research. The FSA emphasis also remained at the farm level addressing production oriented issues with little attention directed at research on the other aspects such as processing and marketing.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Realizing the weaknesses of the FSA at the end of the 1990s the concept of a "national system of innovation" emerged. The framework was developed after the realization that the objective of agricultural technology innovation must shift from increasing outputs and yields to transforming agriculture into a more responsive, dynamic and competitive sector. This shift was triggered by the emergence of major structural changes in the global food and agricultural systems including the integration of agriculture into global markets, the emergence of consumers as key drivers of technological change, the growth of private investment in new agricultural technologies, and the revolution in information and communication technologies combined with the growing recognition that agricultural innovation is far more complex and less linear than once believed.

In Agricultural Innovation Systems (AIS), heterogeneous actors interact in the generation, exchange and use of information and knowledge; individuals and organizations in the system learn and change; and social and economic institutions condition these interactions and processes. The concept embraces not only the science suppliers but the totality and interaction of actors involved in innovation. It includes the farmer as part of a complex network of heterogeneous actors engaged in innovation processes, along with the formal and informal institutions and policy environments that influence these processes.

In effect, this framework represents a move away from a more linear interpretation of innovation as a sequence of research, development and dissemination, to an interpretation that recognizes innovation as a complex web of related individuals and organizations, notably private industry and collective action organizations, all of whom contribute something to the application of new or existing information and knowledge. The concept of agricultural innovation systems can be summarized by at least ten basic principles that include Focus on innovation rather than production; Interaction and learning; Linkages for accessing knowledge and learning; Broad spectrum of actors with new actors and new roles in the innovations process; Attitudes, practices and interaction of behavioral patterns that determine the propensity to innovate; The importance of policies in innovations; The inclusion of stakeholders and the demand side in the innovations process; Experiential learning and capacity building; Changing to cope with change; and Coping with "sticky" information that is local and specific to owners and not easily available to others. In the recent era of 2000 till now, the need to refocus research for development is emphasized. It involves the development of technology transfer approaches, multi-disciplinary and multi institutional approaches, and development of the IAR4D.

THE USE OF IAR4D IN THE SIERRA LEONE AGRICULTURAL RESEARCH INSTITUTE

A growing awareness amongst rural development practitioners of a need for "new and alternative ways of doing business" has created an increased demand for capacity development in how teams and partnerships are formed, planned, operated and managed. This search for an alternative integrated innovation process has led to the development of Integrated Agricultural Research for Development (IAR4D) approach. The IAR4D approach emerged after it was realized that the advances in research through the integrated pest management (IPM), integrated soil fertility management (ISFM) and integrated natural resource management (INRM) approaches offered an alternative approach for integrated research, although they fell short of integrating policies and markets, among others, into the research process. The IAR4D approach sets out a process and progressive procedures and accompanying tools for planning the resolution of complex problems and implementing rural development activities that respond to the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

needs of beneficiaries and involved stakeholders, contribute to broad development objectives and that use multi-dimensional participatory and systems approaches.

The IAR4D is a process-oriented approach that recognizes the need for collective action by involving a broad range of stakeholders and multiple knowledge sources including indigenous knowledge and technology that can be used to address complex development challenges. The IAR4D approach also recognizes both spatial and temporal scales and interdependencies; multiple effects and trade-offs of different options; and the need to involve a wide range of stakeholders often with conflicting interests in collective action. Equally important is the inclusion of the social component including negotiation between differing perspectives, policy formulation, institutional change and development, land use and planning, and conflict and information management.

The need to break away from single disciplinary and conventional research approaches and instead focus more holistically on the context (social, ecological, economical and institutional) which determines success and failure in achieving impact required a range of actions, the most important of which include (i) Facilitating more engagement of farmers and other participants in production to consumption chain; (ii) Enabling farmers to access efficiently functioning agricultural output and input markets; and (iii) Providing support to smallholders and pastoralists to engage in knowledge intensive integrated management of their natural resources and achieve sustainable improved livelihood. In order to achieve the desired results, these services are to be achieved in an integrated manner with closer interactions and wider ranging partnerships between and within research institutions, public, private and civil society organizations.

An Innovation Platform (IP) forms the core of the IAR4D structure. The IP is an informal coalition, collaboration, partnership and alliance of agricultural research for development actors, that is, public and private scientists, extension workers, representatives of farmers, farmers' associations, private firms and NGOs, and government policy makers who communicate, cooperate and interact to set priorities, develop concepts and plans to promote agricultural productivity and profitability. The core competencies brought to bear by IP are greater than the sum of IP's constituents acting independently.

The implementation of IAR4D hinges on four interactive process oriented support pillars namely (i) bringing about organizational and institutional change, capacity building for project teams and institutions; (ii) knowledge management and information sharing; (iii) monitoring, evaluation, impact assessment and lesson learning; and (iv) change and integration of markets, policies, NRM and productivity into innovation processes. The impact pathway for IAR4D begins with the establishment of IP where priorities that would determine the objectives of the research are agreed upon, a concept and plan of action developed and roles of each actor or groups of actors on the platform are clearly defined. The research process would then involve the use of inputs which is further broken into three phases as follows:

1. Identification of a common challenge through the IP and using inputs through an action research process to generate outputs in accordance with the project's priorities and objectives.
2. Innovation stage which involves development of processes to deliver the outputs to beneficiaries (putting research into use, sometimes referred to as the innovation process). This involves putting into use the outputs generated by the research process. This process is facilitated by the IP and leads to incremental changes in relationships and behavior of stakeholders, in particular the users of the research outputs.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. Out-scaling by using agricultural development processes leading to improved food security, income, livelihood assets, the natural resource base and resilience to shocks; that is, impact. The mandate of IP actors ordinarily stretches beyond the IAR4D site. Accordingly, these actors serve as agents for out-scaling the research approach and its outputs beyond the initial site.

CASE STUDY: DISSEMINATION OF NEW AGRICULTURAL TECHNOLOGIES IN AFRICA (DONATA) PROJECT

Background

Promotion of Science and Technology for Agricultural Development in Africa (PSTAD) is an African Development Bank (AfDB) project with DONATA as subproject aims to improve on the agricultural productivity of resource-poor farmers. In 2008 SLARI/NARC with the sponsorship of AfDB, FARA, and ACORAF/WECARD established five demonstration/multiplication plots in five rural communities in the Bombali Shebora chiefdom in the Bombali District of Northern Sierra Leone and the Njaluahun Chiefdom in the Kailahun District of Eastern Sierra Leone. In 2011 another chiefdom, Gbendembu Ngowahun, Bombali District, and two others, Konike Barrina and Kolila Rowala in Tonkolili District, Northern Sierra Leone were added with total of ten platforms. In the same year, the Kayamba and Kori chiefdoms in the Moyamba district were added with a total of eight platforms, while in the Eastern Sierra Leone, Small Bo and Gaura chiefdoms in Kenema district and Luawa chiefdom in the Kailahun district were added with a total of 12 platforms. Overall, a total of thirty five innovation platforms were established between 2008 and 2011.

Farmer-Based Organizations (FBOs) under the Dissemination of New Agricultural Technologies in Africa (DONATA) project in Sierra Leone has been much referred to as an example of successful Innovation Platforms (IPs) in rural markets. The activities of FBOs have developed since 2008, supported by various NGOs and the Njala Agricultural Research Centre (NARC), a constituent centre of the Sierra Leone Agricultural Research Institute (SLARI). During this period, the group collaborated with private sector individual partners in Bo and Makeni townships and effective intermediaries to set up an effective supply system of the desired quantity of quality gari product suitable for the urban markets of Freetown, Conakry and Monrovia. This has resulted in in increased yields and income for the participating farmers, as well as a dependable supply of quality cassava and gari products for the urban consumers of Sierra Leone, Guinea, and Liberia.

DONATA's aim was the wide-scale dissemination and adoption of new and proven agricultural technologies in stakeholders' communities of Sierra Leone, to enhance food security and reduce rural poverty. While the focus of DONATA in Sierra Leone was on cassava based technologies in CORAF/WECARD,

DONATA had three main elements:

- Establishment of Innovation Platforms for Technology Adoption (IPTA) to strengthen the innovation capacity of stakeholders in agricultural research and development on the African continent.
- Dissemination of new proven technologies, and
- Upgrading knowledge and skills.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Innovation Platform for Technology Adoption (IPTA) actors in Sierra Leone include farmers, processors, traders, researchers, extension workers, policymakers, drivers and micro finance organizations. The farmers form the foundation of the Innovation Platform for Technology Adoption (IPTA). They are the producers of the cassava tubers, the basis for processing and transformation. The traders most often buy either cassava tubers and sell to the cassava processors or buy processed products of cassava and sell to consumers. The processors transform cassava into products such as gari, fufu and starch. The researchers develop higher yielding cassava varieties and associated agronomic practices to replace low yielding local strains while the extension workers organize these stakeholders into platforms and facilitate meetings of the actors. The micro finance organizations target these platforms to offer micro credits. Loans are often given to only farmers and traders of the platforms who have the capacity to pay back. The ward councilors facilitate access to land and settle dispute among members of the platform.

The expected outputs from the DONATA project were improved cassava varieties of SLICASS 1, 4, 6 and TME419 promoted and disseminated, and timely planting in Northern Sierra Leone were promoted and adopted. Farmers were actively involved in multiplying cassava cuttings for sale, while selling the tubers to processors, who produce gari and fufu for the markets. Technologies were demonstrated, disseminated and adopted through innovation platforms for technology adoption (IPTAs). To build capacity in development and promotion of selected technologies, training was given to researchers and extension agents. Some researchers received formal (M.Sc. level) training and short-term training, while extension agents receive training from the National Agricultural Research System (NARS).

The development of innovation platforms under the DONATA project was neither a single approach, nor the efforts of a single organization that assisted the FBOs. Rather, it was the FBOs that attracted the attention of the organizations that assisted them in pursuing their objectives, improving their skills and desire to be innovative. There was constant collaboration between the FBOs that constituted the innovation platforms and the Njala Agricultural Research Centre in identifying and selecting other IP stakeholders including processors, transporters, marketers, and input suppliers. This is to say that the IP which initially started with a farmer based organization had only farmers as the pioneers on an innovation platform. The International Institute for Tropical Agriculture (IITA) with a sub-regional office in Sierra Leone also gave important support, directly or through the Sierra Leone Agricultural Research Institute. Research organizations played a service-provision role and, over a longer period, engaged in capacity building of stakeholders within the cassava value chain.

Before the establishment of the IPTAs, improved cassava planting materials were not wide spread. They were only available to contact farmers who were in close touch with the research institute. The IPTA has facilitated a wider spread of improved technologies from research. Farmers' output in cassava production and processing has greatly improved. Cassava was initially processed into two major forms; gari and fufu. Now cassava is both cash and an industrial crop in Sierra Leone. Most of the IPTAs feed the cassava processing factories with raw tubers. Before the IPTAs, most farmers depended on local planting materials that were lower in yields and susceptible to pests and diseases. Cassava products such High Quality Cassava Flour (HQCF), odorless fufu flour and some others are the initiative of the IPTAs in Sierra Leone. Also, through IPTA there has been an effective grasshopper control on most cassava farms through date of planting. The cassava value chain initiative has also been promoted by the IPTAs. Now even cassava leaves are not thrown away but dried in solar driers milled into powder for sale on the market. Much more income is now realized by farmers from cassava production and processing than before the IPTAs.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Knowledge and skills on the cassava value chain were enhanced in most part of the country by the establishment of the IPTAs. In Bombali district, the IPTAs increased cassava production by 50%. That necessitated the cassava value chain initiative at all platforms. Skills on how to process cassava leaves into powder for cassava leaf source were learnt. Processing cassava into HQCF was also learnt by most people through the IPTA. Odorless Fufu flour was until recently completely absent in Sierra Leone. Now most IPTAs with cassava processing facilities process cassava into HQCF and they do so with safer measures by containing them in plastic sachets and label. These skills have enhanced variety of cassava products on the markets and contributed to diversification of food consumption in Sierra Leone. In the past most Sierra Leoneans only accept having eaten when their meal is rice. That is gradually changing as more appealing products are now formed from cassava.

With the IPTAs, income levels of most cassava producers is improving as the land size cultivated to cassava is increased and more processing centers established. In Bombali district most DONATA platforms have graduated into Farmer Based Organization (FBO) and started bank accounts for savings. Some platforms have raised quite some amount of money and initiated a loan revolving scheme for the group members. This to a large extent has improved on the welfare of most IPTA members. The table below gives highlights of the income generated from IPTA farms in Bombali district.

IMPLICATIONS OF THE CASE

The case described above qualifies as a shining example of leadership within the context of adult education (E.g. Agricultural Extension, or Other non-formal education projects). Below is a narrative of how the case has illustrated the principles of adult learning in three areas of adult education and lifelong learning.

Adult Learning Principles Illustrated

Knowles' in the 1970s identified six adult learning principles as listed.

1. Adults are internally motivated and self-directed in setting goals and planning learning activities.
2. Adults bring life experiences and knowledge to learning experiences. Subject matter and learning experiences must be provided that begins where the learner is.
3. Adults are goal oriented. Learning activities should be provided that take into account the wants, needs, interests, and aspirations.
4. Adults are relevancy oriented
5. Adults are practical and they learn what they practice.
6. Adult learners like to be respected.

The question is how can the adult learning principles be illustrated to facilitate stakeholders' learning on an innovation platform within the IAR4D?

Principle 1: Adults are internally motivated and self-directed in setting goals and planning learning activities.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Adult learners according to Fidishun (2000) resist learning when they feel others are imposing information, ideas or action on them. The role of the facilitator on an innovation platform is to move the actors towards more self-directed and responsible learning as well as to foster the actor's internal motivation to learn. As an experienced facilitator, you can:

- Set up a training program that is less structured but gives more responsibility to the actors on the IP with less supervision and at the appropriate place that is challenging but not overloaded for the IP actors/learners.
- Develop dialogue with the actors to optimize your approachability and encourage asking of questions and exploration of concepts. As the actors provide solutions to the facilitator's questions, they feel more confident and more equal with the facilitator in knowledge sharing.
- Show interest in the IP actor's thoughts and opinions by actively and carefully listening to the questions they pose.
- Lead the actors toward inquiry before supplying them with the facts.
- Provide regular constructive and specific feedback, which could be either positive or negative.
- Set projects or tasks for the IP actors which reflect their interests and which they must complete within a specified timeframe.
- Encourage the use of their resources first before considering other options in the pursuit of their goals.
- Acknowledge the actors' preferred way of learning or doing and to discuss this with the group.

Principle 2: Adults bring life experiences and knowledge to learning experiences.

Adults like to be given opportunity to use their existing foundation of knowledge and experiences gained from life, and apply it to their new learning experiences. As an experienced facilitator on the IP, you can:

- Find out about the actors on the platform in terms of their interests and past experiences in the family and at work.
- Assist the actors to draw on past experiences when problem-solving, reflecting and applying critical reasoning processes.
- Facilitate reflective learning opportunities which Fidishun (2000) suggests can also assist the learners to examine existing biases or habits based on life experiences and "move them toward a new understanding of information presented".

Principle 3: Adults are goal oriented.

Adult learners become ready to learn when 'they experience a need to learn it in order to cope more satisfyingly with real-life tasks or problems (Knowles, 1980 p.44) as cited in Fidishun (2000). Your role as an IP facilitator is to facilitate learners' readiness for problem-based learning and increase the actors' awareness of the need for the knowledge or skill presented. As an experienced facilitator, you can:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Provide meaningful learning experiences that are clearly linked to personal, client and fieldwork goals as well as assessment and future life goals.
- Provide real case studies as a basis from which to learn about theory, methods, functional issues and implications of relevance.
- Ask questions that motivate reflection, inquiry and further research.

Principle 4: Adults are relevancy oriented.

Adult learners want to know the relevance of what they are learning to what they want to achieve. Some ways to help learners on an IP is to see the value of their observations and practical experiences throughout their involvement on the platform are to:

- Ask the actors to do some reflection on for example, what they expect to learn prior to the experience, on what they learnt after the experience, and how they might apply what they learnt in the future, or how it will help them to meet their learning goals.
- Provide some choice of fieldwork project by providing two or more options, so that learning is more likely to reflect the actors' interests.

Principle 5: Adults are practical.

Through practical field experiences, interacting with real clients and their real life situations, learners move from classroom and textbook mode to hands-on-problem solving where they can recognize first hand, how what they are learning applies to life and the work context. As an experienced facilitator, you can:

- Clearly explain your critical reasoning when making choices about assessments, interventions and when prioritizing client's needs.
- Be explicit about how what the learner is learning is useful and applicable to the job and client group you are working with.
- Promote active participation by allowing learners to try things rather than observe. Provide plenty of practice opportunity in assessment, interviewing, and intervention processes with ample repetition in order to promote development of skills, confidence and competence.

Principle 6: Adult learners like to be respected. Respect can be demonstrated to your learners by:

- Taking interest
- Acknowledging the wealth of experiences that the learner brings to the platform.
- Regarding them as colleagues who are equal in life experience.
- Encouraging expression of ideas, reasoning and feedback at every opportunity.

It is important to keep in mind that the learner is still developing occupational therapy clinical practice skills. However, with the theory and principles of adult learning in mind, you can facilitate the learning approach of the students to move from novice to more sophisticated learning methods. This facilitates greater integration of knowledge, information and experience. The learner learns to distinguish what is important when assessing and working with clients, how to prioritise client needs, goals and caseload.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

When rules can be put aside and how/when the approach to occupational therapy practice and professional communication emerges from strict modelling of behaviour into a unique therapeutic and professional expression of self (Fidishun, 2000; Lieb, 1991).

Agricultural Extension Principles Illustrated

The case of DONATA project in Sierra Leone has also demonstrated the principles of agricultural extension in the promotion and dissemination of agricultural technology for the benefits of cassava value chain actors. The Njala Agricultural Research Centre has done this with the following guiding principles for growth in agricultural production illustrated:

Principle 1: Empowerment of end-users to ensure their meaningful participation in setting priorities and work program for research, extension and training to ensure their relevance.

Principle 2: Planned subsidiarity to give responsibility and control over resources for agricultural research, extension and training activities at the lowest appropriate level of aggregation (local, national and regional).

Principle 3: Pluralism in the delivery of agricultural research, extension and training services so that the diverse skills and strengths of a broad range of service providers such as universities, non-governmental organizations (NGOs), public and the private sector can contribute to publicly supported agricultural productivity operations.

Principle 4: Evidence-based approaches with emphasis on data analysis, including economic factors and market orientation in policy development, priority setting and strategic planning for agricultural research, extension and training.

Principle 5: Integration of agricultural research with extension services, the private sector, training, capacity building, and education programs to respond in a holistic manner to the needs and opportunities for innovation in the sector.

Principle 6: Explicit incorporation of sustainability criteria in evaluation of public investments in agricultural productivity and innovation programs (fiscal, economic, social and environmental).

Principle 7: Systematic utilization of improved management information systems, in particular for planning, financial management, reporting, and monitoring and evaluation.

Principle 8: Introduction of cost-sharing with end-users, according to their capacity to pay, to increase their stake in the efficiency of service provision and to improve financial sustainability.

Principle 9: Integration of gender considerations at all levels, including farmers and farmers' organizations, the private sector, public institutions, researchers and extension staff.

Principle 10: Farmer operations based on demand driven technologies generated by research.

IAR4D Principles Illustrated

Principle 1: Integration of perspectives, knowledge and actions of different stakeholders around a common theme

The various members of each Farmer Based Organization initially received training in Farmer Field Schools (FFS) on basic farming skills, records keeping, farm management, business skills, group dynamics and governance of social organizations. Graduation of farmers from FFS with these basic farm

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

skills qualified them to form an FBO which further received training on cassava production techniques, cassava disease management and cassava seed multiplication, which has led to an increase in production and productivity. The increase in production presented a marketing problem, and through the assistance from SLARI with financial support from Common Funds for Commodity (CFC) and DONATA Project, contact with potential buyers was established, credit was obtained and farmers were given training in developing business plans. The demand of quality processed cassava led to technical support from IITA with training on various processing equipment for gari and high quality flour products. Training, exposure and interaction of members has made it possible to separate entry points within the same IP with some acting as producers, and others as processors, transporters, and marketers.

Principle 2: Integration of learning that stakeholders achieve through working together

Beyond a simple concerted process, IAR4D according to Hawkins, Keemskert, Daane, Maatman and Adekunle (2009) is a social learning process, with stakeholders learning from the experience of working together. The different collaborative activities between SLARI, IITA, NARC, and local NGOs have provided improved insight into rural innovation process facilitated by DONATA staff but experimented and managed successfully by the various IP all actors. The focus in this kind of learning as noted by Hawkins et al. (2009) is primarily on the processes of stakeholder interaction themselves, rather than on the specific solutions to the research and development challenge, and learning occurs at the individual, innovation platform and institutional levels.

Principle 3: Integration of analysis, action and change across the different dimensions of development

The various IP groups have managed to substantially increase incomes from the cassava sales. As presented in the NARC Annual Technical Report for 2014, a total of ten (10) innovation platforms (IPS) have been established between 2008 to 2011 and are now fully functioning with a total membership of 5650 (3065 males and 2600 females) in the cassava value chain.

In 2013, a total of 45.7t of gari was produced by all the IPs, valued at US$44,244.15 and marketed. This was followed by high quality cassava flower (HQCF) at 6t, fetching US$6976.70 and wet foo-foo and foo-foo flour at 42.25 t which fetched US$22,266.20. The total sale of all processed products was 162.25t and valued at USD121,919.14, and together with the sale of 29,600 bundles of cassava sticks (a bundle = 100 x 1m cassava sticks) valued at US$ 41,400 giving a gross income of US$ 163,359.14 for all the ten IPs. A total area of 452 ha was under cassava cultivation in all the IPs with average yields of 29-30t/ha for SLICASS 4, and 30-35t/ha for SLICASS 6 (Sesay, Massaquoi, & Fomba, 2014).

There is no evidence however if men and women were paid the same prices and whether both gender gained equal benefits. Similarly, the work on DONATA does not show whether gains from the project were invested in natural resource management, which signals the need to address these issues.

Principle 4: Integration of analysis, action and change at different levels of spatial and social organization

To be effective in promoting innovation, IAR4D needs to promote change and enhance learning at all levels of the organization, including field, farm and watershed, product, firm, value chain, business cluster, individual, group, community, organization, and innovation levels (Hawkins et al. (2009). Elements in the success of the Innovation Platforms were the building of group cohesion as a result of the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

FFS training, working together as a FBO and also learning the processes of starting and operating an innovation platform.

Implications of the Case Study for Leadership Development

Leadership as observed by Oduaran (n.d) is one of the most studied, observed and least understood phenomena people have grappled with over the years. The difficulty in understanding the concept according to Oduaran arises from the fact that there are no commonly agreed criteria by which we can describe the essence and process of leadership. The authors of this paper briefly explore the meaning of leadership in this section, and move on to identify the functions of a leader in the IAR4D approach.

A synthesis provided on the definition of leadership by Northouse (2013) is that whether viewed as a personal quality or an organizational function, leadership can only be defined more correctly from at least six perspectives, which include:

- The focus of group processes in which the leader is the individual who is at the middle of group change and activity and entails the ability to get the will of the group on his/her side.
- Perspective of personality elements in which leadership is perceived as "a combination of special traits or characteristics" that an individual has. It is those special traits or characteristics that enable the leader to motivate others to accomplish or complete given tasks.
- Perceived as an act or behavior in which interest is in the kind of things that leaders do in order to bring about change in a given group.
- From the point of view of power relationship when leadership is perceived as the exercise of power in order to bring about a change in the followers.
- Perceived as an instrument of goal achievement, which portrays leadership to be something that could be used in helping members of the group to achieve their goals while at the same time meeting their needs.
- From the skills perspective, when leadership places emphasis on capabilities including knowledge and skills that bring about effective leadership.

In every definition of leadership, the leader and the followers are equally important. However, it is often the leader who is expected to initiate the relationship, create the communication linkages and strive to maintain the relationship that s/he has established. Thus, leadership is a relationship activity in which the leader and followers must be understood thoroughly. From the synthesis provided by Northouse (2014),

Leadership can be defined as a process of influencing others, in which the leader demonstrates ability to develop a vision that is well communicated, builds trust among colleagues, and takes effective action to maximize the efforts of others towards the achievement of a common goal.

Technically speaking a leader could use social influence to just *organize* the efforts of others, without necessarily *maximizing* their effort. However, leadership is not about getting people started for developing cassava and rice technologies to improve productivity and food security." It is rather, "the leader sees the present food insecurity and poverty", and influence the followers to get started and see how fast they can achieve the goal of improving productivity and food security. We can achieve the goal of

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

improving productivity and achieving food security in twenty five years. However, if the same goal can be attained in three years, we are both effective and efficient.

Functions of Leaders:

Common activities for leaders are planning, organizing, directing, and controlling. In a typical research setting, leaders are expected to execute these common activities as shown in Table 1 below:

- Firstly, leaders focus the attention of a group on purpose. For example, a leader will focus attention of colleagues by asking "Why do we constitute the rice research task force?" "What is our mission?"
- Leaders are result oriented. That is leaders organize work around results that will make the vision a reality. This means moving from a written document to action within a specified time frame.
- Leaders help the group internalize the vision through communication and information sharing.
- Leaders define a clear set of values and guiding principles that support the vision and promote individual accountability. This accountability is the glue that holds the vision intact.
- Leaders inspire trust by motivating, challenging, encouraging, empowering and moving their people.
- Leaders take a risk by stepping outside their comfort zone and think outside their mandate.
- Leaders innovate and develop rather than maintaining the status quo.
- Rather than doing things right, leaders do the right things.

CURRENT CHALLENGES FACING THE USE OF INNOVATION PLATFORMS

The use of innovation platforms is a major tool in the implementation of the IAR4D processes. The DONATA projects in Sierra Leone have made significant contributions towards improving productivity in the past seven years through the promotion and dissemination of improved crop varieties particularly cassava coupled with key management practices. The impact indicators of the long-term investments in agricultural research using the case of DONATA are beginning to show but are yet to be evaluated

Table 1. Common activities executed by leaders

	Leader
Planning	• Devises strategy • Sets direction • Creates a vision
Organizing	• Gets people on board for strategy. • Communicates strategy • Networks with those led.
Directing	• Empowers people
Controlling	• Motivates • Inspires • Gives sense of accomplishment

The characteristics of leaders emerging from the functions listed above are critical to reiterate.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

in terms of: (i) the productivity impact that focuses on the efficient use of resources; (ii) the livelihood impact which determines whether gains of increased productivity benefit the mass of society; and (iii) the environmental impact which determines whether the gains achieved by the first two impact indicators can be sustained. Despite the gains realized in DONATA, there are numerous challenges that need to be addressed to achieve a sustainable broad based agricultural growth. These are:

General Challenges

The major challenges facing the agricultural sector include but not limited to the following:

1. Sierra Leone's population stands at 5.93 or 6% but 70.2% of the population leaves below the poverty line of $1.25. Poverty and unemployment is rampant.
2. 26% of the population is undernourished and are food insecure with impaired physical and cognitive values.
3. Poor physical infrastructure e.g. roads, marine transport, markets, communications (ICT) and energy. Without the prerequisite infrastructure it will be difficult to achieve agricultural products value chain activities.
4. Poor knowledge infrastructure and therefore need to advance the harnessing of Science, Technology and Innovations to improve competitiveness That is, there is need to promote science policy and its implementation.
5. Inherently poor soils. Most soils in Sierra Leone are ferralitic in origin and low in mineral nutrients reserves and therefore inherently low in fertility. Soil management including integrated soil fertility management practices should be given priority in our research agenda.
6. Low agricultural production growth rate (5.31%): low adoption of technology and area expansion for yield versus low intensification practices.
7. Planning approach is usually of short horizon and lack of foresight thinking. Our population is projected to double by 2050 and it means doubling or tripling current production levels. Planning approach is also based on limited scenarios and problem solving with little or no focus on exploiting opportunities.
8. Programs are usually fragmentary (between research, extension, training and education, NGO, farmers and policy makes) and are implemented in isolation resulting to duplication. There is weak human and institutional capacity.
9. Need to change mind-set of dependency and waiting for problems to be solved rather than exploiting opportunities.

Challenges in Developing Research Leaders for IAR4D

The major challenges in developing leadership of IAR4D are:

1. Resources for training at various levels of academic certification. The least cost for training research leaders based on our present experience with the World Bank project is as follows:
   a. MSc/Phil degree: $34,000 - $56,000
   b. PhD degree: $74,000 - $126,000

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

To reduce the cost of leadership development, the Sierra Leone Agricultural Research Institute (SLARI) recruits people with a first degree as Research Assistant. Better still SLARI preferably recruit research scientists with a Master of Science degree over first degree holders.

2. Retentions of leaders in research institutions. Very few research institutions in Sub-Saharan Africa have adequate capacity to retain the very leaders they have trained. Incentives such as competitive salaries, standard accommodation, recreational facilities, educational facilities for the children of research leaders, and transportation are lacking. In real cases also there is the lack of laboratories, equipment and financial resources for research scientists to prove their leadership potentials in working with their colleagues.
3. The right gender balance between male and female scientists is hardly achieved because of the lack of female scientists to fill similar leadership positions like their male counterpart. In Sierra Leone, we have traced the gender gap right from the primary and secondary stages of our educational system where the girls are not encouraged to do sciences like physics, chemistry, biology, and mathematics. When this foundation is missed, getting the females into university programs like food sciences, agricultural sciences, engineering sciences, and environmental sciences becomes impossible. The ultimate consequence is that few females are available to take positions of soil scientist, agronomist, breeder, food technologist, entomologist, plant pathologist, hydrologist, irrigation specialist, biotechnologist, and biometrician.
4. Getting the right diversity of scientists to fill the leadership gaps as dictated by our research programs has not been achieved, and will continue to be a major challenge in the near future. Not until recently with the advent of the IAR4D which encourages the use of the Agricultural Product Value Chain (APVC) approach, our research focus has been mainly biological and/or production oriented with little or no attention to non-biological or non-production oriented activities such as processing, fortification, transporting, packaging, marketing, and consumption. Now that research diversity could be enhanced under the IAR4D using the APVC approach, trained leadership is required to achieve the strategic goals of the research institution.

KEY TERMS AND DEFINITIONS

Adult Education: A practice in which adults engage in organized and sustained learning activities intentionally designed for the purpose of bringing about gains in new forms of knowledge, skills, attitudes, or value among those whose age, social roles, or self-perception define them as adults.

Adult Learning: 'The entire range of formal, non-formal and informal learning activities which are undertaken by adults after a break since leaving initial education and training, and which results in the acquisition of new knowledge and skills'.

Agricultural Extension: Is a general term involving the provision of assistance to farmers to help them identify and analyze their production problems and become aware of the opportunities to make improvement through farmer education and the application of scientific research and new knowledge to agricultural practices.

Agricultural Product Value Chain (APVC): Although there is no universally accepted definition of the term, it normally refers to the full range of value adding activities required for an agricultural product or service to move through the different phases of production, including procurement of raw materials and other inputs, assembly, physical transportation, acquisition of required services such as transport or cooling, and ultimately response to the end customer's demand (Kaplinsky and Morris, 2000).

'Demand': What people ask for, need and value so much that they are willing to invest their own resources, such as time and money, in order to receive the services.

Demand Driven Technology Transfer: The demand drive technology transfer maintains the assumption that new technology drives innovation, that generation of this technology is most by publicly funded research institutions (Rogers, 1070), and that this technology is generated and transferred to the end users in a demand/market driven and more outward looking process (Chema, Gilbers & Roseboom, 2003) by involving the end users in assessing their needs and social realities which informs the technology generation and transfer processes.

Farming Systems Approach (FSA): "A multi- (inter- and intra-) disciplinary approach to generation and diffusion of knowledge and technologies for specific target groups of clients with their participation focusing on identified priority problems, constraints and opportunities of the production system under consideration in different biophysical and socioeconomic conditions, with emphasis on improving the productivity of the existing system".

Integrated Agricultural Research for Development (IAR4D): An action research approach for investigating and facilitating the organization of groups of stakeholders, including researchers, to innovate more effectively in response to changing complex agricultural and natural resources management contexts for improved developmental outcomes (FARA, 2007).

Innovation Platform (IP): "A physical and/or virtual network of stakeholders which has been set up around a commodity or system of mutual interest to foster collaboration, partnership and mutual focus to generate innovation on the commodity or system" (Adekunle and Fatundi 2012).

Multidisciplinary Approach: An approach which involves drawing appropriately from multiple disciplines to redefine problems outside of normal boundaries and reach solutions based on a new understanding of complex situations.

Multi-Institutional: Institutional system consisting of more than one service facility which has cooperative administrative arrangements through merger, affiliation, shared services, or other collective ventures.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Multi-Stakeholders: These are persons with common interests and have agreed rules about cooperation. They are involved in learning and are action oriented and system thinking. They are concerned about knowledge and information sharing. Participation and empowerment is their goal.

National Agricultural Research System (NARS): In any given country, all institutions and organizations actually or potentially involved in agricultural research and technology development together constitute the NARS of that country. Strong linkages are necessary between National Agricultural Research Institutes (NARIs) and specialized commodity research institutes, universities, industrial research laboratories, development organizations and the extension services, which are all involved in agriculture-related development activities.

Stakeholders: Stakeholders refer to individuals, groups or organizations that can affect or are affected by a particular issue, system or innovation, Related terms are "interest groups", which indicate that people can be grouped according to a common interest, and "actors" which emphasizes that some or all stakeholders are active and interact with each other (Hawkins et. al, 2009).

Chapter 39
Economic Transformation of Austrian Agriculture Since EU Accession

Erika Quendler
Federal Institute of Agricultural Economics, Austria

Christina Mayer
Statistics Austria, Austria

Karl Michael Ortner
Federal Institute of Agricultural Economics, Austria

ABSTRACT

After joining the European Union (EU) in 1995 Austria adopted the Common Agricultural Policy (CAP). This chapter reviews the changes in agricultural production and the economic situation of agriculture since the accession to the EU. The analysis is primarily based on macro-economic data from the Economic Accounts for Agriculture (EAA) over the period between 1995 and 2014. Select examples identify the developments applicable for Austria – also in comparison to other EU countries and groups of countries as well as to Switzerland. Expectations and forecasts regarding the consequences of integration, e.g. changes in the price levels, have been more or less fulfilled but there is a need for further research on the development of regions and on special issues such as the resilience of Austrian agriculture.

INTRODUCTION

With its accession to the EU Austria adopted all rights and obligations pursuant to the Common Agricultural Policy (CAP) (Art. 137 of the Act of Accession). Market organisations, price policies and payments to agriculture and forestry (in short: "farm payments") had to be adjusted to the EU regime (Schneider, 1997). In general, competition was endorsed by the CAP, interventions in agricultural and food markets were reduced and measures to support prices were cut drastically and replaced by direct payments. With respect to structural policies, more emphasis was devoted to efficiency and performance.

Environmental aspects got increased attention; regional policy including programs for rural areas was upgraded (Schneider, 1997, p. 156). In order to mitigate losses of income due to inherent competitive weaknesses, structural disadvantages and accession-related price cuts, temporary transitional assistance in the form of degressive compensatory payments and aid for the write-down on agricultural products were granted (Ortner, 1996; Sinabell, 2004; Hofreither, 2006, p. 23).

Since then the CAP was subject to four reforms, the last of them in 2009 and 2013. These reforms were gradual adaptations of the mechanisms that were put in place to achieve the objectives spelled out in the Treaty of Rome (Hambrusch, Heinschink, & Tribl, 2015). In the context of these reforms new objectives have been added (Regulation Establishing Rules, 2013; Regulation on Support, 2013). These encompass economic objectives (ensuring food security through sustainable agricultural production, improving competitiveness and increasing Value Added in the food chain), environmental objectives (sustainable use of natural resources and combating climate change), and territorial objectives (ensuring economic and social dynamics of rural areas) (Massot, 2013).

The current chapter addresses the question of how, in this context, the economic situation of Austrian agriculture has developed since accession to the EU. The chapter is organised in several sections, starting with the history of agricultural developments and events in Austria. A brief introduction into the methodology applied is followed by an outline of the importance of agriculture by its Value Added and its contribution to the overall economy; a description of the components of agricultural output and the development of their shares; a portrayal of the composition and significance of farm payments for the development of the economic situation in agriculture; and an illustration of the development of agricultural income. Based on these results authors highlight strategies of how to mitigate or adapt Austrian agriculture to current challenges, followed by a section on possible fields of further research.

The chapter is based on statistical data from Economic Accounts for Agriculture (EAA). Key developments in Austria and other EU countries as well as Switzerland are addressed. Furthermore, payments for Austrian agriculture are compared to the overall budget and the net contribution to the EU budget using data of National Accounts (NA), reports of the Ministry of Finance (Bundesministerium für Finanzen, 2013, 2015), reports of the Ministry of Agriculture (Bundesministerium für Land- und Forstwirtschaft, Umwelt & Wasserwirtschaft, 2015) and the Financial Report of the European Commission (2015b).

BACKGROUND

Austrian agriculture was perceived as a sensitive area with regard to EU integration. The main problems of the sector were:

- Inadequate preparation for the Single Market;
- The country's idiosyncratic natural and structural features;
- Differences in agricultural policies (Schneider, 1989, 1993, 1994).

The adoption of the CAP was associated with a fundamental transformation of economic conditions including profound changes in market organizations, price policy, agricultural support, and competitiveness.

Traditionally, the role of government in agriculture has been strong in Austria, in particular in the dairy and cereals sectors where marketing boards administered prices, managed production and exports. In addition, equity considerations and environmental concerns remained very important. Politicians com-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

mitted themselves not to let per capita farm income fall behind the level of income growth in the overall economy. This was done in order to maintain the small-scale structure of farming (family farms) and to give farmers in disadvantaged (mountainous) regions the opportunity to stay viable through supplementary income payments. However, these direct payments were counterbalanced by production and fertilizer levies and accounted only for a part of support given to the agricultural sector (as measured by the Producer Subsidy Equivalent) (Organisation for Economic Co-operation and Development, 1995). The major policy instrument was market price support through border protection and export subsidies. The result was that farmers increased production until the government introduced quantitative restrictions on milk deliveries and support to oilseeds and protein crops in order to clear cereals markets.

Joining the EU provided an opportunity for market liberalisation and access to the huge EU market for agricultural products, which was almost closed until then except for certain tariff quotas, a situation that forced the government to spend substantial amounts for export subsidies to allow excess production to be sold in world markets. However, the prospect of low agricultural producer prices in the EU was a major concern for farmers and processors who had hitherto been protected from competition in the domestic market. In the EU agricultural producer prices had been lowered following the CAP reform in 1992. In Austria, price adjustments had been postponed but were unavoidable after the conclusion of the Uruguay Round of negotiations of the General Agreement on Tariffs and Trade (GATT), which obliged Member States' agriculture and food sectors to reduce export subsidies, internal support and border protection (Ortner, 1994).

Thus, the challenge was to adjust Austrian agriculture to international markets while meeting policy objectives and securing support for EU accession. Agricultural prices dropped in the wake of EU accession by 22% on average while farmers could expect to pay only slightly less for inputs (Schneider, 1997). In the short run, the challenge was met surprisingly well due primarily to a momentous upgrade of support payments. Degressive compensatory payments were granted upon accession until 1999 to facilitate adjustment. Income support to farmers in mountainous and disadvantaged regions almost doubled, and the scope and volume of payments under the Austrian Program for Environmentally Sound Agriculture increased substantially (Ortner, 1996, 1997a).

While the immediate changes upon accession are well documented in the literature, it is less obvious how Austrian agriculture developed in the longer run. Was there a major drop in agricultural income? Did production go down? How did the structure of agricultural output change? These developments are considerably steered by the evolution of agricultural policies and markets. Rather than outlining these changes here, the authors will comment on them as data which shed light on these issues is presented and discussed.

MAIN FOCUS OF THE CHAPTER

Methodology

The economic situation of Austrian agriculture is the subject of agricultural statistics both from a microeconomic and a macroeconomic perspective. The microeconomic situation is surveyed in terms of standardised accounting results at the level of agricultural holdings in the EU – the Farm Accountancy Data Network (Gahleitner, Kirner, & Resl, 2015). The macroeconomic approach accounts for agriculture

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

overall, using the framework of EAA (Regulation on the Economic Accounts, 2003; European Union, 2013).

Aggregate economic accounts for agriculture have been published within the EU since 1964 and from 1969 onwards based on common definitions and procedures. The EU's EAA has been continuously adapted (Berkeley, 1996, p. 91). Several documents about the methodology on the EAA – with a standard set of concepts, definitions and roles for accounting – are available on the Internet (European Commission, 2000; Regulation, 2003; European Union, 2013).

The EAA is a complementary (satellite) system to National Accounts which provides more detailed and comprehensive branch-specific information on agriculture than would be possible within the framework of NA (European Commission, 2000). The EAA is based on the collection and aggregation of numerous statistical information presented within a consistent framework. It draws upon agricultural production statistics (such as the harvest survey and slaughtering statistics), supply balance sheets, price statistics and farm accounting data as well as administrative data of the paying agency (Agrarmarkt Austria) and the Federal Ministry of Agriculture, Forestry, Environment and Water Management (BMLFUW), information from the Chambers of Agriculture, producer associations and non-agricultural statistics (External Trade Statistics). In the course of preparing and systematically compiling the EAA the data is checked for consistency, plausibility and comprehensiveness (Kniepert, Mayer, & Ortner, 2009, p. 84).

The EAA is made up of a sequence of linked accounts which enable the assessment of the economic performance of the agricultural industry, from production to primary income generated. Financial flows to and from the government (taxes on production, subsidies), wages paid as well as rents and interest are constituent parts in this framework (European Commission, 2000). Furthermore, the EAA records basic data on wealth creation and labour input into agriculture (Bundesamt für Statistik, 2006, p. 40). The EAA provides comparable monetary values which inform about the general structure of agricultural production and changes in the economic values of agricultural production and income. The calculation scheme is presented in Figure 1.

The indicators and figures calculated within the EAA provide the basis for a wide range of possible analyses, e.g. production patterns, input mix, terms of trade and productivity. Changes in the monetary values of output, intermediate consumption and Value Added can be broken down into price and volume components. However, in order to investigate the causes of the trends observed, it is often necessary to consult further information sources not included in the EAA, such as data on world markets, exchange rates, consumer preferences, legislation, economic conditions, policies, etc. (Kniepert et al., 2009, p. 84).

These economic data play a prominent role in CAP policy formation as well as in monitoring past behaviour of the agricultural industry. Even in the absence of an agricultural policy with specific income goals, the economic activities of the agricultural industry would have to be accounted for as there is a general need to monitor the state of the agricultural system (Berkeley, 1996, p. 90). Furthermore, the EAA form the basis for depicting the agricultural industry in National Accounts. Since there are certain conceptual differences between these two systems of economic accounts, the EAA data has to be adapted for inclusion into NA.

In order to maintain consistency, data of NA is used for comparisons of developments of the agricultural industry with that of the overall economy in the following section. The comparisons are based on NA data compiled according to the former European System of Accounts 1995 (ESA 1995) as this data is available since 1976.

Position of Agriculture in the Economy

ESA 1995 data show that from EU accession in 1995 to 2012 the Gross Value Added (GVA) of the overall economy increased nominally from €157.4 billion to €277.6 billion, representing an increase of 76%. During the same period GVA of the primary sector (agriculture, forestry and fishing) increased by only 14%, from €3.9 billion to €4.4 billion (Statistics Austria, 2013). Within the primary sector, GVA of forestry increased significantly more strongly (44%) than that of agriculture (5%). In this regard, however, it is necessary to note that the development of GVA in agriculture – in contrast to that of forestry – was significantly influenced by changes in the types of support to agriculture, i.e., the introduction of degressive compensatory payments from 1995 to 1998 and decoupling of subsidies since 2005.

The direct contribution of agriculture to the economic performance of Austria as a share of agricultural GVA in Total Value Added of the economy dropped from 4.5% in 1976 to 1.9% in 1995. From 1995 to 2005, the share of agriculture decreased further to 1.1%. In the period 2006 to 2012 the share of agriculture in Gross Value Added fluctuated between 1.0% and 1.2% (Figure 2).

In comparison to other EU countries, the share of agriculture in Austria was at 1.2% in 2011, lower than the average of EU-28 (1.5%) and slightly lower than that of EU-15 (1.3%). The relative economic weight of agriculture is significantly lower in Western and Northern Europe than in Eastern and Southern Europe. The contribution to Total Value Added is highest in Romania (2011: 6.8%) and Bulgaria (5.1%), followed by Hungary (4.4%), Poland (3.6%), and Lithuania (3.2%). The lowest levels can be found in Luxembourg (0.3%), Sweden (0.4%), Belgium and the United Kingdom (0.6% each), and Germany (0.7%) (Figure 3). Furthermore, Figure 3 illustrates that countries with a high share of agriculture, forestry and fishing in Total Gross Value Added have been experiencing a strong slowdown since 1995.

The Value Added share of agriculture in the overall economy, however, is an insufficient indicator of the relevance of this industry as agriculture contributes significantly to the economic performance of its upstream and downstream sectors (Ortner, Neuwirth, & Wagner, 2010). Furthermore positive and negative externalities which go along with agricultural production, e.g. the contribution to security

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of food supply, the environmental impact of farming practices, the amenity of certain landscapes and wildlife, etc., remain unconsidered.

Agricultural Production

Output Value: Composition and Development

In 1995 Austrian agriculture produced goods and services at a total value of €5.83 billion (Statistics Austria, 2015). This value includes subsidies on products amounting to €0.95 billion minus taxes on products in the amount of €0.02 billion. Until 1999, the output value of the agricultural industry at basic prices, which is referred to below as total output value of agriculture, declined to €5.4 billion. This decrease was primarily due to the schedule of degressive compensatory payments that were granted to facilitate EU accession. Between 2000 and 2004, the trends in the total output value were primarily dictated by the development of producer prices and output volumes. The annual rates of change of the output value of the agricultural industry fluctuated during this period within a range of (-3.2%) (2002) to (+6.2%) (2001). After a slight increase in 2000 and a hefty price-induced increase in 2001 there were declines in 2002 and 2003 and another increase in 2004. In 2005, decoupling of a large share of acreage premiums and certain livestock premiums led to a strong decrease of the total output value. Year 2006 marked the start of a very dynamic development characterized by a strong upward trend in agricultural output value, which was interrupted by a slump in 2009 in the wake of the financial and economic crisis. Particularly high growth rates occurred in 2007 and 2011. In the years 2012 and 2014, weather-related crop failures

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

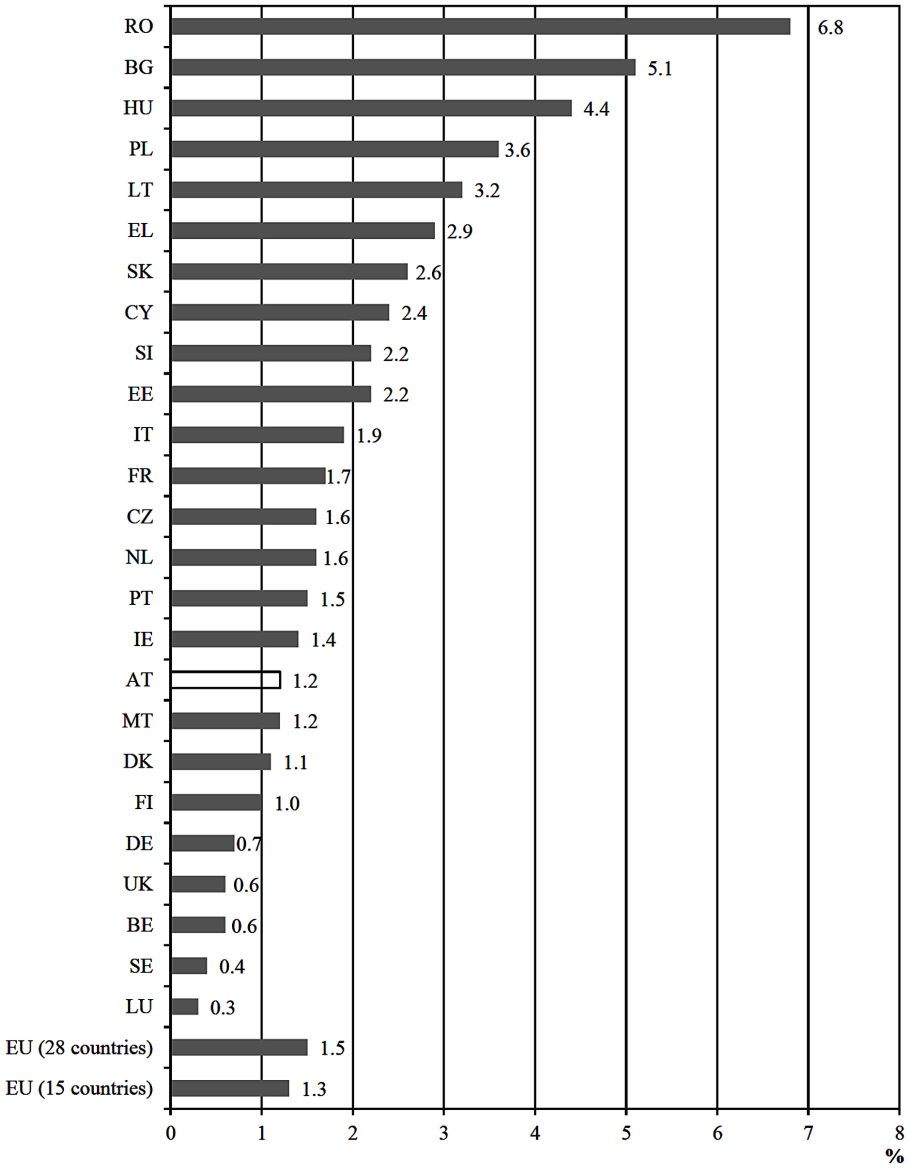
Source: Eurostat, 2015a



No data available for Croatia, Spain and Latvia.

and low yields weakened the result. In 2012, despite generally favourable price developments in agricultural markets, the output value of the agricultural industry increased only slightly, and it dropped according to preliminary calculations by 2.3% to some €7.1 billion in 2014. Only €0.09 billion of this amount were subsidies on products while taxes on products amounted to approximately €0.05 billion in 2013 (Statistics Austria, 2015). Austrian agriculture contributed about 1.7% to the total output value of the agricultural industry of EU-28 in 2013; its share of EU-15 was 2.1% (1995: 2.3%) (Eurostat, 2015b).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The output of the agricultural industry includes agricultural goods (crops and livestock), agricultural services and inseparable non-agricultural secondary activities. On average over the years 1995 to 2013 the share of animal output was 47% (with a minimum of 44% in 1999 and the maximum of 51% in the years 2005 and 2006) and that of crop output 43% (minimum: 39% in 2005; maximum: 46% in 1999 and 2011). Inseparable non-agricultural secondary activities accounted for 5% to 7%. The importance of agricultural services increased slightly although their share was still comparatively low at some 4.5% in 2014 (Statistics Austria, 2015).

In the period 1995 to 2014 there was no systematic shift in the relative contribution of crop and animal output to the total output value of the agricultural industry. Their shares fluctuated from year to year at times rather strongly. However, the importance of individual branches within the crop and animal production changed. Within crop production, the share of special crops (wine, fruit and horticulture) increased from 30% in 1995 to 46% in 2005 while the share of arable crops declined during the same period from 51% to 32%. These shifts were due, inter alia, to the scaling down of degressive compensatory payments granted upon EU accession and decoupling of most acreage premiums in 2005. From 2006 to 2012, the shares of arable crops in crop output fluctuated rather strongly, from slightly less than 30% in 2009 to between 40% and 42% in the years 2007 and 2010 to 2012. A major contributor to these fluctuations was the cereals sector whose output value dropped in 2005 as a result of the replacement of acreage premiums by the single farm premium but increased significantly afterwards, although subject to very large annual fluctuations. Within the cereals sector, the share of maize increased markedly at the expense of barley, oats, and rye. Protein crops lost out and within oilseeds, soy cultivation increased significantly in recent years. In animal production, which is dominated by milk, cattle, and pigs, the share of poultry and eggs increased at the expense of other animals and animal products (Statistics Austria, 2015).

Development of Volumes and Prices

Figure 4 shows the developments of volume and price indices of the agricultural industry's output in the years 1995 to 2014 in comparison to the corresponding indices of intermediate consumption. It reveals a significant increase in the prices from 2006 to 2012 of output as well as intermediate consumption; obviously, the cost of inputs increased more heavily. 2013 and 2014 prices declined, with a stronger decline of output prices. The output volume of the agricultural industry exhibits stronger dynamics after 2006.

The volume of crop output is, due to weather conditions, subject to rather large annual fluctuations while the volume of animal output developed rather evenly. In both crop and animal production, the output volume increased relative to the level in 1995. In crop production, output volumes of arable and special crops increased, whereas fodder production declined. With respect to prices, there was a relatively steady upward trend for special crops while the prices of arable crops were significantly more volatile (Figure 5).

In animal production, the increase in output volume was, inter alia, due to an increase in milk production. Prices followed an upward trend in recent years, which, however, was less pronounced than that of crops (Figure 6).

Agricultural Payments

This section presents the development of agricultural payments overall as well as in the context of the EAA, followed by an analysis of subsidies on products and other subsidies on production and their shares

in factor income. A comparison with select EU countries and groups of countries is made in order to allow for an assessment of these developments.

The European Commission (Regulation Establishing Rules, 2013; Regulation on Support, 2013) uses the term "payments" for monetary transfers from the public sector to the agriculture and forestry sector. Most of these payments are relevant for the EAA, in particular payments under pillar 1 (e.g. direct payments to farmers linked to market organizations) and pillar 2 (e.g. payments in the form of compensation for environmental activities, payments for the modernization of agricultural holdings).

In paragraph 2 the Austrian Agriculture Law of 1992 provides for direct payments, interest subsidies and other grants and subsidies to agriculture: production-neutral direct income support and performance-related direct payments, improvement of quality, support for environmentally sound activities and production-limiting measures in the crop and livestock sectors, measures to improve the competitiveness in agricultural production and marketing, measures to sustain farming and infrastructure, research and development and their adoption in agriculture, forestry and water management, and measures to promote investment into agriculture and forestry (Bundeskanzleramt, 2015).

Overall

In the period of 1959-1994, payments for agriculture and forestry in Austria were granted through the so-called "Green Plan" established by the Agriculture Law and by payments in connection with market

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

organizations (Ortner, 1997b). EU accession and thus the adoption of the CAP called for significant changes in the grant regime, and additional measures of the CAP had to be implemented (Bundesministerium für Land- & Forstwirtschaft, 1996, p. 145; Hambrusch et al., 2015).

Since its creation, the CAP has always been adapted to respond to challenges of the time. Major reforms have been implemented in the wake of the following milestones (European Commission, 2015b):

- The Agenda 2000 reform improving competitiveness in world markets by lowering producer prices and introducing policies to enhance rural areas, the environment and food safety, in particular "cross-compliance" (payments are conditional on environmental, animal welfare and health standards) and the modulation of premium payments (thresholds);
- The 2003 reform or "mid-term review" decoupling of direct payments from production and introducing the single farm payment in connection with cross compliance requirements;
- The 2008 CAP "Health Check" expanding rural development policy, discarding the acreage set-aside obligation and limiting the EU's agricultural expenditure;
- The CAP reform 2014-2020 maintaining the two pillars but increasing the links between them, thus offering a more holistic and integrated approach to policy support. Specifically it introduced a new architecture of direct payments to be better targeted, more equitable and "greener", an enhanced safety net against income loss, and strengthened rural development.

The described policy evolution over roughly a decade and a half can be characterised as a slow transformation process from a set of universal, obligatory, 100% EU-financed, agricultural commodity support measures towards a more market-oriented, decoupled, decentralised and co-financed rural development approach. This seems to recognise that compensatory payments should be transitional and ultimately phased out, leaving the regionalised and co-financed rural development measures as the core of the policy. If this comes about to the extent established by the goals of a common EU policy, common financing will be justified (Buckwell, 2015, p. 515).

Figure 7 shows changes in the development of the payments for Austrian agriculture and forestry in the years between 1990 and 1994 and the following financial periods as an EU member state. Since accession, payments for agriculture and forestry in Austria have been funded by the EU, the Federal State and the Federal Provinces. They were allocated for the EU financial periods 1995-1999, 2000-2006 and 2007-2013 to facilitate planning and evaluation. Since the year 2000, these funds have been split into budgets for direct payments and market-related measures (1st pillar of the CAP), rural development (2nd pillar of the CAP) and other expenditures (Bundesministerium für Land- und Forstwirtschaft, Umwelt und Wasserwirtschaft, 2015, p. 102). The figure clearly shows the effects of accession and the reforms of the CAP during that time.

The EAA only includes payments paid to farmers directly. Payments that are related to agriculture but granted to other industries – such as exports subsidies – are not considered (Kniepert et al., 2009, p. 83). Furthermore payments are divided into three categories: "subsidies on products", "other subsidies on production" and "capital transfers". Income is defined as including payments classified as "subsidies" but not capital transfers which remain unconsidered in the calculation of agricultural income (Regulation on the Economic Accounts, 2003, Annex I, para. 3.051, 3.088).

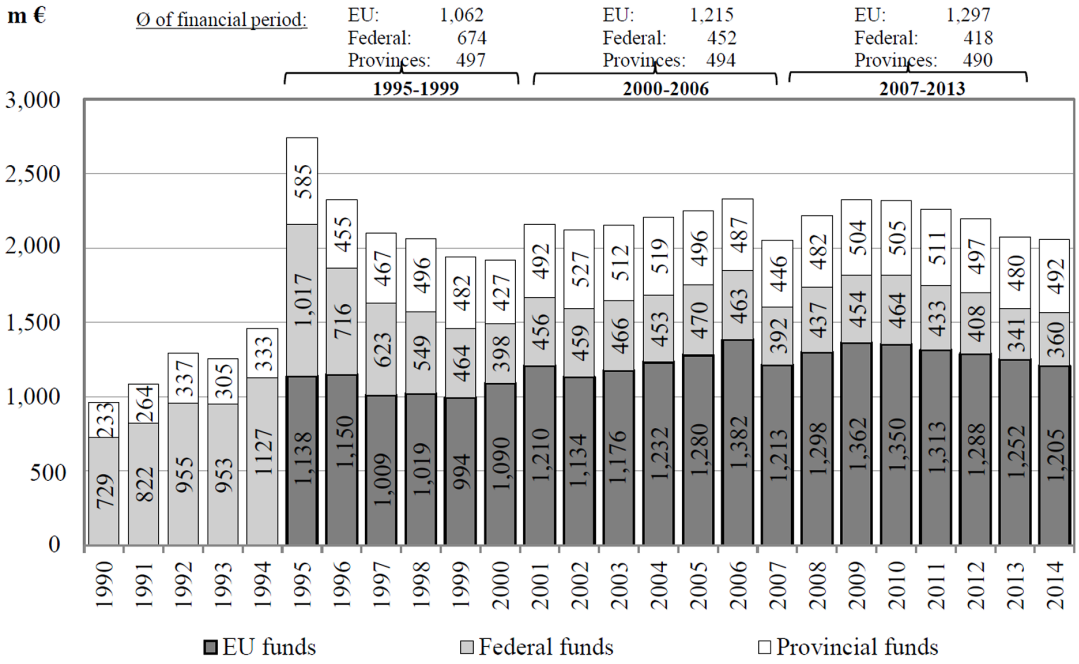
Source: Bundesministerium für Land- und Forstwirtschaft, Umwelt und Wasserwirtschaft, 2015; Bundesministerium für Finanzen, 2013



Development According to EAA

The change in the orientation of the CAP is demonstrated by the evolution of expenditures, echoing the policy shift since 1990. Figure 8 shows that payments which are to be recorded in the EAA (subsidies and capital transfers paid to farmers) increased during the observation period while the share of payments related to agriculture but excluded from the EAA decreased. The share of capital transfers remained almost constant.

Subsidies on products (direct payments for crop and animal production) increased significantly upon EU accession. In 2005, most of them were transformed to constitute the single farm payment. The jump in 1995 followed by the slump until 1999 is due to the implementation of degressive compensatory payments. Since EU accession, payments for environmental activities have constituted a significant share of total payments. The corresponding amounts stayed at about the same level over the years, as did those for compensatory allowances (support to unfavourable areas). While capital transfers exhibited a slight upward trend, the trend of other items in the category "other subsidies on production" (those except agri-environmental measures, compensatory allowance and single farm payment) declined slightly (Figure 9).

Share of Subsidies in Factor Income: Comparative Analysis for Selected EU Countries and Country Groups

The relative contribution of subsidies to farm income is quite different in the various EU countries. Among the countries surveyed here Austria (AT), after Finland (FI), followed by Sweden (SE) is one

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Source: Statistics Austria, 2015

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of the countries with the highest share of subsidies in factor income. Italy (IT) has the lowest share, and France (FR), the United Kingdom (UK), Germany (GE), and Switzerland (CH) occupy the middle ground between Italy and Austria. While the shares in Switzerland and the United Kingdom have changed rather evenly over the years, other countries showed stronger fluctuations (Figure 10 and Figure 11).

The share of product-related subsidies and other subsidies in factor income in the EU East has been aligning itself to that of the EU West over the years. The countries of the EU South clearly exhibit the smallest share. There is an obvious gap between northern and southern EU countries. The shares in the EU North fluctuate more widely. Austria's share is within the range of the EU North (Figure 12 and Figure 13).

A comparison with the EU average shows that the share in the EU South is smaller and the EU East is about average. In the EU West, the EU North and Austria the contribution of subsidies to factor income is significantly higher (Figure 13).

Since these shares are not available differentiated by structural features, it is difficult to analyse the impact of these features. The European data, which are available, support only a macro view, which means that the existence of different average farm sizes in individual countries distorts the comparison between them. In countries with a significant number of small and micro enterprises, subsistence farms and farms with negative profit, the inclusion of these businesses in a survey produces lower average incomes which are difficult to compare. Moreover, these statistics do not convey information about whether agricultural payments are targeted and efficient in achieving their targets at minimum cost.

A Note on the Federal Budget and Net Contribution

Table 1 shows the development of the federal budget and the agricultural budget and its composition during the period from 1995 to 2014. From there it is obvious that the agricultural payments share does

Source: Eurostat, 2015b

not exceed single digits. The highest share was 4.3% of the federal budget in 1995; before it was around 2%, and it hovered around 3% after 2005.

Table 1 also shows that a significant share of agricultural payments is financed by the EU. Nowadays the EU general budget originates mainly from so-called own resources (Art. 311 TFEU, formerly Art. 269 TEC). These funds are collected by Member States and forwarded to the EU budget. A comparison of the contributions of a Member State with its remittances from the EU budget delivers the net financial position (Figure 14 and Figure 15). This parameter gives information about the immediate financial consequences arising from the inclusion of the Member State in the EU budget. However, the net financial position is not sufficient to capture the total economic impact of EU membership. Such general assessments must be based on a far more comprehensive economic theory and statistical studies.

The balance of a country shows whether it is a net contributor (negative sign) or a recipient (positive sign). Although the balance solely compares contributions to and receipts from the EU budget, it is an instrument of budgetary discipline and plays a significant role in negotiations and decisions on the allocation of the EU funds ("net contributor discussion"). The sum of all negative balances (2000: €15.2 billion; 2005: €17.5 billion; 2010: €31.0 billion; 2014: €43.5 billion) measures the extent of redistribution between Member States which is generated by the EU budget (Bundesministerium für Finanzen, 2013, 2015; European Commission, 2015a).

The financial contribution of the Member States to the EU budget evolved very dynamically. As Figure 14 and Figure 15 show, net recipients and contributors change over time. Some Member States, like Germany, Austria, Belgium, and Luxembourg, are net contributors (Figure 14). The main net recipients are less developed regions (Figure 15).

Austria's net contribution to the EU amounted to €435.5 million in 2000; it grew until 2014 to €1,240.6 million (European Commission, 2015a). In the year 2000 Austria received about €0.9 billion and in 2014 approximately €1.3 billion of the EU funds. They were spent primarily for the benefit of Austrian agriculture which received approximately 70% of the total EU budget remittances (Bundesministerium für Finanzen, 2013, p. 36; European Commission, 2015a).

Income From Agricultural Activity

One of the main objectives of the CAP is to ensure a fair standard of living for the agricultural population, in particular by increasing the individual earnings of persons engaged in agriculture (see. Art. 39 of the Treaty on the Functioning of the European Union, TFEU). For an assessment of whether this objective is being achieved data on the composition and evolution of agricultural income is provided, inter alia, by the EAA. Income aggregates and indicators provided by EAA solely relate to income generated by agricultural activities and exclude income from other sources such as income from other gainful activities, wages and salaries or social benefits.

The EAA provides several income figures for the agricultural industry, among them Net Value Added at factor cost ("factor income") which measures the remuneration of the factors of production: land, labour and capital.

In 1995, the total of the output value of the agricultural industry at producer prices plus agricultural payments in the form of subsidies on products and other subsidies on production amounted to €6.8 billion. About a third of this, €2.3 billion, remained as factor income. In subsequent years, this share varied between 27% and 35%; in 2014, the share was 25% of the output value (approximately €8.4 billion). The development of the total of the agricultural output value and subsidies, what it was used for and how much remained as factor income, are presented in Figure 16 and Figure 17.

Net entrepreneurial income is agricultural factor income minus compensation of employees, rents and interest paid, plus interest received. It measures the remuneration of non-paid labour (i.e., labour by family members spent in their agricultural units), owned land and capital.

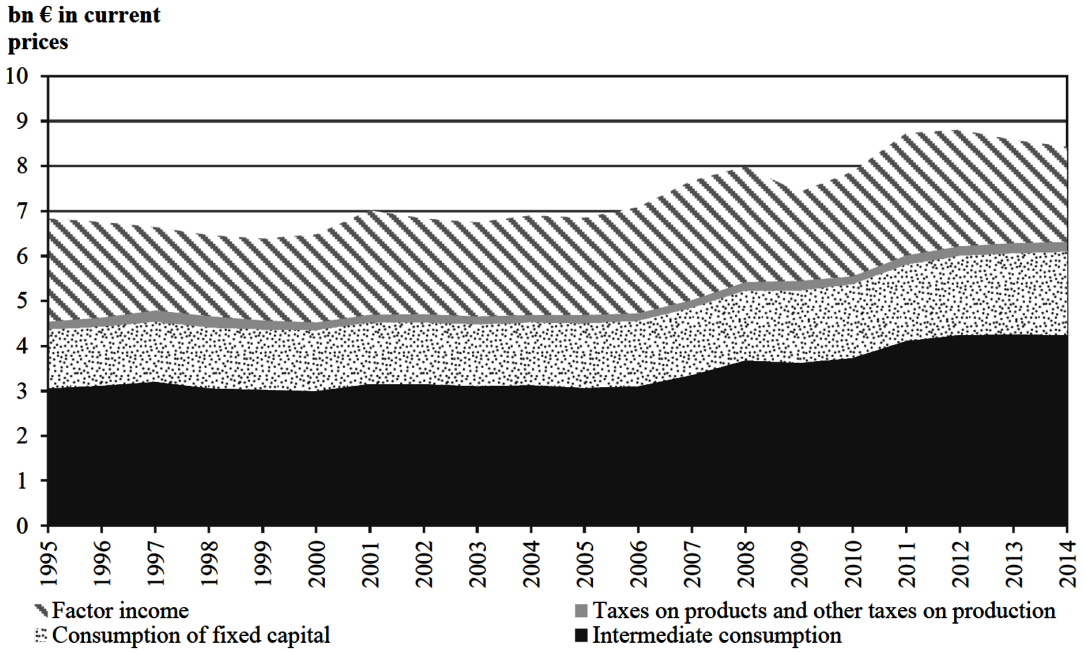
Figure 17. Production costs and factor income of Austrian agriculture, in € billion at current prices, 1995-2014
Source: Statistics Austria, 2015



In 1995, net entrepreneurial income of the agricultural industry amounted to approximately €2 billion, which corresponded to 90% of factor income (Figure 18). Its share in factor income followed a declining trend in the observation period except for annual fluctuations. In 2014, it accounted only for 73% of factor income.

Farm incomes are very volatile over time. The development of factor income is determined by changes in output levels and prices; subsidies and taxes on products; intermediate consumption levels and prices; consumption of fixed capital; other subsidies and taxes on production (Chatellier, Guyomard, Latruffe, & Levert, 2007, p. 3). The development of net entrepreneurial income also depends on changes in compensation of employees, rents paid and interests paid and received.

In Austria, the scheduled reduction of degressive compensatory payments was one of the main causes for the drop in income in the years immediately after EU accession. However, in 2001 factor income returned to the level of 1995 in nominal terms. Significant increases in income were observed in 2006 and 2007 as well as 2010 and 2011. The decline in 2009 was due to a sharp drop in agricultural prices in the wake of the economic and financial crisis. In the years 2012 to 2014, farm incomes decreased again. In real terms, i.e., deflated by the implicit price index of Gross Domestic Product at market prices (GDP), both factor income and net entrepreneurial income declined during the observation period.

Despite the declining amounts of real income generated by agricultural activity in total, income per work unit has exhibited an upward trend since 2001 – although with significant annual fluctuations (Figure 19). This development was due to structural changes in agriculture and the associated decrease in agricultural labour input. According to the EAA, agricultural labour input decreased from 188,400 annual work units (AWU) in 1995 by almost a third to 127,600 AWU in 2010. A decrease of non-salaried

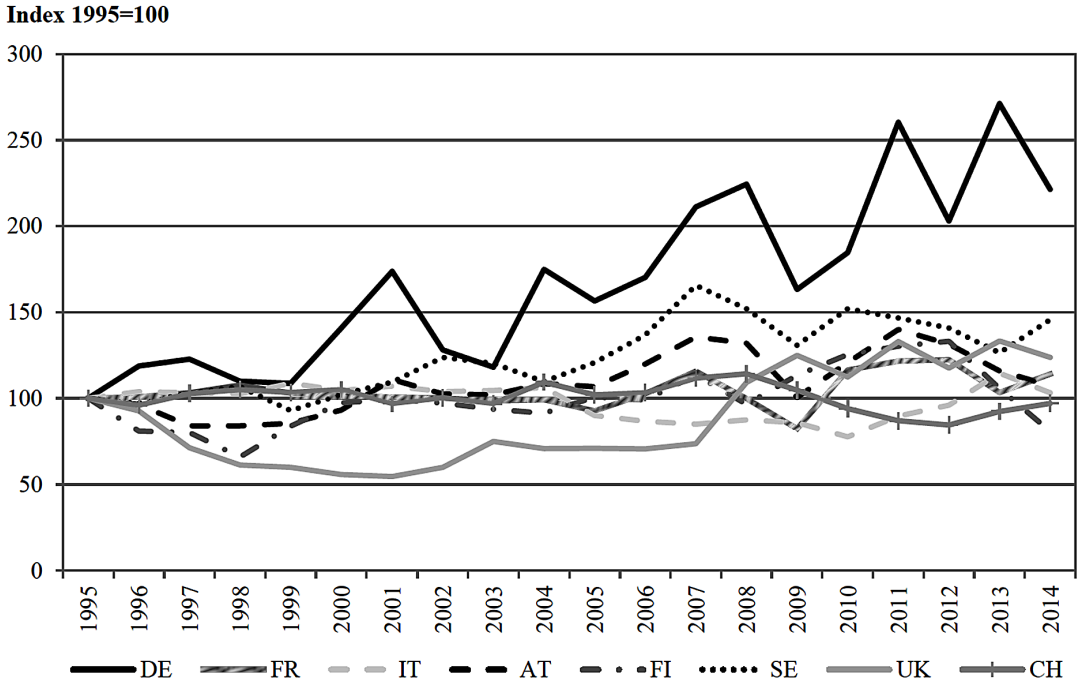
labour was partially offset by an increase of salaried employees whose share in agricultural labour input increased from 6% in 1995 to 11% in 2010.

At the European level, the index of real factor income per annual work unit (which is also referred to as indicator A) is primarily used to monitor agricultural income development and for income comparisons between Member States. As Figure 20 shows, indicator A developed quite differently in Austria, Germany, France, the United Kingdom, Italy, Switzerland, Finland, and Sweden. Germany and Sweden exhibit a trend similar to that of Austria from 2000, with factor income per AWU growing more variedly and steeper in Germany than in Sweden and Austria. In Switzerland, the development was quite stable, with a little slope and slight fluctuations. France, however, had a similar development to that of Austria from 2005, but from 1995 to 2000 factor income per AWU declined slightly, followed by a stable increase. Finland showed an extreme decrease until 1998, followed by a stable increase. In Italy, factor income per work unit remained at the level of 1995 until 2004, decreased until 2010 and recovered until 2013.

Main Developments in a Nutshell

Accession to the EU made Austria part of a single market, thereby intensifying competition through the elimination of trade barriers to other Member States. The preceding analysis showed that Austrian agriculture, which was considered a critical industry regarding EU accession (Schneider, 1997), has managed to weather the last twenty years since joining the EU without incurring massive losses of production and income (Gahleitner et al., 2015; Hambrusch et al., 2015). For Austrian agriculture the consequences of integration have more or less manifested themselves as follows:

Figure 20. Index of real agricultural factor income per AWU, 1995 = 100 – AT, GE, FR, UK, IT, FI, SE, and CH, 1995-2014
Source: Eurostat, 2015b



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The relative economic weight of the primary sector is below the EU-28 average. The economic importance of agriculture, measured as Value Added share in the overall economy, has been declining. The overall economy benefitted from accession as other sectors grew, due to integration effects (research and development, foreign direct investment) which are difficult to determine exactly (Breuss, 2003, p. 551).
- Even though output volume expanded over the observation period and output prices showed a significantly upward trend from 2006 onwards, real factor income as well as real Entrepreneurial Income generated by agricultural activity fell below the levels of 1995. Real income per AWU has however risen due to structural changes in agriculture leading to a significant decrease in the agricultural labour force.
- Agriculture in Austria and other EU countries depends heavily on direct payments. There has been a gradual reduction in subsidies, as a result of continuing pressure from the World Trade Organization (WTO), although subsidies in emerging economies have been increasing in recent years. Furthermore, the 2007-2008 world food price crisis has renewed calls for farm subsidies to be removed in light of evidence that farm subsidies may influence the level of food prices, which has a particularly detrimental impact on farmers in developing countries (EurActor Network, 2008).
- Changes in agricultural subsidies are necessary and occur continuously. The reduction of production-related subsidies andtransfers and the targeting of subsidies are seen as important for the liberalisation of markets and the sustainable development of developing and emerging countries. Current economic developments such as the financial crisis, intensive lobbies in various Member States, elections and political power struggles but also the need to deliver public goods suggest that the transformation of funding and the diminution of EU agricultural subsidies are likely to continue from financial period to financial period (Kraut, 2009, p. 61).

Other critical developments are less predictable. There are significant "wild cards": global warming, biotechnology and the changing role of Africa, China, Russia and the Middle East.

SOLUTIONS AND RECOMMENDATIONS

The fact that Austrian agriculture has managed to weather the last twenty years since joining the EU without incurring massive losses of production and income (Gahleitner et al., 2015; Hambrusch et al., 2015) was mainly due to substantive public measures and structural adjustment. In order to cope with current and futures challenges like global warming, volatile prices and tightening of public budgets, Austrian agriculture can adopt the following strategies:

- New customer segments: The growth in emerging markets of both population and the economy increases the level and quality of demand for agricultural and food products. According to forecasts of the Food and Agriculture Organization (2011) overall food demand will increase by 1.1% a year between 2006 and 2050, or by 70% over the whole period (KPMG International, 2013, p. 13).
- Diversification of output: Whereas the primary goal of agriculture is to produce food, feed and fibre, the sector is also being asked to provide a range of non-commodity outputs which are associated with agriculture such as access, recreation, conservation, amenity, heritage, tourism and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ecosystem services. Farmers and policymakers face the challenge to meet these demands by exploiting opportunities and offering targeted support to specific priorities as exemplified by the 2nd Pillar of the CAP.

- Customer awareness: The population is aware that Austrian agriculture provides important ecological and social services (open landscape, road access, accommodation, skills, education, etc.), especially in the less-favoured areas. In order to match demand for and supply of these services, their level depends on the willingness to pay (WTP) for positive and the avoidance of negative externalities. Agriculture will benefit from 'green subsidies' and adapt to them depending on how they are implemented in different agricultural policy measures, i.e., the rural development programme.

FUTURE RESEARCH DIRECTIONS

Areas of potential interest for future research include the following:

- The ongoing shifts in policy objectives and the volatile income in agriculture increase the necessity for policy-makers and scientists to take into account all sources of income of agricultural households, not just those derived from agricultural activity. Generally, in the EU, data on agricultural household incomes is scarce and calculation methods are not harmonised. Nevertheless, the European Commission (2010, p. 3) concludes "that farm households in many Member States derive a significant share of income from off-farm sources, i.e., mainly other gainful activities, but also social transfers and property income. Importantly, the share of off-farm income has increased in many of the countries for which data is available" (Statistic Canada, 2009; Schnepf, 2015, p. 24).
- In a free market, people ignore the positive externalities of consumption, e.g. when cycling to work, you take the cultivated landscape for granted. This raises the question about the value of these externalities, which are subject to agricultural policy and EU subsidies and can be estimated by WTP. WTP is the amount of money a person would be willing to pay for a higher level of environmental or commodity quality (Golan & Kuchler, 1999; Spencer, 1996). According to James (2002), tools for measuring WTP (which include the contingent valuation, travel cost and hedonic pricing) can be used to answer questions such as how much consumers are willing to pay for a quality upgrade or what impact a particular government intervention might have.
- Agriculture is confronted with the following challenges – as described in the following familiar mix of broad European rural development objectives – of maintaining resilience and improving agricultural productivity to help ensure food security for citizens at a lower resource cost; improving environmental performance of agriculture; contributing to reasonable living standards for primary producers; assisting the development of rural areas, especially remote and marginal areas (Buckwell, 2015, p. 512). In upcoming evaluation activities as well as for further reforms it has to be examined whether these objectives are met.
- Conventional agricultural accounts – such as EAA – allow a macro level follow-up of economic functions but offer no insights into the multifunctional contribution of the agricultural industry to society, nor do they reflect the true costs of agricultural production for society. There is a need to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

analyse the relationship between the economic activities of agriculture and the environment, with agriculture having both positive and negative impacts on the local and surrounding environment. For this purpose, the System of Environmental-Economic Accounting for Agriculture, Forestry and Fisheries (SEEA AFF) is currently being developed within the framework of the SEEA Central Framework. A further step would be to consider social aspects as well as cultural ones.

- And finally, Austrian and European agriculture are becoming more frequently influenced by volatile producer prices, volatile energy markets, localised natural hazards such as flooding, and the effects of regulations on technology use and labour supply. Some agricultural areas continue to lose their competitive edge to other regions with, say, more favourable climate or adequate labour supply. Unfortunately, many agricultural programmes tend to favour stability-enhancing management strategies with little attention to adjustment capacity in agriculture itself. There is a need to examine the adjustment capacity of agriculture and to analyse the role that institutional factors and in particular product market regulations play in this adjustment process.

CONCLUSION

This chapter provides key insights into the evolution of Austrian agriculture within the EU. The authors' results are in line with the literature on Austrian's accession to the EU (Breuss, 2003; Schneider, 1997) and studies at European level (European Commission, 2010). Analyses have demonstrated that Austrian agriculture in general has so far found ways to adapt to the change in the agricultural regime attendant to EU membership and its wide-reaching effects on agricultural markets and production conditions. As the evolution of the CAP gets underway, the future development of Austrian agriculture remains to be seen. It will depend primarily on the development of markets under globalization and climate change as well as technological advancement along with the consumers' demand. Future agricultural reforms are likely to be made in relation to the goals of developing intelligent, sustainable and inclusive growth as outlined in the Europe 2020 strategy, while taking into account the productivity and diversity of agriculture.

NOTE

This chapter is a revised version of a contribution by Christina Mayer and Erika Quendler entitled '*Die österreichische Landwirtschaft seit dem EU-Beitritt aus Sicht der Landwirtschaftlichen Gesamtrechnung'* published in E. Egartner, T. Resl (Hrsg.). Einblicke in Österreichs Landwirtschaft seit dem EU-Beitritt (p. 155-195). Schriftenreihe 108. Wien: Bundesanstalt für Agrarwirtschaft.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

KEY TERMS AND DEFINITIONS

Agricultural Industry: A collection of local kind-of-activity units that carry out agricultural activities including both farms and specialist agricultural contractors. The output of agriculture also includes inseparable non-agricultural secondary activities that these units carry out. It excludes services relating to design, planting and maintenance of gardens, parks, and green areas for sports facilities. It also excludes units producing solely for their own consumption.

Agricultural Labour Input: All employed and self-employed persons that provide paid and unpaid labour input to residential units, which perform characteristic activities (agricultural and inseparable non-agricultural secondary activities) of the agricultural industry. Due to the consideration of part-time and seasonal work, labour force and its changes are measured in annual work units (AWU). One AWU equals one person in full-time employment in agriculture in one year. Employment has an important influence on the calculation of the income indicators.

Agricultural Production at Basic Prices: Equals value of crop and animal output, agricultural services output and the value of inseparable non-agricultural secondary activities, valued at basic prices. Valuation at basic prices means the taxes on products and services are excluded and subsidies on products and services are included. The output of the agricultural industry results from the market production of goods and services as well as non-market production for individual final use (own consumption by agricultural households, own-account produced fixed capital goods of crops and livestock). Furthermore, parts of the output consumed by the agricultural units themselves are included in the output value (crop products that are used as fodder within the unit).

Agricultural Production at Producer Prices: Equals the value of crop output, animal output, agricultural services and the value of inseparable non-agricultural secondary activities, valued at the (farm-gate) producer prices without VAT.

Basic Prices: Amounts received by the producer for a unit of goods or services, minus any tax payable on that unit as a consequence of production or sale (i.e., taxes on products), plus any subsidy receivable on that unit as a consequence of production or sale (i.e., subsidies on products).

Capital Transfers: Require the acquisition or disposal of an asset, or assets, by at least one of the parties to the transaction. Whether made in cash or in kind, they result in a commensurate change in the financial, or non-financial, assets shown in the balance sheets of one or both parties to the transaction.

Economic Accounts for Agriculture (EAA): The purpose is to analyze the production process of the agricultural industry and the primary income generated by this production. It contains provides detailed data on value of output (at producer prices and basic prices), intermediate consumption, subsidies and taxes, consumption of fixed capital, rents and interests, capital formation, etc. The values are in current as well as in constant prices. Furthermore, Agricultural Labour Input (ALI) and Unit Values (UV) are an integrated part of the overall concept of EAA.

Entrepreneurial Income: Equals net operating surplus/net mixed income less rents paid and interest plus received interest that refers exclusively to agricultural production.

Factor Income: An amount for the remuneration of the production factors: labour, capital and land. Factor income incorporates subsidies on agricultural products and other subsidies on agricultural production. Due to the importance of the subsidies in agriculture and redirection of the common agricultural policy in indirect support in the form of other subsidies on production, factor income is more appropri-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ate for reflecting the economic state of agriculture than Value Added. Factor income equals Net Value Added at basic prices less other taxes on production plus other subsidies on production. Factor income also equals the sum of net operating surplus/mixed income and compensation of employees.

Gross Domestic Product (GDP): Aggregate measure of production equal to the sum of the Gross Value Added of all resident institutional units engaged in production (plus any taxes, and minus any subsidies, on products not included in the value of their outputs).

Subsidies: Current unrequited payments which general government or the institutions of the European Union make to resident producers with the objective of influencing their levels of production, their prices or the remuneration of the factors of production. Subsidies on agricultural products are subsidies payable per unit of a good or service produced. Other subsidies on production include all subsidies, other than subsidies on products, from which resident producer units can benefit as a result of engaging in production (for example agri-environmental measures, subsidies for agricultural production in less favoured or mountain areas and compensation for current loses).

Chapter 40
Economic Growth and Climate Change:
An Exploratory Country-Level Analytics Study

Wullianallur Raghupathi
Fordham University, USA

Viju Raghupathi
Brooklyn College (CUNY), USA

ABSTRACT

In this article, the authors use analytics to explore the association between economic growth and climate change at a country-level. They examine different indicators to better understand the macro issues and guide policy decision-making. The authors analyze global economic growth and climate change using the World Bank data of 131 countries and 16 indicators for the period 2005 to 2010. The analysis shows overall economic growth is positively associated with climate change. This implies country leaders should design and implement structured development plans if they are to promote economic growth to alleviate poverty while simultaneously mitigating climate change.

INTRODUCTION

According to scientists and policymakers, the earth's climate is changing. Temperatures are rising, snow and rainfall patterns are shifting, and extreme weather events—intense rainstorms, record-high temperatures, alternating cyclone/hurricane occurrences and long dry spells—are wreaking havoc in different parts of the world (International Monetary Fund, 2008; U.S. Environmental Protection Agency, 2016). Researchers are generally confident that many of these changes and trends are associated with increased levels of carbon dioxide and other greenhouse gases (GHG) in the earth's atmosphere, and that these increases have been brought about by human activities (International Monetary Fund, 2008; U.S. Environmental Protection Agency, 2016)). Climate change refers to "any substantial change in

measures of climate (such as temperature or precipitation), lasting for an extended period (decades or longer). Natural factors have caused the climate to change during previous periods of the Earth's history, but human activities are the primary cause of the changes that are being observed now (International Monetary Fund, 2008; Stern, 2006; The National Academies Press, 2010a, 2010b; U.S. Environmental Protection Agency, 2016)." Human activities are generally understood to include economic development and growth activities (The National Academies Press, 2010a, 2010b; Ward and Shively, 2012).

The primary sources of greenhouse gases, in order of importance, are: electricity generation, land-use changes (e.g., deforestation), agriculture, and transportation (International Monetary Fund, 2008; Stern, 2006; The National Academy of Sciences, 2014). While the literature strongly suggests rich (developed) countries have historically dominated emissions, and poor (developing) countries will contribute to the rise in emissions rapidly, the current debate and global talks on climate change center around how to mitigate climate change while keeping equity and poverty reduction (Soubbotina, 2004; Tol, 2009) in mind (International Monetary Fund, 2008; Markandya, 2011). For example, increases in energy-related emissions of carbon dioxide, the largest and fastest growing source of GHG emissions, are primarily driven by growth in GDP capita and population increases, and these increases are only partially offset by more efficient use of energy (Markandya, 2011; Ward and Shively, 2012). While China, India, and other developing countries contribute to most of the growth in emissions, developed countries account for most energy-related emissions in the past and, thus, for most of the current stock of these emissions (Markandya, 2011). When changes in land-use and deforestation are considered, however, advanced countries are responsible for less than half of the current stock of total emissions (Markandya, 2011). In other words, the amount of carbon dioxide a country emits into the atmosphere depends mainly on the size of that country's economy, the level of its industrialization, and the efficiency of its energy use (Mattoo and Subramanian, 2012; Raghupathi and Raghupathi, 2016; The National Academies Press, 2010b). Until now, though developing countries contain most of the world's population, their industrial production and energy consumption per capita have been relatively low. There can be little doubt that the primary responsibility for global warming lies with developed countries. But the link between economic growth and increased energy consumption, in conjunction with increased carbon dioxide emission, is direct and positive for all countries (Mattoo and Subramanian, 2012). That said, at high-income levels, there are indications of lower per capita energy consumption and pollution despite economic growth (Raghupathi and Raghupathi, 2016; The National Academies Press, 2010b) explained by increased efficiency in energy use thanks to environmentally cleaner technologies. Also, a higher-income country will typically demand a proportionally larger service sector, and service is a far less energy intensive sector compared to, say, manufacturing (Mattoo and Subramanian, 2012).

In summary, we know that developed countries have to reduce emissions, and they need to identify innovative strategies and technologies to develop and use. Furthermore, developed countries need to transfer and make these technologies available to developing countries. Progressive development assistance and aid have to be provided to developing countries, engaging them in rapid economic development and poverty reduction, and at the same time, keeping greenhouse gas emissions in check (The National Academies Press, 2010a). However, considering most developing countries do not commit to reduce greenhouse gas emissions, arguing that these commitments would undermine their economic development and impede poverty alleviation, finding the right balance between economic growth and climate change is a key challenge (Mattoo and Subramanian, 2012; The National Academies Press,2010a; United Nations Development Program, 2013). Naturally, all countries contemplating mitigation will want to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

understand the economic impact and whether climate change mitigation will allow them to enhance or maintain growth (International Monetary Fund, 2008).

Key to this research, therefore, is the question of whether there is an association between economic growth (development) and climate change: Is climate change directly associated with economic growth? If so which indicators are significant? In this exploratory study, we address these questions. The findings have numerous implications. First, if an association exists, developed countries should make reparations for past and current emissions. Second, they should help developing countries engage in structured development by promoting equity to balance poverty alleviation with climate change mitigation and prevention. Third, countries with innovative strategies and technologies should facilitate the transference of such technologies to developing countries to mitigate climate change. Fourth, countries with experience and expertise in climate-change-mitigation strategies, studies, and research should share those experiences with countries that do not have similar experience or resources.

The rest of this paper is organized as follows: First, we describe the methodology of our study; we then discuss results and offer analysis; thirdly, we outline the scope and limitations of the study; fourthly, we offer contributions; finally, we offer conclusions and policy implications.

MATERIALS AND METHODS

We study the association between climate change and economic growth at a global level, using analytics. Analytics is the "application of models, methods, and tools to analyze large data sets to gain insight to make informed decisions (Raghupathi & Raghupathi, 2016). Analytics, a collection of decision support technologies, enables scientists and policymakers to understand and make better/faster decisions related to a domain. As more data is generated digitally and otherwise, decision-makers strive to leverage abundance of rich data using sophisticated analytic techniques - including artificial intelligence, machine learning, statistics, and visualization - so as to be data-driven in their decision-making.

The domain of climate change is complex and multidimensional including facets of climate impacts, adaptation, mitigation and policy (Becken, 2013). Public knowledge of the domain is limited and its effects are perceived as abstract and unclear. In addition, the perception about climate change varies between countries (Capstick et al., 2015). In order to be effective, global concern about climate change should be preceded, at the very least, by knowledge about its nature and effects (Shi et al., 2014). There is therefore a basic need for research to communicate all relevant information related to the domain in a simple and effective manner. With this premise in mind, we deploy the analytic technique of visualization in the current research. Visualization has been used in domains such as environmental and climate science to effectively communicate the meaning in complex and large data sets to a wide audience (Bohman et al., 2015). Additionally, in the realm of climate change, since the impact varies geographically, there is an inherent spatial dimension to its adaptation and mitigation which lends itself very well to visualization. Visual representation of scientific data helps communicate and increase the knowledge and recognition of the effects of climate change and of planning and decision making in the domain (Salter et al., 2009; Sheppard 2012; Sheppard et al. 2011; White et al. 2010). Being an exploratory research, our objective is to be data-driven and identify patterns and meaning in the data by directly interacting with the data, gaining insight, drawing conclusions and making fact-based recommendations. We call this evidence-based climate change analysis.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The research methodology is comprised of the following phases: data collection, indicator selection, data preparation, analytics platform and tool selection, and analytics implementation (Table 1). The phases are general enough to be applied to any domain in which analytics is deployed (Raghupathi & Raghupathi, 2016).

The data for climate change and economic growth indicators for the years 2005 to 2010 were downloaded from the World Bank website (http://data.worldbank.org/data-catalog/world-development-indicators). This was the only available data. There are a few reasons why data was not available for some indicators, countries and years, in the data source. Some indicators are derived from sporadic surveys and are only available every few years. Additionally, some countries do not report data on a regular basis due to several reasons such as conflict, lack of statistical means, and others. Also, in some countries data simply does not exist for some years. Despite these challenges, the indicators from World Bank are generally accepted as authentic indicators of economic growth and climate change (http://data.worldbank.org/indicator). As the World Bank says, "the primary World Bank collection of development indicators, compiled from officially-recognized international sources…presents the most current and accurate global development data available, and includes national, regional and global estimates."

The economic indicators include GDP (current US$), GDP per capita, GDP growth (annual %), Gross savings (% of GDP), Trade (% of GDP), Industry (% of GDP), and Exports of goods and services (% of GDP). The climate change indicators include CO2 emissions (kt), CO2 emissions per capita, Forest area (% of land), Improved water source (% of population with access to improved water), Energy use (kt of oil equipment), Energy use per capita (kg of use per capita), and Electric power consumption per capita (kw per capita). Table 2 shows a description of the variables with measures.

We collected the data for 131 countries and used the income group classifications from the World Bank (http://go.worldbank.org/CWTURYIPS0): low income, lower middle income, upper middle income, and high income. The high-income classification is bifurcated into member and non-member countries of the Organisation for Economic Co-operation and Development (OECD). The OECD strives to promote and maintain the economic and social well-being of its member countries. Most country-level research uses World Bank's income group classification as the benchmark for comparative trend analyses. In our data, 47 countries fall under the high-income classification, 40 under upper middle income, 32 under lower middle income, and 12 under lower income classification. We included the geographic regions where the countries belong, such as East Asia and Pacific, Middle East and North Africa, Europe and Central Asia, Latin America and Caribbean, North America, South Asia, and Sub-Saharan Africa.

Table 1. Research methodology summary

Data Collection	World Bank
Indicator Selection	Economic and Climate Change indicators Control: Income group, Region
Data Preparation	Data extracted from World Bank website in csv format and prepared for loading into analytic tools
Platform /Tool Selection	Multiple tools
Implementation	Analysis and reports implementation using analytic tools

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Description of indicator variables

Climate Change Indicators	
CO2 emissions (kt)	Carbon dioxide emissions are those stemming from the burning of fossil fuels and the manufacture of cement. Excludes carbon dioxide produced during consumption of solid, liquid, and gas fuels, and of gas flaring.
CO2 emissions per capita	CO2 emissions divided by population
Forest area (% of land area)	Land under natural or planted stands of trees of at least 5 meters in situ, whether productive or not, and excludes tree stands in agricultural production systems (e.g., in fruit plantations or agroforestry systems) and trees in urban parks and gardens
Improved water source (% of population with access)	% of population using an improved drinking water source, including piped water on premises and other improved drinking water sources (public taps, standpipes, tube wells, boreholes, protected dug wells and springs, rainwater)
Energy use (kg of oil)	Use of primary energy before transformation to other end-use fuels, which is equal to indigenous production plus imports and stock changes, less exports and fuels supplied to ships and aircraft engaged in international transport
Energy use per capita (kg of oil per capita)	Energy use divided by population
Electric power consumption (kw per capita)	Measures the production of power plants and combined heat and power plants, less transmission, distribution, and transformation losses and own use by heat and power plants
Economic Growth Indicators	
GDP (US$)	Gross Domestic Product
GDP per capita (US$)	GDP divided by population
GDP growth (annual %)	Annual Percentage Growth of GDP at market price based on constant local currency
Gross savings (% of GDP)	Gross national income less total consumption, plus net transfers measured as a share of Gross Domestic Product
Trade (% of GDP)	Sum of exports and imports of goods and services measured as a % of GDP
Industry value added (% of GDP)	Net output of a sector after totaling all outputs and subtracting intermediate inputs. It is calculated without making deductions for depreciation of fabricated assets or depletion and degradation of natural resources. Comprises value added in mining, manufacturing, construction, electricity, water, and gas.
Exports of goods and services (% of GDP)	Value of all goods and market services provided to the rest of the world. Includes the value of merchandise, freight, insurance, transport, travel, royalties, license fees, and other services, including communication, construction, financial, information, business, personal, and government services; excluding compensation of employees, investment income, and transfer payments.
Control Variables	
Income Group	High OECD/non-OECD, upper middle, lower middle, low
Region	East Asia/Pacific, Europe/Central Asia, Latin America/Caribbean, Middle East/North Africa, North America, South Asia, Sub-Saharan Africa

The raw data were extracted in CSV format from the sources, and the extracted data were integrated, cleansed, and standardized for loading into the analytics tool. To perform the analytics, several tools, which utilize visualization and other techniques, were chosen for identifying trends and patterns in the data and for facilitating various analyses. To reiterate, based on the literature, our overall data-driven research proposition is that economic growth is positively associated with climate change. In the data-driven approach, we let the data tell the story (U.S. Environmental Protection Agency, 2016).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

RESULTS AND ANALYSIS

The distribution of the sample by region and by income are shown in Figure 1.

Figure 1 shows that the region of Europe and Central Asia has the majority of high-income OECD countries followed by North America. North America is comprised of all high-income OECD countries. The region of Sub-Saharan has the highest number of low-income countries. We analyzed the different income groups to discern possible trends and variations in economic growth and economic growth.

CO_2 Emissions

Since CO2 emission is an important indicator of climate change, we analyzed it for the sample countries for the period 2005 to 2010 (Figure 2).

Figure 2 reveals a drop in CO_2 emissions in 2008-09 for all income groups. There is a likely explanation for the drop: the 2007-08 global financial crisis saw the failure of large financial institutions, drop of stock markets worldwide, and an overall decline in industrial and economic activity. It's reasonable to presume that the drop in CO_2 emissions is associated with the decline in the global economy that followed the crisis.

We compared the median and average CO_2 emissions across different income groups to gain a better understanding of the pattern of CO_2 emissions over the years (Figure 3).

The top panel in Figure 3 shows average emissions, and the bottom panel shows the median emissions, for the four income groups. In terms of average emissions, upper middle-income countries have surpassed high income countries since 2009, while in median emissions terms, high-income countries take the lead. The low-income group shows the lowest emissions and no variation over the years in terms of average or median emissions. CO_2 emissions seem to be positively associated with the income of

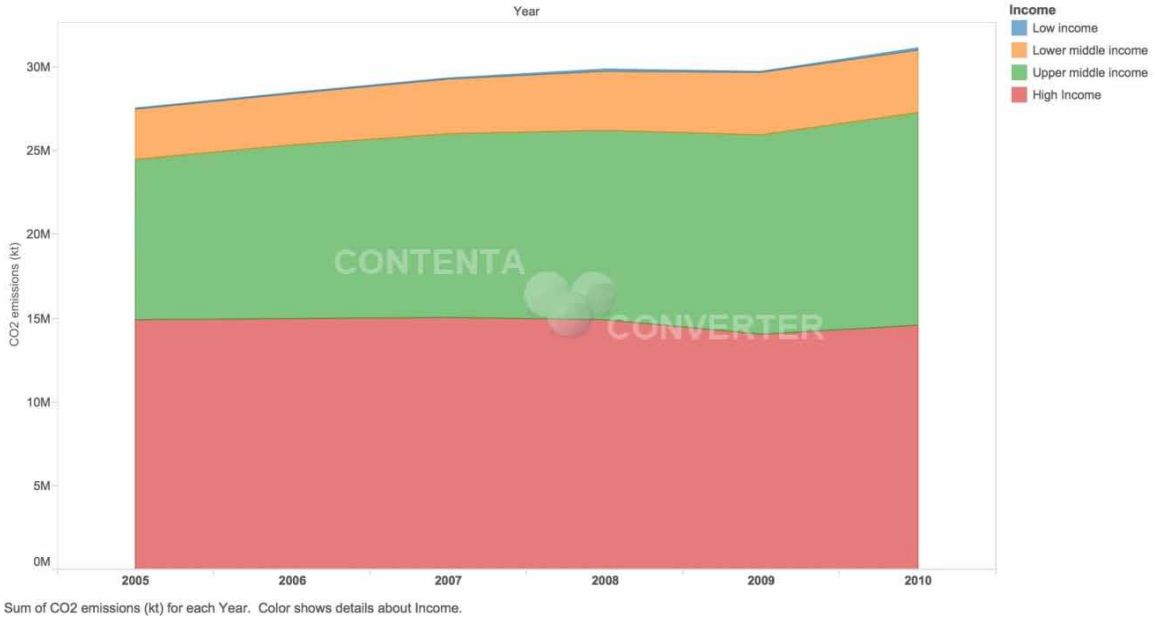
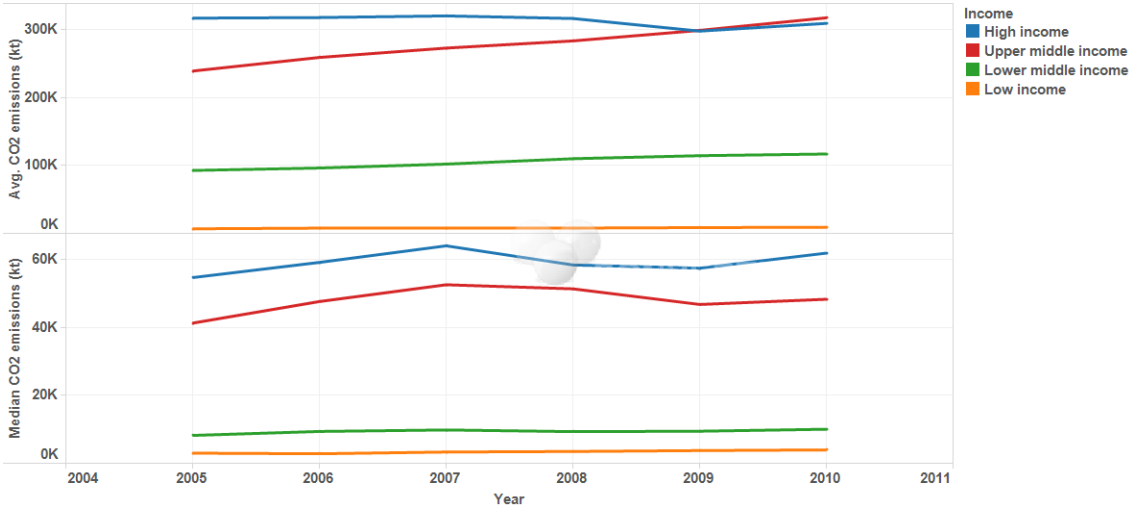
Figure 2. Trend of CO_2 emissions



**For a more accurate representation see the electronic version.*

Figure 3. Trend of median and average CO_2 emissions



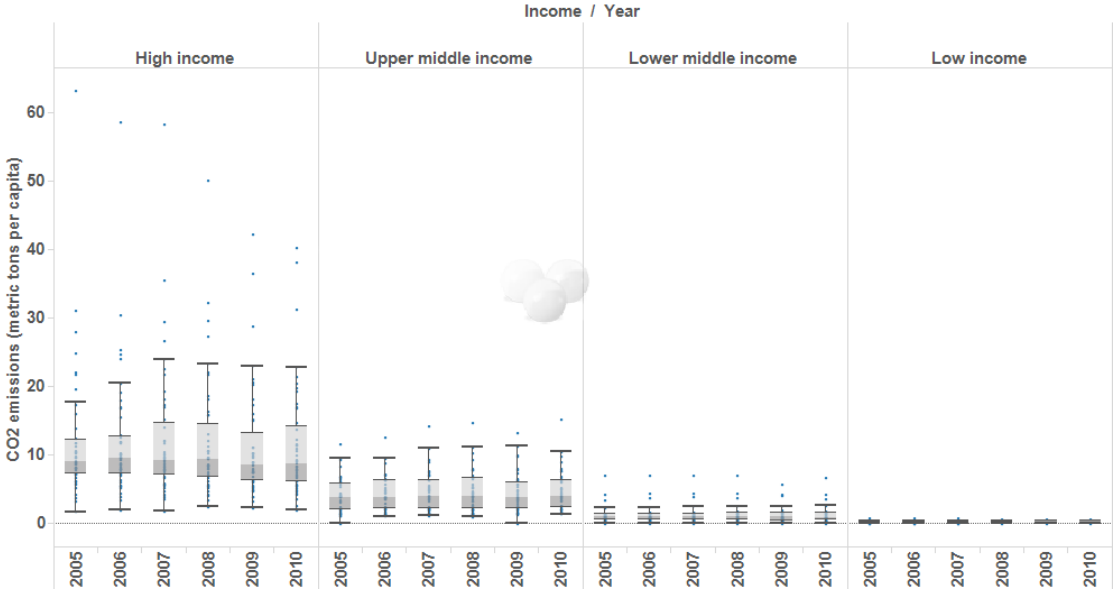
**For a more accurate representation see the electronic version.*

countries. For a clearer picture, we considered CO_2 per capita emissions instead of total CO2 emissions, because per capita takes population into account. It is a fact that low-income countries have a much higher population than high-income countries, and therefore including per capita emission in our study offers a more balanced approach for analysis.

The box chart in Figure 4 clearly shows that the per capita CO_2 emissions is much higher in high-income countries than in others. Elevated levels of industrialization in high-income countries accounts

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. CO_2 emissions per capita



for the high emission levels. Not surprisingly, low-income countries show the lowest emissions per capita. Clearly, there is a positive association between a country's per capita CO_2 emissions and income. Economic growth is associated with higher income and therefore with higher emissions (Ravallion et al., 2000). Countries need to consider a possible trade-off between economic growth and social equity in ensuring prevention of climate change and global warming. The Kyoto Protocol (KP) is an international treaty that extends the 1992 United Nations Framework Convention on Climate Change (UNFCCC) that commits its parties to reduce greenhouse gas emissions, including CO_2 emissions (Iwata and Okada, 2014). The KP was initially adopted in Japan in 1997 and entered into force in 2005 with an objective to reduce GHGs by about 5% from 1990 levels. In the second commitment period, parties committed to reduce GHG emissions by at least 18% below 1990 levels during the years 2013-2020. Countries that have binding emission targets under the KP have consistently lower CO_2 emissions (about 7-105 lower) than they would, in the absence of benchmarks (Almer and Winkler, 2017; Grunewald and Martınez-Zarzoso, 2009). In spite of controversy on the effectiveness of the KP (Bohringer and Vogt, 2003), enforcing such treaty is generally viewed as an integral step to addressing global climate change (Rollings-Magnusson and Magnusson, 2000).

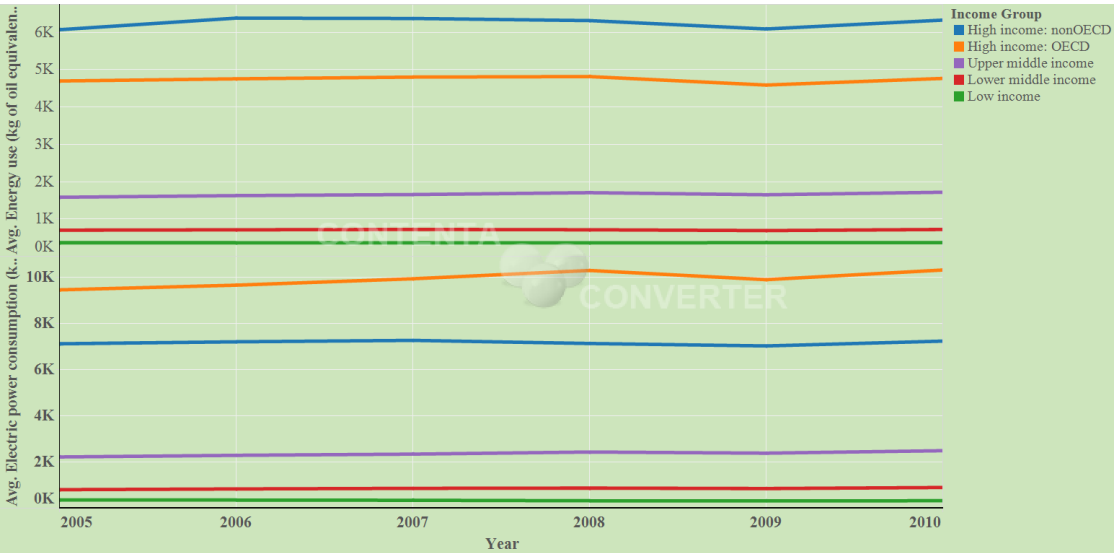
Energy Use and Electricity Consumption

Figure 5 shows the distribution of energy usage and electricity consumption for the four income groups over the six years we are focused on here. The top portion of the graph shows the distribution for energy usage and the lower portion depicts the distribution for electricity consumption.

As seen in Figure 5, high-income OECD countries have the highest electricity consumption, and the consumption has increased steadily over time. The consumption in the low- and middle-income countries has been limited and did not change significantly in the period 2005 to 2010. With respect to energy

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Distribution of energy use and electric power consumption



**For a more accurate representation see the electronic version.*

usage, high-income non-OECD countries exhibit the greatest energy usage, followed by high-income OECD. Lowest usage is by low-income countries.

Our results reflect two important issues that need to be addressed. One is the disparity between high and low-income countries in terms of energy and electricity usage or consumption. The United Nations Framework Convention on Climate Change (UNFCCC) under the Kyoto Protocol set up international funding programs such as the Adaptation Fund to finance projects aimed at helping low income countries adapt to the harmful effects of climate change. This enables transfer of funds and technology from developed/high income to developing/low income countries.

The second issue is to ensure that the high usage and consumption of energy and electricity by high income countries does not adversely impact climate change. It is therefore imperative that these countries reinforce the importance of sustainable energy sources and consumption (Winston et al., 2017). Reducing emissions from the energy sector is a major challenge for climate change since electricity generation is one of the major contributors to anthropogenic emissions (Hansen et al., 2007; Voorspools et al., 2000; Vougioukli et al., 2017). There is a need for countries to explore alternative means of electricity production using renewable rather than non-renewable sources. An example is the hydropower which is a way of producing electricity using moving water (Vougioukli et al., 2017). Hydropower can be used on a small scale to generate electricity in remote or mountainous areas.

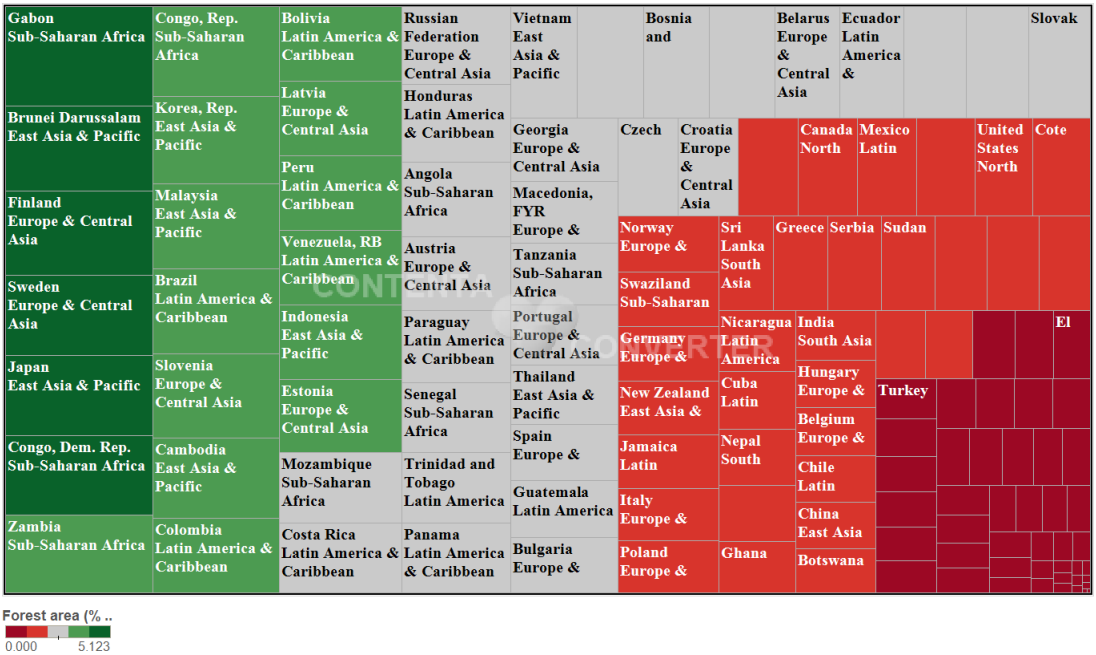
Forest Area

We looked at the distribution of forest area, which represents the percentage of natural or planted trees that are preserved, excluding trees in urban parks and gardens. Figure 6 shows the distribution by region.

Figure 6 depicts a heat map and shows regions with high forest area in green and low forest area in red. Regions such as East Asia and Pacific (Brunei, Japan, Korea, Malaysia, Cambodia, and Indonesia), Europe and Central Asia (Finland, Sweden, Slovenia, Latvia, and Estonia), parts of Sub-Saharan Africa

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Distribution of forest area by region



**For a more accurate representation see the electronic version.*

(Gabon, Congo Democratic Republic), Latin America and Caribbean (Brazil, Columbia, Bolivia, Peru, and Venezuela) show high levels of forest area. The Sub-Saharan region belongs to the low-income country classification, but it also shows a high level of forest area.

We looked next at the distribution of forest area by income to see whether there is any association (Figure 7). We expected to find that high-income countries emphasize industrialization over agriculture and would show greater deforestation compared to medium- and low-income countries.

Figure 7 shows that high-income OECD countries have the largest percentage of forest area, followed by upper middle- and low-income countries. While the level of forest area is fairly consistent for the high and upper middle-income countries, it decreases over time for low-income and lower-middle-income countries. Efforts to increase industrialization may account for this decrease in forest area in low- and lower-middle-income countries. It's noteworthy that, contrary to our expectation, economic development did not adversely affect forest area; high-income countries still show the greatest percentage of forest area. This finding offers promise.

GDP per Capita and Energy Usage per Capita

We looked at the economic indicator of GDP per capita for an association with energy usage per capita to learn whether developed countries with high GDP per capita use more energy than other income groups (Figure 8).

Figure 8 shows the relationship between GDP per capita and energy use per capita to be significant ($p<0.0001$) for all groups except the low-income group. For high-and middle-income groups, the association between GDP per capita and energy usage is positive, indicating that as the GDP per capita increases, energy usage also increases.

GDP per Capita and Forest Area

For each income group in the sample, we looked at GDP per capita and forest area for the different income groups (Figure 9).

In Figure 9, the color of the bubble denotes the % of forest area and the size denotes the GDP per capita. As seen in the figure, countries with high GDP per capita also have a large % of forest area, while countries with low GDP per capita have a low % of forest area. An explanation for this pattern can be drawn from the environmental Kuznets curve which suggests that economic development by a country initially leads to deterioration in the relationship with its environment, but once a certain level of development is achieved, the economy begins to improve its awareness of the environment and the extent of environmental degradation reduces (Cuaresma et al., 2017). Countries with low GDP per capita work towards improving their economic development by de-emphasizing agriculture and emphasizing industrialization. This causes a decrease in forest area at a rapid pace in the initial stages of economic growth. Once these countries achieve a certain level of growth and development, the tendency of deforestation stabilizes and reduces. High income countries, on the other hand, have already reached a level of development which does not require them to pursue more industrialization. Our findings are consistent with research on GDP and regional forestation (Cuaresma et al., 2017).

GDP per Capita and Improved Water Use

We look for an association between GDP per capita and improved water use for each of the income groups in the sample (Figure 10).

Figure 10 shows that for high-income non-OECD and lower middle-income countries, there is no significant relationship between GDP per capita and percentage with access to improved water source.

Figure 9. GDP per capita and forest area

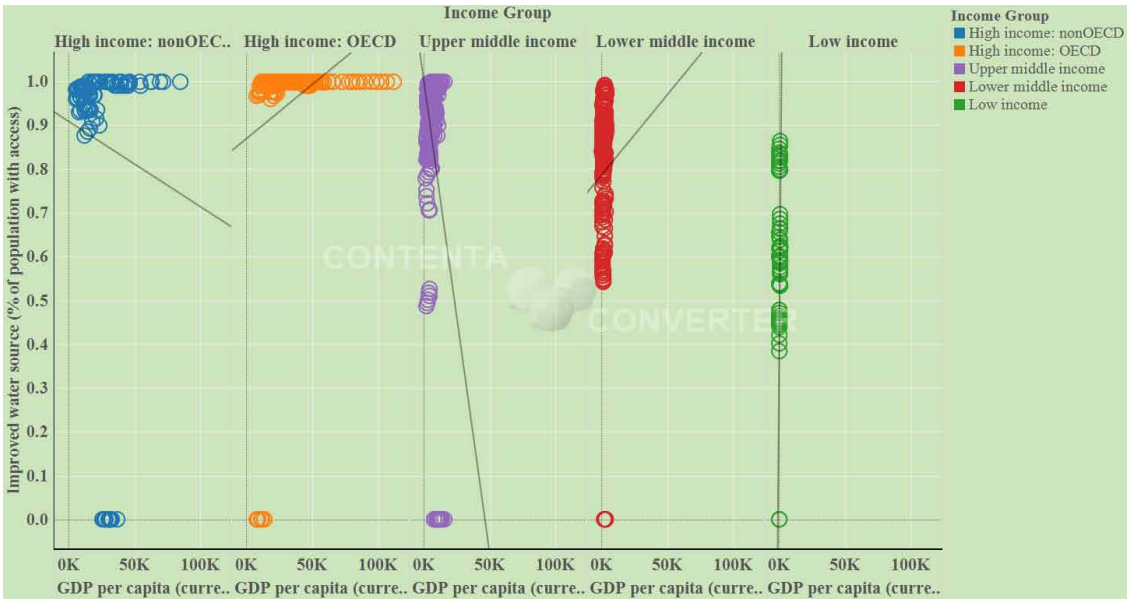
Figure 10. GDP per capita and Improved water source



**For a more accurate representation see the electronic version.*

For high-income OECD countries, there is a significantly positive relationship ($p < 0.001$), which indicates that when the GDP increases the percentage of population with access to improved water sources also increases. On the other hand, for upper middle-income countries, there is a significant negative relationship ($p < 0.0001$) between the two. This demonstrates that for the upper middle-income countries in our study, as the GDP per capita increases there is a related decrease in the percentage of population with access to improved water sources. This implies that upper middle-income countries may not give priority to providing access to improved water sources. There may be other public policies that take precedence. Meanwhile, for low-income countries, there is a significant positive relationship ($p < 0.001$) to show that as the GDP per capita increases, the percentage of the population with access to improved water sources also increases.

CO2 Emissions and Industry Value Added

Industry value added, also known as the gross domestic product (GDP)-by-industry, represents the contribution of a private industry or government sector to overall GDP. It includes components such as compensation of employees, taxes on production and imports less subsidies, and gross operating surplus. We looked for any significant association between the industry value added and CO2 emissions across all income groups in the sample (Figure 11).

Figure 11 shows a significant relationship between CO2 emissions and industry value added, but only for high-income OECD and low-income countries. The relationship is negative for high-income OECD countries: as the value-added increases, CO2 emissions decrease. This is favorable for climate change mitigation. For low-income countries, however, the relationship is positive; as the industry value added increases, CO2 emissions also increase. This is a noteworthy result which will be discussed in the following paragraph summarizing the results.

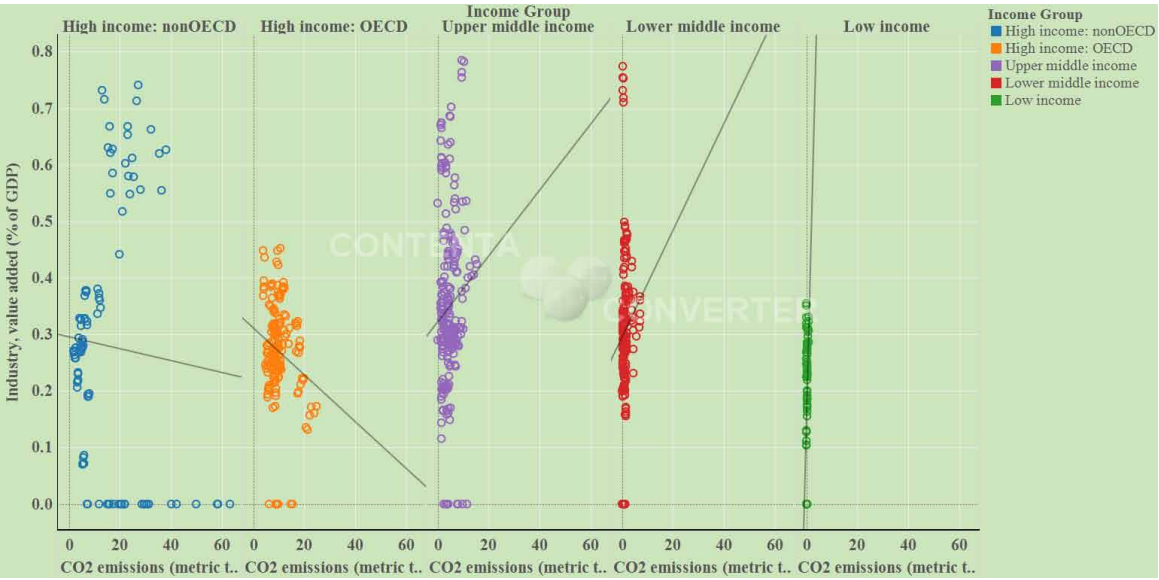
Figure 11. CO2 emissions and industry value added



**For a more accurate representation see the electronic version.*

Table 3 presents a summary of results from the analyses.

In summary, our results show that economic growth is associated with climate change. There is a positive association of income and GDP per capita with CO2 emissions, electricity consumption, and energy usage. These associations are adverse for climate change. However, in terms of forestation, the results are interesting. Upper middle-income countries have the highest forest area, followed by high income countries. Economic growth does not seem to adversely affect forestation, if the income level is already high. However, low income countries, in their efforts at industrialization, need to focus on maintaining forest areas if they intend to be sustainable and mitigate climate change. Industry value added shows a negative association with CO2 emissions for high income countries. This means that the higher a country's industry value added, the lower the carbon emissions. A large proportion of CO2 production comes from industrial activities (Zekos, 2016). We suggest that low income countries should emphasize sustainable industrial sectors such as biotechnology. Industrial biotechnology is a sector based on renewable resources that can save energy and significantly reduce CO2 emissions. Additionally, for this sector to significantly influence climate change, countries need to increase their R&D investment in it so as to promote new products/services that can be brought to market. In fact, the OECD expects industrial biotechnology to contribute up to 39% of biotechnology's gross value added in 2030. This clearly signals the importance and the global need to focus on industries that increase the industry value added percentage without adversely impacting climate change (Zekos, 2016).

While on the one hand our results reflect the need for developed (high income) countries to redress their past and current emissions, on the other, it reinforces the need for developing (low income) countries to have a strategic trade-off between economic development and environmental sustainability by exploring alternative industries that use renewable sources of energy and power. Additionally, there should be transference of knowledge and solutions from the developed to the developing countries to promote universal environmental stability and mitigate global climate change.

Table 3. Summary of results

Figure#	Analysis	Results
1	Distribution of countries by region and income	Shows the number of countries in each region by income group of high non-OECD, high OECD, upper middle, lower middle, and low.
2	Distribution of average CO2 emissions by income	Drop in CO2 emissions for all income groups from 2008-2009.
3	Trend of median and average CO2 emissions by income	In terms of average emissions, upper middle-income countries have surpassed high income countries since 2009, while in median emissions terms, high-income countries take the lead.
4	CO2 emissions per capita and income	High income countries show the highest emissions per capita. Low-income countries show the lowest emissions per capita. There is a positive association between a country's CO2 emissions per capita and income.
5	Distribution of energy use and electricity consumption	High-income OECD countries have the highest electricity consumption. The consumption in the low- and middle-income countries has been limited. With respect to energy usage, high-income non-OECD countries exhibit the greatest energy usage, followed by high-income OECD. Lowest usage is by low-income countries. Positive association of income with electricity consumption and energy usage.
6	Distribution of forest area by region	Regions of East Asia & Pacific; Europe & Central Asia; Sub-Saharan Africa; Latin America & Caribbean show a high distribution of forest area.
7	Distribution of forest area by income	High income countries have the highest forest area followed by upper middle-income countries, and there is not much change in forest area over time. For low income countries, the % of forest area decreases over time.
8	Association between GDP per capita and Energy usage per capita	High-and middle-income countries show a positive association of GDP per capita and energy usage per capita. For low income countries, the association was not significant.
9	GDP per capita and forest area	High and middle-income countries with higher GDP per capita also have a larger forest area than low income countries.
10	GDP per capita and improved water use	For high income countries there was a positive association between GDP per capita and improved water usage. For upper middle countries, this was negative. For low income countries, the association was positive.
11	CO2 emissions & Industry value added	For high income countries the association between CO2 emissions and industry value added was negative. For low income countries, it is positive.

SCOPE AND LIMITATIONS

There are some limitations to our work here. First, our study looks at data for the 2005 to 2010-time period. Future studies can include wider time spans in their investigations and conduct detailed panel analyses that shed light on longer-term patterns and trends. Second, we did not investigate causality in the relationship between economic growth and climate change; we only analyzed the association between economic growth indicators and climate change indicators. Future studies can include explorations of causality. Third, we considered a cross-section of indicators only. Clearly, there is the potential for other intervening indicators at the country level, which may offer additional insight; and identifying these indicators may change the perspective. Also, the data we extracted from the World Bank data set is secondary in nature. The economic growth and climate change indicators are aggregated from multiple models and sources. Moreover, many of the country indicators are interrelated, so it is likely that the omission of correlated indicators has influenced our results.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONTRIBUTIONS

Despite limitations, our study contributes in several ways to the literature on both economic growth and climate change. We also demonstrate the potential of data-driven analytics to help make informed decisions regarding climate change. Using analytics, we offer a panoramic view of the global economic growth and climate change data, and our analysis offers insight for policy-making in climate change. The overall association between economic growth indicators and climate change indicators suggests that developed (rich) countries must make reparations for past emissions. Second, because rapid economic growth could lead to increased emissions, developed countries and aid institutions must help design and implement structured development plans to alleviate poverty while simultaneously mitigating climate change in developing countries. Third, countries with advanced and innovative technologies, such as clean air technologies (e.g., carbon capture), must facilitate the sharing and transfer of these technologies to countries that need them. Without equity, developing countries may resist prioritizing climate change.

CONCLUSION

In summary, economic growth has an adverse impact on climate change. The more developed a country in terms of high GDP or income, the higher the levels of energy usage, consumption of electricity, and CO2 emissions, and the lower the availability of natural forest area. These factors are attributed to the focus on industrialization that accompanies economic growth. We also see that level of CO2 emission has risen steadily over time and will continue to rise with economic growth if efforts at climate change mitigation are not introduced. In terms of sanitation facilities, such as access to improved water, our study shows that for high-income OECD countries there is a positive association between GDP and access to clean water. Emphasis given to green growth and the enforcement of policies encouraging economic growth and sustainable development explain this positive association. However, for upper middle-income countries, we show a negative association between GDP per capita and percentage with access to improved water. At face value, this appears to contradict the general notion that economic growth (as evidenced by high GDP) should ensure increased access to sanitation facilities, but there is a rationale for this result among middle-income countries. Due to the rapid growth in national income, especially during the 2000s, many countries have been reclassified from the category of 'lower income' to that of 'middle income' (United Nations Development Program, 2013). But in these reclassified countries, a majority of the population continues to live in below-average economic conditions, earning $1.25 to $2.00 per day (United Nations Development Program, 2013) and living without access to improved sanitation facilities. Additionally, in these countries, the sudden growth in national income widens the gap between the rich and the poor and the discrepancy in access to facilities.

Industry value added is another important indicator of economic growth that impacts climate change. Our results show an interesting trend in this regard. For developed economies, the relationship between industry value added and CO2 emissions per capita is negative, which means the greater the industry value added, the lesser the CO2 emissions. This trend is encouraging vis-a-vis climate change. However, for low-income economies, the results show that as the industry value added increases, the level of CO2 emissions per capita also increases. One explanation for this trend is the fact that high-income countries 'outsource' most of the production efforts that create CO2 emissions to low-income countries (Goldenberg, 2014). Developing, or low-income, countries, in an effort to build the economy and national

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

income, undertake the manufacture of materials that often produce toxic emissions. The governments of these low-income countries need to focus efforts on promoting 'green growth' in addition to economic growth. Green growth places attention on sustainable development policies as well as economic policies. These green growth efforts have two goals: the continued economic growth needed to reduce poverty and improve wellbeing and the improved environmental management necessary to manage resource scarcity and climate change. There is a pressing global need for the promotion of green growth as a new source of progress, one that helps to advance sustainable development along with economic growth through the practicable use of natural resources, efficient use of energy and electricity, and preservation of the ecosystem. Governmental efforts in this area include carbon taxes, green energy funds, renewable energy initiatives, and natural resource management initiatives.

Chapter 41
The Role of Irrigation in the Development of Agriculture: Srem District (Serbia)

Vesna Ž. Popović
Institute of Agricultural Economics, Serbia

Jonel V. Subić
Institute of Agricultural Economics, Serbia

Nataša Ž. Kljajić
Institute of Agricultural Economics, Serbia

ABSTRACT

The Srem district is home to producers of corn, oilseeds, sugar beet and tobacco, a leading region in the production of pome fruits (apples, pears) and drupes (plums, peaches, cherries) in the country and a perspective area for the development of organic plant and livestock production in protected areas. The current irrigation policy in the Republic of Serbia was not directed at systematic water use with the goal of forming an optimal structure of a market propulsive and a highly profitable agricultural production. The authors in the paper analyse the structure of agricultural production in the Srem district in Serbia and its market potentials as well as the economic effects of irrigation in light of the planned integral irrigation system construction in the Srem district in order to reflect economic benefits of irrigation and its role in the development of agriculture.

1. INTRODUCTION

Irrigation will remain a critical factor in ensuring the production of high quality food in sufficient quantities for a growing world population. The share of irrigated in total world food production will rise from 40% today to more than 45% by 2030 (Faurès et al., 2007). According to International Commission on Irrigation and Drainage [ICID] data for the years 2013-14, the area equipped for irrigation at the world level is about 318 million ha, while the actual irrigated area is about 300 million ha. Most of the irrigated area lies in Asia (72%) followed by America (15%), Europe (8%) and Africa (5%) (ICID, 2014).

According to the 2010 EU Survey on agricultural production methods [SAPM] data, the irrigated area in EU-27 (excluding figures for Belgium, France, Luxembourg, Austria and Slovenia) accounts for 8.4 million ha (5% of the UAA). Almost the full amount of water used for irrigation was used in Spain (45%), Italy (31%), Greece (10.5%) and Portugal (9%), which together account for 96% of the water used for irrigation (European Commission [EC], 2012a).

In the climatic conditions, prevailing in the northwest of the Republic of Serbia irrigation is applied as a supplement to precipitation and is a favourable influence on yields stabilisation. The effect of irrigation is different by years, depending on the amount of precipitation and their distribution in the vegetation period. In favourable years this effect is lacking or is very modest, while in years with serious draught, irrigation increases the yields of agricultural plants by two or more times (Maksimović & Dragović, 2004; Pejić, Maksimović, Milić, & Rajić, 2010).

The agricultural sector is highlighted in national planning and development documents as one of the pillars of the Serbian economy. In 2014, the value of exports in the agriculture and food industries accounted for one-fifth (20.7%) of the total exports of the Serbian economy (Statistical Office of the Republic of Serbia [SORS], 2015a).

There are real opportunities for further growth in exports, especially to the Russian market, as well as to return to the markets of the Middle East, the Maghreb and the United States. Cereals and cereal preparations, vegetables and fruit, then beverages and tobacco, and sugar and sugar preparations hold the biggest share in export value.

The Srem district is a traditional producer of cereals, oilseeds, sugar beet and tobacco, the leading region of intensive fruit production in the country and promising area for the development of organic plant and livestock production in protected areas.

The irrigation policy in the previous period did not aim at systematic use of water in order to form an optimal structure of a market propulsive and highly profitable agricultural production. The entire agricultural and food value chain must be transformed and developed in accordance with the new structure of costs and yields provided by irrigated agriculture.

Agricultural policy must accompany this transformation by focusing support to intensive and stable irrigated agricultural production, adapted to market demands.

Irrigation systems in the Republic of Serbia have mainly been built on the most productive land classified into classes I and II according to suitability for irrigation, which cover over 1.36 million ha and are located mainly in the province of Vojvodina (in Srem only, it comprises nearly 50% of the soil suitable for irrigation) (Official Gazette of the Republic of Serbia [OG RS], no 11/2002).

The hydrosystem Srem is designed to irrigate 185 thousand ha with water, supplied to the main channels from the Danube, Sava and the Bosut rivers, and 15 thousand ha with water from its own catchment (31 accumulations on the Fruška gora mountain) (Official Gazette of the Autonomous Province of Vojvodina [OG APV], no 22/2011). The currently built parts of hydrosystem Srem cover only 3,254 ha of which it is in working order on 1,134 ha (Ministry of Agriculture, Trade, Forestry and Water Management of the Republic of Serbia [MATFWM], 2011).

The Ministry of Agriculture has begun activities on the project of rehabilitation and construction of new irrigation systems in 2012. Strategy of development of water infrastructure is directed towards integrated systems, which allow resolving interdependent issues of use and protection of water, including irrigation, regulation of water regime and flood protection, with respect to environmental and social demands of the surroundings. The new project of integrated irrigation system of the Srem district provides

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

reconstruction of existing and construction of new irrigation systems on an area of more than 225,000ha (Belgrade Banking Academy [BBA] Consortium, 2014).

This paper presents the main results of cost-benefit analysis of irrigation on the projected area in Srem district in light of production and market opportunities of irrigated agriculture. The analysis is aimed at verifying the hypothesis that high and stable yields achieved in irrigated agriculture justify investment in optimizing the structure of production and modernization of the agricultural sector and thus contribute to the valorisation of comparative advantages of Srem county agriculture in domestic and international markets.

2. BACKGROUND

Whereas the importance of R&D investment in agriculture is widely recognised, better allocation of limited funding is essential to improve food production. In this context, the common and often large gap between actual and attainable yield is a critical target (Connor & Mínguez 2012; Sumberg 2012).

In yield gap analysis the relative importance of growth factors and inputs (including water as one of *growth-limiting* factors) is investigated to explain actual yield levels and resource-use efficiencies and to analyse differences between potential and actual yield levels to open ways for improvement (Van Ittersum & Rabbinge 1997).

The gap between potential and water limited yield is an indication of yield gap that can be removed by irrigation (Sadras et al., 2015). Irrigating rainfed areas is expected to lead to higher average yields and to higher quality of crops, essentially changing the production technology in a manner that allows more intense production (Ignaciuk, & Mason-D'Croz, 2014).

Yield responses to irrigation for major annual and perennial crops have been recently reviewed by FAO, with the aim to provide the necessary knowledge and skills for assessing the effect of water shortages on crop production; comparing the results of several water allocations plans; optimizing irrigation scheduling; enhancing management strategies to increase water productivity and water savings; and investigating the impact of climate change on crop yield (Steduto, 2012).

Climate change is altering the role of irrigation in agricultural production, particularly in the region of Southeast Europe. Projections of climate change contained in the Fifth IPCC report (2014) point to a further rise in air temperature and decrease for rainfall in these areas (Kovats et al., 2014). Deteriorative conditions for rainfed agriculture will increase water demand for irrigation (Daccache & Lamaddalena, 2010; Trnka et al., 2011; Savé et al., 2012).

Farmers are oriented towards irrigation as a self-insurance tool against drought and resulting income instability (Amigues et al., 2006; Foudi & Erdlenburch, 2011), but the availability of water for irrigation will be jeopardized by increasing demand and climate change induced decline in groundwater level (Majone, Bovolo, Bellin, Blenkinsop, & Fowler, 2012). To match water demand, irrigation system costs could increase and since the economic benefits are expected to be small, irrigation would require changes in institutional and market conditions (Finger, Hediger, & Schmid, 2011).

A strong call to recognise the importance of improving the efficiency of water and soil use in a sustainable manner by the agricultural sector was made by the G20 leaders in mid-2012. Since then, the OECD and several other international organisations have identified a set of policy recommendations to make water use in agriculture more efficient and to improve water supply infrastructure, including by increasing investments in these areas (Ignaciuk & Mason-D'Croz, 2014).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Water use efficiency programmes in conjunction with incentive pricing policies should provide sustainable use of water in agriculture. More efficient use of water should be achieved through water metering, improving irrigation efficiency and irrigation scheduling (Poláková et al., 2013). The ability of increases of water prices to provide the right incentive for efficient use of water in irrigation is closely linked to price elasticity of water demand, which depends on: a) the initial level of efficiency in water use, b) the availability and relative cost of alternative water sources, c) the availability of alternative crops with the lowest water requirements and more efficient irrigation technology, d) the share of water charges in overall production cost for farmers, and e) the value of cultivated crops (Dworak et al., 2007).

A shift in crop production to higher value crops ensures that margins remain the same, but it is more dependent on the geographic and socio-economic situation than on water prices themselves (EC, 2012b). In general, countries will need to tailor irrigation investment more closely to the availability of land and water resources, stage of national development, share of agriculture in the national economy and comparative advantage in local, regional, and world markets. Irrigation investment needs to be more site-specific and much more closely linked with policies and plans in agriculture and other sectors (Faurès et al., 2007).

3. AGRICULTURAL PRODUCTION AND MARKETS

3.1. Land Use and Agricultural Production Structure

The Srem district is located in the north-western part of the country, in the western part of Vojvodina Province, in the Pannonian Plain, between the Fruška Gora mountain, the Danube and the Sava rivers (including the far north of the Mačva region) and includes the municipalities of Inđija, Irig, Pećinci, Ruma, Sremska Mitrovica, Stara Pazova and Šid (Figures 1 and 2).

The Srem district is inhabited by around 308.5 thousand residents (SORS, 2014), with around 58 thousand living and working on agricultural family holdings, and another 2 thousand people being employed on the agricultural holdings of legal persons and entrepreneurs (SORS, 2013a).

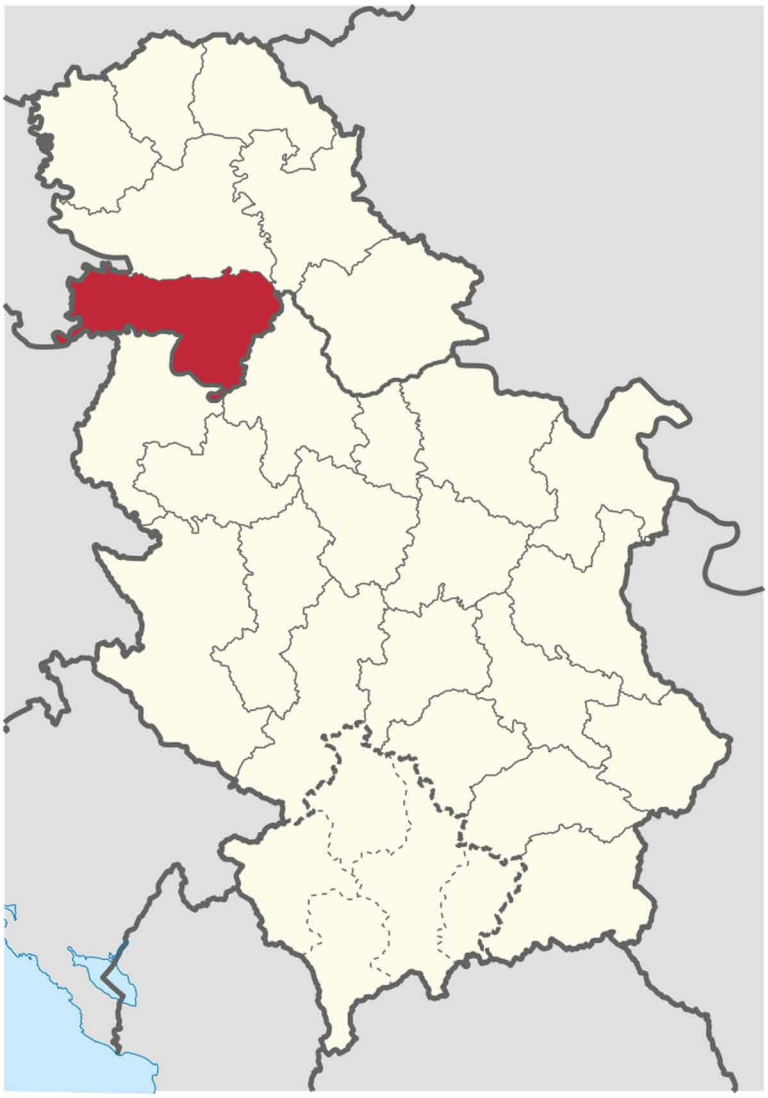
Agricultural land takes about 72.9% of the territory of the Srem district – from 59.9% in the wooded area of the Šid municipality to 85.2% of the Stara Pazova municipality (SORS, 2014).

According to data from the Agricultural Census from 2012 (SORS, 2013a), 28,533 out of 29,313 agricultural holdings have 229,195 ha of utilized agricultural area (UAA) at their disposal. Smaller holdings with up to 5ha are prevalent (70.6%), but they have only 12.8% of the UAA. The greatest part of the UAA (43.8%) is run by 27.1% of holding ranging from 5ha to 50ha of UAA, and almost the same amount (43.4%) is run by the 2.3% of large holdings, larger than 50ha in UAA. These agricultural holdings include a significant number of producers who are market oriented and capable of investing in agricultural production intensification and purchase of modern equipment and mechanisation, including irrigation equipment.

More than 90% of UAA is arable land, except in Irig municipality, where this percentage does not go over 80%. The arable land is mostly used for the cultivation of cereals – maize (40.6%) and wheat (25.7%), and industrial plants – soya (13.5%) and sunflower (4.1%). The municipalities of Sremska Mitrovica and Ruma are home to more than 40% of the land used to cultivate cereals in the Srem district. Soya production is concentrated in the municipalities of Šid and Sremska Mitrovica, while sunflower is most widespread in Pećinci and Inđija. More than half of the total area used for the cultivation of tobacco in

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Srem district in the Republic of Serbia
Source: http://upload.wikimedia.org/wikipedia/



the country is situated in the Srem district, on 1.3% of the arable land, of which more than 90% is on the territories of the municipalities of Stara Pazova, Inđija, Šid and Ruma. Sugar beet is cultivated on about 5.7%, fodder crops (alfalfa, clover, silage maize) on 3%, and vegetables (mostly sweet peppers, tomato and onion), watermelons and strawberries on 1.1% of the arable land. Half of the land under sugar beet is in the municipalities of Stara Pazova and Sremska Mitrovica. The largest amounts of land under fodder crops are situated in Sremska Mitrovica and Pećinci, while vegetable production and watermelon and strawberry production are concentrated in Ruma, Pećinci and Sremska Mitrovica.

Srem district is known for modern fruit and grape plantations. Fruit plantations occupy 5,153 ha (2.2% of UAA), and most of them are those with apples, plums, peaches, cherries and pears. Inđija, Irig and Šid are the leading producers of apples, and Sremska Mitrovica and Irig are the dominant producers

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. The municipalities of Srem district
Source: http://upload.wikimedia.org/wikipedia/

of plums. Peaches and sour cherries are mostly cultivated in Inđija and Irig, while pear cultivation is mostly located in Šid and Irig. Vineyards cover 1,172 ha (0.5% UAA). Varieties for wine with protected designation of origin take up 12% of the land under grape vines, while other grape vines use 70.5% and table grape varieties take up 17.5%. Irig, Šid and Inđija are the municipalities that host the most vineyards. Micro-spatial distribution of fruit production and introducing new technologies into the production of fruit, grapes and wines, including irrigation and the use of an integral and organic production method, following quality standards, associating and constant education of the producers, as well as strengthening family owned wineries and developing wine tourism are basic tasks for improving fruit and wine production.

The number of livestock units in relation to the used agricultural area of agricultural holdings (54 LSU/100ha UAA) is close to the national level of 59 LSU/100ha UAA. The Srem district farms 9.6% of the total number of pigs in the Republic of Serbia. Most pig farmers are situated in the Sremska Mitrovica municipality, while pig farming is also present in Ruma, Stara Pazova and Šid. Sremska Mitrovica is also where the largest number of cattle and sheep are farmed. The Šid municipality is in the second place in number of sheep, but holds the first place in poultry and beehives. Goats are mostly farmed in the municipalities of Inđija and Sremska Mitrovica. Having in mind the fodder base (fodder crops on 2.8% UAA and meadows and pastures on 3.2% of UAA) and the potential for growth in the irrigated production of corn, oilseeds and fodder crops, as well as tradition and market possibilities, livestock farming remains an underused production and export potential of Srem agriculture.

3.2. Land Use Planning and Agriculture

The existing structure of agricultural production and its spatial distribution are synchronised with the heterogeneous natural, resource and agro-ecological capacities of the area and with the infrastructural, technological and socio-economic characteristics of agriculture and local community and economy using appropriate regional development and spatial planning.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The *Spatial Plan for the Republic of Serbia 2010-2020* (OG RS 88/2010) defines the priority directions for spatial distribution of agricultural production. Crop production is defined as the primary sector of market oriented production in the *plain area* of the Srem district, while pig and poultry farming are complementary, with fruit and vegetable farming as distinct specialisations of certain localities. The *hill area* emphasises mixed livestock production and complementary production of organic food, while smaller localities also include growing vine.

The operative goals of agriculture development, included in the *Regional Spatial Plan for the AP Vojvodina* (OG APV, 22/2011) state the following as particularly significant goals for agriculture in the Srem district: 1) increasing agricultural production that will satisfy domestic needs and create export surpluses, 2) intensifying crop production by increasing the yields and changing the sowing structure toward more market valuable crops (vegetables, industrial and fodder plants, orchards, vineyards), 3) intensifying livestock production with regard to the ecological optimum, 4) better use of natural resources, especially through irrigation, and 5) using a part of agricultural resources for multifunctional agriculture (agro-ecotourism, eco-production and production of renewable energy), with the goal of increasing economic efficiency and profitability of agriculture.

The construction and revitalisation of regional systems (Bačka, Banat and Srem) for supplying irrigation water, the technological needs of industry and other needs are among the operative goals for the development of water infrastructure in the *Regional Spatial Plan of the AP Vojvodina*.

Sustainable development of fruit, vine and vegetable farming as well as farming medicinal and honey plants with growing use of the integral and organic production method, and building eco-farms with organic plant and animal production are the basic directions for agriculture development on the special purpose area of the Fruška Gora mountain (parts of the municipalities of Irig, Inđija, Šid, Sremska Mitrovica and Ruma), according to the decisions stated in the *Master Plan for Sustainable Development on Fruška Gora mountain 2012-2022* (The Assembly of AP Vojvodina, 2011).

The Mačva part of the municipality of Sremska Mitrovica is home to the largest part of the Special Nature Reserve "Zasavica". The Special Nature Reserve "Obedska Bara" and its protected zone are part of the municipalities of Pećinci and Ruma. These areas are also equipped with favourable agro-ecological conditions for the development of low-intensity production of vegetables and medicinal and aromatic herbs and flowers, especially in greenhouses with the use of thermal waters.

In the surroundings of the city centres, there is developed intensive, periurban agriculture. According to the *Spatial Plan for the Republic of Serbia (2010-2020)*, the functional urban area (FUP) Belgrade (the category Metropolitan Growth Area – MEGA) includes the following municipalities of the Srem district: Stara Pazova, Pećinci, Ruma, and Inđija, while the FUP Novi Sad includes the municipalities of Irig and Inđija. The location of the mentioned municipalities within the belt of the highest-intensity development in the country has numerous advantages for agricultural production and sale of agricultural products, related to traffic accessibility, the absorptive capability of the market in big cities, availability of input and services from scientific research organisations and advisory services, as well as the proximity of processing capacities and exporters.

3.3. Exports of Agricultural Products

In 2014, agriculture and food industry (divisions 00-09, 11, 12, 21, 22, 29, 41-43 SITC, Rev. 4) have realised an export in the value of 3.068 bln USD (20.7% of total export), while import was 1.729 bln USD (8.4% of total import). The biggest export value was made in the divisions: 04 Cereals and cereal

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

preparations, 05 Vegetables and fruit, 11 Beverages, 12 Tobacco and tobacco manufactures, 06 Sugars, sugar preparations, and honey (SORS, 2015a).

More than 95% (95.9%) of export of agriculture and food industry was realised on the markets of the EU-28, CEFTA, the Russian Federation, Belarus and Kazakhstan – members of the Eurasian Customs Union, EFTA, Turkey and USA, with which the Republic of Serbia has signed free trade agreements, i.e. use the general system of preferences approved by the USA (SORS, 2015b).

The market of the EU-28 receives almost half of all exported agricultural and food products (49.1% in 2014), most cereals (maize, mercantile), fruit (raspberries and sour cherries, frozen), sugars and vegetable fats and oils. Export to the CEFTA countries in 2014 made 33.4% of agriculture and food industry export. The CEFTA countries usually import cereals and cereal preparations and beverages from Serbia. Most of the exported beverages, live animals, dairy products, fish and preparations, and tees and spices go to the markets of these countries. The export to the Russian Federation in 2014 was 10.2% of the total export of agricultural and food products from Serbia. Russia mostly imports fruit and vegetables, meat and preparations and dairy products from Serbia (Table 1).

In 2014 Russia was the biggest importer of Serbian apples, plums, peaches and nectarines, cherries and sour cherries, strawberries, pears and quinces (fresh), fresh grapes and wine, then early season potatoes and cabbage and similar edible vegetables, fresh, and beans and string beans and other vegetables and mixtures of vegetables, frozen. In 2014, Russia imported 96% of the Serbian export of meat of swine, frozen and 93% of export of fresh cheese (SORS, 2015b).

Rising world food prices, trade liberalisation with the EU, CEFTA and the Russian Federation and the efforts to reform the sector and improve competitiveness have led to a growth in export of the Serbian agriculture during the past decade. There is still room for further development (particularly on the Russian market, which is especially important for the agriculture of the Srem district) as well as for the return to the markets of the Middle East, Maghreb and USA.

4. EFFECTS OF IRRIGATION ON YIELDS AND FARM INCOME

4.1. Yields and Irrigation

The central part of the Srem loess plateau which covers the southern slopes of Fruška Gora and stretches to the loess terrace in southern Srem (dominantly covered with chernozem typical, carbonate) and the lower, Srem loess terrace (covered in dry and marsh loess, with predominant chernozem of lesser productivity and a higher level of groundwater), represent the area of intensive crop and livestock production. The production of fodder plants and livestock fall behind the resource and market potentials and the agro-ecological demands of preserving the soil fertility.

The farms of the Srem district achieve above-average yields of cereals, fodder crops and fruits and grapes, compared to the national level, but the yields and quality of field crops, vegetables, fruits and grapes in rainfed production have strong yearly oscillations, both at the level of the Srem district, and on the national level, mostly due to more frequent and longer draught periods. Unstable yields in the production of fodder crops discourage farmers to engage in livestock production (Table 2).

The climate of this region is a temperate continental with warm summers and harsh winters. The average annual precipitation is around 680mm (in the western part of the district and on Fruška Gora up to 780mm, and in the eastern and plain areas 580-650mm). Irrigation in these climate conditions has

Environmental Protection Agency [SEPA], 2013). Uneven and insufficient precipitation threatens the achievement of high and stable agricultural yields. Precipitation deficit accompanied by high temperatures and heat waves have resulted in an increase in the frequency and intensity of droughts (Popović & Ugrenović, 2015). Investing in new irrigation systems is one of the climate change adaptation measures, which must take an important place in the national and regional adaptation action plans and/or sectoral adaptation plans for agriculture (Popović & Mijajlović, 2013).

In the Srem district in the season of 2011/2012, 3,655ha of land was irrigated, i.e. 1.6% of UAA, which is less than the Republic level (2.9%) and the autonomous province level (3.6%). The structure of the irrigated areas consists mostly of arable land – 2,484ha (vegetables, watermelons and strawberries in the open, cereals and silage corn, sugar beet), but the participation of irrigated land in the total area of this UAA category is rather small and has the percentage of 1.2% (3.6% at the AP Vojvodina level, and 3.4% at the Republic level). Attention is directed at orchards, which cover 1,152ha, although the participation of irrigated land in the total orchard areas is smaller than on the province level and is 22.4%, compared to 29.9% in the APV (on the national level, this percentage is far lower at 8.2%). The application of irrigation in vineyards, meadows and other permanent crops is not widespread (Table 3).

Thanks to a high level of fruit plantations in the irrigated areas, the Srem district has a favourable structure for irrigation in the sense of used irrigation methods. The most effective irrigation method from the aspect of water saving, drip irrigation, mostly used in fruit plantations, increasingly in vegetable farming and showing good results in tobacco production, is used on 44.3% of the irrigated area, sprinkler systems on 18.3%, and least effective, surface method is used on 37.4% of the irrigated area. In regard to source of irrigation water, the situation is less favourable. Groundwater (wells) on the holding are used to a high degree (49.0%), followed by surface waters from outside the holding (33.8%) (SORS, 2013a).

The Republic of Serbia, according to the value of the Water Exploitation Index lies in the zone without of water stress, with the value of this index being in the interval between 11% and 20%, which gives it certain comparative advantages in world trade in virtual water compared to the countries with severe

water stress (SEPA, 2013; Petković, 2003). This does not mean that the situation will not change with the development of irrigation. According to research from the Institute for Soil, Belgrade, for the needs of irrigation, including the limited use of water from Danube, it is possible to provide around 400m^3/s of water, which would cover around 450 thousand ha. In order to irrigate areas up to 800 thousand ha, it is necessary to acquire compliance from other countries in the basins of Danube, Sava and Tisa (Božić, 2012).

Ensuring sufficient amounts of water of satisfying quality is turning into a limiting factor for the development of agriculture in the conditions of climate change (Popović, Nikolić & Katić, 2011). That is why it is already now necessary to consider the matters of economic efficiency of irrigation and water productivity, including the water price policy, when rehabilitating and constructing irrigation systems.

4.2. Economic Effects of Irrigation

Average actual yields of rainfed crops in the Srem district are at a satisfying level, if compared to the national average. However, these yields are far below the yield potential of the observed plant species. As already indicated above, the gap between potential and water limited yield is an indication of a yield gap that can be removed with irrigation.

Yield growth in irrigated production is especially visible in sugar beet, potato, clover, carrot, beans, alfalfa and cauliflower. Irrigation is an indispensable agro-technical measure on modern fruit and vine plantations, which are one of the pillars of export of agriculture in the Srem district.

The expected yield growth and the economic effects of irrigation in plant production in the Srem district are presented in Table 4, which shows the calculated average yield, revenue, costs and the net effect (the difference between the income realised in rainfed and irrigation production,) per hectare, for certain plant products.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The best net effect from irrigation can be expected in the production of the following crops: sugar beet (income growth of about 20.1 times), potato and clover (about 4.5 times), carrot, beans and alfalfa (about 3.9 times), cabbage and kale and cauliflower (3.2 and 3.3 times, respectively), grape (3.0 times), tomato and peppers and peas for dry grain (2.7 and 2.4 times, respectively). The producers of silage maize (income growth of 2.9 times), peas (2.8 times) as well as apples, pears and peaches (2.0 times increase) would also benefit significantly from applying irrigation in their production process.

Investment decisions must be based on strict quantitative and qualitative performance measurement, which will ensure investing in the best (most efficient) project variants (Subić, 2010). A high level of investing in irrigated agriculture, especially in fruit production, must be justified with higher yields, revenues and net effects, with reducing and controlling all production risks, considering that the expectations of the producers are aimed at a reasonable payback period and an acceptable rate of return on investment.

Using modern irrigation systems in fruit production refer to a modern date plantation based on fruit-growing technology which includes closer planting, market attractive assortment of fruit varieties and the use of integral production method. Intensive production ensures a better yield with a fruit of better qualitative characteristics, and thus enables contracting production and successful sales on the growingly demanding national and international markets. This fruit production technology, however, requires significantly higher investment, considering that it entails the use of multipurpose irrigation system, with functions of fertirrigation, classic irrigation, anti-frost protection etc., as well as anti-hail protection, the use of special mechanisation and equipment and the construction of cold storages and outbuildings.

According to calculations contained in *The Feasibility Study for Regional Irrigation System of the Srem Region* (BBA Consortium, 2014), it is expected that the use of irrigation system in the Srem district will generate annual net-effects of, on average, 751 EUR/ha in arable crop production (the income would almost triple in comparison to rainfed production), 1,113 EUR/ha in vegetables (the income would increase 1.8 times) and 3,323 EUR/ha in production of fruit and grapes (the income would double) (Table 5).

The total net-effect of the Project is expected to reach 194.1 million EUR at the annual level, which would enable generation of additional profit to farmers of 113.1 million EUR. The expected rate of profit is 9.3%. The projected price of water, based on full-cost recovery principle (operating and capital costs of irrigation) amounts to 0.1297€/m^3 on the user's level, but, regarding the growth of income in irrigated agriculture, it should create high interest among farmers to use the irrigation system services (Table 6).

In terms of sources of the project finance, it is assumed that donations (primarily from EU funds) will account 58.6% of total investment (70% of primary irrigation infrastructure costs and 10% of watering equipment costs), 20% will be provided from loans (20% of primary irrigation infrastructure costs and 20% of watering equipment costs), and 21.4% from own resources (10% of primary irrigation infrastructure costs by investors – irrigation service provider, and 70% of watering equipment costs by users of the irrigation service) (BBA Consortium, 2014).

Source: BBA Consortium, (2014).

The current structure of water charges in the irrigation sector in Serbia, defined by the Law on Waters (OG RS, 30/2010; 93/2012) is complex due to the presence of various irrigation systems of different complexity, but also the intention to ensure the highest possible level of cost recovery. Unfortunately, the existing water tariff levels do not even provide coverage of operation and maintenance costs (Popović & Ugrenović, 2015).

According to calculations of variable costs in irrigated agriculture on selected production lines on the territory of Vojvodina in production of *vegetables* average irrigation costs (fuel and water charges) make for 4.97% of variable costs, where water charges make for 11.15% of irrigation costs; in production of *field crops* 7.37%, with participation of water charges in irrigation costs of 21.85%; and in fruit production 1.00%, with participation of water charges in irrigation costs of 8.54% (Cvijanović, Subić, Popović, Ugrenović, & Jeločnik, 2014).

At their current level, water charges cannot represent the right incentive for efficient use of water in irrigation. The application of the EU Water Framework Directive full-cost recovery principle (Directive 2000/60/EC, Art. 9), which includes a resource and an ecological component besides the financial one, requires significant and well-timed production, market and institutional changes, in order to ensure a level of profitability that enable farmers to use the irrigation system service.

The harmonization with WFD requirements in the policy of water prices will contribute to improving the service quality in the water sector, increasing efficiency in water use and protecting water resources and ecosystems, but this will happen gradually, over a longer transitional period. Until then, the role of the state in financing the rehabilitation and construction of new irrigation systems and subsidizing the cost of irrigation in Serbia remain significant (Cvijanović et al., 2014).

SOLUTIONS AND RECOMMENDATIONS

Bearing in mind underdeveloped irrigation infrastructure and related institutional capacities in the country, there is a clear need for significant investment into irrigation modernisation, which would contribute to the agricultural growth and competitiveness on the international market.

The existing water tariff levels do not even provide coverage of operation and maintenance costs. Capital investments in the revitalization and development of the irrigation infrastructure, including hydrosystem water facilities are financed from budget revenues and foreign credits. Along with the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

construction and upgrading of irrigation systems, it is necessary to make the appropriate legal and institutional changes that will ensure the existing and newly-built irrigation systems an adequate funding, management and advisory services.

The stated results of cost-benefit analysis of the planned irrigation system in the Srem district are based on modified production structure. The optimization of production structure in irrigated agriculture is necessary and should be directed towards increasing area under industrial plants and seeds at the expense of area under cereals, intensifying the production of vegetables and fodder crops, especially in the form of intercropping and further increasing area under fruit plantations, in parallel with the land protection against degradation.

The agricultural advisory and expert service as well as the associations of farmers and water users should play an important role in diffusion and implementation of advanced knowledge and skills in irrigated agriculture.

FUTURE RESEARCH DIRECTIONS

Innovation is one of the key motors for economic and social development of society, and therefore of agriculture as its integral part. Innovation in irrigation systems, which raises resource use efficiency and profitability of agricultural production, promotes organic food production and use of renewable energy, is attracting increasing attention of scientists and society. That refers particularly to research connected to the use of solar panels in irrigation systems in the cultivation of vegetables, cereals, industrial and fodder plants, fruit and forests. Solar water pumping has been found to be economically viable in comparison to electricity or diesel based systems for irrigation and water supplies in rural, urban and remote regions. The investment payback for some photovoltaic water pumping systems has been found to be 4–6 years (Chandel, Naik, & Chandel, 2015).

Another potential solution for efficient use of irrigation in agriculture is the innovative method of subsurface capillary irrigation, where the basic principle is to deliver the water to the root system of the plant through specially designed water transmitters, built in beneath the soil tillage depth. There are three main characteristics that separate this system from all other existing irrigation systems: 1) functionality at extremely low pressure (in terms of energy efficiency, it stands out as the most efficient, as no other irrigation system will work at the low pressure of only 0.2 baryes), 2) the possibility of long-term exploitation of the system (it is characterised by the impossibility of water transmitter clogging, which is a prerequisite for system longevity) and 3) self-regulation in plant watering (no other irrigation system has this option). According to preliminary research, this system is suitable for use in vegetable crops production, in a greenhouse and in open field, and in the continuing research; it is expected to become further developed for use in fruit, and later in field crop production (Zloh, 2013; Zloh et al, 2013).

More efficient use of water should be achieved through *improving irrigation efficiency and irrigation scheduling*. The automated determination of irrigation norms and irrigation time based on high precision satellite data such as the ENORASIS system integrates a range of advanced technologies, methodologies and models in the fields of: 1) weather prediction systems that exploit satellite observations; 2) irrigation optimization techniques; 3) smart card irrigation or other systems in order to arrive at a solution that will be easy to use for farmers and that will be flexible and robust enough for use by irrigation water providers; 4) wireless sensor networks (functioning with solar energy) as key enabling

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

technology for field measurements and monitoring conditions, all with the aim of motivating farmers towards optimizing the use of irrigation water (ENORASIS Consortium, 2012).

As it is mentioned earlier, the role of the state in financing the rehabilitation and construction of new irrigation in Serbia is of key significance for irrigatated agriculture development. In addition to budget resources, the government relies on foreign loans and EU funds to finance irrigation development.

According to the *Loan Agreement between the Government of the Republic of Serbia and Abu Dhabi Fund for Development to finance Development of Irrigated Agriculture – Phase I* (Official Gazette of the Republic of Serbia - International Agreements [OG RS - IA], no. 5/2014), line ministry may withdraw funds in the amount of 356,281,000 dirhams (97 million dollars) by the end of 2017 to finance the construction and revitalization of irrigation systems in 13 locations, mainly in Vojvodina Province (Banat and Bačka regions), with total area of 24,000 ha. The project comprises civil construction works (pumping stations buildings, canal excavation and canal lining), hydro-mechanical and electrical equipments and installation and irrigation equipments.

During 2015, it is expected calls for proposals in the framework of continuing EU Instrument for Pre-Accession Assistance [IPA] cross-border programmes [CBC] - IPA 2, for which there are prepared proposals aimed at addressing the acute problems in the field of water management. In cooperation with partners from Hungary, two strategic projects are prepared and submitted for co-financing with EU grants (*Reconstruction Planning of Baja Bezdan Canal* project and *Water supply and infrastructure development in the catchment area of the Tisza and the border severed watercourses – WASIDCA project*, that include irrigation network development) (PWMC "Vode Vojvodine", 2015).

CONCLUSION

The Srem district is a traditional producer of cereals, oilseeds, sugar beet and tobacco, the leading region of intensive fruit production in the country and promising area for the development of organic plant and livestock production in protected areas.

The central part of the Srem loess plateau, dominantly covered with chernozem typical, carbonate, and the lower, Srem loess terrace, covered in dry and marsh loess, with predominant chernozem of lesser productivity and a higher level of groundwater, represent the area of intensive crop and livestock production. The greatest part of 229,195 ha of utilized agricultural area (43.8%) is run by 27.1% of holding ranging from 5ha to 50ha of UAA, and almost the same amount (43.4%) is run by the 2.3% of large holdings, larger than 50ha in UAA. These agricultural holdings include a significant number of producers who are market oriented and capable of investing in agricultural production intensification and purchase of modern equipment and mechanisation, including irrigation equipment.

Rising world food prices, trade liberalisation with the EU, CEFTA and the Russian Federation and the efforts to reform the agricultural sector and improve competitiveness have led to a growth in export of the Serbian agriculture during the past decade. There is still room for further development, particularly on the Russian market, which is especially important for the agriculture of the Srem district (export of fresh pome fruits, drupes and strawberries, fresh grapes and wine, vegetables fresh and frozen, frozen swine meat and fresh cheese). The proximity of large metropolitan markets of Belgrade and Novi Sad is another advantage for Srem agriculture.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The availability and quality of agricultural resources and the market potentials are good reasons for investments in improving the agricultural production of the Srem district. The farms here achieve above-average yields of cereals, fodder crops and fruits and grapes, compared to the national level, but the yields and quality of field crops, vegetables, fruits and grapes in rainfed production have strong yearly oscillations, both in the Srem district and on the national level, mostly due to more frequent and longer draught periods.

Irrigation is a precondition for ensuring high and stable yields in crop production, which would justify investment in high-quality inputs and modern storage and processing capacities. However, in the season of 2011/2012, only 3,655ha of land was irrigated, i.e. 1.6% of UAA. The new project of integrated irrigation system of the Srem district should provide irrigation on an area of more than 225,000 hectares.

A high level of investing in irrigated agriculture, especially in fruit production, must be justified with higher yields, revenues and net effects, with reducing and controlling all production risks, considering that the expectations of the producers are aimed at a reasonable payback period and an acceptable rate of return on investment. According to calculations, the total net-effect of the Project as well as the projected price of water should create high interest among farmers to use the irrigation system services.

The basic premise of the above results is optimized production structure, adjusted to irrigation agriculture (increased area under industrial plants and seeds at the expense of area under cereals, intensifying the production of vegetables and fodder crops, especially in the form of intercropping, further growth in area under fruit plantations), along with the application of new technologies and production practices in the production of fruit, grapes and wine. The potential for growth in the irrigated production of maize, oilseeds and fodder crops, tradition and market possibilities underline the necessity of livestock production improvement.

ACKNOWLEDGMENT

The paper is prepared within the scientific project *Sustainable agriculture and rural development in the function of accomplishing strategic objectives of the Republic of Serbia in the Danube region (III 46006)*, financed by the Ministry of Education, Science and Technological Development of the Republic of Serbia for the period 2011-2015.

KEY TERMS AND DEFINITIONS

Agricultural Holding: A technically and economically independent production unit with a single management on which an enterprise, farm cooperative, institution or another legal entity, entrepreneur or family household undertakes agricultural production, either as primary or secondary activity.

Average Actual Yield: An average of many recent years of actual yields achieved by crop producers in a given region under dominant management practices and soil properties.

Irrigation Efficiency: The share of water that is effectively used by crops relative to water withdrawal for irrigation. It consists of conveyance efficiency (the efficiency of irrigation system in delivering abstracted water to the field) and field application efficiency (the efficiency of irrigation system in transporting water to the plants).

Irrigation System: A hydraulically distinct network of structures – pumps, channels and pipes used to abstract, distribute and apply irrigation water to a defined land area, including accompanying land, infrastructure and equipment necessary to operate, maintain and repair the system.

Utilised Agricultural Area: Agricultural area used for kitchen garden, arable land (including fallow land), permanent crops (fruit plantations, vineyards, nurseries, and other permanent crops), permanent grassland and pastures.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Water Limitation Index: The gap between the water-limited yield potential (Yw) and the water non-limiting yield potential (Yp) as a percentage of yield potential, so (1 – Yw / Yp) * 100%. For a given location, the water limitation index is calculated for a single crop within the current cropping system and farm management practice.

Water-Limited Yield Potential: Defined for rainfed a crop, the yield of a crop cultivated is limited by water supply, and hence determined by solar radiation, temperature, CO2 concentration, and genetic characteristics and influenced by soil type and field topography.

Yield Potential: Defined for irrigated crops, the yield of a crop cultivated with non-limiting water and nutrients in the conditions of effectively controlled biotic stress. Therefore, it is determined by solar radiation, temperature, CO2 concentration and genetic characteristics.

Chapter 42
Characteristics Development of Agriculture and Agricultural Policy Southeast European Countries

Zoran Simonovic
Institute of Agricultural Economics, Serbia

Predrag Vukovic
Institute of Agricultural Economics, Serbia

ABSTRACT

In general the agricultural policy South East European countries are characterized by high volatility, which is expressed in terms of applied instruments and measures as well as in regard to the products to which it relates. In the first phase of price and trade liberalization, most countries have abolished or significantly reduced non-tariff barriers to the import and export of a wide range of products. Also, most countries have reduced or abolished production subsidies and left import tariffs as the main instrument to protect producers. This chapter emphasizes that the further development of CAP in many ways depended on negotiations with the countries of Southeast Europe. Some of these countries are already in the EU and some candidate countries which are at different levels of negotiation with the EU. Southeast European countries are basically agricultural country with low productivity and low prices of agricultural products to be completely restructured. These countries can be reintegrated into CAP only respect the rules and with the help of EU member states.

INTRODUCTION

Region Southeast Europe (SEE) has achieved significant progress of stability, implementation of economic reforms and in European integration, which also represent one of the most important political and economic challenges the whole region. At the Zagreb Summit in November 2000, leaders from the European Union (EU) and the countries of Southeast Europe have confirmed their full commitment to the

Stabilization and Association Process (SAP), which is led by the EU and at the end of its implementation, would lead to full membership in EU. Countries are currently divided into three groups; Croatia, which became an EU member of 1 July 2013; Macedonia, Montenegro, Serbia and Albania, which have been a candidate for EU membership;[1] Bosnia and Herzegovina, which is a potential candidate country for EU membership. In this context, fulfilling the criteria laid down by the EU for membership is extremely important. (Volk, Erjavec, Mortensen, 2014, p 3)

The SEE countries have clearly identified the European integration as a political priority, which is defined, among other things, reforms of agricultural policy and the need for modernization of agriculture. The accession process involves not only increasing competitiveness over the entire chain of agricultural and food products, but also in a broader sense, adopting a completely different model of agricultural policy which is mainly complicated in its conceptual, administrative and financial aspects. In the countries of South Eastern Europe agriculture and agricultural policy are very different from the agrarian policy applied in the EU. Therefore, it is necessary to reform and harmonize the legal institutions of the EU and to create conditions for integration of the agricultural sector in the countries of Southeastern Europe with the EU single market in the most efficient way possible. (Volk, Erjavec, Mortensen, 2014, p 3-4)

Agrarian policy of the SEE countries is characterized by high volatility which is expressed in terms of applied instruments and measures and in terms of products, referred to in (EC, 1998). In the first phase of price and trade liberalization, most countries have abolished or significantly reduced non-tariff import and export barriers for a wide range of products. Also, most countries have decreased or abolished subsidies in production and retained import tariffs as a basic instrument to protect producers. Input prices have risen considerably for producers, and this has caused a decreased in agricultural income. (Volk, 2004, p. 20-21)

The negative effects of the transition and the real decrease of income, have led to the fact that in many countries they introduced an ad-hoc price and foreign intervention in the function of stabilizing agriculture and the protection of consumers and producers. SEE countries had delayed transition caused by political reasons that have caused primarily disintegration of Yugoslavia. For this reason, countries in the region have led to a strictly controlled agricultural policy.

In principle, the strategic objectives of the country are more or less aligned with the principles of the EU, and can be summarized in ensuring stable production of high-quality food with reasonable prices and safety and food; sustainable resource management; increasing efficiency and ensuring adequate living standards (income) for the farmers and the rural population. However, in terms of operational programs and agricultural policy implementation, as well as customizing ZAP, major differences exist between countries. Croatia has already become part of the European Union. Enough elements to comply with legislation and program documents of the EU, especially in the field of rural development SAPARD5 (2005-2006) and IPARD6 (2007-2013) programs can be found in Macedonia, where it is prepared and implemented IPARD program, in Montenegro, where at the level of programming, all documents (strategies, a national program, legislation) have been prepared in accordance with EU principles. Rural Development Programmed documents which were made on the basis of the regulations of EU rural development were adopted in Albania and Serbia. Bosnia and Herzegovina has a specific situation because there is no single ministry of agriculture at state level. There are two separate strategies for agriculture and rural development at the entity level, while agricultural policies have been partly implemented even at the lower levels (cantons). Although the program documents and the activities planned in these

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

countries closely linked to EU integration, agricultural policy is still carried out mainly on the basis of the annual program budget allocations, which are not stable in terms of resources, support measures and criteria. (Volk, 2010, p. 25-26).

BACKGROUND: CAP AND THE COUNTRIES OF SOUTHEAST EUROPE

Negotiations with the countries of South Eastern Europe represent the next major step in the development of CAP. Countries in this part of Europe are basically agricultural country with low productivity and low prices of agricultural products to be completely restructured. These countries can be reintegrated into CAP only respect the rules and with the help of EU member states. In practice this would mean that the level of productivity and prices of agricultural products will be competitive CAP and EU countries.

For this reason, the countries of Southeast Europe have started with the implementation of various aspects of the reform and modernization, which is contained in the following points:

1. Legal harmonization, which contains four main regulations of the Common Agricultural Policy (CAP) (direct payments, a common market organizations, rural development and financial rules). The country must be able to implement these regulations on the first day of accession. Aligning with this policy prior to accession, it is not mandatory.
2. Improving the capacity to implement. Institutions responsible for legal harmonization and implementation of the rules CAP European Union should be strengthened or, in some cases, to establish them. Implementation of the IPARD pre- accessions support for agriculture and rural development serves as a test of the capacity for the implementation of the country.
3. Policy reform and economic adjustment. The ability of the rural economy in food production in agriculture must modernize and prepare for the "soft landing" in the framework of CAP after accession. Increasing competitiveness and providing alternative income for rural residents must be considered as a major goal. In addition, substantial reform of agricultural policies is necessary before accession in order to prepare future beneficiaries of measures CAP and for the administration to work in the institutional and economic framework of EU agricultural policy.
4. The accession negotiations. Include a summary of the above questions, as well as negotiations on transition periods, or in some rare cases, negotiations on permanent derogations from the legal framework of the EU. Agriculture is also an important part of the financial package and each candidate country requires intense work and preparation. (Volk, Erjavec, Mortensen, 2014, p 4).

Directorate-General for Agriculture and Commission calculated that the transitional period and after the approach is important for harmonization with the new system of CAP. Total financial support for this country amounted from 12 billion to 15 billion ECUS including all important investments in infrastructure, economy and development. Also from the Common Structural Fund is planned to allocate 15 billion ECUS a year. (European Commission, 1997, p. 7)

We would like to point out that after 2004, when the European Union joined the eight countries of Eastern and Central Europe, increased assistance to farmers. There was a regime of agrarian policy of integrating these eight countries with the common agricultural policy of the EU. (Anderson, Swinnen, 2008, p. 54) In this extension, the most successful countries was those that were duly endorsed by the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

application of the above points that proved to be necessary for the implementation of the CAP, while producers are prepared for the procedure and the level of support to be applied after accession. Rational (taking into account the possibilities and needs) and the gradual introduction to CAP represent the best approach. Elements that no longer exist or are significantly different from those applied in the EU should not be adopted. This is particularly important to the candidate countries.

AGRICULTURAL POLICY IN THE COUNTRIES OF SOUTHEAST EUROPE

Development problems of Southeast European countries, especially the countries of the Western Balkans, have been more pronounced than it was in the countries of central and Eastern Europe that joined the EU in 2004. The development process, with limited domestic resources, with dosing financial support on a bilateral and multilateral level with per capita foreign direct investment, which is considerably smaller than it was in the countries of eastern and central Europe, in most of these countries did not lead to overcoming the transition shock or substantial approaching the level of the EU countries 15th. (Gajić, Tošin, 2008, p.84).

Although the share of agricultural sectors in the economy has declined from 2000, still has a relatively important role in Southeast Europe in terms of value added and employment. As subsistence agriculture still dominates in most parts of the region, we can point out that agriculture provides a minimum level of food safety and socio-economic stability in rural areas. Thus, this sector plays an important role as a social and economic buffer for the rural economy. On the other hand, policy-makers are faced with many challenges, such as low competitiveness of the agricultural sector, inadequate use of the potential of agricultural production and the depopulation of rural areas. (Volk, Erjavec, Mortensen, 2014, p.4).

Notwithstanding market-oriented economy of many countries, the role of the state through the development and implementation of agrarian policy represent a significant element. You may say that, if the economy is more market-oriented, the role of the state is larger, or implementing measures in agricultural policy is more comprehensive. (Simonović, Cvijanović, & Hamović, 2010, p.73-82)

Intervention in the domestic and international market characterized agricultural policies in almost all countries where governments have used a large number of often very complex measures in order to support the agricultural sector. These measures include price support, quantitative restrictions on production or input use, budget payments, trade barriers, subsidizing inputs and the like. All these measures affect the allocation of production resources to the productive sectors and regions, and therefore to the use of inputs, farm structure, personal income and rural economy. In general agricultural policy initiated by the increase in the use of inputs and the use of resources in agricultural production. (Lovre, Zekić, 2008, p. 93)

If you look at the level of liberalization of agricultural markets in all these countries it is quite different from country to country. Border protection is the subject of agricultural policy on these countries. In recent years the level of border protection is reduced. For reasons on negotiations in the WTO and quotas (accept preferential) were eliminated (or not introduced at all). Tariffs are set at a relatively low level in Albania, Bosnia and Herzegovina, and Macedonia (0% to 15%), while in Serbia, Croatia and Montenegro, customs duties for some products are higher (up to 40%). All countries these countries signed several free trade agreements (most important of all is CEFTA7), which significantly reduce the current level of efficient foreign trade protection. Generally speaking, one can say that the level of trade protection in for countries is relatively low (Table 1).

Other support measures	-	Yes	-	-	-	-

Source: Research authors.

Export subsidies (refunds) are only important measure of market support in Serbia.In other countries, this measure has not been implemented. The intervention in the market system formally exists only on Croatia and Serbia, but in recent years intervention buying-in was rarely enforced. Among other measures support the market, administered prices is implemented in Bosnia and Herzegovina (wheat and rye).

Measures of direct subsidies to producers are certainly the most important instrument of agricultural policy on all countries. This instrument contains all the basic shapes, except separate payments. However, the composition of support varies by country (Table 2).

Most of the observed means of support, paid on the basis of output (cost), which is still very important to all the countries, but particularly in Bosnia and Herzegovina. Direct payments based on area and number of animals is the most abundant form of grants shall be implemented in all countries. The significance of these payments is particularly important to Macedonia, and also in Croatia. In all these countries, the use of inputs (seeds, fertilizers ...) is also subsidized. In Serbia, input subsidies are the most important form of direct support for producers. The process of splitting these payments in these countries is delayed no matter what you was planned.

Support for public services in agriculture is present in all countries of Southeast Europe. More attention of veterinary and phytosanitary services is provided in the candidate countries (Table 3).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

This part of agricultural policy modestly commented the statements of all these countries. Therefore gets pretty murky picture of the true state of affairs. If we look at the program in terms of volume of agricultural budgetary funds allocated for this purpose, then it could be said that the importance of public services in all these small countries. Some experts believe that these services are financed from other sources (donors, other ministries), but without long-term financing is difficult to expect the development of public institutions necessary to rapidly develop agriculture.

In addition to displaying the total amount earmarked for the support, and is an important structure and support, which is an indicator of agricultural policy. When comparing the evolution of total assets and the evolution of their structure, observed four different models. In Bosnia and Herzegovina, and after 2003, also in Montenegro, with growth in total support, its composition is also changing. Indeed, the share of assets related to rural development measures increases at the expense of reductions in direct funding support to producers. This is not the case of Croatia and Macedonia, which is a structure of recent years quite rigid and the share of direct support to producers has remained very high. Serbia is a special case. In addition to the significant decline in total support since 2005, dramatic changes in the structure of direct support for producers can be seen in recent years - a shift from direct payments to input subsidies. The case of Serbia (Macedonia until 2004) clearly points to the problem of stability of agricultural policy.

As for the budget support we are given in the table show the percentage of how much each country stands out from its budget to agriculture (Table 4). In millions of euro's this can be seen in the following table (Table 5).

If we look at the agricultural policy each of these countries individually we can observe the following situation:

In Albania, support for agricultural policy on the period 2010-2012 was weak, variable in absolute values and in programming. The support scheme is not sufficiently focused attention on the market and direct support to producers due to weak financial resources and an unclear reference to issues such as sustainable use of natural resources, sustainability of rural life and the balance of territorial development. (Thomaj, 2015, p.314-316) Low budgetary support, together with unfavorable infrastructure, high cost of inputs, poor access to services such as credit and market advisory services and highly fragmented production increased vulnerability Albanian farmers by their counterparts from the EU, primarily in the areas of investment and improved productivity. (Zhllima, Gjeci, Imami, 2014, p.68) A comprehensive strategy that will be relevant of agriculture and rural development is absent.

Table 4. The share of expenditure on subsidies in agriculture percentage of the total budget expenditures SEE countries

Country	2010	2011	2012
Albania	3,0	3,0	3,0
Montenegro	1,4	1,4	1,4
Bosnia and Herzegovina	6,2	3,1	3,7
Croatia	4,6	4,8	4,4
Macedonia	4,8	5,4	5,6
Serbia	2,3	2,4	3,9

Agricultural policy of Bosnia and Herzegovina and its entities (Federation, BH, Serbian Republic and the Brcko District) in the period from 2010 to 2012 clearly indicate that formal and substantive implementation process and the adjustment of agrarian policy of Bosnia and Herzegovina with CAP is still unsatisfactory. Agricultural policy of both entities is significantly different from the EU. In both entities, shall be made direct payments per unit of output account for much of the direct support to producers. Such forms of payment basically do not exist on EU countries. Modest transfers of rural development measure almost entirely related to investment in agricultural holdings, while the measures to preserve the environment, as a mandatory part of the CAP, and practically do not exist on Bosnia and Herzegovina. (Bajramović, & Nikolić, 2014. p. 9) Legal harmonization was introduced gradually, but the institutions are still in the development stage. Deficits in institutional structures and in human resources management give a result that produce poor motivation and lack of political will in the past few years, which will inevitably produce consequences of the development of Bosnia and Herzegovina as a state. It can freely be said that the agricultural policy on Bosnia and Herzegovina does not exist. It is quite expensive, contains a lot of elements of the policy, which is conditioned by the entities and cantons, with little coordination among them. (Bajramović, Nikolić, Butković, 2014, p. 92)

Croatian agriculture and agricultural policy is at a crossroads. With the accession to the EU, creates opportunities that Croatia used to increase the funds that are specifically focused on the agricultural sector and the rural economy as a whole. Moreover, the long period of preparation and learning from the experiences of Member States that had joined the EU in 2004 and 2007 should help Croatia to face the challenges of membership. However, Croatia has entered the EU in a moment of global and national economic crisis, with the decline in overall national economic growth has subsided and agricultural production. This has led to a situation where the agricultural sector is not sufficiently prepared for a stronger competition in the EU and has produced more fear of farmers that fear for their future. It is also produced harsh criticism of the authorities on failing to provide proper preparation and implementation of IPT and that could mitigate the unfavorable situation of farmers. (Kumrić, Franić, 2005, p. 34-36) Data onto Croatia's agriculture shows that Croatian agricultural and food products are not competitive in the international market, although there are some products of lower prices and the positive agro-food trade's balance. The reasons for the low competitiveness of the EU and international markets are mainly associated with high production costs, unfavorable agricultural structure of its small farms with low economic power, the lack of cooperation between farmers, poor risk management with high influence of climatic conditions in production, poor physical infrastructure market (storage facilities, cold storage installation). (Mikuš, 2014, p. 95)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The main shortcomings of the Macedonian agricultural policy are frequent deviations from budget transfers to be paid to the long-term as well as the annual program. (Report No: ACS5258, 2013, p 19) The problem lies in the lack of a strategic approach and behavior of stakeholders (farmers' associations and other interested parties) involved in the process. In this way, demonstrate the political resistance which leads to the fact that it does not perceive the real problems. Another serious problem of the Macedonian agricultural policy a number of measures with complicated procedures on the one hand, while on the other hand, 58% of farms cultivate less than one hectare of agricultural land, and many of them have low education levels A large number of measures, in the form of direct support to producers complicate administrative procedures, which increase the cost of implementation and hence lead to user confusion.

Developer's agricultural policy on Macedonia should adapt the same measures and procedures to meet the needs of all types of farmers and at the same time to meet the national objectives in agriculture. In this regard, the recommendations are in line with the latest reform of the CAP, which suggests a simplified support scheme. (Dimitrevski, Kotevska, Janeska Stamenovska, Tuna, Nacka, 2014, p. 95)

The main documents in the design and implementation of agricultural policy and rural development in Montenegro are: Strategy; National program; Law on Agriculture and Rural Development and Strategy agro-budget. Since 2006, Montenegro has focused its reform in three main areas: agricultural policy (CAP gradual introduction); legislation (harmonization of legislation with the EU); and institutions (the modernization and strengthening of institutional capacity to enable effective implementation of policies).

The key problems of Montenegrin agriculture are small farms, the outflow of labor to cities, low level of use of machinery and agro-technical measures, and low income that arise as a consequence of the above reasons. Improving Montenegrin agriculture can be achieved by increasing the credit support to agriculture, increasing amount of subsidies, providing tax relief, raising the level of technical equipment and new agricultural practices, as well as improving general living conditions in the countryside. (Fabris, Pejović, 2012 p. 670)

Agrarian-budgets are adopted each year, on the basis of the Law on Agricultural and Rural Development and the Law on Budget of Montenegro. Regarding the implementation of the designed policy on an annual basis, some measures should be particularly emphasized: better stakeholder participation in the preparation of measures; full respect for the legal and policy framework; Reporting on the execution of each measure. For better implementation, preparation and adoption of the agricultural budget need financial preparations before the start of each fiscal year, which was not the case until now. (Marković, 2014, p. 95)

Key issues in the implementation of agricultural policy of Serbia are the appearance of discontent growing number of agricultural stakeholders, institutions and many other entities. Not yet reached the concept of sustainable agriculture. This gives to rise to the reform of agricultural policy has not yet yielded some results. One gets the impression that the main feature of the reform of agricultural policy of the period from 2000 to 2007 was its unpredictability and inconsistency.

Measures and instruments that Serbia must in the future to undertake and guide through budgetary support in many ways depend on the reform solutions in the Common agricultural policy of the EU. Significant changes in this area in the EU are expected, considering that the last analysis, despite evident positive results in growth of competitiveness and environmental and social sustainability, and pointed to the shortcomings of the existing support schemes against agriculture and rural development. We must point out that the essential difference in compliance Serbia's agricultural policy of CAP is reflected in the fact that the measures of agricultural support on our country still determined sectored rather than spatial, and there is no comprehensive regional policy and rural development. However we must admit

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

that a few years ago adopted a strategy of regional development of the Republic of Serbia and that should soon bring rural development strategy. This means that the agricultural policy of Serbia on its way to be any time soon adapts CAP. (Simonović, 2014, p. 301)

EXPENDITURES FOR ZAP IN 2013 IN THE EU MEMBER STATES BORDERING THE COUNTRIES OF SOUTHEAST EUROPE

Compared to the EU 28, transfers from the budget of agriculture in these countries are relatively low by relative indicators. However, the actual level of support in most of these countries is comparable to levels in some Eastern European countries at the beginning of the accession process. Croatia's pre-accession period during 2007 recorded a much higher level of support to agriculture per capita and per area of some of the countries that are EU member states (Romania and Bulgaria). In addition to the total amount of support, the support structure is also an important indicator of the agricultural policy.

The complexity of the proceedings, which put the countries of Southeast Europe, is enough to say that agriculture was the greatest chapter in the negotiations countries of Eastern Europe before their accession to the EU. With Bulgaria and Romania Negotiations on the agricultural section lasted until the end of 2004, while ten country candidates in 2004 completed in December 2002. Even with direct income support rather than support prices would lead to a drastic increase in the cost of CAP due to enlargement. One of the main topics at the stage of accession of new EU members was whether or not to extend the system to direct payments to the new members. Implementation of the obligations of direct payments has required a substantial increase in the budget of CAP. (Cvijanović, Simonović, & Mihailović, 2011, p. 368-369) Results stemming from negotiations and relate to the fact that the new EU member states gradually fit into the system of direct payments of 2004 and 2013. Direct payments will start from the level of 25% in 2004 compared to the level of the EU 15, 2005 increased to 30% and 35% in 2006. In the coming years will increase by 10%, to 2013 reached a level of 100%. Also new member states will these funds be able to add and national subsidies.

Table 6 whether we show how countries that are members of the European Union and are located in the immediate environment of the countries of Southeast Europe allocate financial resources to its agricultural budget.

If we observe how much has been allocated funds, the level of the whole European Union, we can notice that the subsidies ZAP influenced, in the given circumstances that agriculture in these countries

Table 6. Expenditures for ZAP in 2013 in the EU member states bordering the countries of Southeast Europe 1 000 Euros

EU Country	Direct Payments	Market Measures	Rural Development	Total
Bulgaria	494 436	43 095	395 700	933 231
Greece	2 282 265	63 078	671 478	3 017 092
Romania	1 086 815	122 405	1 356 173	2 565 393
Slovenia	130 184	8 660	113 031	251 875

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to be competitive with other countries (Table 7). This only proves that almost the entire agricultural sector artificially maintained. The reasons for this attitude should be sought in the fact that neither of the countries has a competitive advantage in relation to other countries in Europe or in the world. Just such a situation has led policy of large subsidies that allowed agricultural firms to stay on the market no matter the low efficiency.

Changes CAP adopted before the entry to Eastern European countries into the Union indicate that there will be a weakening of central policies of agriculture and there will be a kind of rationalization of the agrarian policy. In such a changing situation sets up question of what they can from such ZAP to seek the Southeast European countries?

MARKET-PRICE POLICY

Agrarian market in Southeast European countries is still under construction, i.e. It is not built sufficiently. Just arranging agrarian market includes more complex actions. Some of these actions are: the choice of production, technical and technological equipment, financial credit support. Each of these issues is, we have to admit, is very complex. Thus, the choice of production means to find comparative agricultural products that would be competitive. For example, the quality of Serbian raspberries is a real brand even though it is not formally branded. Therefore, landscaped land markets means branding or the introduction to quality standards. All this is a complex task for countries in transition that are just entering their agrarian products wholesale market of the EU.

Market price policy is not just about financial support and production support but also support prices in order to achieve competitiveness. It is itself a market-price policy consists of the following measures:

- Support measures for the market,
- Measures of direct budget support products and
- Other direct payments.

In a large area of Europe are encountered with many countries in transition are different problems. The regulated market would be differentiated and specialized agricultural production of Europe.

The process of price liberalization had different effects in countries in Southeast Europe in relation to the countries of Central and Eastern Europe where he was a greater intensity. Some of the CEE countries such as Hungary and the Czech Republic supported the export of agricultural products by providing export credits. In the early nineties of the twentieth century, Croatia and Albania have liberalized the prices of their agricultural products. In 1997, Romania has liberalized the agricultural policy of abolishing the system of direct control of administered prices relating to agricultural products. In early 1999, Romania

Table 7. Expenditures for CAP in 2013 for all EU member states 1 000 Euros

	Direct Payments	Market Measures	Rural Development	Total
EU	41 658 276, 9	3 193 228.9	14 788 920.8	59 640 426.3

Sources: European Commission, Directorate General for Agriculture and Rural Development (2013 EAGF Financial Report) and Commission Decision 2010/236/EU Updated: October 2014

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

began to implement the second phase of liberalization which relates to the reduction of import tariffs by 45% for imports of sensitive products such as meat and dairy products and introduced a higher rate for other agricultural products. Poland has risen to import tariffs on imports of wheat, corn and sugar products from other CEFTA countries. (OECD. 1999, p. 149-150) At the beginning of the transition period in Bulgaria the prices of agricultural and food products have not been fully liberalized. In this country through the system of price controls and profit margins tried to achieve double protection for consumers and producers. This system was abandoned in 1998 when the liberalization.

The abolition of control of the market price in the countries in transition, prices of domestic products began to jump and to come closer to prices valid on the world market.

In the countries of Southeast Europe, the conditions for macro-economic development of agriculture, this is one of the important characteristics that are important to the development of a market economy. Open rates and a regulatory framework are applied to these countries is more or less in a position to influence the situation on the world market. Support that is allocated to agriculture, but also the protection for the internal market became stronger after 1995 than it was in the first half of 1990. However, the level of indirect and direct support for agriculture continues to be below average, which is valid across the EU. (Csaki, 2000, p.50-51) Frequent changes in the legislation constituted a kind of problem. The introduction to a common agricultural policy of the EU is a positive trend that directly affects the direct application of efficiency and competitiveness, which is increasingly coming to the fore in the system of agricultural support.

Price liberalization in South Eastern Europe has led to the growth of price levels and the fall in domestic aggregate demand of no easy access to foreign markets. For reasons for constant representation of the economic crisis in the former Soviet Union lead to the loss of traditional markets, on the other hand the EU market was largely closed to the largest number of agricultural products, the countries in transition. Measure that states have undertaken in the first half of the nineties were ad hoc and were related to the import tariffs, export subsidies, minimum guaranteed prices, determination of maximal dimensions and import restrictions. In the period that follows in the second half of the nineties and later, the complete liberalization of prices and trade flows of agricultural products, as well as the formulation of comprehensive agricultural policy

PROBLEMS OF INTEGRAL AGRARIAN DEVELOPMENT

Problems of integral agrarian development of the European Union as well as its impact on the agricultural policy of countries in South East Europe must be viewed through a segment of CAP. The common agricultural policy as we have already stated is based on three basic principles. These are the common market, financial solidarity and orientation towards the formation of community.The period of the last few decades of the last century was marked by the search for alternative solutions to economic development, as the antipodes classical model of industrialization and urbanization. These attempts on finding new solutions led to the theoretical and practical valorization of ecology, natural resources and sustainable development. That is how the policy of integral agrarian development, which studies specific concepts, measures and procedures for solving development problems, both in developed EU countries and countries in transition countries and new EU member states and candidate countries.

Integrated Agricultural Development is complete and comprehensive. In it is:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Development of private property,
- The development of agriculture in line with the natural conditions
- Development of irrigation systems and irrigation
- Development of Agricultural Organizations (individual farmers, cooperatives, agricultural enterprises, etc.).
- Development of vertical and horizontal integration and development of agricultural system
- Development of multifunctional agriculture
- Development of rural systems in the agricultural environment
- Development of sustainable development
- Development and conservation of natural resources
- Land legal regulation
- Building of market institutions
    1. Agrarian brands
    2. Agrarian Standards
    3. Agrarian Exchange and fairs
    4. Various agricultural services
- System branding, development and construction, decoration studies for export ISO and others.All these points are present in the initial form. They need to develop further and to raise their level. This process requires a versatile work and extensive preparation if you would like to achieve some results.

During the adjustment of agricultural policy of the countries in transition integral agrarian development, the attention to national governments should be directed, along with primary orientation in the direction of ending the liberalization of prices and markets, land reform, privatization, institutional reforms, primarily on the part of the agricultural infrastructure that is related to public goods, public services. It also should establish regulations that are related to land issues, antitrust regulations, and regulations concerning insurance. Sam adjustment program should include

- The balance of macroeconomic and sectored measures and compliance of the exchange rate and trade policies.
- Completing the process of liberalization of markets and prices, land reform, privatization and institutional reforms.
- The policy of public investment in social and economic infrastructure.
- Prevention of large farms and agro-industrial sector in acquiring a privileged position
- The introduction of measures aimed at developing the agricultural sector where should dominate technologically developed farms that rely on their workforce. (Lovre, Trkulja. 2003, p. 12-14)

CONCLUSION

We believe that the objective of the economies of Southeast Europe coincides with the interests of the EU and that the increase in population welfare of all its members. In order for a country to become a full member of the EU, it must carry out a number of changes which are primarily related to the creation of stable legal, economic and social systems, as well as a fundamental change in the role of government in

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

these countries. Stable institutions need to create the basis for the elimination of transitional deformity, crime, and corruption, which are burdened countries that until recently housed in transition. (Bogdanov, 2007, p.11)

Developed countries underdeveloped only provide a picture of a better future. It is natural that you learn from better to suffer the impact successfully. But in the case of European agrarian model is not about an imaginary model of what was the Soviet model in agriculture, for example, but it is a real model of the experience of developed countries what they want to become and countries that have until recently been in transition.

In development of agriculture and agricultural policy of, observed generally prevailing two elements.

The first is that the European model is successful in all aspects: productivity, quality and quantity of production, the production of healthy food, in terms of sustainable development, the use of waste and others. The second is that the model is based on market principles, as one of the best in the world and which exerts a strong influence on agriculture and agricultural policy in transition countries, primarily European.

On the other hand, the countries of the European Union wished to facilitate access to new countries. In this sense, the changes made to the CAP adopted before the entry of Eastern European countries into the Union. The changes that have been made indicate a weakening of central policies towards agriculture and a kind of rationalization of the agrarian policy. The best examples for this statement represent the premium for exchange rate differences. These premiums are paid out of the national state and since the introduction of the euro exchange rate differences disappeared, premiums in 2000 redefined as a national envelope. They should serve to determine the special premium for beef and milk. (Prokopijević, 2009, p. 223).

The current state of things in the process of adaptation and harmonization of agricultural policies, the countries of South East Europe can be divided into four groups: (1) countries with planned activities and partial implementations with CAP (Serbia); (2) countries with elements of harmonization, mainly at the level of adjustment (Macedonia and Montenegro); (3) countries at the initial stage of partial harmonization with the EU at the level of adjustment (Albania); and (4) with the "pragmatic" approach with no real direction in the development of CAP in their policy instruments (Bosnia and Herzegovina).

Finally, we wish to emphasize that our recommendation to pay more attention to the analysis, monitoring, and evaluation of agricultural policy. In recent years, these countries have started to harmonize methods of data collection and processing with EU practice. However, data sets, especially with regard to agricultural policy measures, still do not meet the analytical needs. In the future, it should improve upon, updates and use them to analyze agricultural policy on a regular basis. Part of these activities could be given to independent researchers and state authorities. Finally, ideas for future joint projects should be developed. In addition, should prepare impact assessment of the effects of EU integration with the price convergence and make studies of the policy harmonization.

ACKNOWLEDGMENT

KEY TERMS AND DEFINITIONS

Agricultural Policy: Agricultural policy is a set of economic policy measures, which includes the whole activity of censors directed towards agriculture. It consists of several interconnected elements – objectives of agricultural policies; means, measures, and methods of action; and bearers of agrarian policy. The objectives of agrarian policy can be long-term and short-term, and with regard to general and specific content. The efficiency of the agrarian policy largely depends on whether and how the objectives in terms of content and time-aligned. The means to achieve the objectives of agricultural policy can be economic, technical, legal and organizational. The most important economic resources are provided, investments, taxes and policy of exports and imports, and technical (mechanization, chemicals, farm measures, redistribution of land, redistribution of fields, crop rotation). Legal means to regulate the implementation of certain measures and actions in the production transport, in the possession relations and others. The organizational measures is relating to the organization of agricultural enterprises, and the forms of linkage in association of individual producers. Measures of agricultural policy according to the mode of implementation may be direct, i.e. voluntary and involuntary. As participants and holders of agricultural policy occur administrative and executive authorities, agricultural producers and their associations, political organizations, professional and scientific institutions.

Agriculture: A key sector in the Western Balkans. How important and so neglected in the transition process? In the Western Balkans country and agriculture is still very important economic factor. The relationship between agriculture and the total land varies from 23% in Croatia (it is arable land) to 66% in Serbia. In the European Union arable land is about 40%.

Common Agricultural Policy (CAP): The agricultural policy of the European Union. The importance of the Common Agricultural Policy is high. It is believed that there was no CAP there would be no EC. Perhaps this statement is pretentious, but the fact remains that economic organizations such as EFTA and NAFTA did not have the common agricultural policy and failed to survive. There is certainly

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the possibility that the Common Agricultural Policy could otherwise arrange for instance that the main principle is marketability rather than administrative measures.

European Union (EU): An intergovernmental and supranational union (the union) twenty-eight countries in Europe. Union takes its roots from the European Economic Community established by the Treaty of Rome in 1957 by six European countries. Since then, the European Union expanded the accession of new member states and gained more power. This community was formed under the present name of the Treaty on European Union (more known as the Maastricht Treaty) in 1992. Many aspects of the EU have existed even before the signing of this agreement, through the various organizations of established 50-ies of the twentieth century. Treaty of Lisbon signed in December 2007 provides for the amendment of the current agreement in order to redress the political and legal structure of the European Union. The ratification process of the Lisbon Treaty was completed in November 2009.

Southeast Europe: Region Southeast Europe geographically and politically in the Balkan Peninsula. Countries in the region are: Albania, Bosnia and Herzegovina, Macedonia, Croatia, Serbia and Montenegro. This region is also called the Western Balkans.

Stabilization and Association Process (SAP): A strategy that relates to the prospect of EU accession and is adjusted to the level of development of each of the countries concerned. This strategy is fact a substitute for the offer prospect of accession. To achieve that countries in the region are committed to fulfill the political and economic conditions that are given for all individual countries (Copenhagen criteria).

Chapter 43
Trends and Transformations in European Agricultural Economy, Rural Communities and Food Sustainability in Context of New Common Agricultural Policy (CAP) Reforms

Andrei Jean-Vasile
Petroleum-Gas University of Ploiesti, Romania

Alexandra Alecu
Petroleum-Gas University of Ploiesti, Romania

ABSTRACT

Agriculture continues to be quite a debate for the last two and a half decades at least at the European level and for Romania Common Agricultural Policy (CAP) reforms has a big impact in developing the convergence to the European agricultural model. Agriculture becomes nowadays a multirole economic sector, with major implications on rural community's sustainability and on food security assurance. In this context, the transformations in European agricultural economy, rural communities and food sustainability in context of Common Agricultural Policy (CAP) reforms represent an important research topic in the context of EU-28 policy diversification from the larger context of Romanian approach.

INTRODUCTION

Refocusing economic activities towards high productivity sectors capable of generating a comparable standard of living and welfare for the population required a major reorientation of production structures, including resource allocation funding and resource mobilization work. In this context, agriculture has proven to be one of those sectors affected by these changes.

Numerous studies have tried to highlight these transformations, starting from various parts of the analysis. Thus (Piotet et al., 2002; Kilian and Salhofer, 2008), Petrick and Zier, 2012), investigate the effects of direct payments and rural development measures of the EU's Common Agricultural Policy (CAP) on employment in agriculture. On the other side, (Luca, 2007; Montiel et al., 2014; Dwibedia and Chaudhurib, 2014) tries in their studies to provide a theoretical explanation why the agricultural subsidy policies fails in ensuring the well-being of the poor working families in terms of a three-sector general equilibrium. Ciutacu et al.2015 tries to identify and explain the similarities and dissimilarities between the EU agricultural and rural development model and Romanian agriculture.

The changes occurred globally in the evolution of agricultural area, as share of land area demonstrates once again that interest towards increasing the agricultural potential, despite diminishing the agricultural area, is still a viable objective for most world economies, based on the need to increase the level of food security. Figure 1 illustrates the evolution of agricultural area as share of land area in some global economies, during 1992 – 2012.

From the analysis of Figure 1 it can be seen that during 1992-2012, the evolution of agricultural area as share of land area in some global economies was negative for most economies given. So it can be seen that the values of EU-28 decreased by 4.9%, while in other economies are recorded slight increases in resource consolidation of land used, as in Argentina (+ 7.4%), Brazil (+ 1.2%) and Mexico (+ 0.1%).

In spite of systematic transformations of the national economic structures due to increasing markets globalization and movements in productivity, rural areas continue to be an important component in the national economy of every state, mobilizing important and diverse resources. Taken from a sectorial perspective, rural areas are affected, at least at European level, by numerous and significant mutations which reflect both changes in agricultural policy and new approaches to integrated rural development and multifunctionality of agriculture.

Rural areas constitute a defining element in achieving economic and social governmental politics and by continuous reporting toward urban areas, dilute its significance, transforming rural areas in an amorphous space in which the only significant activity is agriculture. To erase these false premise comparisons between rural and urban areas has to stop and then, the accent has to be on outlining the multifunctional character of rural areas that can also be able to develop activities from secondary and tertiary sectors. From this perspective Figure 2 and Figure 3 analyzes the changes in the structure of the

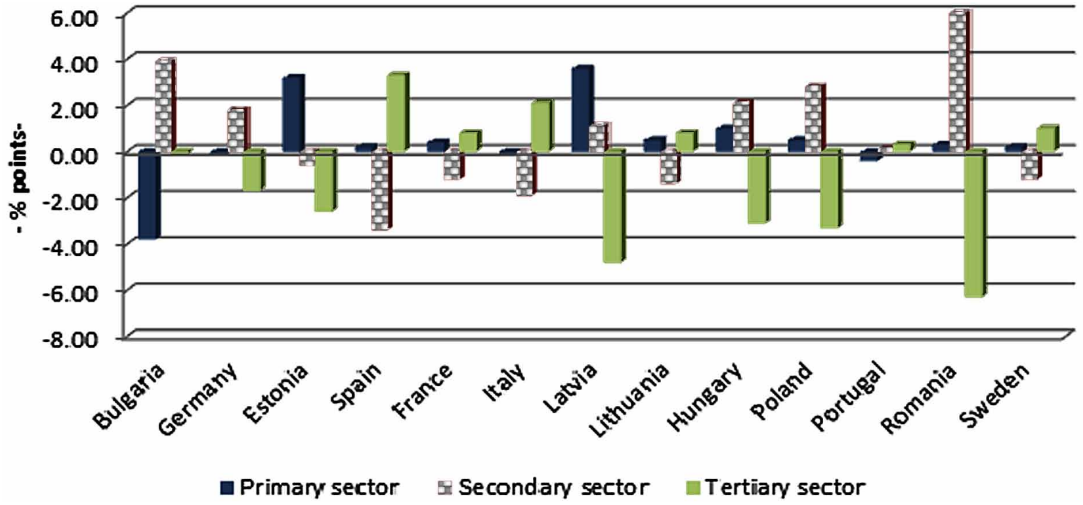

Figure 3. Change in the structure of the primary sector economy, in some EU-28 countries, 2008-2011
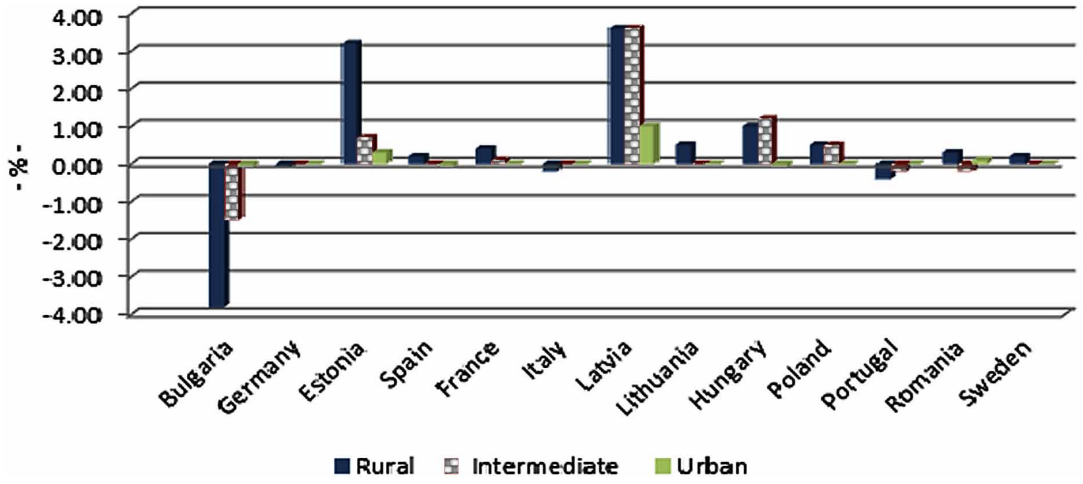
Source: Authors' own computation based on European Commission (2014)



rural economy, both sectorial (primary, secondary and tertiary) and from an environmental perspective (rural, intermediate and urban) in terms of weight and significance of the primary sector (agriculture).

From the perspective of the structure of the rural economy (Figure 2), for EU-28 in the cases of analyzed countries, it can be observed a noticeable decrease in the importance of the tertiary sector (services, infrastructure) in the rural areas, while the agriculture continues to represent the most important branch in these areas. The secondary sector, although it is poorly represented in the rural communities through small industries, recorded declines much lower than that of services.

Thus, regarding the evolution of the primary sector, it can be observed that in rural areas, the highest increase is registered in the case of countries such as Latvia (3.6%), Estonia (3.2%) and Hungary

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

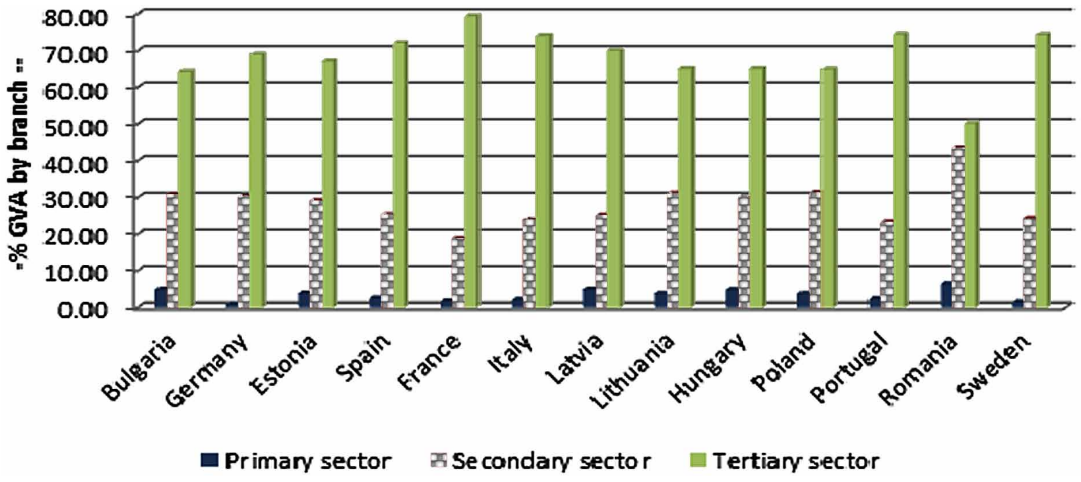
(1%). On the opposite side is Bulgaria with a drop of 3.8%, followed by Portugal with 0.4%, Italy with 0.2% and Germany which recorded a decrease of 0.1%. In the development and evolution of industry in rural areas, the highest increase is registered in Romania, with 6%, followed by Bulgaria with 3.9% and Poland with 2.8%. From this analysis, these trends can be seen as a sectorial evolution in opposite directions. In countries where agriculture recorded the highest increase it can be observed a decline in the secondary sector. Thus, Spain recorded the biggest drop with 3.4%, followed by Italy with 1.9%, France and Sweden with 1.2%.

Analyzing the tertiary sector, the largest decline is recorded in Romania (-6.30%), Latvia (-4.80%), followed by Poland (3.30%) and Hungary (3.10%). The only state that recorded growth in this area is Sweden (+1%). It may be noted that tertiary sector is sensitive to the influences and transformations of the rural economy and also that the tertiary division of the economy does not imply an automatic alignment of the primary sector to this phenomenon. The wish of extending and stimulating the tertiary sector in rural areas, as part of creating a multifunctional agriculture, continue to experience some difficulties, especially in the former socialist states that have joined EU-28.

The analyze of the change in the structure of the primary sector in the national economy, from 2008 to 2011 (Figure 3) pointed out that in terms of agriculture for each of the countries analyzed environmental, rural, urban and intermediary are registered increases in the Nordic countries and also in countries such as Spain, France, Romania, which has a significant agricultural potential and capabilities for sectorial development. The highest increases recorded are found in Latvia, closely followed by Estonia and Hungary. Although most countries analyzed records regarding agriculture increases for all 3 environments, Bulgaria is the only country that records a decline of 3.8% in rural areas, 1.5% in intermediary area and 0.1% in urban area.

The importance of the primary sector in the rural economy is evidenced by its ability to generate gross value added (GVA) and, thus to support the development of rural communities, which often have a high degree of sectorial dependence regarding the agriculture, by the fact that agricultural activities are the only activities that support the income of rural residents. In Figure 4 is presented the importance of the sectorial economy in some EU-28 countries in 2013, in terms of GVA.

Figure 4. Importance of the sectorial economy, in some EU-28 countries, 2013
Source: Authors' own computation based on European Commission (2014)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

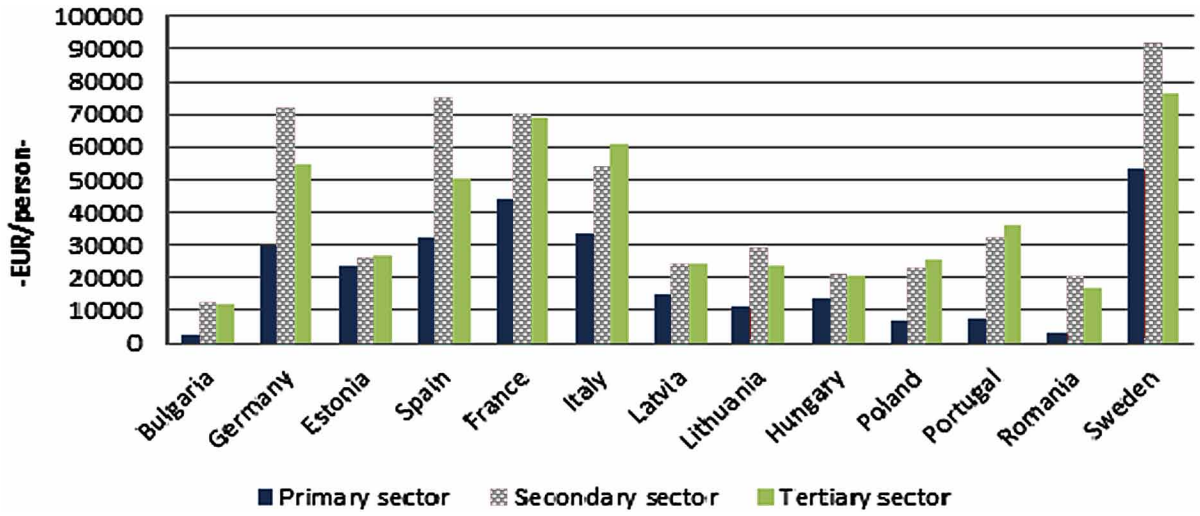
In Figure 4it can be seen that for the year 2013, the tertiary sector achieved the highest contribution to the GVA across all EU-28 Member States analyzed, confirming the tertiary division of the national economies and diminishing the importance of the primary sector (agriculture). Although the importance of agriculture in GVA formation decreased steadily over time in favor of the tertiary sector, it should not be neglected, at least in terms of ensuring its basic functions - providing food resources for the population. This trend can be explained by the level of productivity and resource allocations in the national economy. In Figure 5 is presented the labor productivity level by the economic branch in Some Countries EU-28 in 2013.

Significant differences recorded in labor productivity in the EU-28 Member States reflect a strong gap between the old Member States of the UE and those who have recently joined. In Figure 5 labor productivity is presented by branch in some Countries EU-28 in 2013. Thus from analysis we can see that in 2013, for which there is data (European Commission, 2014) the highest level of labor productivity is registered in the industrial sector, followed by the tertiary sector and in the primary sector are registered the lowest levels for this indicator.

From the Figure 5 it can be noticed that in rich countries are recorded the highest labor productivity values for all three sectors. The overall level of labor productivity recorded in the EU-28 in 2013 was 52.237 EUR/person, with significant differences between economic sectors, starting from a level of labor productivity that is lower than 20.000 EUR/person for agricultural sector and levels of over 50.000 EUR/person for labor productivity in industry and services sector.

It can be seen that the highest levels of labor productivity is registered in the economies of countries such as Sweden which records the higher labor productivity, 91.998 EUR/person obtained in industrial sector (secondary), 76.254 EUR/person for services and 53.166 EUR/person in the agricultural sector (primary), followed by Germany, France, Spain and Italy. However, it can be seen that labor productivity in agriculture and services in France, 44.305 EUR/person and 69.020 EUR/person exceeds the level in Germany, 29.550 EUR/person and 54.863 EUR/person. However, in terms of industry, even though Germany recorded higher values of labor productivity in this sector, the two countries have similar

Figure 5. Labor productivity by branch, in some EU-28 countries, in 2013
Source: Authors' own computation based on European Commission (2014)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

values, 71.733 EUR/person in Germany and 70.164 EUR/person in France, but is still topped by Spain with a value of 74.825 EUR/person.

At the opposite pole are the countries that joined later in the community area at which the values of labor productivity are very low compared with other countries of the EU-28. However, the agricultural sector recorded the lowest values from all, in Bulgaria (2.585EUR/person), followed by Romania (2.893 EUR/person), Poland (7.058 EUR/person) and Portugal (7.369 EUR/person).

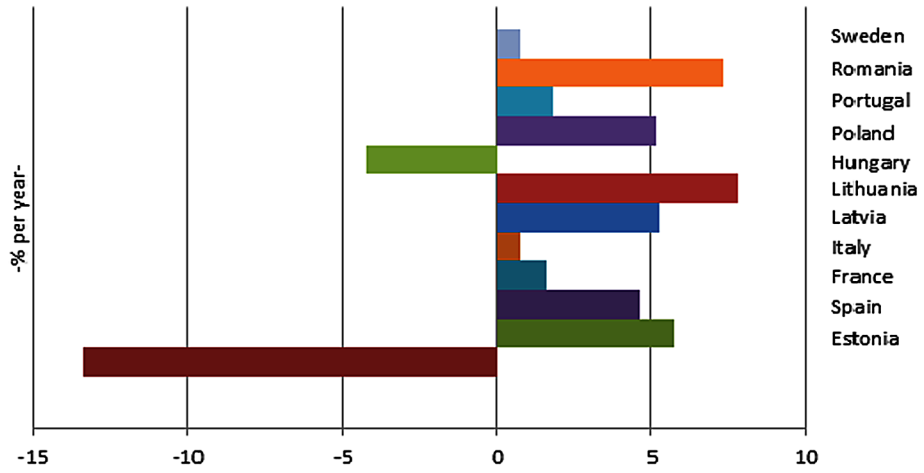
Labor productivity in this case is the most important factor in explaining the existing disparities in EU-28. With the exception of Italy (60.658 EUR/person) and Portugal (36.037 EUR/person) which records the highest level of labor productivity in the case of the tertiary sector, in the other states, the secondary sector defines the highest labor productivity.

AGRICULTURE AND ECONOMIC EFFICIENCY IN EUROPEAN AGRICULTURAL SECTOR: BEYOND CLASSICAL APPROACH

Returning to agriculture, the growth of labor productivity is a problem with major implications nationwide, its evolution influencing automatically the evolution of living standards and in general the competitiveness level of the European economy while in particular for national economies.

Labor productivity analysis involves understanding on how they are deployed, and on how labor resources are used in the national economy. Agriculture, through specific activities involved, mostly mobilize important human resources for members recently integrated in EU-28, faced with low-tech and a low rate of investment in this sector, and on the other hand, a decrease in the use of labor resources, if developed on states that the level of technical and technological resources have displaced labor, by increasing labor substitution ratio - capital in this sector. Therefore, analyzed from the perspective of economic efficiency, the developed countries will continue to record high levels of labor productivity, and in the states in transition to community space, agriculture will continue to be a place of sustenance for a rural population multiplied and devoid of possible investments. In Figure 6 is presented the change in labor productivity in agriculture in some EU-28 countries, from 2008 to 2013.

Figure 6. Change in labor productivity in agriculture in some EU-28 countries, 2008-2013
Source: Authors' own computation based on European Commission (2014)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Regarding agriculture, the weight of labor productivity change in EU-28 for the period 2008-2013 shows in general an increasing trend for those countries that have low labor productivity in agriculture. Thus, although Germany has labor productivity in agriculture of 29948 EUR/AWU in 2008-2013 its weight in EU-28 it decreases by 13.4% per year, representing the biggest drop.

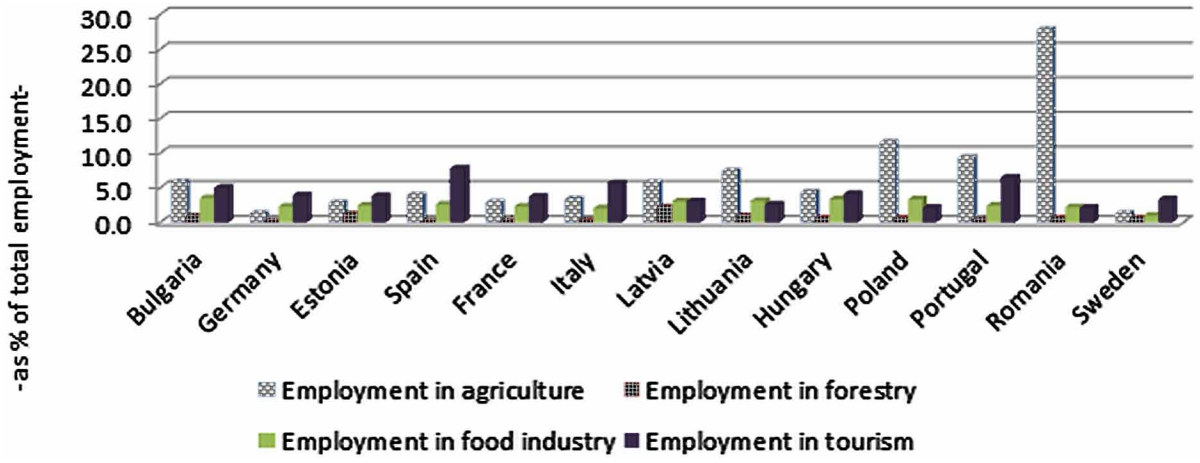
On the opposite pole, lies less developed countries in terms of industrial services with a low labor productivity in agriculture, which in the analyzed period, increased its weight productivity in agriculture in the EU-28, the largest increases being recorded in Lithuania with 7.8% per year, 7.3% per year in Romania and 5.7% per year in Estonia. Compared to these countries, the ones that present the highest level of productivity in agriculture such as France with 37.913 EUR/AWU, Spain 24.969 EUR/AWU and Italy, 23.804 EUR/AWU, record increases in low levels in 2008-2013, France 1.6% per year, Spain 4.6% per year and Italy 0.7% per year. This can be explained in terms of employment structure by economic activity. Therefore, in Figure 7 is shown the employment structure by economic activity in some countries EU-28 in 2013.

Regarding employment, in the Figure from above is seen that the highest level of employment in the EU-28 is registered in agriculture, 9.8577 million persons, followed by the 9.7274 million persons in touristic sector.

As level of the employment rate in 2013, the highest values are recorded in the case of agriculture and tourism. Regarding industrialized countries, it can be seen the rising rates of occupancy workforce relatively low in comparison to other countries. Thus, in Germany are recorded the lowest values, 1.3% in agriculture, 0.1% in forestry, 2.3% in food industry and 3.9% in tourism.

It can also be observed that in the same year, the occupancy workforce grows the most in agriculture, Romania registering the highest level of 27.8% of total, followed by Poland with 11.5% of total and Portugal 9.3% of total. The lowest values of employment in agriculture is registered in Germany and Sweden with 1.3% of total, followed by Estonia with 2.8% of total and France with 2.9% of total. From this perspective, agriculture continues to mobilize important work resources for ex-socialist countries such as Romania and Bulgaria which are facing an excess of occupancy in the agricultural sector and in the light of the relatively low technical and technological and practicing agriculture subsistence strong

Figure 7. Employment by economic activity in some EU-28 countries, in 2013
Source: Authors' own computation based on European Commission (2014)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

polarized holdings, with the exception of Portugal, the employment of labor force is 3.2 times higher than in France.

Regarding tourism, employment rate is lower than in the agricultural sector. The highest values are recorded in Spain with 7.8% of total and in Italy with 5.6%. In contrast, the lowest values are Romania and Poland with 2.1% of total, followed by Lithuania with 2.6% of total.

An important dimension in understanding the performance level of the European agrarian economy is represented by the total factor productivity indicator evolution in agriculture (TFT). The analysis of this indicator can explain the productivity differences between various agricultural sectors in the European economy.

Figure 8 reveals decreases in the value of total factor productivity in agriculture, both in terms of relative and absolute values during 2009-2013. Thus, it is observed that in some states such as France and Sweden are recorded decreased values up to 3% as viewed in absolute values. Viewed in relative terms, Sweden recorded the largest decrease of 3.00%, followed by France with a decrease of 2.91%. Also in other European countries are not recorded any significant increases, if we consider the case of Spain, which during 2009-2013 shows an increase of only 4% absolute and relative of 3.64%, while Italy and Hungary are the only countries that do not recorded changes during the referenced period, total factor productivity values remaining constant.

However, it is observed that in the case of Germany, a state with a strong level of industrialization, there is an absolute increase of 11% and a relative increase of 10.68%, this is also one of the largest increases. But it does not exceed the increases recorded in Romania, an absolute increase of 14% during 2009-2013 and a relative increase of 11.57%, indicating that the productivity in agriculture is growing. Bulgaria also recorded increases in the total factor productivity in agriculture during 2009-2013, increases of 7% in absolute terms and 6.42% in relative terms. Thus, it can be observed that in the case of Romania and Bulgaria, significant increases TFT does not show a significant reduction of productivity gaps compared to the EU-28 or to countries such as France, Germany, Poland or Italy.

Figure 8. Change in the total factor productivity in agriculture, 2009-2013

AGRICULTURAL HOLDINGS AND THEIR IMPORTANCE IN ACHIEVING SUSTAINABLE DEVELOPMENT IN EUROPEAN RURAL COMMUNITIES

Holdings are the main tools in the agricultural potential ensuring the mobilizing available resources of local communities and valorization of, perhaps, the most important existing resources - land resources. Holdings represent in the larger context of agricultural multifunctionality a pillar in ensuring national food security, especially in providing income support for rural population. Although in CAP financial perspective approach during 2014-2010 the focus is on the greening of agricultural policies and on a shift of the size of the from holdings production to greening by decoupling financial support structures of agricultural production will continue to fulfill their classic function of food provider for population and for animals.

Thus, in 2010, the final year for which is statistical data available in the EU-28 is 12,247,850 holdings of which 6,916,690 were holdings with livestock, which represented 56.5% (Eurostat, 2015d). The existence of a high number of holdings explains the importance of the agricultural sector in the EU-28 and, on the one hand, their importance in national and European economy, while on the other hand the importance in the economy of rural communities. In Table 1 and Figure 9 is presented the number of holdings and their distribution for some EU-28 states.

From Table 1 it can be seen that from over 12 million existing EU holdings, in Romania is recorded the largest number of 3,859,040 holdings. The only countries that recorded a higher number then 1 million holdings are either former communist countries such as Romania and Poland (1.506.620 holdings) which, following the agrarian reforms were seen facing accentuated fragmentation of land ownership and consequently the increasing number of holdings or countries such as Italy (1,620,880 holdings) in

Table 1. Number of holdings, in some EU-28 countries in 2010

Country	Total	Holdings with livestock
EU-27	12,247,850	6,916,690
Bulgaria	370,490	279,710
Germany	299,130	216,100
Estonia	19,610	9,680
Spain	989,800	245,160
France	516,100	309,370
Italy	1,620,880	217,330
Latvia	83,390	48,700
Lithuania	199,910	129,630
Hungary	576,810	381,650
Poland	1,506,620	918,870
Portugal	305,270	203,780
Romania	3,859,040	2,836,640
Sweden	71,090	40,360
UK	186,660	139,000

Source: Based on European Commission (2015b)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

which agriculture still mobilizes significant resources at rural communities level. The most important European countries with the most competitive economies record the lowest number of holdings, such as Germany (299.130 holdings), France (516.100 holdings), who despite their important size of agrarian economy manages coherent evolution of the numbers of holdings and not lastly UK (186.660 holdings). Holdings with livestock, as it can be seen from the data presented in the table above represents 56.5% or 6.916.690 units. An essential element in understanding the structure of EU holdings is their distribution at the level of the Community. Below, in Figure 9, is presented the distribution of total numbers of holdings in the EU-27.

Analyzing Figure 9 it may be remarked that holdings with livestock own the highest shares in total, which highlights the complex nature of farming as livestock is the most important for GVA growth at holding level. The weight of holdings with livestock exceeds 50% in all the analyzed countries, except Italy (13.4%), Spain (24.80) and Estonia (49.40%). Thus, the highest rates are recorded in countries such as Bulgaria (75.5%), UK (74.5%), Romania (73.5%), while in case of the majority of the other states registering values exceeding 60%. Instead, pure holdings, only focused on the exploitation of land resources, have a low share in the structure of the agricultural economy, the majority opting for integration of production livestock.

An important dimension in the analysis of the importance of holdings and their role is to understand the physical, economic and labor size of holdings. In Table 2 are presented these parameters, for analyzed states, in 2010.

From Table 2 it can be observed a correlation determined between two of the three dimensions considered, namely those states that have the largest agricultural areas also records the highest values in terms of economic size of the holding, reverse correlated with labor input.

For example, in the case of France for a physical size of the 27,837,290 ha of UAA there is an economic size of 50,733,216,720 EUR. In the case of ex-socialist member states are observed economic values of physical size, as in case of Bulgaria, Lithuania, Latvia or Romania. In Figure 10 are presented three key performance indicators when assessing physical size (UAA per holding), human resources (persons per holding) and using human resources from the perspective of labor productivity.

Figure 9. The distribution of the total number of holdings in the EU, 2010

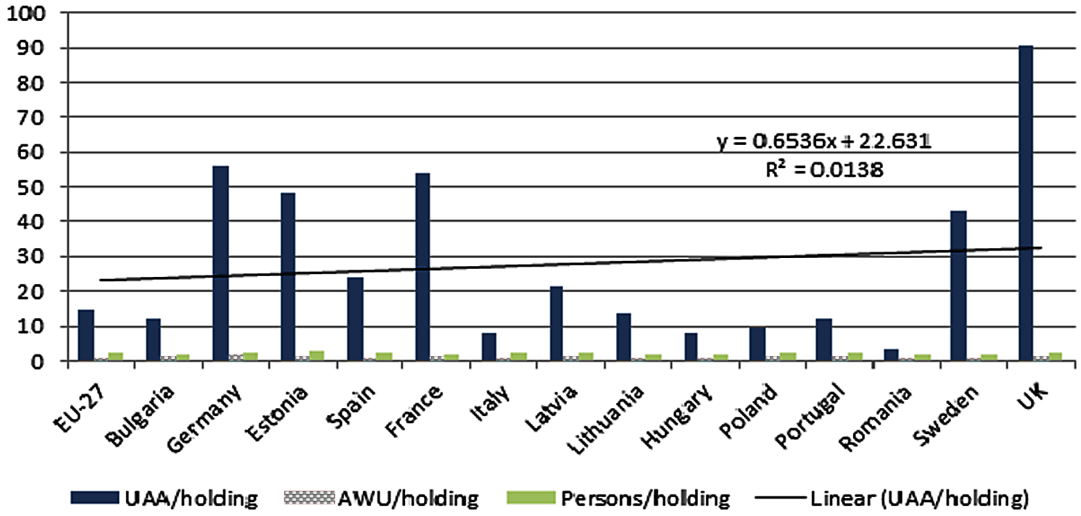
Figure 10. Resource efficiency of land and labor in some EU-27 countries in 2010
Source: Authors' own computation based on European Commission (2015b)



As it can be seen from the Figure 10 the highest values for the indicators considered in the assessment of the three sizes for the analyzed countries are registered on the economies of Germany, France and Italy. From this perspective is important to highlight the polarization of European agricultural economy. Thus in case of industrialized states is revealed a reduction in the workforce (AWU) and an increase in

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

productivity while in the case of others economies, especially in the former communist countries, agriculture continues to mobilize the most important labor resources as a means of ensuring the existence of the rural people.

A decisive component in the capitalization of the agricultural potential and sectorial viability growth beyond its classic side is the size of agricultural holdings influence on the level of productivity and rural community life in general. In this regard, the size of agricultural holdings is a defining element in harnessing the potential of national agriculture having a direct impact on the value of productivity in agriculture sector. The distribution of holdings according to the utilized agricultural area reflects the effect of national and European policies, of support for the intensive production and the creation of large industrial holdings. Table 3 presents the agricultural size of holdings in some EU-27 countries in 2010.

From Table 3 it can be noted that of the 258 640 holdings with zero ha, more than half of them, respectively 134,710 are registered in Romania. A large number of holdings with zero ha is registered in countries such as Hungary (42.790 holdings), Spain (22.500 holdings), Bulgaria (13.150 holdings) and France (9.490 holdings). Small farms, with less than 2 hectares represent 5.759.760 holdings in EU-27, representing the predominant form of farm organization in realizing the exploitation potential of European agriculture. Also, it can be observed a polarization of European agricultural sector between small and very small farms on the one hand and industrial-type farms lower in number but which aggregate important land resources, on the other hand. Figure 11 shows the size distribution of agricultural holdings in some EU-27 countries in 2010, as total holdings.

Taken from an economic perspective, European farms, classified in category Zero EUR, register a slight decrease from the Zero agricultural hectares, 240.680 holdings, actually gratifying, considering that the holdings in this category are subsistence farms, corresponding to small properties land crumb.

Table 3. Agricultural size of holdings in some EU-27 countries, in 2010

	Zero ha	Less than 2 ha	From 2 to 4.9 ha	From 5 to 9.9 ha	From 10 to 19.9 ha	From 20 to 29.9 ha	From 30 to 49.9 ha	From 50 to 99.9 ha	100 ha and over

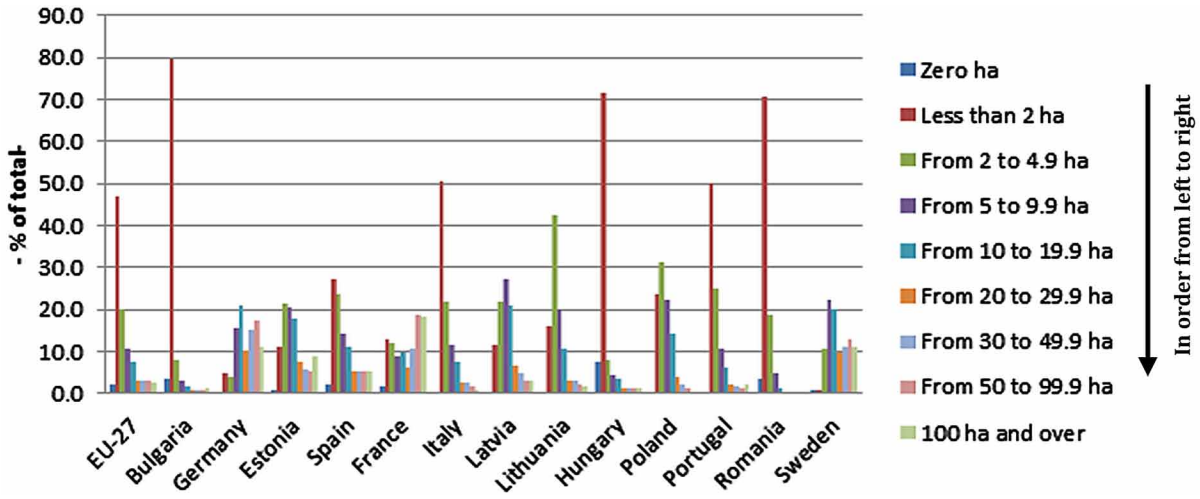
Figure 11. The distribution of holding by the agricultural size in some EU-27 countries, in 2010, (as total holdings)
Source: authors' own computation based on European Commission (2015b),



For comparison in Figure 12 is shown the economic size of holdings, as total holdings in some EU-27 countries in 2010.

By analyzing Figure 11 and Figure 12 it could be noticed a certain similarity in the distribution of holdings, both in terms of physical and economic perspectives, demonstrating the classical correlation of physical influence on holdings' economic performance. In Table 4 is shown in absolute values the size of holdings in some EU-27 countries in 2010. As it is shown in the below table, the economic size of holdings in some EU-27 countries reflect major disparities between the old EU member states and the new ones.

Figure 12. The economic size of holdings in some EU-27 countries, in 2010, (as total holdings)

According to de data (Table 4), Romania register 99,840 holdings with Zero EUR, which represents 41.48% form the total EU-27 (240,680 holdings). Also among the states with higher value of holdings with zero euro economic size could be mention Poland with 42,520 holdings, Italy (23,800 holdings), Hungary (19,900 holdings). Despite the evolution of the land structure consolidation, in Romania only 1,010 holdings have an economic size of 500 000 EUR or over, which could be barley compared with countries as: Germany (13,280 holdings), France (10,870 holdings), Italy (11,770 holdings) or Hungary (1,330 holdings). From this perspective it can be easily remarked the adaptive trend to the CAP tendencies and accentuating disparities in field of holding's consolidation perspective.

EVOLUTION OF AGRICULTURAL OUTPUT IN THE EU-28 IN CONTEXT OF AGRICULTURAL SECTOR TRANSFORMATIONS

With its classic function, agriculture must provide not only better utilization of available land resources, but it has to contribute significantly to improving the living standards of rural communities. Evolution of agricultural output during the years reflects more and more inclination of this sector towards the growth of production and increasing food security and thus to generate additional revenue for European farmers.

CAP reorientation towards greening agricultural industry, and shift from production support and funding on the surface that is boosting agri-environmental measures, was passed to an evolution of crop output syncope and a trend where animal ascendant output. In Table 5 is presented the evolution of agricultural output and gross value added at producer prices in some EU-28 states during 2010-2014 (in million EUR).

As it can be seen from Table 5, during 2010-2014, at EU-28 level there is an absolute increase in crop output of 12.128 million and 26.950 million EUR in the case of animal output. Also gross value added of the agricultural sector for the same period recorded an increase of 16.018 million euro. Spain is the only country that registered a decrease in crop output of 424 million euro. Among the countries with the largest increase in crop output is distinguished Poland (2.060 million euro), Italy (1,452 million euro), Germany (1,270 million euro) and Hungary (1,075million euro). In exchange regarding the evolution of gross value added of the agricultural sector in the same period it can be seen dramatic decreases in case of France (1.529 million euro) and slightly mitigated to some countries such as Spain (-454 million euro), Portugal (-135 million euro) and Latvia (-36 million euro).

Evolution of agricultural output and gross value added at producer prices in some EU-28 states during 2010-2014 highlights significant changes which have occurred in the European agricultural economy under CAP influence and the tendency of states to reform the structures of agricultural production by giving up some financial support. From this perspective, in Figure 13, is presented the evolution of subsidies and taxes in the agricultural sector in some EU-28 countries during 2010-2014.

Regarding subsidies and taxes in the agricultural sector in some EU-28 countries during 2010-2014 it can be noticed trends imposed by the modification of CAP paradigm. Thus the effect of the measures to reform CAP caused many of the subsidies to be eliminated or modified as structure and allocations during 2005-2006. As noted in (Eurostat, 2015c) „whereas production subsidies were more than 14 times as high as product subsidies in 2014, in 2005 they had only been 1.5 times as high. The net impact of these two types of subsidies less taxes in 2014 was to add an extra 31.4% to value added at producer prices; for comparison, in 2005 the increase due to subsidies less taxes was 34.5%"(Eurostat, 2015c).

From Table 6 it can be seen that at EU-28 level out of a total of 334,182.3 thousand tonnes of harvested production, 149,918.9 thousand tonnes were classified as common wheat, which represents the main production for most European countries. Thus in case of Romania out of a total of 22,438.9 thousand tonnes, 12,040.5 thousand tonnes were grain-maize and only 7.769.4 thousand tonnes common wheat. In the following table is presented harvested production and area of production of potatoes and sugar beet, EU-28, 2007-2014. In Figure 14 and Figure 15 are presented the yields/performance/productivity per hectare for wheat and corn.

Potato production and the sugar beet have undergone extensive reform measures in the EU-28, CAP significantly modifying production paradigm for these two products. Therefore in most countries analyzed it can be observed significant decreases both for the harvested production and for the area of production. As example, the table below presents the evolution of the harvested production and area of production of potatoes and sugar beet, in some EU-28, 2007-2014.

CONCLUSION

Agriculture, despite significant transformations that have marked Europe's economy over the past two and a half decades continues to represent a broad economic sector with important implications, especially on rural communities. Being often the only source of income or achievement livelihoods, agriculture defines the evolution of rural communities, instilling in them a deep agricultural character.

Assuming that most of the time rural communities are facing on one side with large sectorial imbalances and the possibility to diversify non-agricultural activities remain sometimes the only goal when economies ex-socialist such as in Romania and Bulgaria, in this chapter, is attempted a radiography analyze by the European agricultural transformations in economy, rural communities and food sustainability in the context of Common Agricultural Policy Reforms.

Analyzed in sectorial terms and from the perspective of economic efficiency indicators, evolution of the European agricultural sector demonstrates the capability of appreciable levels of economic efficiency (TFT, labor productivity, agricultural GVA). In this context, the appreciation of the role and place that agriculture must play in the European economy is inextricably linked to the future of rural communities. General questions that research in this chapter tries to answer at: "It is the agricultural sector competitive enough to reduce the gaps between the other economic sectors at EU-28 and national level?" and "are rural communities strongly dependent on the evolution of the agricultural sector and what are the implications of this dependency?" are elements of continuity to understanding the mechanism of European rural economy as a whole.

KEY TERMS AND DEFINITIONS

Agricultural Holding: The most common instrument in valuing the agricultural potential by combining in an optimum manner all the production factors – land, labour and capital.

Annual Work Unit (AWU): According to EUROSTAT definition, corresponds to the work performed by one person who is occupied on an agricultural holding on a full-time basis.

Common Agricultural Policy (CAP): A sectorial EU-28 policy concerning the agricultural sector. It consists of two pillars – common agricultural market and production organization (first pillar) and rural development (the second pillar).

Permanent Crops: Mainly ligneous crops and play an important role in shaping the rural landscape and it consists of orchards, vineyards and olive tree plantations.

Single Payment Scheme (SPS): Introduced in 2003 as common agricultural policy (CAP) reform, it disconnects the payments from the direct agricultural production by promoting cross-compliance.

Chapter 44
The Use of Complementary Virtual and Real Scientific Models to Engage Students in Inquiry: Teaching and Learning Climate Change Science

ABSTRACT

This chapter reports on a four-year study to change how climate change science is taught and learned in schools. The goal of the Climate Change Narrative Game Education (CHANGE) project is to take what is known about reform-based practices, incorporating students' lived experiences into the curriculum, and the integration of Information and Communications Technology (ICT) into the classroom. CHANGE uses the following: scientifically realistic text narratives (text stories with local characters, 50-100 years in the future, a local, place-based approach, a focus on the built environment, the use of simulations and games based on scientific data, and a web-based "intermedia" eBook narrative where sections of narrative text alternate with simulations and computer games. The chapter reports on the ways that we have used the above principles to connect classrooms and communities and school science with academic science to facilitate student inquiry into climate science by combining virtual serious educational games with in class, hands-on inquiry using scientific models.

INTRODUCTION

It is an interesting time for science education. We are faced with global problems associated with advances in science and technology, while at the same time we seek solutions to them in new scientific knowledge and technological innovations. It is also a time in which there are massive changes in the ways that we share and use information as print and wired media are replaced by digital and wireless communications in the social sphere. All that said, classrooms in schools remain the familiar places in which the teaching and learning of science has changed little over the years. In particular, there are few visible effects of innovative uses of Information and Communications Technology (ICT) or the use of inquiry in the teaching and learning of science in schools.

The use of ICT has become ubiquitous in our contemporary lives. We see this in schools where students use it to write assignments, look up information, and communicate with teachers. Similarly, teachers use ICT to write lesson plans, handouts, quizzes and tests; to look up information; to present lessons; to record and calculate student grades; and to communicate with students, parents and administrators. For the most part these are examples of how ICT has replaced older technology, like printed books, paper and pencil, overhead projectors, calculators, and telephones. While there are teachers and students who engage with ICT in more innovative ways including the use of probeware, access to and analysis of real scientific data, and models and simulations, in the US, where we are located, these innovative uses of ICT are few and far between (e.g., Bang & Luft, 2013).

Similarly, the effects of a more than 50-year effort to transform the teaching of science to be more inquiry oriented are not common. In the mid 20th century governmental agencies around the world funded the development of courses and curriculum in which inquiry was central (e.g., Donahue, 1993; Nuffield Foundation, 2016; Tamir & Jungwirth, 1975). However, Stake and Easley (1978) found that in elementary schools there were only occasional efforts to do more than read about science topics, and that in secondary schools science was seldom taught as scientific inquiry and subjects were presented as what experts had found to be true. Twenty years later the National Science Education Standards (National Research Council, 1996) called again for the teaching of science as inquiry, and more efforts were made to transform teachers' practice (National Research Council, 2000). However, as with ICT, there is little visible evidence that teachers use inquiry oriented pedagogy.

There are many possible reasons why what happens in classrooms changes slowly if at all, including the negative effects of high stakes examinations, ill-prepared teachers, and the overall difficulty of enacting changes in large bureaucracies like school systems. There are also practical problems such as limited access to computers and other devices, and broadband access; and lack of scientific supplies and equipment. Another possible reason is that often the use of ICT and inquiry are presented as add-ons, rather than being incorporated into existing courses and curricula. In this chapter, we report on our efforts to change how climate change science is taught in schools within the context and structure of an existing high school course – Marine Science. We chose this course because many of the topics in its curriculum leant themselves to climate change science.

Our project -- the NSF-funded Climate Change Narrative Game Education (CHANGE)[1] project -- takes what we know about reform-based practices, the need to incorporate students' lived experiences into the curriculum, and the integration of Information and Communications Technology (ICT) to facilitate students' inquiry into climate science. Its aims are for students to gain a better understanding of the impacts of climate change on the natural environment and human-built world particularly within the place-based setting of the southeast US. It attempts to connect climate change and sea level rise

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to students' everyday lives so that they become motivated to learn about issues related to their region (Hallar, McCubbin, & Wright, 2011; Theobald, 2006). CHANGE does so by employing the following principles: (a) the use of scientifically realistic text narratives about future southeast US residents, (b) a local, place-based approach grounded in scientific data, (c) a focus on the built environment, (d) the use of simulations and games to help students learn principles of Global Climate Change (GCC), and (e) a web-based "intermedia" approach where sections of narrative text alternate with simulations and computer games. All CHANGE materials are available on our website (http://climatechange.usf.edu).

BACKGROUND

In this chapter we report on the how CHANGE uses serious educational games (SEGs) and hands-on activities in a complementary manner to engage students in inquiry through the use of models to learn climate change science. In the next sections we provide some background on global climate change, the teaching of climate change science, scientific inquiry, and serious educational games. We then provide examples of the CHANGE materials after which we present data from our pilot testing of them in classrooms.

Global Climate Change

The Earth's climate is rapidly changing as the concentration of atmospheric greenhouse gases increases. These heat-trapping gases, data show, raise global temperatures, which causes sea level to rise and can lead to an increase in the frequency of extreme weather events (IPCC, 2013; World Bank, 2012; UCAR, 2015). All this has a great impact on the built and natural environments (Jollands, Bernier, & Golubiewski, 2007). With more than 100 million Americans living within the areas directly affected by climate change and coastal flooding, the impact is being seen environmentally and economically in the destruction of coastal infrastructure and communities; the incursion of salt water into fresh water aquifers as the seas rise; the disruption and even destruction of beaches and natural coastal habitats, which are the breeding sites for large numbers of marine organisms; and coral bleaching.

Given the above, there are still significant numbers of people in the US who are ill informed and skeptical about climate change. Politicians, policy institutes, and television or radio commentators often misrepresent climate change as a highly controversial and debatable issue. This may be due in part to misinformation campaigns by energy companies like ExxonMobil (Brulle, 2014; Kaiser & Wasserman, 2016), which questions whether climate change is real and the authenticity of anthropogenically induced climate change (McCright & Dunlap, 2011). In addition, many people consider climate change to be a significant threat globally, but do not feel threatened personally (Leiserowitz, 2005). However, agreement among over 97% of scientists worldwide suggests that the globe is warming at an alarming rate, and that humans are largely to blame (IPCC, 2013).

Difficulty of Teaching and Learning Climate Science

An understanding of science, including its processes and methods for warranting knowledge, is fundamental to understanding the forces that produce climate change and its effects on coastal regions. Clearly students need to be better educated about climate change science if they are to make intelligent and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

reasonable decisions about what to do in response to its effects on their communities (Kohut, Doherty, Dimock, & Keeter, 2009; Maibach, Roser-Renouf, & Leiserowitz, 2009). This is particularly important for those living in coastal areas, such as those in Florida, who need to be prepared to make decisions about the future of coasts and infrastructure.

Putting climate change science into national science standards (NGSS Lead States, 2013a) is not enough. Teachers need to be able to teach it, and students need to be able to learn it. However, climate change is a difficult topic to teach because: (1) the science involved is complex and multidisciplinary, (2) people do not notice the changes in climate on a daily basis, and (3) the media portrays it in misleading ways.

Its multidisciplinary nature requires knowledge from different fields such as geography, geology, chemistry, physics, ecology, and marine science. Typically, these topics are taught in a disjointed way, for example, a unit on the carbon cycle, another on weather and climate, and others on environmental effects. Therefore, for students to gain a comprehensive understanding of climate change, researchers and educators agree that an interdisciplinary approach is necessary (Summers, Childs, & Corney, 2005).

The global nature of the problem makes climate change difficult to observe at the local level (Pruneau, Liboiron, Vrain, Gravel, Bourque, & Langis, 2001). While GCC is happening faster than ever before, its effects are incremental and noticeable over decades. Therefore, it is necessary to find ways to zoom in, from the global to the local level, and to somehow reduce the perception that it is a problem of the future, not of the present.

Finally, when an issue is controversial, it can affect teachers' instructional decisions due to, among other things, concern that instruction of the topic will lead to objection from stakeholders within the community (Boykoff & Boykoff, 2004). When this controversy is combined with teachers' lack of understanding of the complexities of climate science (Herman, Feldman, & Vernaza-Hernandez, 2015), teachers may opt out of including it in their enacted curriculum (Gehrke, Knapp, & Sirotnik, 1992). While many teachers believe that climate change is an important topic, discrepancies exist about which aspects of climate change should be taught and how much time to allocate to it (Liu, Roehrig, Bhattacharya, & Varma, 2015). There are clear motives as to why teachers avoid controversial topics in their classrooms, including the complexity of the science, opposition from stakeholders, and curricular constraints. However, teachers' report that the greatest challenge when teaching controversial issues is that students are misinformed, lack knowledge regarding the topic, and are therefore unable to actively engage in classroom discussions and activities (Kuş, 2015). This suggests that successful teaching and learning of climate change science in schools requires new and innovative approaches.

Inquiry, Models, and ICT

In this section we examine what it means to engage in inquiry, the various types of scientific models, and the use of serious educational games in school settings.

The Role of Inquiry in Science Education

The use of inquiry has been promoted as a way to engage students in science so that they develop conceptual understanding of science content and of the nature of science (National Research Council, 2000). While the use of inquiry should not be seen as a panacea, many research studies have shown that it can meet the stated goals of its use (e.g., Anderson, 2002; Crawford, 2007; Hofstein, Navon, Kipnis, & Mamlok-Naaman, 2005).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

What is meant by inquiry in the science education literature has been somewhat ambiguous. In this chapter we use it to mean what scientists actually do when they engage in science (Anderson, 2002; Bybee, 2006; National Research Council, 1996). For example, in their examination of the use of various forms of guidance to support virtual science laboratories, Zacharia et al. (2015) state that when students engage in inquiry, they do so in "an investigative process that resembles what scientists do" (p. 258), in order to develop scientific knowledge and skills as well as gaining an understanding of the nature of inquiry. In defining inquiry, they provide a list of skills and practices that is echoed by other researchers (e.g., Donnelly, O'Reilly, & McGarr, 2013; Linn, Clark, & Slotta, 2003; National Research Council, 2000), and have been included as the practices of science that all students are expected to be able to engage in according the Next Generation Science Standards (NGSS Lead States, 2013a) and the 2013 PISA draft framework (OECD, 2013). The CHANGE materials are designed so that students engage in these types of science practices, both with hands-on and virtual activities as part of SEGs.

Scientific inquiry in schools can also be enacted at different levels of complexity, depending upon how skilled students, and teachers, are in its practices. Level 1, Confirmation Inquiry is when students engage in an activity that confirms a scientific principle for which the results are known in advance. Level 2, Structured Inquiry, is when the teacher originates the question and students follow a prescribed procedure. Level 3, Guided Inquiry is when the question still comes from the teacher but the students design the procedures. The most complex is Level 4, Open Inquiry, in which students investigate questions that they formulate and devise ways to find answers to their questions (Bell, Smetana, & Binns, 2005).

Scientific Models

Climate change is difficult to teach and learn because it is global in scope and takes years to observe its effects. Therefore, climate change education materials need to rely on models to provide students with inquiry opportunities. As with inquiry, the term scientific model has been defined in multiple ways in the literature (e.g., NGSS Lead States, 2013b; Schwarz & Passmore, 2012). In this chapter, we rely on the list of attributes of scientific models laid out by Cartier, Rudolph, and Stewart (2001, pp. 2-5):

- Models are constituted by empirical or theoretical objects and the processes in which they participate.
- Models can be used to explain and predict natural phenomena.
- Models are consistently assessed on the basis of empirical and conceptual criteria.
- Models are useful as guides to future research.

Given the complexity of how we think about and use models, Harrison and Treagust (2000) developed a typology of models and how they are used in science teaching and learning. They divided models into four main categories: (1) *Scientific and teaching models* are used by teachers to explain entities not easily observed in the classroom. (2) *Pedagogical analogical models for conceptual knowledge* include symbolic models, like chemical formulae, mathematical models, and theoretical models designed to help students understand concepts. (3) *Models depicting multiple concepts and/or processes* include maps, diagrams and tables, concept-process models, and simulations. Concept-process models emphasize that scientific concepts, when often represented by nouns, are complex processes. Simulations are a type of model that can help students to understand the underlying processes through manipulation of the various

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

factors that interact in the process. (4) *Personal models* include mental models and students' alternative conceptions that combine their intuitive mental models with accepted scientific models.

Feldman, Cooke, and Ellsworth (2010) provided a list of types of physical models based on how they can be used in scientific inquiry. A physical model 1 (PM1) can be used simply to represent a physical phenomenon in the form of a three-dimensional model, drawing, videos, or animation. PM1s can be used to teach or explain the phenomenon to students, but are not generally useful for inquiry. PM2s allow students to manipulate the model to explain and predict natural phenomena so that they can understand the processes inherent in the phenomena. A PM3 is a representation of the phenomenon that can be manipulated and used to test hypotheses, assess empirical and conceptual criteria, or guide future research (Cartier, Rudolph, & Stewart, 2001).

Feldman et al.'s (2010) typology of physical models can be applied to virtual models such as computer simulations or games. Simulations or games could simply represent the phenomenon (e.g., demonstrating how sea level rises when glaciers melt); students could manipulate them to show, for example, the rising of the seas due to thermal expansion; or they could include ways for students to manipulate them to test ideas that describe the natural phenomena that underlie climate change. We will refer to these as DM1-DM3 digital models (see Table 1). As we will show later in this chapter, when students engage in inquiry with CHANGE materials they are interacting with concept process models (Harrison & Treagust, 2000) that can be manipulated to test hypotheses (Feldman et al., 2010).

The Use of Digital Tools for Inquiry in STEM Learning

In this chapter we examine the ways in which students can use different types of ICT to help them engage in science inquiry activities. Rather than review the uses of ICT in a decontextualized manner, we do so in the context of the CHANGE project, with appropriate references to the literature. The CHANGE project uses a wide variety of forms of educational technology including computer simulations and models, serious educational games (SEGs) (Annetta et al., 2013), electronic measuring technologies, eBooks (G. G. Smith et al., 2013), and webquests (Subramaniam, 2012), among others.

These different forms of educational technology are used for different purposes in the CHANGE project. For example, CHANGE uses a web-based intermedia[2] eBook narrative where sections of narrative text alternate with simulations and computer games to tie together the units that are distributed through the marine science course. The narrative uses a place-based story-telling approach, situating climate change firmly in the west-central Florida Gulf Coast communities, where our high school students live, to make climate change feel more immediate to them (G. A. Smith, 2007). It consists of scientifically realistic, short stories about high school students in the future who grapple both with how climate change plays out in Florida (hurricanes, sea level rise, etc.) and typical issues high school students encounter such as concerns about grades, graduation and job prospects, friendships, and family issues. Each story includes at least one serious educational game (SEG), embodying some of the core climate change science content from the current unit.

SEGs are games "in which education (in its various forms) is the primary goal, rather than entertainment" (Michael & Chen, 2006, p. 17) and "use the artistic medium of games to deliver a message, teach a lesson, or provide an experience" (p. 23). Annetta, Cook, & Schultz (2007) argue that when students are immersed in well-designed SEGs, they engage in metacognition, learn new content, and revise existing schemata through the help of cognitive scaffolds built into the games. In addition, SEGs can provide

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

students with lifelike experiences that are not possible to replicate in traditional classrooms or field trips and can be the site of problem-based learning activities.

CHANGE uses SEGs for several purposes including providing students with science content needed for classroom inquiry, introducing them to the use of actual instruments used by scientists in their research, and to engage in inquiry through a virtual field trip. It is important to note that the CHANGE SEGs are in fact games, and not simply simulations. We can see this for example, in a game called Water Gauge Warrior in which students engage in various activities to construct a tide gauge that can withstand a severe hurricane. Water Gauge Warrior has the key elements of computer games as, described by Malone (1981), Crawford (1982), and Gee (2003), i.e., (1) *rules based on the game play structure*: the player has to stay within their budget as they select parts for their water level gauge, (2) *a start state*: starting with no water level gauge built and no budget, (3) *a goal for winning*: with your budget, earned by answering questions on the topic, create a water level gauge that will withstand the ravages of a tropical storm, (3) *immediate feedback on progress towards the goal*: selecting a set of parts to build your water gauge that stays within your budget, (4) *a game play space with multiple options*: many possible choices to be made in building your water level gauge, (5) *competition*: against yourself, and implicit competition with classmates, and (6) *fantasy:* the storyline that you have been hired by the city of Tarpon Springs to build a water level gauge.

CHANGE also incorporates the use of ICT in its curriculum materials and its pedagogical approach. The materials are provided to teachers via the Internet (http://climatechange.usf.edu), and web-based surveys and other instruments, distributed using sites like SurveyMonkey, facilitate data collection for formative evaluation and research. Most of the background information is provided to teachers in PowerPoint files or MS Word documents, so that teachers can modify them to suit their educational situations.

EXAMPLES OF THE COMPLEMENTARY USE OF VIRTUAL AND REAL SCIENTIFIC MODELS TO PROMOTE LEARNING OF CLIMATE CHANGE SCIENCE IN CHANGE

The primary way that CHANGE engages students in inquiry is by combining SEGs and hands-on classroom laboratory activities. As the school year progresses the amounts and levels of inquiry in the SEGs and activities increases. In this section of the chapter we provide descriptions of the SEGs and hands-on activities for three CHANGE topics: sea level rise, coastal sediments, and harmful algal blooms. Each of these topics are part of a larger unit of the marine science course: ocean exploration, marine geology, and populations: producers, respectively.

Sea Level Rise

To see how global warming affects sea level, one needs to be able to measure it, for example with a tide gauge. Tide gauges are complex pieces of equipment, distributed throughout the world, that continuously measure and record the height of the sea at a fixed point. Modern ones have on-site computers, self-contained power supplies, and can transmit data remotely. To teach students how a tide gauge works and the importance of its different components, CHANGE developed an SEG called "Water Gauge Warrior" (Figure 1). In this game students are challenged to design a tide gauge that would withstand a category 5 hurricane. In the first level of the game, students answer questions about the purpose of the different

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Screenshots from the Water Gauge Warrior game

components to earn money to build their own tide gauge. As they design their gauge they need to make decisions about the cost and properties of the components that they assemble virtually for their gauge. Once completed, their gauge is "tested" to see whether it can withstand a large storm.

We see the Water Gauge Warrior game as an example of a type 2 digital model (DM2) because it does more than simply demonstrate how the tide gauge works, but does not allow for the testing of hypotheses (see Table 1). It is also what Harrison and Treagust (2000) call a concept-process model because it helps students to understand the complex processes that underlie the term sea level. We also see the game as an opportunity for students to engage in Level 2 inquiry because the students are given the problem and the methods with which to solve it.

While the Water Gauge Warrior game provides a way for students to learn about the workings of an actual piece of scientific equipment, we also want them to be able to inquire into how different factors affect sea level using a hands-on laboratory activity. It became clear to us that a physical model that mimics the operation of a tide gauge would either be too expensive, or too complicated to build using low-cost or found materials. We solved the problem by using the ubiquitous (in the U.S.) one-gallon plastic jug. The jug model exemplifies CHANGE's use of low cost of found materials in recognition of the limited budgets that teachers have for the purchase of equipment and supplies. As can be seen in Figure 2, the main part of the jug models the sea, and the hollow handle with a ruler, which is connected to the rest of the jug, models the tide gauge. In this way, the model distinguishes between the body of water and how its level is measured.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Plastic jug that is used as a model for measuring sea level

The students use the jug model to investigate the effects of the melting of sea and continental ice, and of temperature changes on sea level. In this activity the inquiry questions are teacher generated, and students are provided with the tools and materials to investigate them. Hence, it an example of Level 2 inquiry. We see it as a physical model 3 (PM3) because students can manipulate it to the test their ideas about the relationships between the effects of global warming – the melting of sea and continental ice and warming of the oceans – on sea level (see Table 1). It is also what Harrison and Treagust (2000) call a concept-process model because, like the Water Gauge Warrior game, it helps to unpack the complex processes hidden in the noun phrase, *sea level rise*. In addition, this activity incorporates the CHANGE place-based approach. After the students investigate how GCC affects sea level, they then go to a website of the US National Oceanic and Atmospheric Administration (NOAA) (http://www.coast.noaa.gov/slr/) in which they can see predictions for sea level rise would affect their community where they live, as well as those of relatives and friends.

The combination of SEG and hands-on inquiry activity helps to solve a problem identified by Waight and Abd-El-Khalick (2011) in their article about the attempt to use the Biology Student Workbench (BSW), a student version of a web-based tool that enables scientists to model protein and nucleic acid

Table 1. Types of physical and digital models

Type of Physical Model	Type of Digital Model	Properties	Examples
PM1	DM1	Representation that can be used to teach or explain the phenomenon.	Three-dimensional models, drawings, videos, animations,
PM2	DM2	Representation that can be manipulated to explain and predict nature phenomena.	Physical models with moving parts, simulations, serious educational games
PM3	DM3	Representation of the phenomenon that can be manipulated and used to test hypotheses, assess empirical and conceptual criteria, or guide future research.	Bench-scale laboratory models, simulations, serious educational games

Based on Feldman, Cooke and Ellsworth (2010) and Cartier et al. (2001).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

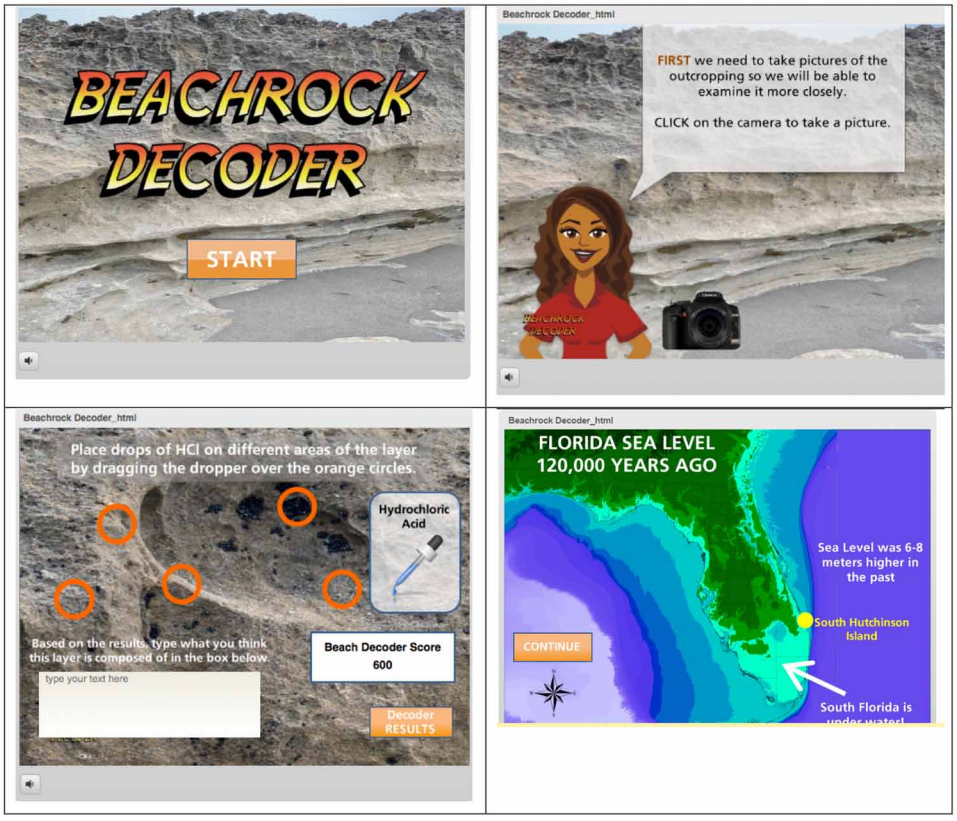
sequencing. They found that the BSW was not enacted in schools for two main reasons: 1) The difference between the ways in which the scientists who developed and used the Biology Workbench did science, and the teachers' beliefs about what constitutes school science. 2) While the BSW was significantly modified from the Biology Workbench, it still was not appropriate technology for the doing of science in school. In the CHANGE sea level activities, we dealt with these issues by having a simplified but accurate model of a tide gauge in the Water Gauge Warrior game, and used school appropriate materials for the hands-on activity. The structure of the hands-on activity helps to scaffold a change in teachers' beliefs, from lab activities that were purely conformational towards ones in which students can begin to inquire into natural phenomena.

Sediments

Students investigate the connection between coastal sediments and historical changes in sea level in the Beachrock Decoder SEG (Figure 3) and a classroom activity in which they investigate a teacher-presented question while using student designed and selected procedures.

In the game students participate in a virtual field trip to Hutchinson Island, Florida. Hutchinson Island has large beachrock outcroppings showing evidence of past sea level, estimated to be six to eight meters higher than it is today. The students travel virtually to the island with Dr. Ping Wang, the geologist on

Figure 3. Screenshots from the Beachrock Decoder game



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the CHANGE team, to investigate the properties of an outcropping by observing it through a magnifying glass and by testing it with acid to determine its composition. Later in the game, students examine an ancient sandbar and a sub-tidal worm reef, both of which were at one time located below sea level, but are now a few meters above it. These investigations lead the students to uncover clues related to the past sea level, concluding that the area's sea level was once six to eight meters higher than it currently is.

The Beachrock Decoder game engages the students in Level 2 structured inquiry because the students are presented with a question to investigate – "What do the observations of the beach rock outcroppings and the other formations tell us about Florida's past sea level?" – and they use the investigative methods built into the game. We also see it as a DM3 (see Table 1) because the students engage it to test hypotheses about the relationships of the characteristics of the swash zones, sandbar and worm reef, with sea level.

After students have completed the virtual field trip, they engage in a hands-on inquiry activity in which they examine the properties of sediment samples, including color, size, Wentworth classification, texture, sorting, and composition, that were collected from different sites around Florida. Using their observations and measurements they deduce the location of the collection site for each of the samples. The characteristics of the samples and where they were collected are then used to formulate hypotheses about Florida's past sea level and coastline. As with the Beachrock Decoder game, this is an example of Level 2 inquiry because students are given both the question and the methods to investigate them.

In this topic students engage in the science practices that Dr. Wang and his students use when they investigate the formations at Hutchinson Island and coastal sediments. In the game they use those practices in a virtual setting, while in the classroom they can work directly with the sediments to engage in structured inquiry. This combination provides an important opportunity for teachers to engage their students in the types of science practices described in the NGSS (NGSS Lead States, 2013) and by PISA (OECD, 2013).

Harmful Algal Blooms (HABs)

A third example from the CHANGE curriculum focuses on the study of Harmful Algal Blooms (HABs), which are often referred to as red tide. HABs are rapid growths of algae in marine or freshwater environments due to influxes of nutrients and warm water temperatures. They have major negative effects on the environment because they deplete the dissolved oxygen in water needed by fish and most other organisms. They can also be toxic to humans and other animals. It is believed that algal blooms will increase in frequency, and possibly in size, as a result of GCC because of both increases in water temperature and increased washing of nutrients in fertilizers used by farmers and homeowners, from the land to the water by larger storm events. Because the study of algae was already a part of the Marine Science curriculum, the CHANGE materials on HABs and climate change fit easily into what the teachers were already expected to cover as part of the course.

The SEG for this topic is Whack Algae (Figure 4) in which students gain information about HABs and the factors that contribute to their growth. It is a DM2 because students can manipulate the factors that cause HABs, but would find it difficult to use it to test hypotheses (see Table 1). We believe that it is generous to call it an inquiry activity because its primary purpose is for students to gain the knowledge of what factors can cause an HAB in Tampa Bay and how they are related to climate change. They then can use this knowledge when they engage in inquiry in the hands-on activity.

The HAB hands-on activity is CHANGE's most authentic use of science practices, modified to be appropriate for schools. The students are given instruction in how to set up a bioreactor — a vessel in

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Screenshot from Whack Algae game showing the factors that students can manipulate to cause a harmful algal bloom

which to grow algae. In the research laboratory at our university, bioreactors are usually custom-built containers constructed of glass or Plexiglas, costing hundreds of dollars. The students' bioreactors are clear plastic 20-ounce (~0.6L) water bottles. Instead of toxic marine algae, they grow a freshwater species provided to them by the university laboratory. At the university, the concentration of algae is measured using a method called fluorospectroscopy (Halfhide, Wilkie, & Ergas, 2016). In the classroom we provide the students with a color chart, which is a set of test tubes, each containing a different concentration of algae (Figure 5). The students match the color of their bioreactor against the colors in the photograph to estimate the concentration algae.

In the activity students make a control by adding fertilizer to a bottle containing the non-toxic algae species and distilled water. They then choose a variable to alter from the control to examine whether it will increase or decrease HAB growth over time. While the teacher provides students with supplies that can be used in their bioreactor, students are free to choose any variable they like that could be related to an effect of climate change. In the piloting of the activity, students have changed the amount of light,

Figure 5. Color chart for measuring the concentration of algae in the bioreactors

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

fertilizer and salinity. They have also looked at the effect of temperature and even the presence of bacteria. For five days the students measure the concentration of the algae in the bioreactor using the color chart. They then use their data to draw conclusions about the relationship between their variable and the growth of algae. We see this as an example of Level 4: Open inquiry in which the students investigate topic-related questions that are student formulated through student designed and selected procedures.

Finally, we ask whether the HAB activity is an example of the use of a model. While the water bottle is a physical model of an actual bioreactor, we prefer to think of the whole activity as a scientific model that fits the criteria suggested by Cartier et al. (2001), and what we would call a DM3. In the HAB activity the students construct ideas that describe the process by which different factors associated with climate change can affect the growth of algae. It is an empirical model in which they make measurement of algae concentrations; they use it to explain and predict the phenomenon of HABs; they test their model against their empirical evidence; and although they are limited by the time constraints of the Marine Science curriculum, they could be used as guides for future research.

THE EFFECTS OF STUDENTS' ENGAGEMENT WITH VIRTUAL AND REAL SCIENTIFIC MODELS IN CHANGE

The CHANGE curriculum materials were developed and pilot-tested during the 2013-14, 2014-15, and 2015-16 academic years. In this section we describe the data collection and analysis methods that we used, and the findings from the pilot testing.

Data Collection

During the three pilot years we collected data to 1) provide formative information for the improvement of the CHANGE materials; and 2) test instruments that we would use in the full implementation year to determine the efficacy of the materials. We collected the data for the former through online surveys that were administered at the end of each unit of the marine science course (End of Unit Surveys). For the latter, we developed student pre- and post-surveys to determine their knowledge and beliefs about climate change (Nation, Feldman, Smith, Wang, & Lou, 2016), and multiple-choice items that were incorporated into the district-wide marine science midterm and final exams.

The end of unit (EOU) surveys were in two parts. The first included Likert-type questions about the materials. Students were also asked the following open-ended questions: In what specific way do you feel that the combination of eBook story, computer game, and hands-on lab in this unit helped you to learn climate change science better and/or increase your interest in this unit? Or are there other things that could be added to the combination that would help make the unit more interesting?

Data were also collected from online surveys, midterm, and final exam to measure student responses to the materials and further understanding of climate change science. The CHANGE student survey, which was administered at the beginning and end of the 2014-2015 and 2015-16 academic years asked students about the causes and implications of climate change, and students' likelihood to take mitigative actions to help reduce the impacts of climate change on the built and natural world. The midterm and final exam were distributed to all marine science students in the district, including those how had not participated in the piloting of CHANGE. An item analysis was performed to determine whether or not experience of the CHANGE curriculum had a significant impact on student understanding of climate

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

change science. In addition to these surveys and exams, data were collected for formative purposes from classroom observations and focus groups made up of the pilot teachers.

Data Analysis

Quantitative data gathered from the CHANGE student survey, midterm, and final exam results were analyzed using SAS (Statistical Analysis System). For the CHANGE student survey analysis, t-tests were used to compare the means from the initial data with the end of year data. Results from the midterm and final exam were also analyzed using a t-test to examine the difference of scores between students who experienced the CHANGE curriculum and the students who did not.

Open-ended qualitative data from the EOU surveys were analyzed using thematic coding to determine how the students feel about the combination of eBook story, computer game, and hands-on lab. After similar codes were grouped together, frequency distributions were generated for the codes (Patton, 2015). Classroom observations and focus groups data were analyzed in a similar fashion. CHANGE project leadership and graduate students engaged in continuous review of data to improve the quality of the findings and conclusions throughout the data analysis.

RESULTS

End of unit (EOU) survey data were collected for all three of the CHANGE topics described in this chapter. However, because of a technical problem with the online survey, we do not have responses to the open-ended or content questions for the topic on HABs. The EOU survey for the piloting of the sea level materials indicated that on the average students (n=117) agreed with the following statements:

- Playing the computer game helped me to engage with the content of this unit.
- I found the computer game relevant to learning the content of the unit.
- The combination of hands-on lab, eBook story and computer game made the unit more relevant to me.
- I felt more engaged in learning this unit because of the combination of hands-on lab, eBook story and computer game.

In addition, more than 75% of the students demonstrated that they gained an understanding of the different effects of the melting of sea and continental ice on sea level. For the coastal sediments topic the EOU data indicated that the students (n=109), on the average, agreed with the statements above. In addition, about three-fourths of them correctly estimated the ancient sea level and knew what types of data geologists use to determine past sea level.

The EOU data from the HAB unit focused on the eBook and the games. Overall the students (n=137) found the games to be fun and informative. In addition, we have formative data from extensive observations that we made of the implementation of the unit in three different schools. The observation data suggest that the unit was successful in engaging the students in authentic research practices, and that they came to understand the relationships between GCC and HABs.

For sea level and coastal sediments, we used a grounded theory approach (Corbin & Strauss, 2015) to analyze the open-ended question in which we asked the students how the combination of SEGs and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

hands-on activities helped them to learn the topics. For the sea level topic, the students were overwhelmingly positive about the combination with only 22 of 121 respondents indicating any negative aspect at all. For example, one student wrote, "I'd rather just read about things instead of all the labs and games." Another responded, "It was a little helpful but should be more hands-on and directly related to the topics."

Of the positive responses about the sea level topic, we coded 32 responses in which students stated that the combination was fun (n=6), interesting (n=13), or simply that they liked it (n=13).[3] More elaborate reasons included that it helped them to learn (n=26), there was a real world connection (n=4), the combination provided them with a variety of learning experiences (n=10), and there were multiple modes for learning and learning styles (n=15). Exemplars for these codes can be found in Table 2.

We found similar results from the open-ended responses to the same question in the end of unit survey for the coastal sediments topic. In this case, 10 of the 99 responses were negative, such as "It honestly needs to be more appealing" and "More games that are for fun and not just lesson based". In addition, there were 15 responses that were either not relevant, unclear, or missing. The remainder of the coded responses were positive about the SEGs and hands-on activities (n=79). Of these, a total of 37 were that the combination was fun, interesting, or simply that they liked the combination. Students responded that the combination helped them to learn about the relationship between coastal sediments and climate change (n=8), it was engaging (n-9), or that it provided them with a variety of experiences that worked with multiple learning styles (n=13). Exemplars of these codes are in Table 3.

The remaining data that we analyzed relate more broadly to the implementation of the CHANGE curriculum materials. For example, in the beginning and end of the year surveys, students were asked, "How likely do you think it is that human actions have changed global climate?" We found that students were ranking humans as a likely contributor to climate change significantly higher ($p<0.01$) after experiencing the CHANGE curriculum. CHANGE items were added to the midterm and final exams of the marine science course for the 2014-15 and 2015-16 academic years. Therefore, all students enrolled in the course responded to those items. We analyzed the data for the midterm and final of 2014-15 and the midterm for 2015-16. The midterm for 2014-15 was used solely to test the items. For the final given that year we found that the students enrolled in the classes that used the CHANGE materials (n=176) scored significantly higher ($p<0.001$) than the students who did not experience the CHANGE materials

Table 2. Exemplars of codes used for analysis of sea level open-ended question from the EOU survey

Code	Exemplar	N
Multiple modes for learning, including learning styles	All the features put together gave me a diversity and variety of learning styles	25
Combination more engaging	I think it helped engage myself and other students because it offered different things to do throughout the lesson.	11
Real world connection	The combination of this trio helped me learn about climate change better because I could apply it to my everyday life	4
Helped me learn	All in all, I felt like I learned a lot about climate change in this unit	26
Positive (no reason given)	The combination was lovely.	13
Negative (various reasons)	I'd rather just read about things, instead of all the labs and games	22
Fun	It was fun and I could 'physically' engage in the unit.	6
Interesting	The mix of things made learning more interesting.	13

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Exemplars of codes used for analysis of coastal sediments open-ended question from the EOU survey

Code	Exemplar	N
Multiple modes for learning, including learning styles	This combination overall worked really well to help learn the science of climate change as well as increase in the interest in the unit. This is because it reaches out to all types of learners. For example: visual, auditory, and kinesthetic learners. The combination together has a stronger impact.	23
Combination more engaging	I felt engaged in what I was doing. It made me feel that if someone needed help with something I would be able to assist them with my background knowledge on geology so it's successful.	7
Real world connection	The story along with the games gives an interesting real life situation.	
Helped me learn	I feel that the course was making a genuine interest in trying to help me learn, unlike most lessons where it's just a PowerPoint followed by a test.	14
Positive (no reason given)	I think the combination works just fine	11
Negative (various reasons)	It honestly needs to be more appealing.	10
Fun	We don't get bored half way through the lesson and we're always engaged in the unit.	1
Interesting	I became more interested because it helped me get a better understanding through a different method.	18

(n=789). For the 2015-16 midterm CHANGE students (n=312) performed significantly higher ($p<0.001$) than the non-CHANGE students (n=1502). The 2014-15 final exam included questions about the HAB topic and the 2015-16 midterm included questions about the sea level and coastal sediments topics.

In addition to the results from the student data reported above, our observations of classrooms suggest that independent of which was done first by the students – the SEG or the hands-on activity – they were better able to complete the second activity in the ways intended by the CHANGE project. In general, the students were more familiar with the content and methods, and were better able to make arguments in whichever came second. Finally, data from the teacher focus groups indicate that they believe that the combination of SEGs and hands-on activities improve student learning by reinforcing the science content.

FUTURE RESEARCH DIRECTIONS

In our introduction to this chapter we argued that there has been little change in the ways in which science is taught in the US and elsewhere even though there has been a concerted effort to implement inquiry teaching and learning methods, as well as the use of ICT. Our study supports our belief that this is due to several factors, including the demands of accountability systems, and the resilience of traditional conceptions of what counts as school science. However, outside of schools, people engage in inquiry and ICT has become an integral part of how they work, play and communicate with one another. The curriculum materials we describe in this chapter were designed to bring everyday activities like reading, playing games, and inquiring into local space into school science. Our study so far supports that it is possible to change how teachers teach and students learn within the context of an existing course by using ICT and inquiry to augment what is already happening in schools. However, there is still much

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

research to be done. For example, we would like to gain a better understanding of how teachers' beliefs about what they teach, like climate change, affects their practice and what their students learn, believe and our willing to do. We would also like to uncover the cognitive mechanisms that connect the reading of a fictional eBook with embedded serious educational games and their interaction with hands-on activities, with the learning of science content and practices. Finally, all our research so far has been relatively short term. Can the types of changes that we have seen so far be sustained in schools? Will teachers continue to use the new methods and materials without our support? Will the school district continue to support the teaching of climate change given the new political landscape in the US? It is our plan to investigate these questions in our future research.

CONCLUSION

In the above three examples of CHANGE curriculum materials, we demonstrated the ways that SEGs and in-class hands-on activities can work together to promote inquiry using digital and physical models. The SEG for the sea level topic, which was a simulation and Type 2 digital model (DM2), engaged students in Level 2 inquiry to learn how an actual tide gauge works. This provided them with the knowledge that they needed to see and understand what the jug model was modeling. For the coastal sediments topic, the SEG allowed students to virtually experience what it is like to go on a geology field trip and examine specimens in situ. This provided them with the background to connect what they did in the lab with the sediment samples to how research is done in the field by geoscientists. The formative data from the piloting of both of these topics, as well as our other data, support the efficacy of the approach.

Finally, for the HAB topic, the SEG provides students with the necessary background information about how and why an HAB could occur in Tampa Bay. However, it did not provide the type of virtual experience that students had with the Water Gauge Warrior and Beach Rock Decoder games. We do not necessarily see this as a problem because in the HAB activity students engaged in a full range of science practices that include developing research questions and hypotheses, determining the best way to use their bioreactors to test their hypotheses, collecting and analyzing data, and coming to defensible conclusions. What is missing from the activity itself is the context and causes of HABs, which they get from the Whack Algae game. Although we did not have the same type of formative data as for the other topics, the exam results and classroom observations support the complementary nature of the SEGs and hands-on activity for the HAB topic.

During this academic year the CHANGE materials are being incorporated into the Marine Science courses in twenty-seven high schools in the district. All indications from our three years of developing and piloting the CHANGE materials suggest that if teachers use them as the pilot teachers did, there will be major changes in what happens in their classrooms. Because the CHANGE materials are only for about 15% of the class meetings we expect that much of their teaching would likely remain similar to what they have already been doing. However, we think that he would be excited to see how the SEGs and hands-on activities are integrated in the CHANGE curriculum materials, resulting in a transformation of how teachers teach and students learn science in their schools.

KEY TERMS AND DEFINITIONS

Climate: The average weather over a region of the earth over a long period of years.

Climate Change: Changes to the earth's climate, usually referring to the effects of increasing amounts of heat trapping gases in the atmosphere due to human actions.

Harmful Algal Blooms (HABs): A sudden increase in the amount of algae in a body of water that typically has negative effects of the health of human and other organisms.

Information and Communications Technology (ICT): An umbrella term that refers to contemporary electronic devices or applications that includes the Internet, mobile telephones, computers, videoconferencing, and so on.

Inquiry: In the context of this chapter, inquiry is the method used by scientists as they seek new knowledge about the natural world.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Models: A representation of a phenomenon that can be physical, digital, or cognitive.

Sea Level Rise: The increase of the global mean sea level due to climate change.

Serious Educational Games (SEGs): Games in which education is the primary goal, rather than entertainment.

ENDNOTES

1 The acronym was derived from the title of the project, although it does not match the letters exactly.

2 The term "intermedia" was defined by Dick Higgins (Higgins & Higgins, 2001) as works of art that "fall conceptually between media that are already known" (p. 52).

3 The total n is greater than 121 because some responses received multiple codes.

Chapter 45
The Temporal and Spatial Development of Organic Agriculture in Turkey

Aylin Yaman Kocadağlı
Istanbul University, Turkey

ABSTRACT

The world's population is increasing rapidly and the food need for the increasing population has been growing also. In the 21st century, efforts for the sustainable use of the natural resources have been raised all around the world. Agriculture has always been on the center of discussions and developments as an activity carried out depending on the nature. Therefore, the sustainable agricultural systems have gained a considerable importance in recent years. This chapter will examine the temporal and spatial development of the organic agriculture in Turkey. The current situation of the agricultural sector in Turkey will be reviewed and the need for a sustainable agricultural system in Turkey be analyzed. The temporal and spatial change of the organic agricultural areas, numbers of producers and products, and organic production amounts in Turkey will be put forward. Also, the organic agricultural potential of Turkey will be evaluated and the reasons for not exploiting this potential will be investigated.

INTRODUCTION

Agriculture is a highly prominent strategic sector for almost all countries as it enables them to produce their basic foodstuff, provides raw materials to other industries, is an area of employment and brings about a foreign currency inflow to the country's economy through exporting activities. In the direction of the world's changing needs and circumstances, in the course of time, some important changes have been seen at the methods and policies applied for the agriculture. As a result of wars bursting out in the last century, and associated food supply problems, application of the technological innovations into agriculture and the rapid increase in the world's population have changed notably the expectations in the agricultural activities. Rapidly increasing population of the world has brought along many necessities, and the need for agricultural products has risen to meet increasing populations. At this stage, the main objective of the agricultural policies has become to raise the productivity and increase the production

quantities (Grigg, 1995). Particularly with the policies applied in the 1960-1970s, high effectiveness and productivity have been reached. On the other hand, in obtaining high productivity, the fact that agriculture-related natural resources are limited has been ignored (Badgley & Perfecto, 2007). Agriculture itself has been managed for many years with the understanding that the natural resources are limitless. As a result of these policies, high productivity has been reached and agricultural economic development has been built, but it has been realized that such development is not sustainable any more (Park & Seaton, 1996).

Agriculture is an economic activity dependent on some fundamental natural resources such as soil, water and air. At the end of the 20th century, it was agreed that natural resources, the base of all agricultural production, are restricted and it was realized how important it is to use these natural resources sustainably (Pretty, 1995). At this stage, people have started searching for sustainable agricultural options without damaging the natural resources. Agricultural systems that promote sustainable production without damaging the natural resources as well as policies which support such systems have been brought to the forefront of the world's agenda.

Thanks to the understanding of sustainable agriculture, natural resources are protected and their productivity is guaranteed for a long term. The concept of sustainable agriculture implies a balanced economic, social and ecologic agricultural system. For people's access to sufficient and safe food, the raising of healthy future generations, enhancing rural development, economic improvement and a liveable environment, agricultural areas should be used in a sustainable manner. Today, the concept of sustainable agriculture has great importance. It is so important to create a society that could meet its necessities by not destroying the natural resources and by sustainable use of the existing natural resources especially in light of increasing populations (Grigg, 1995). For this reason, in order to reach a sustainable life and a sustainable agriculture, organic agriculture is gaining importance as an alternative agricultural method around the world.

Organic agriculture is one of several sustainable agricultural systems and it could be generally defined as a production method that is controlled and certified in all of its stages, aiming for protection of the natural resources, having a human and natural friendly understanding and free of synthetic chemical inputs including fertilizers. It is highly possible to protect the natural resources with organic agriculture at one side while to benefit from these resources to the utmost with a sustainable understanding of agriculture (Lotter, 2003). As compared to the conventional agricultural areas, the world's organic agricultural areas are still too small. However, it has been accepted that the world's need for food is increasing rapidly and that the developments happening on the agricultural fields threaten the future of human beings. Because of the awareness, sustainable use of agricultural areas has been raised across the world. Therefore, in the next years, organic agricultural applications will undoubtedly increase.

Turkey is one of the countries where the organic agriculture has gained importance in recent years all around the world. Turkey is an important agriculture country at the present time (Food and Agriculture Organization [FAO], 2014). In reference to the 2014 data, Turkey has the 7th largest agricultural economy of the world. This figure reveals clearly how the agricultural sector is important in Turkey's economic and social structure. Having a sustainable agriculture in Turkey is so important especially in light of the rapidly increasing population. The concept of organic agriculture started to come into the view in Turkey after 1984 and it has improved gradually within the period of time following 2000. Also, the European Union membership process has made a great contribution to the wide spreading organic agriculture in Turkey. Today, Turkey is one of the top ranked countries in the world with regards to organic agriculture areas, number of producers and products, and organic production amounts (Pugliese, Bteich, & Al-Bitar, 2014). Turkey's prominence in the world organic food market scales up day by day.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The aim of this chapter is to examine the temporal and spatial development of organic agriculture in Turkey. Within this framework, the current situation of the agricultural sector in Turkey will be evaluated and the development process of organic agriculture will be reviewed. In addition, the existing challenges of Turkish agriculture and the necessity for sustainable agricultural systems in Turkey, will be studied. Moreover, the temporal and spatial change of the organic agricultural areas, numbers of producers and products, and organic production amounts in Turkey will also be examined.

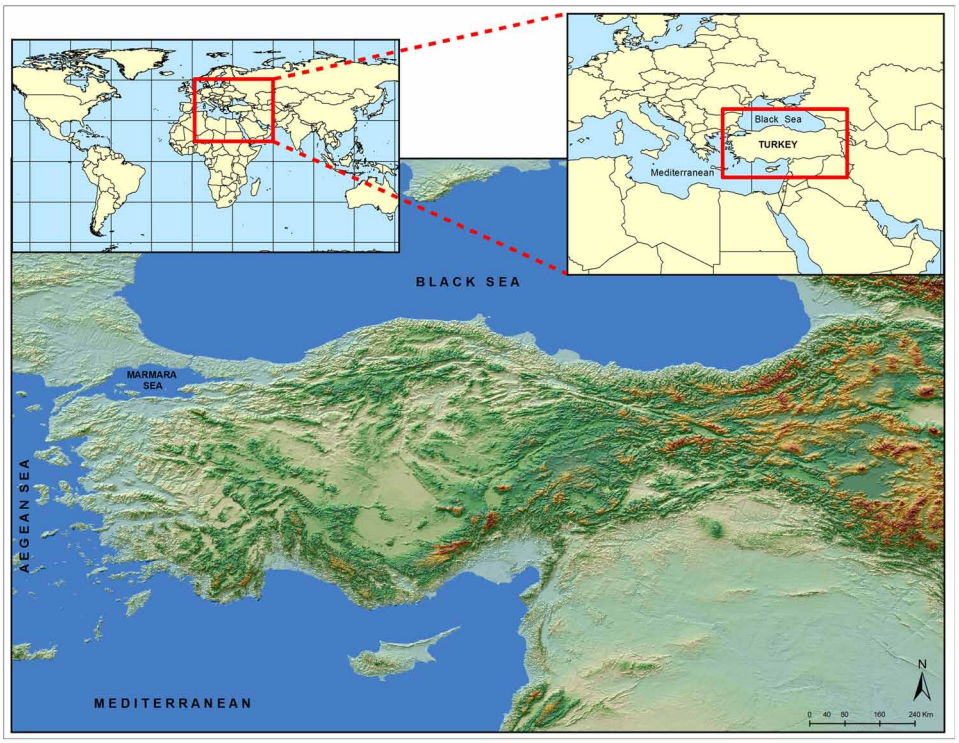
AGRICULTURE IN TURKEY AND THE POTENTIAL FOR ORGANIC AGRICULTURE

Agricultural Structure of Turkey

Turkey, which is the study area, is a country located at the northern hemisphere between the 25° 40' - 44° 49' eastern longitudes and the 35° 48' - 42° 06' northern latitude (Figure 1). The geographical and special position of the country has brought about different climatic types particularly the Mediterranean climate. Turkey has various characteristics in terms of climate, soil and morphologic features. Such variety has paved the way for a rich agriculture potential and a high importance on the agricultural activities of the country (Doğanay, 2007).

Turkey is one of the countries located on the Mediterranean Basin and the most important economic sector of the Mediterranean Basin is agriculture. At the present time, the agricultural sector uses most

Figure 1. Location map of Turkey



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of the land and water resources on the Mediterranean Basin and it provides employment for nearly half of the labor force of the basin (Makhzoumi & Pungetti, 1999). It is quite similar in Turkey as well that is located on the Mediterranean Basin and agriculture is one of the most fundamental economic sectors. Agricultural sector has played a very significant role for the economic and social development of Turkey, not only in the past but also in present times.

Agriculture is tightly coupled to the natural environmental features of the space. Natural environmental conditions have influences on the distribution of the agricultural areas, application of the agricultural systems and variety, type and quality of the agricultural products (Knowles & Wareing, 1983). Turkey's structure of land and accordingly changing climatic features has led to different geographic regions and the formation of various micro climates in these regions. Such diversity in the natural environmental features has brought along a rich agricultural potential. There are 7 geographic regions with different ecologic characteristics in Turkey and the production potentials of these regions are considerably different from each other.

Turkey's lands constitute a very old agricultural area. Looking through the historical development of the agricultural land use in Turkey, one can see substantial changes that have happened over time. Depending on the increasing population and developments happening in the agricultural mechanization, a notable increase was detected in the quantity of agricultural areas up to the early 1990s. From the period since 1990 up to our present day, a reduction has been noted in the quantity of agricultural areas and this is due to several different reasons.

Turkey has 78.534.700 hectares of surface area. While in 1928 only 6.6 million hectares was cultivated, it reached to 25.3 million hectares in 1950 and later on nearly 28 million hectares in the early 1990s (Minister of Development, 2014a). Following the end of 1990 the quantity of agricultural areas started to decrease. It dropped to 26.986.548 hectares in 1996 and finally 23.810.672 hectares in 2013. Within the short period of time, 3.175.876 hectares (-11.2 per cent) of agricultural areas have been lost because of different factors. Today, the proportion of the agricultural areas to the country's surface area is 30.3 per cent.

About 20.6 million hectares of the agricultural areas in Turkey consist of arable crops, fallow and vegetable lands in 2013. Nearly 3.2 million hectares of areas are covered with fruit gardens, vineyards and olive groves (Table 1, Figure 2). In about 66 per cent of the agricultural areas, grain products are cultivated while only 3.4 per cent of these areas are allocated for vegetables and in 8.1 per cent of agricultural lands, various fruits are produced. Vineyards constitute approximately 2 per cent of these agricultural areas while 3.4 of them are covered with olive groves. The proportion of fallow lands is 17.4 per cent by 2013, and in the same year, wheat and barley are the mostly cultivated grain products. Wheat is cultivated on 7.773.000 hectares of area and barley is produced on 2.721.000 hectares of area. By 2013, the areas that only wheat and barley are cultivated on, stand for the 44 per cent of the agricultural areas in Turkey.

The agricultural sector maintains its importance as a resource for employment and economic development in Turkey's economy. An examination of the distribution of country's employment to the sectors, revealed some important changes. In the early 1930s, 90 per cent of the working population was employed in the agricultural sector (Göney, 1979). Such proportion dropped back to 75 per cent in 1960 and up to 1990 agricultural sector was dominant over the employment of the country. After 1990, substantial changes took place in the distribution of country's employment to the sectors, (Table 2). In 1991, almost half (48 per cent) of the working population was employed in the agricultural sector. Depending upon the developments happening in the service and industrial sector since 1990 up to our present day, a notable decrease has been seen in the working population employed in the agricultural

sector and the percentage of the agricultural sector in the total employment has rapidly reduced. Now, the agricultural sector comprises 21 per cent of the total employment of the country. Although the percentage of the agricultural sector in the total employment has reduced, agricultural sector maintains its importance in the rural areas as the primary means of employment (FAO, 2014). Nearly 63 per cent

(TUIK)

of the rural population of the country, in 2011, was employed in the agricultural sector (OECD, 2011). For this reason, to continue the agricultural activities in a sustainable manner is essential for the rural development in the country (Bakırcı, 2007). Apart from these figures, there is illegal employment as well in the agricultural sector of Turkey. In summary, today the agricultural sector maintains its role of being a prominent source of employment for Turkey.

In the development years of Turkey, the agricultural sector contributed a substantial proportion of the national income. In 1970s, the proportion of agricultural sector in Turkey's national income was 30 per cent. Such proportion dropped back to about 10 per cent in 2000, and has decreased to 8 per cent at the present time. Also, the agricultural proportion to total foreign trade has reduced. Agricultural sector constituted 85 per cent of Turkey's foreign trade in 1968 while it was 61 per cent by 1975 (Göney, 1979). The proportion of the agricultural sector in the foreign trade was 6 per cent in 2000 and dropped to 4.7 per cent 2005. In spite of the fact that the proportion of agricultural sector in foreign trade has reduced as compared to other sectors, agricultural sector still maintains its importance in foreign trade. Today, Turkey is one of the world's major agricultural producers and is an exporting country in many prominent agricultural products. In 2012, the agricultural sector in Turkey has 5.2 billion US dollars export volume and it corresponds to 3.4 per cent of country's total exportation.

The agricultural sector is an economic sector which is directly bonded to food production and nutrition of the country's population. Turkey's population is growing rapidly as well. In 1927, country's population was 13.648.270 people and the rural population was more dominant in the country. By 2015, the total population of the country increased to 78.741.053 people, so it means that the total population has increased 5-6 times since 1927. Within the development process of the population, highly important changes have taken place in rural and urban distribution of the population (Table 3). In 1927, 75.8 per cent of the total population lived in the rural areas and the other 24.2 lived in the cities while such percentage has become just the contrary at the present time; in 2012, only 22.8 per cent of the total population lived in the rural areas while the other 77.2 per cent lived in the cities. It is due to the rural-to-urban migration that working population employed in the agricultural sector decreases in spite of the increase in Turkey's total population. Unless such migration is reversed, the decrease in rural population will go on. Keeping the rural population in its place and employment of this population in the agricultural sector are of vital importance for a sustainable agriculture. Even though the rural population has reduced in time, as compared to other European countries, the percentage of rural population is still high in Turkey.

(TUIK)

By 2012, the rural population of Turkey was 17.178.953 people. Today, the unique means of livelihood of Turkey's rural population is agriculture. Therefore, sustainable agriculture is more important for the rural population.

Agriculture plays an important role in providing the food needs of the increasing population. Every country makes efforts to be self-sufficient in the agricultural production. Providing the food needs of the increasing population requires an increase in production at the same time. Soils are used more intensely in order to satisfy the food needs of the increasing population. Agricultural mechanization, developments in the agricultural technologies and increase in use of chemicals and fertilizers brought about high productivity in Turkey, especially between 1970-1990. In this period, the increasing population triggered the motivation to increase production, however the negative effects on the soil and environment of conventional agricultural systems have come to the fore in recent times.

On the other hand, the rapid increase in population has brought along misuse of the lands. The need for new lands due to the pace of urbanization has been answered by opening the agricultural areas to settlement. Needs and tendencies of the rapidly growing cities to enlarge on the agricultural areas gradually threaten the availability of Turkey's fertile agricultural soils. Particularly in the last 15-20 years, the reduction of agricultural areas is highly related to the increase in non-agricultural usage (settlement, industry, tourism, mining and transportation etc.) of these lands. Along with the rapid urbanization in the country, fast growing tourism activities also threaten the agricultural areas as well. The fertile agricultural areas on the coastal regions are almost decimated because of tourism use. Urbanization and tourism activities are intensified generally on the coastal regions and the most productive agricultural areas of Turkey are located on these coastal regions. Data from 2013 show that 41.151.531 people live in the provinces located on Turkey's coastal regions. In these coastal provinces which constitute 28 per cent of Turkey's surface area, 54.4 per cent of country's total population lives. This fact brings into open the population pressure and threat on the productive agricultural areas located on the coastal regions.

Today, one of the other primary problems of Turkey's lands is erosion. Nearly in 79 per cent of the country's lands, there is medium or high level erosion problem. Moreover, there is an erosion problem in 59 per cent of the cultivated agricultural areas and 64 per cent of the pasture areas in Turkey. Such percentages reveal the huge threat to Turkey's soil resources. Erosion decreases the soil depth and removes

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the fertile upper layer of the soil. About 68 per cent of Turkey's soils are shallow (soil depth is between 0-50 cm). Erosion and consequently shallowness of the soils affect agricultural production. Apart from this, problems seen on the soils such as salinity and pollution threaten Turkey's agriculture more every passing day. In our present time, 4.2 million hectares of area have lost its productivity partially or completely owing to the changing salinity proportions (Minister of Development, 2014b).

Such changes in the physical, chemical and biologic structure of the soil diminish its productivity, and to raise the productivity and maintain an increase in production, much more chemical fertilizers are applied. By 2013, use of chemical fertilizers in Turkey's agriculture is 5.813.612 tons. Within such a short period of time since 2008 up to 2013, a 41 per cent of increase in chemical and fertilizer use has been noted. Within the period from 2012 till 2013, use of chemical fertilizers in the country has increased 9 per cent (Ministry of Food, Agriculture and Livestock, 2014). Although the use of chemical inputs and fertilizers has become more common in Turkey especially for recent years, overall amounts are not so high in comparison to other developed countries (Demiryürek, Stopes, & Güzel, 2008). Particularly in the Central Anatolia, Black Sea, Eastern Anatolia and South Eastern Anatolia regions of Turkey, where the conventional agriculture is more common, the soils have not been polluted so much. Usage of chemical fertilizers is however more intensified in the Marmara, Mediterranean and Aegean regions. The fact that a substantial part of the soils in Turkey is not polluted so much with chemical fertilizers is a definite advantage in its transition to a sustainable agriculture system.

It is highly essential for the countries to provide for the nutritional needs of the increasing population. In Turkey, the population has increased rapidly and the nutritional needs of the increasing population have intensified the pressures on agricultural areas. Population projections set forth that the increase in Turkey's population will continue. According to the estimations, Turkey's population will reach to 88.427.604 people by 2030 and 93.475.575 people by 2050 (TUIK). This will aggravate the pressure on agricultural areas. In order to satisfy the nutritional needs of the increasing population, the sustainable use of agricultural areas is required just the because of the fact that agricultural areas in Turkey has already pushed the limits and creating new agricultural areas is not possible any more. On the contrary, the existing agricultural areas could be lost because of natural and human factors such as erosion and misuse of lands. Consequently, the existing agricultural areas should be used in the most rational way. It is a fact that the agricultural areas in Turkey could not be increased, but it is not impossible to provide the needs of the increasing population through a well-planned and sustainable usage. For this reason, organic agricultural applications have started to gain prominence for the last years in Turkey just as in the other parts of the world.

Organic Agriculture in Turkey

The level that the agriculture sector in the world has come in the recent years shows that agriculture is not sustainable anymore and agricultural innovations are required. Natural resources needed for the agricultural production are not limitless. However, for many years all around the world, agricultural activities have been managed with the principle that these resources as limitless. It is a fact one cannot achieve sustainable development by damaging these limited resources and destroying the natural balance. Therefore, sustainable agricultural systems have become more important in last years. Sustainable agriculture embodies maintenance of production with environmental friendly techniques that protect the natural resources. Sustainable agriculture is defined as production systems that maintain continuous productivity and preserve social benefits (Pretty, 2008).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Organic agriculture is one of the sustainable agricultural systems and it aims for rebuilding the natural balance destroyed because of the wrong applications in the ecologic system, as well as to once more bring the human and environmental friendly production systems to the fore. In this sense, organic agriculture stands for an agricultural system armed with an ecologic, social and economic balance (Topp, Stockdale, Watson, & Rees, 2007). Since it is sensitive to human health and nature, organic agriculture has gained much more prominence. In recent years, organic agriculture has been rapidly spreading across the world and global organic food market has been enlarging every passing day. By 2012 across the globe in 164 countries, 37.5 million hectares is under organic agriculture. Nevertheless, in comparison with the conventional agricultural areas, organic agricultural areas in the world are still a small amount (0.87%).

Turkey is one of the foremost countries that organic agricultural system is performed. Initial activities of the organic agriculture did not become with raising public awareness regarding the sustainable agriculture. Instead, organic agriculture was started completely with commercial motivations in Turkey. Organic agriculture in Turkey started in the 1984-1985 production season upon the organic products request of the European companies from Turkey (Istanbul Chamber Commerce, 2006). The first organic production was carried out with raisins and dried fig in the Aegean Region. Afterwards, these products were increased with the addition of dried apricot and hazelnut production in different regions (Ozkan, 2003). Although organic agriculture started quite late in Turkey, especially for the recent years, an important development has been made. However, this development is based mainly on vegetative production, and organic animal production in Turkey is not so common yet. For this reason, in this study, organic vegetative production of Turkey has been examined. Within time, organic vegetative production in Turkey has made notable progress both in terms of number of products and producers and production areas and quantities. In the following discussion, the temporal and spatial change of the organic agriculture in Turkey will be examined.

TEMPORAL AND SPATIAL DEVELOPMENT

Organic agriculture in Turkey has been subjected to notable changes with regards to both temporal and spatial distribution.

Temporal Development

Turkey has such a rich agricultural potential that many various products could be cultivated in its different geographic regions, territories and climates. Turkey has demonstrated its potential with its organic products variety within the last years. Apart from the arid climate plants, many different plant species including subtropical plants are cultivated in the country. In parallel with the enlargement of the world's organic product market in recent years, organic products cultivated in Turkey have become more diversified. The organic agricultural product range started with traditional products (such as fig, grape, apricot, hazelnut and cotton etc.) has since become varied every passing year. The number of organic products in 1990 was only 8. By 2000, number of organic products rose to 95 and in 2005, it reached to 205. By the year of 2013, the total number of certified organic products in Turkey is 213. As it is seen, within these 23 years, a substantial increase has been noted in the number of organic products.

As consumers' demands for organic agricultural products rise, so has the number of producers adopting organic agriculture. International trade has developed owing to the growth of this demand. All in

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

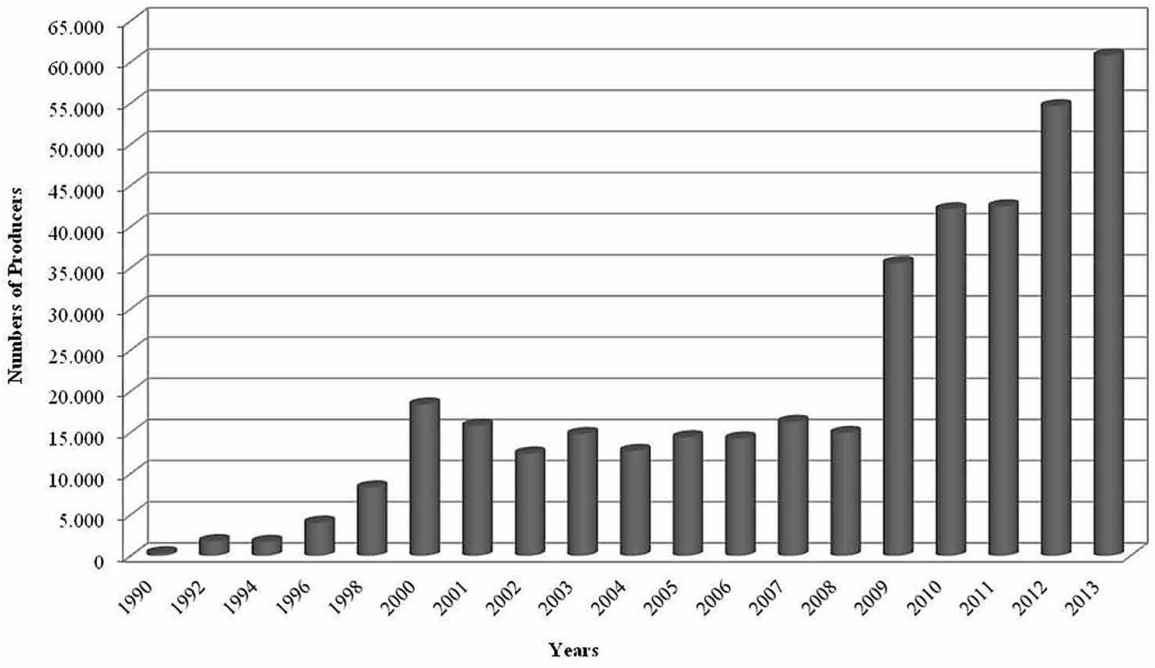
all, some countries have started to cultivate different organic products demanded from other parts of the world and export these products to these countries in spite of the fact that there is no domestic market or demand for the organic products in these countries. This situation is similarly in Turkey (Rehber & Turhan, 2002). Due to the rise in demand for the organic products in the world, the number of organic agricultural producers has increased.

Looking through the change in number of producers in Turkey, some important changes have been noted (Figure 3). Number of producers in Turkey was only 313 in 1990, and it rose up to 4.039 in 1996 and it reached to 18.385 by 2000. However, after 2000, a decrease has been seen in number of producers in Turkey. The economic crisis which occurred in 2001 in Turkey was responsible for the decrease in number of producers following 2000. On the other hand, after 2008, a substantial increase has been seen in number of producers. While the number of producers in 2008 was 14.926, it rose to 35.565 by 2009. In other words, only within 1 year, the number of producers increased almost 2.5 times. As to 2013, the number of producers reached to 60.797. By the year of 2012, there were 1.927.018 organic agriculture producers all around the world and Turkey became the 6th country with the largest number of producers. Also, Turkish producers now constitute 17 per cent of the total producers in Europe.

Both the temporal distribution of number of producers in Turkey and the spatial distribution of them have been subjected to substantial changes. There are 81 provinces in Turkey as per the civil administration structure. The data of provinces regarding the organic agriculture in Turkey is from 2004 and therefore on this data of 2004 will be used to compare the spatial changes of the organic agriculture.

An analysis of maps of 2004 and 2013 demonstrates some important changes in the spatial distribution of the organic agricultural producers. The total number of organic agricultural producers in 2004 was 12.751 and looking at the distribution of producers, no producers can be seen in 28 cities across

Figure 3. The number of producers in Turkey

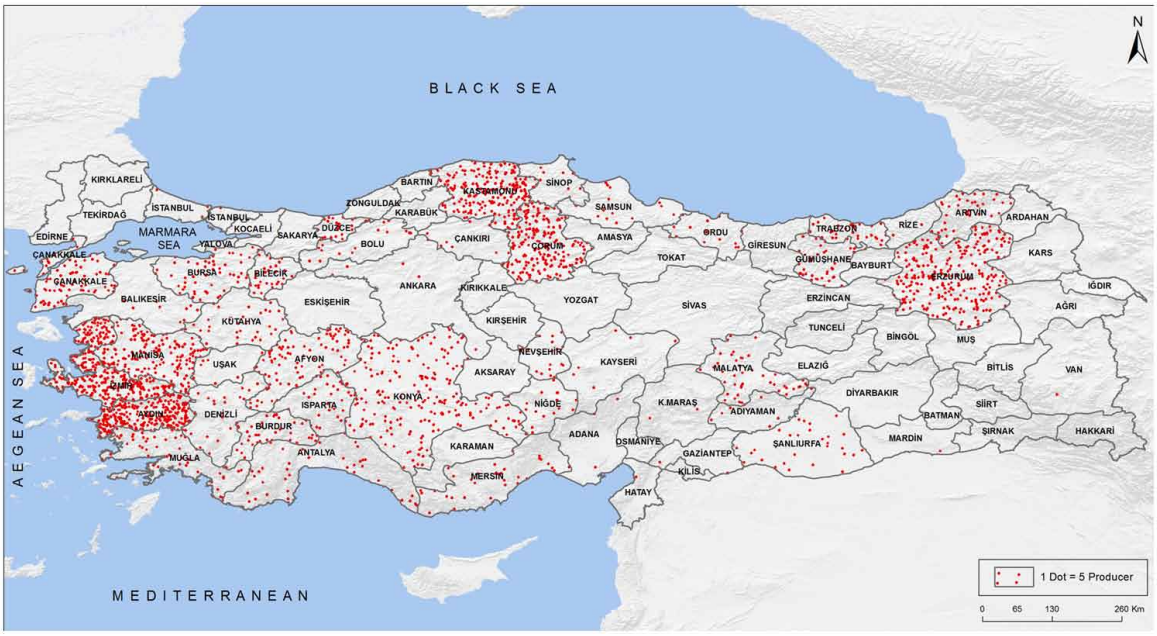


EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the whole country. This means that organic agriculture was not practised in 1 of every 3 cities and the cities without any organic agricultural activities are generally located in the Eastern Anatolia and South Eastern Anatolia regions (Figure 4). In 15 cities, number of producers was less than 10. In this way, we conclude that organic agriculture does not matter so much in more than half (43) of the cities. By 2004, the number of cities having more than 1.000 producers was only 6. These cities are respectively İzmir, Aydın, Erzurum, Kastamonu, Konya, and Çorum. As to the cities having 100 and more producers, they were intensified in the Western Anatolia Region and the city having the largest number of producers (1636) was İzmir in 2004.

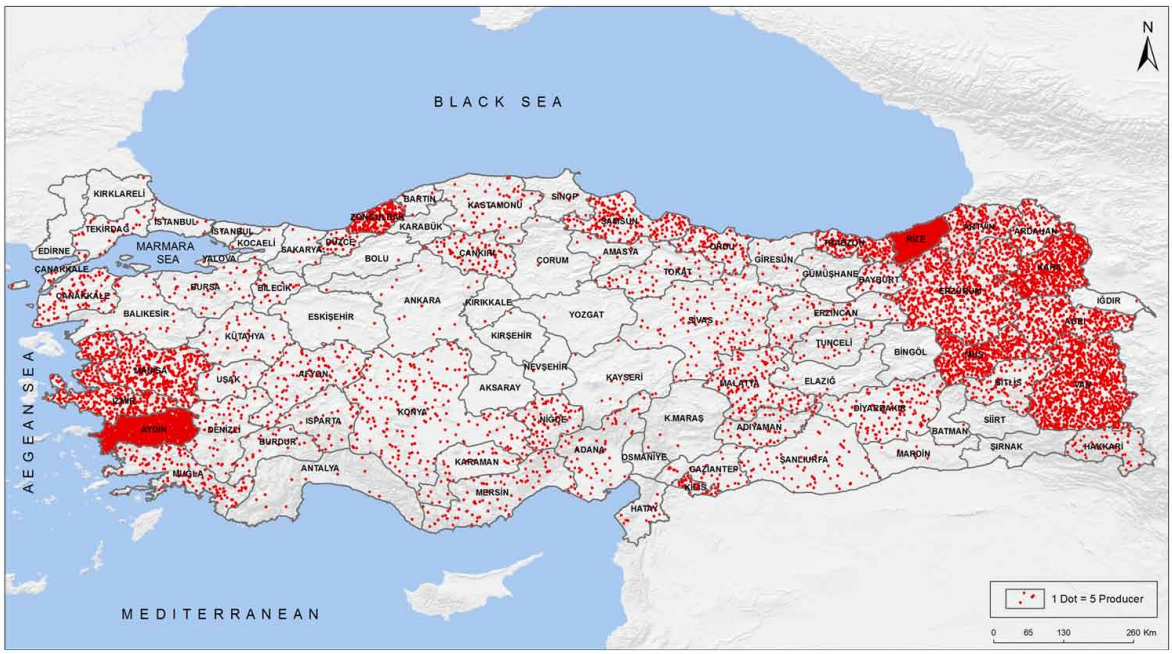
A look at the map of 2013 shows that with respect to the spatial distribution of the organic agricultural producers, notable changes are seen at first glance as compared to 2004. Total number of producers reached to 60.797 by 2013 and there were only 2 cities (Siirt and Şırnak) without any producers in this year. This shows that organic agriculture has expanded all around the country since 2004 up to our present day. Cities with less producers are mostly concentrated in Central Anatolia Region (Figure 5). The most significant point drawing attention in both of the maps is the great increase in number of organic producers in Eastern Anatolia and Eastern Black Sea regions by 2013, where limited producers were once involved in organic agriculture activities in 2004. The number of cities having more than 1.000 producers rose to 13 in 2013. It is seen that these cities are intensified in Aegean, Eastern Anatolia and Eastern Black Sea regions. There are 5 cities in Turkey that has more than 4.000 producers and these cities are respectively Aydın, Rize, Van, Erzurum, and Kars. Aydın is the city having the largest number of producers (9.417) also in this year. Eventually, it is deduced from the examination of both maps showing the distribution of producers' number in 2004 and 2013, that the number of producers adopting organic agriculture has increased and it has started to spread over the country. Between 2004 and 2013, some notable changes have taken place in the distribution of the producers into the geographic regions.

Figure 4. The distribution map of producer in 2004



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. The distribution map of producer in 2013



Actually, in all of the regions, the total number of producers has increased between 2004 and 2013. Nevertheless, such increase rate is quite high in some of the regions. After all, the percentage of regions in total number of producers has been changed in time and the most significant change has happened in the Eastern Anatolia Region. While only 13 per cent of the total producers were located in the Eastern Anatolia Region, it has reached to 37 per cent by 2013 (Table 4).

Upon investigating on the temporal change of the organic agricultural areas in Turkey, we see quite important changes have taken place. Organic agricultural areas have been enlarged ever since the organic agriculture was firstly started in Turkey in 1984. Total area where organic vegetative production is made was solely 1.037 hectares in 1990 and organic agricultural areas were subjected to peaks and

Table 4. Distribution of producer by geographical regions

Geographical Region	2004		2013	
	Numbers of Producers	%	Numbers of Producers	%
Mediterranean Region	744	6	1.183	2
Eastern Anatolia Region	1.627	13	22.179	37
Aegean Region	4.884	38	15.825	26
Central Anatolia Region	1.317	10	2895	5
Black Sea Region	3.093	24	15.451	25
Marmara Region	897	7	1.184	2
Southeastern Anatolia Region	189	2	2.080	3

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

troughs between 1990-2008. However, within this period of time, the general tendency of the organic agricultural areas was to enlarge. This enlargement was more rapid after 2008 (Figure 6) and the reason was the fact that organic agricultural policies were getting stronger. By 2012, total organic agricultural areas reached to 523.627 hectares between 2011-2012, a sizeable enlargement was seen. While Greece was the foremost country having the biggest expansion areal enlargement in organic agricultural areas in 2011-2012, Turkey became the fourth country (Willer & Lernoud, 2014). Organic agricultural areas have become enlarged 445 times in Turkey since 1990 up to 2013.

In the evaluation of the organic agricultural areas and natural collection areas in 2013 together, we see that total organic agricultural area in Turkey is 769.014 hectares (Table 5). 60 per cent (461.395 ha.) of this area is vegetative production area while 40 per cent (307.619 ha.) of it is for natural collection. Although the total organic area in Turkey shows fluctuations in some years, generally it tends to grow (Figure 7). In the case that such tendency in growth continues, in Turkey organic agricultural areas will enlarge much more in the coming years. By 2012, Turkey became the 15th country in the world and 8th country in Europe in terms of organic agricultural areas. These qualifications are the sign of Turkey's development in organic agriculture. As compared to the conventional agricultural areas, today organic agricultural areas in Turkey are not so large; they constitute 1.9 per cent of the total agricultural areas in the country. Such percentage shows how the organic agricultural areas are limited as compared to the total agricultural area in the country. On the other hand, in comparison with the past, we see that this percentage has grown. This proportion was 0.2 per cent in 2002, 0.4 per cent in 2008, 1.6 per cent in 2010 and 1.9 per cent at the present time. It is a proof that organic agriculture has been improving gradually within the Turkish agricultural system.

Spatial Distribution

As it has been in the temporal development of the organic agricultural areas, some notable changes have seen in the spatial distribution of these areas. In 2004, the total organic area in Turkey was 209.573 hectares and nearly 52 per cent (108.598 ha) of it was agricultural area while the other 48 per cent (100.975 ha) was for the natural collection area. In the assessment of the map showing the distribution of the organic areas in 2004, it draws attention that there were significant gaps in the country (Figure 8). There was not any organic agricultural areas in 28 cities; mainly in the Eastern Anatolia Region and the eastern parts of the Central Anatolia Region. No data for 15 cities regarding organic land is available that is why no organic land is seen in the cities in the map such as Balıkesir, Bilecik, Erzurum, Eskişehir, Kocaeli, Konya, Nevşehir, Sakarya, Samsun, Tekirdağ, Tokat, Aksaray, Karaman, Iğdır, and Yalova. In 2004, organic production area was less than 1.000 hectares in nearly half (39) of the cities in Turkey and number of cities having a more than 1.000 hectares of organic area was 14. We see that these cities are intensified in the Aegean and Mediterranean regions and only 4 of these cities had more than 10.000 hectares of organic area; these cities are Antalya, Muğla, Şanlıurfa and İzmir. Antalya had 65.900 ha, Muğla had 21.790 ha, Şanlıurfa had 15.981 ha and İzmir had 10.995 ha of organic area. Total organic production area are in these 4 cities are 114.666 hectares. That is to say, almost 55 per cent of the total organic agricultural areas in Turkey are actually in only 4 cities. This suggests that in 2004 organic agriculture was not distributed equally in the country.

By 2013, there were some major changes in the distribution of the organic agricultural areas in the country (Figure 9). Total organic area in Turkey rose to 769.014 hectares in this year; 60 per cent (461.395 ha) of this area is the agricultural area while the other 40 per cent (307.619 ha) of it is for

Figure 8. The distribution map of organic lands in 2004

Figure 9. The distribution map of organic lands in 2013

natural collection area. While looking at the map showing the distribution of the organic areas in the country in 2013, we see that there 2 cities without any organic agricultural area and these cities are Siirt and Şırnak. However, number of the cities without any organic agricultural areas in 2004 was 28 and the fact that it has decreased to only 2 cities by 2013 demonstrates that organic agriculture has started to spread over the country. (The data of 10 cities have not been obtained and these cities are Bingöl, Edirne, Elazığ, Kırklareli, Kırşehir, Kahramanmaraş, Zonguldak, Aksaray, Karabük and Osmaniye. For this reason, there are not organic any agricultural areas seen in these cities in the map. Nevertheless, it is known that organic agricultural area is quite small in these cities.) By 2013, number of the cities having more than 1.000 hectares of organic area has reached to 41 and it is seen that these cities are distributed almost equally over the country. As to the cities having a more than 10.000 hectares of organic area, the number of them has risen to 16 and these cities are mostly intensified in the Aegean, Eastern Anatolia and Mediterranean regions. The number of the cities with a more than 50.000 hectares of organic area is 6 and these cities are Mersin, Kastamonu, Van, Erzurum, Aydın and Kars. Mersin has 111.868 ha, Kastamonu has 83.714 ha, Van has 67.496 ha, Erzurum has 55.708 ha, Aydın has 52.759 ha and Kars has 52.622 ha of organic area. Between the years of 2004 and 2013, some notable changes have taken place in the distribution of the organic agricultural areas into the geographic regions. In fact, between these years, total organic areas has expanded in all the regions but such expansion rate is quite higher in some regions. This has changed the percentages of the regions in the total organic area of the country within time. We see the most substantial changes happening in the Eastern Anatolia Region (Table 6). While only 4 per cent of the total organic area in the country was in the Eastern Anatolia Region; this percentage reached to 38 per cent in 2013. Consequently, an evaluation of the spatial distribution of the organic agricultural areas in Turkey between 2004 and 2013 shows that organic agricultural areas in Turkey have become larger and they have expanded over the country in time.

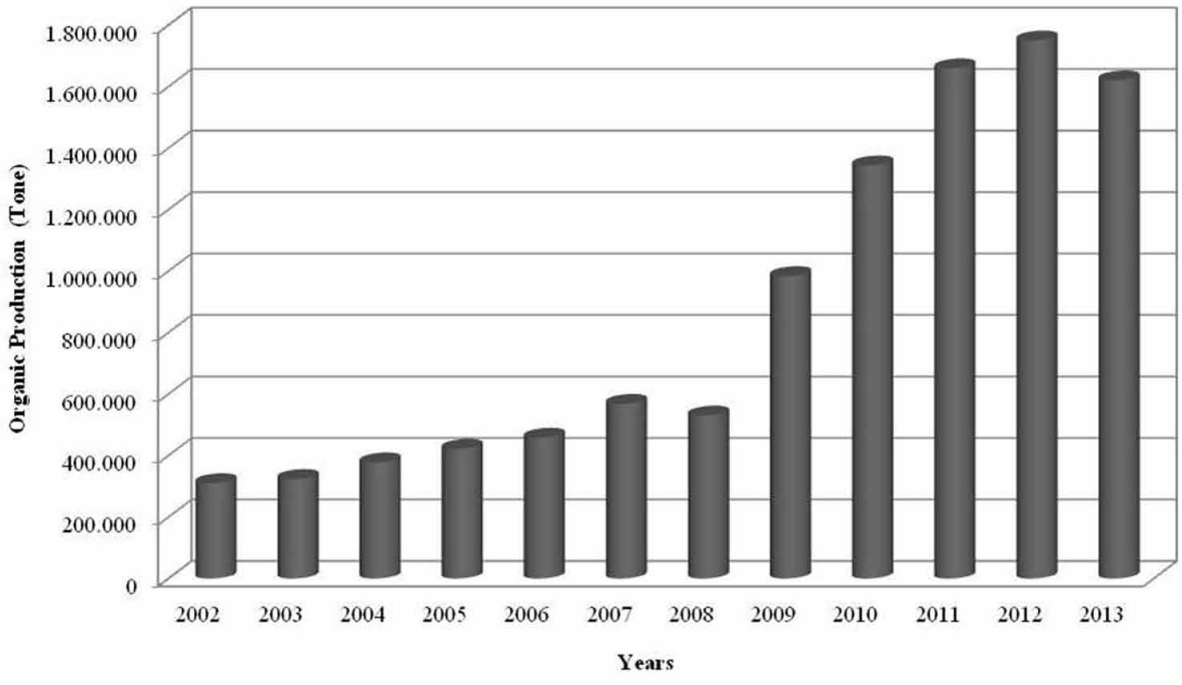
Table 6. Distribution of organic lands by geographical regions

Geographical Region	2004		2013	
	Total Organic Lands (ha)	%	Total Organic Lands (ha)	%
Mediterranean Region	77.341	47	161.322	21
Eastern Anatolia Region	6.115	4	288.993	38
Aegean Region	49.441	30	98.429	13
Central Anatolia Region	1.297	1	23.459	3
Black Sea Region	7.841	5	110.991	14
Marmara Region	2.718	2	54.296	7
Southeastern Anatolia Region	19.089	11	27.402	4

Depending on the increase in number of farmers and production area, the organic vegetative production quantity in Turkey has gotten bigger. We see some important temporal changes happening in the amount of organic production and the general trend of this change is in the direction of increasing. Organic vegetative production quantity, being only 310.125 tons in 2002, rose to 530.224 tons in 2008. Particularly after 2008, a great increase was noted in the organic production (Figure 10). An increase in the number of producers and production area between 2008-2009 is reflected in the production quantity that reached to 983.715 tons by 2009. In other words, organic production quantity increased by about 85 per cent just within 1 year. Aid given to the organic agricultural producers since 2009 gave a boost to the organic production in forage plants and grains and this led to an overall increase in the total produc-

Figure 10. Organic production (Tons)



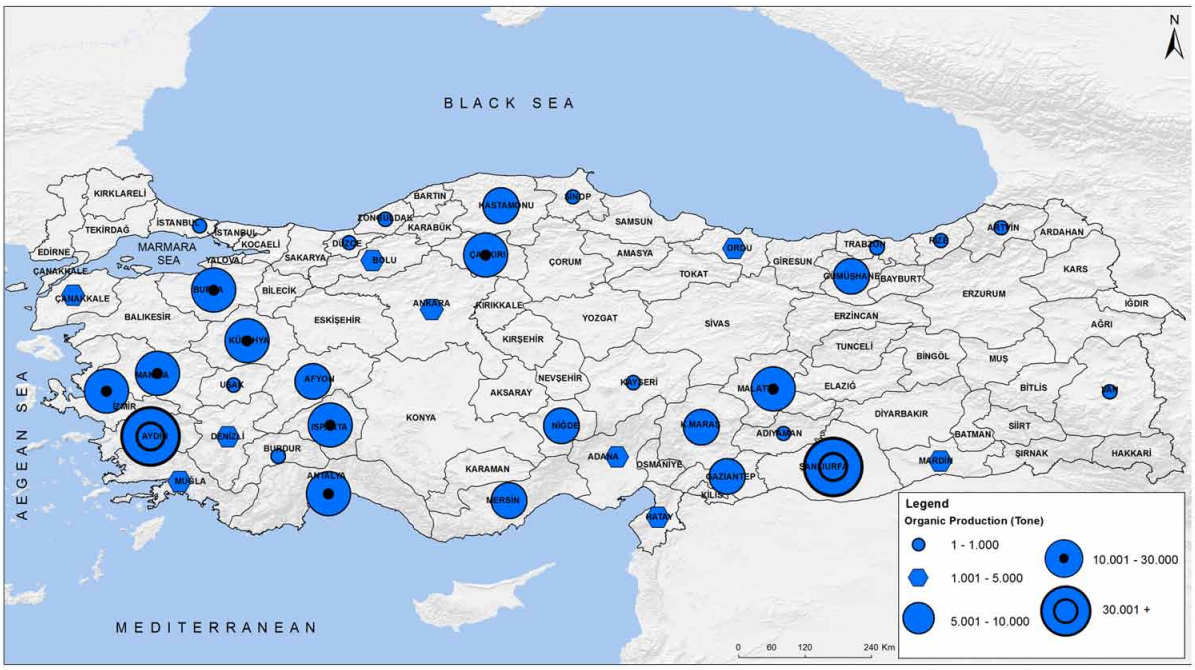
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion (The Union of Chambers and Commodity Exchanges of Turkey, 2013). By 2013, the total organic production quantity has reached to 1.620.466 tons. Organic production quantity in Turkey is shaped by the foreign demands. Since Turkey makes export-based organic production, mostly it is the world market that decides the production quantity. However, owing to the rising demands for organic products in the domestic market, the organic production quantity in Turkey is expected to rise as well.

Some notable changes have also taken place in the spatial distribution of the organic production. In 2004, organic production in Turkey was 377.615 tons. Looking at the spatial distribution of production in 2004, one can see 28 cities without any organic production. There were 26 cities having more than 1.000 tons of production and 10 cities having more than 10.000 tons of production and we see that these cities are intensified in the Western Anatolia. There were only 3 cities having more than 20.000 tons of production which are İzmir, Aydın and Şanlıurfa. Production quantity in İzmir was 26.174 tons, it was 39.787 tons in Aydın and 54.198 tons in Şanlıurfa. It shows that in 2004 organic production was intensified in some certain regions of the country (Figure 11). Organic products at that time were the traditional products that were of vital importance in Turkey's agricultural structure; these were grape, fig, apricot, hazelnut, olive, cotton and citrus fruits.

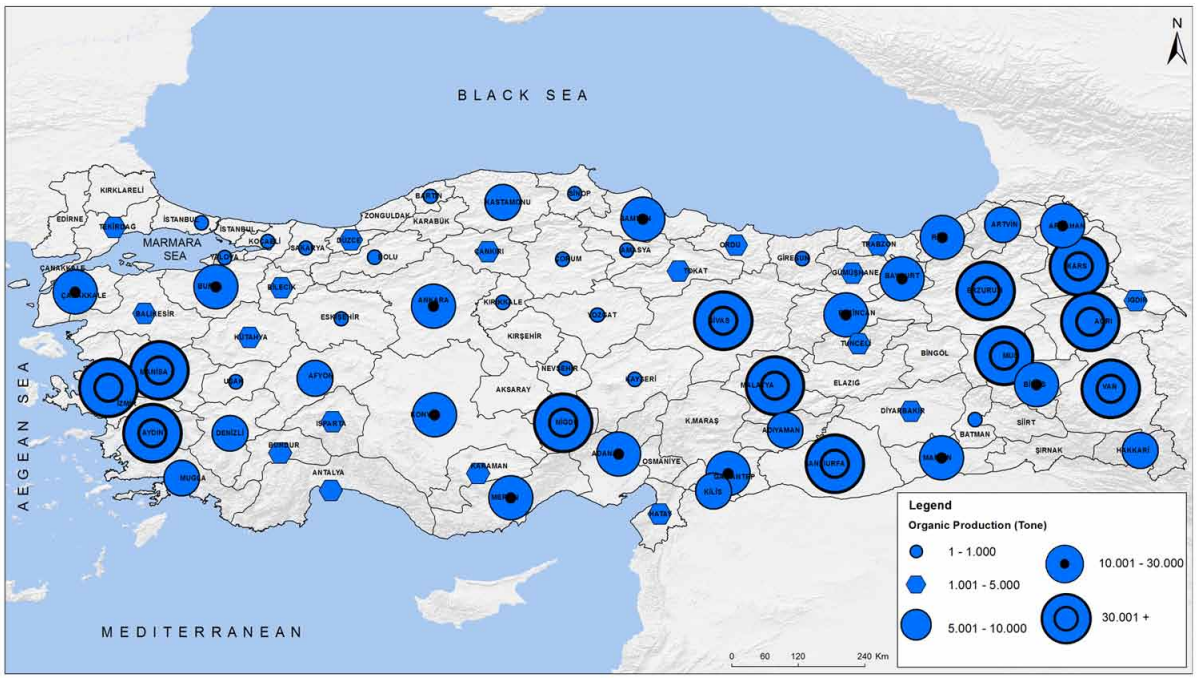
By 2013, the organic production quantity in Turkey rose to 1.620.466 tons and in this year, some substantial changes have been seen in the distribution of the organic production according to the cities (Figure 12). An examination of the map showing the distribution of the organic production into the country in 2013, shows that there are 2 cities without any organic production which are Siirt and Şırnak. (In 2013, we have not accessed to the data of 10 cities regarding the organic production. Therefore, there is no organic production seen in these cities in this map which are Bingöl, Edirne, Elazığ, Kırklareli, Kırşehir, Kahramanmaraş, Zonguldak, Aksaray, Karabük and Osmaniye. However, it is known that there

Figure 11. The distribution map of organic production in 2004



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 12. The distribution map of organic production in 2013



is too small organic production in the aforesaid cities). There are 52 cities having more than 1.000 tons of production. It is possible to conclude that organic production has expanded over the country because organic production is done in most of the cities. The number of the cities having more than 10.000 tons of production is 26 and those having more than 20.000 tons of production are 16. On the contrary, this was limited to 3 cities in 2004. Moreover, there are 12 cities in Turkey having more than 30.000 tons of production and these cities seem to be intensified in the Eastern Anatolia and Aegean regions. In this year, number of the cities having more than 100.000 tons of production is 5 and these cities are respectively Erzurum, Van, Aydın, Kars and Ağrı. The production quantity in Erzurum is 233.408 tons, 198.738 tons in Van, 154.760 tons in Aydın, 137.040 tons in Kars and 135.917 tons in Ağrı. Apart from Aydın, in the rest of the cities, grain production is more dominant. Looking through the maps shows the spatial distribution of the production in 2004 and 2013. At first glance, one can observe that substantial changes have occurred in the spatial distribution of the production within the period of these 10 years, and organic production has expanded all around the country. As to the regional distribution of the organic production, we see a growth in all the regions but there is an extreme growth in the Eastern Anatolia Region (Table 7). In 2004, the organic production in the Eastern Anatolia Region constituted solely 5 per cent of the total production of the country, while it has reached to 57 per cent by 2013. Despite the increase in the organic production in the Aegean Region, the percentage of the Aegean Region within the total production has decreased. A considerable difference can be observed between the Eastern Anatolia and Aegean regions with regards to organic production quantity in 2013. On the other hand, trade volume and organic market value of the products cultivated in the Aegean Region are much more. In the Eastern Anatolia Region, grains are generally cultivated.

Southeastern Anatolia Region	65.074	22	116.033	7

Organic agriculture in Turkey develops depending on the export market (Leeuwen, Voort, Sukkel, & Balci, 2008). Almost all the organic production are exported to the developed countries especially EU countries, the USA and Japan. EU countries stand for the most important exportation market of Turkey between these markets and Germany, France and England are the most prominent exportation markets of Turkey within these EU countries (Gök, 2008). A large part of the exported products is dry and dried fruits and later on fresh fruits and field crops. From 19.4 million US dollars in 1998, organic products exportation rose to 26.3 million US dollars in 2005, but it dropped to 15 million US dollars between 2010 and 2011. Such reduction is associated with the global economic crisis in that time. Following the recovery of the markets after the crisis, organic products exportation rose to 24.7 million US dollars in 2012 while it has reached to 46 million US dollars in 2013. Although the exportation values grade up every passing day, the proportion of Turkey in the world organic agricultural market is still too little. In the evaluation of the product groups, it is noted that Turkey has gained the most foreign currency income from organic hazelnut, fig, apricot, grape, strawberry, olive, cotton and fruit juices. The organic agricultural market, which is growing rapidly in the world, was 63.8 billion US dollars in 2012. Considering the total market value of the world's organic agriculture, the revenue that Turkey gains from this market is still very small. Within the 2023 year targets of Turkey, there is an objective as well to raise the organic agricultural exportation to 2.5 billion US dollars. Turkey has the potential to realize this objective as well as to make agricultural the policies needed to stimulate its potential (Ministry of Food, Agriculture and Livestock, 2012).

In order for the organic agriculture to become widespread in Turkey, the domestic market of organic products needs to grow as well. For the time being, Turkey has an export-oriented organic production. Consumption of organic products is too small in the domestic market of Turkey. It is estimated that the domestic market of organic products of Turkey is around 14 million US dollars. As compared to other countries, this figure shows how much restricted is the domestic market of organic products in Turkey (Demiryürek, 2011). By 2012, consumption value of the organic food per capita in Turkey was 0.16 US dollar. In other words, consumption value of the organic food per capita is not even one US dollar. On the contrary, in the same year, across the globe, average consumption value of the organic food per capita was 9.08 US dollars. It reveals that in Turkey consumption of organic value is very little and Turkey has a lower consumption value of the organic food in comparison with the other parts of the world. If it is desired for the organic agriculture to become more widespread, domestic consumption should be increased. In the recent years, to increase the organic products consumption in the domestic market, some

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

organic products stores, organic products sections in the supermarkets and organic open-air markets in some days of the week have been opened. Particularly in İstanbul, Ankara and İzmir, organic open-air markets are established at 15 points in the country. There are 7 organic open-air markets in İstanbul. İzmir and Ankara have 2 organic open-air markets and Antalya, Bursa, Eskişehir and Samsun have one organic open-air market each. Domestic consumption has been growing gradually thanks to the recent activities. People have started to hear the concepts of organic agriculture and organic products much more. Along with exports, increased domestic consumption of organic products will make the organic agriculture widespread in the country.

BENEFITS OF ORGANIC AGRICULTURE TO TURKEY

Agriculture is one of the sectors that has always maintained its importance in the economic and social development in Turkey from past to present. Turkey has a very prominent agricultural potential such that apart from arid climate plants, many other plant species could be cultivated including subtropical plants. Making optimal use of Turkey's agricultural potential is possible only with the rational use of its natural resources. Turkey is in need of sustainable agricultural systems that do not decimate its natural resources, pollute or destroy them. Sustainable agricultural production could be applied; systems which do not use up its natural resources and eventually cause to the deterioration of these resources, but rather systems which use these resources effectively so that they could be passed on to the next generations. For this reason, start of organic agriculture and its spread in Turkey in recent years are important steps for sustainable agriculture.

Turkey has made notable progress regarding organic agriculture within the last 20 years. By 2013, Turkey has made a 1.620.466 tons of organic production on a 769.014 hectares of area together with 60.797 producers. Turkey has become the 6th country in the world as having the largest number of producers and the 15th country in terms of its organic agricultural areas. Between 1990-2013, the number of producers has increased 195 times more and organic agricultural area has enlarged 445 times more, and between 2002-2013 organic production quantity has grown 5.2 times more. In spite of all these developments, today Turkey still uses only a very small part of its organic agricultural potential. Turkey is a country with a high organic agriculture potential, but these potentials are not evaluated sufficiently. Here are some of the potentials Turkey enjoys concerning organic agriculture.

- Turkey has different ecologic conditions and such diversity in the ecologic conditions make it possible to cultivate many agricultural products in the country. At one side, arid climate plants are cultivated while mild and sub-tropical plants could be cultivated at the same time. It gives an advantage to Turkey for the variety of products.
- Turkey has a biologic richness and diversity.
- Turkey has adequate and productive agricultural areas. The proportion of the agricultural areas in the surface area of Turkey is 30.3 per cent.
- Turkey has sufficient water resources.
- Turkey has thousands years of agricultural knowledge and experience.
- Turkey has adequate labor force. Researches done in this field have revealed that organic agriculture required much labor force as compared to the conventional agriculture (Turhan, 2005). Having a large, young population in Turkey is an advantage for a cost-effective labor force.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Another potential is the country's geographical position. Turkey is close to foreign markets and Turkey is especially advantageous due to it being so close to the European Union market.
- Turkey is an important player in terms of transportation systems in the international trade. Apart from the land and air transportation systems, marine transportation is an advantage as well for Turkey because it has outstanding mercantile ports (such as İstanbul, İzmir, Mersin).
- Turkey is the leading producer in some certain products (such as hazelnut, fig, grape, apricot etc.) in the world's agriculture and it has the chance to continue this advantage along with the organic production.
- In comparison with the industrialized countries, the amount of chemical input in the agricultural areas is lower in Turkey. Therefore, chemical pollution is not so dense in Turkey's soils. This will make the transition easier to organic agriculture.
- It is an advantage as well that Turkey has built the fundamental education required for solving the qualified labor force in the organic agriculture. Some 21 Organic Agriculture Departments have been established in 19 universities in order to support the organic agricultural development.
- Having a national legislation for organic agriculture is another advantage. By 2012, Turkey is one of the countries in the world that fulfilled the necessary regulations regarding the organic agriculture (Willer & Lernoud, 2014).

Embracing organic agriculture in the country will provide additional national benefits. Some of these are:

- Since the organic agriculture is an agricultural system that is sensitive to the environment, it will maintain the sustainable usage of natural resources. Turkey will both protect its natural resources and it will get the maximum benefit from these resources as well.
- Erosion intensity, one of the significant problems in Turkey's agriculture, will be diminished.
- Turkey will satisfy the food needs of the increasing population sustainably with organic agriculture.
- Health food supply with organic agriculture will make contribution to raising healthy generations of people.
- Organic agriculture will find solutions for the employment problems of the large rural population to a considerable extent.
- Rural-to-urban migration will be reduced as organic agriculture will contribute to the rural development.
- Wide spreading of the organic agriculture will increase the agricultural employment.
- Producers will be given guarantee thanks to the contracted agriculture.
- Percentage contribution of agriculture in the national income will again increase.
- Turkey will make good use of its potential in the diversity of organic products and will promote its competitive capacity in the international markets.
- Its agricultural exportation revenues will increase. Reduced percentage of the agriculture in the foreign trade will again raise.
- Increasing the foreign trade of the organic agricultural products will provide a substantial foreign currency inflow to the country. It will make contribution as well to the importation-exportation balance.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- High values of the organic products in the market will enable producers to obtain high revenues.
- Use of chemical inputs including fertilizers in the agriculture will be diminished thanks to the wide spread use of organic agriculture, and accordingly farmers will get rid of additional expenses.
- In case of a reduction in the use of the agricultural chemicals and fertilizers, importation expenses of the country will become less since most of them are imported.
- Every year in Turkey, a considerable amount of the agricultural areas remain fallow. Thanks to the organic agriculture, these areas will become smaller, and more agricultural areas could be used for the production.
- It will make a contribution to the regional development and especially to the development of the Eastern and South Eastern Anatolia regions.
- As organic agriculture becomes more common in Turkey, this will contribute positively to the agricultural negotiations in the membership process of the EU (Bakırcı, 2005).

RECOMMENDATIONS

Future agricultural systems will be those that prioritize the principle of sustainability, and the countries having these systems in-house will enjoy sustainable agricultural development. In this sense, if Turkey has expanded the organic agriculture system as soon as possible, it will be a shining example for the future. We have hereby shared our recommendations regarding the sustainable agriculture:

- A sustainable development in the agricultural production will be only succeed with the coherent use of various agricultural technologies. For this reason, Turkey should benefit much more from the agricultural information technologies.
- Geographic Information Systems (GIS) is an effective tool that should be used for the sustainable agriculture. Use of GIS has increased in the sustainable agriculture applications in the world in recent years. GIS helps in forming the sustainable agricultural applications by storing, managing, analyzing, reporting and monitoring agricultural data in huge numbers (Esri, 2008). Therefore, the first priority of Turkey should be establishing agricultural data bases and such data bases should include environmental information, cadastral information, infrastructural and socio-economic information. In Turkey, these data bases should be city-based. The most important factor of the agriculture is soil, but there is not any significant data base of soils yet. For this reason, activities of preparing agricultural data bases should be accelerated.
- Turkey has different ecologic conditions. Therefore, Turkey should consider agro-ecological zoning for sustainable agriculture. By this way, more effective agricultural programs could be prepared for each of the agro-ecologic zones. For an agro-ecological zoning, primary data bases should be developed, that is to say, necessary foundations should be built.
- The most fundamental deficiency concerning the sustainable agriculture is that Turkey lacks for the agricultural data bases. Therefore, information technologies and information management systems should be considered and the relevant studies should be accelerated. Consequently, without sufficient information regarding the physical and human characteristics of the natural environment, a healthy agricultural planning cannot be made.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Agricultural policies should be based on the concept of sustainability and oriented towards organic agriculture.
- Organic agriculture should be given more priorities in the agricultural development plans.
- The situation of the Turkish farmers should once again be evaluated and in accordance with the local conditions, new agricultural policies should be created.
- Agricultural areas in Turkey are small and partial. Land consolidation of the agricultural areas should be considered and agricultural enterprise areas should be enlarged.
- Support for organic agriculture should be increased.
- Model agricultural applications should be promoted with government aid.
- In order to raise awareness among producers and people, some public service announcements should be prepared.
- Apart from the organic vegetative production, organic animal production should be considered as well and some actions should be taken to improve the production. Large grass and pasture lands (14.617.000 ha) are an advantage that will make it possible an organic animal breeding development in Turkey.
- The entrepreneurs should be encouraged for the organic agriculture and agricultural industrial integration. The number of high value processed organic products should be increased along with the organic raw materials. Thus, the revenue of organic products exports will grow.
- Not only the foreign market but also the domestic markets should be developed.
- An effective and continuous government policy is required for the organic agricultural development in Turkey but the re-shaping of the agricultural policies with every new government will cause instability and slow down organic agriculture development.

CONCLUSION

Nowadays, it has been understood that natural resources are restricted and sustainable use of these resources is highly important. For this reason, future agricultural systems will be those giving priority to the "principle of sustainable agriculture". Organic agriculture, one of the sustainable agricultural systems, has gained considerable importance in the world for recent years. Countries having widespread organic agriculture will enjoy sustainable economic development. Turkey has made substantial progress regarding the organic agriculture for the last 20 years. Moreover, the developments in organic agriculture in the last 5 years are show a lot of promise for the future.

Organic agriculture in Turkey has made notable progress in terms of both number of producers and products and production area and quantity. The number of producers has increased 195 times more and organic agricultural areas have enlarged 445 times more between 1990-2013. Also, organic production quantity has grown 5.2 times more between 2002-2013. Apart from the temporal changes in the organic agriculture of Turkey, some important spatial changes have been noted as well. Intensified in the certain parts of the country at the beginning, the organic agriculture has expanded over the country at the present time. In spite of all these developments, Turkey, today, could not benefit from the potentials and advantages adequately that it has in the organic agriculture. In order for the organic agriculture to be widespread in Turkey, a stable government policy should be developed and applied. Moreover, agricultural information system and management technologies should be considered to aid the sustainable agricultural development in Turkey. Organic agriculture will make great contributions to Turkey's

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

economic development and regional improvement inside the country. Organic agriculture is an important necessity for a sustainable life and a sustainable agriculture. For this reason, it is of essence to spread much wider the organic agriculture in Turkey and all over the world for the sake of bequeathing a livable world to the next generations.

ABSTRACT

Potato is one of the most important vegetable crops in India accounting for 20-25% of area under cultivation of vegetables and grown in a wide range of climatic conditions. It is grown in almost all states under diversified agro-climatic conditions. Nearly 80% of the crop is grown in Indo- Gangetic plains comprising Uttar Pradesh, West Bengal, Punjab, Haryana, Bihar and other parts of India like Gujarat and Karnataka. Moreover, within the country, there is a lot of heterogeneity in potato productivity depending upon mostly on management and climatic conditions. The viability of commercial potato production is influenced by spatial and temporal variability in soils, agro climate, and the availability of water resources. The inter and intra-regional variations in productivity within the country are attributed to the variations in bio-physical factors vis-a-vis specific soil-climatic requirements of the crop. The present chapter discusses the impact of climate change on the land resources requirement for potato crop with reference to Indian context.

INTRODUCTION

Potato (*Solanum tuberosum* L.) plays an important role in global food and nutritional security especially for the poor (Thiele et al., 2010). It is commonly known as 'The king of vegetables and it has emerged as fourth most important food crop in India after rice, wheat and maize. Indian vegetable basket is incomplete without Potato. It is an annual, herbaceous, dicotyledonous and vegetatively propagated plant. The dry matter, edible energy and edible protein content of potato make it nutritionally superior vegetable as well as staple food. Potato is a highly nutritious, easily digestible, wholesome food containing carbohydrates, proteins, minerals, vitamins and high quality dietary fiber. Fresh potato contains about 80 per cent water and 20 per cent dry matter of which 60- 80 per cent is starch. It has low fat content and high vitamin C. A single potato of 150 g can meet 100 mg of vitamin C requirement. Potato is also a good source of iron, vitamins B1, B3 and B6 and important minerals. It also contains dietary fibers, which benefit human health. (Jha, 2015). It produces more quantity of dry matter, edible energy and edible protein in lesser duration of time than cereals like rice and wheat. The crop has also shown better economic viability during the current trend of diversification from cereals to horticultural/vegetable crops. However impending global climate changes are set to alter the potato production systems in the country and hence it is imperative to examine its consequences.

Global warming also termed as greenhouse effect is the result of accelerated emission of greenhouse gases (GHGs) *viz.* carbon dioxide (CO_2), methane (CH_4) and nitrous oxide (N_2O) in to the atmosphere due to anthropogenic activities. Global warming also termed as greenhouse effect is the result of accelerated emission of greenhouse gases (GHGs) *viz.* carbon dioxide (CO_2), methane (CH_4) and nitrous oxide (N_2O) in to the atmosphere due to anthropogenic activities. Atmospheric CH_4 and $N_2O$are attributed to crop cultivation forestry and other land uses. Whereas rise in concentration of CO_2 is attributed to fossil fuel combustion. Agriculture has a minor role in contribution of CO_2 to the atmosphere. It is now established that the global atmospheric concentrations of CO_2, CH4and N_2O have increased markedly as a result of human activities since 1750. The increase in GHGs has resulted in warming of the climate system by 0.74°C between 1906 and 2005. The rate of warming has been much higher in recent decades (Dua et al., 2013).

Although increase in atmospheric CO_2 has a fertilization effect on crops with C_3 photosynthetic pathway and thus promotes their growth and productivity, on the other hand, it can reduce crop duration. Report of Working Group II of Inter-Governmental Panel on Climate Change (IPCC) and a few other global studies (Aggarwal, 2008) indicated a probability of 10–40% loss in crop production in India with increase in temperature by 2080–2100. The discussion in this chapter pertains to potato cultivation in the wake of climate changes.

Global Potato Production Scenario

The potato is the most popular food crop cultivated in the world and area under its cultivation is 4th largest following rice, wheat and maize. The major potato producing countries in the world are China, Russia, India, Poland, U.S.A., Germany and Spain. Presently, China is the biggest potato producer in the world and almost one third of all potatoes harvested globally come from China and India.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Potato Production in India

Potato is an important food crop of India and comes third after rice and wheat in terms of production and food security (Dua et al., 2015). India has made tremendous progress in potato production and the per capita availability of potato has increased from 4.37 kg in 1950 to 21.52 kg in 2012 (National Horticultural Board, 2012). India is the second largest producer of potato in the world after China and both the countries put together contribute nearly one third of the global potato production (Scott and Suarez, 2012). Potato is most important vegetable crop in India accounting for 20-25% of area under cultivation of vegetables. In India 46.609 million tons of potato production was obtained in the year 2013 - 2014 from an area of 2.032 million ha with an average productivity of 22.5 t/ha (Jha, 2015). In India, it is a major vegetable crop and is being grown in a wide range of climatic conditions (Pandit & Chandran, 2011). It is grown in almost all states under diversified agro-climatic conditions. Nearly 80% of the crop is grown in Indo- Gangetic plains comprising Uttar Pradesh, West Bengal, Punjab, Haryana, Bihar and Gujarat. The potato growing states and their distribution in different Agro-Ecological Regions (AER) and Agro-ecological sub regions (AESR) are presented in Table 1.

Though it is grown in all the three seasons with diversified soil-management practices, potato is grown largely in the *rabi* season in major production regions of Uttar Pradesh (UP) West Bengal (WB), Bihar, Gujarat and Punjab. The rainy season (*kharif*) potato production is taking place in Karnataka, Maharashtra and Chhattisgarh. However, the potato productivity in India is still very poor as compared to about 45 t/ha in many countries of Europe and U.S.A. (Bansal & Trehan, 2011). Moreover, within the country, there is a lot of heterogeneity in potato productivity depending upon mostly on nutritional management and climatic conditions (Table 2).

For example, Bihar is the 3rd largest potato growing and producing state of India accounting for nearly 9.8% of total potato area and 4.2% of the total potato production in the country, but with very

poor productivity of 7.89 t/ha as compared to comparatively quite high productivity realized in the two neighboring states of UP (21.97 t/ha) and WB (24.7 t/ha). Similarly, productivity is very poor in Karnataka state as the climate is not very favorable for growing potato.

Potato can be grown on a wide range of soils, ranging from sandy loam to loam and best suited to acidic soils (Reddy & Shiva Prasad, 1999). It prefers friable, well aerated, fairly deep soils and well supplied with organic matter. Well-drained light soils are preferred for uniform tubers. The viability of commercial potato production is influenced by spatial and temporal variability in soils, agro climate, and the availability of water resources. Soil site characteristics and agro-climatic conditions greatly influence the choice of variety, land management practices and the economics of production. The inter and intra regional variations in productivity within the country are attributed to the variations in bio-physical factors *vis-a-vis* specific soil-climatic requirements of the crop. However, some researchers reported that the low use of fertilizers and severely imbalanced use of N, P and K fertilizers are some of the reasons responsible for low production of potato in many parts of the country (Bansal & Trehan, 2011). This study concentrates mainly on the land evaluation for growing potato crop in varied climatic conditions prevailing in India and simulation of likely impact because of climate change.

BACKGOUND

Indian agriculture has made tremendous progress in ensuring food security to its vast population with food grain production touching an on all-time record level of 263+ Mt in 2013-14 and estimated requirement in 2030 and 2050 is 345 and 494 Mt, respectively (Rattan, 2014). The country faces a daunting task of meeting future food demands and providing nutrition security to 17.5% of the global population and providing feed and fodder to 11% of the world's livestock population on 2.3% of the land and only 4% of the fresh water resources. The per capita arable land shall shrink from 0.34 ha in 1950-51 to 0.08 ha in 2025. Since, 1970, the net cultivated area has remained around 142 Mha and highly productive agricultural land has been lost due to urbanizaation, industrialization and other developmental activi-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ties which implies that out of total 120.8 Mha of degraded land, more marginal and degraded lands are being progressively brought under cultivation. Natural resources viz. soil, water and biodiversity have been over exploited and have been consequentially degraded due to loss of organic matter, depletion of nutrients, over exploitation of ground water and depletion of carrying capacity of pastures, grazing land etc. posing severe health hazards which need immediate attention.

LAND EVALUATION AND SOIL-SITE REQUIREMENT FOR POTATO PRODUCTION

The natural resources (soil, climatic features and water) profoundly influence the cropping patterns and control crop productivity in specified region. It is well known that the adaptability of crops in one or the other area is the interaction between edaphic properties and existing climatic features. It is also well known that each plant species requires specific soil-site conditions for its optimum growth. Although, the State -Agricultural Universities and Research Institutes have generated voluminous data for crop production through experimentation, it has not been correlated adequately to work out soil-site suitability models for optimizing agricultural land use in the country (Naidu et al., 2009).

Of late, the importance of land evaluation for better land use options has been receiving greater importance. An efficient land use maintains agricultural sustainability. Land evaluation has been defined by FAO (1976) as "the process of assessment of land performance when used for specified purpose. It involves the execution and interpretation of surveys and the studies on landforms, soils, vegetation, climate and other related aspects of land for a comparison between the promising land use and/or specific land use". Soil - site suitability studies provide information on the choice of crops to be grown on best suited soil unit for maximizing crop production per unit of land, labour and inputs. The land suitability for defined use and the impact of the use on environment is determined by land conditions and land qualities (Table 3). The sustainable land use depends on soil resilience. It is a balance between soil restorative and soil degradation processes. Ecologically every factor of environment exerts directly or indirectly a specific effect on growth and development of the plant. The factors such as, the water, temperature, sunlight, soil aeration and availability of plant nutrients directly control the crop growth. However, it

Table 3. Important land qualities and related soil characteristics

Land quality	Land/Soil characteristics
Temperature and light energy for plant growth	Temperature (Max. and Min.), Sunshine hours and day length
Moisture availability in crop growing season	Rainfall, relative humidity frost. Potential evapotranspiration Soil depth and texture and length of growing period
Root development and anchorage	Soil depth, texture in root zone, structure and hard pans
Oxygen availability to roots	Drainage, depth of ground water table, frequency and period of flooding, moisture retention capacity of soils
Nutrient availability in root zone	Organic matter, CEC, base saturation, NPK status and pH
Sensitivity to Soil toxicity	pH, salinity, sodicity, $CaC0_3$, Al and heavy metals
Workability and management	Slope, surface stoniness/rockiness, moisture retention

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

varies from habitat to habitat and determines the suitability of a plant to any particular environment. For planning and effective utilization of soil resources, the information relating to the soil-site characteristics for cultivation of crops is necessary.

Each plant species requires specific soil-site conditions for its optimum growth. For rationalizing land use, the soil-site suitability for different crops needs to be determined. The suitability models provide guidelines to decide the policy of growing most suitable crops, depending on the suitability/capability of each soil unit.

The adaptability of crops in the area is the interaction between existing edaphic conditions and fitness of the cultivar under these conditions. Plant growth requires a reasonable range of moisture and nutrient supply linked to rooting depth, photosynthesis and in turn the biomass production. Each crop has specific growth requirements. Some of the crop requirements are not always directly measurable in the field. They are to be derived from other associated observations. Many workers attempted (Sehgal et al., 1989; Sys et al., 1991; Davidson, 1992) to identify and specify the suitability criteria for different annual crops through land evaluation approach using multivariate regression models with the help of soil parameters and yield data.

The term Land Evaluation was first used in 1950 at the Amsterdam Congress of the International Society of Soil Science, where Visser (1950) presented a paper entitled, 'The trend of the development of land evaluation in the future'. Stewart (1968) then defined land evaluation as assessment of suitability of land for use in agriculture, forestry, engineering, hydrology, recreation, etc. According to Van Wambeke and Rossiter (1987) land evaluation is the ranking of the soil unit on the basis of its capabilities (under given management levels and socio-economic conditions) to provide optimum returns per unit area besides conserving the natural resources for future use. In other words, it is the process of estimating the potential of land for alternative kinds of use. The basic feature of it is the comparison of the requirements of a crop with the resources offered by the land (Dent & Young, 1981). The land evaluation thus is the assessment of land performance for a specific purpose. It involves the interpretation of basic data on the climate and the characteristics of land under the existing land use (Sehgal, 1991). The principal objective of land evaluation is to select the optimum land use for each defined land unit taking into account both physical and socio-economic considerations and the conservation of environmental resources for sustainable use (FAO, 1983).

The generally used methods for land evaluation are Storie index rating (Storie, 1933). Land and soil irrigability classification (USBR, 1953), USDA land capability classification (Klingebiel & Montgomery, 1961), Productivity Index (Requier et al. 1970) and land suitability classification (FAO, 1976; Sys 1985, 1993). These methods differ from each other in the original purpose for which they were proposed, in terms of terminology, in the number and kind of soil properties taken into account, and in the logic of the procedures followed to arrive at a suitability rating (Van Diepen et al. 1991). The Land Evaluation proposed by FAO (1976) defines the basic concepts and principles followed universally. The basic concepts include the land and its major use, utilization type, characteristics, qualities and diagnostic criteria. Land includes soil, vegetation, hydrology, landform and climate. The framework suggested the classification of land in to different categories viz., Orders, Classes, Subclasses and Units. There are two orders namely, 'S' for suitable lands, and 'N' for non- suitable lands; further, three classes (SI, S2, S3) within the order 'S' and two classes (N1, N2) under the order 'N' depending upon the degree of limitations with respect to specific land use. The appraisal of the classes, within the order is done according to the land limitations. The Subclasses reflect the kinds of limitations or major kinds of improvement

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

measures required within these classes. They are indicated by the symbols using lower case letter following the Arabic numeral.

In the land evaluation, there are four steps namely:

1. Characterization of existing soil, climatic and land use conditions
2. Development of soil-site criteria or crop requirements
3. Matching of the crop requirements with the existing soil and climatic conditions and
4. Choosing of the best fit among the crops and selecting the same as alternative crop strategy.

Development of the Soil-Site Criteria

Among the above four steps given above the formulation of the soil-site criteria to meet the crop requirements forms a vital and important step. The land and soil-site characteristics considered in land evaluation are climate, topography and landscape, wetness conditions, physical and chemical soil conditions (texture, depth, CaC03, etc.) and soil fertility characteristics (CEC, BS, pH, EC and ESP). The soil-site characterization are expressed in terms of degree of limitations (0, I, 2, 3, or 4) as per their optimality with respect to specific land use (Table 4). Limitation '3' is considered critical at which the expected yields decline significantly (upto 50 per cent) and the cultivation is considered marginally economical. The degree of limitations as proposed by Sys (1985), ranging from 0 to 4 suggesting no limitation to severe limitation level was used for determining the criteria of the suitability classes. These soil-site criteria are to be matched with the land qualities of each mapping unit of a study area to arrive at land suitability class.

Matching Crop Growth Requirements With Environmental Data

It is an exercise of comparing existing climatic, soil and physiographic conditions with the soil-site criteria with respect to individual crop. The matching of land qualities with crop requirements exercise includes two steps viz. climatic and a soil-physiographic evaluation. Initially, the climate of the soil unit is compared with that of the crop requirements. For this the specific soil and crop-linked growing season is calculated, using rainfall data, in particular, consumptive use of water of the plant as obtained from the calculated potential evapotranspiration (PET), the crop factor and the soil moisture storage capacity.

Table 4. Climatic and soil-site limitations

Limitations	Symbol	Limitations	Symbol
Climatic hazard	c	Erosion hazard	e
Flood hazard	f	Gravelliness	g
Workability	k	Topography	t
Moisture availability	m	Nutrient availability	l
Crusting	p	Rooting condition	r
Texture	s	Drainage	w
Excess of salt / calcareousness	m		

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The second step refers to the comparison of the individual soil and physiographic properties with the crop requirements in terms of nutrient supply, rooting depth, susceptibility to toxic elements and workability. On the basis of the degree and number of limitations identified the suitability class is established, viz. highly suitable (SI), moderately suitable (S2), marginally suitable (S3) and unsuitable lands (N 1 and N2) for specific kind of land use. S 1 classes correspond to areas which have a yield potential above 80% of the maximal attainable harvest within the climatic area. This figure drops to 60% and 40% for classes S2, and S3 respectively. The soil-site requirement for optimum potato production under Indian conditions worked out by Reddy and Shiva Prasad (1999) is given in Table 5.

CLIMATE CHANGE AND ITS IMPACT ON LAND SUITABILITY AND POTATO CULTIVATION IN INDIA

Climate change is the largest threat ever faced by the world as it affects the earth's natural resources widely from tropical to arctic and from sea to land and atmosphere (Pant, 2009). According to IPCC (2007) reports, warming of the climate system is unequivocal and scientists are more than 90% certain that it is primarily caused by increasing concentrations of greenhouse gases (CO_2, CH_4, O_3, CFCs and N_2O) produced by human activities such as the burning of fossil fuels and deforestation.

Table 5. Soil-site suitability criteria (crop requirements) for potato

Soil-site characteristics			**Rating**			
		Unit	Highly suitable S1	Moderately suitable S2	Marginally suitable S3	Not suitable N
Climatic regime	Mean temperature in growing season	°C	16-25	26-30 13-15	31-32 10-12	>32 <10
Land quality	**Land characteristics**					
Oxygen availability to roots	Soil drainage	class	Well drained	Moderately /imperfectly drained	Poorly drained	Very poorly drained
Nutrient availability	Texture- surface	Class	sl, I, ls	s, scl	sil, cl	Heavy c
	Sub-surface texture	class	scl, sil	s, sil	s	Heavy c
	pH	1:2.5	5.5-6.5	6.6-8.2 5.0-5.4	>8 <5	
	CEC	C mol (p+)/kg	>16	<16	<5	
	OC	%	High	Medium	Low	
Rooting conditions	Effective soil depth	cm	75-100	50-75	25-50	<25
	Stoniness	%	0-10	10-15	15-35	>35
Soil toxicity	Salinity (Ece)	dSm^{-1}	>16	<16		
	Sodicity (ESP)	%	Non sodic	10-15	>15	
Erosion hazard	Slope	Hills %	<5	5-10	10-15	>15
		Plains %	<3	3-5	5-8	>8

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The effects of climate change on crop production can be complex. Depending on the temperature regime and the crop, high temperatures can lead to low yields due to increased development rates and higher respiration. However, a short growth cycle can also be beneficial, e.g., to escape drought or frost, and the use of late-maturing cultivars could offset the effect of high development rates. In environments where low temperatures now limit production, global warming could lead to a beneficial lengthening of the growing season and temperatures close to optimal for assimilation. Moreover, global warming is related to the increase of atmospheric CO_2, con- centration, which is likely to increase crop yields, particularly when water limits crop production (Nonhebel, 1993). Increase in atmospheric CO_2 has a fertilization effect on crops with C_3 photosynthetic pathway as Rubisco, the primary enzyme in leaf photosynthesis of C_3 plants, competes better with dissolved O_2 for binding sites on the Rubisco protein when CO_2 concentration is higher and leads to increased photosynthesis and promotes growth and productivity (Allen & Prasad, 2004). However, on the other hand, it can reduce crop duration.

Potato is grown in many different environments, but it is best adapted to temperate climates. Increase in temperature above optimal is reported to decrease in crop yields, particularly due to increased respiration rate (Takashi et al., 2007). At high temperatures (above 17^0C; Stol et al. 1991) tuberization diminishes (Reynolds and Ewing, 1989a). Potato is also frost sensitive and severe damage may occur when temperature drops below 0^0C (Hijmmans et al. 2003). In this regard various reports on climate change have given their views on rise in temperature in the coming years. It is likely that the currently observed trend of global warming, which has been 0.6 °C $\pm$ 0.2 since 1900, will continue and that the average global temperature will increase by between 1.4 and 5.8 °C over the period 1990 to 2100 (Houghton et al. 2001). For the Indian region (south Asia), the IPCC, (2007) has projected 0.5-1.2°C rise in temperature by 2020, 0.88-3.16 °C by 2050 and 1.56-5.44 °C by 2080. Report of Working Group II of IPCC and a few other global studies (Aggarwal, 2008) indicate a probability of 10–40% loss in crop production in India with increase in temperature by 2080–2100. This would lead to more frequent heat extremes, floods, droughts, cyclones and gradual recession of glaciers, which in turn would result greater instability in food production (Aggarwal, 2008). Having look on these data on changes in temperature over the years, it seems that the classes of land suitability in respect of climatic region with special reference to mean temperature during growing season will go on changing and the lands categorized as highly suitable S1 class may become moderately suitable (S2), while moderately suitable S2 will become marginally suitable (S3) class and marginally suitable S3 class will change to unsuitable class up to 2080. As far as the rise in temperature during growing season is concerned in the coming years there will be great loss in potato production in the arid and semi arid regions of India compared to northern India. Increase in temperature and atmospheric CO_2, both are interlinked and occur simultaneously and the CO_2 enrichment does not appear to compensate for the detrimental effects of higher temperature on tuber yield (Singh *et al.*, 2010).

The climate model projections for the Fifth Assessment Report of the IPCC made using the newly developed representative concentration pathways (RCPs) under the Coupled Model Inter-comparison Project 5 (CMIP5) (Chaturvedi et al. 2012) reveals that surface air temperature including night time temperatures are expected to increase further. The all India rainfall and extreme rainfall events are also expected to increase in future. Under the business-as-usual scenario, mean warming over India is likely to be in the range of 1.7-2.0 °C by 2030s and 3.3-4.8 °C by 2080s relative to pre-industrial time. Likewise, all India precipitation is projected to increase by 4-5% by 2030s and by 6-14% by 2080s compared to the 1961-1990 baselines. There is consistent positive trend in frequency of extreme precipitation days (e.g. > 40 mm/day) for decades 2060s and beyond.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Climate change impacts are variable in different parts of the country. Western Rajasthan, southern Gujarat, Madhya Pradesh, Maharashtra, northern Karnataka, northern Andhra Pradesh, and southern Bihar are likely to be more vulnerable in terms of extreme events (Mall et al. 2006). For every 1°C rise in temperature, yield of wheat, soybean, mustard, groundnut and potato are expected to decline by 3-7 percent (Agrawal, 2009).

Potato can be grown on a wide range of soils, ranging from sandy loam, silt loam, loam and clay soils. It prefers friable, well aerated, fairly deep soils well supplied with organic matter. Well-drained sandy loam and medium loam soils, rich in organic carbon are most suitable for potato. Light soils are preferred because they tend to promote more uniform tubers and make harvesting of the crop easier. Studies on climate change impact on soils of the US Great Plains (Follet et al. 2012) shows that soil carbon and nitrogen stocks are strongly negatively related mean annual temperature and positively related to the ratio of mean annual precipitation to potential evapo-transpiration, suggesting that they are equally vulnerable to increased temperature and decreasing water availability. Crop is well suited to acidic soils (pH 5.0-6.5).

Rising temperature and decease in precipitation would also lead to deterioration of water quality. In north east India under the business-as-usual scenario, soil acidification may further intensify under the influence of rising atmospheric CO_2 concentration. This possibility stems from a frequent experimental observation of increased CO_2 production in soil due to increased root and soil microbial respiration under elevated CO_2 atmosphere. As the CO_2 produced this way forms carbonic acid (H_2CO_3) in soil waters, which removes base cations from the soil systems after leaching and produce soil acidity, enhanced CO_2 production in soil under elevated CO_2 can increase carbonic acid leaching and therefore intensify the already existing acute problem of soil acidity in north east India (Kumar, 2011).

Majority of the Indian soils are unhealthy in terms of very low in organic matter content, nutrient status and degradation. About 120.8 Mha constituting 36.5% of total geographical area of the country are degraded due to soil erosion, salinity/alkalinity, soil acidity, waterlogging and other problems (NBSS & LUP, 2008). There is no doubt about climate change as it is happening very rapidly resulting in drastic effects on the environment, particularly on soil system. Soils are the outcome of different soil forming factors and processes which are directly linked to the atmospheric-climate system through exchange of various gases, solar radiation, temperature, hydrologic cycles (Brevik, 2012). Soil erosion rates, driven by the climatic variables like precipitation and number of rainy days and raining intensity, are sensitive to global climate changes. Soil erosion, major factor causing a decline in agricultural productivity and impairing environmental quality, reduces soil fertility and water availability. Direct impacts on soil erosion include changes in the erosive power of rainfall due to changes in rainfall amounts and intensities (Nearing, 2001); Indirect impacts suggest changes in soil erodibility and soil surface covers.

Increased precipitation will increase the surface runoff in hilly lands; increase infiltration and water storage within the soil in the flat lands; enhance ground water recharge in the highly permeable and well drained soils; and increase the evaporation on soils having low infiltration and transpiration in the case of well-developed canopies (Varallyay, 2007). Soil erosion due to water is the major cause of soil degradation (82.6 Mha) followed by chemical degradation (24.7 Mha). About 5.34 billion tonnes (Gt) of soil is eroded in India at an average rate of 16.3 t ha^{-1} yr^{-1} (Dhruvanarayana & Ram Babu, 1983). While 61% of eroded sediments get redistributed on land, nearly 29% are lost permanently to the sea. The remaining 10% are deposited in reservoirs reducing their holding capacity by 1 to 20% annually (Sharma & Singh, 2012).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Rise in temperature will increase the potential evapo-transpiration and decrease the surface runoff, infiltration, water-storage and ground water recharge, especially if accompanied by low precipitation. The influence of global warming on soil processes is more complex and needs elaborate discussion.

FUTURE RESEARCH DIRECTIONS

There is uncertainty about the future climate on different parts of the globe which may have positive and negative impact on the agricultural production and food security. The crops like potato which are more sensitive to soil and climatic conditions may affect badly due to climate change. Better understanding of past, recent and possible future changes in the climate is an important element for developing suitable soil climatic criteria based suitability of cultivation. Further research is needed ideally be targeted at locally relevant climate impacts and risks. The information provided in the chapter is of value to a wide range of different stakeholders in potato production system eager to learn more about future weather and climate of the Earth and its consequences on potato cultivation. Nevertheless, there is broad agreement that the climate is set to shift significantly, and that new cultivation techniques are needed in order to meet the growing demand of potato. Further, research is needed on the improved varieties of potatoes suitable for wide range of soil and climatic conditions.

CONCLUSION

The world's climate is changing, and the changes will have an enormous impact on the globe. There is threat that climate change will impact potato availability, access, and utilization due to change in the climatic parameters like temperature, precipitation, CO_2.etc. It is also expected to increase soil salinity in many part of the globe which may reduce the suitability of potato cultivation on such soils. In addition, the change in environmental parameters may change availability of water for cultivation of this important crop. However, the demand and changing food demand of growing population is crucial and will exaggerate the problem to greater extent. The impact of non-availability of favorable conditions for potato cultivation will lead to more poverty and degradation of land resources. Though the aggregate impact of climate change on future potato cultivation is not fully understood. The changing climate is playing central role in availability of sufficient supply of potato and individual climatic parameters and their interactions are equally important. There is an emerging consensus that systematic soil site analysis will help farmers in decision making on potato cultivation.

Chapter 47
Strengthening Food Security With Sustainable Practices by Smallholder Farmers in Lesser Developed Economies

Leighton Naraine
Clarence Fitzroy Bryant College, Saint Kitts and Nevis

Kevin Meehan
University of Central Florida, USA

ABSTRACT

Smallholder farming has played a key role in reducing world hunger and the focus now turns to consolidating these gains. What practices and policies will enable smallholders to sustain their livelihoods and strengthen food security? Following a brief discussion of agricultural models, and the global shift to sustainable development goals, this chapter examines practices of smallholder farmers in St. Kitts with examples from elsewhere. Assessing what has worked and what barriers continue to limit smallholder success, the chapter offers a list of adaptive strategies, policy recommendations, and areas for future research that can maximize smallholder farming impact on food security. Suggested priorities include: focusing research and policies on individual farm enterprises; moving toward an integrated farm model; adopting best practices in marketing, distribution, and accounting; improving government support; and adapting education programs to include modernized curricula, non-formal education, and the use of ICTs for training and extension at all levels.

INTRODUCTION

Improved agricultural productivity, especially by small and family farmers, leads to important gains in hunger and poverty reduction. (Food and Agriculture Organization, 2015)

Beginning in 1980s, lesser-developed countries (LDCs) witnessed a trend of declining production of agricultural food products, both crops and livestock, while at the same time more developed countries

(MDCs) experienced increased production. As such, LDCs became more dependent on imported food from MDCs. Because of this, and despite their former status as agrarian societies, emerging economies have had to divert scarce economic resources away from other imports, investments, and foreign debt payments to pay for imported food. Even worse, when a dependency syndrome combines with government instability and social conflict, the result has often been hunger, malnutrition, and even famine in extreme cases.

With these dynamics in mind, governmental and non-governmental entities have worked to combat world hunger within a comprehensive United Nations framework known as Millennium Development Goals (MDG). In 2015, the UN Food and Agriculture Organization reported that 79 out of 129 countries had met the MDG benchmark of reducing hunger by one half. Worldwide, hunger has fallen by almost 20% in the past decade with most of those gains happening in the developing world mainly through the increased productivity of smallholder farms, operated mostly as family enterprises. In order to understand this success, and to envision ways of enhancing it to address the problems of the 796 million people who remain in hunger worldwide, this chapter approaches the topic of food security in emerging economies from several angles. After briefly touching on how MDCs have transformed their agricultural sector to become competitive in world food production, the chapter focuses primarily on the concerns of food production and distribution facing the Caribbean and other emerging economies with the input factors of cultural, socio-politico-economic, technological, and environmental conditions, including climate change. The chapter proposes how such economies may be transformed so that food security may be achieved. It presents examples of best practices and scenarios using a simple model of decision-making based on this range of factors.

In exploring food production and distribution in emerging economies, a central claim is that agricultural diversification is essential to achieve local food security and that diversification rests on four pillars: productivity, flexibility, competitiveness, and sustainability. Therefore, this chapter will examine concerns about food security from the perspectives of these four pillars. While some areas may realize high productivity, there is scarcity in other areas, which prompts a concern with food distribution networks in the context of trade and marketing.

All of the concerns can be addressed systematically by the application of a model of the farming system adopted from Waugh (2009). The unit of analysis is the individual enterprise or individual farmer level. The proposition is that if individual enterprises are successful, then national and regional agricultural economies will be successful. The model will address the prevailing conditions in terms of input factors and what decisions can be made in those respects. It also recommends the evaluation of profit and/or loss and a feedback mechanism to the decision-making process.

Main Characteristics of Agriculture in MDCs

Virtually every industrialized nation, for example, Australia, France, Japan, and the United States, has experienced an agricultural revolution (Nebel and Wright, 1996). The agricultural revolution in such countries had one thing in common, that is, significantly higher utilization of farm machinery not only for land preparation but also for planting, application of fertilizers and pesticides, and harvesting. They brought additional land into production, increased the use of chemical fertilizers and pesticides, increased use of irrigation, and substituted new varieties of crops or hybrids. According to Nebel and Wright (1996), all these developments carried an environmental cost, and expanding production by those methods has reached or exceeded sustainable limits. With competitiveness resulting from such significant inputs by

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

MDCs, there has been a worldwide trend since the 1970s in which food production in MDCs has been rapidly increasing while there has been a rapid decrease in LDCs, resulting in greater export of food from MDCs and higher import of food by LDCs.

From findings based on an analysis of 15 select countries using 5 variables (GDP per capita; Percentage of population engaged in agriculture; Percentage of GDP derived from Agriculture; Amount (kg) of fertilizer used per hectare of agricultural land; and Number of tractors per 100 ha of land) Waugh (2009) postulates that:

- The less developed a country, the greater the percentage of its population involved in agriculture.
- The less developed a country, the greater the percentage of its GDP/GNP is made up from agriculture.
- The less developed a country, the less fertilizer it will use.
- The less developed a country, the less mechanized will be its farming.

The lesson here is that MDCs have transformed their agricultural sector with the incorporation of high capital input for the use of improved technology and by bringing larger expanses of land under cultivation, which is in stark contrast to the input made by LDCs. It also indicates that MDCs generally thrust forward with economic development as a priority over the environment, resulting in larger impact of climate change events and environmental degradation. Once the industry is developed, such countries then place increasing emphasis on environmental integrity.

It is not proposed here that LDCs require the same transformations that MDCs have gone through. Nonetheless, with changing conditions and under different circumstances, it is proposed that LDCs build adaptive capacities, while introducing locally innovative, sustainable, and appropriate technologies for mechanization, irrigation, plant science, and non-traditional growing systems to increase their food security as a high priority. Within this scenario, there are opportunities to satisfy local market demands while building niche markets that enable producers to enter the global market.

Main Characteristics of Agriculture in LDCs

Numerous scholars, economists, and leaders of LDCs have lamented the various ways in which the plantation system, imposed under colonialism, has hindered the development of local food production. As such, some main characteristics of agriculture in LDCs are as follows:

- Small-sized farms (less than 5 acres, with the majority being 2 acres or less).
- Parcels are fragmented.
- Land is marginal, on the periphery of former plantations.
- Population is mainly rural-based peasantry.
- Land tenure is such that the majority of farmers are “landless.”

While acknowledging the lasting impact of plantation systems, this section focuses less on that legacy and more on the current availability of land during the past four to five decades or so since many countries have become independent of colonial rule. In general, LDCs have not had transformations in their agricultural sector as did MDCs. This is perhaps in part due to the lack of comparative advantage, vis-à-vis

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

their "later arrival on the scene" and having to compete with an already advanced agricultural economy in MDCs. Moreover, such transformation requires high capital input that is essentially scarce in LDCs.

With rising food prices and increasing impacts of climate change on food production, LDCs are increasingly challenged to maintain basic nutrition from food, alleviate poverty in rural communities, and reduce their relatively high food import bill. Food security has emerged in recent years as a high priority in LDCs and is often tied to building resilience to the effects of climate change. A hypothesis proposed is that the better the livelihoods of people in communities, the more resilient they would be to the vagaries of climate change and environmental degradation.

According to the CARIBSAVE Partnership, based on participation in CARIBSAVE National Consultation Workshops in Caribbean countries, LDCs' needs are ranked as follows, with food security as the highest priority (CARIBSAVE, 2011):

1. Food security (agriculture with improved methods; less dependent on weather – floods and drought, higher productivity on less land; more reliability of production, less impact on environment).
2. Water supply (rationing already exists in some places).
3. Medical supplies and facilities.
4. Education and awareness (at all levels).
5. Food storage (for extended periods of time).
6. Water harvesting and storage and replenishment of aquifers (cisterns, reforestation, conservation).
7. Shelters and Institutional support (some organizations, public services, and disaster management plans already in place).
8. Political will (not only from leaders but also from citizenry – building consensus - can draw political salience and influence public agenda).
9. Legislation enforcement (appears that legislation is already in place).
10. Reduce sedimentation by reforestation and by limiting construction sites near the sea.
11. Avoid building in high risk areas.
12. Fuel storage and alternative sources of energy (solar, wind, geothermal).
13. Fish sanctuaries and fish farms.

Small Island Developing States (SIDS) are perhaps the most vulnerable to the effects of climate change and sea-level rise, given that their populations are largely located on low-lying, coastal communities, and their relatively large percentage of rural populations are living in poverty and engaged in subsistence agriculture. The observations and predictions are pointing to the Caribbean as an area among the most vulnerable to the effects of climate change. Other SIDS in the South Pacific and Indian Ocean are equally vulnerable with respect to geographical characteristics. Food security goals are seriously at risk!

The climate in SIDS and LDCs is mainly tropical, with some variations from equatorial to tropical maritime, and sometimes with a Mediterranean-type effect. More importantly, it is characterized by high rainfall and hot conditions. Heavy rainfall often results in flooding, but also renders our soils vulnerable to leaching and erosion. Higher rainfall and higher temperatures result in higher rates of bio-decay. It is a misconception to think that tropical soils are the richest; this is perhaps due to the year-round and lush vegetation, and also to its history of agriculture as the main source of GDP. Compared to chernozem and peat soils in temperate regions, tropical soils are relatively impoverished. While there are greater opportunities for reforestation in temperate regions, a critical need exists for soil conservation or soil production, for example, by composting or integrated crop-livestock farming, in the tropics in order to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

maintain optimum nutrients in soils for cultivation. Volcanic ash contributes to high soil fertility, but this component also makes these soils easily drained and thus prone to excessive drying in drought conditions.

In light of these characteristics, many of which the Caribbean shares with other developing societies, we can also outline a set of specific vulnerabilities and opportunities for enhancing food production and food security in emerging economies. These areas are examined in more detail in the next section in the context of translating them into "Areas for Strategic Improvement". Additionally, concrete recommendations are given for smallholder farming. Two mini-case studies that highlight what may be termed a dialectic of vulnerability and opportunity are presented. As these two examples make clear, vulnerabilities often create related opportunities that stakeholders of many interests must strive to understand and are challenged to use for individual and collective advantage.

Example

Nigeria: Government Regulation as Barrier and Incentive

In Nigeria between 1970 and 1985, the government implemented a system of complex bureaucratic requirements that made it difficult for businesses to expand (Balogun, 2003). Furthermore, in the early 2000s, regional Nigerian governors established arbitrary areas where business activity was restricted (Ewah & Ekeng, 2009).

In spite of all the difficulties of business management in developing areas, these regions offer several opportunities and benefits to new firms, including undiscovered markets, government subsidies, a burgeoning middle class, and cheap production inputs (Ewah & Ekeng, 2009).

- Population growth. The size and growth of populations in developing countries presents a huge potential market for local businesses, and a ripe opportunity for marketing to help overcome the preference for foreign goods.
- Absence of competition. Due to their underdevelopment and large populations, developing countries have substantial undiscovered or partially served markets. Often these markets are so large that concerns about competition are nearly nonexistent because there is room for so many entrants.
- Government incentives. Developing countries often provide welcoming business environments through lenient tax codes and subsidies for local enterprise.
- Growing middle class. Incomes are rising in numerous developing countries, bringing with them increased consumption and marketing opportunities.
- Cheap production inputs. Labor and raw materials are usually cheaper in developing countries, making it easier to market and operate local businesses (Ewah and Ekeng, 2009).

Example

Latin America: Supermarkets as Threats to Smallholders and Catalysts for Increased Local Demand

The rise of Latin American supermarkets provides an example of the two-sided nature of marketing in developing countries. Grocery stores and markets emerged as dominant players in Latin America over just ten years, increasing from a population-weighted average of about 10 percent in 1990 to over 50 percent in 2000. This can be compared to the transformation in the U.S. that took over 50 years. Large

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

scale supermarkets and manufacturers' entrance into agrifood markets excluded small Latin American farms because bulk purchase methods lowered the farmers' margins. As a result, only farms with sufficient production to reach substantial economies of scale remained profitable. However, the rise of supermarkets provided opportunities as well, in terms of increased local demand and changing consumer patterns (Reardon & Berdegué, 2002).

SUSTAINABLE FOOD PRODUCTION

Sustainability

Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs (World Commission on Environment and Development, 1987)

This quote from the 1987 Bruntland Report, while greeted with controversy by some, is still the most popular general definition of sustainable development. How, though, does the key concept of *sustainability* apply more specifically to food security, smallholder farming, and adaptations in the Caribbean and other developing regions? In assessing the progress made toward meeting the Millennium Development Goals, the UN Food and Agriculture Organization noted several trends that affect developing societies broadly and the Caribbean specifically. For instance, much of the success in reducing world hunger during the MDG period (2000-2015) was attributed to gains in productivity among smaller farms similar to those that define Caribbean agriculture today. The FAO report also noted that growth in hunger eradication was steady but slower in the Caribbean region. This report correlates with the emphasis on smaller compared to large-scale farming that generates growth through a multiplier effect. The report notes as well, a lengthy transition process from former plantation economies to newer systems where stakeholders search for the right balance in allocating resources among local food production, tourism and other services.

As the millennium development goals are superceded by a new set of 17 interlocking benchmarks known as the Sustainable Development Goals (SDG), food security remains a top priority, with "zero hunger" listed as SDG2. The FAO calls for continued emphasis on smallholder and family farms, social protection for small-scale farming such as government purchase of food supplies, easier access to credit and land, and inclusive growth. Effectively meeting these goals depends on gathering more concrete information about what smallholders are actually doing, and identifying recent innovations that have been more (as well as less) successful. Information should also ascertain the next-step scenarios that seem promising based on a review of actually existing practices, and what policy decisions will best protect, support, and spur the sustainable growth of small-scale Caribbean farming.

The next section will highlight current practices with examples drawn mainly from the Eastern Caribbean. This is, followed by discussion of areas for strategic improvement that can immediately begin to enhance smallholder production. A series of policy recommendations and suggestions for future research needs is presented after the discussion.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Smallholder Practices

According to the FAO, "the term 'smallholder' refers to their limited resource endowments relative to other farmers in the sector" (Dixon et al., 2004). Globally, there are about 2.5 billion people who rely on these farms for their livelihoods. Moreover, smallholders produce over 80 percent of the food in parts of the developing world, specifically Southern Asia and sub-Saharan Africa (IFAD, 2013).

New pathways to sustainable food production demand a holistic approach to understanding sustainability at the local and livelihood level. However, any appreciation of the importance of transforming current agricultural livelihoods into sustainable food production systems must include a deeper understanding and appreciation of the role of major assets in transforming the lives of farmers and their households. Financial capital, land, and knowledge of modern farming techniques are key variables and assets for successful application of small-scale back yard gardening. According to the FAO (A Tool for Gender-Sensitive Agriculture and Rural Development, 2013), inequalities in distribution is linked to women's underperformance in agriculture, but increased investment in smallholder farmers (women in particular) is a pathway out of poverty.

Home Food Production: St. Kitts-Nevis Case Study

A 2010 survey of former sugar workers in St. Kitts-Nevis (five years after sugarcane production ceased) revealed that the best route to alleviating poverty amongst the vulnerable grouping was to reconsider land distribution options and to promote backyard farming as a viable option for food security and livelihood resilience (Clarke, 2013; Naraine, 2005). Former sugarcane workers presented a unique opportunity for understanding how deeply engrained cultures of resource distribution can affect use of land and potential vulnerability.

The growing concerns for land are not only shared by those with livelihoods directly dependent on the asset, but also by the population at large. The former female sugarcane workers were also assigned to farms. The success of this program was short lived with many women distrusting the process of large scale group farming. It is clear that campaigns at the end of sugarcane production which sought to distribute land to every Kittitian did not do much to solve the problem of vulnerability amongst former workers. Larger plots of land distributed to women were burdensome and demanded help, money and access to social capital that was weak or non-existent in their households and extended community networks. Land as a route to diversification and resilience was therefore seen as a burden, not an asset. Increased access to land did not equate with a reduction in vulnerability or an increase in the sustainability profile of livelihoods or production systems, since land was not put to productive use. The lesson learnt was that land resources, a crucial asset in sustainable production and livelihoods, must be distributed according to capital access that makes for optimum use. Based on this, recommendations were made for backyard farming as a viable option.

A sustainable approach to backyard farming starts with a food security oriented approach to land distribution. The FAO (2013) outlined clearly that women face a range of constraints in their access to productive resources such as land, inputs, training and financial services. Giving them access will very well translate into lifting millions out of food insecurity! Land distribution policy must, therefore, include distribution of larger sized residential plots at reasonable rates to provide ample room for backyard gardening.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Backyard gardening must be carefully and delicately guided through instruction in using small spaces for growing vegetables and other food crops. However, backyard gardening can harness all the techniques and skills of the local population without heavy reliance on external inputs. This may encourage more organic approaches to food crop management, as well as non-traditional agricultural systems (for example, hydroponics, organoponics, aquaponics, and hybridponics) which are adaptable to rural, sub-urban and even urban areas.

Protected Agriculture: Shadehouse Model

Protected agriculture has been reintroduced recently into the Caribbean region with the construction and commissioning of tropical shadehouses and greenhouses to increase year-round local production and in an effort to reduce imports.

At the Clarence Fitzroy Bryant College (CFBC) in St. Kitts, researchers, students, government agencies, NGOs, business and community-based stakeholders have partnered to develop a new Climate-Smart System that blends shadehouse protected agriculture with a combination of hydroponics, organoponics, and hybridponics growing systems. The term hybridponics was coined to describe a system in which a seedling is removed from a hydroponic system and transplanted in an organoponics system to complete the growth process. Proven benefits from the Climate-Smart System include the following: year round rather than seasonal production; no leaching of nutrients to the environment; no use of pesticides; no weeds; high nutritional values; maximum production in confined areas; efficient use of water; less labor intensive; can be used in any local location; sustainable; and promotes gender equity. Subsequent to developing a best-practices routine, and commercialization model for a 24' x 20' enclosure, the CFBC system was funded by the Organization of American States for implementation in Guyana, Haiti, Barbados, Trinidad and Nevis.

Pig Farming

Over the years Caribbean pig farmers (for example, Bounty Farms, Guyana; St. Catherine, Jamaica; Plum Tree Farms, St. Kitts) have witnessed a slow but needed transition from poorly kept operations in backyards where pigs were left outdoors in muddy pens to formal operations with enclosed housing complete with concrete floors (see Figures 1-3).

This transition has seen the improvement in techniques for waste management including, use of sewer systems, and heavy reliance on water pumped to the farm site for washing pens.

Local breeds of pigs have been known to mature with a high fat content. The introduction of Yorkshire White and the Duroc (and cross-breeding of the two for meat quality) has drastically increased stock and stock quality. Along with the improvement on stock is the improvement in the variety of pig rations to include starter and grower ration. These upgrades are supplemented with regular visits by Veterinarians to the farmers, especially for disease control, breeding and farrowing. Agricultural staff undergo continued training in disease monitoring and controls. These key inputs have been integral in the cycle of sustainable livestock production.

As these practices make evident, even accounting for the systemic challenges associated with emerging economies, important opportunities exist for smallholder farmers to position themselves more favorably,

Figure 3. Old style of pig housing

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

particularly with strategic assistance from government agencies. In this dynamic, based on sustainable agricultural practices, more consumers of food become producers, and food security is increasingly based on a "many-to-many relationship," with the many feeding the many.

AREAS FOR STRATEGIC IMPROVEMENT

Vulnerabilities and Opportunities for Food Security in Emerging Economies

Sound fundamental business practices are key to building successful agricultural operations. In preceding sections, this chapter explored sustainability, integration of different farm components, and efficiency as they relate to agricultural development. However, creating and managing profitable farms requires additional considerations outside the scope of these internal elements. Here, the conversation turns to the role of basic economic and financial concerns, with an emphasis on marketing and distribution.

Before delving into areas for strategic improvement of smallholder business practices, it is important to better understand the context of operating in a developing economy. Developing economies exhibit three principal characteristics: low incomes, high variance in consumer preferences and infrastructure quality, and relatively cheap labor costs, leading to substitution of labor for capital (Dawar & Chattopadhyay, 2002). Managing a farm in these countries raises unique challenges that revolve around the local social, political, economic, and cultural factors. Specifically, these operational obstacles include low business education, preferences for imported goods, deficient infrastructure, strict government regulations and interference, political instability, and social conflict (Ewah & Ekeng, 2009).

Although there are inevitably several challenges to doing business in developing areas, these regions also offer several opportunities and benefits to small farmers. Consider, for example, that 70 percent of the global poor live in rural areas and rely on agriculture for income and employment (World Bank, 2015). In spite of this gloomy statistic, local farmers are in a unique position to be successful due to their self-employment (free labor), agricultural expertise, and familiarity with the local environment (FAO, Trends and Impacts, 2012). Several of these vulnerabilities and opportunities are now discussed with a focus on identifying concrete recommendations for strengthening food security in emerging economies.

Marketing and Distribution

The act of marketing a good or service is prevalent in nearly all aspects of life. The American Marketing Association (2005) defines marketing as "the activity, set of institutions, and processes for creating, communicating, delivering, and exchanging offerings that have value for customers, clients, partners, and society at large." Marketing helps farmers to find the customers who need their product most (efficient resource allocation), and enables two-way signaling between farmers and customers so that both sides can communicate needs and offerings (Timmer et al. 1983).

Although marketing is a crucial step in the communication between potential producers and consumers, sales cannot occur without the physical distribution of produce. To understand how agricultural firms transport their goods from the farm to shelves or tables, it is important to appreciate the role of distribution in the larger context of food security.

Food security literature focuses on resource access, distribution, and closer connections between producers and consumers as principal issues of concern (Vervisch et al. 2013; Murphy, 2001; Edelman,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2014; Kelly & Schulschenk, 2011; McKenzie & Woodruff, 2015). Several factors help determine the efficacy of distribution, including markets, transportation infrastructure, patterns in consumer demand, and the characteristics of supply. Governments in developing countries have traditionally intervened in food distribution networks by purchasing produce from growers and selling it to consumers nationwide, often at subsidized prices.

Government involvement in production and distribution had both positive and negative effects on farmers. For instance, African governments had interfered with farmers for years by purchasing agricultural produce at less than the cost of production in order to provide cheap food to nearby urban centers. When reforms disbanded this handout program, farmers were initially grateful. However, growers soon realized the restructuring of government activity left them in a void with no alternative to the state-run marketing and distribution arrangement. As a result, farmers either were unable to take their products to market or were forced to rely on private companies to fulfill all the functions previously managed by the government (Murphy, 2001).

Example: The Internet

The Internet not only simplifies distribution for both producers and consumers, but also other market stakeholders including food processors, restaurants, and retailers. Online connectivity helps the entire agribusiness market chain to stay abreast of price changes and production estimates. Furthermore, the Internet facilitates cooperation among farmers, helping them to protect their interests even when separated geographically. As a result, developing countries have seen the emergence of farmer-collaboratives that depend on web marketing to connect directly with consumers (Murphy 2001).

Farmers in South Africa's Stellenbosch region used virtual networks and communication to develop a stronger local food structure by helping local farmers produce more of what was actually needed, and closing the gap between consumers and producers. Moreover, food networks that operate at a community level, including community supported agriculture initiatives (CSAs), farmers' markets, consumer cooperatives, and local distribution centers, can shorten the value chain and help farmers retain more of the retail price (Kelly & Schulschenk, 2011).

Local communities are more receptive to direct marketing, but many poor consumers are not aware of the nutritional content of their food and produce. They also lack knowledge on how to prepare and incorporate new ingredients into meals. Thus, education is an important part of marketing in developing countries. Offering classes on cooking with healthy ingredients, providing free samples, and suggesting convenient recipe ideas are creative ways to persuade local customers to incorporate less familiar fruits and vegetables as ingredients in their diets (Hu et al. 2013).

Smallholder distributors might also consider the existing social network as a favorable marketing prospect. These avenues allow farmers to interact with larger groups and build a sense of pride around locally grown food. For example, small farmers working to attract potential clients can use community centered events as great venues to showcase their produce in educational and interactive ways. Farmers' markets also provide excellent social opportunities for farmers to engage customers and discuss their products, growing methods, and food preparation ideas (Hu et al. 2013).

On a smaller-scale, farmers can take advantage of the fact that community leaders and older citizens are often influential voices for younger generations. Utilizing these groups as marketing allies, lends credibility to the case for healthy eating. Furthermore, these members are in a unique position to model healthy lifestyles for younger generations that would otherwise be unresponsive to these lifestyles. Build-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing support among younger generations adds a new level of consumers that will continue to purchase goods into the future. Moreover, they broaden the word-of-mouth marketing team and help to access a new segment of local consumers (Hu et al. 2013).

Convenient distribution plays a significant role in augmenting innovative marketing efforts. Anticipation for products builds in direct correlation with a farmer's ability to demonstrate affordable pricing, appropriate location, and high frequency. In their surveys of poor areas, Hu et al. (2013) found many participants to be interested in a wide variety of mobile distribution mechanisms, for example, food carts, farm stands. Local customers also identified consistency, price-competitiveness, and frequent advertisements as contributing to their reasons for patronizing particular sellers. According to buyers, there was a huge benefit to knowing in advance what produce would be offered by which farmers (Hu et al. 2013).

Case studies focusing on horticultural marketing abound, and readers interested in the more detailed analysis based on a range of cases can access the references cited in this chapter. For summary purposes, several common threads unify the discussion about marketing for small farmers:

1. Perform basic market research and incorporate the results into decisions made about production and distribution. Dixie (2005) and Mafaru et al. (2007) both offered extensive commentaries on how farmers and farmer co-operatives in Bangladesh, India, Mozambique, South Africa, Tanzania, Yemen, and elsewhere effectively analyzed market conditions across a range of products and scales.
2. Cooperate in order to pool resources and experience, achieve economies of scale, ensure smooth supply, and increase market negotiating strength. Efforts of women farmers and craft workers in Bangladesh are detailed by Dixie (2005).
3. Innovation and forward thinking. Mafaru et al. (2007) provided details on the ability of Tanzanian farmers to effectively control and optimize sales of tomatoes and other crops to local and regional hotels. This was achieved by assigning leadership roles and building an organizational structure. A case study from Uganda provides a discussion of effective tribal leadership resulting in improved onion production in Yemen (Alimuga et al. 2007; Dixie 2005).
4. Cut out middlemen and engage in direct sales whenever possible. Dixie (2005), in his discussion of onion farming in Yemen, provided an insightful discussion of how to increase and benefit from direct sales.

Agro-Processing

After all costs have been paid for land preparation, irrigation, planting, maintenance, and harvesting, and such like, an enterprise is expected to achieve profits from the sale of produce. Post-harvest loss continues to pose high risk to farmers when produce is not sold due to lower market demand. One way to reduce post-harvest loss is by processing of produce, while adding value to the items. It appears that locally packaged produce are not competitive and the perception of farmers or entrepreneurs is that they have to lower their prices to compete with imported packaged foods. However, indications by agro-processors in some Caribbean island nations are that there is a demand for locally packaged foods with growing preference by tourists and local residents alike. Moreover, they are likely to be more "fresh" than the imported packaged foods which have generally longer shelf-life and higher quantities of preservatives.

Furthermore, when foods that can otherwise be produced locally are imported, the local economy loses out on the multiplier effect of farming activities. Therefore, it is prudent to build an economy around the primary sector, with import substitutes where possible, while reducing dependency on imported foods.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Although many emerging economies have had their primary products as raw materials for trade, agro-processing adds value to primary products either for local consumption or for exporting.

Food processing is an extension of the postmodern agricultural industry that involves different sectors such as; research and development, equipment investment, production and marketing management. The processing industry needs to integrate different technologies and production equipment to make mass production possible. Data from the Agro-processing Unit, St. Kitts, show that juices and snacks have a high market demand. The juice revenue ratio is 37.2%, while that of snack foods is 29.2%. The St. Kitts and Nevis food service sector country report of 2006 stated that snack food is the third largest imported food in terms of volume and juices are the fifth (the sequence is; meat, seafood, snack food, processed fruits and vegetables, and juices). Based on this information, there is an opportunity to create economies of scale in juices and snacks in St. Kitts and Nevis.

The St. Kitts-Nevis experience in agro-processing, with infrastructural and technical support from the Republic of China (Taiwan), has been growing steadily over the past few years and still has significant room to grow the meet local demand. There is potential to grow multiple times even with local demand.

ADDITIONAL CHALLENGES AND ADAPTIVE STRATEGIES: TOWARDS A MODEL FOR SUCCESSFUL SMALLHOLDER FARMING

In a 2005 study in the Caribbean small island nation of St. Kitts-Nevis it was found that the characteristics of farmers are representative of SIDS (Naraine, 2005). These findings are detailed below under three general headings: A model for smallholder farming that is 1) diversified and scalable; 2) operational adaptations; and 3) educational and organizational adaptations. Each individual finding will be followed by an adaptive strategy or strategies taken from case study findings of best practices.

Diversified and Scalable

Finding: *Of all commercial farmers, 60% operate on a part-time or seasonal basis.*
Finding: *Farming households are generally larger (about 65% between 3-5 persons) as compared to the national average of 3 per household.*
Finding: *About 60% of farmers operate individually, not as part of a company.*

The first data point indicates that a majority of farmers are not fully-involved in farming and therefore are not likely to depend on farming alone as a source of income. Related to that finding, 30% of all farmers have other occupations. Instead, there is a growing trend in "backyard" and urban gardening on a small scale requiring less time for operation. Production can be in containers where land is not available. It will also maximize productivity with minimal time and with optimum soil nutrients, moisture, and solar radiation (lighting and heat intensity) in the containers. Such a growing system is referred to as organoponics (Naraine, 2005). It can further save time through less weeding and tillage and can adapt to varying weather conditions. It can also expand to varying scales with some not requiring shade, or shade can be introduced by trees. Organoponics can progress to full time farming with the greater attributes and benefits than on a small scale, such as the opportunity to diversify crop types. As it increases in scale, the advantage will grow exponentially, as in the case study of ALT enterprise in St. Kitts, an integrated system with livestock to produce manure and recycling of nutrients among crops and livestock. Scaling

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

up still higher towards commercial and more diversified cropping, a mix of farming types and systems can be introduced, for example, hydroponics, hybridponics, open-air organoponics, and low tillage and point tillage. This facilitates increased sustainability, flexibility, efficiency, productivity and risk reduction. Sustainability and flexibility are key features of adaptation to effects of climate change. A more diversified system is also suitable for natural-biological pest control mechanisms by promoting a farm ecosystem with natural predator-prey relationships and symbiotic feeding relationships. It also promotes the recycling/reusing of water for various farming activities. Moreover, the housing for livestock can be utilized for water harvesting. Many organic materials, whether from crops or livestock, can be composted or processed into ground cover to enhance soil water retention capacity. Compost has the unique ability to improve the chemical (nutritional), physical (structural) and biological characteristics of the soil or growing media which is beneficial to plant growth.

With higher productivity and less labor input required in non-traditional agricultural system, this will enable the formation of true family farms with small households. Higher productivity can also attract other household labor or business partners for shared benefits. The data shows a 60% preference for individual enterprise, which may in fact be due to inadequate training in business techniques. Notwithstanding this, the ALT enterprise in St. Kitts teams up with young entrepreneurs, for example, Standard Hydro, to introduce a hydroponics facility as an addition to its already integrated farming concept. Existing employees partner with others in the various activities or aspects of the total enterprise. In such a partnership, all parties benefit from training in business techniques, including marketing and entrepreneurship.

The Diversity of Jobs and the Multiplier Effect

Finding: *Among the almost 150 farms surveyed, only about 50 persons are employed on about 30 of those farms. There is an almost even distribution of male and female employees working on an occasional basis among those 30 farms.*

Farms should not be viewed only for employment directly on farms. The economy around farming has a multiplier effect in which employment and commerce is created for related businesses, whether directly or indirectly, for example, insurance, retail and/or wholesale shops, traders, and transportation. Oftentimes, food supply is not always the problem for food security and availability, but the problem is marketing and distribution of produce. There is a great potential, based on the results of a needs' assessment conducted in St. Kitts-Nevis, Dominica, and St. Lucia, for labour market information (LMI) to inform the introduction of a new agri-business curriculum at local colleges. The LMI indicated a need for entrepreneurs devoted to marketing and distribution, while creating more employment related to the agricultural sector.

Income and Livelihoods

Finding: *Over 80% of all farmers reported annual household income of less than EC$35,000 (USD$12,900) consistent with the national median income of about $20,000 (USD$7,400) per person with two persons in the household employed.*

Finding: *About 70% of all farmers indicated that less than 25% of their household income is attributed to farming activities.*

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Backyard gardening and non-traditional growing systems on a small scale are excellent for increasing household income, given the part-time nature of farming activities on a small scale. An important consideration in the income equation is that household food bills are reduced when they can supplement their diet with food produced by themselves or bartered with other growers. Moreover, it is a way of building resilience to climate change through better livelihoods.

Operational Adaptations

Land Tenure and Use

Finding: *Very significant is that about 75% of land occupied by farmers is government owned (they are illegal occupiers).*

This is perhaps the most challenging problem for farming to achieve food security in the Caribbean region. Simply put, land is tied to politics. With all the adaptive strategies that farmers use to reduce dependence on land by increasing productivity using non-traditional growing systems, that alone is not sufficient to achieve food security and make agriculture a viable economic activity. Ultimately, agriculture requires more land under production and the development of irrigation. Farmers are less likely to invest in infrastructure and technology when they do not own the land or have secure tenancy agreements. It is also the case that some farmers have the mindset that if they acquire land either by renting or illegal occupation that they would eventually own the land or have infinite access when it may become regularized. There is widespread evidence that some farmers hold onto relatively large parcels of farmland but with little farming activity. In this scenario government, on the one hand, has limitations to its land management policy and, on the other hand, with some farmers not utilizing farmland to the optimum when they have access. In some cases, farmlands remain totally unproductive for years and even decades. Moreover, prime agricultural land cannot compete with other land uses such as for tourism, housing, and manufacturing. Land-use planning would show that some of the best agricultural soils are not always used for farming. There are adequate policy tools and options available to government, but it is unequivocally a matter of choices that rests solely on the political will and ethical principles with regards to land management practices. Where such practices fail, the option for farmers is only with non-traditional growing systems, such as hydroponics, organoponics, and aquaponics, as adaptive strategies to increase productivity. Non-traditional systems can operate in diverse environments such as marginal land, low freshwater availability, backyards, and urban centers. This option when practiced on a small individual scale but on a more widespread basis can have a cumulative and positive impact on food security.

Housing and Losses from Theft, Nuisance, and Predators

Finding: *Many farmers do not live in the same parish as the farm location which poses a problem for surveillance, theft, security*.

Finding: *Monkeys, theft/praedial larceny, and stray roaming livestock, in addition to diseases and pests are significant problems for crop production, but dogs and theft are problems for livestock.*

Losses from theft, nuisance, and predators are perennial problems with smallholder agriculture, especially when the farmer's plot is located at a distance from home. Where government policies prevent

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

housing of people on farms, this presents a barrier to preventing such losses. It is also not feasible for persons to build homes on land on which they are renting or illegally occupying. Backyard farming is definitely one way to combat the issue of theft and praedial larceny, but more extensive farming also has a role to play in food security. On larger smallholder farms, one way of increasing the human presence is to build temporary cabins where workers can dwell. This solution can help to lower living expenses of farm workers, while having mutual benefits to workers and owners if occupation is rent-free, in exchange for surveillance. Cabins have added benefits to their uses by providing a mechanism for water harvesting from rooftops. Additionally, living in cabins on the farm site gives the option of flexibility of work hours so that work can be performed in the cool hours of the morning and late afternoons, as well as on weekends when some routines have to be performed.

While small ruminants are vulnerable to dog attacks, poultry and pigs are protected in pens or cages. It is not feasible to raise ruminants on small plots of land, and this type of farming is more suitable for large operations or designated areas in small countries where they are protected and monitored.

Irrigation

Finding: *About 50% of all commercial farms are below 1 acre in size, with a combined total of about 70% being less than 3 acres, or 75% being less than 5 acres and are predominantly rain-fed or lack consistent water supply.*

Finding: *About 60% of all farms use irrigation and about 70% of these use overhead sprinklers. However, about 60% of those irrigating depend on rain-fed supply.*

In a traditional setting, those farm sizes are too small. It is also not feasible to make the input of costly infrastructure and irrigations systems when farms are small and fragmented. Followed by land availability, water is of utmost importance to increasing productivity and food security, and therefore, government support is essential on both fronts.

The introduction of non-traditional growing reduces the amount of land needed to be productive enough for both subsistence and production at higher scales. However, communal infrastructure may be beneficial to serve several farmers, for example, the system of empoldering found in Guyana and Suriname. Empoldering is essentially a technique of Dutch origin, involving irrigating large expanses of land (thousands of acres) with irrigation and drainage canals running in parallel but with varying levels. The water is supplied from lakes or conservancies (where lakes do not exist, dams can be introduced to form a conservancy) into the irrigation canals and utilized on farms. The spent water is discharged in the drainage canals that are at a lower level than the irrigation canals. The water is regulated by sluices at various intervals along the canals. An overseer for the commune or empoldered area monitors fairness in distribution and usage, with the added benefit of surveillance on farms. In environmental conditions where there is sloping land or porous soils that do not retain surface water, irrigation pipes with open-shut valves can be used to regulate water from artificial reservoirs in higher elevations where rainfall is available. Furthermore, in environments where freshwater is scarce or prone to drought, the problem is typically not a lack of water entering the drainage basin but insufficient water retention or harvesting. In SIDS, the water drains efficiently and rapidly into the sea. Artificial dams and reservoirs are required to increase water retention and availability to replace rain-fed agricultural practices that are prevalent in SIDS.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Where freshwater supply is scarce, drip-irrigation is most effective to conserve water. Drip irrigation is focused on the root systems and minimizes evaporation that is higher when water sprinklers are used. Mulching is also recommended to minimize evapotranspiration, with the caution that plastic mulch also reduces utilization from direct rainfall from which some crops can benefit, although plastic mulch prevents leaching and erosion. Mulch from biomass has beneficial effects in water retention, and also in the control of certain pests. Using mulch is also a way of recycling nutrients from the farm, and it can also be added to compost and then utilized as organic fertilizer instead of mulch. A technique that is used on a large scale in arid and semi-arid conditions is the development of swales simply by creating a depression on the land and piling organic matter from plant cuttings. It is allowed to mature by decomposition and then used for planting of crops. Swales thus enhance soil water retention and increase available organic nutrients.

Livestock, Soil Maintenance, and Feed Supply

Finding: *Livestock are traditionally of five main types: cattle, goats, pigs, poultry, and sheep. Poultry is used mainly for eggs with an insignificant production of broilers resulting in a heavy dependence on imported chicken.*

Finding: *There is a prevailing high demand for food crops and livestock products, but typically an inadequate domestic supply. As such, there is hardly any difficulty in finding a market or needing long-term storage.*

Mixed farming with integration of crops and livestock are found to be more successful (Naraine, 2005). The key to their success is the mutually beneficial effects with recycling of nutrients by which crops benefit from organic fertilizers and livestock benefit from plant matter or unsold produce. As noted previously, in item #1, such farms have achieved optimum diversification with as many as 5 types of crops and livestock combined. Diversification reduces risk.

There are opportunities on mixed farms to produce soil and reduce the need to buy fertilizers. Additionally, aquaponics or fish ponds on farms are excellent for irrigation of plants instead of using chemical fertilizers, while productivity is increased with fish supply, for example, tilapia as a source of protein in our diet. It is not unusual to see soil imported from MDCs for use in LDCs, a practice that is appalling in view of the high feasibility of producing soils locally. Mixed farming is one way to produce soils on a small scale, but there is also the potential in LDCs to produce soils on a large scale, considering that biomass and topsoil from clearing land for construction of residential and commercial properties end up in landfills and dumpsites.

The major issue with production of pork and poultry is the cost of feed. In most cases, there is no local production of feed for pigs and poultry, and when it is produced there is a higher demand than supply. The cost associated with importation of feed, storage, and the short shelf-life before degradation, is essentially too high a risk to render it feasible for farmers. Some pig farmers utilize the spent grain from local breweries as a supplement to imported feed. Poultry for egg production is generally more feasible compared to broilers for meat that require high amounts of protein in a relatively shorter time span than for layers that continue to produce eggs well beyond their rapid growth stage. The production of feed remains more feasible in large countries, for example, Brazil, Guyana, and Suriname with large

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

production of rice, corn, and soybeans. A better system of marketing and distribution is key to supplying SIDS with meat or raw materials from which countries can manufacture feed locally instead of importing feed for which shelf-life and transportation cost present challenges. The local production of feed, even if it were from imported ingredients, can be an opportunity to ensure reliability of fresh supply and higher-quality meat than those imported and frozen for extensive periods.

Capital Investment and Land

Finding: *With regards to farm assets, real property averages only about EC$12,000 (USD$4,444).*

This level of investment is very low in view of the importance of the role of local food production to achieve food security. Essentially, farmers are not willing to invest, maintain, or improve land that they do not own. However, this low level of investment is generally adequate for backyard gardening and non-traditional growing systems at small scales, particularly in small spaces that they own or lease long-term.

Capital Investment and Machinery

Finding: *Heavy equipment averages about $25,000 (USD$9,300) while light equipment averages about $3,000 (USD$1,100), with almost all farms having light equipment.*

Heavy machinery is typically owned and operated by government agriculture departments to give support to farmers. However, these operations are typically inefficient and their machines are often inoperable or in need of maintenance. Therefore, farms, both small and large scale, are not highly mechanized. In isolated instances, there are private owner-operators who contract with various farmers, but there is still a general scarcity of heavy machinery when needed. Where agriculture associations or co-operatives exist, there can be opportunities for community owned machinery with a fee structure that is proportionate to hours of use, but with the fees as primarily a means of covering operation, maintenance, and replacement costs.

Access to Credit

Finding: *Less than 15% of all farmers receive farm input credit, with the main source of credit being private lending institutions, with as much as 13% interest rate*.

Vulnerability in this aspect stems from lack of business skills. Education in business practices and entrepreneurship, addressed below, will lead to better outcomes with banks or other lenders or mechanisms. The Bangladesh model of micro-financing with the now controversial figure of Muhammad Yunnus has had extensive impact in bringing millions out of poverty. Each nation or community has its own circumstances and a solution in one area may not apply in other areas. The lesson to be learnt is that micro-financing is essential for development of communities practicing small-scale farming. Mechanisms can range from formal programs by banking institutions or development banks, to informal small circles of people in communities who pool monies and lend to members on a rotational basis.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Educational and Organizational Adaptations

Agricultural Education and Youth Engagement

Finding: *About 70% of all farmers are between the ages of 35-54 years old, contrary to the literature that suggests most farmers in St. Kitts are older or retired and younger people are not interested in farming*.

However, youth involvement is not fully utilized and has a great potential with non-traditional growing systems such as hydroponics. This was noted in higher enrolments in college programs, for example, at the Clarence Fitzroy Bryant College, in St. Kitts and Nevis with emphasis on this increasingly popular technology. Youth engagement can be achieved by educating more persons to get better results and also by using social media to network farmers to share experiences and knowledge of best practices. According to Simoes et al. (2010), education is a key to adaptive capacity and building resilience through greater understanding of the natural environment and knowing how to develop sustainable systems to increase productivity. Furthermore, with formal and non-formal education, all age-groups, socio-economic groups, and women can be targeted so that a greater percentage of any human population can enter into economically productive activities. The OAS-funded project under the theme, "Transfer of knowledge in science and engineering, and the promotion of innovations and entrepreneurship" engages all age groups, male and female, from formal and non-formal educational backgrounds in non-traditional agricultural systems and is networked through social media. The non-traditional growing systems are suitable for greater inclusion of women, youths, and those physically challenged or with health issues. This is possible because of the lower physical stress required to operate such systems.

Popular Education and Vocational Training

Finding: *Less than 15% of all commercial farmers have attained technical and/or vocational training*.

The OAS-funded project, referred to previously, includes an educational response through a toolkit, a formal curriculum, and a non-formal educational documentary on non-traditional agricultural systems that can be delivered as a short-course with a competency-based approach.

Entrepreneurial Training

Finding: Economic: *About 80% of all farmers do not keep business records and over 90% do not have a farm business plan*.

Related to improved credit access, and arguably a more important adaptive strategy, is business education to do better planning and minimize risks. Formal and non-formal competency-based training with incubation support is prudent, irrespective of whether or not it is from micro-financing sources or self-funded enterprises.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ICTs and Extension Services

Finding: *The majority of farmers by far, receive farming information from radio and other farmers; not from the Agriculture Department.*

With recent developments in smart phones and widespread availability and connectivity on the Internet, there is greater opportunity for information sharing and networking around farming interests. Agriculture Departments can utilize ICTs to disseminate quality information to farmers. One effective arrangement is to have a space in each local community or farming area designated for Extension Officers to set up on-going sessions for demonstrations, experimentation, information dissemination and training on current issues relevant to that area. Too often, Extension Officers spend more time at their offices at a central location, where they also conduct sessions.

Professional Organizations, Political Impact, and Extension Services

Finding: *About 90% of all farmers do not have any membership or affiliation with agricultural based organizations, and there is scarcely any organized farming group.*

With more education, people are more likely to understand the importance of organizing around agriculture. Formal and continuing non-formal education is perhaps the most effective strategy for engaging a generation of more knowledgeable farmers. Although there may be several registered organizations in some communities, membership is low and meetings are infrequent and not effectively organized around issues that are significant to the development of the sector. Encouraging more of such organizations is now likely to yield greater success if guided to overcome these constraints. For this reason, there is a greater need for government agriculture departments to play a more active supporting role and be held more accountable to farmers.

POLICY RECOMMENDATIONS

We yearn for economic systems within our control, within our comprehension and that once again provide space for human interaction – and yet we are constantly overwhelmed by finding ourselves trapped into vast global economic systems that are corrupting and corrupt. (Bunting)

Recommendation for Policy Design and Implementation Strategy

At the apex of the hierarchy of needs—and the most important ethical responsibility faced by policy makers in emerging economies—is food security. Efforts to achieve this goal must begin at the household or individual farm enterprise level to meet basic nutritional needs and to combat hunger and malnutrition. The issues, case studies and examples, and adaptive strategies detailed in the previous sections reveal that land reform is essential to transform agricultural economies.

Land reform in LDCs has not been getting traction either because there is no perceived prospect of competing with large agricultural economies in MDCs, or the power is in the hands of resistant private or public elites, or both. Numerous policies at regional and national levels as well as those outlining

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

sectoral strategies have been formulated with attempts for improvement of this situation. However, they have generally not been fulfilled due to failures at implementation, primarily because of insufficient budgetary support for implementation at the individual farm level, compounded by poor management and governance at all levels.

There has been growing success of smallholder farmers and backyard gardening throughout emerging economies of the world. This phenomenon has had a significant positive impact on world hunger despite myriad challenges. Based on this, policies should be focused in support of adaptive strategies, at least in the short- to medium-term, so that the trend can be continued and multiplied.

The approach should be at the enterprise level where individual farms can be assessed in terms of sustainability along input factors of land tenure, culture, technology, economy and trade/markets, and environment. Consideration should also be given to their output in terms of household benefits such as nutritional requirements, livelihoods, and building resilience to climate-related vulnerabilities (Waugh, 2009). Incubation centers can be introduced as a mechanism to minimize risks of farms that are not successful as well as to support new (and hence vulnerable) farming enterprises. Extension efforts should be restructured in terms of location and delivery formats to aid implementation in this framework or model. Extension should also expose smallholders to the benefits of integrating additional components and supporting efforts to create more integrated enterprises through effective communication. There must be policies to incentivize cooperatives and other strategies for expanding the enterprise to the next level in scale of operations.

In the long-term, in the face of long-range forecasts about climate change impacts, farmers and communities need to continue their fight. They should make representation to their elected officials on the basis of ethical responsibilities for decisions to meet the basic needs of food and nutrition of the general citizenry. They require factors such as; land reform, freshwater catchments and irrigation, machinery, fertilizers, pesticides, transportation, and improved varieties of crops and breeds of livestock and improved storage facilities.

Future Research

In emerging economies, food security may well depend on the success of smaller individual farming enterprises. As such, all interested parties need to develop an awareness of different enterprise scales as they learn to understand and adapt larger-scale forms of agriculture to local conditions. For scholars, policy makers, smallholder farmers and other stakeholders, consolidating recent gains in hunger eradication will depend on future research that focuses on six related areas:

- Building a model for larger-scale integrated farm enterprises where individual farms can achieve sustainability, higher productivity, and flexibility.
- The effective and innovative use of information and communication technologies (ICTs) in extension work.
- The development of government policies that promote social protection for small-scale agriculture through regulation of land tenure, credit, state purchasing, and other factors that influence the success of smallholder farming.
- Quantitative assessments that measure the impact of projects in categories such as productivity, profitability, nutrition, and inclusive growth.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Qualitative assessments that measure factors such as stakeholder uptake of new approaches and techniques, local knowledge, and feedback about extension service and policies.
- Redefining key concepts such as sustainability, subsistence, adaptive capacity and resilience for emerging economies.

CONCLUSION

This chapter has outlined the challenges and opportunities facing smaller, emerging economies as they attempt to improve food security in an ever-changing global economy. While dealing with a range of agricultural sectors, including crop farming, livestock, fisheries, and integrated enterprises that combine elements of some or all of those sectors, several common threads unify the analysis.

First, emerging economies typically depend on smaller individually-owned enterprises and will continue to do so into the future. Research and policy-making must recognize and respond to this reality by seeking to better understand and support the success of smallholder farming in all its permutations.

Second, local, national, and regional governments need to do a better job of supporting individual agriculture enterprises, and educators. Additionally, extension agents need to effectively and creatively target such enterprises with a range of formal and non-formal training and information services. Farmers themselves need to treat their farming—in whatever sector—as a business. This means adopting and maintaining sound techniques in marketing, accounting, communications, and political advocacy. While it goes beyond the scope of this chapter, developing political will on the part of smallholder farmers and the public who rely on them is an essential driver for shaping policies that will benefit smallholder success and ensure food security in developing societies.

Third, there is an assumption in this chapter that smallholder farming successes have a multiplier effect. This idea is validated by the recent FAO report that largely attributes a 20% drop in world hunger to advances in smallholder production. This dynamic is even more important in Small Island Developing States, where individual successes can add up more quickly to positive changes. These can manifest in less vulnerability to food imports and climate variability, more positive indicators in livelihoods and nutrition, and overall strengthening of societal resilience.

As the next generation of agricultural producers and policy-makers takes shape in the Caribbean and across the globe, hopefully this chapter will play a part in highlighting the role of small-holder farmers in sustaining nutritional health and overall food security for emerging economies.

KEY TERMS AND DEFINITIONS

Emerging Economy: Economies that have passed their early growth stage, i.e. from their primary-based economy, and rapidly expanding to an industrialized base to become more developed. Some economies that have not become industrialized may rapidly expand into the service-based economy through tourism and/or offshore banking.

Food Security: The ability of a country to meet its basic food requirements from local agricultural production and without heavy dependence on imported foods.

Resilience: The ability of a community to recover from natural and technological disasters, and external shocks relating to commerce and trade. The better the livelihood of people in communities, the more resilient they are to disasters and external shocks.

Small Island Developing States (SIDS): A category of lesser-developed countries of the world that is mostly located in the tropics, such as the Caribbean Sea, Indian Ocean, and the Pacific Ocean. Their communities are primarily located in low-lying coastal areas and are susceptible to natural disasters, including volcanoes, as well as tropical storms and sea-level rise that have intensified due to climate change.

Smallholder: A farmer who operates a farm of no more than 5 acres on either a subsistence level or semi-commercial level. At such level, the farm is usually not highly mechanized.

Sustainability: In the context of the environment, it is the ability to utilize natural resources without exceeding the capacity to regenerate themselves to meet current needs of a community and without compromising the needs of future generations.

Chapter 48
A Study of Different Color Segmentation Techniques for Crop Bunch in Arecanut

Siddesha S

ABSTRACT

Arecanut is an important cash crop of India and ranks first in the production. Arecanut crop bunch segmentation plays very vital role in the process of harvesting. Work on arecanut crop bunch segmentation is of first kind in the literature and this chapter mainly focuses on exploring different color segmentation techniques such as Thresholding, K-means clustering, Fuzzy C Means (FCM), Fast Fuzzy C Means clustering (FFCM), Watershed and Maximum Similarity based Region Merging (MSRM). The effectiveness of the segmentation methods are evaluated on our own collection of Arecanut image dataset of size 200.

INTRODUCTION

Agriculture plays a major role in any nation's economy and it is the primary livelihood of the mankind. Indian economy is based on agriculture as it is a traditional occupation. A stable agricultural industry ensures a country with food security, source of income and source of employment. This could be achieved by improving agriculture production and its quality by practicing precision agriculture. Precision agriculture, as a crop management concept, could meet much of the increasing environmental, economic, market and public pressures (Stafford 2000). The impact of precision agriculture technologies on agricultural production is expected in two areas: profitability for the producers and ecological and environmental benefits to the public (Zhang et al. 2002). The objectives of precision agriculture

are profit maximization, its input rationalization and environmental damage reduction, by adjusting the agriculture practices to the site demands.

In the field of precision agriculture considerably quite a large effort on research has been focused. This leads the agricultural and engineering companies for manufacturing advanced machine vision devices to facilitate the practice of precision agriculture (Scarlet 2001). The spatial and temporal soil variability and crop management within a farm has been admired for centuries. In the past, the fields are small in size and their demarcations are defined by natural boundaries, like soil type and water courses. This made farmers to change their soil and crop treatments manually. With the enhancement in the area of field, the crop production was substantially increased and to cope up with the large scale of crop production automation coined more importance in the later part of the previous century (Godwin and Miller 2003). Without incorporating and developing the new technology for filed spatial variability and crop management (Goense et al. 1996), it was impossible automate the precision agriculture. With the advancement in technology which vitally made the impact for the development of the precision agriculture concept, in the late 1970s, the Global Positioning System (GPS) using satellites placed in orbit by the Department of Defense in the US. This system helped in locating any position on earth using latitude, longitude and altitude, 24 hours a day, up to the perfect accuracy of a few centimeters. With this information available to machines in the field, the treatment for the crops can be applied locally at the time of field operations within the field for the required amount of area (Stafford 1994). Precision agriculture is the future way ahead for formers to produce quality crop for the millennium. This is because the production of crop become more and more precise, the technologies are highly optimized which results in cost reduction and impact over the environment (Stafford et al. 1996).

Three main obstructions which needed to overcome during the implementation of precision agriculture (Matthews 1983; Stafford 2000)

1. Precision agriculture deals with intensive information related to mapping of different types of soil, crop and factors related to environment of the field. This produces huge data quantities which would be processed by the user. Along with the field data some more data is added based on the experience like weather and market information data. This overload of data has to be maintained and managed properly by suitable data integration, expert and decision support systems (Stafford 1994). To achieve this development some standardization of data formats and transfer protocols need to be followed.
2. There is an absence of balanced systems and methods for deciding application necessities on a restricted premise and a parallel absence of experimentally approved evidences for the benefits guaranteed for the concept. Both of these must be addressed by researching in the area of soil, crop science and agronomic exploration and experimentation.
3. Although information needed on soil, yield and ecological elements can be obtained, most strategies are expensive and intense labor-oriented, (like laboratory set up and subject expert for the analysis of soil). The information can be created through programmed sensor frameworks sensing particular components or suitable substitutes.

Accordingly, improvement of quick sensing frameworks must be needed before practicing precision agriculture. With the improvement of frameworks that can give information at fine spatial determination, the advancement of more exact application innovations and exact and dependable position reckoning has ended up important. Agricultural engineers must take a lead in overcoming the first and third hindrances

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

however, in the most recent decade of research in precision agriculture has demonstrated, that the topic is multidisciplinary thus the inter disciplinary groups are expected to develop solutions for these issues (Stafford 2000).

Precision agriculture is an integrated crop management system that endeavors to match the sort and amount of inputs with the genuine product requirements for small regions within the farm field area. The benefits of precision agriculture in relation with economy and environmental could be envisioned through decreased utilization of water, fertilizers, herbicides and pesticides along with farm equipments. This avoids in managing the entire field based on some theoretical condition, which may not exist anyplace in the field (Godwin and Miller 2003). A precision agriculture approach perceives site-particular differences inside fields and adjusts the management procedures as needed (Goovaerts 2000).

Precision agriculture plays a vital role in cropping systems like yield monitoring, its variability, crop variety comparisons, yield damage reports, and field efficiency (Koch and Khosla 2003). In recent years, with the advancement in machine vision, applications of digital image processing and pattern recognition approaches have become powerful and essential in the field of precision agriculture, which involves computation and processing of intense data in order to provide timely and accurate information (Cox 2002).

With advancement in machine vision in the field of precision agriculture minimizes the human intervention and provides proper information for decision making process. The main problem in machine vision is in determining the presence of particular object, feature or activity in the image data. Even this can normally solved without human intervention, but the outcome results are not as per the expectation (Cox 2002). The available approaches for this problem can be solved for only specific objects, like simple geometric objects, human faces, printed or hand-written characters, or vehicles, and in particular for specific situations, where the images are captured in a well-defined illumination, background, and the direction of the object relative to the camera.

Agricultural automation may take advantage of machine vision resources, which can be applied to a number of different tasks, such as inspection, classification of plants, estimated production, automated collection and guidance of autonomous machines. Crop image segmentation issue on colour difference between mature crops and backgrounds under natural illumination condition is an important and difficult content of crop-harvesting machine vision.

Dealing with voluminous data and detection of proper crop bunch is very much desired in the process of harvesting. Machine vision approaches have been implemented in precision agriculture for various applications. The research works have been also done for harvesting, disease detection in case of crops like Tobacco (Guru et al. 2012), Tomato (Schillaci et al. 2012; Yin et al.2009), Potato (Hassankhani and Navid 2012), Coffee (Johnson et al. 2004), Tea (Singh and Kamal 2013), Mango (Chhabra et al. 2012) etc. Only a few attempts have been made for crops like Arecanut for classification, harvesting, grading and disease detection. Arecanut or Betelnut (Areca catechu L.,) is an important cash crop in the Western Ghats, Eastern Ghats, East and North Eastern regions of India. India ranks first in terms of both area (47%) and production (47%) of Arecanut. Indian productivity is also on par with the world productivity at 1.27 tonnes/ha (Gracy et al. 2010). Mainly, Arecanut is an important component of the religious, social and cultural celebrations and economic life of people in India. Also Arecanut is also used in Ayurvedic and Veterinary medicines.

Crop harvesting is the process of extraction of matured crops from the plant. The selection of right time and right maturity of crop adds quality to the crop. The assessment of proper crop for harvesting is a crucial decision making process. Automating the process mainly needs a solid machine vision model

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

which helps in selecting the crop from the plant. This selection and extraction of crops from the plant can be carried out using image segmentation techniques.

From the literature survey it is evident that very few works have been done on crop segmentation part and in case of arecanut only few works have been done and those involves segmentation of a single nut from the background. So automatic segmentation (Gao et al. 2001) of crop bunches from the arecanut crops are very much needed as the plants are tall and needs skilled labor for harvesting. This increased labor cost in harvesting made small and middle level farmers life very tough. Also it is very dangerous for the labors who involved in harvesting; several cases have been reported by farmers that so many labors got injured by falling from the tree. This is due to the reason that, areca trees trunks are very thin and it grows to the height of 20-30 feet. This triggers us for proposing an automated harvesting process and this basically works based on the machine vision technique. This creates a huge scope for detecting and extraction of crop bunch from the plant using some solid color image segmentation techniques.

Color image segmentation is a prime and very important task in most of the machine vision problems. Color image segmentation is very much needed in the field of precision agriculture especially for harvesting process. One of the main problem with color segmentation in arecanut crop bunch is the complex background i.e., the background consists of other trees or leaves, flowers etc. of these some may have the same color as the crop bunch. Separation of areca crop bunches from the background is very challenging task.

This chapter initiates the exploration of various color segmentation methods (Sridevi and Mala 2012; Elbalaoui et al. 2013) and studies the effectiveness for areca crop bunch segmentation which are based on feature, image domain and edge (Lucchese and Mitra 2001; Pratt 2008). Under these different color segmentation techniques like Threshold (Pratt 2008; Sridevi and Mala 2012), K-Means clustering (Vijay et al 2014), Fuzzy C Means clustering (Cheng 1995; Pantofaru and Herbert 2005; Gonzalez and Woods 2009; Muthukannan and Latha 2012), Fast Fuzzy C Means clustering (Bhoyar and Kakde 2010; Singh and Singh 2010), Watershed segmentation (Belaid and Mourou 2009; Sridevi and Mala 2012), and Maximum Similarity based Region Merging (Ning et al 2009).

BACKGROUND

A novel and robust color space conversion and color index distribution analysis technique for automated date maturity evaluation for harvesting the date fruits was proposed (Lee et al. 2008b). Also Computer vision technology for detecting fruit size, color, bruise, and surface defects evaluation of fruit for the overall quality were discussed. Image analysis and color quantization techniques are used in evaluating fruit maturity for the harvesting process is demonstrated using Medjool date samples collected from field testing (Lee et al. 2008a).

Another system was developed using a genetic algorithm based neural network detecting technique for evaluating maturity of strawberry fruits during harvesting procedure (Xu 2009). A robust and an intelligent algorithm operated on the multispectral images for the estimatation of accurate percentages of green (under-ripe), yellow (proper ripe), and brown (over-ripe) colored coffee cherries displayed on the canopy surface (Furfaro et al. 2007). From the airborne multispectral imagery a feasibility of monitoring the coffee field ripeness was proposed and different approaches are discussed (Johnson et al. 2004).A multivariate based three class problem was incorporated considering a Bayesian classifier for data fusion to classify fresh non damaged tomatoes based on their ripening stages (Baltazar et al. 2008).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Attempts have been made using machine vision in several crop management activities like crop to soil mapping, weed and disease detection, crop grading, and classification for harvesting. A machine vision–based guidance system was developed for grain harvesting (Benson et al. 2003; Mondal and Tiwari 2007). This system involve some stages like image acquisition from the sensor, digitization of the image, segmentation using adaptive using gray level histogram based techniques. Post segmentation process involves filtering using low-pass filters to remove noise. Blob analysis is done for classifying the connected pixels of the same image as a single object.

An automatic classification method for Betelnut/Arecanut is proposed in (Liu et al. 2009). The classification is done by extracting color, shape and texture features of Arecanut. The segmentation of the individual arecanut is done as preprocessing step using bilinear interpolation and wavelet decomposition. Arecanut image has been captured using CCD camera with YCbCr color mode. The image captured by keeping the arecanuts in white background to increase the contrast between object and the background region. As preprocessing mainly works on Y component, the arecanut is segmented based on Y component. Segmentation is achieved by considering only the low frequency image as the expected image and removing the high frequency components.

A method proposed for classification of Arecanut into two classes based on color (Danti and Suresha 2012b). The proposed method has three steps, segmentation, masking and classification. Three sigma control limits are used on the YCBCR image for the effective segmentation of Arecanuts. Classification is made based on the red and green color components of the segmented region of the Arecanuts. The segmentation is on individual arecanut images. The RGB image is first converted to YCBCR mode, the red and blue components from the arecanut image cropped manually for determining the lower and upper control limits of the red and blue colors. Shadow was removed using 3 sigma controls by setting the background color as black. Morphological operations are used for removing the noise on the binary image which was converted by segmented image.

Use of texture features have also been studied for classification of Arecanut (Danti and Suresha 2012c). The segmentation of arecanut from its background is the first step. This is done by converting the RGB image to HIS and YCbCr color model and then the saturation channel from HSI color model is extracted. Threshold based segmentation is carried out based on global image threshold using Otsu method is used. Classification is done using mean around features, gray level co-occurrence matrix (GLCM) features and combined (Mean around & GLCM) features.

Decision trees classifier is used for classification purpose. An approach has been proposed for grading of Arecanuts (Danti and Suresha 2012a). Three sigma control limits on color features are determined for effective segmentation of Arecanuts. Color features are used for the grading of Arecanuts with the help of support vector machines (SVMs) into two grades i.e. boiling and Non-boiling nuts. In the above mentioned work, the segmentation is again done for individual Arecanuts.

An application was developed by neural networks and image processing techniques for detecting and classifying the quality of Arecanuts. Defects with diseases or insects of Arecanuts were segmented by a detection line (DL) method. Six geometric features, three color features, and defect areas were used in the classification procedure. A back-propagation neural network classifier was employed to sort the quality of Arecanuts. Here the segmentation work is done for detecting the diseases spots on the Arecanuts (Huang 2012).

From the above literature survey, it is quite evident that few work has been carried out on segmentation of Arecanut is inadequate and fragmentary. It also reveals that no attempts have been made for segmentation of crop bunches of Arecanut.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Among these the segmentation of Arecanut bunch crops it's of first kind in the literature.

NEED FOR MACHINE VISION IN HARVESTING

Harvesting is a vital and very important stage in production of any crop. If the crop production is qualitative then it should follow a selective harvesting process. Selective harvesting deals with the collection of only proper ripe crops from the plant. Hence, before the process of harvesting a crop, farmers should consider proper and accurate factors like unripe, ripe and over-ripe of crops. Due the human sensory limitations, the manual judgment of crop ripeness by human will not guarantee the accurate and precise result. Also the variability of lighting condition will minimize the efficiency in evaluating crop ripeness over the time. Therefore with these issues, there is a need to develop a robust model against ecological conditions (sunny, cloudy and rainy) to evaluate ripeness of crop during the harvesting process. The visual properties of crop like color, shape and textures need to be exploited for the evaluation of the ripeness of crop for harvesting process.

With this backdrop, there is need for exploring machine vision based algorithmic models for crop bunch segmentation of arecanut crop. The prime applications of arecanut crop bunch segmentation include monitoring and mapping crop yields. Crop-yield monitors to watch both quantitative and qualitative parameters, a great need of timely harvesting based on crop ripeness. Due to the excessive labor cost and chances of making wrong decision at the time crop selection, harvesting and grading, there is an increasing demand for machine vision based technology. Implementation of suitable machine vision techniques in precision agriculture for proper crop management helps farmers to serve the society by providing quality crops (Lee et al. 2011).

Arecanut harvesting is done manually in present scenario and is very cumbersome and dangerous process in case for non-expertise labors. Automation of harvesting process mainly concentrates on extraction or segmentation the crop bunch from the arecanut tree image. Image segmentation is a process of partitioning an image into its constituent regions to extract data from the attributes of the image. A good segmentation should result in regions in which the image elements should have uniform properties in terms of brightness, color or texture etc. Though the image is to be portioned into regions, the considerable changes within the regions should be observable visually. The quality of the segmentation can be measured by the elements of the same region should be similar and should have clear difference between elements of the other regions.

Now there are a number of wide varieties of image segmentation techniques are available, among these some are for general purpose and some are designed for specific types of images for the specific filed. Mainly the techniques were classified as: spatial clustering with measurement space guide, region growing schemes based on single linkage, region growing schemes based on hybrid linkage, region growing schemes with centroid linkage, spatial clustering techniques, and split-and-merge methods (Haralick and Shapiro 1985).

The proposed work concentrates at extracting the crop bunch of arecanut from the given image using different color segmentation approaches which are classified mainly into three classes based on

1. Feature space,
2. Image domain, and
3. Edge-based (Fu and Mui 1981; Lucchese and Mitra 2001 ; (Pantofaru and Herbert 2005).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The feature-space based method is composed of two steps, feature extraction and clustering. Feature extraction is the process to find some characteristics of each pixel or of the region around each pixel, pixel value, pixel color component, windowed average pixel value, windowed variance etc. After we get some typical properties around every pixel, clustering procedure is executed to divide the image into compelling parts focused around these properties. Image space based technique experiences the image and finds the border between segments by few rules. The primary attention to separate two pixels into specific segment is the pixel value differences, so this sort of routines couldn't manage textures well. The main methods in this class are split and merge, region growing, and watershed. The third class is edge-based image segmentation method, which has edge detection and edge linking techniques (Haralick and Shapiro 1985; Lucchese and Mitra 2001).

In spite of the fact that there have been numerous sorts of existed strategies, some basic issue still can't be solved. For class (1), the exact boundaries between segments are still difficult to focus on the grounds that features take properties around however not precisely on every pixel. Class (2) just uses the pixel value, which may bring about over-segmentation on texture regions. The edge detection makes class (3) ends up with over-segmentation issue. The segmentation process can be divided into different category based on the attributes selected like pixel intensity, homogeneity, discontinuity, cluster data, topology etc. Each approach has its own advantages and disadvantages. The result of one approach may not be the same as compared with other. Methods that are specialized to particular applications can often achieve better performance. Selection of an appropriate method to a segmentation problem is very challenging dilemma.

The segmentation procedures can be semi-interactive or automatic. With the major difficulty of ill-posed nature of segmentation it is hard to obtain single answer for segmentation of given image as the interpretation varies from individual approaches. In some cases manual interaction to segment the image may be error-prone (for example, in case of seed selection) while the fully automated approach can give error output (for example in case of watershed segmentation)and in some cases interactive methods can be laborious and time consuming. So a single approach to segment all variety of images may be practical unachievable. The prior knowledge on the image can give better results and gives user the choice to decide proper method to segment the image.

DATASET CREATION

Creation of a suitable dataset is crucial for any research as the dataset is the primary thing for designing and testing the system. A newly designed system has to be empirically tested for various characteristics to assess its effectiveness in meeting requirements. Automation of any stage of precision agriculture for any crop has to be empirically tested for its various characteristics to assess its effectiveness in meeting the requirements for which it has been designed. The arecanut image data set is not readily available. This scarcity is mainly due to the huge manual effort required to collect a sufficiently large number of arecanut images. Due to the non-availability of a sufficiently large benchmarking dataset of arecanut images, it is difficult to compare the performances of different systems. In view of this, we have made an attempt to create a dataset of 200 arecanut images. These images are collected across the Karnataka state by visiting few districts and the images are captured from the ground by focusing the areca nut crop bunch at the top of the tree. This is very laborious process. The images were captured from the ground using NIKON COOLPIX L810 Digital camera with 26X Zoom. The input arecanut image, which has

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

crop bunch along with different parts of arecanut plant like leaves, branches, stem and other tress in the background. Extracting the region of interest i.e., the crop bunch is a really very challenging task. To evaluate the performance of the segmentation techniques, one need to compare the segmented output samples with the ground truth samples. Performance evaluation of the segmentation algorithm is very important step in deciding which method is better by comparing with other methods. In the present case, due to the non availability of arecanut ground truth image dataset, we have created the ground truth dataset and did the performance comparison with other methods.

EXPLORATION OF DIFFERENT SEGMENTATION METHODS

Threshold Method

Intensity is the property shared by the pixels of a region. These regions can be naturally segmented through thresholding, which separates the regions with light and dark pixels.

Threshold based segmentation is the simplest segmentation technique which partitions different regions with different intensity levels based on the threshold value given. Thresholding algorithms are selected manually based on the priori knowledge or automatically by image information. These algorithms further classified based on edge, region and hybrid methods. Segmentation of image using thresholding is simple and promising for segmentation in case of images having light objects with dark background. Thresholding operation converts a multilevel image into a gray scale image and for the selection of a proper threshold *T,* further it divide the pixels of image into different regions and separate the light and useful objects from background. Any pixel (*x, y)* considered as a part of object only when its intensity exceed or in the range of the threshold value, given by, $f\left(x,y\right) \geq T$ otherwise the pixel belongs to background. Thresholding technique can be mathematically represented by (Gonzalez and Woods 2009),

$$T = \left\{x, y, L(x,y), f(x,y)\right\} \tag{1}$$

where (x,y) is the pixel location, $L(x,y)$ is the local property of the input image and $f(x,y)$ is the intensity value of the pixel (x,y).

Based on the selected threshold value, two classes are there, global and local thresholding. Global thresholding method has a fixed threshold value *T*. The threshold value should be proper to get an appropriate Region of Interest (ROI) of the image (Sridevi and Mala 2012). The output image g for the given input image f is obtained using the following (Gonzalez and Woods 2009),

$$g(x,y) = \begin{cases} 1, & \nabla f(x,y) \geq T \\ 0, & otherwise \end{cases} \tag{2}$$

Global threshold method will work only with images having even background illumination.

To overcome the issue with global thresholding method for non uniform background illumination, local thresholding was adopted using mean and standard deviation (SD) of the neighborhood pixels. It

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

selects the threshold value based on the calculating the mean $\left(m_{xy}\right)$ and standard deviation σ_{xy}. The output image g for the given input image f is obtained using the following (Gonzalez and Woods 2009),

$$g(x,y) = \begin{cases} 1, & f(x,y) \geq a\sigma_{xy} + f(x,y) > bm_{xy} \\ 0, & otherwise \end{cases} \tag{3}$$

Local thresholding method uses multiple threshold values to manage the uneven illumination (Agarwal and Xaxa 2014).

In the case of crop bunch segmentation, the image is a color image. In this image each pixel is characterized by three RGB values. Hence 3D histogram has been constructed and is analogous to the method used for one variable. Histograms are plotted for each of color values the red, green and blue and the threshold point are found. The object in the segmented image is distinguished by assigning the average pixel value to the regions separated by thresholds.

Major issue with this method is, it considers only the intensity and does not draw any relation between the pixels. So there is no confirmation that the pixels selected by this are neighbor to one another. Also this nature of this method can introduces unrelated pixels within the same region i.e. nearby the boundaries. Due to this the noise will be maximized due to the variation of intensities of pixels within the region. This sometimes results in either under segmentation or over segmentation issues. This issue is very obvious when dealing with natural images.

From the experimentation and the result it is observed that the results are not as per the expectation. Here the complexity arises in selection of proper threshold values which separates the background from foreground. In the proposed case, it is very difficult to get the proper threshold value as the background is complex, as it consists of leaves, flowers which are having similar color compared to the arecanut crop bunch.

The Segmentation results of arecanut crop bunch using Thresholding are shown in Figure 1 and the performance of this technique is shown in Table-1.

K-Means Clustering

Clustering is a normally a techniques used for classification of samples. Given a vector of N measurements depicting every pixel or collection of pixels (i.e., district) in an image, a similarity of the measurement vectors and in this manner their grouping in the N-dimensional estimation space infers comparability of the similar pixels or pixel groups. Thus, clustering in measurement space indicates the similar regions of an image, and may be used for segmentation purposes.

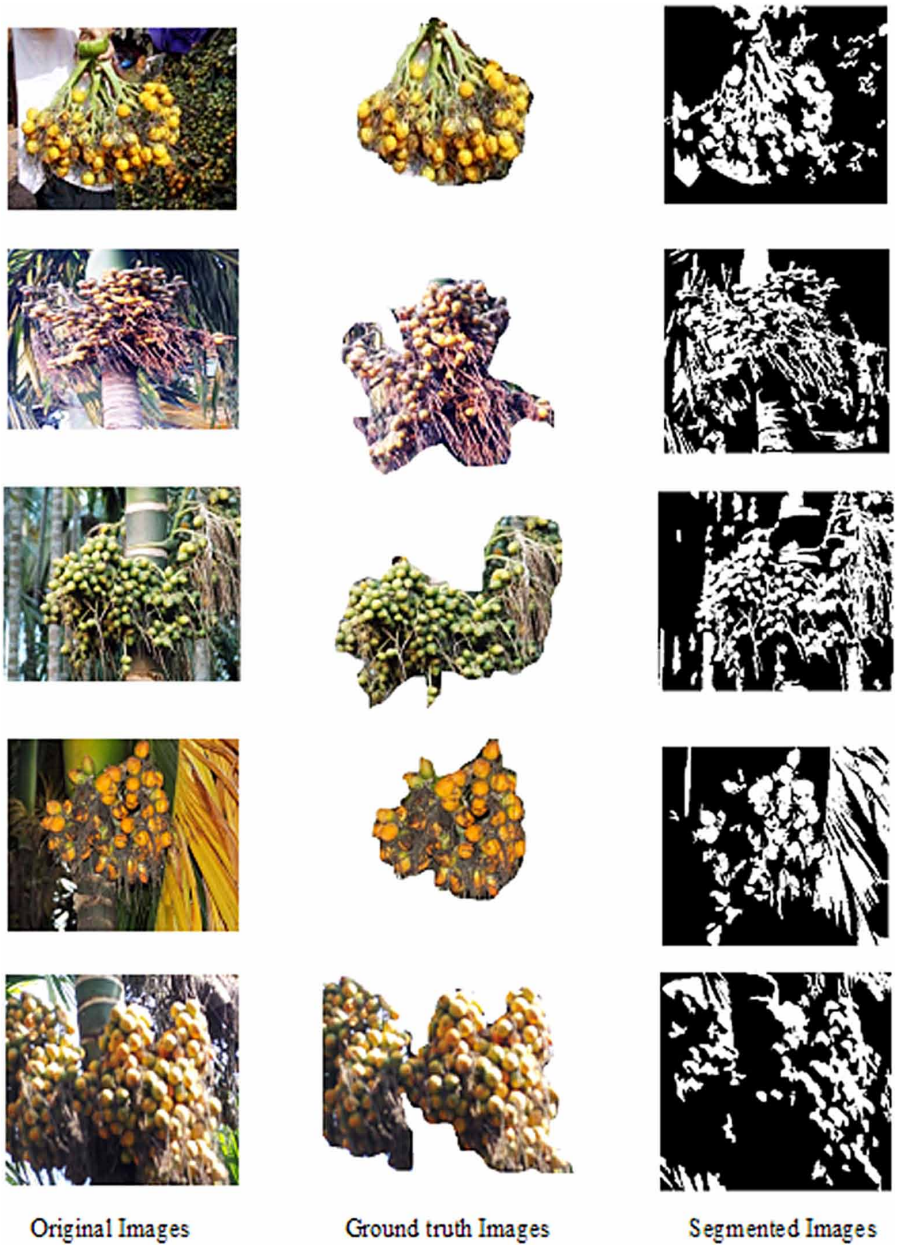
The measurement vectors describe some useful features of the image and are also known as a feature vectors. Similarity between regions of the image or pixels implies in the feature space. Clustering methods are some of the earliest data segmentation techniques to be developed (Vijay et al 2014).

Normally the clustering algorithms suffer from two major issues

1. Predefinition of number of clusters, which makes inadequate using a huge image data base during batch processing.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Results of Arecanut crop bunch segmentation using Threshold method



2. Representation of clusters by their centroid and built based on Euclidean distance inducing a hyper sphere cluster shape, which is incapable of capturing the actual structure of the data. This is especially arises during the case of color clustering with arbitrarily shaped clusters (Celenk 1990; Xi et al.2007).

The K-Means clustering method is one of the well-known methodologies connected to comprehend low-level image segmentation. In K-Means clustering a specific number of disjoint, flat (non-hierarchical)

clusters were generated. It is well suits to the situation related to globular cluster generation. It is an unsupervised, numerical, iterative and non-deterministic method.

This algorithm is joined and its point is to optimize the partitioning choices focused around a user defined initial set of clusters. The applications of the clustering algorithms to division of complex color textured images are confined by two issues. The main issue is created by the beginning condition (the initialization of the initial cluster), while the second is produced by the way that no spatial (regional) attachment is connected amid the space partitioning procedure.

There are two preprocessing steps that are required for the implementation of K-means clustering algorithm: The stage begins first by making device independent color space transformation structure. Device independent color space, the coordinates used to point out the color will deliver the same shade regardless of the device used to draw it. Hence, making the color change structure that characterizes the shade space transformation is needed. At that point, the connection of device independent color space change, which changes over the color values in the image to the color space defined in the color change structure. The color change structure determines different parameters of the change. A device color space is the one where the resultant color relies on upon the supplies used to create it. Case in point the color created utilizing pixel with a given RGB qualities will be adjusted as the splendor and differentiation on the presentation device utilized. Hence the RGB framework is a shade space that is reliant (Agarwal and Xaxa 2014).

Generally, iterative frameworks are used for implementing spatial partitioning methods for either minimizing the variation within the clusters or try to identify the optimal partitions on a set of Gaussian Mixture Models (Farnoosh and Zarpak 2008). It is a nonhierarchical clustering technique and has

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a simple process to classify the given data set through a number of K clusters known apriori. K-Means algorithm iteratively updates space partition of the input data, where the elements exchanged between clusters based on a predefined metric (Euclidian distance and the vector under analysis) for satisfying the criteria of minimization of variation inside each cluster and maximization of variation among the resulting K clusters. The *K*-means clustering is a partitioning method for combining objects to minimize the within-group variance. By minimizing dissimilarity of a local subset, the algorithm will yield an optimal dissimilarity of all subsets globally (Gonzalez and Woods 2009).

The algorithm has following steps to image threshold:

1. Initialize the (K) class centers. Use an unequal-distance method to define the initial class centers:

$$Cen_i^0 = GV_{\min} + \left[\left(\frac{\left(j - j/2\right)\left(GV_{\max} - GV_{\min}\right)}{K}\right)\right] \tag{1}$$

where $j = 1,2,....K$ and where Cen_i^0 is the initial class center for the jth class, $GV_{\max}$ and $GV_{\min}$ are the maximum and minimum of the gray value GV in the sample space.

2. Assign each point to its closest class center. The criterion to assign a point to a class is based on the Euclidean distance in the feature (*GV*) space using:

$$Dist_{i,j} = abs\left(GV_j - Cen_i\right) \tag{2}$$

where $i = 1,2,....M \; and \; j = 1,2,.....N$ and where $Dist_{i,j}$ is the distance from the jth point to the ith class, and *N* is the total number of points in the sample space.

3. Calculate the (K) new class centers from the mean of the points that are assigned to it. The new class centers are calculated by N_i

$$Cent_i^m = \frac{1}{N_j}\sum_{i=1}^{N_i} GV_j \tag{3}$$

where $j = 1,2,...K$ and where N_i, is the total number of points that are assigned to the ith class in step 2.

4. Repeat step 2 if any class centers change, otherwise end the circulation.
5. The threshold value is defined as the average of the Kth class center and the $(K-1)th$ class center:

$$Thresh = \frac{1}{2}\left[Cent_K + Cent(K-1)\right] \tag{4}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

This method is having some limitations; it is difficult to assume the value of K, it will not work well with global clusters, result may have different final clusters due to different initial partitions and this will not well suits to clusters of different size and density.

The result obtained by this technique is not better for segmentation purpose. This is due to the partitions created having similarities in color and to the complex background. This also fails in minimizing the within-group variance.

The Results of arecanut crop bunch segmentation using K-Means Clustering method with K=2 is shown in Figure 2 and the performance of this technique is shown in Table 1.

Fuzzy C-Means (FCM) Method

In case of hard clustering, the sample data is partioned into distinct clusters, among those each data element belongs to specifically to only one cluster. Fuzzy clustering sometimes also known as soft clustering where, data elements can be grouped in to more than one cluster, and those associated with each element is the belongs to the set of membership levels. This highlights the strength of association between the particular data element with a specific cluster. During the process Fuzzy clustering assigns the different membership levels and later using these membership levels assigns the data elements to one or more clusters. Fuzzy c-means (FCM) algorithm incorporates the spatial information of the data into the membership function for clustering. The spatial function is arrived from the summation of the each pixel under consideration with its neighborhood as membership function (Chuang et al. 2006).

Fuzzy Segmentation is considered as one of the interest area of research. Most analytic fuzzy clustering approach is derived from the fuzzy C-means (FCM) algorithm (Chaabane et al. 2008; Muthukannan and Latha 2012). The segmentation carried out using the thresholding technique, while the fine segmentation assigns the unclassified pixels to the closet class using Fuzzy C means (Chaabane et al. 2008; Yang et al. 2005).

The algorithm can be given mathematically as follows,

$$J_m\left(X,Y\right)=\sum_{i=1}^{n}\sum_{j=1}^{c}u_{ji}^{m}d^2\left(p_i q_j\right) \tag{5}$$

with

$$\sum_{i=1}^{c}u_{ij}=1, 1\le i\le n\,,$$

$$u_{ij}\ge 0, 1\le i\le n, 1\le j\le c\,,$$

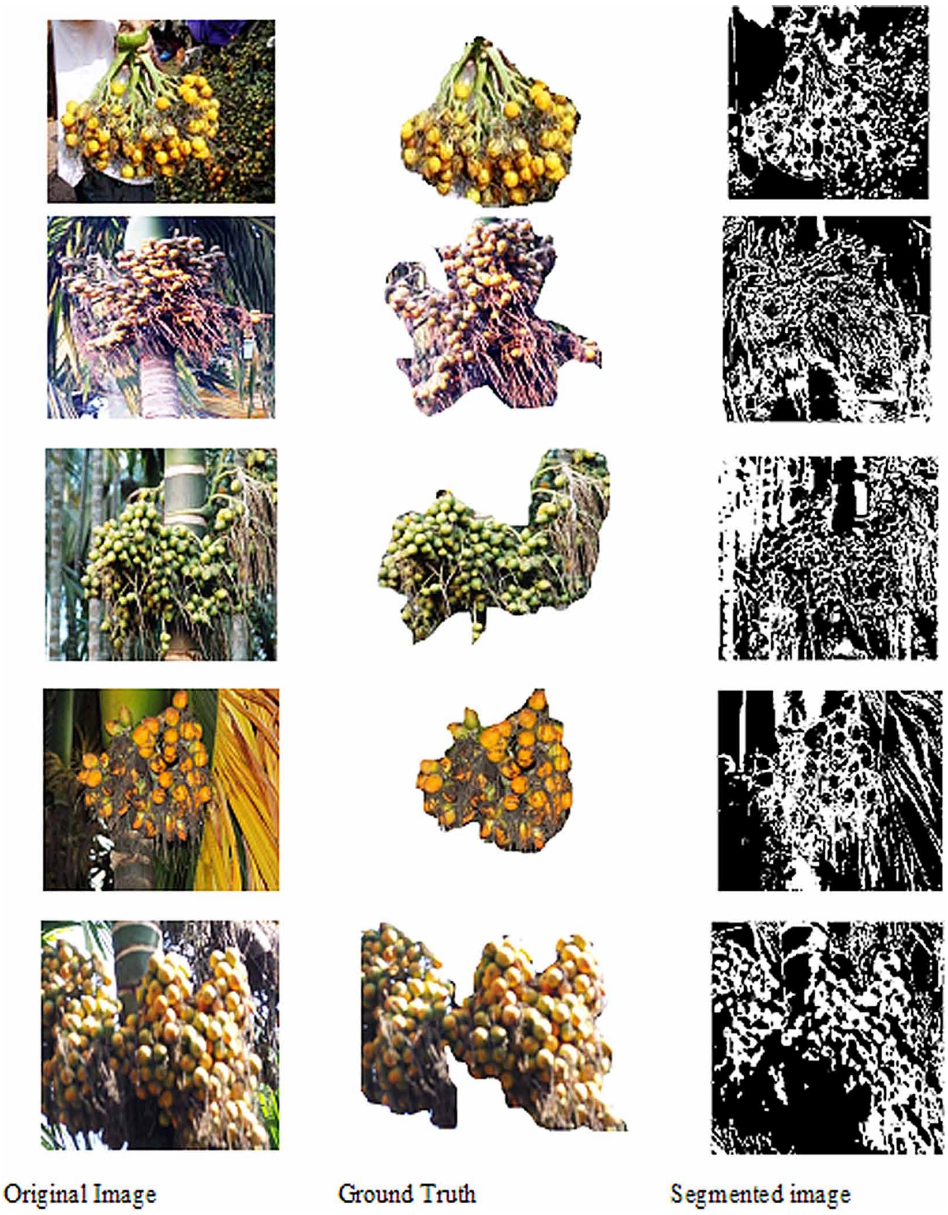
$$\sum_{i=1}^{n}u_{ij}>0, 1\le j\le c$$

where $P=\left\{p_1,p_2,....p_n\right\}\subset R^s$, s is the dimension of space, n is the number of unclassified pixels, c is the number of clusters $(1<c<n)$, m is the fuzzy factor .., $d_{ij}=\left\|p_i-q_j\right\|$ is the distance between sample p_i and clustering center q_j with $(1<j<c)$. p_{ij} is the membership of the j^{th} sample of the i^{th} cluster center. The segmentation results are as shown in Figure 3 and the performance of this technique is shown in Table 1.

The FCM algorithm utilizes shared distances to compute the fuzzy weights. At the point when a feature vector is of equal distance from two cluster centers, it weights the same on the two clusters regardless of what is the distribution of the clusters. It can't separate the two clusters with distinctive distributions of

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Results of Arecanut crop bunch segmentation using Fuzzy C Means (FCM) clustering method



feature vectors. Hence, the FCM algorithm is well suited to data that is pretty much uniformly distributed around the cluster centers. The FCM algorithm divides the two clusters with characteristic shapes but close boundaries into a large cluster.

In this case, the result obtained is quite better compare to the previous two methods. The unclassified pixels are grouped together based on the fuzzy c means. While grouping the foreground pixels there is an overlapping with background pixels.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Fast Fuzzy C-Means (FFCM) Method

Fuzzy C Means clustering algorithm is widely used for image segmentation purpose. This concentrates those points which belong to two or more classes with respective membership. This algorithm gives good segmentation results, only when the input image should be noiseless. This fails to properly segment the images which are corrupted by noise.

To avoid these issues, a modified Fuzzy C Means segmentation method based on spatial constraints can be used (Capitaine and Frelicot 2011). The modified FCM segmentation algorithm will be compensating the intensity non homogeneities by modifying the objective function (Chen and Lu 2002; Pratt 2008).

The FFCM algorithm has following steps;

1. Computing the agglomerated histogram of the color image: Let *n* be the number of colors in the agglomerated histogram and *c* is the number of major segments with $(c < n)$, H_k is the number of pixels having color X_k represents the cluster *k.* The modified FCM with histogram data is given by,

$$Y_i = \frac{\sum_{j=1}^{n} u_{ji}^{m} \cdot p_j \cdot H_k}{\sum_{j=1}^{n} u_{ji}^{m} \cdot H_k} \tag{6}$$

where $j = 1,2,....c$.

2. Generation of Fuzzy functions using the following equation by replacing *N* by *n*

$$m_{ij} = \left[\sum_{j=1}^{c} \left(\frac{d_{ik}}{d_{jk}} \right)^{\frac{2}{m-1}} \right]^{-1}, \; i = 1,2,...c \text{ and } k = 1,2,...N \tag{7}$$

3. Construct the partition matrix for FCM of size $cx(n+1)$ using the following equation

$$m = \frac{1}{1 + \alpha d^2} \tag{8}$$

where *m* is the membership value for every pixel of the image, *d* is the Euclidean distance between the color coefficients and the cluster seed, the color coefficients and the cluster seeds are scaled to the interval [0,1] and α is an arbitrary constant to control the memberships on the distances i.e., the fuzziness, such that $0 \le \alpha \le 1$.

4. Determine the cluster centers using equation (6), store the cluster centers.
5. New partition or the membership values can be computed using the cluster centers from Step 4 and equation (7).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. Steps 4 and 5 are repeated till the error of the respective cluster centers should become below the threshold.
7. Hardening the converged partition will yield the segmented image.

In this technique the results are better compared to Fuzzy C Means but not sufficient. This is once again based on generation of histogram for color image, which again sets a complexity in selection of proper threshold values between back ground and fore ground.

The corresponding arecanut crop bunch segmentation results are shown in Figure 4 and the performance of this technique is shown in Table 1.

Figure 4. Results of Arecanut crop bunch segmentation using Fast Fuzzy C Means (FFCM) method

Watershed Algorithm

Due to the problem of selecting a proper threshold values in case of histogram generation, the region based algorithms are used. Region based segmentation algorithms operates based on grouping the pixels iteratively with its neighbors which are having similar values and splitting the group whose pixels are having dissimilar values (Kim and Kim 2003; Schettini 1993).

Watershed transformation is one of the region based segmentation approaches. The idea is coined from the field of geography which includes landscape or topographic relief flooded by water. Watersheds divide the lines of regions of attraction where rain is falling. This can be imagined when the landscape immersed in a lake, with holes in local minima. The catchment basins starts filling up with water from local minima and at some parts water emerges from different basins would meet and builds the dam. This process will be stopped when the water level reaches the highest peak of the landscape. Based on this, the landscape splits into different regions separated by dams known as watershed (Gonzalez and Woods 2009).

Let $f(x,y)$ with $(x,y) \in R^2$, be a real scalar function describing an image *I*. The morphological gradient of I is defined in (Belaid and Mourou 2009) by,

$$\delta_D f = \left(f \oplus D\right) - \left(f \ominus D\right) \tag{9}$$

where $\left(f \oplus D\right)$ and $(f \ominus D)$ are the elementary dilation and erosion of *f* by the structuring element *D*. The morphological Laplacian is given by

$$\Delta_D f = \left(f \oplus D\right) - 2f + \left(f \ominus D\right) \tag{10}$$

This morphological Laplacian influence zones of minima and suprema: regions with $\Delta_D u < 0$ are considered as influence zones of suprema, while regions with $\Delta_D u > 0$ are influence zones of minima. $\Delta_D u = 0$ interprets edge locations, and represent an essential property for the construction of morphological filters. The idea here is to apply either dilation or erosion to the image *I*, depending on whether the pixel is located within the influence zone of a minimum or a maximum.

The Catchment basin *C(M)* associated to a minimum *M* is the set of pixels *p* of Ω an open bounded domain of *R*, such that a water drop falling at *p* flows down along the relief, following a certain descending path, and eventually reaches *M*. The catchment basins of an image *I* correspond then to the influence zones of its minima, and the watershed will be defined by the lines that separate adjacent catchment basins (Belaid and Mourou 2009; Gonzalez and Woods 2009).

Computation of watersheds and the most commonly used is based on an immersion process analogy. This immersion process can be formulated as follows, Let $h_{\min}$ *and* $h_{\max}$ are the smallest and the largest values taken by *f*. Let $T_h = \left\{p \in \Omega, f(p) \le h\right\}$ be the threshold set of *f* at level *h*. A recursion with the gray level h increasing from $h_{\min}$ *and* $h_{\max}$, in which the basins associated with the minimum of *f* are successively expanded. Let X_h is the union of the set of basins computed at level *h*. A connected component of threshold set $T_h + 1$ at level $h + 1$ can be a new minimum, or an extension of a basin in X_h.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

By denoting $\min_h$, the union of all regional minima at level *h*, the following recursion defines the watershed by immersion.

$$\begin{cases} x_{h_{\min}} = T_{h_{\min}} \\ \forall h \in \left[h_{\min,} h_{\max} - 1\right], X_{n+1} = \min_{h+1} UIZ_{Th+1}(X_n) \end{cases}$$

with $IZ_{Th+1} = \bigcup_{i=1}^{k} iZ_{Th+1}\left(X_{n_i}\right), k-$ is the number of minima of *I* and $iZT_{h+1}\left(X_{hi}\right)$

$$iZ_{\Omega}\left(Y_i\right) = \left\{Z \in \Omega, \forall k \neq i, d_{\Omega}\left(Z, Y_i\right) \leq d_{\Omega}\left(Z, Y_k\right)\right\} \tag{11}$$

The set of the catchment basins of a gray level image *I* is equal to the set $X_{h\max}$. At the end of this process, the watershed of the image *I* is the complement of $X_{h\max}$ in Ω (Belaid and Mourou 2009).

The main issue with watershed technique is that it is highly sensitive to local minima. And at each minima a watershed is created. If there is a noise in the image, it creates a watershed which is not desired. So the image with noise will have an impact on the segmentation. In order to rectify this issue the sigma setting of the Gaussian filter is adjusted to smoothen the image, which minimizes the noise and the local minima in turn. This enhances the usefulness of the watershed segmentation. The level of this sigma can be balanced by the user. While setting up the sigma value if the Gaussian filter care has to be taken with the value of sigma, if the value of sigma is too high, the watershed location will be shifted to some other location due to the impact of Gaussian blurring.

This algorithm is based on region, and tried to create different regions present in the given input image. Later based on the similarities, the region can be split or merged. Once again the complexity of background in the input image creates regions which are the combination of foreground and background in certain points due to similarities.

The watershed segmentation results are shown in Figure 5 and the performance watershed technique is shown in Table 1.

Maximal Similarity Based Region Merging (MSRM)

From the analysis and experimentation of the above methods, it is evident that single segmentation techniques will not suited to the requirement. This makes the automatic segmentation very complex and leads to the need of suitable hybrid segmentation techniques. Automatic segmentation of object from background is very hard in case of natural images with color and texture features. Because of this difficulty, semi-automatic segmentation methods with user interactions have been become very popular. The low level image segmentation methods like mean shift (Cheng 1995; Bailer et al. 2005; Zheng et al. 2009), watershed (Belaid and Mourou 2009) etc. will divide the image into small regions. Even these may suffer with over segmentation issues, these methods provide a good reason for the low level operation such as region merging. This is a Hybrid technique which works using the combination of mean shift and region merging technique. The MSRM method is based on the initial segmentation of mean shift. The interaction information is through markers, which is the input provided by the user

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Results of Arecanut crop bunch segmentation using Watershed method

by indicating roughly the object and background. The markers are simple strokes. Once the strokes are marked on the mean shifted input image, this method calculates the similarity of various regions and merges them based on maximal similarity rule. At the end of merging process, the object is extracted from the background (Singh and Singh 2010).

The mean shift algorithm is defined as in (Bailer et al. 2005; Zheng et al. 2009),

Let $S \subset X$ be a finite set or data or sample. Let *K be* a kernel and $w = S \rightarrow (0, \infty)$ a weight function. The sample mean with kernel *K* at $x \in X$ is defined as,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$m(x) = \frac{\sum_{s \in S} K(s-x)w(s)s}{\sum_{s \in S} K(s-x)w(s)} \tag{12}$$

Let $T \subset X$ be a finite set or (cluster centers). The evolution of *T* is the form of iterations $T \leftarrow m(t)$ with $m(T) = \left\{m(t); t \in T\right\}$ known as a mean shift algorithm (Bailer et al. 2005). For each $t \in T$, there is a sequence $t, m(t), m(m(t)), \ldots.$ is called as the trajectory of t. The weight $w(s)$ can be either fixed all through the process or re-evaluated after each iteration. It may also be a function of the current 'T'. The algorithm works till it reaches a fixed point $\left(m(T) = T\right)$.

In this work, the EDISON system was used to carry out mean shift segmentation (EDISON v1.1 2002). Once the mean shift segmentation is done, there are small regions available. To guide the region merging process, the regions should be represented by certain descriptors with a rule for merging. A region can be described by some features like color, texture, edge, shape and size. Color histogram is used as an effective feature for representing the object color statistics. The RGB color space is used for color histogram and each color channel i.e., R,G,B are quantize into 16 levels and histogram of each color is computed in the feature space of 16x16x16= 4096 bins.

In the interactive program part, users will mark the some regions as object and some as background. The similarity measure (*R*, *Q*) between two regions *R* and *Q* to accommodate the comparison between various regions is defined as,

$$\rho(R,Q) = \sum_{u=1}^{4096} \sqrt{Hist_R^u \cdot Hist_Q^u} \tag{13}$$

where $Hist_R^u$ and $Hist_Q^u$ are normalized histograms of R and Q, and *u* represents the *uth* element of them. ρ is a divergence measure known as Bhattacharyya coefficient (Fukunaga 1990) having a straight forward geometric interpretation. It is the cosine of the angle between the unit vectors.

$$\left(\sqrt{Hist_R^1}, \ldots., \sqrt{Hist_R^{4096}}\right)^T \; and \; \left(\sqrt{Hist_Q^1}, \ldots., \sqrt{Hist_Q^{4096}}\right)^T.$$

The higher the value of Bhattacharyya coefficient between R and Q, the higher the similarity between them.

In the integrative image segmentation, user has to specify the object and the background. This can be marked by drawing some markers, such as a line, curve or a stroke to highlight the object and the background. One the marking is done, each region is labeled with three regions such as, marked object, marked background and non-marked region. For the total extraction of the object, user needs to assign each non-marker region with a correct label of object region or background region automatically.

After marking process is done, the challenge lies in extraction of object contour from background. To identify all non-marker regions with the guidance of object and background markers, an adaptive maximal similarity based merging is used. Let *Q* be an adjacent of *R* and denote by $S_Q = \left\{S_i^Q\right\}, i = 1,2,\ldots,q$ the set of *Q's* adjacent regions. The similarity between *Q* and all its adjacent regions, i.e.,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$\rho\left(Q, S_i^Q\right), i = 1,2,...q$ are calculated. Obviously R is a member of $S_{Q.}$ If the similarity between *R* and *Q* is the maximal one among all the similarities $\rho\left(Q, S_i^Q\right)$, we will merge *R* and *Q*. and the merging rule is given by,

$$Merge\ R\ and\ Q\ if\ \rho(R,Q) = \max_{i=1,2,...q} \rho\left(Q, S_i^Q\right) \tag{14}$$

The MSRM process has two stages; first stage is about merging marker background regions with their adjacent regions. After this merging some non-marker background regions will be merged with the respective background markers. The second stage is focused on non-marker regions which are still remaining after first stage. This procedure is iteratively implemented and the iteration stops when the entire non marker region set will not find new regions for merging (Ning et al 2009).

The corresponding results are shown on Figure 6 and the comparison of performance of this hybrid technique with other techniques is shown in Table 1.

This hybrid segmentation technique gives somewhat promising result compared to the previous methods. This drives the need of hybrid segmentation techniques further for the problems related to natural image segmentation.

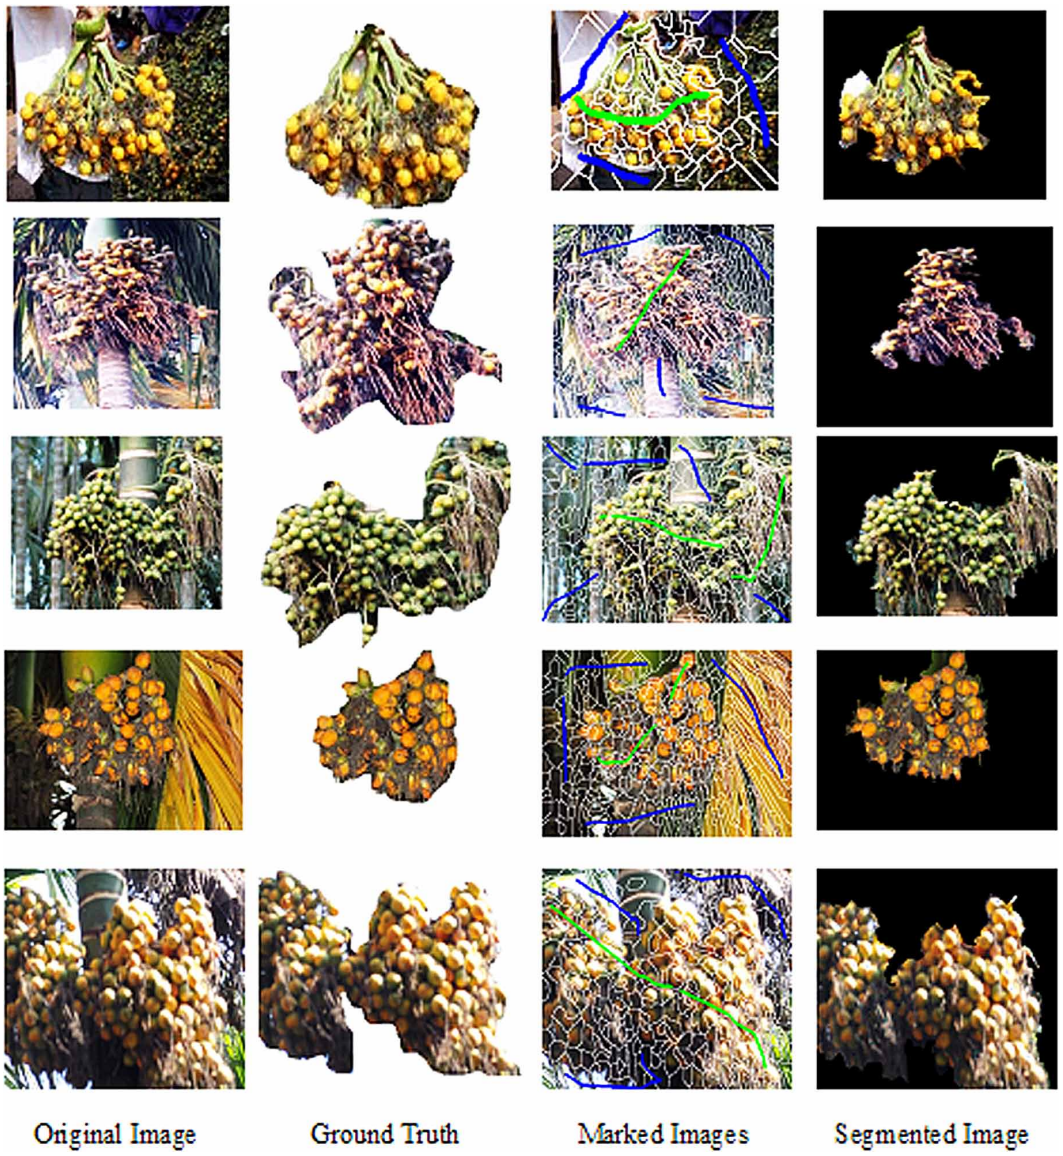
DISCUSSION AND CONCLUSION

The different segmentation techniques explored in this chapter are having certain limitations (Khan and Ravi 2013). The threshold segmentation method neglects the spatial information of the image, it highly noise sensitive and selection of the threshold value is crucial and based on this it suffers either over segmentation or under segmentation issues. Sometimes this leads to pseudo edges or missing edges. In K-means clustering approach the selection of desired number of clusters based on needs to be set earlier. This creates ambiguity while setting of the number of clusters. Fuzzy C-means method raises the ambiguity among the choice of features for better results for the given image. This is somewhat slow; this can be overcome by using certain histograms as in Fast Fuzzy C Means clustering method (Chaabane et al. 2008). Watershed methods even though give good results, it suffers from over segmentation and it unnecessarily segments into a number of regions (Belaid and Mourou 2009). It provides the connected component at the cost of computation time. This faces difficulty when segmenting the image with noise. Maximal Similarity based Region Merging method is semi automatic and needs human intervention for marking the background and the object; this makes this method computationally slow. It is intolerant to noise and moderately detects multiple objects. After exploring the above mentioned color segmentation techniques since we got better results using MSRM in comparison with other techniques, we have evaluated the MSRM technique using the evaluation parameters such as, Correlation, Jaccard coefficient, mean square error (RMSE) and Dice coefficient.

The correlation used as a measure of the similarity between ground truth image and a segmented image. The value of the correlation coefficient is between -1 and 1, where -1 indicates the similarity measure is away from the desired result. The Jaccard similarity coefficient, also known as the Tanimoto coefficient, measures the cover of two sets. It is characterized as the measure of the intersection

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Results of Arecanut crop bunch segmentation using Maximal Similarity based Region Merging (MSRM) method



of the sets partitioned by the span of their union. The Jaccard coefficient is zero if the two sets are disjoint, and is one if they are identical. So when applied this to evaluate the agreement of segmentation results, the goal is to get as close to 1 as possible. The simplest of image quality measurement is Mean square Error (MSE). The large value of MSE means that image is poor quality and The Root MSE (RMSE) is calculated using the formula, $RMSE = \sqrt{MSE}$. The Dice coefficient is similar to Jaccrd coefficient and represents the size of the union of 2 sets divided by the average size of the two sets. Dice coefficient with value of 0 indicates no overlap; and a value of 1 indicates perfect agreement. Higher numbers indicate better agreement.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The maximal similarity based region merging segmentation (MSRM) method is better compared to other methods and the corresponding evaluation is shown in Table 1 for images shown in Figure 6. From Table 1 it is evident that MSRM provides fair segmentation result and needs some improvement. This further drives for the need for some robust color segmentation algorithm for the purpose of Arecanut crop bunch segmentation.

FUTURE RESEARCH

Based on the experimentation on different color segmentation techniques it is clear that there will be a need of efficient and robust color segmentation techniques is essential for natural images. Also with single algorithm the results are not promising, this makes the essentiality of some hybrid color segmentation techniques which is either the fusion of existing algorithms. In the last technique the approach is semi-automatic which require human intervention in choosing the back ground and the object of interest. So based on these issue the future direction of this work focused at the following:

1. Automation of object and background selection part of MSRM algorithm.
2. Exploring graph based segmentation methods for the better results (Baldevbhai and Anand 2012; Shi and Malik 2000).
3. Exploring more hybrid segmentation methods i.e., fusion of segmentation methods.
4. Formulation of robust color segmentation techniques for images with complex background.
5. Exploration and experimentation of new segmentation techniques on different color spaces and hybridization of the color spaces.

Chapter 49
Applying Indigenous Knowledge in Agricultural Extension in Zimbabwe

Tinashe Mugwisi
University of South Africa, South Africa

ABSTRACT

Indigenous knowledge (IK) has been viewed as local knowledge that has been developed and accumulated, over time, by a community and has been passed down over generations. Such knowledge is represented in most spheres of human activity, such as in agriculture, traditional and alternative medicine, human and animal health, forestry and botany, among others. The purpose of this chapter is to discuss how IK is accessed and used by agricultural extension workers in Zimbabwe. The study reviews the relevant literature and focuses largely on Indigenous Agricultural Knowledge (IAK). The study utilises both quantitative and qualitative methods; a questionnaire was distributed and extension workers drawn from eight provinces of Zimbabwe. Mashonaland Central Province produced the highest number of respondents because the population for the province included ward and village extension workers in addition to the district and provincial extension officers and supervisors targeted in each province. From the projected sixty (60), forty four (44) districts participated. The study observed that indigenous knowledge is relevant in modern day agriculture and should be given sufficient attention in extension work. The study recommends that IK be documented and integrated into research, education and training for posterity.

INTRODUCTION

Woytek (1998, p. 1) opines that the literature on indigenous knowledge (IK) does not provide a single definition of the concept, partly due to the differences in background and perspectives of the authors, ranging from social anthropology to agricultural engineering. The United Nations Environmental Programme (2008, p. 21) and Masalu, Shalli and Kitula (2010, p. 4) observe that a variety of terms have been used to describe this form of unique knowledge. These have included such terms as "local knowledge," "traditional knowledge," "indigenous traditional knowledge," "indigenous technical knowledge", "tradi-

tional environmental knowledge", "rural knowledge", "traditional ecological knowledge" and so forth. Warren (1991), Woytek (1998), and Njiraine, Ocholla and Le Roux (2008) view indigenous knowledge as the local knowledge – knowledge that is unique to a given culture or society, which contrasts with the international knowledge system generated by universities, research institutions and private firms. It is the basis for local-level communication and decision making in agriculture, health care, food preparation, education, natural-resource management, and a host of other activities in rural communities. Rajasekaran, Martin and Warren (1994), Ghorbani, Khodamoradi, Bozorgmanesh and Emami (2012), Dixon (2001), Tikai and Kama (2004), Karthikeyan, Veeraragavathatham, Karpagam and Firdouse (2009) view indigenous knowledge as a systematic body of knowledge and skills acquired by local people through the accumulation of experiences, informal experiments, an intimate understanding of the environment. Woytek (1998, p. 2) observes the characteristics of IK, which distinguishes it from other knowledge as:

- **Local:** It is rooted in a particular community and situated within broader cultural traditions; it is a set of experiences generated by people living in those communities. When transferred to other places, there is a potential risk of dislocating IK.
- **Tacit Knowledge:** Not easily codifiable.
- **Transmitted Orally:** Or through imitation and demonstration. Codifying it may lead to the loss of some of its properties.
- **Experiential Rather than Theoretical Knowledge:** Experience and trial and error, tested in the rigorous laboratory of survival of local communities constantly reinforce IK.
- **Learned through Repetition:** this is a defining characteristic of tradition even when new knowledge is added. Repetition aids in the retention and reinforcement of IK.
- **Constantly Changing:** being produced as well as reproduced, discovered as well as lost; though it is often perceived by external observers as being somewhat static.

According to Reij, Scoones and Toulmin (1996), Woytek (1998), and Warren (1991), the indigenous information systems are dynamic, and are continually influenced by internal creativity and experimentation as well as by contact with external systems and influences such as from immigrants, return migrants, extension workers, and visiting businessmen and so on. Woytek (1998, p. i) and Masalu *et al*. (2010, p. 5) perceive that indigenous knowledge is important as it contributes to communities in many ways.

It provides the basis for problem-solving strategies for local communities, especially the poor. It represents an important component of global knowledge on development issues. Learning from IK, by investigating first what local communities know and have, can improve understanding of local conditions and provide a productive context for activities designed to help the communities. Understanding IK can increase responsiveness to clients. Adapting international practices to the local setting can help improve the impact and sustainability of development assistance. Sharing IK within and across communities can help enhance cross-cultural understanding and promote the cultural dimension of development. Help in identify innovative pathways to sustainable human development that enhance local communities and their environment.

The United Nations Environmental Programme (2008) concur, adding that indigenous knowledge systems have enabled the various communities in those countries to live in harmony with their environ-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ments for generations, and the systems are important tools in environmental conservation and natural disaster management.

Some forms of IK are expressed through stories, songs, myths, proverbs, cultural values, beliefs, rituals, community laws and local language. IK is mainly of a practical nature, particularly in such fields as fisheries, agriculture, health, horticulture, forestry and environmental management in general (Masalu *et al.*, 2010, p. 4). In traditional medical practice, certain herbs are known to treat a variety of ailments in both humans and animals. For example, according to the United Nations Environmental Programme (2008, p. 96) the Swazis use lihala (Aloe saponaria) to make preparations for treating high blood pressure, bile for nausea, fever and lethargy, snake bite, colon irritation, stomach ache. Ash from the leaves of the lihala can be used as cooking soda and as an ingredient for snuff, used by adults only.

BACKGROUND

Agricultural extension, "involves the transfer of agricultural information and technology to the farmers and similarly transferring information from farmers to researchers" (Pazvakavambwa & Hakutangwi, 2006, p. 217). Umali-Deininger and Schwartz (1994, p. 1) argue that: "The backbone of all agricultural extension endeavours is the transfer of agricultural information to enhance the productive capacity of farmers." Umali-Deininger and Schwartz (1994) further observe that embracing new technologies and production approaches in farming systems is essential in meeting the challenges of growing populations and the decreasing availability of productive land for agriculture. These efforts can be realised through the utilisation of various extension systems and approaches.

Agricultural extension in Zimbabwe has mostly been public sector driven through the Ministry of Agriculture. Private extension services are largely undertaken and supported by farmers' unions, private research organisations, and agricultural input suppliers such as seed and fertiliser companies as part of their business marketing. NGOs also provide their own extension services. Agricultural extension was introduced in Zimbabwe in 1927 by Emory D. Alvord with the help of nine field demonstrators (FAO, 2003). The Department of Agricultural Technical and Extension Services (AGRITEX) was established in 1981 following the merger of the Department of Conservation and Extension (CONEX) and the Department of Agricultural Development (DEVAG). CONEX had previously provided extension to large scale commercial farms while DEVAG catered for communal/ rural farmers (Rukuni, 2006). AGRITEX is headed by a Principal Director and seconded by two directors who are responsible for the Technical Division and Field Division respectively. The Field Division is headed by a director who is directly responsible for (8) eight provincial extension officers. Below the provinces are sixty (60) district extension officers, and below them are ward level extension personnel. Each province has six subject matter specialists (SMS). At district level (all sixty districts), there are three subject matter specialists and three hundred and eighty (380) zonal agricultural extension supervisors. The flow of information in the communication process follows both the top-down model and the bottom-up approach. Through AGRITEX officers based at the district offices, information is passed on to the AGRITEX extension supervisors and extension workers and then to the farmers. The officers and agricultural extension workers are also responsible for transmitting indigenous knowledge technologies, practices and problems from farmers to specialists and researchers. This creates a research extension network that is critical for appropriate research and extension messages/ communication (MoAMID, Department of AGRITEX, 2010).

MAIN FOCUS OF THE CHAPTER

The aim of this chapter was to investigate the use of indigenous knowledge in agricultural extension by addressing the following research objectives:

1. To establish whether IK is used by agricultural extension workers.
2. To ascertain the frequency of use of IK by agricultural extension workers.
3. To investigate how agricultural extension workers acquire IK.
4. To establish the types of IK obtained from various sources by agricultural extension workers.

ISSUES, CONTROVERSIES, PROBLEMS

Various studies have been conducted on the application of IK across disciplines and across the geographical divide. The section below provides literature on how IK has been applied in agriculture.

Indigenous Knowledge Types and Agriculture

Abioye, Zaid and Egberongbe (2011, p. 3) perceive that farmers adopt a wide range of indigenous agricultural practices based on generations of experience, informal experiments and intimate understanding of their environments. They further observe that the application of indigenous agricultural farming has been reflected in the following:

- Indigenous methods of maintaining soil fertility.
- Indigenous methods of controlling pests and diseases.
- Indigenous soil preparation and planting materials.
- Indigenous methods of controlling weeds.
- Indigenous methods of harvesting and storage.

Indigenous Methods of Maintaining Soil Fertility and Water Conservation

Shetto (1999, p. 67) opines that **t**raditional agriculture in the past was compatible with the level of population and ecological environment; long bush fallow periods were effective in restoring soil fertility for the prevailing level of crop yields and intensity of cropping. He further asserts that conventional flat cultivation, which is associated with modern (mechanised) agriculture tillage, encourages splash and sheet erosion as it leaves the soil surface bare, under sporadic tropical downpours. There are several IK methods of maintaining soil fertility and these include; shifting cultivation, mixed cropping, intercropping, mulching, compost (dead leaves), animal manure, (cow dung and goat droppings), chicken waste, planting local legumes (green manure), and charcoal ashes (Tikai & Karma 2004, p. 73; Lakra, Singh, Sinha, & Kudada 2010; Singh & Sureja, 2008, p. 645; Fowler & Rockstrom, 2001; Kolawole, 2005; Mowo, Janssen, Oenema, German, Mrema and Shemdoe, 2006; Notsi 2012, and Mishra & Rai 2013). Non-tillage farming techniques, which involve clearing land by hand or burning, help maintain fertility and have minimum disturbance to the soil as only holes to accommodate the plant are dug using sticks (Tikai & Karma, 2004).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Singh and Sureja (2008, p. 643) observe that farmers are able to classify soils, broadly as agricultural and non-agricultural soils used for farming and domestic purposes. Based on their experience, farmers are also able to classify soils according to topography, texture and colour, stickiness, depth and crop comparability (Singh & Sureja, 2008, p. 643). Similarly, Mowo *et al*. (2006, p. 52), Buthelezi (2010), and Osbahra and Allanb (2003) note that the local qualities of good soils include colour (black), cracks during the dry season, presents vigorous growth of certain plants, good yield, and low watering frequency, and an abundance of earth worms. Notsi (2012, p. 13) indicates that one method among both Batswana and Basotho of evaluating soil moisture is the hand – feel and soil appearance method, determining soil moisture by hand only gives relative soil moisture and is more accurate than other methods. According to Singh and Sureja (2008, p. 647), Tekwa, Belel and Alhassan (2010), and Shetto (1999) other methods of soil and water conservation include making entire fields into smaller plots, planting shrubs and perennial grass on the edges to prevent runoffs, mulching of seeds to avoid wind erosion, in sloppy lands, hill terraces, earth contour ridges, construction and maintenance of waterways, ploughing and sowing across slopes reduces erosion and stone bunds/lines.

Fenta (2009, p. 4) posits that farmers perceive soil fertility in terms of the capacity of soils for long-term productivity, their permeability, and water holding capacity, drainage, tillage, manure requirement and cultivability. To ascertain the accuracy of IK, Mowo *et al.* (2006, p. 47) compared soil fertility evaluation based on experience and knowledge of smallholder farmer communities with the evaluation by scientists based on soil analysis and model calculations. Farmers' experience and knowledge of local indicators of soil quality were used in identifying soil fertility constraints and in generating resource flow maps. The study established that farmers' indigenous knowledge in soil fertility evaluation mostly agreed with laboratory analysis and model calculations. Buthelezi (2010, p. 44) concurs observing that despite many differences between the scientific and indigenous approaches, farmers' soil suitability evaluation and fertility perception corresponds with the scientific evaluation. Tekwa *et al.* (2010), and Mishra and Rai (2013) concluded that IK technologies appeared viable and relevant in conserving soil and water required for sustainable crop production.

Indigenous Methods of Controlling Pests

Abate, Van Huis and Ampofo (2000, p. 642) assert that traditional control practices are still the major means of pest management to small-scale farmers in Africa and these control practices are based on built-in features in cropping systems, such as farm plot location, crop rotation, and intercropping, or on specific responsive actions to reduce pest attack, such as timing of weeding, use of plants with repellent or insecticide action, traps, scarecrows, smoke, and digging up grasshopper egg masses. Mugisha-Kamatenesi, Deng, Ogendo, Omolo, Mihale, Otim, Buyungo and Bett (2008) identify the major field pests reported by farmers which included banana weevil, bean fly, cereal stem borers, pod feeders, grain moth, rodents, moths, termites, birds, aphids and cutworms. They observe that the use of synthetic pesticides has raised a number of both ecological and medicinal problems while botanical pesticides are hailed for having a broad spectrum of activity, being easy to process and use, with a short residual activity (Mugisha-Kamatenesi *et al.,* 2008, p. 343). According to Tikai and Karma (2004, p. 71), and Mugisha-Kamatenesi *et al.* (2008, p. 343) some of the methods of controlling pests and diseases among crops include sanitation, burning and smoking, dusted plant materials (ashes and sand), and hand picking, fallowing and shifting cultivation, hand picking and squashing of beetles, slashing and burning, to use of physical barriers. Singh and Sureja (2008, p. 651) add that indigenous methods applied against

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

insects attack include that adult insects/caterpillars of different vegetables and pulse crops are physically picked from the plants of the infected fields and destroyed by burning and the resultant ashes are broadcasted to control the pests.

Natural plant materials, using ash on crops, hot pepper mixed with ash, and spraying animal urine are found to provide effective substitutes for agrochemicals (Gana, 2003; Akullo *et al.,* 2007, p. 7; Kiplang'at & Rotich, 2008, p. 725; Fenta, 2009, p. 3). Most of the indigenous insect pest control methods included measures to disrupt pests' life cycle by periodically denying them food and to achieve maximum control where the manipulation of ordinary agricultural practices would follow. Odeyemi, Masika and Afolayan (2006, p. 169) observe that in the Eastern Cape, the stem borer (for example, *Chilo partellus* [Swinhoe]), grasshoppers, cut worms, millipedes, moles, birds and the maize storage weevil (*Sitophilus zeamais*) are some of the pests which pose a major threat to maize growers. Besides using synthetic pesticides, the authors note that intercropping was one way used to overcome this problem in which crops such as onion and garlic are known to have characteristic pungent smells that repel insects. They also observed that aqueous extract from plants such as wild marigold (*unukanuke*) and cape aloe (*umhlaba*) is prepared and sprayed on crops. Mugisha-Kamatenesi *et al.* (2008, p. 343) concluded that traditional pest control methods, particularly the use of indigenous pesticide plants if improved, offer a safer, eco-friendly, low cost and more dependable method of field crops protection.

Indigenous Methods of Controlling Weeds

Weeding is generally conducted to eliminate plants which grow where they are not wanted as they may cause harm to legitimate crops. Tikai and Karma (2004, p. 74), and Notsi (2012) observe that methods of controlling weeds include hand weeding, shifting cultivation and fallowing, slashing and burning, intercropping and shallow cultivation. Singh and Sureja (2008, p. 646) also note that to enhance soil and water management, ploughing is a popular practice as it enables farmers to control pests, weeds and diseases by exposing the egg masses of insects and dormant spores of pathogenic organisms to the hot sun, killing embryos of weed seeds, while enhancing the water holding capacity of soil through reduced runoff losses. Rathore, Krose, Naro, Shekhawat and Bhatt (2012, p. 356) observed that the use of common salt for weed control under acidic conditions of a *jhum* paddy was not only effective in minimizing weed competition with planted crop, but also resulted in high productivity without negative impact on the fields. The method was also found to be cost effective compared to traditional methods such as hand weeding.

Indigenous Methods of Post Harvesting and Storage

Studies have shown that communities preserve and store food for consumption after harvest as most crops are seasonal. The United Nations Environmental Programme (2008) for example, observes that in western Kenya beanstalks were burnt and the ashes used as a preservative for grain and cereals. Cowpea, apart from providing food during the rainy season, is harvested, boiled, dried and stored in granaries to be consumed during the dry season. Grain is harvested and dried in the sun after which it is sprinkled with ashes as long term preservation against pests and impending attacks. Ali, Yadav, Stobdan, and Singh (2012) identify three methods of storing vegetables, being *sadong* (underground pit), *tsothbang*

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(vegetable cellar), and *charches* (hanging) and these could keep fresh root crops, carrots, cabbage, onion and turnip fresh for periods ranging from two to eight months and in sub-zero temperature winter months. They observe that these methods can be helpful in developing low cost innovative methods of preservations, minimize the post-harvest losses and increase the availability of vegetables during winter months. Smit (1997), and Tikai and Karma (2004, p. 75) concur and add that storing crops in cool places such as sheds, pit storage and timely harvesting of crops to reduce high moisture content are some of the practiced IK methods. Also, Akullo *et al.* (2007, p. 6) observe that when farmers harvest cassava, for example, the tubers are buried in moist soil measuring one foot deep, while another method involves peeling, slicing, drying and storing in baskets. The harvested crops are dried and stored in various ways, including granaries for crops such as maize and other cereals. The granaries need to be well ventilated as moisture may cause the grain to rot (Kiplang'at & Rotich 2008, p. 726). Sinha (2010, p. 537) also notes that various trappings, rice mixed with toxic seeds, and leaves or branches of *A.vulgaris* are put in and around granaries for repelling insects as well as rats.

Karthikeyan *et al*. (2009) looked at traditional storage practices in India observing that in the past, insect infestation was often a less serious problem because farmers cultivated traditional varieties, which although low yielding, were general less susceptible to insects attack. Karthikeyan *et al*. (2009), Sinha (2010), and Bett and Nguyo (2007) observe that the introduction of high yield varieties has resulted in high storage losses since the varieties are prone to insect attack, hence the need for remedies of which IK methods are considered low cost, avoid chemicals and use resources which are readily available.

Seed Preservation

For some communities, seed for planting, during the following season, is usually selected from the current harvest. As Moreno *et al*. (2006, p. 1778) observe the most common characteristics that Yaxcaba farmers take into account when selecting for seed are ear size and health uniformity of grain colour, and grain size, which are considered to be indicators of germination reliability. Kiplang'at and Rotich (2008, p. 725), and Sinha (2010) observe that farmers select seed which is healthy and a good size. These are then placed in baskets and hung on kitchen ceilings so that the smoke and heat can dry and preserve them. Ash and other concoctions are sprinkled over the seed to prevent the grain from being attacked by rodents, insects and other potentially harmful pests (Karthikeyan *et al*. 2009). Similarly, Moreno *et al*. (2006, p. 1782) note that in addition to granaries, some farmers make use of various containers to store their seed, placing them in different locations and maize seed ears are stored in the rafters of a household kitchen.

Notsi (2012, p. 11) notes that among the Batswana and Basotho the seeds of indigenous vegetables such as *Rothwe, theepe, tenane* and *morogo wa dinawa* are collected when they are dry. Women dispatch the seeds by shaking or threshing dried indigenous vegetables; this will usually suffice for extracting the seeds, and the seeds are protected from over-drying by covering them with leaves or other specially prepared mixtures bags, or clay pots are also used to minimize the risk of over drying. Most seed or seedlings, if cleaned and stored properly, will remain viable for many years. Likewise, Karthikeyan *et al*. (2009) note that vegetable growers store seed indigenously, for use during the next seasons through methods like pressing the seed with the thumb, biting or smelling the seeds, to storing them in cow dung. Other methods include dusting seed with lime, mixing seed with ash or salt which was considered to have abrasive action on the insect skin preventing it from moving inside storage containers such as mud pots.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Animal Health and Diseases

Indigenous knowledge practices in animal husbandry involve both reproductive health and the treatment of diseases. Various disease control mechanisms for chickens are observed in Akullo *et al*. (2007, p. 9) and these include *enkubebe* (small ants), *muziri* (tiny fish) and cannabis leaves pounded and added to water, to treat the Newcastle disease, while diarrhoea is treated using a mixture of cowpea leaves and salt. Begna leaf sap, sap of Ada (*Ginger*) and crushed black pepper is mixed and fed to the cattle for coughs and colds; seven pieces of chicken egg per day, to be fed for seven days, for the treatment of anoestrus; while to treat wounds, powder is made by grinding the seeds of Ata (custard apple, *Annona squamosa*), which is applied topically on a worm-infested wound (De Amitendu, Tudu &Goswami 2004).

Akullo *et al*. (2007, p. 9), The United Nations Environmental Programme (2008) observe that being mainly livestock keepers, the Maasai in Tanzania have a rich heritage of herbal cures for livestock. For example, they use osendu (Combretum mucronatum) to treat olchotai (guinea worm that attack throats of cows which they catch while drinking water), armme (Euphonobia cuneata) to treat abortion (brucellosis) in cattle and olorien (Olea africana) to sterilize milk gourds and treat East Coast fever in cattle. The leaves of the umsilinga (Melia azedarach) are used by the Swazis to prepare medicine for vomiting, running stomach, ulcers, high blood pressure, de-worming dogs and treating wounds in livestock. Adekunle, Oladele and Olukaiyeja (2002) observe that the frequently practiced indigenous control methods of pests and diseases by herdsmen are hygiene, self-diagnosis, use of herbs, movement from place to place, bush burning and spiritual incantation, magic and religious healing, mostly done by reading the Koran. Practical treatment including herbalism, ie treatment with parts of plants or other natural products, for example feeding animals with plants containing a high level of salt, that results in ticks falling off. Adekunle *et al.* (2002) also note that herdsmen's ages, marital status, contact with extension agents and years of experience influence their decision in practicing indigenous control methods.

Indigenous Knowledge and Weather Focus

Nyong, Adesina and Elasha (2007), and Elia, Mutula and Stilwell (2014) observe that there is a wealth of local knowledge based on predicting weather and climate and farmers have developed intricate systems for gathering, predicting, interpreting and decision making in relation to weather. According to United Nations Environmental Programme (2008) the Nganyi clan of Bunyore in western Kenya is known for their powers in predicting rain for more than 100 years and people believe that the Nganyi clan can make or stop rains, lightning and hailstorms, hence they take their weather advisories seriously and pay some fees to the family at the end of each season in the form of a share of their harvest. The clan perfected their rain-prediction art through observation of vegetation, trees, reptiles, birds and insects in the shrines.

The United Nations Environmental Programme (2008, p. 61) opine that the art of traditional rainfall prediction is, however, shrouded in mystery and is considered as a gift for a few. The potential person to inherit the art is identified in good time and is taken through the process of learning the art. Mutasa (2011) establishes that farmers rely on indigenous knowledge to determine weather patterns as a result of the absence of conventional weather reports from the Agritex Department while the United Nations Environmental Programme (2008, p. 26) cites a case of peasant farmers who listen to weather forecasts on the radio by the meteorological department but still prefer to rely on their own traditional knowledge of when to start planting. The more the "scientific" forecasting deviates from traditional knowledge the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

less it is used for planning purposes by the indigenous communities (United Nations Environmental Programme, 2008, p. 26).

Egeru (2012, p. 223) observes that the traditional rain prediction practices of using events, moon characteristics, tree phenology, diviners and particular animal behaviour patterns were still being utilized. Some of the prediction indicators used include a high density of spider webs in the locality is a sign of a very wet season. The indigenous methods used to predict drought and famine included the abundance of butterflies (Danaus plexippus) during the farming season, presence of army worms (Spodoptera exempta), animal and plant behavior, the availability of wild fruits and wind direction prior to the rainy season also gives indications of the season ahead (Mutasa, 2011; United Nations Environmental Programme, 2008). Maasai elders frequently use the behavior of animals and their health to foretell weather. For example, goat guts would be examined by a specialized Maasai elder, and if they were found to be having watery cysts on them during the month of August this would be taken to predict that the forthcoming season would have a lot of rains, but if the small intestine was found to be empty, drought, famine, hostility and war were to be expected in the chiefdom (United Nations Environmental Programme, 2008). Indigenous people living close to natural resources often observe activities around them and are the first to notice, identify and adapt to any changes. These changes may include the appearance of certain birds (seasonal migration), the mating of certain animals and the flowering of certain plants (Aluma 2001, p. 2; Gyampoh, Amisah, Idinoba and Nkem 2009, p. 70; Akullo *et al.* 2007). The indigenous knowledge on disaster prediction and early warning is based on keen observation of the behavior of animals, birds, insects, vegetation, trees, winds, air and water temperatures, clouds, earth movements and celestial bodies (United Nations Environmental Programme, 2008, p. 64).

Sources and Methods Used in Disseminating Indigenous Agricultural Knowledge

Singh and Sureja (2008, p. 651) observe that people learn about local practices of managing indigenous agriculture and natural resources through various localized sources where parents, nature, rural schools and social institutions, friends, neighbours and village wise men act as sources of knowledge providers. Egeru (2012, p. 217) asserts that the transfer of this knowledge and associated practices has been embedded in the culture through various rites of passage such as birth, initiation into adulthood, marriage, death, twin dancing and social gatherings which include beer parties. These views are shared by Shetto (1999, p. 69), and Mishra and Rai (2013) who note that traditional or indigenous technologies evolved as a result of a gradual learning process and emerge from a knowledge base accumulated by rural people by observation, experimentation and a process of handing down across generations, peoples' experiences and wisdom. Osbahra and Allanb (2003) expound that knowledge is acquired through personal experiences and overlapping communication pathways, both of which are influenced by social factors, including age, gender and family ties. Mundy and Compton (1991) observe that indigenous communication can take many different forms, which include the following:

- **Folk Media:** Used mostly for entertainment, but also educative (for example dance, song, plays, and storytelling among others).
- **Indigenous Organisations and Social Gatherings:** For example religious groups, village meetings, and women's groups, among others.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Deliberate Instruction:** Most cultures have traditional schools where cultural practices are imparted and subject coverage ranges from general to specific areas, including medicinal and agricultural practices (for example initiation ceremonies).
- **Records:** Many societies keep formal records, and these may be written, curved, or painted; African storytellers narrate memorised historical epics and genealogies at length.
- **Unstructured Channels:** Indigenous communication occurs in many settings in Africa (Sturges & Neil, 1998): on the road, in the fields, at the market, and wherever people meet and talk, and such communication is spontaneous and informal.
- **Direct Observation:** Communication does not necessarily involve a second person; by observing a neighbour's bumper crop, a farmer may conclude that the technique or variety used is good.

A study by Protz (1998) establishes how drama is developed to better understand how the nature of gender relationships within the farm family affects agricultural decision making, particularly with respect to fertiliser use and soil fertility issues.

METHODOLOGY

Qualitative and quantitative techniques were applied in this study and data was collected through a questionnaire distributed to extension workers, and through interviews with key informants at the Ministry of Agriculture's national offices. Zimbabwe has ten provinces of which two, Harare and Bulawayo, are urban and did not participate in the study. Extension workers were drawn from eight (8) provinces, which yielded eight provincial extension officers and sixty (60) district extension officers. Ninety-one (91) Subject Matter Specialists in the eight provinces and those stationed at the Head Office were also included in the study. The categories of Agricultural Extension Officers, Agricultural Extension Supervisors and Agritex workers were drawn from Mashonaland Central Province to constitute a representative sample of agro-regions II to V. Foti, Nyakudya, Moyo and Chikuvire (2007:30) explain that Mashonaland Central Province is made up of areas of varied agricultural potential ranging from agro-ecological region II to region V. Zimbabwe's agro-ecological zones range from region I to V, hence owing to the large number of extension workers involved at ward level in the country's eight provinces, the study of this category was restricted to Mashonaland Central Province, which was considered representative in terms of agricultural practices. From the 551 village/ward extension workers in the province, a sample of 10% (55) was selected. Purposive sampling was applied so that each of the seven districts in the province was represented. Random sampling was then applied to select village/ward extension workers in each district. Additional village/ward extension workers from fourteen districts (14) (agro-ecological zone I-V) were randomly selected to provide field experiences, although this category was extensively investigated in Mashonaland Central Province.

Key informants (policy makers) were interviewed and these were the Director – Field Services division and Acting Director – Technical Services division.

The questionnaires were distributed by the researcher and research assistants, and through the assistance of the provincial extension offices, for both Mashonaland and Manicaland regions. In order to validate the research instruments, a pilot study was conducted with the Ministry of Agriculture's Department of Veterinary Services, which was not part of the main study. Data was analysed using SPSS and through content analysis.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

RESULTS AND DISCUSSION

The following sections present the results and discussion of the study.

Characteristics of the Respondents

As indicated in Table 1, of the respondents who completed the questionnaire, one (0.6%) was a Director and another one (0.6%) was a Chief Agricultural Specialist. Twenty-one (12.2%) were in the category of Agricultural Specialist/Snr/Principal. Six out of eight Provincial Agricultural Extension Officers completed the questionnaire, being 3.5% of the total responses. Likewise, 38 (22%) district agricultural extension officers completed the questionnaires although 44 districts participated in the study.

The other categories of respondents were: Agricultural Extension Officer/Snr Principal 30 (17.4%); 24 (14%) Agricultural Extension Supervisors and these were from Mashonaland Central districts and those randomly selected from other districts. In the lower category, 51 (29.7%) were Village/ward Agricultural Extension Workers, being extension personnel at grassroots level, i.e. village/ward level, and these were selected from Mashonaland Central for reasons already indicated in the methodology.

With regards to qualifications of respondents, 66 (38.4%) were holders of a certificate in agriculture, and these were mostly extension workers at ward/village level. Twenty-four (14%) had a diploma; 67 (39%) had a bachelor's degree; 3 (1.7%) had a post-graduate diploma; while 12(7%) were holders of a master's degree. None of the respondents had a doctoral qualification.

Indigenous Knowledge Systems in Agricultural Extension

The use and application of indigenous knowledge in agriculture has been demonstrated in literature. The study sought to ascertain the importance of indigenous knowledge in agricultural extension by looking at its utilisation, frequency of use and type of sources used. Indigenous knowledge was found to be highly utilised in the generation of agricultural innovations, 153 (89%). Extension workers who indicated in the negative were 19 (11%).

Table 1. Designation of respondents

Designation	Frequency	
	N=172	%
Director	1	0.6
Deputy Director	-	-
Chief Agricultural Specialist	1	0.6
Agricultural Specialist/Snr/Principal	21	12.2
Provincial Agricultural Extension Officer	6	3.5
District Agricultural Extension Officer	38	22
Agricultural Extension Officer/Snr Principal	30	17.4
Agricultural Extension Supervisor	24	14
Village/Ward Agricultural Extension worker	51	29.7
Total	**172**	**100**

Frequency of Indigenous Knowledge Utilisation

This section was an extension of 5.2 above and sought to find out how frequently indigenous knowledge was utilised by the respondents. The results indicated that a minority 19 (11%) of extension workers never used IK for extension while the remainder varied in their use of IK. Results also indicate that a significant number, 35 (20.3%), of extension workers very often utilised IK, while 59 (34.3%) indicated that they "often" and "sometimes" utilise IK for extension, respectively. Table 2 summarises the findings.

Indigenous knowledge can be used to facilitate communication in rural development programmes, for example communication between project personnel and farmers is often very poor, particularly in projects with a structure that favours literacy, and this often results in a serious comprehension gap (Warren & Cashman, 1988, p. 4). It was thus significant to note that there was a high utilisation of indigenous knowledge among the respondents, although there were variations in the frequencies of utilisation among them. This is despite the fact that Bagnall-Oakeley *et al*. (2004, p. 119) observe that "although farmers utilise an indigenous knowledge system, the coverage of their indigenous knowledge system is frequently restricted and does not mesh well with the more formal research and extension networks". Van den Ban and Hawkins (1996, p. 20) also observe that "it is generally recognised that indigenous farmers' knowledge is crucially important for developing sustainable agriculture because this way of farming should be adjusted to local situations which the farmer usually knows better than the researcher or the extension agents".

Sources of Indigenous Agricultural Knowledge

Indigenous knowledge is acquired or derived from various sources, both formal and informal. This section sought to establish the sources of indigenous agriculture among the respondents. The results indicated that books were the chief source mentioned at 88 (51.2%), followed by 85 (49.4%) for conferences and workshops, and colleagues with 71 (41.3%). On the lower end of the scale, the sources which were considered the least by extension workers were village leaders/elders, and social gatherings, both mentioned by 34 (19.8%), and farmers' groups, mentioned by 28 (16.3%). The farmer groups are based on voluntary membership although the membership tends to be high due to benefits derived. Table 3 provides a summary of the findings.

The formal and non-formal nature of IKS was also reflected by the sources mentioned by the respondents. The study revealed that indigenous agricultural knowledge acquisition was derived from a variety

Table 2. Frequency of indigenous knowledge utilisation

Use of Indigenous Knowledge	Frequency	
	N=172	%
Very often	35	20.3
Often	59	34.3
Sometimes	59	34.3
Never	19	11
Total	**172**	**100**

Table 3. Sources of indigenous agricultural knowledge

Sources of Indigenous Agricultural Knowledge	Frequency	
	N=172	%
Personal experience	51	29.7
Books	88	51.2
Social gatherings	34	19.8
Conferences/workshops	85	49.4
Village leaders/elders	34	19.8
Agricultural shows	37	21.5
Village meetings	42	24.4
Farmer's groups	28	16.3
Demonstration and observation	51	29.7
Colleagues	71	41.3

*Table indicates multiple responses.

of sources, both formal and informal. The responses show that formal sources, ie books and conferences/ workshops, were mentioned by the majority – 51.2% and 49.4% respectively – while colleagues were mentioned by 41.3% of the respondents. Whereas studies have shown that the transfer of IK and associated customs has been embedded in the culture and communicated mostly through informal sources (Mundy & Compton 1991, Akullo *et al.* 2007, p. 2, Kiplang'at & Rotich 2008, Gyampoh *et al.* 2009, Egeru 2012, p. 217) and others, it is interesting to note that books, conferences and workshops were ranked highly as chief sources by the respondents. What the study did not request were these sources for clarity. Studies have also shown that IK is at risk of becoming extinct if it is not documented (Singh & Sureja (2008), Lwoga, Ngulube & Stilwell (2010), Ghorbani *et al*. (2012), and Egeru (2012).

Demonstrations/observations and personal experiences were also ranked high by the respondents, with the least mentioned being farmers' groups. This observation is in concurrence with views from Shetto (1999), Osbahra and Allanb (2003), Mishra and Rai (2013) cited above. In contrast, for example, Lwoga, Ngulube and Stilwell (2010, p. 178) observed that in Tanzania IK was acquired through local sources such as parents/guardian/family, neighbours and friends, and personal experience. Sources such as books and other publications are not highly rated. Studies by Akullo *et al.* (2007), Kiplang'at and Rotich (2008), and Gyampoh *et al.* (2009) demonstrated that the elderly people in traditional societies provide the main source of IK based on experience accumulated over generations. Contrary to these observations from literature, it was also important to note that the elderly was not considered highly as sources of IK. The study has also shown that social gatherings and agricultural shows were among the numerous sources of indigenous knowledge by extension workers.

Interviews were conducted with the two key informants (policy makers) drawn from Field Services division Technical Services division. The respondents acknowledged the importance of indigenous in extension services, indicating that IK was embedded in the Department of Research and Specialist Services' (DR&SS) programmes and as AREX, when the two departments were previously merged. These observations dovetail with the responses in Table 3 in which village elders, village meetings and personal experiences were found to be among the key sources of information by extension personnel.

Types of Indigenous Agricultural Knowledge Obtained From Sources

The respondents were asked to indicate the types of IAK they obtained from the sources they had mentioned in the preceding question and based on agricultural topics and subtopics. Plant diseases and pests were mentioned by the majority of extension workers, 152 (88.4%), followed by plant breeding, 139 (80.8%), with dairy farming being third, mentioned by 135 (78.5%) respondents. The least mentioned was crop harvest and storage by 31 (18%) respondents. The responses are summarised in Table 4.

Crop harvesting and storage was the least mentioned by 31 (18%) respondents. However, this is despite the observation that crop protection is closely linked to plant diseases and pests, which was mentioned by a high of 88.4% of the total respondents. Singh and Sureja (2008), Akullo *et al.* (2007, p. 2), Egeru (2012), argue that Indigenous Knowledge (IK) has for many years steered farmers in planning agricultural production and conservation of natural resources. In view of this, different types of Indigenous Agricultural Knowledge can be obtained from different sources. Pests and other diseases have been viewed as a major threat to farmers' yields (Odeyemi, Masika and Afolayan, 2006, p. 169, Bett & Nguyo, 2007, Karthikeyan *et al.* 2009, Sinha, 2010). The study concurs as shown among the respondents, the higher categories of information obtained were plant diseases and pests (88.4%), plant breeding (80.8%), and dairy farming (78.5%), while information on plant pathology, animal breeding and soil classification were also reportedly obtained by more than 70% of extension workers. Information on crop harvesting and storage was the least mentioned by extension workers.

The effectiveness of IK in agriculture is demonstrated in the studies by Dakora (1996), Tikai and Kama (2004), Abu (2005), Odeyemi, Masika and Afolayan (2006), Kiplang'at and Rotich (2008), Fenta

Table 4. Types of indigenous agricultural knowledge obtained from sources

Type of Indigenous Agricultural Knowledge Obtained	Frequency	
	N	%
Soil fertility	75	43.6
Horticulture	81	47.1
Soil classification	123	71.5
Plant breeding	139	80.8
Poultry	102	59.3
Plant pathology	133	77.3
Dairy farming	135	78.5
Plant diseases and pests	152	88.4
Crop protection	36	20.9
Animal health	90	52.3
Tobacco culture	105	61
Animal breeding	127	73.8
Weather patterns	55	32
Crop harvesting and storage	31	18
Crop varieties	62	36

*Table denotes multiple responses.

(2009), Handayani and Prowito (2010), Lakra, Singh, Sinha, and Kudada (2010), Mutasa (2011), and Mugisha-Kamatenesi *et al*. (2008). These studies look at the different types of IK, which include soil fertility, diseases and pests as sources of Indigenous knowledge as well as methods of disseminating IK. The study thus reveals that different types of Indigenous Agricultural Knowledge are obtained from a variety of sources by extension workers, with varying emphasis among the types.

FUTURE RESEARCH DIRECTIONS

The utilisation of indigenous knowledge provides relevant and timely interventions in agricultural activities. As Abioye, Zaid and Egberongbe (2011, p. 9) noted "The urgency of indigenous knowledge documentation in Africa can be appreciated from the fact that when an old man dies in Africa, a whole library/archive perishes with him due to the oral nature of African indigenous knowledge". Hence, Lwoga, Ngulube and Stilwell (2010, p. 175), point out that there is an urgent need to acquire, document and preserve IK for agriculture before much of it is completely lost. In order to continuously harness such knowledge, further research could be conducted on the perspectives from the indigenous farming communities. For example, the impact of climate changes on traditional practices, and on the availability of traditional plants which are used in most remedies.

CONCLUSION

Indigenous Agricultural Knowledge was utilised as indicated by the majority of extension workers, although the frequency of utilisation varied among the respondents. The study also showed that Indigenous knowledge was used and highly appreciated by extension workers and was acquired from a variety of sources, both formal and informal. The top three sources of IK for extension workers were books, conferences/workshops and colleagues, with farmers' groups being the least mentioned source for the two groups. The study revealed that Indigenous knowledge derivation transcended across the different agriculture disciplines (crop science, soil science, animal science, and post-harvest storage).

Indigenous knowledge is used by farmers and extension workers as is evident from literature and the findings presented. It is applied in the crop production processes, which include planting, and protection against pests and other diseases, as well as in post-harvest. IK is also applied in animal husbandry in treating wounds and other diseases. Literature has, however, shown that there are challenges related to IK use in agriculture, which include the incapacity of traditional remedies to cure some ailments and how modern medicinal approaches become substitutes. As Ghorbani *et al*. (2012, p. 89) indicate indigenous knowledge is deteriorating quickly: by every death of old indigenous people, great knowledge resources would be lost also, so every action toward gathering indigenous knowledge is necessary. Singh and Sureja (2008, p. 653) challenge the need to educate policy makers and planners on the value of local and indigenous systems and the importance of integrating them in the development processes in South Africa, the government recognises and appreciates the importance of Indigenous knowledge and this has resulted in the establishment of a national IKS policy and dedicated secretariat (Njiraine, Ocholla & Onyancha, 2010, p. 195). Efforts have already been made for such integration in Uganda (Gorjestani, 2001) and Kenya (Kiplang'at & Rotich, 2008).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The study recommends that IK methods should be documented and integrated into the curricula, especially extension training. The validity of IK against scientific measures is evident and supported by Mowo et al. (2006, p. 52), Buthelezi (2010), Osbahra and Allanb (2003). As noted by Rajasekaran, Martin and Warren (1994, p. 29), incorporating IK into agricultural extension education will among other things help to understand perspectives of local people, recognize the accomplishments of local farmers as well as increasing the participation of farmers and their organisations in integrating, utilizing and dissemination of what already exist.

KEY TERMS AND DEFINITIONS

Agriculture Extension: The transfer of agricultural information and technology to the farmers and similarly transferring information from farmers to researchers.

Indigenous Agricultural Knowledge: The agricultural knowledge that peasant farmers have at any one time. It is constituted both by the empirical contents of that knowledge and by the principles that underlie its production, organization and meaning (Bebbington, 1990, p. 15).

Indigenous Knowledge: The sum of experience and knowledge of a given ethnic group that forms the basis for decision-making in the face of familiar and unfamiliar problems and challenges (Warren & Cashman, 1988, p. 3).

Sustainable Agriculture: An agriculture that can evolve indefinitely toward greater human utility, greater efficiency of resource use, and a balance with the environment that is favourable both to humans and to most other species (Harwood, 1990, p. 4).

This research was previously published in the Handbook of Research on Social, Cultural, and Educational Considerations of Indigenous Knowledge in Developing Countries edited by Patrick Ngulube, pages 303-323, copyright year 2017 by Information Science Reference (an imprint of IGI Global).

Chapter 50
Multiple Exploration of Entrepreneurs' Suggestions for Agricultural Development of Local Regional Units in Greece

Odysseas Moschidis
University of Macedonia, Greece

Vasileios Ismyrlis
Greek Statistical Authority, Greece

ABSTRACT

The purpose of the present article is to evaluate the factors which are considered to be important for the agribusiness development of a local economy, with data derived from the entrepreneurs' perspective. For this purpose, an appropriate methodology was designed, in order to include the most of the aforementioned factors. Emphasis was given to questions which can illustrate the level of technological innovation with actions and initiatives like digital marketing, innovative ability and others. Therefore, a questionnaire was created and was then applied to many regions in northern Greece. In respect of data analysis, the contribution of Correspondence Analysis (CA), a method from the multidimensional statistics field, was crucial because it easily revealed the characteristics that intensively differentiated themselves. The above methodologies and their special characteristics facilitated also the implementation of SWOT analysis. In the case of the Regional Units examined in the current research, the positive and negative factors-points were easily revealed and presented.

INTRODUCTION

The agribusiness sector is facing many challenges worldwide, as the globalization affects its structure and access to markets. Having already many additional problems due to the complexities and uncertainties linked to the sector, it is nowadays even more essential to try to cope with and implement new methods and technologies. One major example of these complexities is the global production networks (Hampton et al., 2007).

The present chapter is the beginning of a new research with a principle goal to help the administrations of the local authorities or/and central government evaluate their performance in aiming to pursue rural economic development. In their effort to contribute to this field, one of the most important actions is to implement initiatives that can assist the agricultural enterprises to develop and stabilize strong entrepreneurship values. Another important activity in the same direction, is to evaluate and record the current situation in their local regional unit. This can be succeeded with the utilization of suitable instruments that collect information from the entrepreneurs themselves.

The above suggestion to collect information, can be realized with an effort to measure the factors that enhance agricultural development from the entrepreneurs' perspective. In order to collect the relevant information, the research presented here, is based on data obtained by a questionnaire survey. The questionnaire that created by the authors, contained a section about demographics and another one concerning the entrepreneurs' perception of the existed local agricultural development's actions-factors. The main goal is to provide an important tool that administrators of the local authorities could use to make decisions, with an aim to improve the economic climate, and furthermore to pursue development.

For the analysis of the data, Correspondence Analysis, a multidimensional statistical methodology, is mainly used, as the most suitable for discovering correspondences (Benzecri, 1992) between the variables. It is an exploratory methodology of data analysis that does not assume any distribution of the data and puts forward possible trends that exist in the data graphically (Greenacre, 2007), as well. The results are presented on graphs that represent the configuration of points in projection planes formed by the first principal axes (Lebart et al., 1984, p. 44). This approach enables the researcher not only to analyze the phenomenon in a more holistic way, but also to highlight potential issues and questions that have not been previously identified. Two proposed tables, which enable the evaluation of ordinal data in a different aspect, will also be utilized (Moschidis, 2006; 2009).

The methodology utilized for the determination of the relationships of the different characteristics, is S.W.O.T analysis. The specific technique is used to evaluate the Strengths, Weaknesses/Limitations, Opportunities, and Threats involved in any business project (Piercy & Giles, 1989). It involves specifying the objective of the business venture or project and identifying the internal and external factors that are favorable and unfavorable to achieve that objective (Helms & Nixon, 2010). In the present case it can be used as a measure for evaluating and presenting the factors that can contribute to the economic development of a local regional unit.

The research had started from regional units from Northern Greece, with a view to be generalized in national level. The study concluded in some interesting results; firstly, in some distinguished factors for the agricultural growth that should be taken into consideration by the authorities, and secondly in the realization that there appeared to be no differences in the opinions of entrepreneurs with different demographic backgrounds. The methodology used, seemed to be perfectly suitable to extract the elements that distinguished as from the present chapter.

BACKGROUND

Agricultural Economic Development and Innovation

Agriculture is a business sector of the economy, but it seems to be a strategic one as it handles food safety and quality, it produces interdependencies with other sectors of the economy and deals with most of the natural resources of a country's economy (Ariza et al., 2013). The global demand for food will increase by 70% until 2050, but the productivity of the agricultural sector has decelerated the last years (GSRT, 2013;Moschidis & Arabatzis, 2013). For all the above factors, governments are obliged to pay a close attention to this part of the economy. For example, in the unified Europe, there are some common targets and policies for the agricultural policy.

As referred to the ''European Commission rural development program for 2014-2020'' (European Commission, 2014), some of the priorities to be followed are:

- Fostering knowledge transfer
- Enhancing competitiveness
- Promoting food chain organization and risk management
- Restoring, preserving and enhancing ecosystems
- Promoting resource efficiency and supporting the shift toward a low-carbon and climate-resilient economy
- Promoting social inclusion, poverty reduction and economic development in rural areas.

From all the above priorities it can be concluded that the agricultural sector inside the European Union should expand to fields like innovation or/and technology, that they may be seem peculiar (especially to Greek farmers) and perhaps a new addition for this sector, but they are implemented to all other business sectors and activities for many years and they seem to be essential to enhance competitiveness and to survive the demanding global environment. In addition, many researches have highlighted that topics as innovation, entrepreneurship and the learning organization have a linkage with market orientation (Johnson et al., 2009). Market orientation is also a key factor for the appropriate connection with the markets and the customer and this aspect has already been examined in the agribusiness field (van Duren et al., 2003).

Development of agricultural entrepreneurship has been an important policy in order to increase the value of agricultural production and open up the sector for businesses which is a clear departure from what obtained in the past, when oil prices were at their peak (Olawa & Olawa, 2015). Agribusinesses should compete not only on domestic markets, but on global as well (Esterhuizen, 2006) as competition and customer orientation have further increased (Dlamini & Kirsten, 2014). Developing entrepreneurial skills of the farmers seem to be essential to expand the competitive ness of their enterprises, many times needed just to survive or to find chances to expand more. A contribution to this effort can always be an effective regional policy (Polyzos & Arabatzis, 2005), which involves the increase of economic productivity. The productivity of the agricultural sector can be further associated with factors like good rural infrastructure (Llanto, 2012) and access to appropriate technology (Pinstrup-Andersen & Shimokawa, 2007). Investment in infrastructure contributes to the reduction in transport and marketing costs and therefore producers are better linked to markets (Ashok & Balasubramanian, 2006). Surely,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

governments through public investment can further contribute to the establishment of the above factors (Nadeem et al., 2011).

Innovation seems to be another key factor for economic growth and development, both for enterprises and countries. Innovation can be implemented in the fields of product, processes, organization and market (Śledzik, 2013) and can include and can be facilitated by technological aspects and actions (Papaioannou et al, 2015). Many of these actions are examined in the present questionnaire.

Greece's Status in Agricultural Entrepreneurship, Innovation, and Technology

Agriculture is the fourth most important economic activity (see economic sectors in ''Key terms and Definitions'' section) within the structure of Greek GDP(Gross Domestic Product) and represents 3.7% of the total (ELSTAT, 2016), which makes it essential for the Greek economy, although there was a decline in this percentage from 6.08% in 2000 to 3.7% in 2013. Certainly, the economic turmoil existed since 2008 has a serious negative impact to the Greek food sector (Chatzipetrou & Moshidis, 2016). In terms of employment, agriculture accounts for 13.2% of the total in the country (European Commission, 2016). The Northern Greece regions, which are examined in the present study, include those of Central, Eastern and Western Macedonia, Hepirus and Thrace. All together they assemble the 29.4% of the total number of Greek agricultural enterprises and the 26.7% of the added values of agricultural production (ELSTAT, 2009).

It seems that globalization has affected seriously the Greek agricultural sector, as it comes up afainst faces a situation with intense competitiveness with many other economies/countries that are in a position to offer much better prices and very often products of better quality. On the other hand, this globalization is always a big opportunity to enter into new markets and countries. Nevertheless, the Greek agricultural sector is confronts many negative issues, as the great number of small farms (European Commission, 2014) and the high rate of economically active people employed by the sector (Polyzos & Arabatzis, 2005).

Concerning the innovation implemented in this sector, there is a lag in innovation measurement for agricultural firms (Ariza et al., 2013) all over the world and therefore data from two big surveys, the Global Competitiveness and the Global Innovation were also utilized. These surveys present specific indices to express many aspects of economic activities, but surely the most important ones, like competitiveness and innovation (Cornell University, INSEAD & WIPO, 2015; World Economic Forum, 2013). Greece seems to have achieved notable results in the last years (Cornell University, INSEAD & WIPO, 2015; World Economic Forum, 2015), concerning the Competitiveness and Innovation indices and certain pillars (Graduates in science, Quality research institutes, Ease of protecting investions) have distinguished. However, these results refer to the overall Greek economy and entrepreneurship and there is no specific data for the agricultural sector.

METHODOLOGY

Questionnaire

The fifty-five (55) questions of the current questionnaire (Table 11, Appendix), were taken from the relevant bibliography and included topics concerning competitiveness, innovation and other aspects of entrepreneurship.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

More specifically the fifty-five questions (E1-E55), could be grouped in the following categories (in the parentheses some of them are referred):

- Economic factors (ease of getting credit, economic climate, strength of investors protection, effects of taxation, funding from ESPA program, supports new workplaces, agritourism's expansion).
- Marketing factors (effective advertising, consumer satisfaction (examination of trends), possibility of exports, local demand, intensity of local competition)
- Quality of products and processes (quality of local suppliers, possession of quality standards as ISO 9001, 22000 or Agrocert)
- Human capital-Training-Skills (education, extent of staff training, skills possession)
- Infrastructure Logistics-Transports: (quality of roads, connection with big urban centers)
- Internet access and usage: (ICT Access, ICT Use)
- Information and knowledge diffusion-technology: (knowledge diffusion)
- Environment and Energy (ecological sustainability, photovoltaic parks, natural resource protection, protection of biodiversity)
- Innovation in production and marketing: capacity for innovation, use of digital marketing, number of new products, patents.

There were also four questions about demographics: age, level of education, profession and sex. This study covers the results from a research started in the beginning of 2015 and completed in the April of the same year in all the Regional Units of Northern Greece. The questionnaire was distributed to a broad sample of entrepreneurs in the local economy over eighteen years old, covered all professions and education levels. The question for the entrepreneurs was: "To what degree do you think the following characteristics exist in your business sector or local economy?", and the possible answers were, 1:"not at all", 2:"little", 3:"somewhat", 4:"much", 5:"a great deal". Consequently, higher scores on this scale indicate the strong existence of the characteristic. Moreover, there was a definite distinction to which factors referred to the local economy and which to the local business sector.

The main subject to be answered was to seek the most and least featured factors that existed in the local economy or business sector. Afterwards, merely the questions from the agricultural entrepreneurs where distinguished and are presented from now on.

SWOT

The S.W.O.T. analysis is a methodology from the field of management science, which is used to evaluate the Strengths, Weaknesses/Limitations, Opportunities, and Threats existed in any business project. It involves specifying the objective of the business venture or project and identifying the internal and external factors that are favorable and unfavorable to achieve that objective. The final step of the method is a presentation of a table, which includes all the factors for the Strengths, Weaknesses/Limitations, Opportunities, and Threats that exist in the current project.

In the case of the regional public administration, SWOT analysis is a means of reviewing and evaluating on the performance and potentials of the local economy. With the execution of this process, to identify the local, regional unit economic performance, SWOT analysis can be a valuable evaluation tool for the management of the regional administration.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Correspondence Analysis and Special Tables of Coincidences

C.A. is an exploratory technique of the data analysis field, which does not assume any distribution of the data and is putting forward intensively differentiated trends that exist in the data, graphically as well. (Moschidis et al., 2009).

In this project C.A. is applied to two proposed tables of coincidences:

1. The table of evaluation: this table displays the distribution of the n_1 individuals of group A in 3 grades of the three-grade scale (we assume for convenience that the p questions E1, E2,…, Ep are formulated in a three-grade scale (not at all(1)-moderate(2)- very much(3)), therefore the table of evaluation has the following form (Table 1):

For the meaning of the numbers $K_{ij,}$ we note that number, e.g. K_{23} equals the number of the individuals of group A that chose for the question E2 the grade 3.

2. The table of comparative evaluation (Moschidis, 2006, 2009, 2015), which is defined in the comparative evaluation of the questions E1, E2,…, Ep from the two (or more generally) groups A and B. This table derives from the horizontal union of the tables of evaluations of groups A and B, therefore the table of comparative evaluation has the following form (Table 2):

Subsequently, implementing the correspondence analysis to the table of comparative evaluation and the points-columns e.g. A2, B3 are close to the point-line E2 in the first factorial space, it transpires

Table 1. The table of evaluation of the group A

	A			**Sum**
	A1	**A2**	**A3**	
E1	K_{11}	K_{12}	K_{13}	n_1
E2	K_{21}	K_{22}	$\mathbf{K_{23}}$	n_1
Ep	K_{p1}	K_{p2}	K_{p3}	n_1
Sum	K_1	K_2	K_3	pn_1

Table 2. The table of comparative evaluation of groups A, B

	A			**B**			**Sum**
	A1	**A2**	**A3**	**B1**	**B2**	**B3**	
E1	K_{11}	K_{12}	K_{13}	K'_{11}	K'_{12}	K'_{13}	$n_1+n_2=n$
E2	K_{21}	K_{22}	K_{23}	K'_{21}	K'_{22}	K'_{23}	n
Ep	K_{p1}	K_{p2}	K_{p3}	K'_{p1}	K'_{p2}	K'_{p3}	n
Sum	$K_{.1}$	$K_{.2}$	$K_{.3}$	$K'_{.1}$	$K'_{.2}$	$K'_{.3}$	pn

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

that group A evaluated the criterion E2 with the grade "moderate"(2), while the group B with the grade "very much" (3). With this aspect, the comparison of the views of the different groups A and B, for the criteria E1, E2,…, Ep is realized (Moschidis, 2006).

ANALYSIS

Descriptive Statistics

A brief presentation of some descriptive statistics of the sample analysed, are presented below:

The average grade of the responses in the fifty-five questions, of all the agricultural entrepreneurs in the 5-point scale was 2.65, which means that the economic characteristics examined in this research, are not very well implemented in the regions. For example the percentage of the entrepreneurs that replied "somewhat" was 32.72% (Table 4).

Application of the Proposed Methodology

Multivariate Analysis

Firstly, for the implementation of the Correspondence analysis, the table of evaluation for the fifty-five questions was created (see Table 5). This table, is the realized application of the first one of the proposed tables, which were referred above in the methodology section.

Table 3. Demographics of the respondents (agricultural entrepreneurs)

Gender	%	Age	%	Education Level	%
Male	65.2	18-30	36.1	Not attended	1.0
Female	34.8	30-44	28.1	Primary	33.5
		>45	35.8	Secondary	44.6
				Univ.graduate	19.2
				Post graduate	1.7

Table 4. Percentages of the responses in the 5-grade scale

Response-Grade	Percentage-%
1:not at all	18.00
2: little	27.00
3:somewhat	32.72
4:much	16.93
5:a great deal	5.35

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Table of evaluation of the fifty-five questions

Questions	Grades						Questions	Grades						Questions	Grades				
	1	2	3	4	5			1	2	3	4	5			1	2	3	4	5
E1	20	51	78	29	2		**E19**	34	60	60	23	3		**E38**	76	50	40	9	5
E2	28	66	55	28	3		**E20**	20	45	71	37	7		**E39**	37	58	50	24	11
E3	20	50	76	28	6		**E21**	19	40	50	57	14		**E40**	24	62	67	22	5
E4	18	49	75	33	5		**E22**	23	50	79	27	1		**E41**	12	36	48	65	19
E5	19	58	71	29	3		**E23**	61	55	51	13	0		**E42**	12	27	46	63	32
E6	57	53	51	19	0		**E24**	28	52	75	22	3		**E43**	37	47	63	27	6
E7	44	**50**	69	16	1		**E25**	24	45	69	37	5		**E44**	50	64	53	11	2
⋮	⋮	⋮	⋮	⋮	⋮		⋮	⋮	⋮	⋮	⋮	⋮		⋮	⋮	⋮	⋮	⋮	⋮
E15	72	62	37	7	2		**E33**	16	12	34	51	67		**E52**	25	56	71	25	3
E16	35	22	57	44	22		**E34**	23	45	85	20	7		**E53**	29	53	71	25	2
E17	30	28	49	43	30		**E35**	11	48	66	45	10		**E54**	16	46	54	48	16
E18	71	52	42	14	1		**E36**	45	62	50	21	2		**E55**	22	56	76	26	0

For the better understanding of the numbers in the above cells, an example is given. Number 50 in question E7, corresponds to the grade 2 of the scale, which means that fifty respondents have answered "little" in this question.

The results after the implementation of the correspondence analysis, to the table of evaluation are following.

Firstly, the table of eigenvalues is presented, where the total inertia is 0.25167 (Table 6).

- The first factorial axis (first main trend) interprets with a percentage of 72.66 the researched issue.
- The second factorial axis (second main trend) has a 19.79 interpretation percentage.

The first factorial space interprets data with a percentage of 92.45, which is a very good and adequate percentage for further analysis.

From the results of correspondence analysis, which are presented in Table 7, we will use the most important interpretation indicator of point (characteristic) towards axis, which is Contribution (CTR), as it expresses its contribution's percentage, in axis construction. The points with large CTR towards the axis, construct and many times highlight its physical importance.

Table 6. Eigenvalues-Inertia for the table of evaluation

TOTAL INERTIA		0.25167		
AXIS	**INERTIA**	**%EXPLAN**	**SUM**	**SCREE PLOT**
1	0.1828533	72.66	72.66	**********
2	0.0498098	19.79	92.45	**********
3	0.0120358	4.78	97.23	***
4	0.0069669	2.77	100.00	**

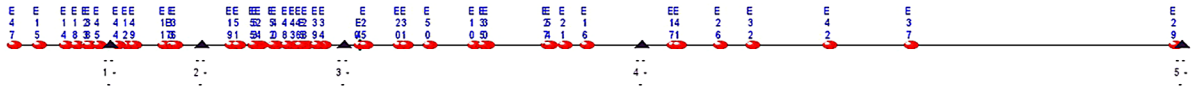
Using F indicator (coordinate) we define the side of the axis in which the point (characteristic) is represented. Therefore, the points with positive coordinate are situated on the right side and on the other side are those with negative. We note that the average CTR is 1000:55= 18.18, where 55 is the number of the points-questions. Therefore, we can consider points of high contribution in axis construction, those with CTR values above average (CTR values over 20 are in bold for the first axis and over 25 for the second). Having in mind the above estimations and the help of the visualization of the axes (see Fig. 1, 2, 3), we conclude in the following results (Greenacre, 2007).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. First factorial axis



The first axis (Figure 1), opposes characteristics, that have proved to exist in a great extent in the local economy or agricultural sector, the following: "Productivity of the sector" (E29), ''Connection with big urban centers (E32), "Unemployment" (E33), "Sectorial unemployment" (E37), "Tourist sector's development perspectives" (E41) "Secondary production perspectives" (E42), "Green development" (E17), '' Connection with other sectors'' (E26), to characteristics that their existence have been realized to be negligible, like: "Investments from outsiders" (E15) and "Innovative companies in the sector" (E47), ''Digital marketing in the sector'' (E14) and ''Photovoltaic parks (E18) .

The second axis (Figure 2) opposes factors that were ranked with 1 or 5, as: the "Investments from outsiders" (E15), "Photovoltaic parks" (E18), "Productivity in the sector" (E29), "Unemployment" (E33), "Knowledge diffusion in the sector" (E38), "Innovative companies in the sector" (E47) with factors that got the mediate values (3,4) like, "Care for biodiversity" (E1), "Access to internet" (E10), "Possession of quality certificates" (E55).

From the preceding analysis and Figure 3, we can conclude (Greenacre, 2007), that there are many factors that seem to strongly differentiate themselves. Firstly, the positive ones (that contribute positively to the economic environment and entrepreneurship) are: "Productivity of the sector" (E29), ''Connection with big urban centers (E32), "Tourist sector development perspectives" (E41) "Secondary production perspectives" (E42), "Green development" (E17), "Connection with other sectors" (E26). From the opposing point of view, the negative ones are presented: "Investments from outsiders" (E15), ''Innovative companies" (E47), ''Digital marketing" (E14), ''Knowledge diffusion" (E38), ''Connection with other sectors" (E26), ''Unemployment in the sector" (E37), "Unemployment" (E33), ''General state of the economy" (E5). From the above results, important conclusions can be drawn from the SWOT analysis, which can be seen in Tables 8,9 for the local economy and the agricultural sector, respectively.

Consequently, it is obvious that unemployment (inside the sector or not) from the perspective of the entrepreneurs, is a serious threat in the regions examined. On the other hand, there is an opportunity for the secondary production as well the tourist sector to further expand. Both previous factors are considered very important for the economic prosperity of any region. The agricultural sector of the regions examined, seems to experience some other problems too, like the lack of: innovation, knowledge diffusion and digital marketing, all of which are entrepreneurship friendly. On the other hand, the local

Table 8. SWOT analysis of the local economy

Strengths	Weaknesses	Opportunities	Threats
Green development	Investments from outsiders	Secondary production perspectives	Unemployment
	Photovoltaic parks	Tourism development perspectives	General state of economy
		Connection with big urban centers	

Table 9. SWOT analysis for the agricultural sector of the local economy

Strengths	Weaknesses	Opportunities	Threats
Productivity	Digital marketing	Connection with other sectors	Unemployment in the sector
	Innovative companies		
	Knowledge diffusion		

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

agricultural sector seems to have an adequate connection with other sectors, and its productivity is well established. The general state of the economy is not well and there existed few investions from outside the local area. However, some other factors like green development, connecting with big urban centers, seem to be sufficiently featured in the regions examined.

Comparative Evaluation

Except from the above analysis, the effect of all the demographic variables on the factors was also examined. Here, the table of comparative evaluation, which gives the possibility to compare the performance of different groups is applied. The findings showed that the opinions of the citizens do not change when they have different demographic characteristics, a result that means the evaluation from an entrepreneur's perspective, is not affected by other factors.

As an example, the comparative table of the fifty-five questions and the level of education, was also analyzed, after the implementation of Correspondence Analysis in the table of comparative evaluation (Table 10). The symbolization "Sec" belongs to entrepreneurs having completed education below bachelor (secondary or primary or no) and "Univ" to entrepreneurs with bachelor or even higher education. Certainly, Sec1 is the first grade of the category "Sec", Sec2 is the second grade of the category and so on.

The results derived, concluded that there is no difference in the opinions between entrepreneurs with a different level of education. This is also obvious in the visualization of the results, which are displayed in the first factorial space (Figure 4). The entrepreneurs with different level of education 1:Sec, and 2:Univ, have given similar responses, which can be resulted by the closeness of the points. For example, it can be seen from the points 15 and 25 (in the circle), where 15 is the fifth grade of education level 1 and 25 is the fifth grade of education level 2.

FUTURE RESEARCH DIRECTION

The methodology presented in this research could be generalized in all Greek regions and therefore this offers a possibility to compare the economic situation in the different regions.

More questions could be included in the questionnaire, in order to explore the possible reasons for the delay of the economic development and moreover the implementation of technology innovations in the agribusiness sector in Greece.

Local and central governments can adopt measures to improve the situation regarding the economic climate and the same research could be repeated after some years in the same regions, in order to make longitudinal comparisons.

CONCLUSION

The questionnaire designed for the purpose of the present study and which was pilot tested in regions of Northern Greece, has achieved with great ease to extract the most important factors of the economic environment and economic performance, assisted in this effort by a method of the multidimensional statistics field. Regarding the final results, about the local entrepreneurship's opinions of the factors appropriate for economic development in all the regions, differences were detected in some factors.

This result makes it possible for the researcher to discover the strengths and weaknesses of municipality's economic performance and the possible potentials, for further improvement. In addition, it can be concluded that the general perception of the current situation in the regions examined is not influenced by the social characteristics of the entrepreneurs like level of education, age and sex. Concerning the innovation and technological aspects that companies could use, it can be deducted that the agricultural sector in the regions examined in this study, did not manage to implement most of them.

Moreover, the present questionnaire can be an important tool to evaluate factors that contribute to the local economic development and can be used to extract the crucial factors that SWOT analysis requires. The correspondence analysis method seems to be perfectly suited for the extraction of the elements needed to perform the SWOT analysis. Particularly, with the contribution of the two proposed tables of evaluation, the final choice of the crucial factors was precise and immediate. This proposed method, can also be used as an instrument to measure and compare different regions' performance, with the help of the indicators (questions) presented in the current study. This project can provide a measurement tool for Central Administration-Government, in order to compare and evaluate the economic performance and environment to different regions. It is a way to implement benchmarking, with the creation of a network of public administrations' organizations which have common practices, and to develop a peer evaluation among them (Cappelli et al., 2011). This performance can be a criterion for another evaluation; the appropriate exploitation of the resources, that municipalities have at hand, in order to achieve their goals.

KEY TERMS AND DEFINITIONS

Central Administration-Government: The government of a nation-state and this is a characteristic of a unitary state.

Digital Marketing: The advancement of items or brands through one or more types of electronic media. For instance, publicizing mediums that may be utilized as a major aspect of the advanced advertising system of a business could incorporate limited time endeavors made by means of the Internet, online networking, cellular telephones and electronic boards, and in addition through computerized and TV and radio stations.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Green Development: It is an area use arranging idea that incorporates thought of group wide or local natural ramifications of improvement, and site-particular green building ideas. This incorporates city arranging, natural arranging, engineering, scene design and group building.

Infrastructure: Relatively lasting and foundational capital venture of a nation, firm, or venture that underlies and makes conceivable all its monetary movement. It incorporates authoritative, information transfers, transportation, utilities, and waste expulsion and preparing offices. A few definitions additionally incorporate instruction, human services and innovative work.

Innovation: The way toward deciphering a thought or development into a decent or administration that makes esteem or for which clients will pay. In business, advancement frequently comes about when thoughts are connected by the organization with a specific end goal to facilitate fulfill the necessities and desires of the clients.

Knowledge Diffusion: The way toward imparting exploration, developments as well as information to people, gatherings or associations.

Learning Organization: An association that gains learning and enhances sufficiently quick to survive and flourish in a quickly evolving environment. Learning associations (1) make a society that empowers and backings nonstop representative learning, basic considering, and hazard bringing with new thoughts, (2) permit mix-ups, and esteem worker commitments, (3) gain for a fact and test, and (4) disperse the new information all through the association for fuse into everyday exercises.

Market Orientation: A business methodology or logic that spotlights on distinguishing and meeting the expressed or shrouded needs or needs of clients.

Productivity: A measure of the productivity of a man, machine, processing plant, framework, and so on., in changing over inputs into valuable yields. Productivity is processed by partitioning normal yield per period by the aggregate costs caused or assets (capital, vitality, material, faculty) devoured in that period.

Sector (Economy/Business): The economic-business sector or corporate sector is a part of the economy made up by companies with the same characteristics. The three-sector theory in the economics, subdivides them into: The Primary Sector (Raw Materials): Agriculture, Fishery, Forestry. The Secondary Sector (Manufacturing): Manufacturing, Construction. The Tertiary Sector (Sales and Services): Services, Trade.

Technology: The intentional use of data in the configuration, generation, and usage of products and administrations, and in the association of human exercises.

This research was previously published in Driving Agribusiness With Technology Innovations edited by Theodore Tarnanidis, Maro Vlachopoulou, and Jason Papathanasiou, pages 191-209, copyright year 2017 by Business Science Reference (an imprint of IGI Global).

Chapter 51
Agricultural Productivity in Indonesian Provinces

Khee Giap Tan

ABSTRACT

Indonesia has been recognized as a country with significant potential in agriculture, not only to be self-sufficient in terms of food, but also to be the "food basket" for the world. However, given limited and competing use of resources, raising agricultural productivity is of paramount importance. To date, most of the existing work on Indonesia's agricultural sector is at the national level. Considering the extent of Indonesia's regional diversity, a provincial-level analysis of the country's agricultural sector would be more useful from a policy perspective. In this light, this paper examines agricultural productivity growth in Indonesian provinces during 2000-2011 and draws policy implications from such empirical analysis. The paper uses two methodologies, namely growth accounting and Malmquist index data envelopment analysis. Results suggest that technological change has been improving for most provinces, though there is wide variation in technical efficiency change which in turn is driving differences in total factor productivity growth across provinces.

1. INTRODUCTION

Indonesia is a vast archipelagic country with tremendous potential in its agricultural output. Although agriculture's contribution to the country's gross domestic product (GDP) has steadily decreased from 35.3 percent in 1960 to 11.5 percent in 2012, the sector still employed about 35 percent of Indonesia's labour force as of 2012. Within the agricultural sector, in terms of the contribution of each sub-sector, farm food crops and horticulture together contributed to nearly half of the agriculture's share of GDP

in 2012. While estate crops[1] and livestock represented about 22.8 and 12.6 percent, respectively, the remaining 17.6 percent came from fisheries and forestry (Biro Pusat Statistik, 2012).

Indonesia's trade surplus in agriculture is mainly a result of its exports of estate crops while its major imports include wheat, cotton, sugar, soybeans, and maize. In fact, Indonesia is one of the world's major producers and exporters of estate crops such as palm oil, rubber, palm kernel, coffee, coconut (copra), cocoa, tea, and spices. Within Asia, Indonesia contributed to more than one third of total agricultural output of the Association of Southeast Asian Nations (ASEAN) (Food and Agriculture Organization, 2012).

Agricultural development policy in Indonesia has evolved in four significant phases (Fuglie, 2010). During 1961-1967, Indonesia had poor macroeconomic performance characterized by slow output growth with very few modern inputs and small improvements in productivity. From 1968-1992, a green revolution took place and agriculture was the top priority in the economic development agenda which gave rise to the invention and wide dissemination of a number of high-yielding varieties, as well as implementation of pro-agricultural policies. During 1993-2001, the agricultural sector faced stagnation, coupled with the Asian Financial Crisis (AFC) in 1997, with fewer sources for public spending in agriculture. Post AFC, the period of 2002-2006 marked the liberalization era of Indonesia's agricultural sector, where import restrictions on food crops were removed. This was a period of significant diversification of agricultural output with land expansion mostly for estate crops. The agricultural value-added in Indonesia expanded by more than one-third from 1993 to 2006 (World Bank, 2012b).

The trend for agricultural output remained positive as strong macroeconomic performance translated into more resources to pursue pro-agricultural policies. This was intertwined with the government's pro-poor policy as agricultural growth and productivity were often cited as the means to reduce rural poverty. According to the OECD (2012), incidence of poverty in rural areas was twice as high as in urban areas and almost three-fifth of the poor depended on agriculture as the main source of income. Hence, continued progress in agricultural productivity and incomes from agriculture plays an important role in diminishing rural poverty. Indonesia has been recognized as a country with significant potential in agriculture, not only to be self-sufficient in terms of food, but also to be the "food basket" for ASEAN and the world. However, given limited and competing use of resources, raising agricultural productivity is of paramount importance.

Indonesia has a considerably diverse agricultural sector and it is most evident when one compares the relative resource endowments and commodities across islands. Rice as a staple crop is widely cultivated in Java Island, with Sumatra being well known for its vast palm oil plantations and Sulawesi for cocoa. Beyond that, diversity persists in other aspects as well, such as in terms of the size of agricultural sector in their own economy and also their contribution to the national agricultural output. For instance, in terms of agricultural sector as a share of GDP in 2011, it was 46 percent in West Sulawesi GDP but a negligible 0.1 percent for DKI Jakarta. The Java Island -- consisting of East Java, West Java, Central Java, Banten, DI Yogyakarta, and DKI Jakarta -- contributed to just over two-fifth percent of national agricultural output in 2011 even though agriculture itself was no longer a prominent economic driver to the island, contributing to only 9.7 percent of Java's GDP. On the contrary, agriculture is still the main economic driver for easternmost provinces such as North Maluku, Maluku, West Papua, and Papua. In fact, agriculture contributed to 20.5 percent of their GDP as a whole. However, their agricultural output only made up 2.5 percent of national agricultural output in 2011.

Despite variations in agricultural contribution to GDP for each province, what persists is a sizeable share of employment in agricultural sector across provinces. In West Sulawesi for example, 59 percent of its labour force worked in agricultural sector and contributed to about 46 percent of its GDP in 2011.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sizeable agricultural employment was also found in East Java and Central Java, at about 40 percent and 34 percent in 2011, respectively, even though the share of agriculture in their GDP was relatively small at 14 percent and 18 percent, respectively.

While most of the existing work on Indonesia's agriculture is at the national level, considering the extent of Indonesia's regional diversity as outlined above, a provincial-level analysis of the country's agricultural sector would prove to be more useful from a policy perspective. In this light, this paper examines agricultural productivity growth in Indonesian provinces during 2000-2011 and draws policy implications from such an empirical analysis.

The remainder of the paper is structured as follows. Section 2 provides a literature review on the studies on Indonesia's agricultural productivity to date. Section 3 details the methodology and data to be used in this paper. Section 4 discusses the findings. Section 5 concludes the paper with some policy implications.

2. LITERATURE REVIEW

Various papers have examined agricultural total factor productivity (TFP) in Indonesia with largely varied findings owing to the use of different methodologies, time periods, specification of variables, and data sources, as summarized in Table 1. Relying on more than four decades of time series data, Avila & Evenson (2010) and Fuglie (2010) reported a relatively high TFP growth of 2 percent and 1.8 percent, respectively. They further decomposed the TFP growth into different periods of analysis. The authors found that TFP growth was higher in 1961-1980 at around 4.4 percent than during 1981-2001 with a negative productivity growth of -0.39 percent.

Similar trends could be found in Fuglie (2010) who reported decadal TFP growth rates and found it to be around 3 percent during 1961-1970; followed by about 2 percent growth in the next decade; a little more than 1 percent during 1981-1990; a little less than 1 percent in 1991-2000; and finally about 2.4 percent between 2001 and 2006. A follow-up study by Fuglie (2012) covered close to five decades of data. The paper found that the most recent period 2001-2009 charted the highest TFP growth at around 3.7 percent. The steep decline in TFP growth from the 1980s till 2000 compared the period between 1960 and 1980 was triggered by period of economic stagnation, while the turnaround since 2001 could be attributed to more resources devoted to agriculture, as well as diversification towards estate crops.

The papers listed in Table 1 employed either growth accounting, the Tornqvist-Thiel Index or the Malmquist Index to estimate TFP growth. They also used different sets of output and inputs. For instance, Mundlak et al. (2002) and Warr (2009) used broad agricultural GDP as their output that typically also included forestry and fishery from Indonesia's Statistical Bureau, *Biro Pusat Statistik* (BPS). Meanwhile, Fuglie (2010) limited the output to only include crops, livestock, and aquaculture. Avila & Evenson (2010), Coelli & Rao (2005), and Suhariyanto & Thirtle (2001) used only production of crops and livestock to measure output. For inputs, these papers generally included land, labour, fertilizer, and machinery. National-level data were often sourced from FAO database, BPS, and/or estimated by the authors using available proxies.

The literature listed in Table 1 revealed that most of the existing literature measuring agricultural TFP growth had been done at national-level. However, given the significant regional differences in Indonesia, as explained earlier, this paper will contribute to the growing literature by shedding light on the dynamics of agricultural TFP growth across provinces in Indonesia.

Table 1. Summary of literature

Author	Methodology	Time Period	Specification of Variables	Data Source	TFP Growth
Suhariyanto & Thirtle (2001)	Malmquist Index	1965-1996	Output: Total value of agricultural production in crops and livestock; Input: land, labour, livestock, fertilizer, and machinery;	USDA World Agricultural Trends and Indicators; FAO Agrostat Database	0.17
Mundlak et al. (2002)	Aggregate production function similar to Cobb-Douglas with a major difference from constant coefficients function in that the coefficients in equation are functions of the state variables and possibly of the inputs.	1971-1998	Output: log of agricultural GDP; Input: irrigated land, rainfed land, fertilizers, capital, and labour; The state variables included: roads, measures of education, health, and incentives;	BPS; FAO	1.49
Coelli & Rao (2005)	Malmquist Index	1980-2000	Output: crops and livestock output; Input: land, tractors, labour, fertilizer, livestock, and irrigation.	FAO Agrostat Database	0.98
Warr (2009)	Growth accounting	1980-2006	Output: agricultural GDP; Input: land, labour, human capital, and physical capital.	BPS; SAKERNAS; Ministry of agriculture	0.90
Avila & Evenson (2010)	Growth accounting	1961-2001	Output: Output growth from FAO Laspeyres indexes using FAO dollar price; Input: for crops – cropland, labour, fertilizer, animal power, and machine services (tractors plus harvesters); for livestock: pastureland, labour, fertilizer, animal capital, and feed;	FAO	2.02
Fuglie (2010)	Tornqvist-Thiel TFP Index	1961-2006	Output: crops, livestock, and aquaculture output; Input: land in crops and ponds, agricultural labour, education, and wages, fertilizer and chemicals, machinery, livestock, and poultry, and feed and seed;	Van der Eng (1996); FAO; BPS; SAKERNAS	1.82
Fuglie (2012)	Growth accounting	1961-2009	Output: crop and livestock commodity production; Input: land, labour, livestock capital, fertilizer, and machinery resources;	FAO	1961-1970 (1.75); 1971-1980 (1.40); 1981-1990 (0.59); 1991-2000 (0.99); 2001-2009 (3.68)

3. METHODOLOGY AND DATA

TFP growth can be measured using two major approaches - parametric and non-parametric. While more widely used, the accuracy of the parametric approach such as Cobb-Douglas heavily depends on the specification of the production function form. An inaccurate specification of the production function could likely result in a misinterpretation of TFP. Parametric approaches also make strict assumptions on the functional form, such as constant returns to scale and technological efficiency, which are difficult to justify in practice. In contrast, non-parametric approaches such as the Malmquist index methodology are sensitive to outliers and data quality (Tong et al., 2008) but not dependent on model specification per se. This paper applies both methodologies to gain a comprehensive understanding of the agricultural TFP growth in Indonesia. Given the lack of observations to conduct a panel analysis at the provincial-level, we applied the growth accounting method only at the national and regional level. The regional grouping is island-based and aligned with the Master Plan for Acceleration and Expansion of Indonesia's Economic Development (MP3EI) initiated by Indonesia's Coordinating Ministry for Economic Affairs (2011). In order to have a deeper understanding of the driving factors of TFP growth, we adopted the Malmquist index method at the provincial level, which allowed us to decompose TFP change into technological change and efficiency change.

3.1. Growth Accounting Methodology

In this paper, the production function for Indonesia's agricultural sector is defined using a Cobb-Douglas specification, given by:

$$Y_{it} = A_{it} X_{1it}^{\beta_1} \tag{1}$$

where *i* and *t* indicate economy and time respectively. Y_{it} represents the agricultural value added per labour for economy *i* at time *t*. X_{1it} indicates land per labour for economy *i* at time *t* respectively. A_{it} is defined as the measure for TFP, which includes technology factors, and efficiency factors. By taking natural logarithms on both sides of Equation (1) one can obtain Equation (2), which determines the contribution of input to output and is used in calculating TFP growth.

$$\ln Y_{it} = \beta_0 + \beta_1 \ln X_{1it} + \varepsilon_{it} \tag{2}$$

TFP growth is the difference between real agricultural output growth and the weighted sum of input. Hence, TFP growth is calculated as the residual change in output. Therefore, TFP growth can be measured by Equation (3).[2]

$$TFP\,growth_{it} = y_{it} - \hat{\beta}_1 x_{1it} \tag{3}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.2. Malmquist Index Data Envelopment Analysis

Considering the various limitations of parametric approaches to estimating TFP and given the limited time series data available, this paper also applies non-parametric approaches to measure agricultural TFP growth in Indonesia in the form of the Malmquist index.[3]

The Malmquist index is defined in a distance function by Färe et al. (1994). The subscript *y* in Equation (4) shows that it is an output oriented Malmquist index.

$$M_y(x^t, x^{t+1}, y^t, y^{t+1}) = \left[\left(\frac{D_y^t(x^{t+1}, y^{t+1})}{D_y^t(x^t, y^t)} \right) \left(\frac{D_y^{t+1}(x^{t+1}, y^{t+1})}{D_y^{t+1}(x^t, y^t)} \right) \right]^{1/2} \tag{4}$$

By mathematical transformation, Equation (4) can be written in the form of Equation (5), which allows us to decompose the TFP change into technological change (TC) and technical efficiency change (TEC) (Färe et al., 1994).

$$M_y(x^t, x^{t+1}, y^t, y^{t+1}) = \frac{D_y^{t+1}(x^{t+1}, y^{t+1})}{D_y^t(x^t, y^t)} \left[\left(\frac{D_y^t(x^{t+1}, y^{t+1})}{D_y^{t+1}(x^{t+1}, y^{t+1})} \right) \left(\frac{D_y^t(x^t, y^t)}{D_y^{t+1}(x^t, y^t)} \right) \right]^{1/2} \tag{5}$$

TEC refers to activities which can enhance the efficiency of production, including better resource utilization and management. TC refers to a set of developments that can move the productivity frontier forward such as innovation. As specified by Färe et al. (1994), Equation (5) can be written in a more illustrative form as Equation (6).

$$TFPC = TEC \times TC \tag{6}$$

The appendix to the paper describes this approach to TFP measurement in more detail.

3.3. Data

Finding relevant data at provincial-level is challenging as there is no central database that provides all indicators. The data were collected from 2000-2011. For output, the paper used provincial agricultural GDP from World Bank (2012a), as part of Indonesia Database for Policy and Economic Research (INDO-DAPOER) that captures crops, livestock, forestry, and fishery. Labour and land are used as inputs. For labour, the data were also sourced from World Bank INDO-DAPOER that referred to a number of people employed in crops, livestock, fishery, and forestry sector. The land indicator covers wetland, garden, dry land, shifting cultivation, temporary/fallow land, and utilized land for main estate crops, sourced from BPS (2000-2012a; 2000-2012b; 2000-2012c) and Ministry of Agriculture (2012).

Data on machinery are not available on a consistent time series basis. Fuglie (2010) used the number of tractors in use adjusted for size; 12 horsepower (hp) for two-wheel-tractor and 20, 33, and 50hp per small, medium, and large four-wheel tractor, respectively. *Statistical Yearbook of Indonesia* published these indicators only up to 2002. The data became available again in 2011, but did not report the four-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

wheel tractor. The Ministry of Agriculture also reported the number of tractors but only documented those that were part of government assistance. For fertilizers, Ministry of Agriculture only released the statistics on subsidized fertilizer for recent period, from 2009 onwards. The publication on *Farm Cost Structure of Paddy and Secondary Food Crops* gave fertilizer application rates per hectare for rice and secondary food crops, however, such data were only available in 2008 publication for paddy, 2009 for corn, and 2010 for soybean (BPS, 2008-2010). Nevertheless, such information was only available for half of the provinces. Since the goal of the paper was to cover as many provinces as possible and finding proxies to fill in unavailable data across provinces over time could further distort the results, the data used in the paper was limited to two input variables including labour and land, which had comprehensive time series and provincial coverage.

As of 2014, Indonesia has 34 provinces. The newest province is North Kalimantan which was created in 2012 and hence not included in our analysis. During the period of analysis in the study -- 2000-2011 -- there were seven newly created provinces: North Maluku (carved out from Maluku in 1999), West Papua (carved out from Papua in 1999), Banten (carved out from West Java in 2000), Bangka Belitung (carved out from South Sumatra in 2000), Gorontalo (carved out from North Sulawesi in 2000), Riau Islands (carved out from Riau in 2002), and West Sulawesi (carved out from South Sulawesi in 2004). For some indicators that were not adjusted at source reflecting these changes, data points were estimated based on their past growth trend and relative proportion to their parent province. DKI Jakarta was also not included in the analysis due to the negligible share of its agriculture in the Indonesian economy (0.1 percent).

4. FINDINGS

4.1. Labour Productivity

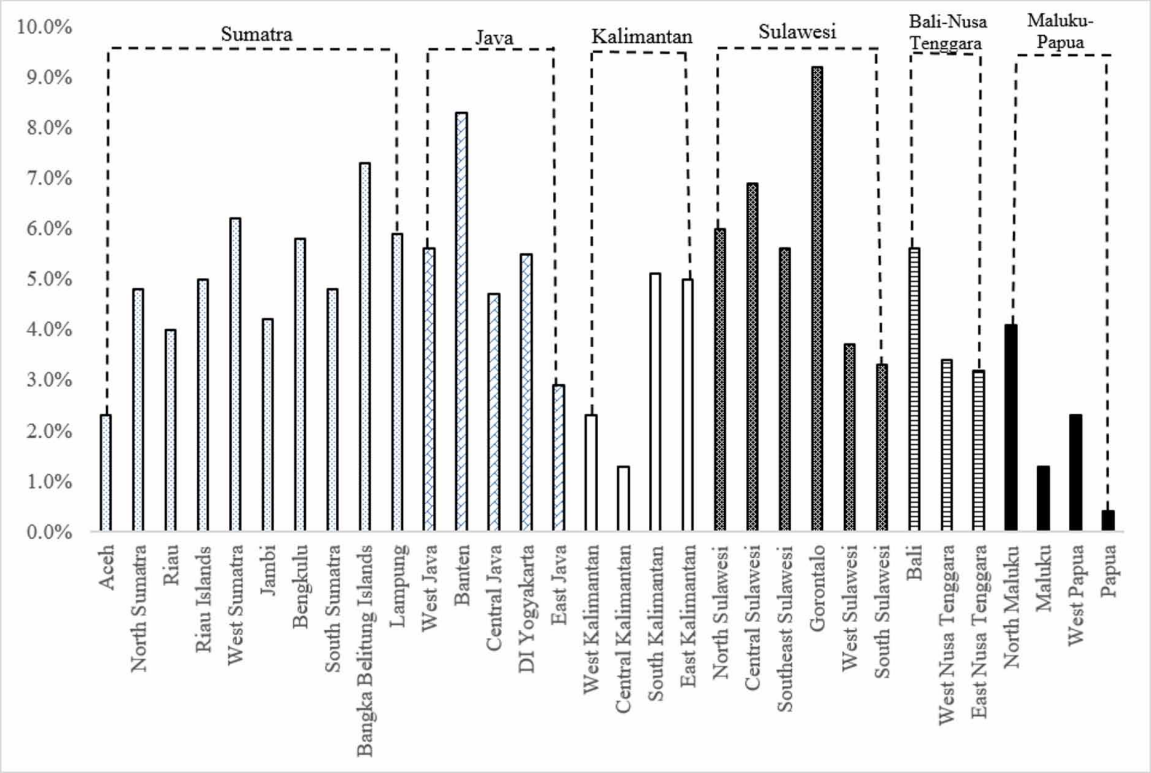
In the case of Indonesia there were significant disparities across provinces in terms of labour productivity in agriculture. Labour productivity was calculated by dividing agricultural GDP by employment in agricultural sector. For average annual growth rate in labour productivity from 2000-2011 in Figure 1, most provinces in Java Island grew faster than the average rate of 4.5 percent, except East Java where more than seven million people were still employed in agricultural sector.

There were wide variations of labour productivity within provinces in each region. When the figures were aggregated at the regional level, labour productivity in Java was actually lower than that of Kalimantan, Sumatra, and Sulawesi where expansions in high value estate crops such as palm oil, rubber, and cocoa took place. In fact, the highest labour productivity growth was found in Gorontalo (9.2 percent). Other provinces in Sulawesi also reported favourable labour productivity growth rates of 6.9 percent for Central Sulawesi, 6 percent for North Sulawesi, and 5.6 percent for Southeast Sulawesi. On the other hand, the highest labour productivity growth rates in Sumatra and Kalimantan were found in Bangka Belitung Islands (7.3 percent) and South Kalimantan (5.1 percent), respectively.

In contrast, labour productivity for Bali–Nusa Tenggara and Maluku–Papua were lower than the national average. From these two regions, Bali was the only province with higher than average labour productivity growth. Among the eastern provinces, North Maluku reported the highest average of labour productivity growth of 4.1 percent while its neighbors recorded much lower rates; Maluku (1.3 percent), West Papua (2.3 percent), and Papua (0.4 percent). International Fund for Agricultural Development

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Labour productivity across provinces (average annual growth rates from 2000-2011)



(2011) has cited a number of ingrained issues found in Maluku and North Maluku that led to poor productivity in agricultural sector such as local conflicts, poor marketing and infrastructure, and insufficient natural resource management.[4]

4.2. Total Factor Productivity (TFP)

Based on panel data analysis using growth accounting, as shown in Table 2, TFP growth for 2000-2011 was 3.1 percent for Indonesia as a whole. Further analysis at the regional level revealed that Sulawesi had the highest TFP growth at 3.5 percent. Other regions which reported higher than national TFP growth were Sumatra (3.3 percent), Java (3.3 percent), and Bali–Nusa Tenggara (3.2 percent). Kalimantan and Maluku-Papua were the laggards with 2.0 percent and 1.5 percent of TFP growth, respectively. The recent initiative to push for Merauke Integrated Food and Energy Estate (MIFEE) that will cover over a million hectares of plantations and industrialised agriculture may contribute to higher TFP growth in Maluku-Papua region in the future.[5] Due to limited sample size we did not calculate TFP growth at provincial-level using the growth accounting method.

Based on the Malmquist–DEA results, TFP grew at an annual average rate of 3.2 percent from 2000-2011, which was somewhat aligned with the estimation using growth accounting method. The TC's contribution was 2.9 percent while TEC's contribution was 0.3 percent. While this likely overstated the importance of TFP (since we have excluded other inputs for which data are not available), the TFP estimate was slightly below the 3.7 percent found by Fuglie (2012) during 2001-2009.[6]

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

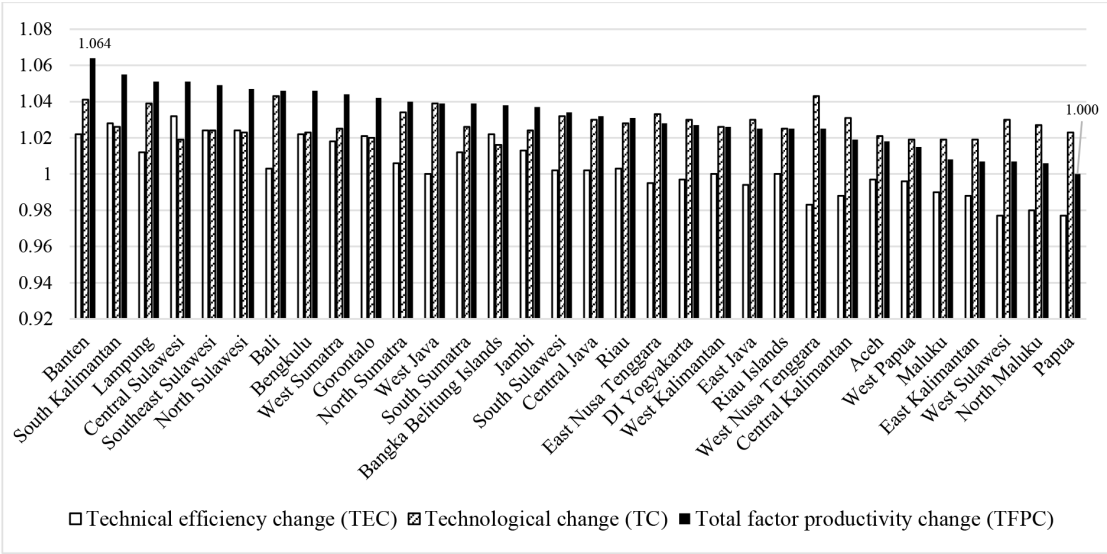
Table 2. TFP growth using growth accounting method (2000-2011)

	β_0	β_1	TFP growth
National	0.030***	0.602***	3.06%
Sulawesi	0.033***	0.579**	3.47%
Sumatra	0.032***	0.674***	3.34%
Java	0.032***	0.921***	3.26%
Bali – Nusa Tenggara	0.030***	0.453	3.24%
Kalimantan	0.024***	0.568***	1.98%
Maluku - Papua	0.015***	0.564*	1.48%

Note: ***, **, and * indicate statistics significance at the 1, 5 and 10 percent levels respectively.

There remained significant variations in TFP growth across provinces as can be seen from Figure 2 which is sorted from the highest to lowest TFP. Banten recorded the highest TFP – a 6.4 percent increase -- and Papua the lowest – attaining a status quo or zero change. Banten performed equally well both in TEC (2.2 percent) and TC (4.1 percent). On the other hand, Papua's low TEC, a decrease of 2.3 percent, drove down its TFP while its TC grew at about 2.3 percent.

Figure 2. Average TFPC and its decomposition from 2000-2011 for 32 provinces



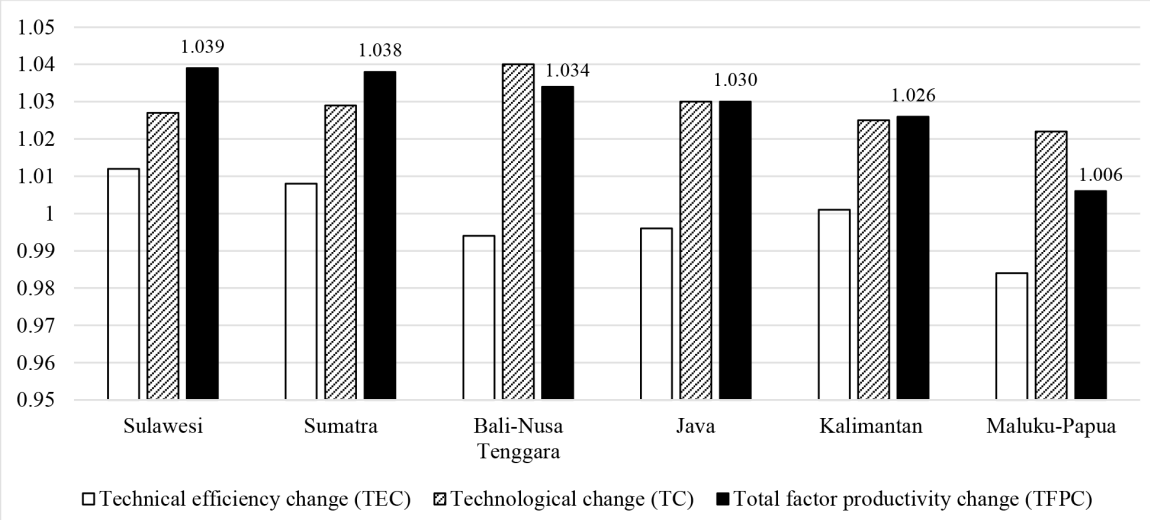
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The majority of provinces with high labour productivity growth also reported high TFP growth. For instance, the ten-highest TFP growth provinces recorded labour productivity growth of above 5.1 percent. In fact, the range is between 5.1 percent and 9.2 percent. For the top 10 TFP growth, four provinces were from Sulawesi, three provinces from Sumatra, one from each of Java, Kalimantan, and Bali–Nusa Tenggara.

Across the provinces, results suggest that TFP growth could be predominantly attributed to TC with the growth in TEC being marginal and even negative in most provinces (such as Papua and West Sulawesi with a decrease of 2.3 percent). The fact that TC was relatively similar across provinces might be mainly due to the fact that R&D and innovation was still driven by the central government. The funding would typically be allocated to Ministry of Agriculture, Indonesian Agency for Agricultural Research and Development (IAARD) in particular, and then distributed to its local offices in each province. For estate crops, Indonesian Research Institute for Estate Crops (IRIEC) has mainly been funded by the plantation sector itself, through Indonesian Planters Association for Research and Development (IPARD). IRIEC was relatively better funded as research expenditures per scientist were about four times higher than that of IAARD (Fuglie & Piggott, 2006). TEC largely lagged in provinces with profound infrastructure bottlenecks, such as East Nusa Tenggara, West Nusa Tenggara, West Sulawesi, West Papua, Maluku, and North Maluku, all of which reported negative growth.

The regional TFPC, TEC, and TC were calculated based on the weighted average of provincial contribution to the region's agricultural output. Based on Figure 3, Sulawesi outperformed the rest with TFP growth of 3.9 percent, with 1.2 percent coming from improvements in TEC and 2.7 percent from TC. The results corroborated the findings using growth accounting method. Four out of six provinces in Sulawesi were also part of those that registered the ten-highest TFP growth rates. This supports the region's designated role as a center for production and processing of national agriculture, plantation, and fishery, as stipulated in MP3EI (Coordinating Ministry of Economic Affairs, 2011).

Figure 3. Average TFPC and its decomposition from 2000-2011 for six regions



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Similar to the estimation by the growth accounting method, Maluku-Papua became the laggard with the lowest TFP growth of 0.6 percent. Based on further decompositions we found out that the TC grew at 2.2 percent, however, its TEC decreased by 1.6 percent. As the easternmost region, Maluku-Papua faces perennial challenges of rudimentary hard and soft infrastructure that hampers its agricultural productivity growth.

5. CONCLUSION AND POLICY IMPLICATIONS

The new leadership under President Joko Widodo has emphasized the importance of achieving food sovereignty in Indonesia. The MP3EI also stressed agriculture as one of the eight main programs, with the production of palm oil, rubber, cocoa, animal husbandry, timber, fishery, and food crops as part of 22 main economic activities. Such policies signal the importance of agricultural productivity to the country, especially given the significant regional variations in terms of productivity. In this light, this paper has provided the most recent analysis on estimating agricultural productivity in Indonesia, focusing on the dynamics at the provincial-level.

From 2000-2011, TFP grew on average by 3.1 to 3.2 percent using both the growth accounting methods and the Malmquist index. TFP growth at the regional-level is also broadly consistent, indicating the robustness in the estimates. According to the Malmquist index, TFP growth was predominantly due to improvements in TC which was broadly uniform across provinces. This uniformity is not very surprising as TC is driven primarily by R&D, new innovations, and technology under the provision of the central government. It is important to recognize the role of the IAARD in this context, especially for food crops and livestock research, as IRIEC has been driving the research in estate crops. Going forward, IAARD should continue building its technological capacity to gradually strengthen its focus on non-staple foods with higher value-added and its interaction with the private sector.

For estate crops that are still dominated by small farms, the challenge is to address the low productivity of smallholders with limited access to high quality inputs. Developing effective systems for small farms is key to improving productivity in estate crops such as in the case of nucleus-plasma program based on partnerships between large estates and smallholders.[7]

According to World Bank (2010), the intensity with which Indonesia invests in agricultural research, even after adding the R&D spending from private sector, is relatively low (0.22 percent) which is on par with that of Lao PDR (0.24 percent), and much lower than Malaysia (1.92 percent) and the Philippines (0.44 percent). The budget allocation for agricultural R&D in Indonesia tends to be volatile, especially when time gets tough, as in the case of AFC when the budget was cut by more than 60 percent (Fuglie & Piggott, 2006).

In addition to increasing R&D funding, it is important to forge greater collaboration with the private sector, involvement of universities, and linkages with those of international R&D providers. Various incentives can be set by the government to encourage private investments in agriculture, such as intellectual property protection and provision of tax concessions to make private investment in agricultural R&D and knowledge creation in better farming techniques more appealing. The role of extension services is crucial to ensuring effective adoption and adaptation of new technology at the local level. There is

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

room for improvement in enhancing extension service delivery such as using performance-based budgeting, training and ICT utilization to stay abreast with the latest developments as well as reforming the institutional and management of agricultural extension system to improve efficiency and clarity of direction and roles.

As the empirical results point out, the main differences of TFP growth across provinces arise from TEC which can be improved in lagging provinces through better resource utilization. With provincial-level analysis there is an opportunity for inter-province learning to enhance more efficient resource deployment and management techniques. For many lagging provinces, if they are able to learn from high-performing provinces and enhance TEC, overall agricultural sector can be expanded with minimal increase in resources.

Lastly, it is essential to improve the provision of reliable and timely statistics across provinces and over time. With better quality and availability of appropriate data, more evidence-based policy decisions can be made and eventually enhance policy performance.

ENDNOTES

1 Estate crops, called *perkebunan* in local term, refer to rubber, coconut, palm oil, coffee, tea, pepper, clove, cocoa, cashew nut, sugar cane, tobacco, and cotton.

2 $y_{it} = ln Y_{it} - ln Y_{i,t-1}$

3 The other commonly used nonparametric measure is the Törnqvist Index. However, this methodology has rather strict data requirements, including prices and quantitative data of both inputs and output. In addition, it also has some assumptions such as a perfectly competitive market and profit maximisation, which are not suitable for agricultural studies.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

[4] On top of that, other issues included limited knowledge of modern agricultural practices and lack of effective extension services, research outreach, supply of production input, and financing. As a result, most agricultural output was of poor quality with low market value as there was no local value addition through processing and marketing. Hence, it was not surprising that most food crop production solely aimed for meeting subsistence needs.

[5] MIFEE is part of the MP3EI projects which designate Merauke as the center of food and energy reserves in eastern part of Indonesia. It was reported that the program has attracted a dozens of domestic and foreign investors who were interested in growing rice, corn, soybean, sugar cane, and palm oil.

[6] Another study by Fuglie (2010) found 2.4 percent TFP growth from 2001-2006.

[7] Under this program, large estates (nucleus) will be provided subsidized capital and long-term leases to state land for crop production with the conditions that they provide inputs, credit, and other services such as technical and marketing services to smallholders (plasma) surrounding their plantations.

[8] TEC can be further decomposed into two parts which are Pure Technical Efficiency Change (PTEC) and Scale Efficiency Change (SEC) as illustrated by Equation (A10).

This research was previously published in the International Journal of Asian Business and Information Management (IJABIM), 7(3); edited by Patricia Ordóñez de Pablos, pages 26-39, copyright year 2016 by IGI Publishing (an imprint of IGI Global).

APPENDIX

The Malmquist Index Data Envelopment Analysis (DEA) Methodology

According to Färe et al. (1994), the change of TFP can be decomposed into TC and TEC through the Malmquist index. Every time point has its specific technology level. Therefore, if a selected time point is represented by *t*, its corresponding technology level can be labelled as S^t. In this context, x^t can be used to represent all inputs of the production activity, and y^t can be used to represent all outputs of the production activity. Under these circumstances, S^t can be defined in the form of equation (A1) which captures all possible combinations of inputs x^t and outputs y^t under the available technology at time *t*.

$$\mathrm{S}^t = \{(\mathrm{x}^t, \mathrm{y}^t), \mathrm{x}^t \ \text{ produce } \ \mathrm{y}^t\} \tag{A1}$$

Since the agricultural production activity in the real world can hardly fully achieve and implement all cutting edge technologies in a specific time point *t*, a differentiation between the actual output and the ideal output could be spotted. According to Färe et al. (1994), the differentiation can be defined as Equation (A2).

$$D_y^t = \inf\{\theta : (\mathrm{x}^t, \mathrm{y}^t / \theta) \in \mathrm{S}^t\} = \{\sup[\theta : (\mathrm{x}^t, \theta\, \mathrm{y}^t) \in \mathrm{S}^t]\}^{-1} \tag{A2}$$

Equation (A2) is an output-oriented distance function, in which D_y^t represents the reciprocal of the maximum change in output *y* through fully exploiting the input *x*. Given the input level x^t at time *t*, Equation (A2) can be used to measure the maximum expansion θ of the output y^t. Meanwhile, D_y^t can also be interpreted as the reciprocal of the maximum efficiency change of the output y^t by fully exploiting input x^t.

Similarly, as shown in Equation (A3), the input-oriented distance function can measure the change of inputs given the output level.

$$D_x^t = \sup\{\lambda : (x^t / \lambda, y^t) \in S^t\} \tag{A3}$$

$$D_y^t = \inf\{\theta : (x^{t+1}, y^{t+1} / \theta) \in S^t\} = \{\sup[\theta : (x^{t+1}, \theta y^{t+1}) \in S^t\}^{-1} \tag{A4}$$

Equation (A4) represents the reciprocal of maximum change of output, given input x^{t+1}, to make y^{t+1} feasible at time *t*. Hence, the Malmquist index can be written in the form of Equation (A5) and Equation (A6).

$$M_y^t = \frac{D_y^t(x^{t+1}, y^{t+1})}{D_y^t(x^t, y^t)} \tag{A5}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$M_{y}^{t+1} = \frac{D_{y}^{t+1}(x^{t+1}, y^{t+1})}{D_{y}^{t+1}(x^{t}, y^{t})} \tag{A6}$$

If a specific time *t* is selected, the corresponding technology level will become the reference technology level. Under these circumstances, Equation (A5) can be used to measure the necessary change to generate the output y^{t+1} through utilizing the input x^{t+1} with the feasible technology S^{t}. In order to avoid choosing an arbitrage benchmark, the geometric mean of the two Malmquist indices can be calculated to form a benchmark (Färe et al. 1994).

$$\begin{aligned} M_{y}(x^{t}, x^{t+1}, y^{t}, y^{t+1}) &= \sqrt{M_{y}^{t} * M_{y}^{t+1}} \\ &= \left[\left(\frac{D_{y}^{t}(x^{t+1}, y^{t+1})}{D_{y}^{t}(x^{t}, y^{t})}\right)\left(\frac{D_{y}^{t+1}(x^{t+1}, y^{t+1})}{D_{y}^{t+1}(x^{t}, y^{t})}\right)\right]^{1/2} \end{aligned} \tag{A7}$$

Equation (A7) can be decomposed into two parts through mathematical transformation as illustrated by Equation (A8).

$$M_{y}(x^{t}, x^{t+1}, y^{t}, y^{t+1}) = \frac{D_{y}^{t+1}(x^{t+1}, y^{t+1})}{D_{y}^{t}(x^{t}, y^{t})}\left[\left(\frac{D_{y}^{t}(x^{t+1}, y^{t+1})}{D_{y}^{t+1}(x^{t+1}, y^{t+1})}\right)\left(\frac{D_{y}^{t}(x^{t}, y^{t})}{D_{y}^{t+1}(x^{t}, y^{t})}\right)\right]^{1/2} \tag{A8}$$

Equation (A8) can be perceived as two components. The first component represents the technical efficiency change between time *t* and time *t+1*, and the second component represents the technological change between time *t* and time *t+1*. The practical meaning of this transformation is that, the Total Factor Productivity Change (TFPC) can be decomposed into Technical Efficiency Change (TEC) and Technological Change (TC), as shown in Equation (A9) (Färe et al. 1994).

$$TFPC = TEC \times TC \tag{A9}$$

TEC is broadly related to better resource utilization or deployment as well as more efficient management. TC broadly refers to the technology innovation or progress, which can shift the production frontier. For example, an invention of new technology could shift the agricultural production frontier. Thereafter, the true driving factor could be identified through the decomposition of TFPC, which may potentially draw valuable lessons for future development of the agriculture sector.[8]

Linear Programming approach is used to calculate the Malmquist index in this paper. In short, the Malmquist index methodology not only allows us to decompose TFPC into TEC and TC, but also provides relative rankings of economies based on their distance to the efficiency frontier.

Chapter 52
Importance of Sustainable Rural Development Through Agrarian Reforms:
An Indian Scenario

Partha Mukhopadhyay
National Institute of Technology Durgapur, India

Madhabendra Sinha
National Institute of Technology Durgapur, India

Partha Pratim Sengupta
National Institute of Technology Durgapur, India

ABSTRACT

The chapter tries to find out the relationship between public expenditures on infrastructure related to agriculture and allied factors and agricultural sustainability in Indian context. India has been suffering from appalling chronic poverty and to reduce the same, we need to focus on rural development, particularly in agriculture as it is unavoidable relation with economic development. Gini index of India is 33.9 (2011) i.e. asymmetrical wealth distribution exists. India is being burdened with a population of 1.2 billion as in 2015. The reciprocal relationship between agrarian reform and democratic development is pronounced. Agrarian reform was one of the focal points around which social mobilization occurred. Sustainable rural development could be achieved by a new balance as we find from some econometric model, which is being sought between agriculture and public expenditure and also export of agricultural produce. Adopting bottom-up agricultural development approaches which emphasize the involvement of the rural people in the implementations of different development programmes may escalate agrarian reforms.

INTRODUCTION

Development is a concept construing changes in the conditions of well being of the people irrespective of income level. It is generally evaluated in terms of changes in aesthetic qualities of the community, i.e. demographics, housing, employment, income, market effects, public services etc. Of late India shows as one of the fastest growing economies in the world. This chapter brushes one more stroke the emerging relationship of infrastructure availability and productivity growth. This analysis relies on both qualitative and quantitative measures of impacts.

Infrastructure, no doubt, is the backbone of any society. Infrastructure development is a *sine qua non* for accelerating progress of the quality of human life. Though infrastructure projects, involve huge initial capital investments, high incremental capital output ratio, high risk with long gestation periods, and low rate of returns on investments but infrastructure development particularly, rural infrastructure encompass economic development of the country. Rural infrastructure has a direct and strong relationship with farmers. Rural infrastructure development is supposed to be a benchmark to transform the existing traditional agriculture or subsistence farming into a most modern, commercial and dynamic farming system so that India could oust the surplus labourers to any other productive jobs. We can group infrastructure under some categories as given in Table 1.

Role of Agriculture in Infrastructure Development

Agriculture ensures supply of food to industrial sector (Lewis, 1954) and hence it is a driving force of overall economic development (Mellor, 1966; Schultz, 1964). Technology spillovers also increase in productivity of Land and labour and as a result income of farmers increase which enhance their purchasing powers. A number of empirical studies (Hazell & Roel, 1983; Hammer & Hazel, 1991; Delgado, 1998; Zhang, 2002) ensured that multiplier effects of agricultural growth are greater than two.

Table 1. Categorization of infrastructure

Based	Resources	Rural Sector	Urban Sector
Input Based	-	Agricultural input like Seed, Fertilizer, Pesticides, Farm equipment and machinery etc.	-
Resource Based:	Water	Irrigation and Drinking	Drinking
	Electricity	Pump and Household	Household and Industrial Purpose
Physical Infrastructure:	Telecommunication, Road connectivity, Transport, storage (including Cold storage), processing, preservation, and Sanitation etc.	Required all Resources	Required all Resources
Institutional Infrastructure:	Education, research, information & communication services, financial services, market, etc.	Required all Resources	Required all Resources

Source: Authors' Own Observation

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Several studies explain the elasticity of poverty reduction with respect to agricultural productivity is significant ((Thirtle, Lin & Piesse, 2003). Some econometric studies (Binswanger & Rosenzweig, 1993; Butzer, 2002; Zhang, 2004) estimated that there is a positive significant relationship between agricultural output and infrastructure investment.

Agricultural sector has also played an important role as foreign exchange earner too. Agricultural exports accounted for 44 percent of India's total merchandise export during 1960-61and in 2013-14 it is more than 17 percent of export earnings of India.

There is a positive correlation between GDP and Public Expenditure on Agriculture (0.98) and similarly, GDP to export of Agricultural and allied product (0.96). So, agricultural infrastructural growth plays a significant role to the economic development in the context of India in particular.

A Brief Discussion on Indian Agriculture

Agriculture is consistently losing its importance in India's economic growth. According to CIA Factbook-2014, agriculture sector contributes 17.9 percent of India's Gross Domestic Product (GDP), and in 2015, in the Budget it is reported that more than 50 percent of the population is still dependent on it. The farm sector, including forestry and fishing, grew by 3.2 percent in the quarter ending September, as compared o 3.8 percent in previous quarter and 4.7 percent in 2013-14. For the entire financial year, it was 1.4 percent. Backed by continued technological innovations in the sector, India's food grain production has more than doubled over the decades to a record 264 million tons in 2014, but the same is not being

Figure 1. Role of Infrastructure in Agricultural Development

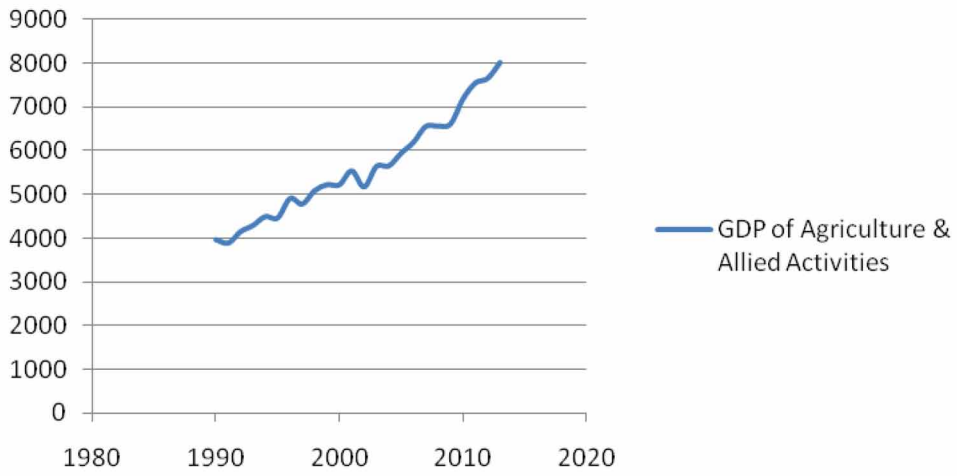
Source: CSO, Government of India, Annual Data from 1990-2015



capitalized to increase the profit margins and revenue of farmers. There is still a large dependency on rainfall and other climatic conditions for good yield, and post-harvest logistics remains an area of concern.

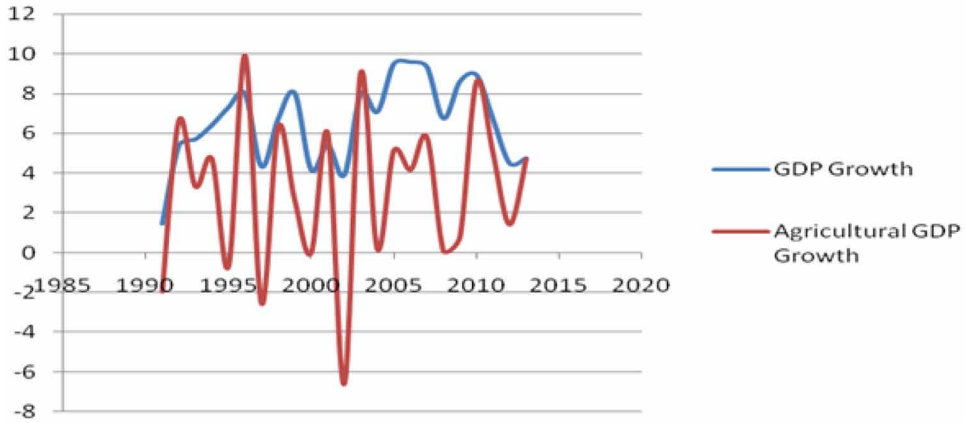
In the post-1990s period, there has been a continuous decline in government support in the form of declining investments in agriculture. The withdrawal of the State has led to a much greater dependence of farmers on private sources. Very unfortunate to say that there has also been an upward trend in the cases of farmer suicides over the years and the victims have largely been marginal and small farmers. Increasing costs of cultivation leading to higher indebtedness, crop failures, inability to face price rise with greater liberalization of the agricultural sector and profile of gobbling up of lion's share of profit margin by the marketing middleman have forced farmers to take this extreme step a death trap to speak of.

A report was published by zee news exclusive of union budget-2015 that it's a fact in India; farmers are receiving only around 25 to 30 percent of the price paid by the consumers. The loss appears not due to their inefficiencies but also for unwanted role of middlemen. Farmers in developed economies of Europe and the United States, in contrast, receive around 75 percent of the price that consumers pay. The wide gap between ultimate sellers of agricultural goods and the ultimate purchasers of the same makes the system vulnerable in view of sustainability when market is treated as an institution in the age of globalization. The entire system is likely to be changed without any more delay. The growth performance of the agriculture sector has been fluctuating across the time periods 1990 to 2015.

Inflationary trend of food items has got a close link with the supply crunch, triggered by the international market. To deal with this type of vulnerability, there is also a need to make long-term plan. India is still dependent on the other Countries for some commodities such as edible oil (mostly palm oil) and pulses, despite the prevailing agriculture-intensity profile of India. India imports more than 50 percent of its cooking oil. Long-term approach in trade policy and lack of consistency make us dependable for these commodities on overseas market. Government of India generally reduces the import duty of a particular commodity to tame price rise but in the long run escalates the inflow of that commodity in the domestic market and increase our dependability. While taking a decision on duty, the government should take into account the concerns of all stakeholders related to that commodity, mainly producers,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

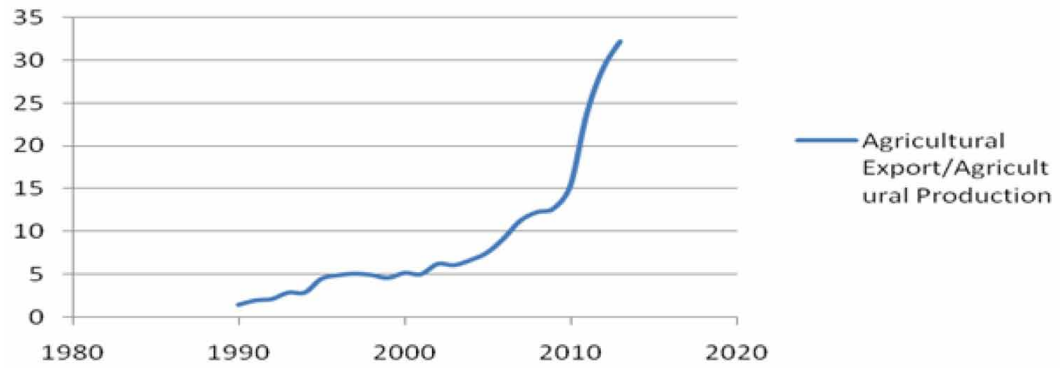
Figure 3. Pattern of growth of GDP and GDP of agriculture
Source: CSO, Government of India, Annual Data from 1990-2015



exporters and consumers too. When the government reduces import duty, it impacts all stakeholders simultaneously. Cutting of import duty makes the same domestic commodity uncompetitive. But consumers get that international commodity at a lower price. When government decides to increase import duty, the same impact appears. In that situation, at the best competitive price, the produce for which import duty is increased minimizes the only option for consumers to get same international commodity.

As export is one of components of GDP the growth by export led hypothesis postulates that export expansion is one of the main determinants of growth. India's export performance is fluctuating in nature from 1990-2015. In 1997, for the first time after liberalization, India's exports registered with negative growth of 2.33 because of the East Asian Crisis. Since the ASEAN countries and Japan were most acutely affected by the crisis, their respective currencies lost value, which also meant that the Indian rupee appreciated against these currencies (due to interest rate differentials). Agricultural export of India faces the impact of negative growth in the year 1999-2000 than previous year. The next major setback for India's exports was the global crisis of 2008. India's trade deficit dampened in 2009-10 with a negative import growth (-0.78 percent) were also impacted with a negative growth rate of 2.9 percent in 2008-09 than

Figure 4. Agricultural export as a share of agricultural GDP
Source: DGCIS and CSO, Government of India, Annual Data from 1990-2015



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

previous years. India has been following overall an increasing path in agricultural exports throughout the period from1990 to 2015 except the years 1999-2000 and 2009-2010.

Some commodities such as wheat, sugar, cotton, edible oil, rubber etc are directly related to the government's trade decisions and control. It is observed that in the past few years, the government's approach to deal with the trade of the commodities has been widely exposed. Indian Government has to adopt bottom-up agricultural approaches which emphasize the involvement of the rural people and first prioritize the concerns of our own farmers. Composition of exports means goods that we are selling to other countries. At the time of Independence, exports of India were consisted of agricultural products like tea, spices, tobacco and other raw materials etc. We were also exporting cotton textiles and jute products in large quantities. We are now exporting large quantities of items such as machinery and transport equipment, chemicals allied products, marine products, and handicrafts, however export of items such as fish, cotton, fabric, tea, Jute, manufactures spices etc.

Rural Infrastructure

Rural infrastructure is a major bottleneck in achieving the potential growth-path under globalization. In a Study, (Oshikoya & Hussain, 2002) it is revealed that better rural infrastructure improves price-competitiveness and attracting Foreign Direct Investment (FDI).

In their studies (Wheeler & Ashoka, 1992; Asiedu & Donald, 2004) they found that status of domestic infrastructure is an important determinant of the magnitude of private capital inflow such as FDI. Efficient transportation system with modern telecommunication facilities, reliable energy supply and access to safe water are the essential conditions for attracting investments from outside the country.

Market

Market integration over space and time requires sound infrastructure with all other facilities. Market integration is assumed to be poor in India resulting in drastic drops in local prices and restricted access to commercial finance. We are suffering from poor transport, storage capacity and weak form of communication infrastructure. Rule of law hardly works due low quality of governance; effective competition among the markets is absent. Hence market transaction is highly non-transparent in India. So, development of transparent rules and regulations is essential for infrastructure development as everything is hanging together. As the economic environment becomes adverse, then global financial crisis arises (J.N. Verma, W.P. No. 2009-02-06).

Despite the bottleneck of agrarian crisis, India's food grain production has more than doubled over the decades to a record 264 million tonnes in 2014 because of technological spillover and other factors too, whereas the wellbeing of the growth of output is not transmitted to the farmers with a same rate, a gross inequality. There is still a large dependency on rainfall and other climatic conditions for better yield and post-harvest logistics remains an area of concern. Over the years, marginal and small farmers' suicidal upward trend is observed due to increasing costs of cultivation, higher indebtedness, crop failures and inability to get adequate price.

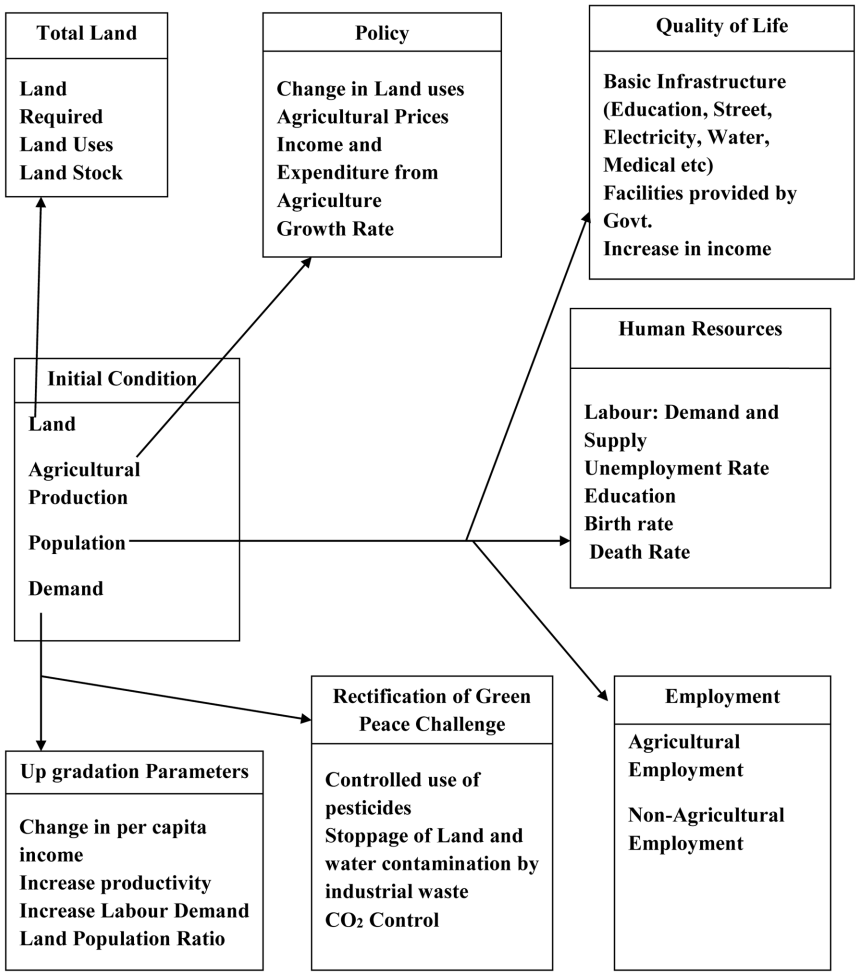
Figure 5. Infrastructure as a base of overall development including agricultural development
Source: Authors' Own Observation



Problem Background

Does investment in "Infrastructure" is beneficial? Govt. of India invests Rs. 12810.22 billion in 2013-14 Union Budget and Rs. 4845.33 Billion in 2014-15 Union Budget for total Infrastructure Development. Only a few researches are available in investment in infrastructure. Bennathan and Canning (2000) indicate that investments in electricity generating and paved roads are more profitable than other public investments. But the question is why the investment is low?

In the view of agrarian crisis, India's food grain production has more than doubled over the decades to a record 264 million tonnes in 2014 backed by Technological spillover, but the same is not being capitalized to increase the revenue and profit margins of farmers. There is still a large dependency on rainfall and other climatic conditions for good yield and post-harvest logistics remains an area of concern. Farmers are greater dependence on private sources led by withdrawal of state. Over the years, marginal and small farmers' suicidal upward trend is observed due to increasing costs of cultivation, higher indebtedness, crop failures and inability to get adequate price.

REVIEW OF LITERATURE

Tripathi (2008) examined the performance of agricultural productivity in India during the last 37 years, and found stagnation of TFP growth in Indian agriculture. Using the time series data for the period from 1970 to 2005, Shombe (2005) investigated causal relationships among agriculture, manufacturing and exports in Tanzania. The empirical results show that the evidence of Granger causality but agriculture causes both exports and manufacturing. It is really an interesting study where scenario of exports and manufacturing sector become better off with the progress of agricultural activities in developing nation. Khalafalla and Webb (2000) empirically tested the growth hypothesis of export leading for Malaysian economy undergoing major structural changes. Khalafalla and Webb also investigated the relationship between the exports and economic growth in Malaysia using the quarterly data from 1965-1996. Bashir (2003) studied the Pakistan's impacts of economic reforms and trade liberalization on agricultural export performance. He suggested that economic reforms affected the agricultural export performance which is more sensitive to the domestic factors. Shirazi and Manap (2004) re-investigate the exports-economic growth nexus, using the data from 1960 to 2003 period and the results strongly support a long-run relationship among the three variables (imports, export and output). As far as the causality between the exports and output growth is concerned, exports cause output growth, but converse is not true. Khan *et. al.* (1995) investigated the export- growth and economic growth using the granger causality test and co-integration methods and found stable long-run two way relationship between total exports and output while one way relationship between output and primary exports. In their findings, there is a bi-directional causality between total exports growth and economic growth exclude. Huges and Penson (1985) have shown a marked increase in volume of agricultural exports over the years. The authors measured the effects of GDP movements on agriculture. In his research, Chandra (2000) found the bi-directional causal relationship between the growth of exports and GDP growth; short run causal relation is pronounced, because co-integration between GDP growth and growth of exports was not found. Sharma and Panagiotidis (2005) test the export-led growth hypothesis in the Indian context, and the results strengthen the arguments against the export-led growth hypothesis in the context of India. Raju and Kurien (2005) analyzed the relationship between exports and economic growth in India over the period of pre-liberalization (1960-1992), and found strong support for unidirectional causality from exports to economic growth. They have use Granger causality regressions based on stationary variables, with and without an error-correction term. The causal relationship between growth of exports and economic growth in India for the post-liberalization period 1992-2007, analyzed by Dash (2009) ; the results indicate that there exists a long-run relationship between output and exports, and it is unidirectional from growth of exports to output growth.

RESEARCH OBJECTIVE

We are estimating the relationship between public expenditures on infrastructure related to agriculture and allied factors and agricultural sustainability measured in terms of production and export for a given period.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is an attempt to provide the emerging relationship of infrastructure availability and productivity growth. By measuring the impact of availability of different type of infrastructural facilities on growth of total factor productivity in state economies in India we may conclude whether the trend is sustainable or not.

HYPOTHESES

On the basis of introductory background, following two null hypotheses are to be tested for achieving the above mentioned objective of the study. They are categorized as following:

H1: Public expenditure on agriculture does not cause output of agriculture in terms of market value.
H2: Public expenditure on agriculture does not have any impact on agricultural export.

DATA SOURCES

The study relies on secondary data compiled from various published sources such as RBI Handbook, World Bank Data etc. The other major sources for the collection of the information are found to be available literature as, journals, books, and news of Government of India and states Governments related to the agriculture, energy, transport, education etc. For trend analysis, we are collecting data from the year 1970-71 to 2014-15. GDP data and export of agriculture and allied product data of same time span are collected for comparing the trend also.

RESEARCH METHODOLOGY

A large number of methods or econometric tools are used in the literature to study the relationship, including infrastructural growth, agricultural-export and GDP. The independent variables used, as a proxy for infrastructure is either some measure of investment or a physical indicator (Straub, 2008).

We know that time series data on any quantitative character or variable may contain either deterministic trend or stochastic trend or both. But implications are obviously different in nature. The time series with deterministic trend follows trend stationary process (TSP), while a non-stationary time series showing stochastic trend is a difference stationary process (DSP). The issue whether a macroeconomic time series is of DSP or TSP is extremely important because the dynamic properties of the two processes are different (Nelson & Plosser, 1982). While the former is predictable, the latter is completely unpredictable. In a series following TSP, cyclical fluctuations are temporary around a stable trend, while for DSP any random shock to the series has a permanent effect. The cyclical components of a TSP originate from the residuals of a regression of the series on the variable time, and a DSP involves regression of a series on its own lagged values and time. A TSP has a trend in the mean but no trend in the variance, but a DSP has a trend in the variance with or without trend in the mean and here it should be mentioned that a random walk without drift has no trend in the mean values of the variable.

The most widely used model to take over stochastic trend is autoregressive of order p [AR(p)]:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$X_t = \alpha + \beta_1 X_{t-1} + \beta_2 X_{t-2} + \beta_3 X_{t-3} + \ldots\ldots\ldots\ldots + \beta_p X_{t-p} + \varepsilon_t \quad (1)$$

X_t gives values in log form in time t and ε_t is a stationary series with mean zero and variance σ^2.

This model can generate the trend behaviour of macroeconomic time series and the randomly fluctuating behaviour of their growth rates. If, for example, X_t is generated by the model:

$$X_t = \alpha + X_{t-1} + \varepsilon_t \quad (2)$$

Equation (2) is AR (1) with β_1=1, accumulating X_t starting with an initial value X_0 we get,

$$X_t = X_0 + \alpha t + \sum_{j=1}^{t} \varepsilon_j \quad (3)$$

The Equation (3) has the same form as the conventional log-linear trend equation, excepting for the fact that the disturbance is not stationary.

One important property of time series data, not usually present in cross-sectional data, is the existence of correlation across observations. Income today, for example, is highly correlated with income of the last year. Thus X_t tends to exhibit trend behaviour and to be highly correlated over time. The non-stationary time series containing a unit root will give a stochastic trend. If $\beta_1 = 1$ for the AR(1) model, then X_t has a unit root and exhibit trend behaviour, especially when $\alpha \neq 0$. Unit root series contain a so called stochastic trend.

The Augmented Dickey-Fuller (ADF) test is performed for unit root hypothesis. The more appropriate model for testing a unit root is the AR(p) with deterministic trend:

$$\Delta X_t = \alpha + \rho X_{t-1} + \eta_1 \Delta X_{t-1} + \eta_2 \Delta X_{t-2} + \ldots\ldots\ldots\ldots + \eta_{p-1} \Delta X_{t-p+1} + \delta t + \varepsilon_t, \quad (4)$$

A series belongs to the class DSP exhibiting stochastic trend if ρ =0, δ=0, and the TSP class if $\rho <$ 0. If $\rho = 0$, then X_t contains a unit root. In this case we cannot perform hypothesis testing by utilising the usual distributions appropriate for least square. Thus we have to follow ADF test. If the t-statistics on ρ are less negative than the Dickey-Fuller critical value, we conclude that the series X_t has a unit root.

To test whether the series has a unit root, we have to choose lag length (p). Many sophisticated statistical criteria and testing methods are available to determine the appropriate lag length in an AR(p) model. But we have performed a simple route by choosing a maximum lag length and then sequentially drop lag lengths if the relevant coefficients are insignificant. The maximum lag length is chosen by following Schwert (1989) rule:

$$P_{max} = \text{integer part of } [12(T/100)^{.25}]. \quad (5)$$

AIC is also used for selecting the appropriate lag length. By following such criteria, the maximum lag length is found to be 1. Thus our model would be:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\Delta X_t = \alpha + \rho X_{t-1} + \eta_1 \Delta X_{t-1} + \delta t + \varepsilon_t, \tag{6}$$

The stochastic properties of the time series data in this study have been examined by carrying out Augmented Dickey Fuller (ADF) and Phillips-Perron (PP) unit root tests. Both the intercept and trend components have been incorporated in the ADF estimated relation as following:

$$\Delta X_t = \varphi_0 + \beta t + \rho X_{t-1} + \sum_{i=1}^{P} \gamma_i \Delta X_{t-1} + \varepsilon_t \tag{7}$$

The ADF statistic is the *t*-value associated with the estimated coefficient of ρ, the probability distribution of which is a functional of the Weiner process, the process used in explaining Brownian motion of a particle with large number of molecular shocks (Maddala & Kim, 1998). The PP test is the non-parametric extension of the DF unit root test by adding a correction factor to the DF t statistic. The tests have been performed for all the logarithmic series and their first differences. The choice of lag length is very much crucial at this stage and the number of lags used in the ADF regressions is selected by the Akaike (1969) Information Criterion (AIC).

We have applied cointegration theory developed in Engle and Granger (1987) by utilizing the methodology developed by Johansen and Juselius (1990). The concept of cointegration, first developed in Granger (1981), is relevant to the problem of the determination of long-run equilibrium relationships in economics in a sense that the variables move together over time so that short-term disturbances from the long-term trend will be corrected (Manning & Andrianacos, 1993).

Engle and Granger (1987) have shown that if two time series are cointegrated there will be a causal relation in at least one direction. Furthermore, the Granger Representation Theorem demonstrates how to model cointegrated I(1) series in the form of vector autoregression (VAR). In particular, the VAR can be constructed either in terms of the levels (logarithmic values) of the data, the I(1) variables; or in terms of their first differences, the I(0) variables, with the addition of an error correction mechanism (ECM, which is first used by Sargan (1984) and later popularized by Engle and Granger (1987)) to capture the short-run dynamics. If the data are I(1) but not cointegrated, causality tests cannot accurately be performed unless the data series are transformed into stationary series.

For two variables Y and X, the model can be presented either of the following form:

$$\ln X_t = \theta + \sum_{i=1}^{p} \pi_i \ln X_{t-i} + \sum_{j=1}^{r} \varphi_j \ln Y_{t-j} + v_t \tag{8}$$

$$\ln Y_t = \alpha + \sum_{i=1}^{m} \beta_i \ln X_{t-i} + \sum_{j=1}^{n} \gamma_j \ln Y_{t-j} + u_t \tag{9}$$

or,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\Delta \ln X_t = \theta + \sum_{i=1}^{p} \pi_i \Delta \ln X_{t-i} + \sum_{j=1}^{r} \varphi_j \Delta \ln Y_{t-j} + \lambda ECM_{t-1} + v_t \quad (8.a)$$

$$\Delta \ln Y_t = \alpha + \sum_{i=1}^{m} \beta_i \Delta \ln X_{t-i} + \sum_{j=1}^{n} \gamma_j \Delta \ln Y_{t-j} + \delta ECM_{t-1} + u_t \quad (9.a)$$

Where u_t and v_t are zero-mean, serially uncorrelated, random disturbances, error-correction mechanism is denoted by *ECM*. If the data are I(1) but not cointegrated, valid tests may be done by using the first differences without the error correction term:

$$\Delta \ln X_t = \theta + \sum_{i=1}^{p} \pi_i \Delta \ln X_{t-i} + \sum_{j=1}^{r} \varphi_j \Delta \ln Y_{t-j} + v_t \quad (10)$$

$$\Delta \ln Y_t = \alpha + \sum_{i=1}^{m} \beta_i \Delta \ln X_{t-i} + \sum_{j=1}^{n} \gamma_j \Delta \ln Y_{t-j} + u_t \quad (11)$$

RESULTS AND DISCUSSION

We present our results of unit root test on the basis of methodology taken in our study as mentioned in earlier.

Unit Root Test

Table 2 represents the ADF and PP test statistics for testing unit roots of all the series. Unlike most of the time series analysis, here the null hypothesis of the presence of unit roots is rejected in the original series indicating that all the series are stationary at level in case of both ADF and PP test.

Table 2. Estimated Statistics of Unit Root Tests

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

To find the dynamic relationships between agricultural export and different measures of India's public expenditure on agriculture as mentioned above we have used cointegration theory developed in Engle and Granger (1987). The ADF and PP unit root tests suggest that the all the series of the variables are integrated of order one I(1). All the stationary variables at same order of integration may have a common trend and it is reasonable to search for a possible cointegrating relationship among them. In this context we plan for co-integration test. We can also argue that agricultural exports from India continuously follow a time trend.

Cointegration Test

The estimated results of Johansen's cointegration tests have been shown by Table 3. Both the trace or LR test statistic and the eigenvalues are used for testing the hypothesis of presence of cointegrating relation, against the alternative hypothesis of full rank. Findings suggest that are three cointegrating equations as trace statistic reports at 5 percent level. But maximum eigenvalue test indicates no cointegration at the 5 percent level, also denotes the rejection of the hypothesis in case of at most two hypothesized number of cointegrating equations. So we think there may have a long run relationship between India's agricultural export and India's public expenditure on agriculture.

Now we have to test the long run dynamic relationship among the variables by utilizing the structure of vector error correction mechanism (VECM) by incorporating two period lag as suggested by the minimum AIC rule

If a set of variables have one or more cointegrating vectors then a suitable estimation technique is a VECM (Vector Error Correction Model). VECM adjusts to both short run changes in variables and deviations from equilibrium. The vector error correction model (VECM) is a special case of the VAR for variables that are stationary in their differences (i.e., I(1)). The VEC can also take into account any co-integrating relationships among the variables.

Source: Authors' own estimation by using data from HBSIE, RBI database in E-views 7

Table 4 shows the estimation of coefficients with corresponding t statistics in [] from the mechanism of vector error correction. Results indicate that only the GDP growth of India is significantly determined by the India's Agricultural export with one period lag.

CONCLUSION AND POLICY SUGGESTION

The chapter tried to contribute a new dimension to the study of sustainable rural development through agrarian reforms by investigating the impact of public expenditure on agriculture in terms of production and export empirically in India for a long period from 1970-71 to 2014-15. Our findings, by applying Johansen cointegration tests on the basis of unit root test results, imply that there is at least one co-integrating equation as suggested by both trace and maximum eigen value statistics. So there may have a long run equilibrium relationship among variables. The results of vector error correction mechanism model to find the long run dynamics show that growth of agricultural output is significantly influenced by public expenditures on agricultural and allied sectors with one period lag.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Low productivity with high cost of production and absenteeism of labour are the important barriers to the Indian agriculture. To develop agricultural market, value addition in the current infrastructure, such as more number of cold storage, roads, green mandi are urgently required. Currently India is facing some problems in productivity gain and in lowering cost of production. FAO suggested that the unit cost must be reduced through productivity gain.

It is most challenging time for introduction of energy and cost effective technology and equipment so that long-term strategy with a good infrastructure only pays the agricultural sustainability. There is also a huge scope to carry forward this research study further by looking at the aspects of long run relationship with direction of causality between agricultural performance and private investment in Indian agriculture in India. This would ensure more robust results and much more meaningful analysis which could be helpful for the policymakers as well as researchers in India to frame an Infrastructure led growth policies in the years to come.

KEY TERMS AND DEFINITIONS

Agrarian Reform: Agrarian reform is government-initiated or government-backed redistribution of agricultural land.

Agricultural Development: Agricultural development includes providing assistance, employing latest techniques, controlling pests and facilitating diversity to the crop producers with the help of various agricultural resources.

Agriculture: Agriculture is the cultivation of plants and animals for food, fiber, bio fuel, medicine and other products which are used to sustain and enhance human life.

Econometric Model: Econometric models are based on statistical models used in econometrics which specifies the statistical relationship to hold among the various economic quantities pertaining to a particular economic phenomenon under study.

Economic Development: Economic development is the efforts that seek to improve the economic well-being and improve quality of life for a community by creating jobs and supporting or growing incomes and the tax base.

Implementation: The process of execution of a decision or plan into effect.

Infrastructure Development: For economic development and prosperity of a country, infrastructure development is essential. Infrastructure includes the basic physical systems of a nation communication, transportation, sewage, water and electric systems etc.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Policy: A course or principle of action adopted or proposed by an individual or organization.

Public Expenditure: When spending is made by the government of a country based on collective needs and wants such as pension, provision, infrastructure, etc.

Rural Development: Rural development is the process of improving the quality of life and economic well-being of people living in sparsely populated areas.

Social Mobilization: Social mobilization is the primary step of community development for awareness and to organize and initiate action for their recovery with their own initiative and creativity to protect from disasters etc.

Chapter 53
Mitigation of Climate Change Impacts Through Treatment and Management of Low Quality Water for Irrigation in Pakistan

ABSTRACT

The Indus Plains of Pakistan are situated in arid to semi-arid climate where monsoon rains are erratic and mostly fall in the months of July and August. These rains are not only insufficient to grow even a single crop without artificial irrigation but also cause flood havoc very frequently that is associated with the climate change. The Indus river transports water for agriculture, industry and domestic usage within the basin and downstream. The Indus Basin is among the few basins severely affected by global warming and resulting climate change. The alteration in temporal and spatial patterns of rainfall has resulted in unexpected drought and floods. About 70 to 80% of total river flows occur in summer season due to snow melt and monsoonal rainfalls. Lack of storage reservoirs has decreased the ability to regulate flood water as well as its potential use during the drought season along with cheap hydro-electricity generation. The sedimentation in the system has limited the storage capacity of the existing three reservoirs by 28%. Consequently carry over capacity of these storage structures is only 30 days compared to 120 to 220 days in India and 900 days in Colorado Basin. Pakistan is facing shortage of good quality water

due to competition among agricultural and non-agricultural sectors, this scenario will continue rather will further aggravate in future. According to the climate change scenario, the warming is reflected in the river-flow data of Pakistan, especially during the past 2-3 decades. To bridge the gap between fresh water availability and demand, ground water is being pumped to meet the irrigation requirements of crops. The pumped ground water (70-80%) is brackish and could become a sustainability issue in the long run. The prolonged agricultural uses of such water will deteriorate soils, crops and human living environments. Water quality parameters usually considered include electrical conductivity (EC) for total soluble salts, and sodium adsorption ratio (SAR) and residual sodium carbonate (RSC) reflect the sodicity hazards. In order to limit or even to eliminate adverse effects of such waters, certain treatment and/or management options are considered as important pre-requisites. For bringing down high concentration of total soluble salts, dilution with good quality water is the doable practice. To decrease high SAR of irrigation water, a source of calcium is needed, dilution (with good quality water) will decrease SAR by the square root times of the dilution factor, while use of acids will be cost-intensive rather may adversely impact the soil health. For high RSC, dilution with low $CO_3^{2-}+HCO_3^-$ water will serve the purpose, addition of Ca-salts will raise $Ca^{2+}+Mg^{2+}$ to bring a decrease in water RSC, while acids will neutralize $CO_3^{2-}+HCO_3^-$ to lower water RSC. Gypsum is the most economical and safe amendment while acids could also decrease RSC but at higher relative cost. City wastewater and seed priming in aerated gypsum solution is also presented. Such practices at small and/or large scale surely will help a lot to sustain the food security and the environment in the days to come where climate change has to be experienced round the world. Therefore, a well-coordinated program is necessary to create awareness among different sections of the society including the policy makers, general public, organizations, industrialists and farmers.

INTRODUCTION

The Indus Plains of Pakistan are situated in arid to semi-arid climate zones where rains during monsoon are erratic and mostly fall during the months of July to September. These rains cause flood havoc very frequently that is associated with the climate change; floods during the years of 2010, 2011 and 2014 are very good examples to such climate change impacts those resulted in hundreds of human and animal deaths as well as caused billion dollar loss to infrastructures, soil quality and crops. The Indus river transports water for agriculture, industry and domestic usage within the basin and downstream. About 70 to 80% of total river flows occur in summer due to snow melt and monsoonal rains.

The effect of climate change is not limited to water availability only but it also affects crop yields and thus the food security and worsens the human living environments. The increasing soil salinity might cause additional harm in future, if less annual rainfall and higher temperatures prevailed at the current rate in future due to climate change. Due to reduction in annual rainfall, sufficient leaching of salts will not be achieved and higher temperatures will further aggravate the salt stress in regions already threatened by soil salinity (Sommer et al., 2013). The availability of water in Pakistan has decreased from 5300 m^3/year/person in 1950's to 1066 m^3/person/year in 2010 and it is estimated to be < 850 m^3 per capita by the year 2025 (WAPDA, 2011). The World Bank has included Pakistan in the list of 17 countries predicted to encounter severe water shortages by 2025. There is immense need and scope to develop additional surface water storage for drought periods since a plenty of river water is discharging into the Arabian Sea, ≈ about 34 to 37 million acre foot (MAF) water is discharged into the sea. Such policy issues have

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to be decided by overlooking the political interests and giving priority to national interests by all the sections of society including politicians, policy makers and techno-crates.

An additional option is ground water (unfortunately poor quality) that may supplement growing irrigation needs because of increased cropping intensity and competition for fresh water by non–agricultural sectors. At present, $> 1.07 \times 10^6$ tube wells are pumping 9.05×10^6 ha–m ground water in Pakistan (Federal Bureau of Statistics, 2011-12), of which≈ 70-80% is unfit for agriculture because of high EC, SAR and/or RSC (Ghafoor et al., 2004). The irrigation with poor quality water may cause soil salinity/sodicity, poor infiltration, hard setting of soils, specific ion toxicity in plants; all combined to adversely affect the growth and economic yields of crops along with human living environments. Further to this, sub-soil drying due to draw-down of water table could be an important future concern (Wichelns and Qadir, 2015).

The ground water, storm water during floods and raw city sewage (from industry-mix) may pose serious hazards because of high EC ($\geq$1.0 dS m^{-1}), SAR ($\geq$10.0), RSC ($\geq$2.5 $mmol_c$ L^{-1}), heavy metals, high Mg to Ca ratio, diseases, pathogens, detergents, azo-dyes and pesticide residues (Murtaza et al., 2010; Qadir et al., 2010). However, management or treatment depends upon many factors like crop type, plant growth stage, physical/chemical properties of soils, and reactions between water and soil solids, climatic factors, farmers' skills, drainage water quality, requirements of consumers and socio-economic conditions and acceptable decrease in produce yield as well as quality. Recently United Nations Climate Change Conference (COP21, 2015) was held in Paris ended up with the conclusions to decrease global greenhouse gases (GHGs) emission to zero level and to limit the average rise in global temperature to 2 degrees Celsius. To follow the goals and accomplish them saline water can be used for irrigation to bring more lands under cultivation. Bio saline agriculture can help in improving salt-affected soils such as cultivation of salt tolerant crops and growing of forest trees in barren lands instead of leaving them fallow. This would help in sequestering environmental CO_2 and alleviates global temperature rise. Deserts can also be made productive by installing solar energy panels. Recently, Morocco has floated a tender for 400 MW solar power project (COP21, 2015). In Pakistan a solar power project has also been installed in Bahawalpur with a capacity of 100 MW.

This chapter describes efforts related to brackish water treatment and/or management that must be critically examined to learn lessons and shape the future for safe and sustainable use of brackish water. This chapter also highlights the economic feasibility of using gypsum, acids and/or acid formers and like amendments for brackish water treatment with least disturbing the biosphere equilibrium.

Brackish Water

Brackish water is a general term for water having high EC, SAR and/or RSC. Canal water supply has become short to cope with the crop requirements because of prolonged and un-expected droughts mostly in response to climate change, silting of water reservoirs, competition between agricultural and non-agricultural demands and increased cropping intensity. As a result, pumping of ground water has increased tremendously over the years. Due to canal water shortage, number of tube wells is increasing at an alarming rate, i.e. 3000 in 1950 to > a million in 2014. Unfortunately, the pumped ground water is unsuitable for irrigation, since ≈ 70-75% tube wells were and are pumping brackish water (high EC, SAR and/or RSC) during the period of 1995 to 2014 (personal communication from Directorate of Soil Fertility Res. Inst., Lahore). Continued use of such waters for irrigation is one of the major reasons to induce soil salination/sodication along with hard setting, deterioration in produce quality/shelf life, and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

creating environment problems (Ghafoor et al., 2001a). In addition, sub-soil drying due to draw-down of water table is another future concern and must be addressed immediately and wisely. Indiscriminate pumping of ground water is also deteriorating the ground water quality, particularly under the decreased of ground water recharge due to lining of water courses, canals and increasing water use efficiency leading less leaching fraction; a minimum leaching fraction is the key to arrest the salt accumulation in the root zone under arid and semi-arid climates even with canal water irrigation. It is the rule of thumb that as one goes deeper into subsoil and away from rivers, ground water quality becomes poorer and poorer.

The shortage of quality irrigation water in Pakistan has attracted the international interest. Some private organizations are trying to market their products for the treatment of brackish water without proper testing to prove validity/usefulness under local agro-climatic conditions as explained in a later section.

Water Quality Criteria for Irrigation

Numerous water quality guidelines have been proposed by various scientists in Pakistan (Hussain, 1978; Sheikh, 1989; Yunus, 1977) and India (Gupta, 1990) but lack support of experimental data. The guidelines developed by the US Salinity Lab. Staff (1954) and Ayers and Westcot (1985) have been most commonly followed which more accurately predict the effect of water quality on soils and crops. Extensive experimentation is required to develop water quality guidelines keeping in view the physical and chemical properties of soils and agro-climatic conditions of Pakistan. Depending upon the degree of restriction, the three poor quality water classes (saline, saline-sodic and sodic) could be further grouped each into three homogenous subgroups (Table 1), since each subgroup needs specific management practice(s). This classification also helps to serve the purpose at regional levels.

Table 1. Grouping ground water for quality parameters

Water Quality	EC_{iw} (dS m^{-1})	SAR_{iw}	RSC ($mmol_c$ L^{-})
E. Good	< 1. 5	< 1 0	< 2. 5
F. Saline			
Marginally saline	1.5-3.0	< 10	< 2.5
Saline	≥ 3.0	< 10	< 2.5
High-SAR saline	≥3.0	≥ 10	< 2.5
G. Saline-sodic			
Marginally saline-sodic	1.5-3.0	10-15	2.5-4.0
Moderately saline-sodic	1.5-4.0	10-15	≥ 4.0
Highly saline-sodic	≥ 4.0	≥ 15	≥ 4.0
H. Sodic			
Marginally sodic	0.5-3.0	10-15	2.5-4.0
Moderately sodic	1.5-3.0	≥ 15	≥ 4.0
Highly sodic	< 3.0	≥15	≥ 4.0

GROUND WATER RESERVES

Previously, the quality of ground water was assessed on the basis of total soluble salts (TSS). The extent of areas possessing groundwater of different salinities within 350 feet is 40.73 MA (Ahmad & Chaudhry, 1997). It may also be noted that groundwater of the reported quality does not exist within the full depth of 350 feet. Generally, quality of water in the upper depth is relatively better owing to recharge through seepage from canal water irrigation structures and useable except at certain sites. But, in general, groundwater quality deteriorates as we move deeper and away from the rivers and canals. However, highly hazardous properties of water, RSC and SAR have been neglected in the past surveys which even need scientifically more emphasis. Furthermore, EC: SAR, Ca^{2+}: Mg^{2+}, Na^{+}: K^{+} and Ca^{2+}: total cation ratios in water have seldom been considered.

TREATMENT OF BRACKISH WATER

Salinity

The EC_{iw} is an index of total soluble salts. The only treatment option to bring a decrease in total soluble salts is dilution with low salt water. Use of any chemical like gypsum, acid or acid formers will increase salt contents making the use of treated water even more hazardous. However, high EC_{iw} for initial reclamation of saline-sodic/sodic soils have proved better because of favorable effects of electrolytes on soil hydraulic properties (Ghafoor et al., 2004; Murtaza et al., 2009). Addition of organic matter to soil could help counter partially or extend the time to appear ill effects of high EC_{iw} on soils and crops (Ghafoor et al., 2002). Dilution required for high EC_{iw} can be calculated by the formula:

$$EC_{BW} = [(EC_a)F_a)] + [EC_b)(F_b)] \text{ if } a + b = 1, \text{ then } a = 1 - b \text{ or } b = 1 - a \quad (1)$$

where EC_{BW} = EC of blended water, EC_a = EC of water a, F_a = Fraction of water a, EC_b = EC of water b, F_b = Fraction of water b.

Dilution

The SAR will decrease by the square root times of the dilution factor (DF) or will increase square root times of the concentration factor (CF), i.e. Blended water SAR = Original SAR/$(DF)^{1/2}$ or Original $SAR_{iw} \times (CF)^{1/2}$

Desalination

Desalination is a process to remove excess salts and other minerals from water to make it suitable for irrigation. Sometimes table salt is obtained as a by-product. In order to sustain irrigated agriculture, construction of water desalting plants provides another option. The traditional process used in these operations is like to distillation. In this technique, systems require large amounts of energy to produce desalted water. This is possible only where low cost energy is available. Another technique (reverse osmosis) is used to remove all the types of soluble salts from brackish water. The brackish water is passed

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

through semi-permeable membranes under pressure and concentrated brine is collected separately down the stream for safe disposal. Because of decreased volume, the concentrated brine can be used to extract some commercial-grade salts. In reverse osmosis, a pressure greater than the osmotic pressure of water is applied to saline water which causes desalted water to flow through membranes while retaining back salts. The higher the applied pressure above the osmotic pressure, the higher the rate of desalted water transports across membranes. This technology is well established and systems have been fabricated at economical costs. Such systems are in operation in USA, Saudi Arabia, China, USSR and Morocco at under government management (Ghafoor et al., 2004). This technology seems very difficult and expensive for the time being to practice in Pakistan due to energy crises and high prices.

SODICITY

Sodium Adsorption Ratio (SAR)

It is calculated using soluble ions in water or soil solution (US Salinity Lab. Staff, 1954) as:

$$SAR = Na^{+}/ (Ca^{2+} + Mg^{2+}/2)^{1/2} \quad (2)$$

ions concentration in $mmol_c\ L^{-1}$ OR

$$SAR = Na^{+}/ (Ca^{2+} + Mg^{2+})^{1/2} \quad (2)$$

ions concentration in $mmol\ L^{-1}$

Dilution

Like $EC_{iw,}$ mixing with low SAR or high $Ca^{2+} + Mg^{2+}$ water will decrease it by square root times of the dilution factor.

Addition of Ca-Source

Concentration of Na^{+} in irrigation water could not be decreased economically because of large volumes required for agriculture except dilution with low Na^{+} water. Concentration of Ca^{2+} can be increased through lining of water courses with gypsum stones as baffled structures/ geometry to enhance the flow velocity of water as well as to maximize the water-stone contact. This strategy is safe and economical although some problems of rodents, weeding of water courses or decreasing gypsum stone dissolution with time due to lime coating ($CaCO_3$) on gypsum stone surfaces if water has high RSC and thus may prove cost-intensive (Oster, 1994) because frequent acid flushing of stones will be essential to sustain the dissolution rate of gypsum stones in order to have effective treatment of water. The calculated amount of gypsum powder required to decrease the SAR hazards (or to counter the adverse water SAR effects) could also be soil-applied before planting the designed crop. The soil-application of gypsum considering volume of water can be calculated as:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Water has EC 3.25 dS m^{-1}, $Ca^{2+} + Mg^{2+}$ 6 $mmol_c\ L^{-1}$, Na^+ 24 and SAR 13.87. How much 90% pure gypsum is required to lower SAR to 10 of a 10 cm-ha irrigation.

$$SAR = \frac{Na\ 24}{(Ca + Mg/2)^{1/2}} = \frac{}{(6/2)^{1/2}} = 13.87$$

Additional $Ca^{2+} + Mg^{2+}$ required = 13.87 – 6.00 = 7.87 $mmol_c\ L^{-1}$

100% pure gypsum required for 10 cm-ha irrigation = $10^6 \times 7.87\ mmol_c\ L^{-1} \times 86 \times 10^{-6}$

= 676.82 kg of 100% pure

752.20 kg required of 90% pure gypsum

Residual Sodium Carbonate (RSC)

The RSC calculations are based on the assumption of quantitative precipitation of CO_3^{2-}, HCO_3^- and Ca^{2+} ions in soils (Eaton, 1950) which could not be always true. Quantity and rate of salt precipitation is governed by the least amount of any one of these ions. Upon irrigation (dilution), the recently formed $CaCO_3$ precipitates are dissolved while reverse (re-precipitation) may be true upon concentration of soil solution through evapo-transpiration. The formula for RSC calculation is:

$$RSC = (CO_3^{2-} + HCO_3^-) - (Ca^{2+} + Mg^{2+}) \quad (3)$$

where ions concentration in $mmol_c\ L^{-1}$.

Addition of Ca Source

This treatment could be achieved by the water course lining with gypsum stone as baffled structures/ geometry to enhance the flow velocity of water as well as to maximize the water-stone contact. The calculated amount of gypsum powder required to decrease the RSC hazards (or to counter the adverse water RSC effects) could also be soil-applied before planting the designed crop.

Neutralization of CO_3^{2-} and HCO_3^-

This could be accomplished with mineral acids (H_2SO_4, HCl, HNO_3) or acid former (S, CaS_5, FeS) but the option is and has to be highly site-specific because this treatment will simultaneously increase EC. General chemical reactions of carbonates with acids (say Na_2CO_3 and H_2SO_4) will be:

$$2Na_2CO_3 + H_2SO_4 = 2NaHCO_3 + Na_2SO_4 \quad (4)$$

$$2NaHCO_3 + H_2SO_4 = Na_2SO_4 + 2H_2O + 2CO_2 \quad (5)$$

Without changing its SAR, these reactions will tend to lower pH of water and the soil irrigated with such treated water for reasonably longer periods.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Dilution

Like $EC_{iw,}$ mixing with low RSC or high $Ca^{2+} + Mg^{2+}$ water will decrease it in direct proportion of the dilution factor.

Among amendments for lowering RSC, gypsum is the most economical and safe, while acids could serve the purpose but at 5-8 times higher cost than gypsum (Ghafoor et al., 2004). The best economical solution for high SAR and/or RSC waters is soil-applied gypsum with or without farm manure or green manure before each crop considering the delta of water of crops and intensity of SAR and/or RSC problem. The blended/mixed use of canal and brackish waters is not possible in our conditions as the canal water supplies are not in the control of farmers.

High Concentration of Mg^{2+}

In some areas, irrigation water may contain high concentration of Mg^{2+} with Mg^{2+} to Ca^{2+} ratio > 1. The use of such water for irrigation and reclamation may increase exchangeable Mg^{2+} in soils (Karajeh et al., 2004). Exchangeable Mg^{2+} at excessively high levels may result in soil degradation because of its adverse effects on physical properties of soils. According to McNeal et al. (1968) soils having mixed Na^{+}–Mg^{2+} will have lower hydraulic conductivity than did soils with Na^{+}–Ca^{2+} under similar conditions. This could be due to the fact that t the hydration energy as well as hydration radius of Mg^{2+} are greater than that of Ca^{2+} (Strawn et al., 2015). Thus soil surface retains more water than where exchangeable Ca^{2+} is present, causing weakening of forces that stabilize soil structure. This, in turn, decreases the amount of energy needed to break down soil aggregates (Oster & Jayawardane, 1998). Further to this, at low levels of exchangeable sodium percentage (ESP), Mg^{2+} also exaggerates the effects of Na^{+} on clay dispersion and hydraulic conductivity (Qadir & Schubert, 2002). Oster (2001) reported that when Mg^{2+} proportion compared to Ca^{2+} increases than exchangeable Mg^{2+} resulted in greater dispersion thus causing a larger decline in hydraulic conductivity. Similarly, at a given ESP, replacing the exchangeable Ca^{2+} with Mg^{2+} decreased the infiltration rate of soils (Rengasamy et al., 1986). A recent review (dating back to the 1930s) by Smith et al. (2015) supports the general conclusion that the relative order of deleterious effects on soil hydraulic properties of the four common cations in soils was in the order of $Na^{+} > K^{+} > Mg^{2+} > Ca^{2+}$. It was concluded that Mg^{2+} was significantly less effective than Ca^{2+} in improving soil structure and water permeability.

The achieved results from the above stated brackish water quality improvements, several other untested technologies by some vested interest people are claiming. These technologies include Sulphurous Acid Generator (SAG) by Sweet Water Solution of USA, EM/BM technology from Japan, RISTECH Technology from UK, and Electro-Magnetic Membrane technology from Germany. Novel claims of these technologies are to desalinate the brackish water, convert sodium into nitrogen, change in soil texture over a period of 2-3 years, and bacteria in these recipes eat salts as well as sodium present in water or soils. Unfortunately, none of these have been demonstrated at any university or research farm. In spite of this fact, they are be-fooling the farmers at a very large scale to make money. Government should give attention immediately to stop their business and save hard earnings of farmers since farmers are drowning and try to catch a straw to save themselves.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

EC_{iw} to SAR_{iw} Ratio

Low EC_{iw} or EC_e at a given SAR_{iw} or SAR_{ss} tends to decrease soil infiltration through decreasing the thickness of Diffused Double Layer (DDL) (Ayers & Westcott, 1985; Ghafoor et al., 2004). Water having low SAR_{iw} and high EC_{iw} was found better for normal and salt-affected soils because of favorable effects of electrolytes on soil infiltration and hydraulic conductivity, while reverse was true for high SAR_{iw} with low EC_{iw}. Therefore at start of reclamation of saline-sodic or sodic soils, waters having high EC: SAR ratios were found equally useful (Ghafoor et al., 2001b) but has to switch to better quality water (low EC_{iw}, low SAR_{iw}) with the advancement of soil reclamation (Murtaza et al., 2009). It is important to consider this quality parameter for sustainable management of brackish water in order to maintain a leaching fraction as well as if used for reclaiming salt-affected soils. Some studies were conducted by authors in the Fourth Drainage Project Area (FDPA), Faisalabad using brackish water, wherein it was concluded that such waters can be used safely at the early stages of reclamation (Ghafoor et al., 2008, 2011, 2012; Murtaza et al., 2009). However, presently this parameter is not given very much importance and must be considered for future irrigation water quality guidelines.

PERMEABILITY PROBLEMS

Permeability refers to the percolation of infiltrated water through soils. Doneen (1975) suggested a formula to predict the infiltration rate which was designated as Permeability Index (PI).

$$PI = [100\ \{Na^+ + (HCO_3^-)^{1/2}\}/\{Na^+ + Ca^{2+} + Mg^{2+}\}] \quad (6)$$

where ionic concentrations in water are in $mmol_c\ L^{-1}$.

This relationship is quite useful in predicting the effect of water on permeability of soil and also this does not need extra determination in routine water analysis.

INFILTRATION PROBLEM

The rate at which water enters into soils is referred to as the rate of infiltration. An infiltration rate (IR) as low as 3 mm h^{-1} is considered low while a rate > 12 mm h^{-1} is high (US Salinity Lab. Staff, 1954). This parameter is affected by many factors other than water quality, like soil physical characteristics (soil texture, type of clay minerals) and chemical characteristics (exchangeable cations). The IR generally increases with increasing salinity (EC) and decreases with either decreasing EC or increasing Na^+ concentration relative to Ca^{2+} and Mg^{2+}, i.e. SAR (Murtaza et al., 2006). Therefore, EC and SAR must be considered for a proper evaluation of the ultimate effect of water on its infiltration rate.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

SPECIFIC ION EFFECTS

It is the concentration of an ion relative to total concentration which when exceeds beyond a certain limit cause specific ion effect. If Na^+ concentration is > 60% of the total cations, water becomes hazardous for irrigation because it induces K^+ and/or Ca^{2+} deficiency and scorching of leaf tips in addition to deteriorating physical and chemical properties of soils. It is worth mentioning that deterioration in physical properties of soils starts much earlier than specific ion effects of Na^+ on plant growth. The concentrations of Cl^- and SO_4^{2-} strongly correlate with EC of irrigation water (EC_{iw}). About 5-10 $mmol_c\ L^{-1}$ Cl^- becomes harmful to sensitive plants. However, relatively wide range of sensitivity to Na^+ and Cl^- effects among different plants exists which is more pronounced under sprinkler irrigation. Woody plants are more sensitive to Cl^- than annual crops. If Cl^-: SO_4^{2-} ratio becomes greater than 1: 3, the water is considered more hazardous than that where this ratio is 3: 1. The SO_4^{2-} ions are considered more harmful for roots and disturb internal metabolism of plants. These ions induce precipitation of Ca^{2+} as $CaSO_4$ which causes a rise in soil pH and SAR, and thus make the soil environment unfavorable for nutrient availability to plants. Generally waters having high EC under arid to semi-arid conditions may contain $Mg^{2+} > Ca^{2+}$. Magnesium >50% among $Ca^{2+} + Mg^{2+}$ adversely affects soils and plants. Increasing Mg^{2+} over Ca^{2+} in irrigation water increased the sodicity in soils at a given SAR_{iw} and EC_{iw} and its effects were more pronounced at higher than that at lower SAR_{iw}. Release of Ca^{2+} from the in-situ soil weathering and native lime increased with increasing Mg^{2+}: Ca^{2+} ratio in irrigation water. With an increase in Mg^{2+}: Ca^{2+} ratio and SAR of soil and/or irrigation water, the degree of dispersion increased significantly. The Ca^{2+}: Mg^{2+} ratio $\geq$ 1.0 is considered safe for most of the crops and soils. Generally, grasses are more sensitive to Mg^{2+} than other plants since former crops acquire high Mg^{2+} in living tissues. From previous studies, it was also noted that high Mg^{2+} water is relatively more harmful to affect rice yield as compared to wheat and cotton crops (Ghafoor et al., 1997). This aspect needs further research since a lot of ground waters contain Mg^{2+} higher than Ca^{2+} under arid regions of the world. However, the productivity of Mg^{2+} dominated soils can be improved by increasing levels of Ca^{2+} on the cation exchange complex to counter the adverse impacts of Mg^{2+}. This could be accomplished by applying sufficient amount of Ca^{2+} to soils (Vyshpolsky et al., 2008).

SEED PRIMING

Seed priming is a process where seed is hydrated for specified time periods under controlled conditions followed by re-drying that allows all the pre-germination metabolic activities but prevents radicle protrusion (Khan et al., 1992). Poor stand establishment is a widespread constraint for crop production in salt-affected soils (Harris et al., 1999; Saifullah et al., 2002). Presence of excessive soluble salts and/or exchangeable Na^+ may adversely impact the physical, chemical and nutritional properties of soil that in turn may lead to lower plant population (Qadir et al., 2014). Moreover, such plants after emergence often grow slowly and are highly susceptible to stresses such as drought, salinity, pests and diseases (Francois et al., 1986). Under such conditions farmers may choose to re-sow, although this entails severe yield penalties, increased labor and financial losses. Pre-sowing seed treatments with salts, nutrients or hormones have been advocated to enhance seed germination in saline medium (Afzal et al., 2013; Ashraf & Foolad, 2005). However, it fails in saline-sodic or sodic soils due to poor physical condition. In these soils, seeds fail to emerge out of soil due to surface crust. Gypsum helps to improve soil physical and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

chemical properties. In this backdrop, a three years project was initiated on salt-affected soil to monitor the effect of combined application of seed priming and soil-applied gypsum on growth and yield of wheat and rice crops using brackish water for irrigation. The results indicated that combined application of gypsum and seed treatment with saturated solution of gypsum was the best treatment in terms of soil health improvement, yield enhancement and economic output. Priming enhanced the seed germination through protein synthesis, repair of nucleic acid and membranes (Hameed et al., 2010; Fujikura & Karssen, 1995). In a recent study (Saifullah, 2012), it was concluded that sowing of wheat seed soaked for 24 hours in aerated gypsum saturated solution + gypsum at 50% of soil gypsum requirement helped better crop stand and ultimately the economic yields.

WASTEWATER

In developing countries including Pakistan, it is a common practice to discharge domestic and industrial effluent (premixed due to common water carrying channels) directly to a sewer system, a natural drain or water body, a nearby field or an internal septic tank. Unfortunately, this wastewater is not properly treated because of non-functioning and/or availability treatment plants. The sewage in drains is mostly have high EC, SAR, RSC and elevated levels of several metals, organics and associated pathogens that warrant site-specific management strategies. The wastewater used for irrigation is becoming an attractive commodity for farmers mainly because of its nutrient contents and reliability of supply (Ensink et al., 2004; Murtaza et al., 2010). It can have positive impacts on agriculture and monthly income despite producing adverse effects on soil physical and chemical properties in addition to contamination of human food chain and related health risks (Hanjra et al., 2012; Qadir et al., 2010; Vincent, 2014). Recent estimates depict (Table 2) that total volume of wastewater generated in Pakistan is about 962,335 million gallons (4.369×10^9 m^3/yr) out of which 674,009 million gallons (3.060×10^9 m^3/yr; and 5.54×10^9 m^3/yr for the year 2011) are shared by municipalities and 288,326 million gallons (1.309×10^9 m^3/yr) from industries. As with other developing countries, in Pakistan, wastewater is not subjected to any treatment and none of the cities have any biological treatment process except Islamabad and Karachi, and even these cities treat only a small proportion before disposal (Table 3). Estimates suggest that the amount of treated wastewater is not > 1% (Murtaza & Zia, 2012). The treated wastewater generally flows into open drains, and there are no provisions for its reuse for agriculture.

Table 2. Sector-wise wastewater production in Pakistan in the year

Sr. No.	Source	Volume	
		10^6 m^3 y^{-1}	Percent (%)
1	Industry	395	6
2	Commercial	266	5
3	Urban residential	1,628	25
4	Rural residential	3,059	48
5	Agriculture	1,036	16

Source: Master Plan for Urban Wastewater (Municipal and Industrial) Treatment Facilities in Pakistan. Final Report, Lahore: Engineering, Planning and Management Consultants, 2002.

It is highly recommended that the wastewater should be treated at source. Different chemical and plant based technologies are available for the remediation of wastewater (Murtaza et al., 2014). One opportunity to address these concerns is the use of low cost agrowaste adsorbents for the treatment of urban wastewater for irrigation of crops, trees, forests and greenbelts (Abdolali et al., 2013). There seems week national policy and implementation on sustainable use of wastewater in developing countries including Pakistan. The problems of wastewater disposal emerge from distortions due to economy-wide policies, failure of targeted environmental policies and institutional failures. Therefore, a well-coordinated program is necessary to create awareness among different sections of the society including the policy makers, general public, organizations, industrialists and farmers to save future of nations.

CONCLUSION AND RECOMMENDATIONS

It is important to consider and adopt preventive measures immediately to avoid the disaster of soil salination and sodication in response to poor quality tube well water irrigation. The deterioration of soils adversely affects the ambient environments for all the living organisms including human beings. Thus, it seems essential and wise to reclaim the saline and/or sodic soils and adopt measures to limit the adverse

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

effects of hazards associated with low quality irrigation waters in favor of crops/plants growth in order to keep the environment clean.

The best economical solution to high SAR and/or RSC waters is to soil-apply gypsum along with farm manure or green manure before each crop, considering the delta of water of a crop and gravity of SAR and/or RSC problem. Blended/mixed use of canal and brackish waters is not possible under our conditions since canal water supplies are not at the disposal of farmers. The cyclic (alternate irrigation, or one crop with canal and next with brackish water) are already in practice (Oster & Grattan, 2002; Rhoades et al., 1992). The farmers should try to avoid irrigation with brackish water at critical crop growth stages. They should also try to use good water on good soils and poor quality water on poor soils.

There is an immense need to initiate the tube well water analyses for appropriate and site-specific advice by soil and water experts, and simultaneously it must be made mandatory and legal for tube well owners to get the water analyzed and act upon the advice. Assuming 70% pumped ground water hazardous which require addition of gypsum at 4 $mmol_c\ L^{-1}$ of irrigation water, 400 kg for each acre-foot and 15.6 million tons gypsum for 39 MAF tube well water annually will be required, i.e. 234 million tons quality gypsum will be essential to soil-apply in order to mitigate the adverse effects of high SAR/RSC tube well water. For a door-step supply of this much gypsum has to be ensured on credit for sustainability of irrigated agriculture and safe environment since the salt-stress land and tube well owners might not be in a position to purchase gypsum on cash payment.

The potential of virtual use of water could be exploited at regional/provincial/national levels. The idea of virtual use of water compares the amount of water embodied in a crop that can be purchased at regional/provincial/international levels with the amount of water that should be required to produce that crop natively. For example, transferring every kilogram of wheat into water stress area means to transfer about 1000 L of virtual water at a much less price than the price of the same quantity of water from the native water resources in the area itself (Qadir et al., 2003).

There is significant loss in storage capacity of water reservoirs which is increasing gradually and this loss will become about 33% of the designed capacity by the year 2020. It is strongly recommended that additional storage facility is developed, and the silt load of in-coming water into existing dams is decreased through controlling/ promoting vegetation with or without the help of engineering structures in the catchment areas. Seed priming in saturated gypsum solution for 4-8 hours did help early and enhanced germination of cereal crops which latter improved crop stand for better yield since as plants grow older, their performance in salt-stress environment (saline and/or sodic soils or irrigation waters) become promising.

The city wastewater poses threats of heavy metals. Under such situations, metals could be made less available with the soil-applied gypsum, mono-ammonium phosphate, DAP or some other economical Ca-salts. The metals could also be removed by enhancing their availability through soil-application of acids, acid formers and EDTA salts with crops not directly consumed by human beings. However, growing leafy vegetables with sewage water must be banned.

Another feasible practice for brackish water irrigation is to cultivate salt-tolerant crops requiring less irrigation, particularly to decrease the input of chemicals into soils and ground water contamination. This practice will also help decrease the problem of waterlogging. The breeders should come forward and conduct research in the fields of genomics, proteomics, biotechnology, and nanotechnology to breed salt-resistant and drought-tolerant crops (Roy et al., 2014; Seabra et al., 2014).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The allocation of irrigation water is not uniform in various provinces of Pakistan. The water allocation is more in Sindh compared to Punjab. Moreover, water allocation is higher in Southern Punjab as compared to central and upper Punjab. Improvement in water allocation is required to achieve sustainable irrigation and to avoid salinity and waterlogging.

POLICIES

To tackle the water quality problems some policies are suggested 1) give priority to increasing irrigation efficiencies, essentially with allowance for salinity/ sodicity control through effective leaching of in-coming salts, 2) move towards a demand based irrigation water supply, 3) promote water use associations (WUA) and thereafter Federation of WUA, 4) maintain the existing drainage infrastructure with site-specific emphasis on new projects, 5) strengthen the advisory service to farmers and training to extension staff.

MEASURES

Some specific measures for the safe use of brackish water on sustainable basis are 1) take incremental but specific measures towards volumetric consumption as the ultimate basis for water charges, 2) undertake studies in community management of a few distributaries on a pilot scale, 3) address problems of water table draw-down by holistic approaches, encompassing both the demand management and methods to increase water recharge, 4) promote farmer education and extension activities as well as in-service training of staff, 5) review funding, goal should be 60:40 ratio for research: administration, 6) in kind credit facility for gypsum in time and space, particularly to small and resource poor farmers, 7) make it legal for farmers to get their tube well water analyzed, mobile teams of experts be organized to collect, analyze and advice solutions for tube well water quality.

Chapter 54
Rural Innovations:
Text and Cases

Roopesh Rao
Shri Ramdeobaba College of Engineering and Management, India

ABSTRACT

In a country like India innovations are more referred as "jugaad". Though the dictionary does not explain such kind of words, but every person in India understands the importance of jugaad. India has one of the largest systems for agricultural research in the world. However this system has focused predominantly on strengthening of cereal production under irrigated conditions. It would be essential that they participate in all decision making which cater to overall development of rural India. India also needs to increase its efforts to tap into the rapidly growing stock of global knowledge through channels such as FDI, technology licensing, importation of capital merchandise that embody knowledge, as well as advanced products, components, and services. This chapter analyses and focuses on various innovative practices done with the help of Government, Public Private Partnership, private Players, Individuals, NGOS, etc.

BACKGROUND

Innovation is increasingly being seen as the currency of 21st century. The future prosperity of India in the new knowledge economy will increasingly depend on its ability to generate new ideas, processes and solutions, and through the process of innovation convert knowledge into social good and economic wealth. (India Innovation Portal Decade of Innovation 2010-20)

India lives in numerous villages scattered thorough out the country. Rural areas are nearly three-fourth of the country of India and accounted for more than half of economic consumption. In spite of urbanization about 63 percent of population will continue to live in rural areas in year 2025. And the total potential of Indian rural market will reach to about 500 billion by 2020. According to 2011 census there is 640000 villages in India. India has substantial population below poverty line and having literacy level.

INNOVATION

"The process of translating an idea or invention into a good or service that creates value or for which customers will pay. To be called an innovation, an idea must be replicable at an economical cost and must satisfy a specific need. "Innovation involves deliberate application of information, imagination and initiative in deriving greater or different values from resources, and includes all processes by which new ideas are generated and converted into useful products. In business, innovation often results when ideas are applied by the company in order to further satisfy the needs and expectations of the customers. 'Innovation is defined as a process by which varying degrees of measurable value enhancement is planned and achieved, in any commercial activity. This process may be breakthrough or incremental, and it may occur systematically in a company or sporadically; it may be achieved by introducing new or improved goods or services and/or implementing new or improved operational processes and/or implementing new or improved organizational/ managerial processes in order to improve market share, competitiveness and quality, while reducing costs.' Business Dictionary (2014) Innovation and competitiveness have a dynamic, mutual relationship. Innovation thrives in a competitive environment and in turn, plays a key role in the achievement of such an environment. Innovation generates economic value, new jobs in the economy and cultures of entrepreneurship. By virtue of its relationship with competitiveness, Innovation emerges as a factor in promoting economic growth. Given the fact that the Indian economy is growing at 6-8% per year, while exports are growing at 30% Cumulative Annual Growth Rate (CAGR), India Innovation (2014) and many Indian firms are successfully competing against international firms and brands, it can be concluded that this has been made possible by a combination of factors, including enabling environment, rising capital and labor productivity as well as improved quality of goods and services at lower costs. In a social context, innovation helps create new methods for alliance creation, joint venturing, flexible work hours, and creation of buyer's purchasing power. Innovator need not be a person who comes from a wealth background, with a huge credential and qualification. Innovation can be done and are happening at grass-root levels. The story of Mandar Talukar, a small town boy from Nagpur winning the "best innovator in the world" award at USA for his innovation mobile shoe charger, show that innovators are not born; they are developed in adversity thus proving that "necessity is the mother of invention". Rao et al (2012)

In a country like India innovations are more referred as "jugaad". Though the dictionary does not explain such kind of words, but every person in India understands the importance of jugaad. The classic examples of jugaad are the use of washing machine to make huge amount of "lassi" (sweet butter milk, sold in northern part of India), pressure cooker used for making espresso coffee, etc.

As we can see India is the land of innovation (jugaad) and innovation is here to stay for a long time. Innovations have become a way of life and life without innovations is unimaginable. To its credit, India has been taking bold steps to strengthen its R&D infrastructure, developing technological innovations and altering the mind-set of its people toward better creation, acquisition, and use of technology. It is endowed with a critical mass of scientists, engineers, and technicians in R&D and is home to dynamic hubs of innovation, such as Bangalore and Hyderabad. It also has vast and diversified publicly funded R&D institutions, as well as world class institutions of higher learning, all of which provide critical human capital. India is also emerging as a major global R&D platform; about 100 multinational corporations (MNCs) have already set up R&D centers in the country, leading to the deepening of technological and innovative capabilities among Indian firms.

AUTOMATED TELLER MACHINES IN RURAL PARTS OF INDIA

Though it has given its remarkable footprints in rural development but still there are some parts were there are lack of facilities in rural parts and remote areas. When studied awareness of ATM facilities in rural part we come to know that, within two decades, ATM technology development is happening at an alarming rate. Qureshi, Kumar, Jhunjhunwala (2002). Gone are the days when customers were limited to only withdrawing cash from ATM's. We have now reached an era, where we can use multi function and biometric ATM, (See Figure 1) equipped with touch sensitive and user friendly options to transfer funds, book air and train tickets, go for mobile recharge, and even deposit cheque with scanning.

The consumers in the rural areas lack awareness about various schemes and e-banking services of bank. The emergence of new technology allows to access the banking service without physical direct re-course to the bank premise by the customer at present atm is city oriented in the country. Agarwal (2012) The growth of rural it industry fosters financial inclusion by providing financial services to people in the farthest reach of the country. Qureshi, Kumar, Jhunjhunwala (2002)

Rural marketing plays an important role in development strategy, particularly in the areas of diversification, modernization, globalization and self-reliance. 70% of Indian population belongs to rural part of the country.

When it specifically comes to contribution of information technology ATM (automated teller machine) had played a very important role in rural development. The emergence of new technology has effect the consumer awareness in rural parts to a remarkable extent. (Srinivasa Rao, 2013) (See FIGURE 2)

It has also give awareness and education to undeveloped part of the region. It has also influenced over the population with financial support. Agarwal, Dadhich (2012)

India lives in numerous villages scattered thorough out the country. Rural areas are nearly three-fourth of the country of India and accounted for more than half of economic consumption. In spite of urbanization about 63 percent of population will continue to live in rural areas in year 2025. And the total potential of Indian rural market will reach to about 500 billion by 2020. According to 2011 census there is 640000 villages in India. India has substantial population below poverty line and having literacy level. Rural banking system with emergence of information technology is influencing the population

Figure 1. An ATM (automated teller machine) in a small village in INDIA

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

towards banking services like ATM cards, credit cards and other quick and easy services. Even now, rural development defies any clear definition as it has gone through a number of changes over a period of time. Persuasive communication for rural development has been given highest priority for bringing about desirable social and behavioral change among the most vulnerable rural poor and women. Initially, the approach lacked gender sensitivity and empathy of the communicators and development agents who came from urban elite homes. Agarwal, Dadhich(2012) Added to these constraints is political will that still influences the pace and progress of rural development. We are one of the world's oldest and ancient civilizations that evolved, matured and decayed over several millennia.

After independence we have been experimenting and carving a path of revitalization for development through democracy. The existing sharp divide between the small but economically, politically and socially "rich elite ruling class" and a very big but "economically poor and socially deprived" continue to persist as a legacy of the past.

After independence, the government took upon itself the major responsibility of development. Hence, the central and state governments carried out development projects. The experiment was carried out from February to April 1956 in five districts of Maharashtra state by all India radio (air). Rao (2013)

Rural listener groups were organized, who would listen to radio broadcasts twice a week. The summative impact evaluation indicated positive outcome of radio rural forum. Impressive knowledge gains as a result of radio listening were reported across illiterates and literates, agriculturists and non-agriculturists, village leaders and others. Almost all healthcare projects for rural poor, especially women and children have used demand driven social marketing approach for rural the development.

HDFC Bank 'Project Jharkhand': An IT Enabled Financial Inclusion Program

HDFC Bank, launched 'Project Jharkhand' a financial inclusion program. As part of the program, the Bank launched its world class services at a Common Service Center in Kanke comprising over 1.5 lac households spread across 100 villages in 30 Panchayats. The Bank also adopted Chakala village near Ranchi as part of the Common Service Center program. Under Project Jharkhand HDFC Bank will

Figure 2. A solar operated ATM – innovation for greener tomorrow

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

look to cover over 45 lac households in the state through both the Common Service Center and village adoption models, subject to regulatory provision.CSC is an integral component of the Central Government's National e-Governance Plan (NEGP) that seeks to set up over 5000 CSCs in Jharkhand and about 100,000 in the country.

These Common Service Centers will make available to the rural population a slew of services ranging from public information services, e-governance services, educational services to agri related and financial services. Common Service Center will also work like a 'Human ATM' that the rural people can use to withdraw and deposit cash. (HDFC Bank launches 'Project Jharkhand 2008, http://www.hdfcbank.com/htdocs/common/pdf/Project_Jharkhand.pdf)

TRANSFORMING RURAL INDIA THROUGH AGRICULTURAL INNOVATION

"Agricultural jeopardy is related with undesirable outcomes that shoot from badly expectable biological, climatic, and price agents. These variables include natural calamities and climatic factors not within the control of agricultural producers." Shanmugam, Chandrasekaran, Vijayasarathy. (2011)

They also include adverse changes in both input and output prices. To set the stage for the discussion on how to deal with risk in agriculture, we classify the different sources of risk that affect agriculture. Agriculture is often characterized by high variability of production outcomes or, production risk. Unlike most other entrepreneurs, agricultural producers are not able to predict with certainty the amount of output that the production process will yield due to external factors such as weather, pests, and diseases. Agricultural producers can also be hindered by adverse events during harvesting or collecting that may result in production losses. Agriculture community (2014)

Figure 3. Some Agricultural Innovations

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Input and output price volatility is important sources of market risk in agriculture. Prices of agricultural commodities are extremely volatile. Output price variability originates from both endogenous and exogenous market shocks. Segmented agricultural markets will be influenced mainly by local supply and demand conditions, while more globally integrated markets will be significantly affected by international production dynamics. In integrated markets, a reduction in prices is generally not correlated with local supply conditions and therefore price shocks may affect producers in a more significant way. Another kind of market risk arises in the process of delivering production to the marketplace. The inability to deliver perishable products to the right market at the right time can impair the efforts of producers. The lack of infrastructure and well-developed markets make this a significant source of risk in many developing countries. The ways businesses finance their activities is a major concern for many economic enterprises. However, in this respect, agriculture also has its own peculiarities. Many agricultural production cycles stretch over long periods of time, and farmers must anticipate expenses that they will only be able to recuperate once the product is marketed. This leads to potential cash flow problems exacerbated by lack of access to credit and the high cost of borrowing. These problems can be classified as financial risk. Agriculture community (2014)

Another important source of uncertainty for agricultural producers is institutional risk, generated by unexpected changes in regulations that influence producers' activities. Changes in regulations can significantly alter the profitability of farming activities. This is particularly true for import/export regimes and for dedicated support schemes, but it is also important in the case of sanitary regulations that can restrict the activity of producers and impose costs on households.

Like most other entrepreneurs, agricultural producers are responsible for all the consequences of their activities. However, the growing concern for the impact of agriculture on the environment, including the introduction of genetically modified organisms (GMO), may cause an increase in producer liability risk. Finally, agricultural households, along with other economic enterprises, are exposed to personal risks to the wellbeing of people who work on the farm, and asset risks, the possible damage or theft of production equipment and assets. With a majority of its population living in villages, rural poverty is a major problem in India. The disparity between the urban and rural incomes is also on the rise. This leads to migration to urban areas resulting in urban blight as well. Therefore addressing the problem of rural poverty assumes urgency. Agriculture community (2014)

Rural innovations has been involved in a range of interventions—infusion of technology, soil enrichment, efficient farm and water management, improved cattle development, functional literacy, rural sanitation and public health, human resource development, establishment of self-help groups particularly among women, self-employment opportunities and facilitating institutional credit—to address the problem of farm productivity in India. Rural innovations focus on the poor and marginal farmers, women, unemployed youth, and depressed communities. Rural innovations work in about 250 villages in tamil nadu and have reached 30,000 rural families. A large part of rural innovations' effort with farmers is to help break their initial emotional barriers to new technologies. This has provided the platform to launch into other initiatives. The success of these measures has had a demonstrative impact on the farmers' willingness to adopt and internalize new technologies. This may be considered an attitudinal breakthrough (Figure 3).

Another initiative, the center for rural development (CFRD), a training cum village knowledge center, has been established in illedu village of kancheepuram district with classrooms, computer lab with internet facilities, input and product handling center, farm machinery workshop, model experimental farm, residential complex for trainees and an open air theatre to cater to the needs of various sections of

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

rural community. Rural innovations also helps in housing a comprehensive soil testing laboratory, food safety and standards laboratory and a plant tissue culture lab to provide agriculture support services.

Agriculture productivity improvements through resource conserving "lean farming": paddy (55%), groundnut (113%), vegetables (116%), sugarcane (40%), and corn (150%). Through successful lead farmers, technology transfer has been effected over an area of 10,000 acres with a "lead farmer—lead village" concept. Addressing the agriculture value chain—soil testing, facilitation of inputs and credit, market linkage, and field advisory services—is part and parcel of agriculture development initiatives. Promotion of climate resilient agriculture, resource conserving technologies and promotion of use of information communication technology (ICT) in agriculture are being attempted too. Watershed and natural resource management initiatives have resulted in increase in water table ranging from 3.5 meters to 5 meters in the project area of over 6,000 hectares. Cropping intensity has been doubled (two crop cultivation in a year instead of one crop) and about 20% additional area which had been left fallow has also been brought under cultivation. Soil erosion, nutrient loss, damage due to flooding during rainy seasons has reduced significantly. Agriculture community (2014)

To sustain the benefits derived, the social development initiatives of rural innovations have helped village communities in establishing community-based institutions like farmers clubs, self help groups and joint liability groups, farmers producer organizations, watershed committees, etc for collective decision and action.

India has many of the key ingredients for making this transition. The time is very appropriate for India to make its evolution to the knowledge economy—an economy that creates, disseminates, and uses knowledge to enhance its growth and development. It has a critical mass of skilled, English-speaking knowledge workers, especially in the sciences. Its local market is one of the world's largest. The knowledge economy is often taken to mean only high-technology industries or information and communication technologies (ICTs). It would be more appropriate, however, to use the concept more broadly to cover how any economy harnesses and uses new and existing knowledge to improve the productivity of agriculture, industry, and services and increase overall welfare. In India, great potential exists for increasing productivity by shifting labor from low productivity and subsistence activities in agriculture, informal industry, and informal service activities to more productive modern sectors, as well as to new knowledge-based activities—and in so doing, to reduce poverty and touch every member of society. India should continue to leverage its strengths to become a leader in knowledge creation and use. To get the greatest benefits from the knowledge revolution, the country needs to press on with the economic reform agenda that it put into motion more than a decade ago and continue to implement the various policy and institutional changes needed to accelerate growth. It has a large and impressive Diaspora, creating valuable knowledge linkages and networks. The list goes on: macroeconomic stability, a dynamic private sector, institutions of a free market economy, a well-developed financial sector, and a broad and diversified science and technology(S&T) infrastructure. In addition, the development of the ICT sector in recent years has been remarkable. India has created profitable niches in information technology (IT) and is been remarkable. India has created profitable niches in information technology (IT). Rapid advances in ICTs are dramatically affecting economic and social activities, as well as the acquisition, creation, dissemination, and use of knowledge. The use of ICTs is reducing transaction costs and lowering the barriers of time and space, allowing the mass production of customized goods and services.

Some of the examples of rural innovations which are changing the lifestyle, business and way of life are as follows

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

INFORMATION AND COMMUNICATION TECHNOLOGY (ICT) GYANDOOT

Situated in Dhar district of Madhya Pradesh, Gyandoot is an Intranet based Government to Citizen (G2C) service delivery portal it was launched in January 2000. Gyandoot aims to create a lucrative, replicable, economically independent and financially viable model for the rural population to take the benefits of Information and Communication Technology (ICT). Gyandoot: The Purveyor of Knowledge (2014)

E-CHOUPAL BY ITC

Choupal is a Hindi word which means "village meeting place". Market is a meeting place where vendors and customers come together to do transactions. e-choupal is a virtual market place where farmers can transact directly with a processor and can realize better price for their produce. The main charisma of e-choupal is that it can be used for connecting large producers/small producers and small users/large users, thereby eliminating the need for chain of command of brokers.

Geographical distances do not restrict participation in the e-choupal. E-choupal has the advantages of the market but spans very large varieties of vendors and customers. The main disadvantage of Traditional market is that information asymmetry is inherent in the market where as e-choupal provides for transparent transactions. This enables the participation of smaller as well as larger players. Exclusion of intermediaries allows for larger share of profits to reach the bottom end of value chain.(https://www.echoupal.com/)

UNIQUE IDENTIFICATION PROJECT

In a country like India, absence of social security number or its equivalent has made more than 380 millions of poor suffer in the hands of the existing corrupt system because they are unable to participate in the official financial system of the country. The government of India's Unique Identification (UID) project has created avenues for this people to become a part of the different projects and plans developed for self sufficiency, growth and improvement in living standards. This innovation has revolutionized the way Identification is done. The linking of bank account to the card has helped government send direct subsidy to the poor and the needy, thus removing the middle men and barriers. The gas subsidy is directly transferred to the card holders every time they purchase a cylinder thus creating a barrier for black marketing of gas cylinders. Adhar card (2014)

INNOVATION FOR IMPROVING HEALTH IN RURAL INDIA

Innovation is required to address health needs at the bottom of the pyramid. Delivering affordable and quality health care to India's billion-plus people presents enormous challenges and opportunities. Innovations could be a way out for a large number of people get quality care at a cost that the nation can afford.

Addressing healthcare challenges in rural India is a complex proposition. Healthcare starts with generating awareness of risk factors, disease symptoms and the benefits of healthy living to the rural masses for the betterment of the rural population. Measures are taken to convert these messages into actions

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

resulting in the prevention of disease or morbidity. Patients suffering from disease would then require provision of primary, secondary or tertiary care. This is followed by protection of patients from relapse or future risks through management of disease, regular monitoring and health maintenance. Addressing this continuum of care is more complicated owing to the 'double burden of disease' i.e. the co-existence of both communicable and non-communicable diseases. While the country is still dealing with the issue of communicable diseases, the share of non-communicable diseases is also increasing rapidly requiring the health system to come up with a wide range of diverse interventions to address the varying financing, prevention, provision and protection needs of the diseases. Governments schemes (2012)

In addition, a number of other external factors have a bearing on health and health seeking behavior. Recent research increasingly relates health inequalities to social factors such as poverty, nutrition, hygiene, water and sanitation, education, empowerment of women and living space. This would mean that to make any lasting impact on population health outcomes, addressing issues along the complete gamut including these social determinants of health is essential.

TOTAL SANITATION CAMPAIGN

In spite of noteworthy investments over the last 20 years, India faces the most daunting sanitation challenge in any region in the world. The Total Sanitation Campaign in Ahmednagar (Maharashtra) has bought innovation into Sanitation systems. Innovation in the Ahmednagar pilot project is in its use of conditional financial incentives. Most sanitation front individual household subsidies used to assist private toilet construction. Yet stopping open defecation requires collective action, which suggests that the financial incentives would be more effective if used to encourage the attainment of community, rather than individual, goals. In Ahmednagar, every household has to fund its own toilet. Governments schemes (2012)

However, the BPL households do so on the understanding that they will be paid US$ 8.10 if everyone builds a toilet and the community is declared 'open defecation free'.

The remainder of the TSC subsidy (US$ 2.69 per BPL household), paid to the GP on achieving universal access, thus acts as an incentive for the GP to assist in stopping open defecation, including the promotion and facilitation of the construction of toilets by the landless, the very poor, and those unwilling to invest. A similar financial incentive is provided to the NGO working in the village. It is paid US$ 1.07 commission for every household that builds a toilet (from the IEC funds), but does not receive any of this money until the village is declared 'open defecation free'.

For more than 800 million men, women and children across India living on USD 1-3 a day, the idea of accessible and affordable medicines is often as remote as their rural homes.

Arogya Parivar ("Healthy Family" in Hindi): A social initiative developed by Novartis to reach the underserved millions living at the bottom of the pyramid in rural India.

After just five years, Arogya Parivar is proving to be both a force for improving health in rural communities and a sustainable business. Arogya Parivar provides opportunities to expand business in an innovative and responsible way. The program offers education on diseases, treatment options and prevention as well as increases access to affordable medicines. Health educators, usually local women, raise awareness about local diseases and preventive health measures. They also refer sick people to doctors and cooperate with local NGOs to further spread their message. Each educator covers a few villages every day, with an Arogya Parivar branded cap, shirt and banner, making them easily recognizable. Sales supervisors serve as the initiative's local sales force. They interact with local pharmacies and collaborate

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

with doctors, hospitals and NGOs to organize health camps where villagers can receive treatment and preventive care. Arogya Parivar focuses on the diseases most prevalent in rural India. Further, products and services are tailored to meet the needs of underserved rural populations with a low disposable income, usually earned on a daily basis. Novartis arogya (2014)

IKURE TECHSOFT

Delivering affordable healthcare to the doorsteps of rural masses, India continues to face enormous challenges. With a population over one billion, rural India comprising of 840 million people are served by only 30 per cent of the country's combined medical force. Out of which, three per cent of India's physicians live in rural areas, and 25 per cent in semi-urban areas. This is disproportionate, and an example of the Pareto Principle – where 20 per cent of the doctors serve 80 per cent of the population.

This is disproportionate, and an example of the Pareto Principle – where 20 per cent of the doctors serve 80 per cent of the population. Moreover, the morbidity rate in people reporting the same, in rural areas increased to 70 per cent in 2011 against 64 per cent in 2004. Rural India is critically flawed with inefficient heath care system. They either remain short of medical personnel or untrained officers. According to NRHM report, out of 22,000 primary healthcare centers, eight per cent do not have a doctor, 39% remain unattended without a lab technician and 17.7% without a pharmacist, and this is when, each primary health center is supposed to have at least one medical practitioner. Based in Kolkata ikure sets up rural health centers across India. with an initial funding of Rs 45 lakh from Intellecap Impact Investment Network and Calcutta Angels; Rs 70 lakh from WEBEL iKure Techsoft has built a network of rural health centers where doctors are available through the week and pharmacists dispense only ac. (http:/www.ikuretechsoft.com)

DRINKING WATER QUALITY IN RURAL INDIA: ISSUES AND APPROACHES

The rural population of India comprises more than 700 million people residing in about 1.42 million habitations spread over 15 diverse ecological regions. It is true that providing drinking water to such a large population is an enormous challenge. Our country is also characterized by non-uniformity in level of awareness, socio-economic development, education, poverty, practices and rituals which add to the complexity of providing water.

The health burden of poor water quality is enormous. It is estimated that around 37.7 million Indians are affected by waterborne diseases annually, 1.5 million children are estimated to die of diarrhoea alone and 73 million working days are lost due to waterborne disease each year. The resulting economic burden is estimated at $600 million a year. The problems of chemical contamination are also prevalent in India with 1,95,813 habitations in the country are affected by poor water quality. The major chemical parameters of concern are fluoride and arsenic. Iron is also emerging as a major problem with many habitations showing excess iron in the water samples. Transforming rural India, (2014)

The provision of clean drinking water has been given priority in the Constitution of India, with Article 47 conferring the duty of providing clean drinking water and improving public health standards to the State. The government has undertaken various programs since independence to provide safe drinking water to the rural masses. Till the 10th plan, an estimated total of Rs.1,105 billion spent on providing

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

safe drinking water. One would argue that the expenditure is huge but it is also true that despite such expenditure lack of safe and secure drinking water continues to be a major hurdle and a national economic burden.

COMMUNITY BASED MAINTENANCE OF WATER SOURCES MAINTENANCE OF WATER SOURCES

Ramakrishna Mission Lokasiksha Parishad (RKMLP) is one of the biggest units of the Ramakrishna Mission Ashram, Narendrapur. It has done remarkable work in the field of maintaining water sources and has successfully demonstrated community based maintenance of 800 hand pumps in Medinipur. To carry out this process, a seven-member 'water committee' with four female and three male members from the beneficiary families were formed for each hand pump. These members were trained in operation and maintenance by the RKMLP. A maintenance chest fund was developed for individual pumps, with each family contributing one rupee per month. The money is collected once or twice a year depending on the paying capacity of the family. An innovative strategy developed is to collect the money during religious ceremonies after the harvest season as people have money during this time of the year. In this way, the water committee was able to collect Rs. 300-500 from the beneficiary families. The members of the committee also organized awareness generation activities relating to safe collection, storage and handling of drinking water simultaneously promoting sanitation and personal hygiene practices. Transforming rural India (2014) & Indian rural water supply (2014)

DUAL WATER SUPPLY AND WASTE WATER TREATMENT

To reduce the burden on fresh water sources, the option of dual water system is being worked out in several parts of the country. The success of this system lies in the fact that filtered purified water is used only for drinking purposes while other source of water may be used for purposes other than drinking. This is also is cost saving measure as resources spent on providing clean water is saved by using alternate sources. Waste water treatment can also be another effective means of reducing the burden on freshwater sources. The treated waste water can be used for purposes other than drinking. One example of effective wastewater treatment is in Mehsana district of Gujarat where wastewater from homes in villages is used for agriculture. The wastewater coming out of homes is collected in a pond which is then auctioned to farmers for use in agriculture.

Magod Dungri village in Valsad district in Gujarat has a population of 4,264. An old well served as a water source, but the water was saline and not potable. In 2006, this village was brought under the Bigri Malwan group water supply scheme of the GWSSB and it started getting safe drinking water. But in-village distribution of water continued to pose difficulty. Under the Swajaldhara programme, the village community decided to develop a system of household connections. The entire community made a 10 per cent contribution towards capital costs and the responsibility of collecting the contribution was taken up by one individual in each habitation. In the process, a 5,000 liter water tank in the village school, electricity connections, a 2,208 meter distribution pipeline, a 318 meter gravity pipeline and 15 stand posts were made. Out of a total expenditure of Rs.5, 20,000, the community contributed Rs.80,000. The foremost priority of the village was to get regular and safe water to meet their drinking water require-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ments. As far as water for other purposes was concerned, this need could easily be met from the village well. For drinking water, the villagers make use of the treated water supplied through the regional water supply scheme. This is accessed from the 15 stand posts constructed in the 15 habitations in the village. Drinking water is received for about 30-45 minutes every day Thus by making use of dual sources of water, the community has ensured that treated water is not wasted and is used only for drinking purposes. Indian rural water supply (2014)

The villagers regularly pay water tariff fixed by the Pani Samiti. The Pani Samiti regularly pays Rs 14 per person as water tariff to the water supply department and if need be the villagers are ready to contribute more. The villagers also contribute Rs.16 per person towards electricity and maintenance charges.

SOLAR HOME SYSTEMS FOR RURAL ELECTRIFICATION

Lack of access to electricity is one of the biggest issues facing the world's poor, with over 1.6 billion left in the dark globally. The vast majorities of these people live in rural areas of developing countries because they are too poor and may be in too remote a location to be reached by the national grid. For their lighting needs they rely on candles, kerosene lanterns, and firewood which results in a daily expense that is expensive in the long run. Furthermore, this type of indoor lighting causes indoor pollution and chronic lung problems. Long-term, solar energy is the most practical and economical way of bringing power to poor and remote communities. Small-scale, distributed solar home systems provide an effective and affordable way to bring light to people without electricity. A basic system consists of a small solar panel, a battery, a charge controller, LED lights, and a universal outlet for charging cell-phones or other small appliances.(See Figure 4) A basic system can be made affordable through microfinance options. Partnering with local banks and/or microfinance organizations to create payment plans can help overcome the large initial investment associated with purchasing a system. Energy savings result from not having to buy candles or kerosene fuel, and can make the monthly payments affordable. When proposing this technology to a new area, it is important to target a community that has expressed a need and desire for solar electricity. Identifying and allying oneself with a respected community leader who is receptive and supportive is a good idea.

THE CLASSIC CASE OF SELCO IN SOLAR ELECTRIFICATION

SELCO's pioneering efforts with microfinance in rural India is a large reason why they have become a world leader in the field. However, their case also brings to light another issue relating to "free riders." Innovative companies willing to be first in the game can be put at a competitive disadvantage when they spend resources on innovation and capacity building. This is due to other companies taking advantage of their earlier efforts, getting a "free-ride." For example, after SELCO spent many years and dollars on developing India's rural financial infrastructure, other companies benefited from it. There were even some banks that, after giving out successful loans for SELCO systems, started selling their own systems for personal social development programs. Broadly speaking this isn't a bad thing, as it results in greater adoption of the technology and increased electrification for the poor. However, it does result in a decreased incentive for individual companies to innovate if their competitors are accruing benefits from their investment. To overcome the free-rider problem, governments and non-profit development

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

institutions should provide funding and incentives for enterprises to innovate. This could be in the form of technical and financial support for businesses entering a not served geographical area. Furthermore, a government or non-profit could provide financing for early-stage systems, which would allow local banks in the private sector to see the technology successfully implemented before they decide to take on the risk of loans. (http:/www.selco-india.com)

Sunkalp Energy

A solar power company Sunkalp Electricity is launching a project called Solar Soldiers to involve people in Rural Electrification in Uttar Pradesh through the innovative use of Solar Power. A number of corporate are stepping up the green ante this day. This is what Sunkalp asks, "No TV. No internet. No AC. In fact, no LIGHT!!! Can you imagine a world without electricity? Not for a minute, an hour– but for 25 years. This Indian village in Uttar Pradesh has lived without power for so long that they can't remember what electricity means. We are here to bring them back from the past." Hence the idea is to rescue a forgotten community from the clutches of darkness. With this mission, it is building a solar mini-grid to power the lives of around 200 villagers without access to electricity. About 93% of the villagers in Gulabganj have already signed up for an electricity connection from the mini-grid. Sunkalp Energy has developed a low cost micro grid tailored to the needs of off-grid villages. Sunkalp Energy is constructing and will operate a pilot project initially in a small village of 25 households and will approximately extend to 4 new village-level micro grid lighting facilities to reach 300 new customers and 1,800 new beneficiaries in Hamirpur districts of Uttar Pradesh, India (http:/www.sunkalp.com).

DRAWBACKS OF RURAL INNOVATION

While innovation helps in attaining cost efficiency, reliability and ease of use, the investment in terms of land, labor, machinery and other fixed assets may be huge. As far as Innovations in electrification

Figure 4. Some Solar Instruments for electrification

Solar Pannels and Euipments for Lighting Using Solar Energy

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and water purification is concerned, it requires huge initial investments. Implementation part is also a major concern when it comes to government policies. Challenges are huge when we talk about the implementation part. How much work is actually done on ground will be a million dollar question. Moreover if private investors are encouraged to invest in these rural innovations sector will inculcate in drawing quickly the return on their investment. This may hamper the main concern of helping the rural people for which the process was started altogether. Moreover less private players would like to put their liquidity into these matters as they may not find the area interesting for their bottom line. Minor drawbacks can be catered to in long term but projects like solar electrification, water purification and rural electrification may also lead to environmental hazards which can be cause of great concern.

CONCLUSION

So after going through various context, cases, contention and issues we can conclude that many innovations are coming up for the agricultural sector but they are not widely known nor have they been systematically monitored and evaluated. Many of the innovative models are still relatively new, but through time and the use of appropriate systems to monitor and evaluate their achievements, we will be able to draw more complete lessons that can help in scaling up and replicating them. This will help us better understand what works and what does not, and under what conditions. What seems to be missing at this point is some repository of innovative models, systems to monitor, and methodologies to evaluate them. In addition, we need to think of incentives to strengthen existing innovative models and also promote further innovation

As said early in the chapter 'Innovation is defined as a process by which varying degrees of measurable value enhancement is planned and achieved, in any commercial activity. This process may be breakthrough or incremental, and it may occur systematically in a company; it may be achieved by introducing new or improved goods or services and/or implementing new or improved operational processes and/or implementing new or improved organizational/ managerial processes in order to improve market share, competitiveness and quality, while reducing costs.' India has one of the largest systems for agricultural research in the world. However this system has focused predominantly on intensification of cereal production under irrigated conditions. There has been criticism that this research system enabled an exploitative agriculture without a proper understanding of the various consequences of every one of the changes introduced into traditional agriculture. So it becomes imperative, based on previous experience of change in Indian agriculture to empower the resource poor smallholder and marginal farmers to be able to negotiate with stakeholders to their development their needs for political, social, economic and technological development. It would be essential that they participate in all decision making. The technologies they need will not therefore be limited to those related to agriculture alone but also to politically, socially and economically aggregate and collectively decide. Those who will generate enable adoption and, if need be, adaptation and innovation, will need to understand how development works along with how technology works and adapt each other for success. The has to be focus on innovation and the rebuilding will be based on social research of the needs of small holder farmers and that includes the study of socio-economics of the new technologies of Agriculture, ICT, Irrigation technologies, Solar

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Electrification that are developed to meet the needs of smallholder farmer. But, more important, it will be important to understand how development and technology, with all its facets and components, work side by side. And within this context, this would need entire communities, especially agricultural, to be included in decision making through participation.

In cases where the total sanitation approach had been used, program managers and local government officials were aware that their main objective was to stop open defecation, and that this required community-wide action, universal toilet use, and hygiene behavior change. Opinion was divided as to how these changes should be effected, but there was little argument about the approach. In this respect, the 'total sanitation' concept is a major step forward, as this level of shared understanding and purpose was sadly lacking in many earlier sanitation programs. It would be also important to redirect research for agriculture so that its purpose is to provide the innovations needed by small holder farmers as a direct product and not as a spillover or trickledown effect. The system has to recognize that a large number of technologies influencing each other and working together and in tandem contribute to agricultural development and all these need to be brought about appropriately. It can also be concluded that no single innovation can be considered the miracle or "silver bullet" solution, and this is despite the various calls over time to come up with grand schemes and search for big solutions. Creation of a forum of large agribusinesses that could be encouraged to leverage their networks in emerging markets and create openness that could be encouraged to leverage their networks in emerging markets and create opportunities for attracting financial institutions that could fund parts of their value chain, like local small traders, processors, farmers, etc. Financing could be linked and become the catalyst for technology improvements and promotion of environmental and social standards along specific value chains.

Based on the current state of healthcare system in rural part of Indian States the scope for Innovation is there. Through Government sponsored schemes, private sector interventions and the recent string of PPP Projects are intervening and trying to build up an infrastructure to make possibilities of inroads for betterment of facilities, it is understood that there is still a long way to go in terms of uplifting of the healthcare sector and reaching the desired health goals. It is very much evident that huge investment will be required in developing upgrading of healthcare infrastructure, in order to improve accessibility and quality of care. The private sector must consider this as business opportunity to establish their presence and expand their operations/ market share in the healthcare delivery market in India either by partnering with the different state governments or pursuing a pure private model. The government at the same time needs to understand the issues faced by private sector currently (working independently or in the existing PPP programs) and take measures to improve the investment climate in the respective states. The states will need to put in place clear policies and guidelines in the healthcare sector which will enable to attract large private investments in the health care industry

In the end it can be concluded that Rural Innovation will envision what is there in store for India as a country to develop as the next super power which will dominate the Subcontinent and create inroads and benchmarks for countries to follow. Under developed countries in Africa and other parts of the world are looking forward towards India to create a magnum opus so that the same model can be followed and replicated in their countries.

KEY TERMS AND DEFINITIONS

ATM (Automated Teller Machines): Machines with the help of which money can be stored by a bank and retrieved by the customer of a bank without any human intervention.

ICT: Information communication technology helps in connecting people with the help of tools like telephone, mobile phones and Internet.

Innovations: Innovation is defined as a process by which varying degrees of measurable value enhancement is planned and achieved, in any commercial activity.

Rural Innovations: Innovations happening in underdeveloped and rural parts of a country.

Sunkalp Energy: A solar power company Sunkalp Electricity is launching a project called Solar Soldiers to involve people in Rural Electrification in Uttar Pradesh through the innovative use of Solar Power.

UID (Unique Identification Project): The government of India's Unique Identification (UID) project has created avenues for this people to become a part of the different projects and plans developed for self-sufficiency, growth and improvement in living standards.

Chapter 55
Low Carbon Energy Innovations Systems in Natural Resource Rich Developing Countries: The Case of Brazil

André Tosi Furtado
University of Campinas, Brazil

ABSTRACT

The transition to low carbon economy requires deep changes in the energy systems of the great majority of developing countries. However, only a small group of these countries is engaging significant efforts to develop renewable energies. The success in the diffusion of renewable energy technologies requires dynamic systems of innovation. In this chapter we analyze the recent evolution Brazilian sugarcane innovation system that was pioneering in the development and diffusion of bioethanol. This system is increasingly challenged by the acceleration of the technological regime, which is provoked by the energy crisis and the transition to the low carbon economy. The Brazilian innovation system has different capacities to cope with this challenge. In this chapter we differentiate the agriculture subsystem, which function in a STI (Science, Technology, and Innovation) mode from the industrial subsystem, which operates in a DIU (Doing, Using, and Interacting) mode. The agricultural subsystem has demonstrated a better ability to cope with the technological challenges of the new biotech research methodologies while the capital goods industry has much less propensity to deal with the second generation technologies for bioethanol. We describe also the present ethanol supply crises and its probable causes.

INTRODUCTION

The transition to Low Carbon Economies entails significant challenges for most of the developing countries. Their future seems to be related to fossil fuels by two main reasons. At one side their energy demand is increasing rapidly, in part because important sectors of their population are excluded from modern energy welfare benefits, and at the other side most of their energy supply lend on fossil fuels[1].

As it is unfair to suppose that energy demand in developing countries could be contained, even if energy efficiency has an important contribution to give[2]. Thus we should expect that fossil fuel consumption will continue to increase if nothing happens at the side of renewable sources of energy. These dynamics makes the non Annex I countries responsible also by most of the increase in the world CO2 emissions since 1990 (IEA, 2012).

In present days most of the renewable used by developing countries are related to biomass. Biomass accounts for 10% of the global primary energy supply, mostly (6%) related to traditional uses of biomass like cooking and heating in the rural areas of developing countries. The share of traditional biomass is expected to decline since urbanization increases and modern energy carriers penetrate in poor households. Otherwise modern renewable energies technologies are projected to increase their share in future energy system. The main new sources are modern biomass, wind, photovoltaic, thermal solar, geothermal, and hydropower. Their share in the world energy supply was 10% in 2012 (REN 21, 2014).

Modern renewable have progressed impressively in developed countries during the recent years due to their environmental policies that determined quantitative targets for renewables, and also because of their innovation and industrial policies related to these technologies. In 2013, European Union and United States had 58.6% of the world renewable electric power generation capacity without hydro. However we notice also that a group of emerging economies is well positioned in the promotion of these new sources of energy. BRICS countries have a 28.9% share that is rapidly increasing mainly due to China. This country alone has the world largest wind power capacity (28.6%) in 2013. For solar thermal heating the Chinese hegemony is impressive with 64% of the world capacity. In hydroelectricity China also is first placed with 26% of the generation capacity, followed by Brazil (8.6%). More than being a world leader in power generation capacity, China also is at the forefront position for equipment supply. In Photovoltaic and Wind energy, Chinese companies are among the world leaders (REN 21, 2014).

Biomass is a very promising primary energy source for many developing countries. It is already an important energy source mainly due to traditional Biomass. In the future, modern biomass will increase its presence in the energy matrix (Goldemberg & Coelho, 2004). The leadership in modern biomass always belonged to developed countries. However, Brazil had been longtime the world leader for liquid biofuels. Nevertheless, more recently the Brazilian sugarcane ethanol lagged behind the USA corn ethanol. In 2013, US and Brazil accounted for 57.6% and 29.4% of the world bioethanol production. In the other kinds of biomass, developed countries still the world leaders like in biomass power generation, biogas and wood pellets, where European Union and United States are the world leaders (Ren 21, 2014).

In this paper, we would like to consider the effective potentials of a resource rich developing country to become a world leader in modern biomass supply and technology. Our argument is that, alongside favorable resources endowment, national innovation system requires continuous learning in order to advance in the absorption and the development of new technologies.

BIOMASS IN THE BRAZILIAN ECONOMY

Brazilian economy has a very dynamic biomass production system. Biomass commercial production, not only connected with energy, and related industries had an impressive evolution in the present century. The production of grains rose from 100 million tons in 2000/2001 harvest to 198 million tons in 2014/2015, most of it soya and corn. Sugarcane expanded impressively from 254 to 642 million tons in the same period (CONAB, 2015). Other biomass activities are also expanding quickly. Cellulosic Pulp

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

production has almost doubled in more than a decade from 2000 until 2013 from 7.4 to 15.1 million tons. These figures illustrate the productive dynamism of the Brazilian agro-industrial system. They result from land expansion but also of a deep increase in the land productivity, which is connected to an important process of technological learning. Crop varieties had to be adapted to the Brazilian soil and climate conditions, which varies impressively according to the region, state or even locally. At the other side Brazilian tropical climate conditions like the very high level of sun exposure or the lack of a cold winter season gave the opportunity to develop new agriculture technologies.

The dynamism of the Brazilian agriculture is also fostering renewables technologies in the National Energy Matrix. Renewable energy had, in 2012, 42.3% of the country energy supply (EPE, 2014), which is much higher than world (13.5%) and OECD (9%) averages (IEA, 2014). This involvement is firstly related to biomass (27.5%), but unlike many others developing countries the greatest share (23.4%) belongs to modern biomass, which is deeply integrated in the agro-industrial production system. Brazil is the third in the world ranking of electricity biomass generation after United States and Germany, and almost 7.6% of all its domestic electricity supply is related to biomass conversion[3], where sugarcane has a dominant role.

The vitality of the Brazilian agriculture can be attributed to the junction of several factors. At one side there is a large potential of available land, even without the appropriation of forest and savannas ecosystems. There is close to 100 million hectares of degraded pasture lands that can be used by the agriculture. At the other side, Brazil has an innovation system formed by a set of public and private actors cooperating to develop new technologies or adapt the existing technologies to new ecosystems. The leading actor of the Brazilian agriculture – Embrapa - is a federal organization in charge of the main research efforts in this sector, but there are also several others state and private organization working for the development and adoption of new technologies.

THE BRAZILIAN SUGARCANE INNOVATION SYSTEM

Sugarcane is a very active segment of the modern biomass agro-industry, which dynamism lends on a long-lasting technological learning process. The dynamic trajectory of the sugarcane agro-industry in Brazil started when this culture was progressively transferred from the Northeast region to the state of São Paulo. In the Northeast, sugarcane created a very conservative sociotechnical system based mainly in slavery, which was preserved with small changes after the end of this social regime. This sociotechnical system had a limited ability to introduce technological innovation and to produce local development. Because of its restricted food supply capacity, it became a serious constraint for the development the urbanization and the industrialization of this region (Furtado, 1959).

Things started to change when this culture was introduced in the State of São Paulo, where capitalist social relations were better established. In this region sugarcane agroindustry emerged more dynamically, based in modern production techniques, surrounded by an industrial complex of equipment producers and by significant research institutions as the Agronomic Institute of Campinas (IAC) and the Agronomic School of Piracicaba (ESALQ).

The expansion of the sugarcane production in Brazil was supported by the state of São Paulo. The sectoral innovation system for sugarcane production tended to expand more dynamically in the richest region of the country. And the dynamism of the São Paulo region was based in the conjunction of several factors from which one can emphasize the abundant good quality natural resources, better transport and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy infrastructure, nearness to the country's biggest market and, above this all, the insertion into a regional system of innovation which congregate producers, capital goods manufacturers, research institutes and universities. The region experimented gradual increases in its sugarcane productivity based on the varieties developed in the same region.

For this reason, the Brazilian sugarcane innovation system is essentially from São Paulo. This region supports and sustains important institutions that are behind the dynamism of this system. The originality of the sugarcane innovation system in São Paulo is the supremacy of private research over the public one, although it was not always like this, contrary to the rest of the agro industry.

Brazilian agricultural research is predominantly financed by the public sector. A study conducted by Embrapa (Beintema, N. M.; Avila A. F. D.; Pardey, P. G. 2001) estimated that Federal research institutions (mostly Embrapa) as well as the state ones and universities were responsible for 89% of the Brazilian research efforts on agriculture and cattle-raising. This does not seem to be the situation of the sugarcane sector. The most important sugarcane research center, the Centro de Tecnologia Canavieira - CTC, is a private institution. Federal Government has a limited contribution in this area, since the extinction of the IAA (Institute of Sugar and Ethanol), in the beginning of the Collor Government in the 90's.

The leading players of the São Paulo innovation system do research mainly in agriculture developing new sugar cane varieties. The increase of sugar cane yields measured by tons by hectare or the sugar content of the sugarcane were obtained developing new varieties more adapted to Brazilian weather and soil conditions, and also more resistant to plant diseases. This improvement allowed to reduce the ethanol cost, and to increase its production. However, important advances were also obtained in industrial plants by improving sugar juice extraction, vinasse reuse for land fertilization, improvements in the fermentation process and in the energy co-generation of bagasse. Alongside with research centers, the federal and São Paulo research funding organizations are also important to fund innovation and organize sugarcane and bioethanol technological programs.

The innovation activities were mainly directed towards improving and perfecting the large sugar mills productive system, which was already established since mid of the last century. There wasn't any radical innovation that could change drastically the productive process of sugar and ethanol. However, the productivity gains were expressive and placed Brazil at the first level in terms of production costs, while the use of bagasse reduced dramatically the fossil fuels and external electricity needs in the industrial process. Thus mainly based in an incremental technological trajectory, Brazil sugarcane ethanol became competitive in terms of costs, and also in terms of environmental sustainability, because of its low green house gas emissions (Macedo & Nogueira, 2004; EPA, 2010; Wang et al. 2012).

As it was analyzed in a previous article (Furtado et al., 2011) and by several others authors (Dunham et al. 2011; Andersen, 2015) the Brazilian sugarcane innovation system have undergone several important steps and transformations since its constitution. Even though the production of biofuels was already in place almost since the 1930, the system was technologically laggard until the Proalcohol program was launched in 1975. Since that, the sugarcane production started to grow regularly. The program created a new market[4] for sugarcane – biofuels – and at the same time directed credit facilities to fund new mills and land expansion. This favorable environment changed deeply in the middle of the 80's when oil prices dropped and the Brazilian economy went through a deep crisis. Ethanol loosed its attractiveness, while government abandoned progressively its policy to promote biofuels supply and demand. Because of this political dismiss, local market ethanol scarcity happened in the beginning of the 90's and resulted in the collapse of the new ethanol cars demand. However, the deepest change came in 1990 when the main public organization in charge of the sector, the Sugar and Alcohol Institute– IAA, was shut down.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The main public research program – Planalsucar - in charge of the modernization of the industry was also discarded.

The bioethanol did not collapse because the sectoral innovation system was able to create new opportunities. Hydrated ethanol, used by pure ethanol cars, was progressively substituted by anhydrous ethanol consumed melted with gasoline. Sugarcane production was diverted to sugar external market that increased strongly since the 90's. Almost at the same time private and public actors replaced the federal IAA system in its promoting role of the sugarcane agro-industry. The Planalsucar plant breeding program was replaced by Ridesa, a network of Universities that continued the previous public program with private funds from sugar mills. At the other side CTC private breeding program continued its development, and the Campinas Agronomic Institute breeding program recovered after a longstanding stagnation. The engagement of the State of São Paulo Research Agency – FAPESP - funding sugar cane basic research expanded. All this aspects demonstrated the great resilience of the Brazilian sugarcane innovation system that was able to adjust to new circumstances and finance with private funds its own research.

In the years 2000, when the oil prices peaked again, making more attractive ethanol to car owners, the sugarcane innovation system and also the car industry were able to respond quickly to the new reality. The automotive industry introduced the flex fuel cars, solving the problem of the missing demand policy for pure ethanol, since the end of the Proalcohol program. This technology, by reducing the risk of the consumers, allowed the pure ethanol car market to increase again. The sugarcane production was able to expand quickly and the investments in sugar and ethanol mills started to grow again. These favorable conditions created the circumstances for a new cycle of expansion of ethanol and sugarcane (Figure 1).

Figure 1. Brazil Sugarcane, Sugar and Ethanol Production

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Thus, the technological trajectory of the Brazilian sugarcane innovation system rests mostly on incremental innovations, which means the improvement and adaptation of existing technologies inside a dominant technological system. Several authors (Dahlman & Westphal, 1982; Lall, 1982; Katz, 1987) studied this kind of technological change in developing countries, which initiates by a cumulative learning process on the implementation and use of imported technologies. Firms and others research institutions of the innovation system have to devote increasing technological efforts to improve the existing technologies and also to create the new ones. However, the possibility to maintain the technological capabilities created in the local learning process is allied to the relative stability of a dominant design or of a certain technological paradigm (Dosi, 1982). If the technological trajectory switches significantly, the capabilities connected with the prior technological system can easily be lost. According to this assertion, the fastening of the technological frontier can impair local capabilities and also make more difficult to follow up the technological frontier.

Some authors in development economics diverge from this view about the real chances of latecomers to catching up advanced countries (Soete, 1985; Perez & Soete, 1988). According to them there is a great advantage to be a latecomer in times of important technological ruptures. They recognize that technological development has a cumulative nature, but asserts that when radical technological changes happens, newcomers are less engaged in large investments in the previous dominant technological paradigm than the leading countries. Because they can commit larger amount of resources in new dynamic technologies, technological ruptures can be windows of opportunity for latecomers. Other factors can contribute to these to these windows of opportunity as demand changes and policy-based regulatory changes (Lee & Malerba, 2013). In our opinion this approach is useful to explain how in XIX Century happened the catching up of Great Britain by Germany and United States, and in XX Century how North America and Europe were catch up by Japan and after by South Korea. China more recently seems to be reproducing this same evolution.

However this kind of evolution poorly concerns much of the technological learning cases that happens in developing countries. It often occurs in mature sectors and are of an incremental and adaptive nature. In this context, as we will see as follows, changes in the selection mechanisms can jeopardize local learning process. In the present context, energy crisis and the challenges of a new low carbon economy are fastening the international technological regime and improving the technological efforts of developed countries and of some emerging countries in renewable energies. In this sense, the actors of the Brazilian sugarcane sectoral innovation system are trying to cope with these new challenges but there seem not always be prepared to it.

TECHNOLOGICAL DISCONTINUITIES IN BIOFUELS

The energy prices upswing in the present century together with changes of the energy policy in several developed and developing countries has hastened technological change in new renewable energies. The very fast evolution in wind power and photovoltaic power generation technologies has impressively dropped the production costs in many countries, and they are becoming more and more competitive with the dominant fossil fuels technologies. Liquids biofuels have a similar challenge. Important technological discontinuities need to be introduced to make biofuel competitive with fossil fuels and to improve its supply at the size required by liquid fuel markets.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The analysis about energy transition agrees that mature renewables energy technologies, called first generation, will not be enough to face this challenge. The first generation technologies applies fermentation to convert sugarcane juice or cornstarch into ethanol[5]. These technologies are almost mature and can be considered as the main factors of recent expansion of supply. However, these technologies are bounded by raw materials supply, and also by the fact that these cultures also compete for land against food and others industrial crops.

To overcome the limits of first generation technologies, disruptive technologies called second or third generation technologies need to be developed and diffused (Johnstone et al., 2008). In the case of liquid biofuels, the most representative second generation biofuels technologies are enzymatic hydrolysis and biorefineries. In both cases, a greater diversity of raw material like biomass cellulose and agriculture residues are used to produce liquid biofuels.

This promise has increased the technological efforts in second generation biofuels, especially because developed countries are feeling more deeply the constrain of raw material supply in the first generation biofuels. Second generation can process others biomass raw materials than food crops like cellulose rich crops, or treat the part of the biomass food crops that is not directed towards food consumption like straw and bagasse, commonly called agricultural residues.

Cellulose rich biomass requires an additional conversion process into biofuels. Several possible technological routes can allow this conversion. One of the most promising technological process is hydrolysis, which can convert cellulose and hemicellulose into glucose. The acid trajectory is used since more than a century by chemical and food industry, but is not considered economically feasible because of its worse process conditions and a great quantity of residues. Meanwhile the enzymatic hydrolysis is a much more promising route. The developed countries like United States and Europe Union are investing large amounts of resources in this emerging technology (Pereira, Bomtempo & Chaves, 2015).

At the other side, sugarcane plant breeding is also submitted to a similar technological evolution. The conventional methodologies used in sugarcane breeding are long lasting. A new sugarcane variety takes almost 12 years to be developed. New biotechnologies can shorten this period of time and be more precise in the development of more performing new plant varieties. In this sense, the use of gene markers can help to identify specific characters in new plants. New plants can also be genetically engineered. However, this kind of technology requires long legal tests process, which finally can last more time than conventional breeding methodologies.

The transition to second generation technologies is changing the technological regime of liquid biofuels agro-industry. The hastening of the international technological frontier makes more difficult for developing countries, which accumulated local technological capabilities based on incremental innovations, to follow-up new technological developments (Katz, 1987). Thus, this quickening of the technological regime increasingly challenges the Brazilian sugarcane system of innovation, which was very successful in the first generation technologies. The Brazilian innovation system has different capabilities to cope with this challenge.

Innovation system are defined as a set of technologies, actors of different natures as firms, universities, research centers and government, networks and institutions that are engaged in the generation, adoption and diffusion of new technologies (Lundvall et al., 2009). These innovation systems especially in developing countries can have missing links, weak institutions or missing organizations (Chaminade et al., 2009). Our main assumption in this chapter is that shorter the network of actors, greater are difficulties to follow-up the technological frontier.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

To understand the evolution of the Brazilian sugarcane system of innovation we separate the agriculture subsystem from the industrial subsystem. In the agriculture subsystem research efforts are higher and the linkages with basic research done in universities are stronger while in the industry side the R&D efforts and the connection with academic research are weaker. The agriculture subsystem functions in a STI (science, technology and innovation) mode while the industrial subsystem, which operates in a DIU (doing, using and interacting) mode (Jensen et al., 2007; Varrichio, 2012). In this sense, the agricultural subsystem demonstrated a better ability to cope with the technological challenges of the new biotech research methodologies while the capital goods industry has weaker propensity to deal with the second generation industrial technologies for bioethanol.

BRAZILIAN SECTORAL INNOVATION SYSTEM RESPONSE

The years 2000 have brought new dynamics to the Brazilian innovation systems. At one side, there was an increasing concern from Federal and State Governments about the sugarcane and renewable bioethanol relevance for the national economic wealth. Federal Government decided to create the Centre of Bioethanol Technologies (CTBE) at the side of UNICAMP in 2009 and enlarged dramatically the funding channels to finance the productive expansion and the innovation in the sugarcane agro-industry.

BNDES, the Brazilian National Development Bank, financed new mills, requiring more energy efficient co-generation facilities in these projects[6]. At side FINEP (Federal Innovation Agency) launched in 2006 the economic subvention program, a special non reimbursable account to finance innovation in firms. In 2007 and 2008 14 firms received R$ 65 million[7] to develop new technologies, mostly second generation industrial technologies, biotechnologies applied to sugar cane, and new crop technologies.

The federal government funding policy get a step forwards recently in 2011 when the PAISS program was launched. The BNDES in charge of funding new plant facilities, and FINEP financing innovation and R&D had their instruments put together in this program, allowing government to support radical innovations at a deeper level. Before, new technologies were only financed at the federal level until the laboratory stage but faced great difficulties to reach the preindustrial or industrial stage. With the new program, large firms have engaged innovation efforts towards the industrial plants in second generation technologies, making more feasible the whole innovation process. In this sense Federal Government innovation policy has learned from the past failures, and is trying to improve its efficacy.

The change in the direction of the Brazilian biofuels innovation policy is also influenced by the USA and European experience at the same level. The financial amounts, the variety of funding instruments and the mechanism of coordination are larger and much more sophisticated in the similar American and European programs than in Brazilian case (Nyko et al., 2010). Trying to respond to this new technological challenge, the two federal agencies assigned R$ 1,57 billion to the PAISS program. The program is directed to 3 areas: 1) second generation biofuels; 2) new sugar cane products; 3) gasification. In the first call, 25 firms had their business plan approved mostly in the first and second areas (Table 1).

The State of São Paulo is also a central actor of the sugarcane innovation system. Since the 1990, FAPESP (São Paulo Research Agency) has an increasing role funding basic research mostly in biotechnologies related to this cultivation. The Sugarcane Genome Project started in 1998. The advances made by this project were fundamental for the surge of a biotech firm like Alellix. After 2000 the agency engaged in the funding of industrial technologies as the Dedini HDR project of fast acid hydrolysis. FAPESP made several partnerships with important national firms like Braskem, ETH-Oderbrecht, Oxiteno and

Dedini for funding academic research. The more recent initiative was the FAPESP and ETH partnership, which approved in 2011, 11 research project amounting R$ 20 million.

There is no doubt that at the side of innovative funding, new instruments were created to face the industry technological challenges. The problems came from the main actors of the industry itself and the lack of a demand policy for biofuels. To better understand this evolution, the sugarcane innovation system can be split in 2 main subsystems: The agriculture and the industrial subsystem. Agriculture subsystem concerns technology and knowledge related to sugarcane plantation and harvesting, while industrial subsystem is associated to sugarcane processing, and to sugar, ethanol and electricity production.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The agronomic research is much stronger in the agriculture subsystem. There are already four sugarcane plant breeding programs (Ridesa, CTC, IAC, Alellix/Canavialis) that have in a way or another strong contact with academic research. Thus, the sugarcane agriculture subsystem can be labeled as a Science, Technology and Innovation system by the terms of Jensen et al. (2007), in which there is a strong linkage between academic and firm research. The discontinuity introduced by the genetic engineering technologies could be assimilated without great harm, in part due to the Fapesp Genoma project.

The main problem came with the financial crisis of 2008, when Votorantin Group decided to sell Canavialis and Alellix to Monsanto. The acquisition of the two start-ups by the American multinational has broken the links between the academic research and the private sector in an important Brazilian initiative especially for genetic engineering.

The strong tendency of privatization in the technological research has also provoked relational problems between Brazilian private and public research. CTC, which is a private R&D company, roughly restrained the access of its agronomic station for seedlings hybridization at Camamu in the State of Bahia to IAC program. The Agronomic institute of São Paulo had to create its own hybridization station near CTC to maintain its own genetic breeding activities.

The industrial research is facing a similar technological discontinuity. The transition from 1st to 2nd generation means an important rupture with the previous technological base. However, the capital goods industry is the weakest actor of the national system of innovation. Even if Brazil is almost self-sufficient in capital goods for first generation bioethanol technologies, a study in 10 representative firms of these industries oriented to sugarcane industry revealed very limited technological efforts, especially in R&D (Varrichio, 2012). While 7 out 10 of this representative sample were large firms with more than 500 employees, only 2 had R&D activities. There innovation were mostly of an incremental nature and resulted from their close interaction with sugarcane mills. In the terms of Varrichio (2012), the maturity of 1st generation technologies almost of public nature makes the adaptive kind of innovation much more based on tacit knowledge. Thus, the industrial innovation subsystem is based in Doing, Using and Interacting mode of learning (Jensen et al., 2007).

In this sense while having a great mastery of the 1st generation technologies, the local capital goods industry seems not to be prepared to face the 2nd generation challenge. The main reason is that the new knowledge related to second generation comes from biotech and chemical industry, while first generation is a traditional agriculture capital good industry. The only capital goods firm that was making significant technological efforts in this new area was Dedini. However the company for reasons related to the financial crisis interrupted its Acid Hydrolysis HDR semi-industrial project. This project in spite of having technical interest was outdated because of the dominant bet of the industry is in enzymatic hydrolysis technology (Silva, 2013).

The way that the Brazilian industry is facing the scientific and technological challenge is by the entrance of new actors. Few local firms were engaged in the 2011 PAISS public offer (Table 1). In this program only Petrobras and CTC are committed with significant technological efforts of the 2nd generation biofuels and green chemistry. At the other side a great number are foreign owned firms like Abengoa, Amyris, Bunge, Dow, Dupont, Mascoma, Novozymes, Solazyme, had their own project approved in the program. Dedini, the capital goods national leader, couldn't get inside in spite of its association with Novozymes.

The loose of national control over the second generation technologies can be perceived in new biofuels industrial plants. These industrial projects are owned by local companies, but these firms have weak control over the main technologies. There are 2 important second generation industrial projects that have

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

already started their activities in Brazil, which are using enzymatic hydrolysis to transform sugarcane bagasse and straw into bioethanol.

The first case is Granbio, which is a private national group without industrial tradition that created a technology driven bioethanol company. This company launched in 2014/09 the first Brazilian enzymatic hydrolysis industrial plant at San Matheus, Alagoas. In spite of important efforts done in the development of new sugarcane cellulose oriented varieties and yeast for the conversion of the pentose into glucose, all the technology concerning the industrial process from pretreatment, hydrolysis until fermentation were transferred from an Italian company named Beta Renewables. The industrial capital goods were purchased from Biochemtex, and Novozymes has an exclusive supply contract of the enzymes. The yeast technology is licenced from DSM (Corrêa, 2014).

Cosan, the Brazilian largest sugar and ethanol Company, has merged with Shell do Brasil establishing a new company called Raizen. Raizen wined the last subvention call of 2010 to build a flexible 2nd generation industrial plant and started producing 40 million litres of ethanol per year 2014/11. Iogen, a Canadian Company, licensed to Raizen all the process technology from pretreatment to fermentation. Novozymes has also an exclusive supplier contract for the enzymes (Corrêa, 2014).

In this two cases, while the companies are totally or partially national owned, the control of the most important process technologies like pretreatment, hydrolysis and fermentation are completely controlled by new biotech foreign companies. The advances of the national companies happens in peripheral or complementary technologies like new sugar cane varieties or yeast.

The only case of a greater control of national technology is CTC, the private research organization located in Piracicaba. CTC has already a patented hydrolysis process and is running a 1,000 liters by day pilot plant. However, in spite of being sponsored by PAISS program the industrial plant has no fixed date to be launched.

Thus, it is clear the increasing difficulty of the Brazilian national industrials firms to cope alone with the technological discontinuity of the 2nd generation biofuels. Even in the case of strategic alliances, the level of technology transfer of core technologies is limited. This evolution is happening in spite of the federal government efforts to create appropriate funding and credit conditions for the Brazilian firms and new research organizations like CTBE (Centre of Bioethanol Technologies).

The presence of foreign firms in the control of sugar and ethanol mills increased dramatically. In 2010, foreign firms controlled 28% of the Ribeirão Preto region in the State of São Paulo and 23% of the Unica mills (Folha de São Paulo, 03/11/2010). Informal estimate calculate that in 2013 this share has increased until 40%.

WHY THE BRAZILIAN SUGAR CANE PRODUCTION IS LAGGING?

The technological evolution does not completely explains why the Brazilian sugarcane and particularly bioethanol production is lagging behind. These elements are connected to the business cycle that happened in sugarcane agroindustry during the last decade. In the beginning of the decade, there was a widespread expectation that Brazilian sugarcane production could increase continuously several times (CTBE, 2009). Effectively, the production more than double in a decade, rising from 254 million tons in 2000/2001 to 624 million tons in 2010/2011. However, thereafter the sugar cane production oscillated stabilizing in 650 millions in the last harvest (Table 2). Brazil lost its first place as a bioethanol producer

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to United States. Only after seven years of crisis Brazilian ethanol production is increasing reaching the score 29 billion liters in 2015/2016 harvest.

Several factors can explain the slower evolution of the sugarcane agro industry since the 2008 crisis. At the first level, the Government has abandoned an effective demand policy since the end of Proalcohol at the beginning of the 90's. During the program, IAA set ethanol prices in an advantageous parity with gasoline and guarantee the purchase of a predefined ethanol volume, like in the Feed-in tariff system, which was used by several countries to promote their renewable energies. However since the 90`s liberal reforms, the sugarcane industry had to face a competitive environment with no guarantee of fixed prices. This lack of demand policy was one of the main reason for the crisis because during a certain period of time, before and after the financial crisis of 2008, ethanol prices dropped dramatically in the internal market. The mills, which largely run into debt for expanding their activities in the previous period, get in red and had to cut their investment in the agriculture treatment. The result was a drop of the sugarcane land productivity.

The second challenge, also related to a lack of an ethanol demand policy, is the Federal Government control of gasoline prices. Because of the widespread of flexfuel cars, ethanol price need to be competitive with gasoline prices. Given that Government determined the gasoline price under the general prices index, especially since 2010, the ethanol prices has gown down in real terms. Meanwhile sugarcane production cost increased substantially eroding the profitability of the industry.

This lack of demand policy confronted bioethanol with a third challenge, which is the competition with sugar market for the use of sugarcane. A large portion of the mills in Brazil produces simultaneously ethanol and sugar. When ethanol prices dropped in the internal market the sugar prices raised at the international level. Thus the share of sugarcane processed for sugar production increased and the sugar production did not declined as much as ethanol (see Table 2).

At the fourth level, the expansion of the sugarcane production motivated deep changes in the geographic distribution of this crop. Until the middle of the last decade, sugarcane was restricted to regions with high soil fertility and good weathers conditions, mainly the central and the Northern regions of the State of São Paulo. Since then sugarcane culture expanded to western areas of this State and to outside in the Middle West States of Brazil (Goiás, Mato Grosso do Sul, Minas Gerais) where the weather and the soils conditions are very different from the previous regions. These new expansion areas are mostly located in the Cerrado region, which is a certain kind of savanna that occupies the central part of Brazil. The adaptation of São Paulo sugarcane varieties to Cerrado's weather and soil conditions do not seem to be an easy task. This requires important efforts of the sugarcane breeding programs. The largest Brazilian programs are attending to this challenge by displacing their agronomic research activities to central part of the country. The results are beginning to emerge. CTC has launched 3 new sugarcane varieties adapted to Cerrado's conditions.

The other challenge came from harvest mechanization. The use of mechanical harvesting in place of the hand cut traditional method is mainly the result of the evolution of São Paulo's environmental legislation that obliged sugarcane growers to avoid sugarcane burning, which is a necessary step before hand cut harvesting. The mechanization became inevitable and disseminated very fast but it brought several problems like soil compression and the lack of qualified personnel to operate the harvest machines. Sugarcane varieties need also to be adapted to mechanical harvesting because machines can more easily cut erected plants. Sugarcane culture is incurring deep changes in its main work methodologies and in the natural environment where it is cultivated. The impact of these changes was translated in reduced productivity yields.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another element contributing to the drop of crop yields was the more adverse climate conditions. These changes can be attributed in part to global climate change. The future climate scenarios point out that São Paulo weather conditions will be closer to the today's Cerrado conditions.

FINAL COMMENTS

The transition to a low carbon economy is a great challenge for the great majority of the developing countries. Most of their energy matrix is based in non renewable energy sources and their internal energy demand is increasing very quickly. Only a small group of the leading developing countries is making significant efforts to master and innovate in renewable sources of energy. China and at a lesser length India have great relevance in the wind and photovoltaic energies, but Brazil has a longstanding position in biomass, especially in bioethanol. This leadership is related to the strong technological dynamism of the Brazilian agro-industrial productive system. Renewables sources of energy, and specially biomass, have a strong share of the Brazilian energy matrix.

Based on favorable natural resources endowments alongside with long term innovation policies the Brazilian sugarcane innovation system bring about a longstanding learning process in bioethanol that gave an important leadership to Brazil in the 1st generation bioethanol. However the Brazilian leading position in bioethanol is challenged by the speeding-up of the technological frontier motivated by the transition from 1st generation to 2nd generation biofuels technologies, and also from traditional breeding technologies to modern biotechnologies. The Brazilian sugarcane innovation system is losing its coherence and its leadership.

The difficulty seems higher in the industry subsystem of innovation, which is oriented towards incremental innovation and is based in doing and using kind of learning. In this subsystem the Brazilian capital goods industry are little alike to follow-up fast changes in the technological base. The only local industrial firms that are intending to move behind like Oderbrecht, Braskem, Raizen and Petrobras belongs to chemical and oil industry and are acquiring hydrolysis technology from foreign sources. At the other side foreign companies infiltrated deeply the Brazilian innovation system. This entrance of external influences cannot only be considered negative for Brazil because it's allowing the national system to cope with modern technologies, nevertheless it reveals clearly the increasing difficulties of the traditional Brazilian capital goods firms to become players in this new innovative environment.

In the agriculture subsystem the situation seems more favorable. The connection between industry, agronomic research centers and universities is much more intense. Several public and private initiatives are intending to introduce new biotech technologies in the sugarcane breeding programs. However, the transfer of Alellix and Canavialis to Monsanto control has also weakened the cohesion of this subsystem.

Thus the main assumption that shorter the network of actors, greater are difficulties to follow-up the technological frontier was confirmed in the two different technological subsystems. In the agricultural subsystem the larger network of innovation, including research institution, makes it more adaptable to the technological transition to the biotechnology, while in the industrial subsystem limited capabilities and short network restrained the ability of capital good industry to attend to the challenge of second generation technologies.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The problems of the Brazilian innovation system are not limited to the loose of national control. The stabilization of the ethanol production in the last years reveals a structural fragility of the energy policy that was unable to create appropriate conditions for a regular expansion of the supply. The increase of the production requires the displacement of the sugarcane culture to new area, which are creating new technological challenges that needs also to be faced.

ENDNOTES

1. In 2012, fossil fuels satisfied 80% of the total energy needs of non OECD countries, while renewables responded for 16.3% (IEA, 2014).
2. Even in its 450 Scenario, IEA estimates that non OECD energy demand will increase 7.4 billons toe in 2011 to 9.6 in 2035 (IE, 2013).
3. The biopower capacity in United States was 15.8 Gw that produced 60 TWh in 2013, Germany had an 8.6 GW capacity with an 48 TWh electricity supply while Brazil had 11.4 GW capacity that generated 46.4 TWh. (Ren 21, 2014).
4. The market wasn't completely new because ethanol was mixed to gasoline in small proportion (E05) since the 1930's. However Proalcohol program established a E20 mixture and afterwards created the pure ethanol market.
5. Cornstarch need previously to be converted into glucose before being fermented.
6. Total BNDES disbursements to sugarcane industry amounted 42.8 billions reals (2011 values) between 2000 and 2011 (Milanez e Miko, 2012).
7. The exchange rate is approximately 2 reals = 1 US$.

Chapter 56
The Collective Aestheticization of Farming as Participatory Civic Engagement

Cala Coats
Stephen F. Austin State University, USA

ABSTRACT

This chapter is a case study that traces the life of a young artist farmer who developed a community-based educational farm. The case study illuminates networked connections between small-scale farming, a revitalized interest in handmade production, and a burgeoning desire for a living ethics rooted in direct engagements. This chapter reveals the breadth of the handmade revolution, tracing a singular example to investigate the desire to become a small-scale farmer; the network of apprenticing makers, farmers, and artists; the necessary participatory aestheticization of the farm as a marketing strategy and mode of cultural consumption; and the ethical complexity of sustaining the life of a young farmer in the current organic and locally-grown marketplace.

I drove up the path to Amanda's new house. Typically, there were volunteers, friends, or the other farm staff there. Today, she was home alone. I went into the kitchen, and she was warming butternut squash soup and cornbread that she made the day before. We took our bowls outside and sat on a park bench in the lawn. We talked about what was happening in our lives, and she explained how different she felt now that she owned her own home.

She told me she needed to move some greenhouses that had been donated from a church nearby, so I offered to help. We drove to a field, where five large greenhouse frames stood. They were composed of rows of steel beam arches fixed into pegs in the ground. I had never been in a greenhouse, much less a constructed one. Amanda needed help dismantling two of them, and her farm apprentice would be out soon. My job was to remove a series of rusted bolts from a bar that ran down the center and connected all of the arched poles. It was relatively dangerous. I had to stand atop a ten-foot ladder and repeatedly use my left hand to hold a nut in place, while unscrewing a rusted bolt from the bar with my right hand.

Up to that point, I had developed a relationship with Amanda through her role as a research participant in the work that led to this paper. Over the year that we had been working together, I had joined her CSA and my son had attended her Young Farmers classes. Our friendship always felt mediated by her as research participant or me as researcher, customer or client. The research seemed to structure the relationship, but the work on the greenhouses—outside in a field, as a friend—that was different. It was how I had wanted to be involved. I think I wanted her to see that I was not some bullshit academic, buried in books and theory.

Construction and manual labor were common weekend activities for my family when I was growing up. We often came together to help whomever was moving or improving their house. Work was compensated with chicken and beer for the adults, and the kids would help if they were old enough. I had not lived near my family for over a decade and had forgotten about those experiences until I started this research on DIY practices and artists' homes. This day with Amanda reminded me how much I learned through those experiences with my family.

I got all the bolts out, and the next step was dismantling the whole thing. I was there for four hours. It was a big task. I felt strong and proud. I had almost passed on the chance to help her that day because I felt overwhelmed with the stress of work, school, and family. All of that swirling in my mind from the morning had stopped. This felt like doing something that mattered.

INTRODUCTION

Amanda developed a working and educational farm in 2010 called, Cardo's Farm Project (CFP). My work with her was one of a group of case studies that focused on the homes of artists and makers to consider how their current art practice was shaped, in part, by histories of formal and/or informal arts education. Amanda was a young artist, who had recently graduated with a degree in painting and drawing. The site of CFP was a working farm, residence, and educational center. Through the farm, she offered educational programming, which "uses sustainable agriculture to engage the community, empowering youth adults to learn the source of our food, connect with the land, and to take responsibility for positive change" (Cardo's Farm Project, 2014). Amanda was interested in the educational and community-building potential of environmentally conscious agricultural work. As the quote suggests, she is focused on individuals' potential to realize their role in affecting "positive change."

CFP is one example of an increasing interest in localized agricultural work, urban farming, and hands-on production in response to factory farming, increasing globalization of food systems, and genetic modification. Post-Fordism[1] and our globalized economy have exacerbated physical and cognitive disconnects from agricultural and textile production that was born from industrialization (Hardt & Negri, 2004; Jeppesen, 2011; Thrift, 2012) – facilitating the often-overlooked exploitation of many life forms. This chapter explores one example of a renewed and expanding interest from artists in local farming and agriculture as an ecological expression of their art practices. By tracing Amanda's early influences, her choices during art school, internship at a social justice farm, work with contemporary artists in New York, and finally developing her own educational farm, this paper illuminates farming as one offshoot of participatory aesthetics (Bishop, 2012b) in response to neoliberal globalized capitalism.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Over the last three decades, a movement merging craft and activism has grown in popularity. These material practices stem from a shift in values and are part of broader activist efforts for human and animal rights, environmentalism, and food justice as modes of cultural resistance to corporate globalization (Holtzman, et. al, 2005; McKay, 1998; Spencer, 2005). These modes of resistance are not without contradictions, as many of these practices have been co-opted by corporate entities to develop lifestyle-marketing campaigns based on a craft aesthetic and embedded in neoliberal rhetoric about individuation, choice, freedom, and a knowledge economy (Bishop, 2012a).

Small-scale and local farming have gained broad attention (Inwood, 2010; Meehan, 2012; Spaid, 2012) as part of this broader craft and hands-on revolution, as some call it (Levine, 2008). In Amanda's story, we see networks of apprenticing makers, farmers, and artists that illuminate the local/global relationship of agriculture-cum-art in response to the increasingly biopolitical terrain of food, art, and education. By mapping her process, the complexity of resisting global capitalism through localized, hands-on efforts with an emphasis on embodied learning and collective action is illuminated.

Moreover, her story is an illustration of the contemporary cultural desire for participation and consumption as event (Bishop, 2012b; Dunlap, 2013; Kalin, 2014; Kester, 2011). Amanda frequently incorporates hands-on experiences for visitors, customers, and students as a form of cultural participation; the act of farming, selling, and teaching become communal and aestheticized, and her agricultural output, farm, home, and lifestyle become commodities (Schaefer, 2013). But just as in my narrative, brief evens of direct engagement can produce the shallow satisfaction that we have performed a civic duty, overlooking vast systemic inequality that has become invisible through globalization. The farm illuminates the messy spectrum between resisting neoliberal capitalism and becoming subject to it, considering how the farm owner must negotiate and perform to our globalized economy to stay viable.

The chapter is ordered through education, art, and farming. I focus on themes of collective effort, fundamental skills, participatory civic engagement, and sacrifice to explore contemporary social conditions produced from neoliberal global capitalism through Amanda's story. I start by contextualizing the growing popularity of small scale farming in relation to histories of craft and community engagement as an art of resistance. Then, I trace Amanda's process of coming to and developing the farm through her art practice. Finally, I analyze ways that Amanda's experiences illuminate the complexity of the current relationship between craft activism and neoliberal capitalism, where "so many other aspects of this art practice dovetail even more perfectly with neoliberalism's recent forms (networks, mobility, project work, affective labor)" (Bishop, 2012a, p. 39).

AESTHETIC ACTIVISM IN RESPONSE TO INDUSTRIALIZATION

At each historical moment participatory art takes a different form, because it seeks to negate different artistic and sociopolitical objects. In our own times, its resurgence accompanies the consequences of the collapse of really existing communism in 1989, the apparent absence of a viable left alternative, the emergence of contemporary "post-political" consensus, and the near total marketization of art and education. The paradox of this situation is that participation in the West now has more to do with the populist agendas of neoliberal governments. Even though participatory artists stand against neoliberal capitalism, the values they impute to their work are understood formally (in terms of opposing individualism and the commodity object), without recognizing that so many other aspects of this art practice

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

dovetail even more perfectly with neoliberalism's recent forms (networks, mobility, project work, affective labor). (Bishop, 2012a, p. 39)

As early as the Arts and Crafts movement, William Morris used creative and material practices to question capitalism, industrialization, and the increased fragmentation of humans from nature (Efland, 1990; Zabel, 1993). Dewey (1916/2007) later questioned how the spaces of institutional education and pedagogical content of public schooling were intrinsically removed from everyday life and argued for an enlivened way of being in the world as a form of living aesthetics (Efland, 1990). Progressive education of the 1930s was a form of social reconstruction encouraging skills and practices, including arts and craft production as part of everyday life, unifying communities through a pragmatic and problem-based education (Efland, 1990). Similar efforts to merge craft production as way of being in the world can be seen at the Bauhaus, Jane Addams Hull House, the Owatonna Project, and Black Mountain College. Each of these sites used craft as a form of education and civic engagement, where creative participation in the everyday functioned collectively and as a certain amount of political resistance.

A similar form of social reconstructivism emerged in the 1960s and 70s as part of the arts-in-education movement. Again, proponents argued against the fragmenting force of "disciplining" education, where art is set apart as a creative practice (Efland, 1990). They promoted problem-based learning in local environments, through activities that functioned as necessary skills for life, and saw art as integral to all subjects. Unlike the Progressivist efforts of the 1930s, arts-in-education advocates of the 1960s and 70s looked to the work of performance artists and encouraged the direct involvement of practicing artists in educational settings (Efland, 1990).

Since the 1970s, politically active cultural groups driven by a DIY ethic have revealed alternatives to the increasing power of corporate capitalist structures often using participatory approaches to intervene in daily acts of consumption (Duncombe, 1997). These types of interventions in state and civil society are geared at changing or highlighting inequality in the everyday. Artistic interventions in the everyday become increasingly visible primarily during times of broad social upheaval or political transition.

This ethic has reemerged in the last two decades in response to the ubiquitous nature of corporate capitalism in every aspect of life. Unlike previous public efforts to combat unjust labor conditions and social inequality that took the form of labor unions and public protests, the networked nature of our contemporary global economy has produced the necessity for equally networked forms of resistance. These efforts attempt to intervene on individual, grassroots, and systemic levels.

In the late 1990s, Green (1999) identified *new genre public art education* as a combination of traditional and non-traditional art methods merging art and life to make socially-conscious art. She promoted socially-based pedagogy through constructive projects with the use of critical thinking strategies in community-based art education that work with and in the community to develop problem-solving skills that are socially relevant and merge art and life.

Neoliberal capitalism today makes resistance different than it has been in previous generations. An increasing desire for post-politics and anti-intellectualism have created conditions where creative resistance must tactically engage participants and viewers in activities that open new modes of understanding without overtly supporting a political agenda. Many artists and activists start with their local environment, focusing on place as a generative concept. Pedagogies of place (Callejo Perez, Fain, & Slater, 2004; Ellsworth, 2005; Gruenewald, & Smith, 2008) draw attention to the vitality of a physical setting to instruct, oppress, structure, and inspire. In art education, place-based studies often focus on the potential of learning beyond the institutional setting, into domestic spaces (Ballengee Morris, 2000;

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Congdon, 2006), public places (Duncum, 2011; Trafi-Prats, 2006, 2009), in the natural environment (Blandy & Hoffman, 1993; Garoian, 1998, jagodzinski, 1987), and through direct engagements with built environments (Gude, 2004; Powell, 2008, 2010). Others argue the institutional environment's potentially negative impact across ecologies (Graham, 2007; Wallin, 2007). Environmentally-conscious research in art education has questioned the hierarchy of humans over the environment (jagodzinsky, 1987) and "demonstrate the interdependence of all living and non-living things" (Blandy & Hoffman, 1993, pp. 24-25). Scholarship about place is often rooted in environmental awareness and the desire to affect change in local and global communities.

ART AS PARTICIPATORY CULTURAL ENGAGEMENT

First, there is growing interest in collaborative and collective approaches in contemporary art. And second, … there is a movement toward participatory, process-based experience and away from a 'textual' mode of production in which the artist fashions an object or event that is subsequently presented to the viewer. (Kester, 2011, pp. 7-8)

Kester (2011) describes two modes of participatory art, collaborative and participatory, that have emerged in part from the fragmented character of our contemporary society embedded in neoliberal conditions. Kester (1998) claimed, "the current political moment demands an activist aesthetic based on performativity and localism…. An activist art…defined as an intersubjective 'communicative action'" (p. 15). Kester positions activist art as performative act in the local.

This approach also parallels a shift to the relational in contemporary art considered by Bourriard (2002) as, "the realm of human interactions and its social context" (p. 14). Similarly, Bourriard (2002) highlights contemporary possibilities of work that addresses "learning to inhabit the world in a better way, instead of trying to construct it based on a preconceived idea of historical evolution" (p. 13). Such a conception of the centrality of newly generated forms of social relations is essential to the idea of an activist art that engages questions of politics and power relations.

Art based in relational encounters can have a superficial effect, though, of lulling viewers and participants into the notion that they have become politically active, or performed as active members of society. Bishop (2004) argues that the very messiness of contemporary artistic activism is critical to its efficacy, embracing the destabilizing meaning of relational aesthetics, and claiming that congenial encounters are not enough to produce critical affects. Instead, a critical situation must express a *relational antagonism* that troubles customary modes of representation "going to public space to engage with ways that participants perceive 'conflict, division, and instability'" (Bishop, 2004, p. 65) in local communities. The resulting discomfort of defamiliarized experience can trouble subjectivities in ways that illuminate new possibilities.

Artist activists have become interested in Socially Engaged Art, which embodies a pedagogy of ethical encounters that rely on the performative aspects of our lives in the world and an emphasis on affect. Helguera (2011) describes a social interest in contemporary art, where artists are "interested in creating a kind of collective art that affects the public sphere in a deep and meaningful way" (p. 7). A shift to a socially engaged art involves a focus on public participation that is local, performative, and often political. These political and public shifts to a performative action are emerging in response to increased private ownership of all public space, as well as an institutional critique of the state, the school, and the art

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

world. Artists, educators, and scholars are coming together publicly as members of larger communities to enact change and attempt to produce a collective intersubjective shift in our global society through direct engagement (Thompson, 2014). Socially engaged art aims to disrupt and transform "through a form of practical or experiential production, the outcome of which is not predetermined" (Kester, 2011, p. 185).

Farming as Socially Engaged Art

Small local and urban farms operate through the same hands-on ethos that is driving craftivism and socially engaged art. Today, common public spaces, such as malls, parks, and shops are typically constituted at least in part by capitalist forces. In response, the handmade revolution described above along with other forms of craft activism have made an effort to intervene in these sites to resist globalized capitalism. Farmer's markets and local or urban farms have become popular spaces of civic engagement through interactions directly with farmers, craft artisans, and their land. Participatory and socially engaged art have infiltrated the public sphere in an effort to activate political discourse in the commons. Practitioners, which are often artists, are interested in bringing people together through collective, first-hand engagements with agricultural work to eliminate the cognitive and corporeal fracture historically constituted through capitalist production.

While the popularity of farming and local agriculture has increased, artists are also responding to and engaging with farming. Farms have been represented in artwork for centuries, from pastoral landscape paintings to the photographs created by the WPA. Paralleling contemporary shifts toward participatory art, farms have taken on a performative role for artists today. Links between art and farming are now being investigated in relation to similarities of process and activities of production, and less for as commodities or modes of representation (Barney, 2009).

Contemporary artists are using processes embedded in farming and the construction of farms in a variety of ways and locations, including urban lots, abandoned fields, and community sites (Meehan, 2012; Spaid, 2012). Sue Spaid curated an exhibition addressing forty years of farming as art in the Contemporary Arts Center in Baltimore in 2012. Art dealer Cynthia Mulcah, and artist Robert Hamilton developed a farm as a community center in the middle of an urban area in South Dallas. These are just two examples among many of ecologically minded artists and cultural workers developing green spaces and/or educational programming around combined efforts between art and farming.

As I introduce Amanda's narrative in the following sections, I view her farming practice and her aesthetic practices as performative craft production. In her story, we see networks of apprenticing makers, farmers, artists, and educators that illuminate the local/global relationship of agriculture-cum-art in response to the increasingly biopolitical terrain of food, art, and education.

Methodology

This research was part of a two-year inquiry that considered how narratives embedded in the objects and material elements of artists' and makers' homes might teach about ways that subjectivity was produced through their social and material practices. To understand the singular and systemic aspects of Amanda's farm project, I approached the research through a methodological bricolage (Kincheloe, 2005) that included traditional ethnographic methods, cultural and historical research, and autoethnography. Over the course of two years I made initial formal visits to the original site of her farm project to administer two formal interviews with tours of the site and many informal visits and interactions during which I learned

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

how the ideas shared in the initial visits were lived. During the research, my children took part in the educational programming offered at CFP, and I joined her community farm share program, which is a form of Community Supported Agriculture (CSA). I also volunteered time to help with tasks associated with the farm, such as the experience described in the opening of the chapter. In addition to experiences on the farm, I interacted with Amanda in public spaces, such as the local farmer's market. Data included interview transcripts, photographs, personal reflections, publicly posted and online artifacts produced to advertise her project, and historical and cultural research.

Amanda was the last participant I met, and her home was an anomaly for a number of reasons. Amanda's domestic space, which shifted during the research process, was unusual because the home was on the farm that also served as the site of her small business. In the two years that we worked together, she moved from a trailer located on the original site of CFP to her own home on acreage that would continue to serve as Cardo's Farm Project but as a more independent business venture. As a result of this overlap, I was able to learn about Farm Based Education, the small farmers movement, and challenges of developing a local agricultural operation. All of these factors intersected with her background as an artist and her interest in histories of female farmers.

I use Amanda's narrative to consider how the farm project as business and educational site illuminates the complexity of neoliberal globalization, where participation is both aesthetic and civic engagement and simultaneously a marketing strategy. To analyze the data in response to these questions, I consider how Amanda's choices, sacrifices, opinions, and material practices highlight potential for broader collective efforts and illuminate the systemic conditions that limit them.

ARTIST-CUM-FARMER

In this section, I describe Amanda's influences, education, and experiences that produced the shift from being a practicing artist to a developing CFP. As noted earlier, a renewed interest in craft has emerged in part as a response to global capitalism. Many artists are drawing attention to the importance of fundamental skills, such as gardening and sewing as a way of developing a sense of agency in relation to material necessities and of living with less dependency on globalized capitalist production. The argument exists that there is no way to live outside of capitalism, but many artists and makers feel that highlighting the significance of skills in fundamental material production is one small mode of resistance.

Art and Education but Not Art Education

Women's narratives and an interest in fundamental skills fueled Amanda's concentration on craft and agricultural knowledge, but her institutional education in art in public school and the university have equally influenced her desire to become an educator, artist, and farmer. A nurturing art teacher, Ms. Wilson, helped Amanda develop confidence in her drawing skills. As she thought about going to college, she saw Ms. Wilson as a model for future potential. Amanda decided to pursue art education and studio courses in painting and drawing at the university. She considered art education a subject that was about usable skills that were physical and productive—information that could be applied.

After one art education course, she decided not to continue a traditional certification route. As she explained,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

And then I dropped the art education. Because I, well, I took one class, and I was like, 'these people are going to educate children about art? We're not even making art.' They don't know anything about art. It didn't make any sense to me. (Amanda, personal communication, February 19, 2013)

As I heard Amanda say this, I wondered what would have turned off someone who genuinely cared about making art and had a sincere desire to educate. What is art education training? I will explore possible answers to this question and how this experience is not unusual in the discussion at the end of this chapter. Amanda decided to take her desire to educate to community work instead, focusing on farm-based education and craft in community settings.

Hidden Villa and Social Justice

To learn about farm-based education while finishing her art degree, Amanda took an internship at an educational farm outside of San Jose, California. "Hidden Villa is a nonprofit educational organization that uses its organic farm, wilderness, and community to teach and provide opportunities to learn about the environment and social justice" (Hidden Villa, 2014). Hidden Villa invited school and community groups out to engage in learning experiences through direct contact with animals and agriculture. Its approach is rooted in farm-based education (FBE). FBE is,

...a form of experiential, interdisciplinary education that connects people to the environment, their community, and the role of agriculture in our lives. Farm-based education promotes land stewardship, the value of meaningful work, and supports the local food systems that sustain us. (Farm Based Education Network, 2014)

This focus on direct engagement with the land through experiential and interdisciplinary learning was critical to Amanda. Just as Amanda was drawn to the stories of her grandmother's large family where each sibling played a role in the family's well-being, FBE can instill a sense of purpose in students.

This type of education does not just take place at farms. We can see similar experiences in urban and school-based gardens (Inwood, 2010). Students are able to take ownership over something and nurture its growth.

I think kids are really good at picking up on where they are in the world and in a system whenever they are asked to be the caretaker of the animal or the plant. And then they know that this is my responsibility to care for this and then they are working next to each other and they are trying to figure it out and how to do and how to use the tools – like all of this confidence building. (Amanda, personal communication, April 5, 2013)

In addition to developing sensitivity to all life forms, FBE promotes social justice through the experience of being on the land together and in teaching about what it means to take only what you need and build consideration for the larger global community through a collective responsibility. The founder of Hidden Villa started the first multi-racial summer camp in 1944 with the idea that children playing outside together might be able to forget their socially constructed differences at least temporarily. The Duvenecks, who had purchased Hidden Villa in 1924, had an ongoing mission of using the land to advance social justice.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In addition to starting the first multiracial summer camp, they "sheltered refugees fleeing from the Nazis, assisted Japanese-American families returning from internment camps, and hosted groups for social and educational reform." Later the family "opened their home to the United Farm Workers movement in the 1960s and provided a safe space for Cesar Chavez to organize California's first farm workers strike" (Hidden Villa, 2014).

Social justice is woven into farm-based education as people come together to care for the environment and for each other through direct engagement and personal responsibility. Amanda highlighted the kind of camaraderie that develops among those who are working together to build a local garden or a large farm. It is a kind of camaraderie that children and adults alike often lack in our globalized and media-driven society.

Performing the Farm Through Collective Responsibility and Fundamental Skills

When Amanda returned for her last year of school, she visited Cardo's Sprout Farm. She had other friends who had volunteered there and thought it might be a good place to continue exploring FBE. During her final year of school, Amanda was growing and delivering sprouts for Cardo while pulling together her final work for her BFA show. Her internship in California the previous summer revealed to her the potential for teaching and learning through work on the farm. There she saw a new domain for teaching.

Amanda's grandmother influenced both the subject matter and ethical drive for her shift to farming and her art practice. Her grandmother was a seamstress who lived on a small farm. Amanda learned to sew from her when she was young. Together they would crochet and make quilts. As a young art student, Amanda took an interest in histories of female farmers. Her work dealt with what it might means "to be a farmer and have a life that was so different and to be a woman who was working physically as hard as the man" (personal communication, February 19, 2013).

Amanda spent a lot of time on her grandmothers' farm growing up, and a map of that farm (Figure 1) was the visual and conceptual inspiration for Amanda's BFA show. Amanda's grandmother drew the map, illustrating the layout of the farm (refer to Figure 1). The details of the drawing provide insight to the life of her farm with a variety of crops, a garden, calves and chickens, and also a number of different physical structures.

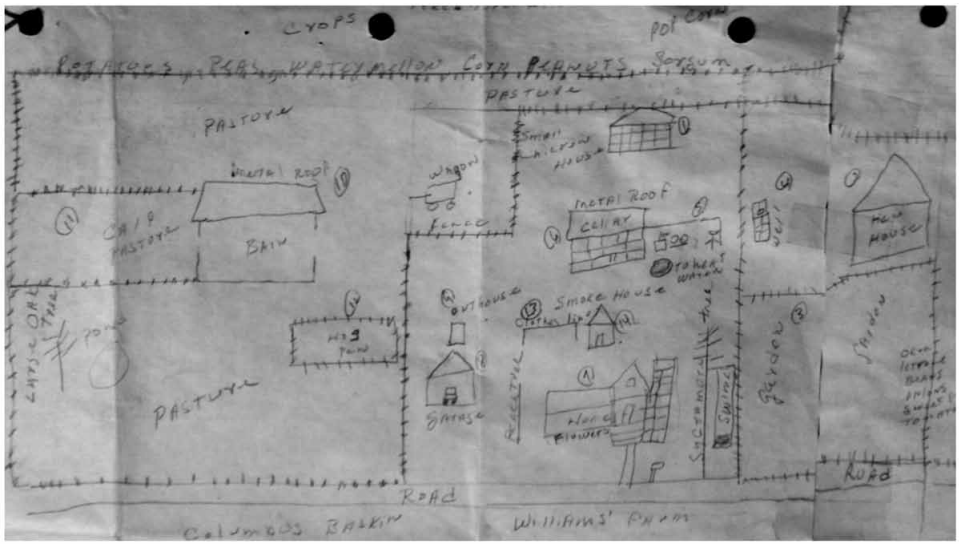
Through her time with her grandmother, Amanda learned the importance of individual responsibility and collective effort. Collective engagement by all members of the family was critical to the operation of a farm. As she described,

[My grandma] had a real role – she was a kid and her siblings were kids but they had a real contribution to the existence of their families. And I don't think they were resentful at all. Like she talks about doing the work and being so excited they could go out and swim in the river that afternoon. And before school you milk the cow and then you come home and do whatever chore you have to do. I think that would help me appreciate what it means to be here and to be part of the world. (Personal communication, April 5, 2013)

With a life engaged in the direct production of food and other necessities came purpose as well as the joyful reward of leisure thereafter. For Amanda, collective processes of coming together through essential and direct practices are the root of subsistence and survival.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Close-up of map drawing Amanda's Grandmother's house



I just wanted so badly to have the simplified version – I guess it was a kind of romanticism, but these foundational or fundamental skills – all of it – all of the DIY skills, crafting, sewing, weaving, growing food, building, cooking – I just really wanted to know those things – for me it meant some kind of simplification – like a simpler form of living. (personal communication, April 5, 2013)

As we discussed learning fundamental skills in Amanda's trailer, I noticed a spinning wheel (Figure 2), but I was not sure of its purpose. Juxtaposed against the prefabricated walls of the trailer, the wooden apparatus seemed both a living being and a relic simultaneously. I asked her what it was, and the concept of fundamental skills was instantly clear.

Amanda explained that she was constructing pieces for her BFA show that would be an installation work that addressed life on the farm and stories she had heard, she repeatedly asked her grandmother for hand-spun yarn. Finally, her grandmother introduced her to a woman who taught her to spin her own yarn from animal hair. She used it to produce string installations (Figure 3) that would represent the crop rows from her grandmother's drawn map (Figure 1).

The work in Amanda's senior show wove together her interests in women's histories, a lifetime of developing skills in craft and making, memories of experience on her grandma's farm, the visual inspiration of her grandmother's hand-drawn map, and her recent embodied knowledge of farm work. She was becoming the subject of her memories and realized a parallel in her life and the research on female farmers' memoirs she had studied. The desire that fueled her work on the farm was the same passion that drove her artwork—a desire to make, teach, and learn.

So it just kind of evolved out of a practice from where I was drawing fields to where I was working in the fields. And then it was, like I would take vegetables that I was growing here and put them in my artwork. And then eventually it was like – a lot of it was time – I was working from sun-up to sun-down, but I have always thought of this like it was kind of like it was a big performance of the work that I had been making on paper for so long. It felt that way because it was kind of self-centered – like I was making

these artworks and it was all kind of the same thing for me, and then I started going through the motions of becoming a farmer that I had been making this art about because I felt like I kind of idolized it. (Amanda, personal communication, April 19, 2013)

Common Ground and Contemporary Art

After graduation, Amanda served as an apprentice at Common Ground Farm outside of Beacon, NY for six months. Like Hidden Villa, the farm provided educational programming for all ages and it emphasized food justice as part of its mission. Possibly because of its proximity to New York City and only a few miles from the Dia, Beacon was a large artist presence between volunteers, workers, and CSA members at Hidden Villa.

I asked Amanda why there seems to be such a strong overlap between artists and the young farmers movement. Having attended conferences and coming to know the farmer community, she explained that many young farmers are either the artist or the scientist type. She saw similarities between farming and art making in the way that both elicit a sensitivity to connect and exchange ideas, and require using your hands and mind to problem solve. For a young artist, farming can be much more rewarding than administrative or managerial jobs. Furthermore, Amanda stressed the potential for change that can come from agricultural work—change that might take the form of a week's vegetables, developing a community supported agriculture program, or a summer camp that introduces kids to the roots of much of their food.

During her apprenticeship at Common Ground, Cathy Lebowitz was the artist in residence on the farm. Lebowitz was an editor for *Art in America.* She introduced Amanda to a number of artists who would visit the farm, and they would attend shows in New York City together. Amanda's background as an artist opened doors to expand and become part of the larger community involved with Common Ground.

While interning at Common Ground, Simon Draper, a contemporary artist who was developing an artists collective called *Habitat for Artists* (Lipton, 2014), was also working there. Amanda explained that Draper wanted to take artists from their traditional studios and put them out in the community or in nature because he was interested in how that shift might affect an artist's consciousness. With a team of artists, he built small mobile studios and placed them around the Hudson Valley, allowing artists to use them. This work was collective and environmentally conscious, in the sense that the spaces were not based on profit, but on a shared time and labor to produce a different sense of connection with the world and question how that might affect their artistic production. His work was a response to global capitalism in its resistance to the privatization of time, space, and knowledge production.

After finishing her apprenticeship at Common Ground, Amanda apprenticed with Draper. She took testimonies of the artists who were occupying the spaces he built as part of her work with him, again blurring the lines between art, anthropology, education, design, and science. "I remember whenever I came home from New York, I was like, I'm an artist, and I just didn't know. I am an artist and I am a farmer and I'm a teacher." (Amanda, personal communication, April 5, 2013).

PRODUCING CARDO'S FARM PROJECT

Amanda returned home motivated to expand Cardo's Farm from a sprout farm into a local working and educational farm. She quickly realized that she was running a business and must learn how to manage it as such by teaching herself accounting and inventory software and honing her negotiation skills. Amanda's

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

experience building the farm project highlights the complexity of developing ethical business practices that rely on and are responsible to a community and the environment.

The first summer, the temperature rose to over one hundred degrees for sixty days. She worked with another farmer she had met in California to put on a makeshift summer camp with a surprisingly large turnout. The camps were full and the kids were excited. They also held adult workshops on gardening and farming. By the end of the summer, they were committed to seeing the Farm Project grow. Amanda raised $15,000 through a successful Kickstarter campaign. With the capital in place, she renovated the barn to make it a more functional education center (see Figure 4) and community kitchen, expanded the growing space to another plot of land, put in irrigation, and started their first CSA. The capital campaign allowed them to develop a business model that could function as a more self-sustaining system.

Sacrifice, Communal Living, and Collective Responsibility

While the Farm Project has been successful, Amanda was honest about sacrifices she felt she had to make to maintain its integrity. She was forthright about her fatigue with living outside and often without hot water. During their first winter, Amanda moved to the farm and lived in the small (approximately four foot by four foot inside) dome structure that Cardo built years earlier (see Figure 5). Amanda lived in the dome for over a year. There was no indoor restroom facility and no hot water. She would start a fire to use the shower and it was still not in a walled structure. The kitchen in their barn is the only kitchen on the land, so they share it with Cardo and any of his guests as well.

She eventually saved up the money to buy the trailer she was living in during the interview (see Figure 6). She said, "Sometimes I am just like, 'When, when can I have a normal house? Turn on the faucet and have hot water came out" (Amanda, personal communication, April 5, 2013).

Outside of the broader community in town, life on the farm was its own living system that relied on sharing, moderation, respect, and a collective responsibility. Amanda was only able to keep the farm going because it was based in a material form of communalism. With Cardo's land also came all of his equipment, barns, and fences. That kind of infrastructure would have cost far more than the cost of rent to start up.

Amanda shared the land with two farm managers. They shared an outdoor solar shower. They bought food staples in bulk for the farm based on a strict shared budget, and they ate all meals together because the cost of each member to eat individually would have been too high to manage with the resources they earned from produce. She explained that the cooking also operated on a rotation,

It's like you work your ass off every day and then to cook every night, it just gets really hard, I remember last summer before we had a system like this. Then it was just me and Dan, and Dan didn't cook very much so I was really just cooking for myself, and I pretty much lived off fried egg sandwiches. (Amanda, personal communication, April 5, 2013)

While I am focusing on farm production in this paper, many artist cooperatives are realizing that they must make similar sacrifices to resist neoliberal capitalism and exist in a world dominated by corporations. The micro-community of CFP reflects what needs to happen on a global scale to affect significant change. Amanda's sacrifice on the farm is one example of ways that people can live more ethically through communalism and limiting their use of natural resources. I recognize that few people would make the choice to live in a hut without hot water for a year, but the sacrifices made to conserve food and share responsibilities are examples of everyday changes that could make a broad impact.

Exploiting Rhetoric

Through our conversation, I learned about the realities of organic and locally grown produce sales. As we talked about sustainable practices and organic farming, Amanda spoke with disdain about a local organic grocer. As she described, "he's a peddler in town who hides under fancy words like organic, sustainability, and community" (Amanda, personal communication, April 5, 2013). Essentially, he was using marketing rhetoric for a disingenuous practice. He does not grow anything himself. He drives to a number of local farms and buys the most visually appealing produce wholesale.

It's so hard for us to compete with because he can drive all over and take out the stuff that looks bad, and we've worked our asses off and we're next to his glorious stand with our little bruised vegetables…. I just realized how many people are buying his stuff because of the words – sustainable and organic – we don't have any of those words. I refuse. You can talk about our growing practices, but I'm not interested in being associated with Monsanto and sustainability. It's a load of shit. But he's totally capitalizing on it. (Amanda, personal communication, April 5, 2013)

Amanda explained that wholesale distribution that relies on the middleman kills small farms because they do not get market value for their produce. Without the middleman distributor, farmers get market value for their food. In addition, when you buy directly from farmers, you may also have a better understanding or appreciation of what goes into growing it. Industrialized global agricultural production has exacerbated the struggles of small farms.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Amanda and I repeatedly talked about food justice and the challenges with providing healthy foods to low-income populations. Thinking about what it means to feed people who cannot afford to buy food introduces much broader issues about education. Eating healthy food often costs more than industrialized food, and it can take more time to cook and a familiarity with the produce being grown. Kale and rhubarb are commonly sold to her CSA members, but donating these to low-income families is not beneficial if they do not know what to do with them. These are some of the challenges that food justice efforts are facing. Solutions are not as simple as giving out free vegetables. Amanda sees ways that after-school programs on a farm, where students are paid with the food they have grown, could be one positive approach that is educational, service-oriented, and purpose-driven.

Participatory Pedagogy and Affective Potential

Since that first summer, Amanda ran summer camps for children ages Kindergarten through 6th grade annually. She served approximately eighty kids in each summer session, and activities include planting, working with animals, drawing, mapping, and tending the chickens, among other programming. They use multi-sensory investigations to learn about plants and other elements of the farm environment. She also teaches adult and children's classes at a community center, and invites local schools to visit the farm.

She explained that her approach to teaching is embedded in the belief that embodied learning and a focus on problem solving builds confidence in kids. By being able to see a direct connection between themselves and food and plants grown in the ground or to work closely with animals teaches kids a sense of responsibility and place. Amanda also frequently incorporates hands-on experiences for visitors, customers, and students as a form of cultural participation. Even for myself, my first real physical work was on a day that I volunteered to help dismantle greenhouses, described in the reflection that opened the chapter. I learned something every time I visited the farm for interviews, to pick up vegetables, or drop off my kids.

DISCUSSION

Amanda's process coming to and developing Cardo's Farm Project as a business and educational site illuminates the complexity of art, education, and community building in a period of increasing neoliberal globalization, where participation can become both civic engagement and simultaneously marketing strategy. Amanda's narrative reveals the potential of aesthetic practices to affect change in individuals and presents the challenges and possibilities of collective efforts in the face of an increasingly globalized economy. To analyze her process, I consider how participation as direct engagement produced a sense of agency and became an index of collective force through each aspect of her development from artist to farmer-educator.

Leaving Institutional Education

I realized that what was different in Amanda's direction with the farm and her misgivings about institutionalized art education were the lack of direct engagement and teacher preparation's increasing focus on corporate time in the form of accountability measures and the commodification of knowledge. Education courses are often based in decontextualized pedagogical methods. Students are disconnected

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

from lived experiences, often thinking through detached representations of classroom practices, where humans and experiences are generalized into procedures and data.

Effects of neoliberal policies on education have resulted in exponential increases in assessment measures in an effort to produce data. With more focus on assessment, education has become increasingly fractured and mediated by codes and rules. Through his explanation of the corporatization of universities, Giroux (2003/2006) describes the difference between what he calls corporate time versus public time. In this argument, the corporate university is "wedded to a notion of accelerated time in which the principle of self-interest replaces politics, and consumerism replaces a broader notion of social agency" (Giroux, 2003/2006, p. 260). Public time, on the other hand, "demands and encourages forms of political agency based on a passion for self-governing, actions informed by critical judgment, and a commitment to linking social responsibility and social transformation" (Giroux, 2003/2006, p. 261).

When the possibility of knowing outside of what already exists is foreclosed by codification of methods and the commodification of time, education becomes a product rather than a process. Amanda's frustration with and abandoning of institutionalized teacher preparation was in part recognition of this condition. Her experience in a formalized teacher education program was embedded in training rather than in the development of social agency. On the other hand, Amanda's community-based education at Common Ground and Hidden Villa operated entirely through what Giroux (2003/2006) described as public time: embedded in self-governing, social responsibility, and social transformation.

While Amanda's educational work at her current residence and at Cardo's Farm is not operating in a public space, it is open to the public where kids work both agriculturally and creatively to develop critical thinking skills about processes of production, natural resources, and the roots of material goods. For children, such as my son, her educational programming produced a different kind of subjectivity in relation to the natural environment, where the fruits of their labor are realized as plants grow and eggs hatch over multiple visits.

When kids attend Amanda's young farmers classes, she has to spend time helping students understand the difference in expectations on the farm from those in a traditional classroom because most are embedded in an institutional disconnect from life that is too often produced in public education. She feels that children are given little opportunity to take responsibility in a classroom, particularly with experiences dealing directly with living organisms.

Amanda shifted her focus to farm-based and community-focused education to return to a model closer to that which she experienced with her grandmother. Farm Based Education continues a mode of progressive education that Dewey (1934) encouraged a century ago. Amanda described how artists and scientists are drawn to the hands-on and problem-solving aspects of farming. Local, community-supported farms provide a place to practice ethical behavior through collective efforts with a visible community. In this sense, farms like Common Ground, Hidden Villa, and Cardo's Farm Project can be seen as sights of community based education through socially-engaged pedagogy, and if we view farming as an aesthetic practice, they intersect with and expand the potential of art education.

While artists have been drawn to this kind of embodied learning historically, Amanda's experience of working with Draper and Lebowitz in New York exemplifies ways that links between arts-based thinking and authentic learning exist today. Amanda's experience echoes that of performance artist and art educator, Charles Garoian, who described feeling "like a fish out of water" as a student at Stanford where "much of my studies there were based in academic models of pedagogy and curriculum" (Cempellin, 2013, 83). Garoian described (1999), "From the beginning, I wanted to teach in a way that invited the creative disruptions I found so valuable from my days growing up on my parents' farm and in my art

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

education" (p. 201). Garoian realized his interest in the performative process of art was the necessary component for powerful teaching:

The best teaching occurs when you are engaged with your students in exploratory, experimental, and improvisational processes; in the liveness of what art does, its conceptual operations, rather than illustration and representation. Academic representations will always constitute schooling, but what emerges from creative activity in the classroom is the source from which transformation and agency are made possible. (As cited in Cempellin, 2013, p. 83)

Amanda's decision to leave institutional education was a result of the absence of what Garoian calls "liveness of what art does."

Farming as Hands-On Resistance to Globalization

Neoliberal policies and practices have exacerbated modes of injustice through the exploitation of environmental and human resources, often in third world countries. A primary of globalization has been the move of manufacturing operations to countries with less human rights regulations. Moving these industries to less developed locations makes the effects of capitalist exploitation invisible to consumers in large industrialized nations. As one way of reconnecting with skills that have been lost in over two generations of outsourcing manual labor, the growing maker's movement has reinvigorated interest in craft, electronics, gaming, design, music, cooking, and much more. Artistic, DIY, and educational responses to globalization have embraced first-hand experiences focused on process and direct engagement.

Like the Arts and Crafts movement at the end of the 19th century, the farm movement is rooted in resisting the fragmenting nature of capitalism to separate laborers from their products. The ethic that girds many of the efforts of young farmers attempting to develop their own sustainable agricultural operations aligns with the anti-capitalist work and a sincere belief in importance of teaching fundamental skills through direct engagements and experiential learning. Amanda learned this ethic early on from life on her grandmother's farm. Life on the farm allowed Amanda to see the importance of collective effort and communal practices. Moreover, Amanda's grandmother taught her how to work through necessities, such as spinning yarn and knitting rather than purchasing mass-produced products.

Contemporary artists' "growing interest in collaborative and collective approaches in contemporary art…. toward participatory, process-based experience" (Kester, 2011, p. 7-8) were evidenced through Amanda's work at Common Ground. There, she witnessed a growing force of artists turning to agriculture and craft production embedded in a revolutionary spirit that connects art, activism, and education (Campana, 2011).

Participation as Ethical and Aesthetic Encounter

An ethic embedded in living as a form of art is becoming more relevant, where artists are illuminating vital interconnections of material practices or aesthetics as encounters with the world, where participatory engagement become aesthetic event (Thompson, 2014). With this in mind, I am viewing the farm as an aesthetic site, where Amanda's work performs Kester's (1998) claim for "collaborative and collective approaches…toward participatory, process-based experience" (p. 7-8).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this way, the aesthetic engagement with the farm is profoundly creative. jagodzinski (2009) describes that the force of the artistic event is its ability to change, rupture, and transform a system of set relations. If a traditional formal aesthetics engages with the ways art allows us to see beauty as a transcendental force, then couldn't this participatory approach to aesthetics grounded in the "dynamics of being" and the "performative affect of becoming" describe engagements with natural spaces through farming as aesthetic experiences? Encounters with the vitality of her farm become art events that can teach us about a more ethical way of living. Eyermen suggests art as 'experiential space':

A form of social activity through which new kinds of identities and practices emerge… as a cognitive praxis, art is a space for individual and collective creation that can provide society with ideas, identities, and ideals… like a social movement, art opens space for experimentation, social and political, as well as aesthetic. (as cited in Campana, 2011, p. 281)

Amanda's individual and collective practices on the farm engage with this kind of experimental, social, and political activity. Moreover, the farm as participatory aesthetic space aligns with Green's (1999) characterization of new genre public art education merging life and material production as a socially-engaged pedagogy.

Through my embodied participation with Amanda and CFP, I was able to recognize effects of industrialized agriculture that I had never seen before, rupturing my habituated understanding of agricultural production. While I experienced a shift in consciousness from even brief encounters with farm work, brief, enjoyable experiences do not engage with the much more complex and challenging issues of inequality embedded in the broader system of factory farming, such as migrant labor, environmental destruction, animal cruelty, and genetic modification. We must be careful to not become blind to broader forms of exploitation

Moreover, the limited time involved in brief, privileged encounters of "playing farmer" (Dunlap, 2011), rather than farming out of necessity, provides a sense of civic engagement while being spared from the messiness, struggle, and sacrifice that go along with actually running a small farm. Amanda's years of sacrifices and significant lifestyle changes were also invisible.

Unfortunately, the reality becomes more equivalent to pseudo-ethnographies (Desai, 2002) or edutainment (Kalin, 2014) because the event being consumed is so far removed from the challenges that go into the process. In her analysis of the ethnographic turn in art, Desai (2002) examines the complex and problematic relationship between experience, interpretation, and representation when the public sphere becomes an arena for active investigation. Desai (2002) especially scrutinizes the weakness of "pseudo-ethnography," wherein an artist enters a community for a day or week to engage in a brief cultural investigation, leaving "the socio-economic and political relations, which underscore the representation . . . hidden" (p. 314).

Bishop (2004) addressed this kind of superficiality with relational encounters in art of the 1990's, concerned that viewers and participants were lulled into thinking that they have become politically active. She argued instead for "relational antagonism" that might produce discomfort among participants to illuminate new possibilities. While I would argue that the exhausting work on Amanda's farm goes some way in affecting new ways of understanding the plight of small farms, participation on a large industrial agricultural operation might go a lot further in understanding the impact of globalization.

Participatory Engagement as Neoliberal Practice and Collective Resistance

As many young people choose to become farmers in an effort to act as individually responsible agents for a more environmentally sustainable future, they are often unknowingly buying into the system they are resisting. The maker's movement, in large part, privileges local markets, handmade products, efforts for more ethical forms of consumption, and a resistance to corporate production, but as Bishop (2012a) describes, one characteristic of neoliberal capitalism is its ability to co-opt modes of resistance into profitable commodities. One way of co-opting modes of resistance is through Post-Fordist tactic of marketing a lifestyle over individual material objects. This phenomenon highlights the complexity of cultural participation.

For instance, Amanda invites clients to pick their own vegetables and flowers. On the one hand, this is not unlike bagging one's own groceries. In the grocery store, the quick check out can be seen as a form of convenience or freedom from the line. We often fail to think that we are helping the grocery store increase their profits by working for them for free and eliminating a cashier's position.

At CFP, picking one's own flowers or vegetables can be viewed as freedom, choice, or cultural participation. It works as a marketing strategy and as a mode of resistance-as-hands-on engagement to people interested in cultural participation. Her invitation is both a reaction to globalized agricultural production and a need to exist within that market. By making the farm a participatory site, Amanda has "infiltrated the world of market and social relations" (Ranciere, 2010, p. 149) because the customer is, to a certain degree, becoming producer. At the same time, this strategy is now part of the neoliberal nexus. Collective participatory on the farm exists somewhere on a continuum between neoliberal marketing strategy and mode of cultural consumption as collective resistance.

Furthermore, Amanda's Community Supported Agriculture (CSA) program and Farmer's Market stand can be viewed as another performative public intervention in inequitable capitalist practices. There are 80 members of the CSA, but she did not have specific figures for the average weekend sales at the local Farmer's Market. As a CSA member, I would drive to Amanda's house one time per week to pick up a load of vegetables. I paid Amanda directly. I feel that on a micro level, this mode of direct exchange is one way to intervene in the capitalist drive for surplus. The exchange also became personal, local, and embodied. If we view processes of consumption as political acts, then my choice to buy directly from Amanda was a community-building act in opposition to neoliberal privatization that views all objects and relations as potential profit. My act of consumption shifted to a focus on communication, interpersonal relations, and local investment.

Even as I was helping the farmers at the local farmer's market and CSA, the privileged position of buying food direct from farmers often reifies racial and ethnic divides in local populations (Joassart-Marcelli & Bosco, 2014). For instance, the location of farmers markets driven by primarily Caucasian artisans and craft makers are often not the same as those that are driven by minority populations, such as Bazaars in Latino neighborhoods. This is the case of the Farmer's Market where Amanda sells produce. While there are Latino grocery stores nearby that sell local produce, the Saturday Farmer's and Artisans market in the center of town is frequented by primarily middle to upper middle class Caucasian clients. The differences point to a continued class-based and ethnic segregation.

Finally, through Amanda's challenges, I was better able to understand how rhetoric is exploited to appeal to the lifestyle politics of well-intentioned consumers. Amanda's frustration over the local wholesale produce dealer stemmed from the disingenuous use of popular rhetoric misleading well-intentioned consumers into thinking they were buying directly from a small farmer. The conflation of terms like

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

sustainable and organic again becomes a tool to attract people who don't know the processes embedded in their production. Many people attracted to those labels have good intentions. I would never have known about these unfair market practices. I thought that the local distributor was good because he was "local." She pointed out how people like me think they are doing the right thing because he uses misleading labels.

Amanda's small operation was compromised by buyers' desire for more ethical modes of consumption while also wanting aesthetically pleasing produce, not realizing that the rhetoric used to sell the products was erroneous. Again, neoliberal policies and Post-Fordist capitalism have produced a complex network of relations between production and consumption, commodifying desire, lifestyle, and rhetoric to make traditional models of resistance feel nearly impossible.

CONCLUSION

People need to be educated for democracy not only by expanding their capacities to think critically, but also for assuming public responsibility through active participation in the very process of governing and engaging important social problems. (Giroux, 2003/2006, p. 276)

To conclude this chapter, I return to the narrative that opened it. Our time spent on the greenhouses that day produced a connection with Amanda and the farm that transcended our intellectual or academic work. Through a pedagogy of participation, I realized how little I knew about the breadth of manual labor required to run a farm. Amanda taught me how the daily physical engagement of agricultural production could be an activist art practice embedded in the community-building force of direct engagements.

When I left that day, I felt a sense of agency and hope for the power that collective efforts might make against the exploitative conditions of globalized corporate capitalism by taking even a small amount of responsibility for the success of the farm through my time and physical effort. Her farm helped me see how a shift in cultural values is performed through the ways we spend our time, money, energy, and knowledge. Amanda's participatory aestheticization of farming through Cardo's Farm Project represented a site of resistance to industrialized farming practices as a way to teach daily methods of making that enact a DIY ethic of liberation from neoliberal capitalism (Holtzman, et. al, 2005; Kester, 2011; Levine 2008).

KEY TERMS AND DEFINITIONS

Aestheticization: The application of an aesthetic lens to analyze contemporary shifts toward local farming as a political act by farmers and artisans. This term is historically related to the work of Walter Benjamin in an analysis of the political nature of art and a broader analysis of life as being innately aesthetic.

Civic Engagement: Citizen participation for the betterment of a community.

Collective Responsibility: Group effort toward a collectively determined goal that is based in democratic membership and individual responsibility.

Farm-Based Education: Community-focused, interdisciplinary education based in farming and agricultural processes aimed at teaching about connections between living organisms, as well as links between nature and industrialization. Teaching methods are primarily experiential, hands-on, and student centered.

Globalization: Process of integration across global nations. The term often relates to trade markets, but also ideas, cultural artifacts, and worldviews spread through the development of new technologies, increases in international migration, and international trade policies.

Localized Agriculture: Shifts to smaller farms run by one or a few farmers in a region near or within urban areas, primarily in response to industrialized agriculture.

Neoliberalism: An economic philosophy that relates to market policies focused on deregulation and a laissez-faire capitalist approach. Since the 1970's this term relates to broader social shifts that emphasize individualism, free enterprise, accountability, privatization, and a focus on profitability.

Participatory Action: This term relates to collective action in terms of art, activism, research, and everyday community involvement aimed at human agency and social transformation.

ENDNOTES

[1] Stuart Hall (1991) defines Post-Fordism in this way: "'Post-Fordism' is a broader term, suggesting a whole new epoch distinct from the era of mass production…. It covers at least some of the following characteristics: a shift to the new information 'technologies'; more flexible, decentralized forms of labor process and organization; decline of the old manufacturing base and the growth of the 'sunrise,' computer-based industries; the hiving off or contracting out of functions and services; a greater emphasis on choice and product differentiation, on marketing packaging, and design, on the 'targeting' of consumers by lifestyle, taste, and culture rather than by the categories of social class; a decline in the proportion of skilled, male, manual working class, the rise of the service and white-collar classes and the 'feminization' of the work force; an economy dominated by multinationals, with their new international division of labor and their greater autonomy from nation-state control; and the 'globalization' of the new financial markets, linked by the communications revolution.

Chapter 57
Inter Linkages of Water, Climate, and Agriculture

Sunil Londhe
World Agroforestry Centre (ICRAF), India

ABSTRACT

Climate is the primary determinant of agricultural productivity and evidence shows possibility of shifts in earth's climate. Concern over the potential effects of long-term climatic change on agriculture has been raised over the past decade. Change in the climatic conditions on the globe created threat to the availability water for agriculture production. The present chapter is an attempt to distil what is known about the likely effects of climate change on water availability to agriculture for food security and nutrition in coming decades. Apart from few exceptions, the likely impacts of climate change on agriculture water resources in the future are not understood in any great depth. There are many uncertainties as to how changes in various environmental parameters will interact with the availability of water and further agriculture production. The future consequences of water resources on agriculture are discussed and summarized. Possible mitigation and adaptations to changing water availability for agriculture are also discusses.

INTRODUCTION

The world population, which took more than 50,000 years to reach the first billion, has just surpassed 7 billion. Even if fertility continues to decline at the world level and with it population growth rates, the United Nations projects that the world population could reach 9.3 billion by 2050 and surpass 10 billion by the end of the century (United Nations, 2011). If fertility were to be higher than in that projection, the population may surpass 10 billion by 2050 and may be several billions higher by 2100.

To feed a growing world population, we have no option but to intensify agriculture and crop production. Further, numerous factors shape and drive the agricultural sector and climate is the primary determinant of agricultural productivity. Given its inherent link to natural resources, agricultural production is also at the compassion of uncertainties driven by climate variation, including extreme events such as flooding and drought. The fundamental role of agriculture in human welfare, concern has been expressed

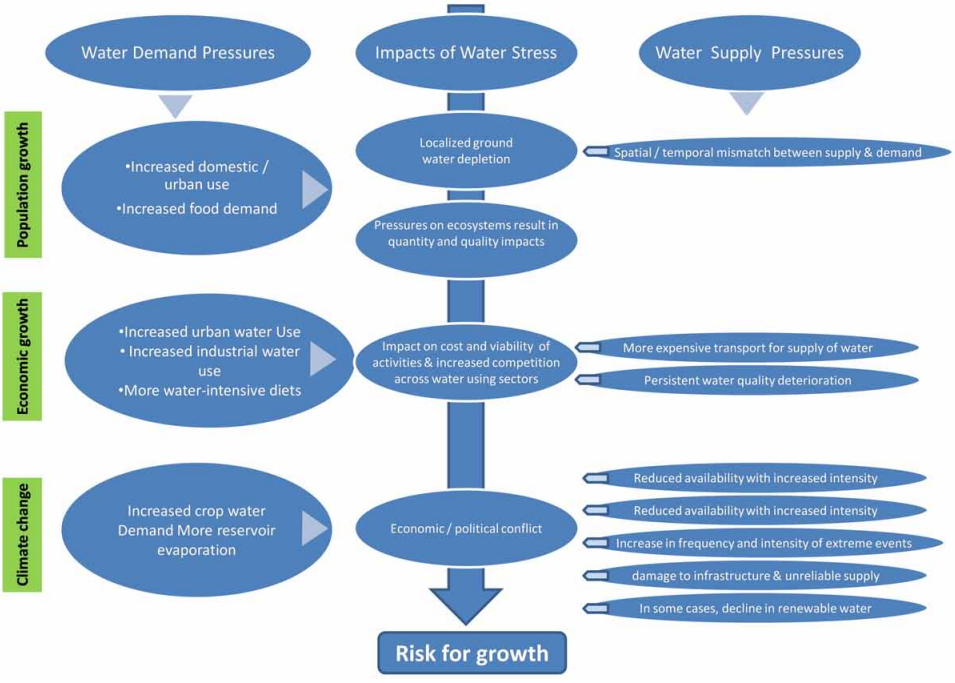
by federal agencies and others regarding the potential effects of climate change on agricultural productivity. Interest in this issue has motivated an extensive of research on climate change and its impact on agriculture production over the past decade.

There may be increasing threat to agriculture production due to climate change which is now largely accepted as a real, pressing and truly global problem. There is also increasingly aware that the risks of climate change are so great, that ignoring or delaying in addressing them would be far more costly than not doing so. Climate change is now global problem for the agriculture production and food security on the globe.

The long-term climatic risk to agricultural assets and agricultural production may be linked to availability of water which is known with great uncertainty. There may be threat to risk of loss of rural livelihoods and income due to insufficient access to drinking water. The risk of alarms for agricultural irrigation and reduced agricultural productivity, particularly for farmers and pastoralists in semi-arid regions. There may be risk of loss of terrestrial and inland water ecosystems, biodiversity, and the ecosystem goods, functions, and services they provide for human being and their livelihoods. In general agriculture production and food security may face serious consequences due to inadequate water resources. Apart from this increasing demand for water from urban, industry, etc. has exaggerated the problem in many folds. From the available literature overall demand and supply relationship with linkage to risk for overall development is compiled and presented in Figure 1.

It is well known fact that agriculture production is dependent on set of climatic conditions. Climatic resources are the deciding factor for successful cultivation of any crop and which cannot be manipulated by the human beings. The availability of water for irrigation and the source of the water both are climate dependent factors. Both shortage and excess of water will interfere the agriculture production

Figure 1. Water demand and supply relationship



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to greater loss. The latest reports (FAO, 2013) of statistics of utilization of world land says that thirty percent of the earth's land is used for crops and pastures and seventy percent of all abstracted freshwater is directed towards irrigation to produce the food that people and livestock need for a stable food supply. This large-scale utilization of land and water resources is increasingly threatening environments. Furthermore, farming is important because it provides the livelihood of hundreds of millions of people. Water resources are important for agriculture production in all the regions of the globe. Agriculture system is vulnerable because of too hot and dry climate, limited and variable water supply, low and degraded soil quality and lack of adaptive capacity.

The chapter "Inter linkages of water, climate, and agriculture" discuss about the probable impacts of climate change on availability of water for agriculture. The document encompasses not only irrigation, but also other forms of water control intended to optimize growing conditions for crops, livestock and pasture. Change in climatic conditions like precipitation, temperature, Carbon dioxide (CO_2), etc. may be having adverse effect on global agriculture production. Hence the core of the document concerns adaptive and mitigation options and activities that can contribute to maintaining global food security and supporting farmers' livelihoods in changing water availability.

Keeping in the view the challenges of availability of quality water for agriculture in changing climate, the chapter focuses on the impact of climate change on agriculture, knowledge on the relationship between climate change, water and food security and how agriculture is able to adapt such climate change. The chapter also explores future availability of water and what will be the impending impact of availability and what mechanisms can be implemented to mitigate the resulting impact?

In order to meet the elevated flow of agricultural production further research and extension activity need to be focused keeping in mind the changing climatic situations. Hence, at the end, the chapter discuss about the latest trends in the water and agriculture research for changing climatic situations. However, the impact on agriculture and its ability for adaption may vary with different parts of world.

The purpose of the chapter is to enrich the current state of knowledge of readers on the relationship between water availability, climate change and food security and nutrition to provide an evidence base discussion. The chapter provides an analysis of empirical evidence results to highlight the relationship between water for agricultural production in climate change situations and food security.

Background

Survival of human and livestock on the globe is highly dependent on the agriculture. Agriculture and allied activities are highly climate dependent and change in the climatic parameters may severely affect food security on the globe. Apart from few exceptions, the likely impacts of climate change on agricultural sector in the future are not understood in any great depth. There are many uncertainties as to how changes in temperature, rainfall and atmospheric carbon dioxide concentrations will interact in relation to agricultural productivity (Londhe, 2016). Lobell & Gourdji (2012) noticed that climate trends over the past few decades have been fairly rapid in many agricultural regions around the world, and increases in atmospheric carbon dioxide (CO_2) and ozone (O_3) levels have also been ubiquitous. The virtual certainty that climate and CO_2 will continue to trend in the future raises many questions related to food security and health. One of the important research question mingling in agriculture research environment across globe is weather agricultural production will affect due to changing climatic conditions. One of the most important input for agriculture is availability of sufficient quantity of quality water. Change in climatic condition may result some regions with scarcity of water where as others with excess water. Both the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

situations are not cozy for agriculture and will having serious impacts on global agricultural production and livelihood of rural poor and marginal farmers in various agro-ecological regions.

In addition to water many factors will shape global food security over the next few decades which includes increasing human population, agricultural productivity, income growth and distribution, dietary preferences and disease incidence. Apart from agriculture, there will be increased demand for land and water resources for nonagricultural uses also. In this situation, maintaining increased flow of agricultural production is important to meet the need of growing population and new food habits. The main question of interest here is: how important will climate change in the contest of quality and timely water availability in shaping future crop yields and other agricultural production at the global scale. This question helps to set the challenge of climate change adaptation in context.

Apart from these important climatic parameters like atmospheric concentrations of carbon dioxide (CO_2) and Ozone (O_3), and changes in temperature and precipitation conditions will be having direct or indirect impact on water availability and agriculture production. It may be expected that due to climate change there is possibility of change in climatic regimes and shift in seasons. This will create need based on the water availability to change in cropping patterns in some of the regions.

The vast majority of the Earth's water resources are salt water, with only 2.5% being fresh water. Approximately 70% of the fresh water available on the planet is frozen in the icecaps of Antarctica and Greenland leaving the remaining 30% (equal to only 0.7% of total water resources worldwide) available for consumption. From this remaining 0.7%, roughly 87% is allocated to agricultural purposes (IPCC, 2007). According to the Comprehensive Assessment of Water Management in Agriculture, one in three people are already facing water shortages (CA, 2007). Further FAO and UN Water (Anonymous, 2007) reported that around 1.2 billion people, or almost one-fifth of the world's population, live in areas of physical scarcity, while another 1.6 billion people, or almost one quarter of the world's population, live in the developing country that lacks the necessary infrastructure to take water from rivers and aquifers which is known as an economic water shortage.

Projections of climate change are inherently uncertain, due to the natural variability in the climate system, imperfect ability to model the atmosphere's response to any given emissions scenario. Taken in to consideration the recommendations of Intergovernmental Panel on Climate Change (Christensen et al., 2013) with identified model agreement on future changes, the global monsoon, aggregated over all monsoon systems, is likely to strengthen in the 21st century with increase in its area and intensity, while the monsoon circulation weakens. Monsoon onset dates are likely to become earlier or not to change much and monsoon retreat dates are likely to delay, resulting in lengthening of the monsoon season in many regions. The Predictions of Intergovernmental Panel on Climate Change may further increase the complexity of food security many folds. Again these uncertainties are compounded by the paucity and unreliability of basic information related to agricultural production.

Water resource availability may be altered by changed rainfall patterns and increased rates of evaporation. Changes in rainfall will also increase variability in groundwater recharge and river flow, thus may affect all water sources. For many of the world's poorest people, rainfall variability may be a major impediment to their livelihoods. The inability to predict and manage rainfall, and consequent runoff, variability is a key contributing factor to their food insecurity and poverty. Frequent periods with too much water are followed by periods with too little and intermittent water scarcity is often a direct consequence of rainfall variability.

National economies, highly dependent on rain-fed agricultural production, are exceedingly vulnerable to fluctuations in rainfall. Although there are opposing views, there is little evidence that water

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

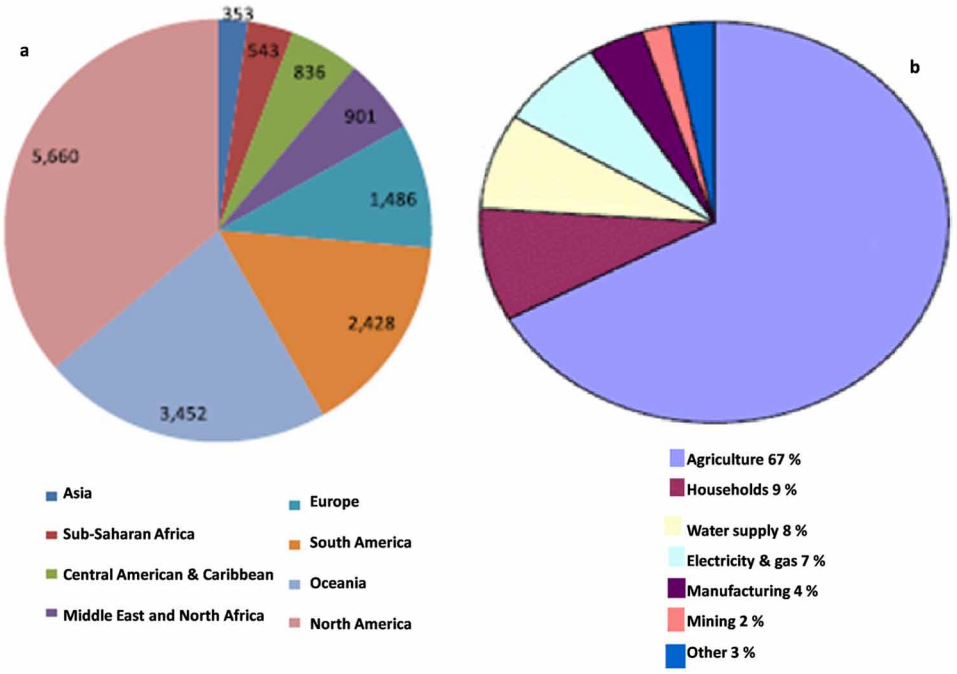
scarcity by itself is a major factor limiting economic growth in most countries (Barbier, 2004). However, in contrast, rainfall variability has been shown to be a significant factor that has an effect on economic growth (Brown & Lall, 2006).

Under these circumstances, water storage can, by safeguarding domestic supplies and supporting crops and/or livestock during dry periods, significantly increase agricultural and economic productivity and enhance people's well-being. Sector-wise utilization and per capita water consumption is given in Figure 2. Water storage can also contribute to electricity generation and providing water supply to commercial and industrial enterprises. Consequently, it has an important role to play in poverty reduction, sustainable development and adaptation to climate change. Yet, despite greater rainfall variability than many other places, per capita water storage is lower in Africa and Asia than elsewhere in the World. Lack of water storage infrastructure is posited by some as a major constraint to economic development in many developing countries (Grey & Sadoff, 2006).

Physical water storage, for the future needs to rethink water storage in a future of rapidly rising population and increasing uncertainty related to climate change, and for better planning and management

large dams are often the first thing that comes to mind when "water storage" is mentioned. Mainly because of their considerable financial requirements, as well as the political opportunities that they represent, large dams (defined as those greater than 15 meters (m) high or with storage capacity exceeding 3 million cubic meters (Mm^3) for heights between 5 and 15 m (ICOLD, 2003) have often been the principal focus of water storage efforts in recent decades. Just under 50% of the 50,000 large dams constructed globally - since the 1950s - have been built to support irrigation.

Figure 2. Per capita water storage in cubic meters (m^3) in human-made reservoirs by continent
Source: White, 2005
**For a more accurate representation of this figure, please see the electronic version.*



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Many others have been built to provide hydropower and domestic and industrial water supply as well as to provide flood protection. In many cases a single dam supports many of these functions (ICOLD, 2003). Numerous large dams have brought significant social and economic benefits. The broad links between infrastructure development (including dams), increased agricultural productivity and economic growth have been documented (Hanjra et al., 2009; Hussain & Hanjra, 2004). However, having a high per capita storage in large reservoirs is no guarantee of national economic development.

In common with all human development, large dams also have costs. Still water storage is important because in changing climatic situations, the water requirement of agriculture may be more and the stored water in the large dams may be having the potential for fulfilling the water scarcity. From the available literature it is not very clear that the large dams will fully satisfy the future need completely in climate change situations.

Agricultural and Water Management

Increasing agriculture production with population growth is the most important issue in almost all over the globe. In order to achieve this objective, the immediate solution to the farmer is enhancing the inputs to the agriculture which may not always proper for environmental health. One of the study (Fuglie, 2012) analyzed that how much of the growth in output is due to increased resources, and how much of it is due to improved productivity? After nearly four decades, of primarily resource-driven growth, a dramatic shift to productivity-driven increases in global agricultural output began around the early 1990s (Figure 3). Between 1961 and 2009, total resources and inputs grew about 60 percent as fast as growth in total agricultural output, implying that improvement in Total Factor Productivity (TFP) accounted for only 40 percent of total output growth. But TFP's contribution to output rose over time, and between 2001 and 2009 it accounted for about 75 percent of the growth in global agricultural production. The contribution of natural resources (including land and water) to output growth has decreased gradually over time while that of input intensification (including the amount of labor, capital, and materials per hectare of land) has fallen sharply.

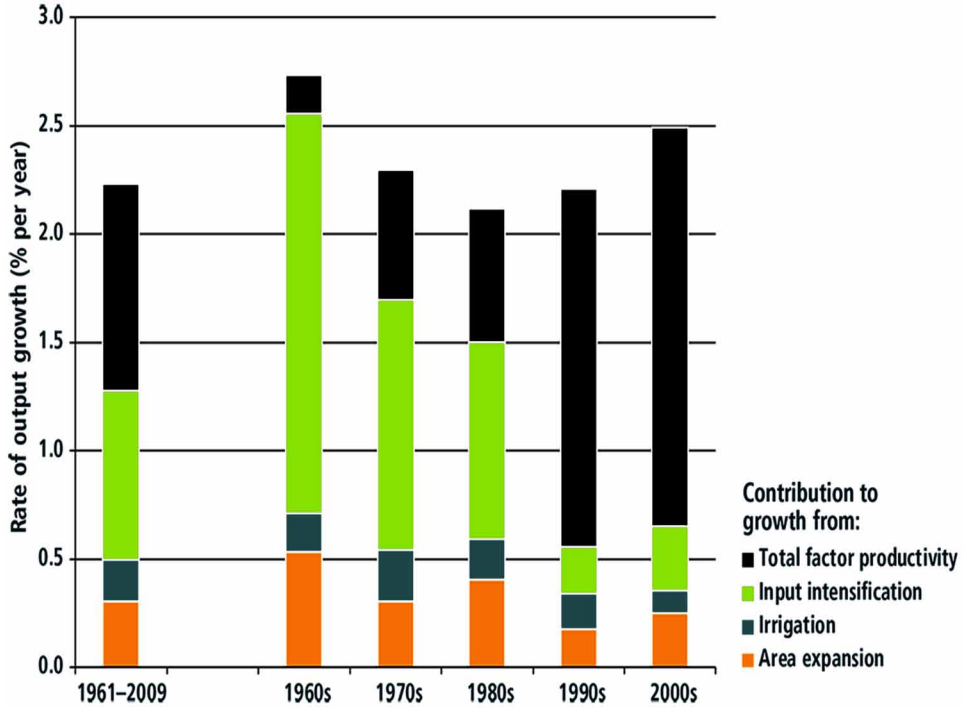
Water management in agriculture production is one of the important parameter for high and sustainable yields. Water requirement for growth and development of every crop is different. Some crops like paddy requires more water for the growth as compared with others like sorghum and bajara. Crop stress at critical growth stages my severely reduce yield of crops or completely failure of the crop. The water requirement also vary with region as well as season. It depends on the other environmental parameters like temperature, CO_2 etc. along with type of soils they grow. Rain-fed agriculture can be severely affected by long dry spells and uneven distribution of rainfall. Hence water management in agriculture depends on many parameters. Some of the environmental factors which influence crop water requirement are described briefly in below paragraphs.

C3 and C4 Plants

Most agricultural plants are categorized by their photosynthetic mechanisms that control the chemical processes in their glucose manufacture from CO_2 and H_2O (water) as C3 and C4 species because of their photosynthetic pathways. Other plants are called CAM that stands for Crassulacean Acid Metabolism after the plant family in which it was first found (Crassulaceae) and because the CO_2 is stored in the form of an acid before use in photosynthesis. Common C3 species include wheat, cotton, soybean, and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Sources of growth in global agricultural production
Source: Fuglie, 2012



most legumes like alfalfa while common C4 crop species include sorghum, corn, and sugarcane. Some grass species are either C3 or C4 types. C3 plants fix atmospheric CO_2 directly onto 5 carbon sugar RuBP (ribulose bisphosphate) and thus into glucose. C4 plants first fix atmospheric CO_2 into 4-carbon acids in the mesophyll of the leaf and decarboxylate the 4-carbon acids in the bundle sheath cells where the CO_2 is then fixed by RuBP carboxylase (all of this takes place during the day). CAM plants first fix atmospheric CO_2 into malic acid and other 4C-acids at night. During the day, malic acid is decarboxylated and the CO_2 released is then fixed by rubisco (all of this takes place in the same cell). Generally, the C4 photosynthetic pathway is considered more water efficient than C3 species. However, C3 species typically are more sensitive to elevated CO_2 (Rosenberg et al., 1988). The carbon-fixing efficacy of Rubisco depends on the ratio of CO_2:O_2. For C3 plants, this is closely coupled to ambient conditions, and efficacy is approximately 2/3 while for C4 plants, the CO_2:O_2ratio is much greater and carboxylation efficacy is nearly 100% (Ainsworth & Rogers, 2007). Therefore, increased CO_2 in air should directly increase assimilation for plants with C3 physiology. For C4 plants, the elevated CO_2 effects are indirect due to increased stomatal resistance and reduced transpiration.

Climate change (changes in temperature and/or precipitation regimes) would likely lead growers to change crops, cultivars, and management practices, including irrigation, to mitigate any adverse effects or to take advantage of more favorable conditions. Peterson & Keller (1990) suggested that higher temperatures and reduced precipitation could increase crop water demand in some areas and prompt the development of irrigation in regions previously devoted to dry-land or rain-fed cropping.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

CLIMATE CHANGE IMPACTS ON AGRICULTURAL WATER MANAGEMENT

Agriculture encompasses various activities including raising crops, raring livestock, poultry, fisheries etc. Availability of water for successful agriculture production is very important. As discussed above each crop water requirement is specific which is based on soil and various climatic parameters. Cropping pattern of any region is established over period of time based on available soil and climatic situation and farmer's knowledge base. Scientific evidences shows that due to global warming the climatic parameters are changing which may be having direct or indirect impact on global agriculture production.

Plant systems, and hence crop yields, are influenced by many environmental factors, and these factors, such as moisture and temperature, may act either synergistically or antagonistically with other factors in determining yields (Waggoner, 1983). In most land regions the frequency of warm days and warm nights may likely increase in the next decades, while that of cold days and cold nights will decrease. The impact of various climatic parameters on global agriculture from available literature is summarized in table 1.The below discussion is trying to analyze the impact of climate change on water availability to agriculture and its production.

Precipitation

Precipitation that regulates life on Earth and soil moisture is essential to sustain plant growth and biodiversity flourishes where water is abundant. Precipitation also has a bearing on local climate (Priestley, 1966). Variation in the precipitation may be having large impact on agriculture production on the globe. The general pattern of wet-get-wetter (also referred to as 'rich-get-richer', e.g., Held & Soden 2006; Chou et al., 2009; Allan et al., 2010) and dry-get-drier has been confirmed, although with deviations in some dry regions at present that are projected to become wetter by some models.

It has been demonstrated that the wet-get-wetter pattern implies an enhanced seasonal precipitation range between wet and dry seasons in the tropics, and enhanced inter-hemispheric precipitation gradients (Chou et al., 2007).

Intergovernmental Panel on Climate Change in AR5 report (Kirtman et al., 2013) presented results of Coupled Model Intercomparison Project (CMIP5) for projections of near-time changes in precipitation (Figure 4). It is clear from the Figure 4 that the basic pattern of wet regions tending to get wetter and dry regions tending to get dryer is apparent. There may be some regional deviations in the precipitation pattern. There may be possibility of the uncertainty in the substantial spread in the magnitude of projected change based on the simulation models used. The Figure 4 also highlight the large amplitude of the natural internal variability of mean precipitation. On regional scales, mean projected changes are almost everywhere smaller than the estimated standard deviation of natural internal variability. For zonal means and at high latitudes, the projected changes relative to the recent past exceed the estimated standard deviation of internal variability. The Figure 4 also depicts that the overall, zonal mean precipitation will very likely increase in high and some of the mid latitudes, and will more likely than not decrease in the subtropics. In case of the regional scales precipitation changes may be influenced by anthropogenic aerosol emissions and may be strongly influenced by natural internal variability.

Figure 4 Time series of relative change relative to 1986–2005 in precipitation averaged over land grid points over the globe in October to March. Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5^{th}, 25^{th}, 50^{th} (median), 75^{th} and 95^{th} percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Climate change fact and impact on crop production

Parameter	Fact	Effect
Temperature	Global Mean Surface Temperature	Has increased since the late 19th century.
	Comparison with past	Each of the past three decades has been successively warmer at the earth's surface than all the previous decades in the instrumental record, and the first decade of the 21st century has been the warmest.
	Global Mean Temperatures	Will continue to rise over the 21st century if Greenhouse Gas (GHG) emissions continue unabated.
	Impact on different regions	Temperature change will not be regionally uniform.
	Temperature extremes	In most places, there will be more hot and fewer cold temperature extremes.
	Global temperatures rise.	Mean sea level pressure is projected to decrease in high latitudes and increase in the mid-latitudes.
Water Cycle	Precipitation	In the long term, global precipitation will increase with increased global mean surface temperature.
	Average precipitation in warmer world	Will exhibit substantial spatial variation. Some regions will experience increases, other regions will experience decreases and yet others will not experience significant changes at all.
	Annual surface evaporation	Projected to increase as global temperatures rise over most of the ocean and is projected to increase over land.
	Humidity	Global near surface and tropospheric air specific humidity have increased since the 1970s.
Extreme Events	Day and night temperature	It is very likely that the numbers of cold days and nights have decreased and the numbers of warm days and nights have increased globally since about 1950.
	Warm days and warm nights	In most land regions the frequency will likely increase in the next decades.
	Cold days and cold nights	In most land regions the frequency will likely decrease in the next decades.
	Precipitation	Since about 1950 the number of heavy precipitation events over land has increased in more regions than it has decreased.
Sea Level	The rate of sea level rise	Increased from the early 19th century to the early 20th century, and increased further over the 20th century.
GHG	CO_2	Increased by 40% from 278 ppm about 1750 to 390.5 ppm in 2011.
	CH_4	Increased by 150% from 722 ppb about 1750 to 1803 ppb in 2011.
	N_2O	Increased by 20% from 271 ppb about 1750 to 324.2 ppb in 2011.
Land Use Change	Radiative Forcing (RF)	There is robust evidence that anthropogenic land use change has increased the land surface albedo, which leads to Radiative Forcing (RF) of -0.15 ± 0.10 W m^{-2}.
	Zonal mean precipitation	Will very likely increase in high and some of the mid latitudes, and will more likely than not decrease in the subtropics.
	Specific humidity	Increases in near-surface over land are very likely.
	Evaporation	Increases in over land are likely in many regions.
Earth's Energy Budget	Independent estimates of effective RF of the climate system	The observed heat storage, and surface warming combine to give an energy budget for the Earth that is closed within uncertainties (high confidence), and is consistent with the likely range of climate sensitivity.

Table 1. Continued

Parameter	Fact	Effect
Monsoon Systems	Future changes	The global monsoon, aggregated over all monsoon systems, is likely to strengthen in the 21st century with increases in its area and intensity.
	Monsoon circulation	The global monsoon circulation weakens.
	Monsoon onset and retreat dates	Onset likely to become earlier or not to change much and monsoon retreat dates are likely to delay, resulting in lengthening of the monsoon season in many regions.
	Annual precipitation change	Follows a 'warmer-get- warmer'pattern, increasing where warming of sea surface temperature exceeds the tropical mean and vice versa.
Cyclones	Projections	It is likely that the global frequency of occurrence of tropical cyclones will either decrease or remain essentially unchanged, concurrent with a likely increase in both global mean tropical cyclone maximum wind speed and precipitation rates.
	Regional projections	The future influence of climate change on tropical cyclones is likely to vary by region.
Crop Yield	Crop yield	In developing countries, climate change will cause yield declines for the most important crops. South Asia will be particularly hard hit.
	Irrigated crop	Will have varying effects on yields across regions, but yields for all crops in South Asia will experience large declines.
	Higher maximum temperatures, more hot days and heat waves over nearly land areas	Increased risk of damage to a number of crops
	Increased summer drying over most mid-latitude continental interiors and associated risk of drought	Decreased water resource quantity and crop yields.
	Intensified droughts and floods associated with El niño events in many different regions	Decreased agricultural and rangeland productivity in drought- and flood-prone regions.
	Increased intensity of mid-latitude storms	Increased damage to coastal ecosystems.
	Food price	Will result in additional price increases for the most important agricultural crops–rice, wheat, maize, and soybeans.
	Fodder price	Higher feed prices will result in higher meat prices. As a result, will reduce the growth in meat consumption slightly.
	Calorie	Calorie availability in 2050 will not only be lower than in the no-climate-change scenario-it will actually decline relative to 2000 levels throughout the developing world.
	Calorie and child nutrition	By 2050, the decline in calorie availability will increase child malnutrition by 20 percent relative to a world with no climate change. Climate change will eliminate much of the improvement in child malnourishment levels that would occur with no climate change.
Livestock	Higher maximum temperatures, more hot days and heat waves over nearly land areas	Increased heat stress in livestock and wildlife

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In response to GHG forcing, dry land areas tend to show a reduction of evaporation and often precipitation, accompanied by a drying of the soil and an increase of surface temperature, in response to decreases in latent heat fluxes from the surface (e.g., Fischer et al., 2007; Seneviratne et al., 2010).

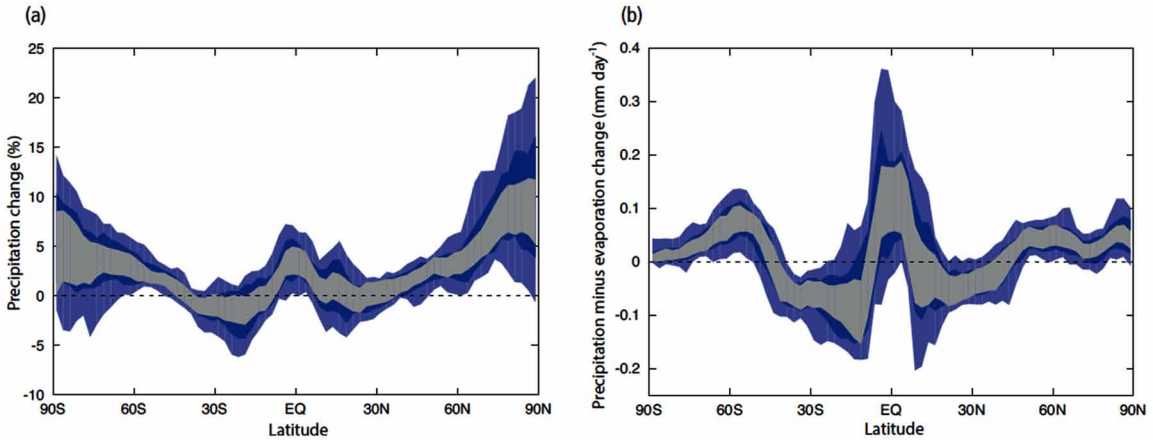
Evapotranspiration

The main source of water for agriculture production is through precipitation and the loss of water in the form of evaporation depends on the climatic conditions of the region. It has long been recognized (Priestley, 1966) that the availability of surface water regulates evaporation and local temperature. Where there is abundant surface water and plant growth, the local evaporation constrains temperature and in hot climates temperatures are very much higher in the absence of surface evaporation. So it is necessary to have proper balance between precipitation and evaporation for agriculture production.

The evaporation of surface water and condensation of atmospheric water vapor to form clouds and precipitation, is an essential component of energy flow through the climate system. This phenomenon may be explained by the Clausius-Clapeyron relationship which is the rate of increase of saturated vapor pressure with temperature and is important in regulating many of the processes of the hydrological cycle. The global atmospheric water content is constrained by the Clausius–Clapeyron equation to increase at around 7% K^{-1}; however, both the global precipitation and evaporation in global warming simulations increase at 1 to 3% K^{-1} (Lambert & Webb, 2008; Lu & Cai, 2009).

Consideration of hydrological drought conditions employs a range of different dryness indicators, such as soil moisture or other drought indices that integrate precipitation and evaporation effects (Seneviratne et al. 2012). In order to provide an indication of future changes of water availability, figure 4 (b) presents zonal mean changes in precipitation minus evaporation (P - E) from Common Management Information Protocol CMIP5 (Kirtman et al., 2013). As in the case of precipitation (Figure 4), the uncertainty is

Figure 4. Multi-model projections of changes in annual and zonal mean (a) precipitation (%) and (b) precipitation minus evaporation (mm day–1) for the period 2016–2035 relative to 1986–2005 under RCP4.5. The light blue denotes the 5 to 95% range, the dark blue the 17 to 83% range of model spread. The grey indicates the 1σrange of natural variability derived from the pre-industrial control runs
Source: Kirtman et al., 2013



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

dominated by model differences as opposed to natural variability (compare blue versus grey shading). The results are consistent with above discussion on the wet-get-wetter and dry-get-drier pattern. In the high latitudes and the tropics, most of the models project zonal-mean increases in P – E, which over land would need to be compensated by increases in runoff. In contrast, zonal mean projected changes in the subtropics are negative, indicating decreases in water availability.

Evapotranspiration is the combined effect of evaporation and transpiration, and it is a key part of the hydrologic cycle. Evaporation is simply the phase change from liquid water to water vapor as temperature increases. Transpiration involves the uptake of water in soil by plants, the transport of water through the plant, and its eventual evaporation from plant leaves and other surfaces. Evapotranspiration is a natural cooling process because heat at the earth's surface is captured by water droplets, which, through evaporation, disperse the heat out of the atmosphere and into space.

Change in CO_2 Levels

The prevailing view among researchers is that global climate change may prove beneficial to many farmers at least in the short term. The logic is straightforward: Plants need atmospheric carbon dioxide to produce food, and by emitting more CO_2 into the air will cause some crops and trees to grow bigger and faster.

The latest analysis of observations from the Global Atmosphere Watch (GAW) Programme (WMO 2014) shows that the globally averaged mole fractions of Carbon dioxide (CO_2), Methane (CH_4) and Nitrous Oxide (N_2O) reached new highs in 2013, with CO_2 at 396.0±0.1 ppm, CH_4 at 1824±2 ppb and N_2O at 325.9±0.1 ppb (Table 2).

The change in atmospheric CO_2 levels will have impact on the vegetation. Changes in evapotranspiration over land are influenced not only by the response to Radiative Forcing (RF), but also by the vegetation response to elevated CO_2 concentrations. Physiological effects of CO_2 may involve both the stomatal response, which acts to restrict transpiration (Cao et al. 2009; Field et al. 1995; Hungate et al. 2002; 2010; Lammertsma et al., 2011), and an increase in plant growth and leaf area, which acts to increase evapotranspiration (Bounoua et al. 2010; El Nadi, 1974).

Table 2. Global annual mean abundances (2013) and trends of key greenhouse gases. Units are dry-air mole fractions, and uncertainties are 68% confidence limits

	CO_2	CH_4	N_2O
Global abundance in 2013	396.0 ± 0.1 ppm	1824 ± 2 ppb	325.9 ± 0.1 ppb
2013 abundance relative to year 1750[a]	142%	253%	121%
2012–2013 absolute increase	2.9 ppm	6 ppb	0.8 ppb
2012–2013 relative increase	0.74%	0.33%	0.25%
Mean annual absolute increase during last10 years	2.07 ppm/yr	3.8 ppb/yr	0.82 ppb/yr

[a]Assuming a pre-industrial mole fraction of 278 ppm for CO_2, 722 ppb for CH_4 and 270 ppb for N_2O. Stations used for the analyses numbered 124 for CO_2, 121 for CH_4 and 33 for N_2O.

PROSPECTS FOR ADAPTATION MITIGATION

Intergovernmental Panel on Climate Change (IPCC, 2001), suggested that adaptation is gaining attention as an expected answer to the challenges posed by climate change. The increasingly uncertain climatic conditions to which actors are exposed may becoming a constraint for their well-being. Given the range of warming predicted by the scientific community, regional and local variation in impacts on the agricultural production may likely to be high. A critical challenge for farmers in developing countries is how to cope with increased variability and uncertainty in current and future rainfall patterns, a phenomenon which is affecting rain-fed and irrigated farming alike. Further, the concern with climate change is sensitive given the linkage of the agricultural sector to the poverty. It may be anticipated that adverse impacts on the agricultural sector will exacerbate the incidence of rural poverty. Hence, improved water resource management will be vital to sustaining crop productivity in the face of climate variability. Food insecurity may continue to be a serious issue in coming decades. Climate change may significantly increase production risk and rural vulnerability, particularly in regions that already suffering from chronic soil and water resource scarcity, high exposure to climatic extremes including droughts, flooding, poverty and hunger.

In order to sink with the climatic variability and retain enhanced flow of food production, some measures in the form of adaptation and mitigation will be required. Adaptation to climate impacts in the agricultural sector is not a new phenomenon. According to Rosenzweig & Liverman (1992) and Rosenberg (1992) natural systems have continuously been adapting autonomously, or in accordance with a plan, to a changing environment throughout history.

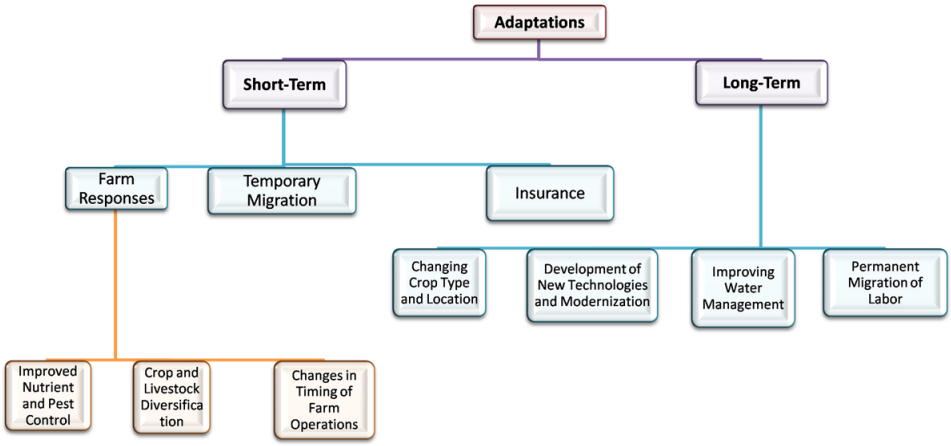
Adaptation may be defined as a process or action of adjusting to different circumstances or conditions, in this case as a result of a changing climate. Availability of water for agriculture depends on many climatic parameters like precipitation, temperature, atmospheric $CO_{2,}$ etc. Hence judicious management of water resource for sustainable agriculture development may require proper adoption to the changing climatic parameters. The adaptations includes several steps starting from micro level adaptation as farm production adjustments such as diversification and intensification of crop and livestock production; changing land use and irrigation; and altering the timing of operations. The adaptations can also include numerous market responses that have emerged as potentially effective adaptation measures to climate change, development of crop and flood insurance schemes, innovative investment opportunities in crop shares and futures, credit schemes, and income diversification opportunities. The options of adaptations may include government responses and institutional changes, pricing policy adjustments and technological developments. Hence, adaptations can be broadly grouped in to Short-Term and Long-Term adaptations (Figure 5).

Short-Term Adaptations

The short- term adaptations to the climate change may be having benefits to the farmers for shorter period of time and can be implemented immediately. Existing literature suggests that such types of adaptations are more appropriate to address short-term climatic concerns. These adaptations may include the following.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Apaptations in agriculture



Farm Responses

Among the most important and direct current adaptations to climate variability are some of the farm level responses. The farm response adaptations can include the crop and livestock diversification as well as changes in timings of various farm operations. Improved nutrient and pest control management can also be part of adaptation in farm response.

A. Crop and Livestock Diversification and Changes in Timing of Farm Operations

Crop diversification refers to the addition of new crops or cropping systems to agricultural production on a particular farm taking into account the different returns from value-added crops with complementary marketing opportunities. Diversification may be a key factor in reducing risk and means of coping with an uncertain climate and further unpredicted water for agriculture production. Crop is the major activity worldwide for livelihood followed by livestock production. Diversification of crop and livestock varieties, having the potential to increase productivity in the face of temperature and moisture stresses may be helpful. Diversity in seed genetic structure and composition may be an effective defense against numerous factors, including water stress, disease and pest outbreak and importantly climate hazards.

It is also predicted, there may be shift of cropping seasons and adjusting to such situations options include changes in the timing and intensity of production. Delcourt & Van kooten (1995), Brklacich et al. (2000), de Loe et al. (1999) have given following options for addressing impacts on yields and soils from climate change.

- Changing land-use practices such as the location of crop and livestock production.
- Rotating or shifting production between crops and livestock.
- Shifting production away from marginal areas can help reduce soil erosion and improve moisture and nutrient retention.
- Altering the intensity of fertilizer and pesticide application as well as capital and labor inputs.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Adjusting the cropping sequence, including changing the timing of sowing, planting, spraying, and harvesting, to take advantage of the changing duration of growing seasons and associated heat and moisture levels.
- Altering the time at which fields are sowed or planted can also help farmers regulate the length of the growing season.
- Changing the timing of irrigation.

Many researchers suggested various adaptation measures for livestock and rangeland management. Following are few suggestions for livestock and rangeland management outlined by Baker and Viglizzo (1998), Chiotti et al. (1997), IPCC (1996).

- Change in grazing timing, duration, and location.
- Varying supplemental feeding.
- Changing the location of watering points.
- Altering the breeding management program.
- Changes in rangeland management practices.
- Modifying operation production strategies as well as changing market strategies.
- In temperate climatic areas, planned adaptation measures in livestock management that are advocated include the use of vegetative barriers or snow fences to increase soil moisture, or windbreaks to protect soil from erosion.
- In warmer climates, adverse climatic conditions such as heat stress can be moderated by the adoption of appropriate technology such as the use of sprinklers in livestock buildings or feedlots.
- Adjusting livestock stocking rates.
- Implementing feed conservation techniques and fodder banks to moderate the consequences for animal production during periods of poor crops.
- Increasing native rangeland vegetation or plant-adapted species.

Working with various adoptions there may be numerous constraints farmers and livestock holders may encounter which make these farm level adaptations difficult. The short term adaptations are not costless. For example (Skees et al. 1999) the most significant problem to overcome is that diversification is costly in terms of the income opportunities that farmers forego (that is, switching crop varieties can be expensive, making crop diversification typically less profitable than specialization). In addition to this traditions can often by difficult to overcome and will dictate local practices. In such situation, if a local region has a long and rich tradition of planting a particular crop variety, the change to newer and more suitable varieties can be hard.

B. Improved Nutrient and Pest Control Management

Increased CO_2 levels and higher temperatures are likely to create stress in crops and livestock and may induce a need for more plant protection. Changes in the application of various chemicals may further enhance the problem. For the climate change situation alternative production techniques and crops, as well as locations, that are resistant to water stress, infestations and other risks may also be relied upon as effective response strategies. Following are a range of management practices have emerged that can

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

assist farmers adapt to loss of soil moisture and organic carbon contents and increased soil erosion as a result of changing climate situations (Erda 1996 and Parry 2000).

- Improved nutrient management techniques to maintain soil fertility and prevent erosion.
- For the increased frequency of droughts, farmers can further adapt by changing the selection of crops.
- Introduction of management techniques that conserve soil moisture, such as reduced or no tillage, in order to maintain soil organic carbon contents can result in improved soil structure and fertility.
- Increasing production per unit of evapotranspiration with the use of new and improved varieties.
- Reducing water use in land preparation as well as loss (through seepage and percolation) during the crop growth period.
- Adoption of efficient water use methods.
- The diffusion of appropriate technology to enhance greater water use efficiency like drip-irrigation.

C. Temporary Migration

Temporary migration is also called circular migration in agriculture. It includes seasonal migration, where workers undertake off-farm or non-farm activities for some part of the year, and returning back during harvest time. The temporary migration is the movement of labor from one agricultural area to another area, or across sectors. This also includes migration between and within urban and rural to ensure security in livelihood.

It is not much clear from the available literature to what extent climate change per se can be attributed as the primary factor in the decision making process of households engaged in agriculture on whether or not to migrate. But in case of adverse climate the livelihood of poor and marginal household families may be difficult. However, in such situation the temporary migration to the other agriculture or non-agriculture areas for the period of adverse condition may be an option of livelihood. The option of such types of migration for livelihood may be useful for extreme events in climate change.

D. Insurance

There may be much uncertainty about the agriculture production as successful crop yield depends on the availability of water and climate of the region. So the households engaged in agriculture may face problem for the livelihood in case of crop failure and inherently need insurance mechanisms to cope with income risks. The types of risks faced by the agricultural sector are outlined below (Moreddu 2000).

- Production risks due to weather variation, crop disease and various other causalities,
- Ecological risks from climate change, pollution, and natural resource management,
- Market risks, which depend on input and output price variability, and
- Regulatory or institutional risks due to state intervention in agriculture.

Furthermore, households with extremely low incomes may be at highly risk and will limits their financial ability and willingness to adopt new technologies that can maintain and enhance crop productivity. In such situation, the insurance will help farmers to reduce the financial risk when they adopt for

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

new technology or adaptation. The insurance may encourage the farmers to with stand in small climatic variations by reducing financial risk of livelihood in case of failure of the crops.

Long-Term Adaptations

Efforts are necessary to withstand and minimize the adverse impacts of short term climate variability and uneven water availability for agriculture. The measures will be necessary to reduce vulnerability to anticipated future impacts of climate change. So the combination of adaptations both at farm and policy level will be necessary for long term adaptation for future water related consequences scarcity due to climate change. Following paragraphs describes a range of adaptation options as most relevant in water availability and overall climate change.

The interaction of water for agriculture production is governed by climatic situation. However, given that warming is largely a concern of the future, long term adaptation must also be in the future. Kurukulasuriya and Rosenthal (2003) also reported that addressing climate change- a long term phenomena, should entail a comprehensive long term response strategy at the national or local level but will require a dynamic approach. Some of the important long term strategies for adaptation of availability of water for agriculture and climate change are discussed below.

A. Changing Crop Type and Location

The main purpose of changing the crop types or location of cultivation of crops is to cultivate stress resistant crops on its suitable location. The potential options include switching to more robust varieties that are better suited to the changing environment.

Agricultural analyses of future climates indicate also that crops will move poleward with warming (Mendelsohn and Neumann 1999). The extent of this migration depends upon the severity of the warming. This types of adaptation require a number of underlying prerequisites are in place. Obviously, the scope for shifting production to new lands, particularly in developing countries where, may be limited because of population pressures and the availability of cultivable land. There may be another constrain that farmers may not be willing and ability to move. Further, land use regulations on agricultural production are governed by country laws and may hinder such adaptations in some of the countries. In such situation, crop rotations that may not be optimal in interest of available water for agriculture production and a changed environment may be persisted. This may consequence in severe losses in the long term.

Appropriate land reform policies that establish or strengthen property rights in changing demand of water for agriculture need to be enforced. It is also necessary that appropriate measures that boost farmer's financial ability to undertake the necessary adaptation may be necessary. These financial measures may include improving access to credit and banking facilities in rural areas. Furthermore, investment in diffusion of access to sufficient and timely irrigation is important. Appropriate institutional support to promote the dissemination of knowledge through dedicated extension network may play important role in such situations.

There is good amount of debate in agriculture research that the new crops are equally (if not, more) profitable to the farmer. There is also serious concern that changing crop types will not automatically maintain previous levels of food production as well as or nutritional quality levels. While the national objective may be to grow crops that will fulfill food security with minimum water requirement.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

B. Development of New Technologies and Modernization

Agriculture research on the globe has crossed many milestones and has many success stories. Research and technological innovation in crop and animal productivity is important to achieve food security in changing environmental conditions. This will enable farmers to cope with various climatic conditions and may be fundamental to the growth and development of agriculture. There are two basic types of technological options (Smithers and Blay-Palmer 2001), important for agriculture viz. mechanical and biological. Mechanical innovations include irrigation, conservation tillage, and integrated drainage systems. On the other hand, biological options also have an important role in enabling cropping systems to adapt to a wide range of climatic conditions. Investment in crop breeding, the promotion of climate-resistant varieties that offer improved resistance to changing diseases and insects, breeding of heat- and drought-resistant crop varieties, the use of traditional varieties bred for storm and drought resistance, and investment in seed banks may be necessary for success in overcoming vulnerability to climate.

Further, advances in science and biotechnology offer much powerful tools that hold promise to overcome the challenges posed by scarcity of water resources and threats posed to the agricultural production. However, it is not very clear that how much role the advocacy of biotechnology will play as adaptation in climate change scenario. In addition to this the issue of affordability of new technology to poor farmers may be serious concern for effective climate change. Several innovative concepts and technologies like geographical information systems, software-based weather systems, low-cost and decentralized technologies, industrial symbiosis (Rao & Patil, 2015) and as well as innovative waste treatment with simultaneous resource conservation method have also been reported (Patil & Rao, 2015).

C. Improving Water Management

Availability of water is most important for successful agriculture production. Improved water resource management will be vital to sustaining crop productivity levels in the face of both climate variability and longer-term change. In areas that are currently dependent primarily on rain-fed agriculture, the conjunctive use of surface and ground water resources will play an increasingly important role in enabling farmers to adapt to fast changing climatic conditions. However, it is also clear that in the face of rising domestic and industrial demand, additional efforts are necessary to ensure efficient management of water resources. With climate change and variability increasing pressure on available water resources, improved water management is one of the most important long-term adaptation options that countries must pursue. According to recent estimates, irrigation efficiency in developing countries is extremely low. The average efficiency of irrigated agriculture in developing countries is very low.

Preserving water resources using suitable storage may play a crucial role in availability of water in changing climate. However, if the planning of water storage is not improved, it may likely that many investments may fail to deliver intended benefits. McCartney et al. (2013) reported that, national economies, highly dependent on rainfed agricultural production, are exceedingly vulnerable to both intra-annual and inter-annual fluctuations in rainfall and hydrology. In addition to this traditional adaptation techniques may also be effective to deal with shortages in water.

Apart from water storages there may be challenges with regard to water use and availability that also need to be overcome. Increased demand for water by municipal and industrial sectors may further become serious issue in future. Un-sustained and over exploited irrigation may lead to groundwater depletion, soil salinization and water-logging. In some regions, numerous challenges need to be overcome in order

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to increase water supply. As emphasized by Dinar (2000), these challenges include financial crises; low-cost recovery of the investment in the water system; the role of political parties, electoral systems and interest groups. Dinar argues for improved forecasting procedures, simulation models, and improved data monitoring systems. Other necessary preconditions include overcoming economic constraints. The improvements in irrigation and other high-efficiency water conservation technology require major, long-term and costly investments. Furthermore, undertaking requisite institutional reforms that hinder the pursuit of effective water resource management strategies may also be helpful. However, given the uncertainty surrounding forecasts of regional changes in precipitation, it has not yet been proven that making water adaptations in advance of climate changes is in fact very practical.

D. Permanent Migration of Labor

Encompasses permanent migration in the form of the movement of migrants into new economic areas. The possible reasons for migration may be possibly due to policies or permanent changes in their previous environment. The agriculture labor migration may be from poorer agricultural areas in one region to lowlands in other regions. Desanker (2002) stresses, long-lasting climate pressures, such as prolonged drought, which increase the vulnerability of migratory groups to climate change (by limiting the scope of areas to move to), can be disastrous. Short-term migrants may be forced into becoming more permanent migrants, resulting in dire consequences such as pressures on land and water resources.

The adaptations outlined in the above sections may not fully address the concerns of permanent labor migration with short term climate variability may not be adequate in the face of new and long lasting climate conditions. Reilly et al. (2003) reported that even insurance programs will not be sufficient if productivity of land becomes unviable and may in fact act as a deterrent to change despite market signals that indicate otherwise. If unmanaged or uncontrolled, large-scale migration of this type may have consequence in significant impacts on the environmental resource bases as well as indigenous societies.

In such complex situations, a clearly defined system of property rights and enforcement may be necessary to prevent potential stress. The establishment of an appropriate system of property rights both at the individual or community level may be part of the likely solution. Well placed training and extension services may be act as other solutions that would be needed based on the situations.

E. Adaptations Irrespective of the Temporal Dimension of Climate Impacts

Non-climatic parameters are also equally important for agriculture production on sustainable basis. Suitable policies aimed at growing the resiliency of the agriculture sector to other, including non-climatic factors may be necessary and may help in improving capacity to cope with both climate variability and climate change. Further, Smit and Olga (2001) emphasized on solving immediate concerns facing domestic agriculture sectors do not delay the formulation and implementation of efficient responses to promote long term sustainability issues.

Such effective adaptation may also depend considerably on primary local environmental, institutional, and socio-economic conditions. Both domestic, and regional cooperation in science, resource management, and development may be extremely important. Some of the major economic and institutional issues may likely to be beneficial irrespective of the nature of the climate change are as follows.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Investment and accumulation of capital.
- Reform of pricing schemes, development of open markets, and other reforms.
- Adoption of new technologies.

F. Promotion of Trade

Suitable market and appropriate return to the agriculture produce is the key to success for the farmers. Suitable market for agriculture produce is important for both buyers and consumers. Here suitable trade may play an important role during periods of variable climatic. There may be possibility that agricultural trade may moderate impacts by enabling farmers in regions less adversely affected to sell their produce in areas more severely affected by climate change. The role of trade policy may important because of repercussions on the prospects for adaptation. Further, regional and international trade may lead to improvements in access to international markets, which in turn may help a country diversify and reduce of risk of food security from water scarcity and climate change.

G. Extension Services

Extension services have played a key role in promoting agricultural productivity in developing countries. Their role in promoting various adaptations to climate change may be very important. Traditionally, extension services have generally been in the purview of services provided by government, given that agricultural research is typically a public good. However, private and non-governmental agencies or the formation of research cooperatives do play a significant role in some countries. Crucially, as Evenson (1997) notes, the economic contribution of extension services is governed by location-specific factors. In this regard, numerous programs have been found to be ineffective given the underperformance of agents, design limitations, and management failures. Overall, efficient, farmer friendly extension policies may coup farmer's efforts to maintain sustainable flow of agriculture production in uneven availability of water in changing climate.

H. Diversification of Income-Earning and Employment Opportunities

Seasonal effects and climatic uncertainty that characterize the agricultural sector effectively mean that diversification of income and employment opportunities may be an important adaptation strategy for households in the agriculture sector. In dryland areas, traditional practices to help cope with drought include the accrual of a surplus in a superior year, in the form of cash or assets (for example, cattle) for use in poorer years (Burton 2001). While measures such as crop storage, sales, and household savings can and do offer relief from temporary or seasonality effects, risk and market imperfections that abound in rural settings render diversification into off-farm opportunities necessary to reduce income instability (Alderman and Paxson 1992). Consequently, policies that provide the opportunities to pursue alternative livelihood options need to be encouraged.

I. Dissemination of Climate Data

A reason in literature frequently cited for not adapting in time to climatic impacts is the lack of reliable climate monitoring and forecasting data. Barnett (2001) argues that an increase in the availability of

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

information to understand the biophysical and social environment is necessary. The timely dissemination of climate forecasting information and early warning to farmers including information on risks can strengthen the ability of farmers to cope and optimize the management of hydrological variability and change. Monitoring data and indicators of change are also necessary across all sectors in society, not just policy makers. Along with information on risks, the information on suitable mitigation measures may be helpful to farmers.

J. Institutional Planning and Implementation

Insufficient institutional and decision making structures to support long-term planning in governments in developing countries has long been recognized to be a problem in pursuing general development objectives. At World Bank report underscored the finding that in some countries, such as Bangladesh, planning for climate change is not even mandatory, an outcome of planning agencies' being "formed not by law but by administrative resolution" (Kurukulasuriya and Rosenthal 2003). Long term institutional planning related to climatic variability and suitable implementations are important.

Mitigation

Mitigation is human intervention to reduce the extent of climate change. It includes strategies to reduce greenhouse gas sources and emissions, and enhancing greenhouse gas sinks. A number of mitigation strategies in the agriculture and forestry sectors have been identified as useful in achieving the goal of stabilization of atmospheric concentrations between 450-550 ppm CO_2. These include reduced deforestation and degradation of tropical forests (REDD), sustainable forest management (SFM) and forest restoration (FR), including afforestation and reforestation (A/R). In agriculture, they involve reduction of non-CO_2 gases through improved crop and livestock management and agroforestry practices, enhanced soil carbon sequestration in agricultural soils via reduced tillage and soil biomass restoration (Table 3).

Table 3. Mitigation potential in agriculture and forestry in 2030

Sr. No.	2030 Reductions	G tonnes CO_2 e yr^{-1}
1	Global	15-25
2	Agriculture	1.5-5.0
3	Methane, N_2O	0.3-1.5
4	Agroforestry	0.5-2
5	Agricultural soils	0.5-1.5
6	Forest	2.5-12
7	REDD	1-4
8	Sustainable forest management (SFM) SFM	1-5
9	Forest Restoration (FR)	0.5-3
10	Bioenergy	0.1-1.0
	Total	4-18

Global reductions in 2030 correspond to those needed to achieve stabilization of atmospheric concentrations between 450-550 ppm CO_2, under a mid-range IPCC SRES.

In case of long term sustainable availability of water for agriculture can be achieved by investing in wider best practices. These practices can include the following.

I. Reducing Emissions of Green House Gases

The greenhouse gases include CO_2, methane and nitrous oxide and keep green gases under the limit, by adopting the effective ways. The practices that will help to reduce Carbon dioxide (CO_2) levels may include land conversion, reduced deforestation, improved ways to manage wildfires and alternatives to the burning of crop residues. The Methane and Nitrous Oxide in the environment can be managed using practices like improved nutrition for ruminant livestock, efficient management of livestock waste, and efficient management of irrigation water on rice fields, efficient applications of nitrogen fertilizer on cultivated fields and reclamation of treated municipal wastewater for aquifer recharge and irrigation.

The mitigation practice may also include reduction of emissions from commercial fishing operations and more efficient energy use by forest dwellers, commercial agriculture and agro-industries.

II. Sequestering Carbon

Sequestering Carbon is fixing the excess of Carbon dioxide in to ecosystem. The some of the means for such sequestering CO_2 includes improved management of soil organic matter, conservation agriculture involving permanent organic soil cover with minimum mechanical soil disturbance and appropriate crop rotation. The Carbon sequestering can also be achieved by reducing use of fossil fuel, improving management of pastures and sustainable grazing practices on natural grasslands. In the agriculture introduction of integrated agro-forestry systems, proper use of degraded and marginal lands and planting of carbon sink trees will also help in sequestering Carbon in the ecosystem.

FUTURE RESEARCH DIRECTIONS

The increased demand for other uses coupled with recurrent drought and climatic changes in countries of limited water resources, is producing unprecedented pressure for reducing the share of fresh water used in irrigation. Many countries give priority of water allocation to the domestic sector followed by tourism and industry, and what is left is allocated to agriculture. At the same time that agriculture is asked to give water to other uses, the increasing population demand requires increase in food production. This creates a conflict that may be resolved and by examining different options of water uses for sustainable agriculture. Increasing the efficient use of water is a key non-structural approach to water resources management. The agriculture water use efficiency and water productivity is very important as they are largely inefficient in many countries due to poor distribution systems and excess irrigation. The average agricultural water use efficiency in developing countries is very poor. Water planners and decision makers as well as researchers are facing with difficulties and challenges. Some options for

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

such constraint may be helpful to sustain agriculture in changing climate in the various regions on the globe. The probable solution to this conflict requires greater understanding and systematic research. The future agriculture production depends on water resources and their allocation and management in agriculture. The domains of future research may include: improving water use efficiency, reducing crop consumption of water, irrigation with reclaimed water, practicing deficit irrigation and irrigation with desalinated water. The research vision for the next few years could include the few set of actions *viz.* have more efficient use and allocation for water use in irrigation; improved water productivity by introduction of new management measures such as deficit irrigation; and introduction of high yielding low water demanding varieties.

Desalination of brackish and sea water can offer limitless fresh water that can be used for agriculture. There is a need to find cheap methods of desalination such as the use of solar and renewable energy. Therefore, researchers should consider these needs in setting up their research priorities.

CONCLUSION

The world's climate is changing, and the changes will have an enormous impact on people, ecosystems, and energy use on the globe. There is threat that climate change will impact food availability, access, and utilization due to change in the climatic parameters like temperature, precipitation, CO_2.etc. The change in environmental parameters may change availability of water for agriculture. The demand of growing population for food security is crucial and uneven availability of water due to climate change will exaggerate the problem to greater extent. The impact of non-availability of sufficient and timely water for agriculture will lead to more poverty and degradation of land resources. Apart from this there is also increasing requirement of water for urban and industries. So increasing agriculture production, sharing water for nonagricultural uses and uneven availability of water due to climate change may exaggerate the problem to the greater extent in the future. Though researchers and water managers are trying hard for the solution and the complexity of the issue will be more serious in coming decades.

The aggregate impact of climate change on the water resources of the globe is not fully understood. The changing climate is playing central role in availability of water for agriculture production and individual climatic parameters and their interactions are equally important. There is an emerging consensus that changes in water resources can have detrimental impacts on the food security, in the absence of adaptation. Most of the impacts are not easy to quantify because they depend on a range of assumptions. The available quantitative scientific studies suggest that the wet regions will be more wet and dry will be more dry in coming decades which is serious concern for food security. This may reduce crop yields and the land suitable for agricultural production or change in cropping pattern and planting and harvesting schedules. Institutional development will have to play a greater role through polices supported by efficient extension programmes for mitigation of the future impact of climate change. Overall, the climate change may be having positive as well as negative effect on the water resources, agriculture production and food security of the world. This seems a huge challenge on the globe and require proper mitigations and adaptations measures.

KEY TERMS AND DEFINITIONS

Adaptation: Adaptation is the process by which living organism changes to become better suited to survive in their environment. Adaptation can be a physical or genetic trait that helps an organism to be better suited to survive in the environment.

Agricultural Productivity: Agricultural productivity is the ratio of agricultural outputs to agricultural inputs. The agriculture inputs may include water, chemicals, fertilizers etc. used to grow crops to achieve desired yield as output.

Climate: It can be described as average temperature and precipitation over a period of time. Climate can be defined as an area's long-term weather patterns. The useful elements for describing climate include the type and the timing of precipitation, amount of sunshine, average wind speeds and directions, number of days above freezing, weather extremes, and local geography.

Climate Change: Climate change refers to any significant change in the measures of climate parameters lasting for an extended period of time. Climate change includes major changes in temperature, precipitation, or wind patterns, among other effects, that prevailing in a region over several decades or longer.

Mitigation: Mitigation in the context of climate change is an intervention intended to reduce adverse human influence on the climate system which includes strategies to reduce greenhouse gas sources, emissions and enhance greenhouse gas sinks.

Resilience: Resilience is the capacity of organism or system to withstand stress and catastrophe. In case of climate change the capacity of crop and livestock to withstand and sustain in the changing environment is the resilience.

Water Use Efficiency (WUE): Water use efficiency is the amount of water uptake by the plant and the amount of water used for metabolism and transpiration by the plant. WUE is simply ratio of water used in plant metabolism to water lost by the plant through transpiration.

ABSTRACT

The study investigates the impact of nonfarm income (NFI) on agricultural income and investment using the Pakistan Social and Living Measurement survey data for the year 2005-06. Results show that NFI negatively affects agricultural income and investment whenever it is statistically significant; and these effects are not same across the four provinces of Pakistan. The one to one comparison between the four provinces of the country shows that the effects of NFI on agricultural income and investment differ across provinces. The policy implication is that as compared to other sectors of the economy, agriculture generates low returns and consequently NFI is invested in other more productive sectors of the economy.

INTRODUCTION

Not all people receive their earnings from a single source, hold their wealth as one asset and employ their labor in one activity. Multiple motives encourage families and individuals to diversify their assets and income generating activities (Barett and Reardon, 2001). Participating in the nonfarm income (NFI) generating activities are one of the ways for rural households to diversify their earning sources and increase their gross income. In return, these earnings affect farm productivity by enhancing investment in farming. Studies show that NFI has positive effects on farm investment (Heartz, 2009) and increase expenditure on inputs (Kilic et al.,2009; Oseni & Winters, 2009; Pfeiffer et al., 2009). Consequently, farm productivity increases (Huang et al., 2009) and poverty reduces (Kijima et al., 2006; Ruben & Van Den Berg, 2001). NFI can also finance longer term on-farm capital investment such as construction of irrigation channels, purchase of machinery which can positively affect farm productivity (Barett and Reardon, 2001). Little et al. (2006) found that farm households diversify their earning sources to improve insurance against the risks of agro-climatic natural shocks, help overcome credit constraints and stabilize aggregate income flows. However, contrary to studies cited above, Pfeiffer et al. (2009) show that NFI negatively affects crop production, but positively effect the purchase of inputs. Hence, NFI has divergent effects on production and inputs use.It is the focus of this research in Pakistan, where agriculture is the second largest sector of country's economy contributing 21 percent to the GDP and provides livelihoods to 40 percent of the population.

It is generally believed that only poor households may diversify their earning sources to increase their aggregate income. However, this may not be true. Rich rural households diversify their earning sources to further maximize their profit while poor diversify to minimize risk, stabilize income and secure food access (Kilic et al., 2009). Haggblade et al. (2010) and Davis et al. (2007) identified the growth linkages between the agriculture sector and rural nonfarm employment. These linkages are: 1) the increase in income, increasing effective consumption of nonfarm products, affecting nonfarm employment; 2) the effect of demand-induced changes on downstream production linkages from processing and distribution; and 3) the changes in input-demand and its effect on production. This study focuses on the third linkage that is the nonfarm-income-induced demand for agricultural inputs and its effect on agricultural productivity. The selection is motivated by our lack of knowledge of the effect of NFI on agriculture sector in Pakistan. In an emerging economy like that of Pakistan, it is important to understand that why some farmer perform better than others? Does NFI create positive spillover effects on agriculture and livestock investment and consequently income? The four provinces of the country are agriculturally very different. Punjab and Sindh produce cash crops like cotton, rice and sugarcane while Baluchistan and Khyber Pakhtunkhwa have small natural resource base supporting livestock keeping. These differences raise the question that whether NFI have divergent effects on agriculture and livestock income and ivestment across these regions. This study estimates the effect of NFI on expenditure made on farm inputs and consequently farm income in Pakistan. Alternatively, the study investigates whether farmers who diversify their income have higher farm incomes as compared to other producers.

The study makes a three important contributions to the existing literature. First, it develops empirical models illustrating the effect of NFI on agricultural income and expenditures on crops and livestock raising in the country. Second, these models are used to test specific hypotheses about the effect of NFI on agricultural income and expenditures on crops and livestock raising across the four provinces of Pakistan. It is also important to mention that understanding behavior of agricultural households with respect to income and investment is important to analyze the effects of government interventions (e.g.,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

pricing policies, investment projects) and external changes in market conditions on the rural economy and livelihoods. Such knowledge becomes more important for a country like Pakistan where agriculture is the second largest sector of the economy. Third, the study provides empirical evidence on the effect of NFI on agricultural income and expenditures on crops and livestock raising which can help in developing the relevant policies for creating and promoting opportunities of earning NFI.

The next section presents the empirical model used to estimate the effect of NFI on agricultural income and investment, followed by discussion about data used in the analysis in section three. The estimated results are presented and discussed in section four, followed by conclusions given in section five.

The Agricultural Sector in Pakistan

Pakistan has two seasons, namely the '*kharif*' and '*rabi*'. *Kharif* begins in April-June and ends during October-December when *rabi* begins which ends in April-May. *Kharif* crops include rice, sugarcane, cotton, maize, mong and mash while *rabi* crops include wheat, gram, lentil, tobacco, rapeseed, barley and mustard. The agriculture sector is divided into crops, livestock, forestry and fishing sub-sectors. Crops sector is further divided into important crops, other crops and cotton ginning. Important crop sector includes cotton, sugarcane, wheat, rice and maize while the other crop sector consists of lentils, peas, potatoes, onions and chilies. The Agriculture sector accounts for 20.9 percent of the country's Gross Domestic Product (GDP) in 2015. The crop sector accounts for 43.7 percent of the 20.9 percent agricultural sector contributions to a country's GDP in 2015. In the crop sector, important crop sub-sector contributes 64.6 percent to the value added in the crops sector, followed by other crops (28.1%) and cotton ginning (7.3%). The livestock sector contributes 11.8 percent to the country's GDP and 56.3 percent to the agricultural GDP (GoP, 2011). The collective contribution of forestry and fishing to a country's GDP is less than one percent.

The Empirical Model

Consider an agrarian household endowed with land, capital, and inputs. The household faces decision variables of consumption, investment, and purchase of inputs for production. The household is assumed to maximize profit as producer and utility as a consumer. In case of capital constraint, the household can get any amount of credit from a perfect financial market. However, given the imperfect financial market in a developing country like Pakistan, household faces credit constraint. In such a case, household production and consumption decisions are inseparable (Taylor and Martin, 2001; de Janvry and Sadoulet, 2003). Hence, the household sacrifices its leisure time and participate in the NFI generating activities to earn more income and overcome the credit constraint. The NFI is then available for investment in the crops and livestock sectors. Consequently, agricultural (collectively crops and livestock) investment and income are expected to increase. Our specification of the econometric model is based on Kilic et al. (2009), and Osenia and Winters (2009). The empirical model postulates that the variable of interest (Y_i)in thousand rupees[1] is the function of socioeconomic variables, NFI of household i ($NFIii$) in thousand rupees and regional dummies (RD_i). Regional dummies (RDi) represent the four provinces of Pakistan such that RD_{i1}. represents Punjab, RD_{i2} represents Sind, RD_{i3} represents Khyber Pakhtunkhwa and RD_{i4} represents Baluchistan. The variable of interest includes agricultural income and expenditure made on crops production and livestock keeping. In the empirical model, farm charac-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

teristics such as land, poverty status (Evans and Nagau, 1991), education (Ellis, 2000), family size and marital status of the respondents are included. Marital status and family size are included in the model because these factors directly affect the supply of labor to NFI generating activities. Larger families can release more labor from farm production towards NFI generating activities.

$$\begin{aligned} Y_i = {} & \alpha_0 + \alpha_1 lNFI_i + \alpha_2 RD_{i1} + \alpha_3 RD_{i2} + \alpha_4 RD_{i3} + \alpha_5 RD_{i3} + \\ & \alpha_6 Poor_i + \alpha_7 lAge_i + \alpha_8 lFSize_i + \alpha_9 lFArea_i + \alpha_{10} Urban_i + \\ & \alpha_{11} lExpc_i + \alpha_{12} lExpl_i + \alpha_{13} Married_i + \alpha_{14} Literate_i + \varepsilon_i \end{aligned} \quad (1)$$

where i indexes households, Age_i represents age of the household head in years, $FSize_i$ is family size measured as number of family members, $FArea_i$ is farm area in hectares, $Urban_i$ is dummy, one representing urban areas zero otherwise, $Expc_i$ represents expenditure on crops in thousand rupees, $Expl_i$ is expenditure on livestock in thousand rupees, $Married_i$ is dummy, one for married household head zero otherwise, *Literatei* is a dummy, one for literate households zero otherwise, ε_i represents the random error assumed to be distributed normally with mean zero and variance σ^2, l stands for logarithm and α_i are the parameters to be estimated. The parameter α_1 indicates the effect of NFI (in thousand rupees) on the variable of interest in Pakistan. It is interpreted as the elasticity of NFI with respected to either agricultural income or farm investment.

Following Haq and Meilke (2010), and in order to compare the effects of NFI_i on Y_i across the provinces of Pakistan, regional (provincial) slope-shifters of NFI_i. were derived using the following relationship. These slopes allow testing regional specific hypotheses about the effect of NFI_i on variable of interest.

$$NFI_{iP} = Y_i * RD_{i1}\ NFI_{iS} = Y_i * RD_{i2} \quad (2)$$

$$NFI_{iK} = Y_i * RD_{i3}\ NFI_{iB} = Y_i * RD_{i4}$$

where NFI_{iP} represents nonfarm income of household i in Punjab, NFI_{iS} represents nonfarm income of household i in Sind, NFI_{iK} represents nonfarm income of household i in KP and NFI_{iB} represents nonfarm income of household i in Baluchistan. Augmenting equation (1) with the regional NFI_i shifters yields equation (3).

$$\begin{aligned} Y_i = {} & \delta_0 + \delta_1 lNFI_{ip} + \delta_2 lNFI_{iS} + \delta_3 lNFI_{iK} + \delta_4 lNFI_{iB} + \\ & \delta_5 Poor_i + \delta_6 lAge_i + \delta_7 lFSize_i + \delta_8 lFArea_i + \delta_9 Urban_i + \\ & \delta_{10} lExpc_i + \delta_{11} lExpl_i + \delta_{12} Married_i + \delta_{13} Literate_i + \varepsilon_i \end{aligned} \quad (3)$$

Consider Y_i Y_i to be agricultural income than the following hypotheses are tested using equation (3).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

H_1: Nonfarm income does not determine agricultural income in the provinces of Pakistan.
H_2: The effect of NFI on agricultural income is similar across the four provinces of the country.

Similarly other hypotheses are tested using the same equation, results of which are compiled in tables 5 and 6.

DATA

This study uses the cross-sectional data collected under the Pakistan Social and Living Measurement Survey (PSLM) for the year 2005-06. The survey was carried in all the four provinces of the country. The survey is conducted by Federal Bauru of Statistics (FBS) bi-annually. FBS has developed its own sampling frame for urban and rural areas. Each frame is split into enumeration blocks. Each enumeration block consists of 200 to 250 households. Each block is divided into lower, middle and high income groups. FBS obtains list of villages from the Population Census Organization of the country. Urban domain consists of big cities like Islamabad, Lahore, Gujranwala, Faisalabad, Rawalpindi, Multan etc. Stratum from urban areas also classified according to income levels. After excluding population of the large sized cities, the remaining urban population in each defunct Division in all the provinces has been grouped together to form a stratum. Each district in the provinces are grouped to constitute a stratum, whereas defunct administrative division has been treated as stratum in Baluchistan province.

FBS determined a sample size of 15512 households in the country. This sample size is obtained from 1113 sample enumeration blocks. Our sample includes only those households who cultivate land. In this way the sample reduces to 3704 households. Detail of the sample frame across the four provinces is given in Table 1.

RESULTS AND DISCUSSION

This first part presents the effect of NFI on agricultural income and investment (Table 2), followed by similar effects estimated for crops (Table 3) and livestock (Table 4) sectors. Each table consists of four models, two each for expenditure and income both distinguished by the inclusion/exclusion of regional dummies.

Table 1. Distribution of sample across provinces

Province	Count	Percent
Punjab	1631.0	44.0
Sindh	844.0	22.8
NWFP	796.0	21.5
Balochistan	433.0	11.7
Pakistan	3704.0	100.0

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In case of agricultural income and investment, results are compiled in table 2. Model-1 shows the effect of NFI on agricultural income while Model-2 shows the same effect for the four provinces of Pakistan. Model-3 and 4 shows the effect of NFI on farm investment in the country and across the four provinces respectively. Results show that all the estimated models fit the data as well as the coefficient of determination ranges from 30.9% for model-4 to 72.8 for model-1. F-statistics show that all the estimated models are statistically significant, indicating that the hypotheses that the coefficients of regression models except the intercept are zero, is rejected at the 0.01 level of significance.

Table 2 further shows that as compared to poor households, non-poor households invest more in agricultural production and generate more agricultural income. Non-poor invest 50.7[2] percent of agricultural production and generate 18.2 percent more agricultural incomes, keeping other variables constant. However, with the inclusion of provincial slope shifters in the model (Model-1 and 3), this effect fades away. Age of the household head does not statistically significantly affect agricultural income and farm investment. Family size is statistically significant determinant when NFI provincial slope shifters are included in the model (Model-2). The effect of farm area on agricultural income and farm investment is statistically significant, but inelastic implying that increase in the farm area increases investment cost more, but yields proportionately less income. Its coefficient in model-4 shows that a one percent increase in the farm area increases farm investment by 0.45 percent, keeping other variables constant. However, its effect on farm investment is high as compared to its effect on agricultural income. Households located in the urban areas invest 37.6 percent less (model-3) and generate 28.7 percent more income. The effect of marriage and literacy on agricultural income as well as investment is statistically insignificant in all the models. Further, the effect of NFI on agricultural income is statistically not significant (Model-1), however, it is an important determinant of the farm investment (Model-3). The regional dummies show that as compared to Baluchistan, agricultural income is high by 41.2 percent in Sind and 22.4 percent in Khyber Pakhtunkhwa. Similarly, as compared to Baluchistan, production costs are higher by 107.5 percent in Punjab, 145.5 percent in Sind and lower by 38 percent in Khyber Pakhtunkhwa. Hence, production costs and agricultural income vary across the provinces.

The table also shows that the effect of Niño agricultural income in Punjab and Khyber Pakhtunkhwa (KP) is statistically significant while its effect on agricultural investment is also statistically significant and negative in KP and Baluchistan. The estimated results show that a ten percent increase in NFI decreases agricultural income by 0.4 percent in Punjab and by 0.2 percent in Khyber Pakhtunkhwa. Similarly, a ten farm increase in nonfarm in Khyber Pakhtunkhwa and Baluchistan decreases farm investment by 2.5 and 2.8 percent, respectively. The collective implications of these results are that returns in agriculture sector as compared to other sectors of the economy are low. Further, NFI may not be readily available to the farm sector for investment due to many reasons including the consumption, social and financial requirements of rural households. Also, the effect of the NFI on farm income and investment may be different not only across the crops and livestock sectors but also across time and regions. Hence, farm households do not invest the additional income in agriculture production and consequently its effect on agricultural income is negative.

Agricultural income and investment are then split into crops and livestock income and investments and the effect of the NFI is separately estimated on these sectors. Estimated results for the crops and livestock sectors are given in tables 3 and 4 respectively. However, separately estimating the models for crops and livestock sectors did not change the effect of most of the variables on both income and investment. For both the sectors (Tables 3 and 4), the effect of NFI on the variable of choice is negative when statistically significant with the exception of livestock sector in Balochistan (Table 4). In Balochistan,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a ten percent increase in the NFI marginally (0.8%) increases investment in livestock sector. Hence, on an overall, the direction of the results presented in table 2 hold for both crops and livestock sectors.

The estimated parameters of NFI are then used to estimate a number of hypotheses about agricultural income and investment and results are compiled in Tables 5 and 6, respectively.

Results show that NFI is an important determinant of both agricultural investments (Table 5) and income (Table 6). The impact of NFI on agricultural investment (Table 5) and income (table 6) differs across the four provinces of the country. Its effect on agricultural income between Punjab and Sindh, Punjab and KP, Sind and KP and Sind and Baluchistan are statistically different. Similarly, the effect of NFI on agricultural investment is also statistically significant (Table 6). Its effect on agricultural investment between Punjab and KP, Punjab and Baluchistan and Sind and KP and Sind and Baluchistan are statistically different.

CONCLUSION

Nonfarm income can be used to timely purchase crops and livestock inputs and undertake scheduled farm production and harvesting activities. However, there is no evidence suggesting that NFI has positive effects on agricultural income and investment in Pakistan. This study underscores the existing literature by providing the evidence on the effect of NFI on agricultural productivity in Pakistan using the Pakistan Social and Living Measurement survey.

The econometric analysis investigating the effect of NFI on agricultural income and expenditure shows that nonfarm is an important determinant of agricultural income. The effect of NFI on agricultural income is not same across the four provinces of Pakistan. Its effect on agricultural income between Punjab and Sindh, Punjab and KP, Sind and KP and Sind and Baluchistan are statistically different. Similarly, the effect of NFI on agricultural investment is also statistically significant. Its effect on agricultural investment between Punjab and KP, Punjab and Baluchistan and Sind and KP and Sind and Baluchistan are statistically different.

The authors highlighted that if there are negative linkages between NFI and agricultural production, then understanding the nature of these linkages could prove useful in designing programs to facilitate agricultural households' adjustment to rural economic change.

LIMITATIONS AND FUTURE DIRECTION

The study uses PSLM data in the analysis. PSLM data provides enterprise specific output data but does not provide similar data for inputs. Hence, using PSLM data it is not possible to determine the effect of NFI on major crops raised in different agro-ecological zones of the country. Hence, an investigation of the effect of NFI on major crops in different agro-geographical regions of the country is required. Further, since agriculture is one of the biggest sectors of the economy and is a source of livelihood for about one-half of the population, it is important to understand the effect of NFI on poverty in the country. This study also ignored the effect of NFI on variability and distribution of rural household's income.

Chapter 59
Social and Environmental Impacts on Agricultural Development

Frances Bekele
The University of the West Indies – St. Augustine, Trinidad and Tobago

Isaac Bekele
The University of the West Indies – St. Augustine, Trinidad and Tobago

ABSTRACT

Addressing environmental and social impacts on agricultural development and food security is a global priority since increased food production of 60-70% is estimated to be required by 2050 to feed the growing world population. In developing nations, the situation is more acute since fewer social, technological and financial resources are available to combat climate change, which is expected to have negative effects on agricultural production, and there are other constraints to achieving food security. This chapter explores the social and environmental issues affecting agricultural production facing farmers and other agricultural practitioners, policy makers, institutions and stakeholders in the developing world. It will also address how progress in research in emerging economies can be put to maximum benefit in the face of these existing social and environmental challenges. A cohesive strategy to address these challenges is presented.

INTRODUCTION

The world's population is expected to increase to 9 billion by 2050 (Hubert, Rosegrant, Van Boekel & Ortiz, 2010), and it is estimated that a 60-70% global increase in food production is needed to feed this growing population (Consultative Group for International Agricultural Research (CGIAR), 2015; FAO, 2007, 2014; Mba, Guimaraes, & Ghosh, 2012). Currently, approximately 2 billion persons are food insecure since they do not meet one or several of the Food and Agriculture Organisation's (FAO's) dimensions of food security (access to adequate food, availability and utilization of nutritious food and stable supply (Hubert et al., 2010; Wheeler & von Braun, 2013)). Furthermore, 805 million persons did

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

not have access to sufficient food during 2012-2014 (Maggio, Van Criekinge, & Malingreau, 2015). Food availability must increase to meet demand by 100% in developing countries (CGIAR, 2015). This can be achieved through increasing production as well as reducing losses (food waste). Improving agriculture[1] to meet the Millennium Development Goals[2] of the United Nations, which include halving extreme poverty and hunger by 2015 and eliminating it by 2030 (under the sustainable development agenda), requires optimisation of agricultural practices and systems, and dealing effectively with technological, social, environmental as well as economic issues that influence the sustainability of agricultural production. The United Nations Framework Convention on Climate change (UNFCCC) (2007) described the developing nations as most vulnerable to climate change impacts that are expected to have negative effects on agricultural production and food security, as described by the International Food Policy Research Institute (IFPRI, 2009). This is attributed to the limited social, technological and financial resources available to address climate change in these countries.

Currently, sustainable food security and agricultural development are constrained globally by degradation and loss of agricultural land, the loss of biodiversity, depletion of water and other resources and pollution (Chaudhury, Vervoort, Kristjanson, Ericksen, & Ainslie, 2103; Sonnino, Moragues Faus, & Maggio, 2014). These factors are exacerbated by the negative impacts of climate change and may also contribute to climate change.

This chapter explores the social and environmental issues facing agricultural practitioners (producers and entrepreneurs alike) in the developing world, who are striving to contribute to food security in their communities and, by extension, the world. It will also address how the progress in research in emerging economies can be put to maximum benefit in the face of existing social and environmental challenges in developing nations, as described by Ejeta (2009).

Heat stress could affect developing countries by 2030 (Inter-Governmental Panel on Climate Change (IPCC), 2007, 2013). Expenditure of USD 200 and 250 billion a year may be required to address negative impacts of climate change in developing countries (Peterson, 2011). These impacts can significantly reduce sustainability of livelihoods and the well-being of citizens in developing nations (Noble et al., 2014).

A multi-sector approach is advocated to deal with the challenges and potential impact of social and environmental factors such as climate change on food security. The proposed model encompasses the role of farmers, entrepreneurs, social policy makers, governments, the private sector, scientists and organisations in a cohesive strategy. The role of education and extension in preparing for the impacts of climate change, as described by Bekele and Ganpat (2014) in the context of small island developing states (SIDS), is also discussed.

In order to illustrate the current situation, constraints and putative solutions to social and environmental impacts on agricultural development and food security in developing countries, several staple crops in Africa, Latin America and the Caribbean (LAC) and the commodity, cocoa, are highlighted in this chapter.

CURRENT STATUS OF AGRICULTURAL DEVELOPMENT AND FOOD SECURITY IN DEVELOPING NATIONS

1. Africa

In Africa, the agriculture sector employs 60% of the total population, contributes 20% to the gross domestic product (GDP) and earns more than 10% of export revenues (Sasson, 2102). It is expected that access to adequate and secure food would be a priority in Africa. However, in 2010, the number of food insecure persons in Sub-Saharan Africa was estimated at 239 million, and in North Africa it was 37 million (Sasson, 2012). The main cause of food insecurity in Africa was identified as insufficient food production (Beddington et al., 2012; Sasson, 2012). Soaring world food prices and rural migration have exacerbated the situation, and the impacts of climate change could be detrimental. High food prices have resulted in a significant percentage of the African population spending more than half their income on food. There have been recurrent droughts in the Horn of Africa since 2009 as well as a history of famines due to drought. Mba et al. (2012) described Africa as one of the most vulnerable continents to climate change and variability. The expected decrease in the length of the growing seasons of African crops (Thornton & Herrero, 2015) will result in the further loss of production in marginal agriculture.

Crop yields in Africa can decrease by as much as 50% by 2020 due to climate change, and this could result in lower calorific intake by humans (by as much as 500 calories per capita in 2050, a 21% decline) (Toulmin, 2009). Jarvis, Ramirez-Villegas, Campo, and Navarro-Racines (2012) found that while cassava is likely be affected positively by climate change in many areas of Africa (−3.7% to +17.5% changes in climate suitability across the continent), other major food staples in Africa are expected to face negative impacts, with the most significant predicted for beans ($-16\% \pm 8.8$), potato (-14.7 ± 8.2), banana ($-2.5\% \pm 4.9$), and sorghum ($-2.66\% \pm 6.45$). For resource-poor farmers in developing countries such as Africa, the use of fertilizers that could improve plant vigour, root growth and access to soil moisture, and irrigation to combat drought may not be feasible options to address climate change (Beebe et al., 2011).

Mixed farming (crop-livestock) systems form the mainstay of African agriculture and have certain benefits (Thornton & Herrero, 2015). The adaptation potential of these systems must be examined in the face of climate change since they are complex. Furthermore, there is very little data currently available on putative climate change impacts on these systems.

2. Latin America and the Caribbean

In Latin America and the Caribbean (LAC), approximately 15.9% of the labour force is directly involved in agriculture (Andersen et al., 2014). LAC's agricultural market share increased from 9.5% in 1980 to 18.1% in 2010 (Flachsbarth et al., 2015). The largest agricultural sectors in LAC are based on livestock, feedstuff and biofuel crops (Flachsbarth et al., 2015).

The contribution of agriculture to overall GDP ranges from 3.1% in Mexico to more than 5.5% in Brazil and to 7.8% in Peru (Andersen et al., 2014). From 1961 to 2007, LAC had the highest growth rate in agricultural productivity among developing regions (1.9%) (Ludena, 2010). The LAC countries with the highest land availability, such as Brazil, Argentina, Chile, Colombia, Mexico and Venezuela, have the most significant agricultural production (Ludena, 2010). Caribbean countries experienced limited growth by comparison (0.5%) (Ludena, 2010). Most of that growth occurred in the livestock sector,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

especially for non-ruminants (pigs and poultry). The most valuable agricultural export products from LAC currently are soybeans and cane sugar (Flachsbarth et al., 2015).

Wickham (1992) underscored the need for further development in vegetable production in the Caribbean to foster self-sufficiency in this area. Priority areas identified were germplasm enrichment and enhancement, selection of superior cultivars, development of more efficient production systems (including disease and pest management) and application of post-harvest technologies to promote the shelf-life of vegetables. Several other issues related to agricultural development and food security have been identified as requiring attention in LAC. These include improved partnerships among public sector, agencies, research institutions and the private sector to deliver food production programmes and transfer post-harvest and other technologies to farmers to assure food quality and availability (Roberts, Ganpat, Narine, Heinert, & Rodriguez, 2015). Farmer training through extension services is essential.

Climate change can also adversely affect crop production in LAC. Andersen et al. (2014) modelled the impact of climate change in the major agricultural producing countries in LAC, *viz.*, Brazil, Peru and Mexico. They projected that in Brazil, the effect on soybean production could be of the magnitude of –0.5 and +0.3% per annum. In Mexico, maize is the main agricultural product and accounts for 14 to 22% of the regional agricultural GDP. A decrease of 0.3% per annum was predicted for this crop. In Peru, the production of potatoes was forecasted to change by –0.6 to +0.2%.

Jarvis et al. (2008) predicted reductions in rice yields in Latin America by the 2020s, but increases in soybean production due to possible increases in carbon emissions. They also forecasted:

- Reduced acreage of land available for coffee production in Brazil,
- Lower coffee production in Mexico,
- Salinization and desertification of agricultural lands in drier areas of Latin America, and
- Probable increased incidence of the coffee leaf miner (*Perileucoptera coffeella*) and the nematode *Meloidogyne incognita* in Brazilian coffee-growing areas.

In addition, the risk of *Fusarium* head blight in wheat may increase under climate change in southern Brazil and Uruguay (Fernandes et al., 2004).

Overall, the combined impacts of climate change are estimated to amount to less than 1% of household incomes during the next 40 years in Brazil, Peru and Mexico (Andersen et al., 2014). The negative impacts on agricultural production in these countries were forecasted to be somewhat balanced by increased commodity prices. This was based on the premise that any large increases in the global prices of agricultural products, caused by climate change, will tend to benefit these agricultural producers of the respective commodities. However, for the land-constrained Caribbean countries, any further reduction in agricultural productivity will restrict the likelihood of achieving food security and poverty reduction. These countries are currently mainly net food importers. The Windward Islands have suffered significantly with the removal of the European Union preferential trade tariffs for banana imports. According to Ganpat and Isaac (2014) and Hutchinson et al. (2013), these SIDS are very vulnerable to the impact of climate change.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ENVIRONMENTAL ISSUES CRITICAL TO AGRICULTURAL DEVELOPMENT AND FOOD SECURITY

The following are some of the pertinent environmental issues to be considered with regard to agricultural development and food security in developing nations:

- Environmental impacts on production, productivity and product quality;
  - Impacts of climate change on agriculture and post-harvest production;
- Ensuring a reliable supply of produce or commodity under climate change;
- Use of superior (in terms of yield/productivity, vigour and pest and disease resistance) and climate-smart crop varieties;
- Improving energy efficiency of crop and livestock production (reduction in carbon emissions and prudent use of energy):
  - Application of eco-friendly sustainable practices such as organic fertilisation and pruning of crops;
  - Choosing the most efficient crop production system for specific crops and environments (such as terrains on steep slopes and multi-cropping on impoverished soils (Bekele & Ganpat, 2014)); and
- Monitoring land conversion/biodiversity losses.

Climate-Change Impacts on Agricultural Development and Food Security

According to FAO (2007), climate change impacts can be classified into two groups, *viz.*, biophysical impacts:

- Physiological effects on crops, forests and livestock (quantity, quality) and availability of fodder and pastures;
- Changes in land, soil and water resources (quantity, quality);
- Increased weed and pest challenges;
- Shifts in spatial and temporal distribution of impacts;
- Sea level rise, changes to ocean salinity and
- Sea temperature rise causing fish to inhabit different ranges.

and socio-economic impacts:

- Decline in yields and production;
- Reduced GDP from agriculture;
- Fluctuations in world market prices;
- Changes in geographical distribution of trade regimes;
- Increased number of people at risk of hunger and food insecurity and
- Migration and civil unrest (increased crime).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Climate Change Impacts on Crop Production

Global

Global warming and the El Niño effect, with the attendant drought, floods, increased temperature of the atmosphere and oceans and salinity and shifts in weather patterns, have the capacity to significantly reduce yields of food crops (refer to Figure 1) including staples such as rice, wheat, corn and barley (Beddington et al., 2012; Rosegrant, 2011). The potential impacts in small island developing states (SIDS) have been discussed by Roberts and Rodriguez (2014). The situation is compounded by the need to produce bio-fuels to reduce the carbon footprint of nations and meet the increasing demand for energy/fuel. This implies competition for food crops with biomass attributes favoured for biofuel production. Crop production will also be constrained by the spread of invasive species such as pests and fungi that may proliferate under altered climatic conditions (Leishman & Gallagher, 2015). It has been reported that even a 2-degree change in temperature over time can affect agricultural productivity adversely in the absence of adaptation (Ramirez-Villegas & Thornton, 2015; Wheeler & von Braun, 2013).

Figure 1. The effects of climate change on agricultural production

In Africa

In a Working Paper of the CGIAR Research Program on *Climate Change, Agriculture and Food Security* (CCAFS), Ramirez-Villegas and Thornton (2015) have provided a detailed overview of the potential (based on published studies) and projected (based on crop model simulations) effects of climate change (extreme and changing weather conditions) on the production of maize, common bean, sorghum, cassava, yam, pearl millet, groundnut, banana and coffee in rainfed Africa. Projections were analysed and it was concluded that climate change affects crops and regions differently in Africa. For instance, in the Sahel, it was predicted that some crops may no longer be suitable for cultivation and a shift to drought and heat-resistant varieties of crops such as cassava (Jarvis et al., 2012), yams and sorghum may be a necessary adaptation measure to consider. By comparison, the production of maize in South Africa may be reduced by 30% (Sasson, 2012), but northern South Africa, Botswana, Namibia, Zimbabwe and Lesotho are not expected to experience any significant change in maize production (Ramirez-Villegas & Thornton, 2015).

The yield of common bean is very responsive to climate and the areas suitable for its cultivation in Africa can be reduced by unfavourable climatic conditions (Ramirez-Villegas & Thornton, 2015). The same applies for maize, banana and finger millet as well as coffee in different regions of Africa. For coffee, a reduction in suitable growing area for *Coffea arabica* in Ethiopia is projected with increased temperatures. Cultivation of this premium variety may need to be shifted towards higher elevations and more heat-tolerant *Coffea robusta* may be required at altitudes of less than 1500 m above sea level. Maize productivity (yield) could be reduced by 5-10% in Africa for every degree of warming (Knox, Hess, Daccache, & Wheeler, 2012). This is alarming since maize contributes the greatest portion of calories in the African diet (a mean of 16% and range of 0 – 60% across the continent). The current production is roughly 42 million tons per year (Ramirez-Villegas & Thornton, 2015). The most at risk area in terms of maize production under climate change is the Sahel.

STRATEGY TO MAINTAIN SUSTAINABLE CROP PRODUCTION INTENSIFICATION (SCPI) IN DEVELOPING COUNTRIES

Increased agricultural production requires higher yields and improved management strategies to reduce abiotic and biotic stresses. However, in order to avoid the depletion of land, energy and water resources, sustainable intensification has become crucial (Flachsbarth et al., 2015). Achieving SCPI may be realised through the following practices:

- Maintaining healthy soil to enhance soil-related ecosystem services and crop nutrition;
- Cultivation of a wider range of species and varieties in rotations, sequences and combinations to minimize overall risk of crop failure;
- Using quality seeds and planting material of well-adapted, high-yielding varieties;
- Adopting integrated management of nutrients, pests, diseases and weeds; and
- Efficient water use (FAO, 2013).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

SCPI requires effective use of technological and scientific innovations so that food supply may be increased without converting larger acreages to agricultural production or unleashing negative impacts on the environment and human health (Dempewolf et al., 2014; FAO, 2011; Sonnino et al., 2014).

ADAPTATION AND MITIGATION STRATEGIES TO OFF-SET THE IMPACT OF CLIMATE CHANGE ON AGRICULTURAL DEVELOPMENT AND FOOD SECURITY

Several adaptation strategies have been proposed to combat the potential negative impacts of climate change such as rising temperatures, intense and more frequent storms, droughts *etc*. These include diversification of livelihoods through agroforestry, integration approaches such as crop-livestock systems and rice-fish systems (Palombi & Sessa, 2013) and cultivation of heat, drought and other abiotic stress tolerant crops. The latter, described as climate-smart varieties, can be developed through crop varietal selection and breeding and should be cultivated under improved crop and eco-system management systems through precision agriculture, tailored to optimise production of particular crops under specific growing environments (FAO, 2009a; Palombi & Sessa, 2013).

Improved crop production management techniques can contribute to mitigating climate change by reducing greenhouse gas (GHG) emission. This may be achieved by limiting the use of inorganic fertilisers, avoiding soil compaction or flooding to reduce methane emissions, as in paddy rice systems, and sequestering carbon by planting perennial crops, forest trees (Dawson et al., 2011) and grass species (Palombi & Sessa, 2013). The latter practices fall under the umbrella of conservation agriculture.

Agricultural Approaches and Practices That Contribute to Climate Change Adaptation

Certain approaches and practices for sustainable crop production can contribute to climate change adaptation. They provide options for location-specific scenarios and should be adapted with local farmers/farming communities. Examples, provided by Palombi and Sessa (2013, p. 203), include SCPI listed above (FAO, 2013) and others such as:

- Mulch and cover cropping;
- Landscape-level pollination management; and
- Land fragmentation (riparian[3] areas, forest land within the agricultural landscape) (FAO, 2008, 2009b, 2012; FAO-PAR, 2011; Lin, 2011).

Tol (2002) presented comparative values of adopting versus not adopting measures to off-set climate change impacts on agriculture for a 2.5°C increase in global mean temperature. In LAC, the projected change in GDP from agriculture without climate change adaptation was –0.8 (0.6) whereas it was 0.6 (0.7) with adaptation measures. In Africa, the projected GDP adjustment was –0.2 (0.2) without adaptation measures compared to 0.5 (0.3) with adaptation measures. This research effectively underscores the value of adaptation measures.

Agricultural Approaches and Practices That Contribute to Climate Change Mitigation

As with climate change adaptation, approaches and practices for climate change mitigation can provide options for specific locations and should also be adapted in conjunction with local farmers/farming communities. Examples, provided by Palombi & Sessa (2013, 204), include in addition to some of the adaptation strategies listed above:

- Soil compaction management;
- Promotion of legumes in crop rotations;
- Restoration of cultivated peaty soils and degraded lands;
- Soil management practices that reduce fertilizer use (*e.g.* deep placement of urea);
- Growing nutrient-use efficient crop varieties;
- Integrated crop and livestock systems (also recommended by Boland et al., 2013; FAO, 2010a);
- Dedicated production of energy crops to replace fossil fuel use;
- Emission control and reduction (combustion engines, animal waste);
- Improved rice cultivation techniques; and
- Agroforestry (FAO, 2004, 2008, 2009b, 2012).

FAO (2007) has also recommended harnessing the knowledge and experience of farmers to select types of animal breeds or varieties that can best withstand changing climatic conditions. In addition, FAO (2007) also advocated mitigating the negative impact of ruminants on GHG emissions via animal husbandry practices such as adjusting ruminant diets and stocking ratios. Monitoring and rapid appraisal of the impacts of disasters on local fishing communities and aquatic ecosystems so that immediate and longer-term remedial action could be implemented in a timely manner were also recommended. FAO has adopted an Ecosystem Approach to management of fishery resources and the ecosystems on which they depend, in the face of climate change.

Climate-adapted companion cropping is another sustainable agricultural approach that can contribute to climate change mitigation. In sub-Saharan Africa, a push-pull companion cropping practice has been adopted to address constraints of the parasitic weed, *Striga hermonthica*, stem borer (lepidopterous insect) attack and poor soil fertility (Midega et al., 2015). The climate-adapted, drought-tolerant *Brachiaria* cv mulato (bred by the International Center for Tropical Agriculture (CIAT)) is used as a border crop with cereals such as maize, and greenleaf desmodium is used as an inter-crop. Desmodium fixes nitrogen, and thus provides some fertilizer to the crop. Highly significant reductions in *Striga* and stem borer damage to maize along with improved plant height, grain yield and soil fertility were achieved via this climate-adapted, push-pull system studied (Midega et al., 2015). *Brachiaria* cv mulato also serves as feed for livestock and, as stated previously, is drought-tolerant unlike traditional fodder, Napier grass (*Pennisetum purpureum*). Similarly, in St. Vincent and the Grenadines, the research of Isaac, Brathwaite, Cohen, and Bekele (2007) demonstrated that *Desmodium heterocarpon* controls weeds such as *Commelina diffusa* and nematodes and improves soil fertility when intercropped with banana (*Musa* spp.).

This push-pull approach provides a renewable, organic, affordable source of herbicide, insecticide, fertilizer and fodder for rural farmers such as those in sub-Saharan Africa and LAC. Thus it can improve food security, allow diversification of the farming system and contribute to poverty alleviation in the face of climate change.

Implementation of Early Warning and Risk Management Systems

Early warning and risk management systems can facilitate the timely implementation of adaptation measures to address climate variability and change. These are listed by FAO (2007) as:

- A historical climate data archive; an archive on climate impacts on agriculture;
- Monitoring tools using systematic meteorological observations;
- Climate data analysis (to determine the patterns of inter-annual and intra-seasonal variability and extremes);
- Information on the characteristics of system vulnerability and adaptation;
- Monitoring evidence of resilience under climate change as well as critical meteorological and environmental thresholds for manifestation of negative impacts of climate change; and
- Crop weather insurance indices to reduce the risk of climate impacts for lower-income farmers.

Adaptation Strategies for Crop Production in Africa

The crucial role of adaptation in countering the putative negative impacts of climate change in Africa, particularly that of global warming, was emphasised by Ramirez-Villegas and Thornton (2015). In general, these authors advocated complex systemic and transformational changes in farming systems in Africa to cater for increased temperatures. Shifts in cropping patterns to allow for cultivation of new crops that are more drought-tolerant are recommended along with a concomitant adjustment in diets and trade policies.

Yield losses for maize can be minimised by shortened cropping seasons and heat stress during the crop's reproductive phase (Ramirez-Villegas & Thornton, 2015). For the common bean (highly sensitive to climate change), Ramirez-Villegas and Thornton (2015) projected decreases in yield across Africa. However, a heat-tolerant accession of a wild relative of the common bean (*Phaseolus vulgaris*), tepary bean (*Phaseolus acutifolius*) was identified at CIAT for use in breeding heat-tolerant common bean lines (Beebe et al., 2011). Thus far, breeding lines in the greenhouse have been found to maintain productivity at +3 °C over the current temperature limit of common bean. The potential for such heat tolerant lines will be achieved with further investment in research and incentives for farmers to test and adopt promising new varieties in developing countries.

THE ADOPTION OF CLIMATE-SMART AGRICULTURE

Climate smart agriculture and landscapes are widely regarded as the panacea for addressing social and environmental impacts that threaten agricultural development and food security in the face of climate change. The widespread cultivation of climate-smart crops that are well-adapted to climatic change and changing growing environments will assure food security in a sustainable manner (Harvey et al., 2014; Neufeldt et al., 2013). Smart crops are better able to withstand drought than wheat or rice and do not require as much water to thrive (Swaminathan, 2012). They can be grown by rural families without irrigation. They are also nutritionally rich and have much higher protein and thus nutritional value. Consequently, these crops, many of them currently orphan crops (Cheng, Mayes, Dalle, Demissew &, Massawe, 2015), have ecological, social and nutritional benefits. Swaminathan thus recommended diversification

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of cropping patterns and the cultivation of more climate-smart crops to address the potential impact of climate change and year-to-year variability in weather patterns.

Features of Climate-Smart Agricultural Landscapes

Climate-smart agriculture will mitigate against the impact of climate change by harnessing natural biological processes to improve production in a more environmentally-friendly way and avoiding degradation of natural resources (Branca, McCarthy, Lipper and Jolejole, 2011; Palombi & Sessa, 2013). This sustainable system will be less vulnerable to shocks and stresses. It will harness the best of crop varieties and livestock breeds under optimum agro-ecological and agronomic management (Beddington et al., 2012).

Mba et al. (2012) recommended that in order to achieve food security under worsening climatic conditions and with constrained natural resources, higher yields must be achieved per unit of input; yield efficiency must be optimised. In Brazil, Martinelli, Naylor, Vitousek, and Moutinho (2010) emphasised the importance of this sustainable approach of increased productivity on existing agricultural land without further environmental degradation and deforestation. The cultivation of diverse, climate-smart crop varieties that can produce more with less is the objective of climate-smart agriculture. High yielding, well-adapted, resilient crop varieties that use inputs such as water and nutrients efficiently are required. They must combine superior genetic constitutions and be managed optimally. The case of the New Rice for Africa (NERICA) (West African Rice Development Association, 2001) was cited as an example of climate smart agriculture, which has already accounted for significant increases in rice production in sub-Saharan Africa.

Strategy for Achieving Climate-Smart Agricultural Landscapes

CGIAR's new strategy and research programmes: Answering to poverty, health and climate change (CGIAR, 2015) is an excellent example of a strategic and integrated approach towards achieving food security in developing countries (refer to Figure 2).

THE APPLICATION OF SCIENCE AND TECHNOLOGY AND KNOWLEDGE TRANSFER IN SECURING FOOD PRODUCTION

Pollinator-Friendly Management Practices

Pollinator-friendly management practices are also essential for climate-smart landscapes since they will enhance yields, quality, diversity and resilience of crops and cropping systems. Such practices include:

- Conservation of wild habitats;
- Managing of cropping systems and environs to protect habitats and forage;
- Cultivation of shade trees;
- Protection of bee and other pollinator nest sites;
- Reduced applications of pesticides and other hazards in production systems and
- Establishing landscapes with natural habitats and resources that favour pollinator population survival and services (FAO, 2009a).

In Costa Rica, it was found that coffee farms located in close proximity to forested areas benefit from greater diversity and number of pollinators visiting the coffee plants. This translates into increased coffee yields and improved coffee quality (FAO, 2009a). Furthermore, the maintenance of forests provides other ecosystem services such as carbon sequestration.

Maintaining pollination biodiversity in agricultural landscapes serves the dual role of ensuring pollination of crop species while serving as insurance against pest and disease threats among managed pollinator populations (FAO, 2009a). However, the system requires that farmers be trained about the value of adopting this strategy and the resources that pollinators require so as to encourage their proliferation in niches in the landscape.

Management of Soils: Nutrient Status, Porosity and Structure

Climate-smart landscapes must be characterised by healthy, fertile soils that support intensive production systems. Optimal crop production cannot be achieved on degraded soils with nutrient deficiencies and soil-borne pests and diseases. The cultivation of pulses is recommended in climate-smart landscapes since legumes fix nitrogen and thus reduce the need for inputs such as nitrogen fertilizers.

A case for conservation agriculture that includes zero soil tillage has been advanced by FAO (2007, 2012) and Mba et al. (2012). Reichert et al. (2015) recommended the latter for common beans based on their observations under highly variable weather conditions on sandy soils in a sub-tropical environment (Brazil). Conservation agriculture involves the maintenance of soils in an undisturbed state with a sufficient supply of organic matter that provides a good habitat for soil fauna. The avoidance of mechanical tillage increases the populations of earthworms, millipedes and other micro fauna that take over the role of tillage and build soil porosity and, with organic matter, improve soil structure. This makes land less susceptible to flooding and erosion (Palombi & Sessa, 2013). Knowledge transfer to farmers of these sustainable soil management practices is thus crucial.

Developing Climate Smart Crop Varieties Through Research in Breeding and Technological Advances

The threat of crop failures due to biotic and abiotic stress under climate change may be addressed through breeding climate-smart varieties (refer to Table 1). In 1982, Swaminathan advocated that Third World countries should master all recent developments in genetics. This should be widened now to embrace all areas of advanced crop breeding and biotechnology including molecular biology, next-generation sequencing (Bansal, Lenka and Mondal, 2014; Edwards & Batley, 2010); genomics, genomic selection and marker-assisted selection and breeding (Tester & Langridge, 2010), gene pyramiding (Gennaro et al., 2007) and tissue culture. Landscape genomics can be employed to identify the environmental factors that affect adaptive genetic variation and gene variants that facilitate local adaptation (Anami et al., 2015; Rellstab, Gugerli, Eckert, Hancock, & Holderegger, 2015). Mba et al. (2012) concluded that a re-invigorated plant breeding approach is necessary to translate climate-smart heritable variations into crop varieties to achieve increased yields and enhanced adaptation to abiotic and biotic stresses due to climate change.

Fereres, Orgaz, and Gonzalez-Dugo (2011) identified the recommended strategy towards developing smart crop varieties as combining research on plant breeding, crop physiology, and agronomy, and exploiting their interactions. Furthermore, they advocated more balanced funding of agricultural research disciplines to achieve success.

Conservation of Biological Diversity: *In Situ* and *Ex Situ*, Protection of Landraces and Farmers' Selections

One of the strategies towards achieving climate-smart crop varieties is the widening of the genetic base or sources of heritable variations in crops (FAO, 2009c; Mba et al. 2012). This is in keeping with the Global Crop Diversity Trust's efforts to promote the collection, conservation and use of wild relatives of crops in pre-breeding and breeding (Dempewolf et al., 2014; Guarino & Lobell, 2011). The value of national and national genebanks for *ex situ* conservation and conservation plots in farmers' fields as well as of wild types in their natural habitats (*in situ* conservation) cannot be over-emphasised (FAO, 2010b).

The advantage of using the tepary bean (a wild relative of the common bean) in developing heat-tolerant common bean lines at CIAT has already been discussed (Beebe et al., 2011). Gur and Zamir (2004) reported on the success achieved using a wild relative of tomato, *Solanum pennelli*, to introduce genes for drought tolerance into the commercial *Solanum lycopersicum* tomato variety with an attendant yield increase of 50%. At IITA, Nigeria, several genes of wild relatives of cassava were used to introduce genes to enhance cassava mosaic disease resistance, as well as to improve nutritional quality and extend shelf life of a commercial variety (Mba et al., 2012).

An Example of an *Ex-Situ* Collection Used to Cater for the Impact of Climate Change: The *Seeds for Needs* Project in Ethiopia

The Seeds for Needs project in Ethiopia uses *ex-situ* collections to help farmers, mainly women, cope with impact of climate change on crop production (Bioversity International, 2013). Accessions, maintained at the Ethiopian National Genebank's Institute of Biodiversity and Conservation, were catalogued

Table 1. Adaptive traits to introduce through crop improvement/breeding in select climate-smart crop varieties

Crop	Adaptive traits
	Drought
Rice	Early flowering, deeper and thicker roots, root pulling resistance, root penetration, osmotic adjustment (OA), rapid stomatal closure, water-use efficiency (WUE), membrane stability, leaf rolling score, and leaf relative water content
Wheat	Early flowering, stem water-soluble carbohydrate (SWSC), green flag-leaf persistence, WUE, transpiration efficiency (TE)
Maize,	Early flowering, anthesis silking interval (ASI), ears per plant, stay-green chlorophyll content, osmotic adjustment (OA), root traits, leaf abscisic acid (L-ABA)
Barley	Early flowering, plant stature, ear type, WUE, OA, high biomass combined with SWSC, water extraction, and transpiration efficiency (TE)
Sorghum	Early flowering, stay-green, SWSC, TE, rooting depth and patterns, epicuticular wax
Pearl millet	Early flowering, few tillers, low biomass and high harvest index including panicle harvest index, grain yield, individual grain mass Profuse rooting in the deeper layers of soil
Chickpea	Early flowering, deep rooting and higher root length density
Groundnut	Early flowering, WUE, transpiration, TE, specific leaf area (SLA), and chlorophyll meter reading
	Heat
Rice	Time of day when flowering (TDF) commences (early TDF protects fertility from high temperature), high temperature tolerance at grain filling (pollen shedding, pollen germination and pollen tube extension) Higher leaf transpiration rate to maintain lower leaf temperature combined with opening of flowers in morning (*O. glaberrima*)
	Salinity
Rice	Early vegetative stage: salt exclusion or low uptake, compartmenting of toxic ions in structural and older tissues, higher tissue tolerance by compartmenting salt into vacuoles, stomata that close faster upon exposure to salt stress Reproductive development stage: salt exclusion from flag leaves and developing panicles
Wheat and barley	Na+ exclusion, K+/Na+ discrimination, sheath retention of ions, tissue tolerance, ion partitioning into different-aged leaves, OA, enhanced vigour, WUE, and early flowering
Maize	OA and abscisic acid (ABA)
Sorghum	Whole plant tolerance resulted from reduced shoot Na+ concentration, a major mechanism involved in salt tolerance
Pearl millet	Whole plant tolerance associated with reduced shoot N content, increased K+ and Na+ contents; with shoot Na+ concentration a potential non-destructive selection criterion at vegetative-stage screening
Chickpea	Ability to maintain large number of filled pods; shoot Na+ or K+ not related to salinity
Pigeon pea	Reduced shoot Na+ concentration
Groundnut	Pod numbers per plant
	Flood Tolerance/Submergence
Rice	Vigorous seedling growth, elongation ability, submergence tolerance, resistance to lodging or recovery from lodging after water level reduction

(Adapted from Jarvis et al., 2008)

in terms of climate profiles. Accessions most likely to be adapted to future growing conditions in areas with similar environmental profiles were identified using the collection, characterisation and evaluation data from germplasm collections and Geographic Information System (GIS) technology. Varieties were then tested by selected farmers under their respective growing conditions, and based on their indigenous knowledge and adaptation strategies. After the testing process, the best performing and most adaptable varieties were distributed to farming communities for multiplication and observation.

Utilisation of Crop Genetic Diversity in Selecting Climate Adaptation Traits
