Library of Congress Cataloging-in-Publication Data

Names: Information Resources Management Association, editor.
Title: Environmental and agricultural informatics : concepts, methodologies, tools, and applications / Information Resources Management Association, editor.
Description: Hershey, PA : Engineering Science Reference, an imprint of IGI Global, [2020] | Includes bibliographical references and index. | Summary: "This book examines the design, development, and implementation of complex agricultural and environmental information systems to quickly process and access environmental data in order to make informed decisions for the protection of the environment"-- Provided by publisher.
Identifiers: LCCN 2019006765 | ISBN 9781522596219 (hardcover) | ISBN 9781522596226 (ebook)
Subjects: LCSH: Environmental sciences--Data processing. | Environmental monitoring. | Agricultural informatics.
Classification: LCC GE45.D37 E5384 2020 | DDC 333.70285--dc23
LC record available at https://lccn.loc.gov/2019006765

British Cataloguing in Publication Data
A Cataloguing in Publication record for this book is available from the British Library.

Table of Contents

Preface xxi

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
Technological Innovation and the Agricultural Sustainability: What Compatibility for the Mechanization? 1
Rachida Khaled, University of Sousse, Tunisia
Lamine Hammas, University of Sousse, Tunisia

Chapter 2
Practice of Green Marketıng Activities in the Organic Agricultural Sector in Turkey 17
Veysel Asoğlu, Harran Unıversıty, Turkey
Halil İbrahim Şengün, Dicle University, Turkey

Chapter 3
Rights of Nature to Protect Human Rights in Times of Environmental Crisis 38
Susana Borràs, Rovira i Virgili University, Spain

Chapter 4
The Impact of Kisan Call Centers on the Farming Sector 66
Kartik Chachra, Institute of Management Technology Ghaziabad, India
Gowtham Seelam, Institute of Management Technology Ghaziabad, India
Harshit Singh, Institute of Management Technology Ghaziabad, India
Mayukh Sarkar, Institute of Management Technology Ghaziabad, India
Anshul Jain, Institute of Management Technology Ghaziabad, India
Ankush Jain, Institute of Management Technology Ghaziabad, India

Chapter 5
Fundamentals of Electrostatic Spraying: Basic Concepts and Engineering Practices 79
Manoj Kumar Patel, Academy of Scientific and Innovative Research, India & CSIR-Central Scientific Instruments Organisation, India
Chirravoori Ghanshyam, CSIR-Central Scientific Instruments Organisation, India

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 6
Aggressions of the Socio-Economic System on the Natural Capital 108
Constanţa Popescu, Valahia University of Târgovişte, Romania
Constantin Popescu, Valahia University of Târgovişte, Romania
Maria Luiza Hrestic, Valahia University of Târgovişte, Romania

Section 2
Development and Design Methodologies

Chapter 7
Appropriate Extension Methodologies for Agricultural Development in Emerging Economies 133
B. S. Famuyiwa, Cocoa Research Institute of Nigeria (CRIN), Nigeria
O. A. Olaniyi, Ladoke Akintola University of Technology, Nigeria
S. A. Adesoji, Obafemi Awolowo University, Nigeria

Chapter 8
Agropreneurship Among Gen Y in Malaysia: The Role of Academic Institutions 157
Asliza Yusoff, Universiti Sains Malaysia, Malaysia
Noor Hazlina Ahmad, Universiti Sains Malaysia, Malaysia
Hasliza Abdul Halim, Universiti Sains Malaysia, Malaysia

Chapter 9
Application of Information Communication Technologies for Agricultural Development Through Extension Services: A Review 182
L. K. Mabe, North-West University – Mafikeng, South Africa
O. I. Oladele, North-West University – Mafikeng, South Africa

Chapter 10
Strategic Positioning of Turkey Agricultural Products on the Agricultural World Market 233
Hamadoun Sidibe, Université de Moncton, Canada

Chapter 11
Stakeholder Agriculture: Innovation From Farm to Store 258
Alexandros Antonaras, University of Nicosia, Cyprus
Alexandros Kostopoulos, CSR Hellas, Greece

Chapter 12
Striking a Perfect Fit in Leadership Style for Effective Farmer Training in Botswana 282
Flora M. Tladi, University of Botswana, Botswana

Chapter 13
Rebirth of a Program via Community, Industry, and Philanthropic Support 298
Cathleen Brandi Ruch, Lake Region State College, USA

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 14
Impact on Agricultural Sustainability of Maghreb Countries: An Empirical Analysis by 3SLS 316
Rachida Khaled, University of Sousse, Tunisia

Chapter 15
Deployment of Wireless Sensor Networks for Soil Macronutrients Measurements in Farms 332
Daudi Samson Simbeye, Dar es Salaam Institute of Technology, Tanzania

Chapter 16
Industrial Wastewater Management in the Context of Climate Change Adaptation in Selected Cities of India: A Business Approach 347
Rahul Hiremath, SCMHRD, Symbiosis International University, India
Bimlesh Kumar, Indian Institute of Technology Guwahati, India
Sheelratan S. Bansode, Solapur University, India
Gurudas Nulkar, SCMHRD, Symbiosis International University, India & Trustee Ecological Society, India
Sharmila S. Patil, Walchand Institute of Technology, India
J. Murali, Environmental Solutions and Consultancy, UAE

Chapter 17
Sericulture Industry: A Bonanza to Strengthen Rural Population in India 366
P. J. Raju, Andhra Pradesh State Sericulture Research and Development Institute, India
D. M. Mamatha, Sri Padmavathi Mahila Visvavidyalayam (Women's University), India
S. V. Seshagiri, Andhra Pradesh State Sericulture Research and Development Institute, India

Chapter 18
Design for Autonomy: Water Resources in Ladakh 388
Carey Clouse, University of Massachusetts – Amherst, USA

Section 3
Tools and Technologies

Chapter 19
Web Based Automatic Soil Chemical Contents Monitoring System 405
Samuel Dayo Okegbile, Obafemi Awolowo University, Nigeria
Adeniran Ishola Oluwaranti, Obafemi Awolowo University, Nigeria
Adekunle Aderibigbe, Obafemi Awolowo University, Nigeria

Chapter 20
The Empirical Study on the Evolutionary Game Based Agricultural Products Supply Chain 419
Jun Sun, Dalian Polytechnic University, China
Ruben Xing, Montclair State University, USA

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 21
IoT Based Agriculture as a Cloud and Big Data Service: The Beginning of Digital India 438
Sukhpal Singh Gill, University of Melbourne, Australia
Inderveer Chana, Thapar University, India
Rajkumar Buyya, University of Melbourne, Australia

Chapter 22
ICTs for Agricultural Development and Food Security in Developing Nations 462
Bhattacharjee Suchiradipta, Independent Researcher, India
Raj Saravanan, National Institute of Agricultural Extension Management (MANAGE), India

Chapter 23
Exploring Alternative Distribution Channels of Agricultural Products 485
Kallirroi Nikolaou, Aristotle University of Thessaloniki, Greece
Efthimia Tsakiridou, Aristotle University of Thessaloniki, Greece
Foivos Anastasiadis, Aristotle University of Thessaloniki, Greece
Konstadinos Mattas, Aristotle University of Thessaloniki, Greece

Chapter 24
Mobile Networks and Indian Agricultural Sector 516
Lokesh Jain, UIET, Panjab University, India
Harish Kumar, UIET, Panjab University, India

Chapter 25
Sustainability Assessment in a Geographical Region and of the Activities Performed 536
Berrin Kurşun, Marmara University, Turkey
Bhavik R. Bakshi, The Ohio State University, USA

Volume II

Chapter 26
Environmental Audit in Integrated Audit System 562
Chirața Caraiani, Bucharest University of Economic Studies, Romania
Camelia I. Lungu, Bucharest University of Economic Studies, Romania
Cornelia Dascălu, Bucharest University of Economic Studies, Romania
Florian Colceag, Bucharest University of Economic Studies, Romania

Chapter 27
Spatio-Temporal Variability of Seasonal Drought Over the Dobrogea Region 590
Monica Ionita, Alfred Wegener Institute Helmholtz Centre for Polar and Marine Research, Germany
Silvia Chelcea, National Institute of Hydrology and Water Management, Romania

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 28
The Role of Mobile Phones Use on Agricultural Output and Household Income in Rural Rwanda 618
Ildephonse Musafiri, University of Rwanda, Rwanda

Chapter 29
Mobile Robotics 630
Isak Karabegović, University of Bihać, Bosnia and Herzegovina
Vlatko Doleček, Academy of Sciences and Arts, Bosnia and Herzegovina

Chapter 30
Farmers' Access and Use of Mobile Phones for Improving the Coverage of Agricultural Extension Service: A Case of Kilosa District, Tanzania 661
Boaz Stanslaus Kiberiti, Sokoine University of Agriculture, Tanzania
Camilius Aloyce Sanga, Sokoine University of Agriculture, Tanzania
Mussa Mussa, Sokoine University of Agriculture, Tanzania
S. D. Tumbo, Centre for Agric. Mechanization and Rural Technologies, Tanzania
Malongo R.S. Mlozi, Sokoine University of Agriculture, Tanzania
Ruth Haug, Norwegian University of Life Sciences (NMBU), Norway

Chapter 31
Biological Alchemy: Gold From Garbage or Garbage Into Gold 687
Mamta, Jiwaji University, India
Rayavarapu Jaganadha Rao, Jiwaji University, India
Anil Dhar, Regional Sericulture Research Station, Jammu, India
Khursheed Ahmad Wani, ITM University Gwalior, India

Chapter 32
Making Agricultural Learning Accessible: Examining Gender in the Use of Animations via Mobile Phones 716
Julia Bello, University of Illinois at Urbana-Champaign, USA
Anne Namatsi Lutomia, University of Illinois at Urbana-Champaign, USA
Eric Abbott, Iowa State University, USA
Robert Mazur, Iowa State University, USA
Sostino Mocumbe, Iowa State University, USA
Barry R. Pittendrigh, Michigan State University, USA

Chapter 33
A Genetic Algorithm to Goal Programming Model for Crop Production With Interval Data Uncertainty 737
Bijay Baran Pal, University of Kalyani, India
Sankhajit Roy, Bidhan Chandra Krishi Viswavidyalaya, India
Mousumi Kumar, Aghorekamini Prakashchandra Mahavidyalaya, India

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 34
Mobile Vision for Plant Biometric System 773
Shitala Prasad, GREYC – Imaging Lab, CNRS, France

Chapter 35
Demand for Food Diversity in Romania 792
Lucian Luca, Institute of Agricultural Economics, Romania
Cecilia Alexandri, Institute of Agricultural Economics, Romania
Bianca Păuna, National Institute of Economic Research, Romania

Chapter 36
Simulation-Based Approaches for Ecological Niche Modelling: A Geospatial Reference 805
Anusheema Chakraborty, TERI University, India
P K Joshi, Jawaharlal Nehru University, India

Section 4
Utilization and Applications

Chapter 37
Information Societies to Interactive Societies: ICT Adoptions in the Agriculture Sector in Sri Lanka 829
Uvasara Dissanayeke, University of Peradeniya, Sri Lanka
H.V.A. Wickramasuriya, University of Peradeniya, Sri Lanka

Chapter 38
A Case Study of Innovation Platforms for Agricultural Research, Extension, and Development: Implications for Non-Formal Leadership and Adult Learning 855
Matthew L. S. Gboku, Sierra Leone Agricultural Research Institute, Sierra Leone
Oitshepile M. Modise, University of Botswana, Botswana
Jenneh F. Bebeley, Sierra Leone Agricultural Research Institute, Sierra Leone

Chapter 39
Economic Transformation of Austrian Agriculture Since EU Accession 875
Erika Quendler, Federal Institute of Agricultural Economics, Austria
Christina Mayer, Statistics Austria, Austria
Karl Michael Ortner, Federal Institute of Agricultural Economics, Austria

Chapter 40
Economic Growth and Climate Change: An Exploratory Country-Level Analytics Study 906
Wullianallur Raghupathi, Fordham University, USA
Viju Raghupathi, Brooklyn College (CUNY), USA

Chapter 41
The Role of Irrigation in the Development of Agriculture: Srem District (Serbia) 925
Vesna Ž. Popović, Institute of Agricultural Economics, Serbia
Jonel V. Subić, Institute of Agricultural Economics, Serbia
Nataša Ž. Kljajić, Institute of Agricultural Economics, Serbia

Preface

Due to continual advancements in technological applications, contemporary society has the ability to rapidly process large amounts of information and data in a variety of fields in order to solve complex problems and issues. In the field of environmental science, informatics can be used to quickly process and access environmental data in order to plan preventive measures and solve current environmental problems for the protection of the environment. These advancements are providing assistance, tools, applications, and solutions for agriculturalists and environmentalists on a number of issues such as the sustainable use of water and land, crop growth and maintenance, climate change, water pollution, deforestation, etc.

The constantly changing landscape of environmental and agricultural informatics makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why IGI Global is pleased to offer this three-volume reference collection that will empower environmentalists, agriculturalists, researchers, professionals, academics, students, and scientists with a strong understanding of critical issues surrounding environmental and agricultural informatics by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as to provide insight into emerging trends and future opportunities within the field.

Environmental and Agricultural Informatics: Concepts, Methodologies, Tools, and Applications is organized into seven distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications;
6. Managerial Impact; and
7. Critical Issues and Challenges.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of Environmental and Agricultural Informatics. Introducing the book is "Technological Innovation and the Agricultural Sustainability: What Compatibility for the Mechanization?" by Rachida Khaled (Faculty of Economics and Management of Sousse, Department of Economics, University of Sousse, Sousse, Tunisia) and Lamine Hammas (Faculty

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of Economics and Management of Sousse, Department of Economics, University of Sousse, Sousse, Tunisia): a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Section 1 concludes and leads into the following portion of the book with a nice segue chapter, "Aggressions of the Socio-Economic System on the Natural Capital," by Constanţa Popescu (Valahia University of Târgovişte, Romania), Constantin Popescu (Valahia University of Târgovişte, Romania), and Maria Luiza Hrestic (Valahia University of Târgovişte, Romania).

Section 2, "Development and Design Methodologies," presents in-depth coverage of the conceptual design and architecture of Environmental and Agricultural Informatics. Opening this section is "Appropriate Extension Methodologies for Agricultural Development in Emerging Economies," by B. S. Famuyiwa (Cocoa Research Institute of Nigeria [CRIN], Nigeria), O. A. Olaniyi (Ladoke Akintola University of Technology, Nigeria), and S. A. Adesoji (Obafemi Awolowo University, Nigeria). Through case studies, this section lays excellent groundwork for later sections that will get into present and future applications for Environmental and Agricultural Informatics. This section concludes with an excellent work by Carey Clouse (University of Massachusetts – Amherst, USA), "Design for Autonomy: Water Resources in Ladakh."

Section 3, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of Environmental and Agricultural Informatics. The first chapter, "Web Based Automatic Soil Chemical Contents Monitoring System," by Samuel Dayo Okegbile (Obafemi Awolowo University, Ile-Ife, Nigeria), Adeniran Ishola Oluwaranti (Obafemi Awolowo University, Ile-Ife, Nigeria), and Adekunle Aderibigbe (Obafemi Awolowo University, Ile-Ife, Nigeria) lays a framework for the types of works that can be found in this section. This section concludes with "Simulation-Based Approaches for Ecological Niche Modelling: A Geospatial Reference" by Anusheema Chakraborty (TERI University, India) and P K. Joshi (Jawaharlal Nehru University, India). Where Section 3 described specific tools and technologies at the disposal of practitioners, Section 4 describes the use and applications of the tools and frameworks discussed in previous sections.

Section 4, "Utilization and Applications," describes how the broad range of Environmental and Agricultural Informatics efforts has been utilized and offers insight on and important lessons for their applications and impact. The first chapter in this section is "Information Societies to Interactive Societies: ICT Adoptions in the Agriculture Sector in Sri Lanka," written by Uvasara Dissanayeke (University of Peradeniya, Sri Lanka) and H.V.A. Wickramasuriya (University of Peradeniya, Sri Lanka). This section includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theory, analysis, and guides for implementation. The breadth of topics covered in this section is also reflected in the diversity of its authors from countries all over the globe. This section concludes with "Low Carbon Energy Innovations Systems in Natural Resource Rich Developing Countries: The Case of Brazil" by André Tosi Furtado (University of Campinas, Brazil), a great transition chapter into the next section.

Section 5, "Organizational and Social Implications," includes chapters discussing the organizational and social impact of Environmental and Agricultural Informatics. This section opens with "The Collective Aestheticization of Farming as Participatory Civic Engagement" by Cala Coats (Stephen F. Austin State University, USA). This section focuses exclusively on how these technologies affect human lives, either through the way they interact with each other or through how they affect behavioral/workplace situations. This section concludes with "Impact of Overpopulation on Land Use Pattern" by Shivani Garg (Kurukshetra University, India).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Section 6, "Managerial Impact," presents focused coverage of Environmental and Agricultural Informatics in a managerial perspective. This section begins with "Characterization and Management Concerns of Water Resources around Pallikaranai Marsh, South Chennai" by Avantika Bhaskar (Care Earth Trust, India), G. Babu Rao (Care Earth Trust, India), and Jayshree Vencatesan (Care Earth Trust, India). This section serves as a vital resource for developers who want to utilize the latest research to bolster the capabilities and functionalities of their processes. The chapters in this section offer unmistakable value to managers looking to implement new strategies that work at larger bureaucratic levels. This section concludes with "Assessing the Readiness of Farmers towards Cold Chain Management: Evidences from India" by Rohit Joshi (IIM Shillong, India) and Sudhanshu Joshi (Doon University, India).

Section 7, "Critical Issues and Challenges," presents coverage of academic and research perspectives on Environmental and Agricultural Informatics tools and applications. This section begins with "The Loss and Damage of Environmental Ethics in the Threshold of African Culture: Environmental Ethics and African Culture" by Essien D. Essien (University of Uyo, Uyo, Nigeria). Chapters in this section look into theoretical approaches and offer alternatives to crucial questions on the subject of Environmental and Agricultural Informatics. This section concludes with "Human Overpopulation: Impact on Environment" by Shivani Uniyal (Banaras Hindu University, India), Rashmi Paliwal (Kurukshetra University, India), Bhumija Kaphaliya (Kurukshetra University, India), and R. K. Sharma (Banaras Hindu University, India).

Although the primary organization of the contents in this multi-volume work is based on its seven sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Environmental and Agricultural Informatics: Concepts, Methodologies, Tools, and Applications* provides researchers, administrators, and all audiences with a complete understanding of the development of applications and concepts in Environmental and Agricultural Informatics. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of Environmental and Agricultural Informatics in countries around the world, *Environmental and Agricultural Informatics: Concepts, Methodologies, Tools, and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of Environmental and Agricultural Informatics.

Chapter 1
Technological Innovation and the Agricultural Sustainability: What Compatibility for the Mechanization?

Rachida Khaled
University of Sousse, Tunisia

Lamine Hammas
University of Sousse, Tunisia

ABSTRACT

The diffusion of the technological innovation can affect the agricultural sector in the three-sided (social, economic and environmental), a hand, it can contribute to solve problems of the agricultural sector: the effects of the climatic changes, the farming exodus and the migration and the problems of poverty and it can improve the agricultural productivity. But on the other hand, he can lead to new problems, such as depletion of energy resources caused by excessive use of energizing technologies, pollution of air and water and the destruction of soil by industrial waste. This paper aims to theoretically and empirically analyze the role of technological innovation in improving agricultural sustainability through the impact of mechanization on agricultural productivity, energy production and net income per capita for a panel of three Maghreb countries (Algeria, Morocco and Tunisia) during the period 1997-2012. By using simultaneous equations, the authors' finding that technological innovation cannot achieve the purpose of sustainable development in the agriculture sector in the Maghreb countries through the negative impact of mechanization and research and development on agricultural productivity.

1. INTRODUCTION

The world today endures some several economic, social, political and environmental problems, as the climatic change, the reduction of biodiversity, the destruction of soils, the shortcomings of production and consumption, poverty, the transferable illness development, the problems of unemployment, etc.

A new approach has emerged in development economics for solving these problems, which incorporates the concept of sustainability is «sustainable development».

On this new basis, a sustainable development was defined by the Brundtland Report (1987) as:

Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet in their generations. (Franck-Dominique, 2003; Karen Delchet, 2004; Olivier Godard, 2002)

In 1992, have Rio politicians negotiated during a summit of the earth, the development situation and environment, their issues and constraints (Franck-Dominique, 2003; Karen Delchet; Olivier Godard, 2002). In this summit was also attended by men of science and technology, recognizing that environmental issues should be a major concern in all areas of humanity.

The innovation is indispensable to the sustainable development and reciprocally the sustainable development determines the orientation of the innovation. These two principles are complementary and their convergence can constitute a big advantage for the economy of tomorrow.

While the question of whether technological innovation, particularly the mechanization improves or prevents the agricultural sustainability opens the door to the birth of several economic and political debates, there are little theoretical and empirical studies on the factors of development and economic durability of irrigation system in Maghreb countries.

The objective of this paper is to make up the void in the literature and make an in-depth analysis the agriculture sector of the Maghreb countries in order to identify their main factors.

To better understand what leads the mechanization effect on the Maghreb agriculture sustainability, we browse in this paper three types of factors, social, economic and environmental. The scope of our study covered 3 Maghreb countries during the 1997-2012 periods. We utilized an econometric methodology based on the simultaneous equations.

Our results show that the technological innovation such as mechanization, research and development cannot achieve the sustainable development purpose in the agricultural sector of the Maghreb country in particular economic efficiency.

The rest of the paper is organized as follows. Section 2 furnishes a brief literature review of the impact of technological innovation in the agricultural sustainability. Section 3 presents the trend of agriculture and mechanization in the Maghreb countries. Section 4 shows the data and the adopted econometric methodology. The empirical results are obtained and interpreted in section 5. Finally, section 6 presents some conclusions and policy implications.

2. TECHNOLOGICAL INNOVATION AND SUSTAINABLE DEVELOPMENT IN AGRICULTURE: A BRIEF LITERATURE REVIEW

Major prior studies related to the present paper include Jimmy Alani (2012), Jean - Marc Blazy, Alain carpentier and Alban Thomas (2011), Roberto Esposti (2002),Fédes van Rijn, Erwin Bulte and Adewale Adekunle (2012), Graeme J. Doole (2012),Gershon Feder and Dina L. Umali (1993),Vernon W. Ruttan (1977), Khaled et Hammas (2014). These studies focus on the effects of technological innovation on the development of agricultural sustainability in developed and developing countries.

Jimmy Alani (2012) shows that improving agricultural productivity is linked with technical progress, he argues their work by a theoretical model derived from a production function type Cobb - Douglas.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Jean - Marc Blazy Alain Carpentier and Alban Thomas (2011) indicate that improvement in agricultural production based on the reduction of pesticide use and renovation of soil fertility in the fight against weed, provide the nitrogen to the soil without insecticides increases in numbers, each of this way has led to technological innovation. According to the authors the innovations also have different effects on the net operating income and the productivity. The implementation of some innovating method in the sectors agricultural based on conditions environmental, social and economic.

Recent research shows that agricultural development is improving by the technological innovation, but whereas the durability can affect positively or negatively by the mechanization as it explains Colin Thirtle, Robert Townsend and Joban van Zyl (1995) in his empirical analysis that is founded on the OLS modelling.

The innovation in agriculture and rural enterprise comes from whatever source (formal or informal) of new modes in the production and organization of agricultural activity.

The rural populations have a human capital integrating essential sources of knowledge and new procedures through their knowledge and modes of organization.

Good solutions found by small farmers themselves are a necessary source for enhancing agricultural productivity of developing countries.

Nigel Poole (2006) shows that the mechanism and the level of research and innovation in the formal agricultural system have increased in the eighteenth and/or nineteenth century later has the use of scientific methods in relatively advanced economies.

The R&D preferences in agriculture were encouraged during the last century by the government, which led to the birth of the formal national research systems in advanced and developing countries and the creation of organism's international research.

The green revolution is represented as a result of public research or as a classic example of a method giving land ownership to the farmer.

At this point, we can say that innovation is constituted by various researches and it can be spread through different distribution procedures by economic historical, political, institutional and climate contexts. In recent years, the increasing advances in technology led to the creation of technology platforms such as information and communication technology (ICT) and biotechnology.

3. EVALUATION OF ENVIRONMENTAL, ECONOMIC AND SOCIAL FACTORS

3.1. Energy

The farming surroundings and the agricultural sectors endure mediocrity of the infrastructure and the lack of information. These two difficulties cause the reduction of the outputs of the agricultural production and the decrease of the level of employment in this sector, what conducted to the apparition of poverty in these surroundings.

For solving these problems, it is necessary to encourage the investment in the energy since he/it is considered like means of enhancing the life quality for rural populations, while being based on the technologies, in particular of information and the communication.

The lack of infrastructure and high costs are often explained by the lack of rural energy associated with various social, economic and political difficulties.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The energy is necessary to reinforce the non-agricultural farming economy directly and the agricultural farming economy indirectly.

The current price of oil and its derivatives can release hazardous effects that affect various areas such as air pollution, sea pollution that led to the decline the marine resources and soil pollution and thus to reduce the fertility of agricultural land and subsequently to lower yields and lower employment in this sector, Which encourages migration from rural to industrial or other services.

Energy supply associated with conventional technologies in rural areas can be more expensive. The social and environmental benefits of the development of services based on energy sources other than oil are viable.

We must invest in the energy sectors other than oil for environmental and economic reasons, such as wind and solar energy, which are technically feasible for local markets in rural areas.

3.2. Poverty Reduction

The project " objectives of the millennium for the development " (OMD) defined real strategies to avoid poverty while improving the investments in the infrastructure and the human capital in the farming surroundings, what permits to improve the agricultural sector by a qualified manpower, as well as the increase of production following the increase of the transportation means and thereafter a growth of the outputs and a reduction of poverty in the background farming, while motivating the equality between the sexes and the protection of the environment.

The project of the OMD includes the science, the technology and the innovation and permits to apply the knowledge to the development.

The difficulties faced by developing countries in innovation are not related to the creation of new knowledge, but the effective use of existing techniques.

3.3. The System of Supermarkets

The impact of the international proliferation of large series on food retail sectors was generally analysed for developing countries and also in several other regions such as Latin America, Central and Eastern Europe, sub-Saharan Africa and Asia.

In developing countries, to reason at a time of demand bound to the tendency of the local life forms and to the big international business entry, the food systems are quickly going to be complex. In Tunisia the international supermarket entry is increasing with the time the sample Carrefour Market that has developed in most regions of Tunisia.

However, the international supermarket is a novelty that ensures the sale of food products, such as fresh produce, namely fruits, vegetables, meat and fish, which promotes the growth of production in the two sectors agriculture and fisheries.

So the international supermarket is an innovation that improves several areas such as fisheries and agriculture, and for industry.

The international supermarket system offers the advantages that are the development of the employment in these stores and in their specific supply chains, an overall increase in the quality of food coming from the technology transfer and commercial uses of farmers.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

National supermarkets are represented as major suppliers and demanders of local products, in the less advanced countries. These companies run into relationship marketing and ensure the root of supply series. This new business model is distinguished by low margins and high quality, creating new opportunities and new challenges for providers, such as self-service sales, healthy environments, indicating prices, the aggressive marketing and the promotions are henceforth the strategic norm (Cadilhom et al, 2006).

The development of monopsony system and economies of scale associated with the production, the basis of the standards and the organization rule and multiplication of knowledge to make, transmission of the markets that explains the situation of the small agriculturists of the difficult zones that is outside of these markets.

3.4. The Lack of Information

Because of the lack for a communication system that includes not only the technology, but also information there for smallholders a significant information deficit (Poole et al, 2000).

Small farmers do not inform about the price, on the situation of effective demand, or the quality of favourite products, in this situation the producers cannot negotiate traders.

The information available in the rural area may not be equally distributed, and producers who are excluded from markets are the most disadvantaged. Other factors act on the commercial efficiency and can form difficulties of horizontal nature to the orientation of the markets and the fluxes of information as the sex, the family, the level of education.

4. AGRICULTURAL EVOLUATION IN THE MAGHREB COUNTRY

The Maghreb region includes richest country in oil and gas (Libya, Algeria) and countries whose resources are very limited compared to their populations (Tunisia, Morocco and especially Mauritania) throughout the region of Africa north (Houssem Eooine Chebbi, Lassao Lachaal, 2004).

To solve this problem of limited natural resources, many economic and political leaders put agriculture in question. For all the Maghreb countries, the agricultural sector remains of major importance in the economic, social and political level.

Table 1. Summarize the number of exploitation, cultivated surface, number of mechanization and spending in R&D in the three Maghreb countries in 2005

Country	Agriculture Productivity	Energy Production	Number of Mechanization	Net income per capita
Algeria	8.221	166662.44	1693.00	10270.00
Morocco	14.677	610.282	1397.00	4710.00
Tunisia	10.127	6681.4	1700.00	7360.00

Legend: the agriculture productivity is the value added (% of GDP), energy production includes forms of primary energy, or oil, natural gas, other solid fuels and renewable and waste-derived fuels and primary electricity, all converted into oil, number of mechanization measured by the number of tractors per 100 square km of arable land, net income per capita based on rate parity purchasing power (PPP).

Source: WDI, 2011

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The sector must continue to achieve two strategic objectives: the protection of the development of basic agricultural products so-called strategic (cereals, milk, potatoes and sugar) and compensation for producers in the event of agricultural disasters.

Globally, on the basis of the green revolution goal, the success of these R&D should result increased the production volume of basic agricultural products, by increasing yields and agricultural productivity and lower the level of agricultural imports expensive and rarely by the degree of respect and apply the principles of sustainable development.

So the use of new technologies such as cultural diversity or animal genetic material shows very contradictory results, with rising environmental costs (protection of forest areas and backgrounds, the use of mechanization on fragile soils with increased erosion, ...) and the social costs (loss of a genetic heritage applied to the arid conditions, deterioration of the collective actions with the individual production motivations).

In some difficult areas, these new technologies do not find their place because of the lack of infrastructure for production and transport, and low participation in services such credits to finance the costly inputs.

Also applied research, partly in experimental research institutions overlooked the local expertise of the actors and the spread of this research was done at the expense of local knowledge which ensured a balance between the medium and the community.

In the arid media, the options distribution difficulties are in intensive systems, which have been frequently reduced for social reasons, such as non-rationality of producers or low level of education in marginal and disadvantaged areas, etc.

The basic consequence is the reduction of the actions to the destructive technical applications of the nature to restrict the environmental risks, in particular the risks of drought.

However, facing the demographic increase of the Maghreb countries, and in light of the urbanization and unemployment increases rates attached to the emigration from the marginal surroundings, of the pastoral zones deterioration, the increasing desertification problem, and the weak technological transfer of research in the difficult zones that correspond to more of 85% of the territory, the agricultural research was interested again controlled in the small and medium agricultural farmers of the arid and semi-arid zones, but this new orientation made itself it in a setting of liberalization, from the years 80, named pre – adjustment period.

5. ECONOMETRIC METHODOLOGY AND DATA

The approach selected in this paper was to model the mechanization impact on the agriculture sustainability in the Maghreb countries. Our initial intention was to cover all countries in the Maghreb, but given that some countries have not yet data of agricultural productivity (for example, Libya, Mauritania), the samples are included only 3 Maghreb countries: over the period of 1997-2010.

5.1. Data

Data were extracted from two sources, the data will be used for the measurement of variables are taken from the database of the World Development Indicators (WDI 2010) and food agriculture organization (FAO 2010).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Information related the expenses in research and development "R&D" (ERD), the expenses in information and communication technology "ICT" (EICT), the energy production (EP) and the net income per capita (NI) are collected from Worlds Development Indicators (World Bank, 2010). Other information related to agricultural productivity (AP), the mechanization, the Labor (L), the farming population (FP) is collected from food agriculture organization (FAO, 2010).

The dependent variables of interest are agriculture productivity, energy production and net income per capita.

5.2. The Variables

Our analysis founded on macroeconomic factors:

- **Agricultural Productivity (AP):** is agriculture in value added by the worker (% of GDP) (WDI, 2009). V. Ruttan (1977) indicates that the agricultural growth, improvement begins with the apparition of one sustained increase period in the total productivity via the use of new factors and new technologies; our technology is the system of irrigation (Rachida Khaled and Lamine Hammas, 2014).
- **The Expenses in Research and Development (ERD):** Clark and Youngblood (1992) showed that the variable " technology ", as the expenses of the R&D changes the supple utilitarian shape with time is included in the specification of the function of profit, this variable permits to solve the problem of tendency of time (Colin Thirtle, Robert Townsend et Joban van Zyl, 1995). The R&D is the key of development and modernization of the agricultural sector.

Even in the developed country, the agricultural systems of research meaningful are dedicated to testing and refined the innovations of the agriculturists and to test the adaptation of exotic exploitation varieties and the species of the animal (Vernon W. Ruttan, 1977).

- **The Expenses in Information and Communication Technology (EICT):** permits to improve the sector by the diffusion of innovation to the world level and the diffusion of the R&D toward the producers and the consumers.

The ICT decreases the uncertainty of the producers concerning the bought input and of the consumers concerning the consumed product (Gershon Feder and Dina L. Umali, 1993).

- **The Mechanization (M):** it is a very important technology to improve the outputs of producers. (E.J.Clay, 1982).
- **The Labor (L):** Jimmy Alani (2012) proved that the labor is considered as a technology that permits of replaced the machinery in some cases to keep the durability of the sector.
- **The Farming Population (FP):** is himself the producers, the consumers and the manpower. The farming sociologist research has contributed to the diffusion efficiency of technology (Vernon W. Ruttan, 1977).
- **The Energy Production (EP):** energy production includes forms of primary energy, or oil (crude oil, natural gas liquids, and oil from unconventional sources), natural gas, other solid fuels (coal,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

lignite, and other derived fuels) and renewable and waste-derived fuels and primary electricity, all converted into oil equivalent (WDI, 2011).

- **Net Income Per Capita (NI):** net income per capita based on rate parity purchasing power (PPP). Net income per capita in PPP is gross national income converted to international dollars using the rate parity purchasing power (PPP). An international dollar has the same purchasing power over net income per capita stating that a US dollar in the United States. The net income per capita is the sum of value added produced by all residents, most all tax revenues (less subsidies) not included in the value of production plus net receipts of income (compensation of employees and property income) from the abroad. The data are in current dollars International (WDI, 2014).

5.3. Econometric Methodology

From a methodological viewpoint, we chose to value the involvement of the innovations technological to the durability and the growth of the agricultural sector based on the standard production function of Cobb - Douglas type (1928) improves by Dowricks and Rogers (2002) respecting the properties traditional neoclassical (Teheni El Ghak, 2009).

$$Y = AK^{\alpha_k} H^{\alpha_h} L^{\beta} \text{ or } \beta = 1 - \left(\alpha_k + \alpha_h\right) \tag{1}$$

where, Y is a dependent variable which is defined by agricultural productivity, energy production and net income per capita. K, H, L and A are, respectively, the physical capital, the human capital, the labor that grows to the rate exogenous and constant " n ", the technical progress is neutral in the sense of Hicks (1932) and αk, α_h, β are the production elasticity's (Teheni el Ghak, 2009).

However to evaluate the participation of technological innovation, we decomposed the stock of physical capital in two parts: the material, physical capital is the mechanization (M) and the immaterial physical capital is the expenses in the information and communication technology ICT (EICT).

The ERD is the investment in human capital, according to the theory of human capital (Malam Mom Nafiou, 2009).

The expenses in R&D (ERD) and the expenses in the technology of information and communication, ICT (EICT) are considered like an investment in the innovation (OECD, 1999).

The stock of the labor is decomposed into two parts: the labor in the agricultural sector (L) and the farming population (FP).

The goal of this paper is to examine the relationship between technological innovation and agricultural sustainability through the impact of mechanization on agricultural productivity, energy production and net income per capita.

This relationship is measured by a simultaneous equations model (3SLS) extended as follows:

$$\begin{aligned} AP_{it} &= \alpha + \beta_1 \left(EICT\right)_{i,t} + \beta_2 \left(M\right)_{i,t} + \beta_3 \left(ERD\right)_{i,t} \\ &+ \beta_4 \left(L\right)_{i,t} + \beta_5 \left(FP\right)_{i,t} + \beta_6 \left(EP\right)_{i,t} + \beta_7 \left(NI\right)_{i,t} + \xi_{i,t} \end{aligned} \tag{2}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$EP_{it} = \alpha + \beta_1 \left(EICT\right)_{i,t} + \beta_2 \left(M\right)_{i,t} + \beta_3 \left(ERD\right)_{i,t} + \beta_4 \left(L\right)_{i,t} + \beta_5 \left(FP\right)_{i,t} + \beta_6 \left(AP\right)_{i,t} + \beta_7 \left(NI\right)_{i,t} + \xi_{i,t} \quad (3)$$

$$NI_{i,t} = \alpha + \beta_1 \left(EICT\right)_{i,t} + \beta_2 \left(M\right)_{i,t} + \beta_3 \left(ERD\right)_{i,t} + \beta_4 \left(L\right)_{i,t} + \beta_5 \left(FP\right)_{i,t} + \beta_6 \left(AP\right)_{i,t} + \beta_7 \left(EP\right)_{i,t} + \xi_{i,t} \quad (4)$$

i = 1, 2,…N, t = 1,2,…Ti

where AP, EP and NI are the dependent variables, are defined respectively as agricultural productivity, energy production and net income per capita. The Independent variables are the expenses in research and development (ERD), the expenses in information and communication technology (EICT), the mechanization (M), the labor (L), and the farming population (FP).

Equation (2), allows measure the impact of technological innovation on economic sustainability through the effect of the mechanization (M) on the agriculture productivity (AP), as well as the spending of research and development (ERD) and spending of information and communication technology (EICT) impact.

Equation (3), allows examine the impact of technological innovation on environmental sustainability through the effect of the mechanization (M) on the energy production (EP), as well as the spending of research and development (ERD) and spending of information and communication technology (EICT) impact.

Equation (4), examines the impact of technological innovation on social sustainability through the effect of the mechanization (M) on the net income per capita (NI), as well as the spending of research and development (ERD) and spending of information and communication technology (EICT) impact.

Our methodology is based on an estimate of the simultaneous equations model (3SLS), a sample of 3 Maghreb countries (Algeria, Morocco, Tunisia) and a measurement of the variables from the data for the countries will of 1997 until to 2010.

This simultaneous equations model is estimated by the generalized method of moments (GMM). Since generally, the results of GMM are robust.

6. RESULTS AND INTERPRETATION

Table 2 provides summary statistics on the variables.

Table 2 shows that the average agricultural productivity, the entire sample is 2.437398%. The inter-individual variance (between) 0.0908%, while the intra individual variance (time) is equal to 0.0172%, in our case the inter-individual dimension (3 countries) is very important that the intra-individual dimension (17 years country) (0.0908%> 0.0172%). The same for the regression (3) and (4).

Table 3 summarized the results of three least squares (3SLS) models for the sample of the 3 Maghreb countries from 1997 to 2013.

Constante	2.894438 (0.001)	-4.792734 (0.006)	9.310632 (0.000)
Observations	37	37	37
R^2	0.9243	0.9867	0.9879

Note. — Panel estimations of the 3 Maghreb countries. The dependent variable is the agriculture productivity (AP), energy production (EP) and the net income per capita (NI). Variables in parentheses are at the significance level of 1% *, 5%** and 10%***.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The first column presents the effect of mechanization on economic sustainability through her impact on agricultural productivity. The second column indicates the effect of the mechanization on environmental sustainability through her effect in energy production. The third column shows the impact of mechanization on social sustainability through her effect on net income per capita.

According to the regression (2), we show that where agricultural productivity (AP) increases by 1 percentage points, mechanization (M) decreases by 0.0075109 percentage points, labor (L) decreases by 0.0595136 percentage points, net income per capita (NI) drops by 0.0000302 percentage points, R&D expenditure (ERD) and communication and information technology expenditure (EICT) increase respectively by 0.2154256 percentage point and 0.0140135 percentage point, farming population (FP) raises by .0148279 percentage points, and energy production (EP) increases by 2.66 percentage points.

This negative impact of mechanization on the sustainability economic explains that the mechanization cannot achieve economic efficiency in the Maghreb countries due to the intensive use of mechanization in the sector, allowing deteriorate soil fertility over time and eventually lowers productivity and performance in the agricultural sector.

In the regression (3), we mark that wen energy production rises by 1 percentage points, mechanization (M) increases by 0.0752307 percentage points, labor (L) increases by 0.2157 percentage points, net income per capita (NI) drops by 0.0000361 percentage points, R&D expenditure (ERD) drops by 2.626171 percentage points, communication and information technology expenditure (EICT) increase by 0.0401492 percentage points, farming population (FP) raises by .1443269 percentage points, and agriculture productivity (AP) increases by 0.0443973 percentage points.

According to the study of L. Kallivroussis; A. Natsis; G. Papadakis (2002), the mechanization ensures the transportation of the oleaginous plant energy to processing for the production of biodiesel. The use of mechanization in agriculture increases the energy work by reducing the working hours of each employer. So the mechanization increases energy production.

Regression (4), indicate that when net income per capita (NI) increases by 1 percentage points mechanization (M) increases by 0.0032048 percentage points, labor (L) increases by 0.0197317 percentage points, energy production (EP) rises by 3.25 percentage points, R&D expenditure (ERD) increases by 0.1818109 percentage points, communication and information technology expenditure (ECIT) increase by 0.0365969 percentage points, farming population (FP) decreases by 0.037439 percentage points, and agriculture productivity (AP) increases by 0.0053343 percentage points.

Usually technological innovation affects positively the social aspect, mechanization is produced by innovative societies and eventually allows increased wages of companies and their purchasing power that leads as the decline in poverty.

Mechanization improves the purchasing power of Employers in the industrial sector such as an equipment manufacturing society, for against the rural population suffers from very high level of poverty. As he explains C.P.Timmer (1992), the agricultural sector is like a black box, it provides power to all the other sectors against it is not growing.

In the Maghreb countries, the mechanization affects positively the sustainability's environmental and social but it affects negatively the sustainability economic.

According to the results of the simultaneous equations model (3SLS) estimation, we noticed that the workforce has an important role in the functioning of agricultural machines. The three regressions (2), (3) and (4) show that the relationship between mechanization and labor is positive.

The impact of mechanization on economic, social and environmental aspects is explained by the effect of labor on the three durabilities. The workforce in agriculture of the Maghreb countries is unqualified.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The lack of learning by doing in the agricultural sector prevents increasing performance and productivity through step full of ecological, poor use of fertilizers, spreading pollution and over-exploitation of water resources (Feder and Umali, 1993).

The result of the estimated regression No. 3 shows that the level of research and development to a negative impact on the environmental aspect through their impact on energy production, this result can be interpreted by the novelty of the sustainable agriculture in the Maghreb countries, such as organic farming.

Biological research and development remains until today in the laboratories and has not yet applied to a field.

The information and communication technology (ICT) has a positive effect on all three aspects (economic, social and environmental), this result is explained by the introduction of new technology (mobile, internet, etc.) in rural areas and their participation in the agricultural sector through improved marketing of agricultural product line, development and definition of sustainable agriculture concept and organic products in the Maghreb countries.

The result of the estimated regression No. 4 indicates the farming population affects the affects negatively the social aspect through their impact on the net income per capita.

The population increase in rural areas increases the pollution in the zone and increases the use of water resources, leading to over-exploitation of natural resources.

Despite the positive effect of mechanization on the social and environmental aspect, mechanization used by Maghreb countries is not sustainable since it cannot achieve economic efficiency.

7. CONCLUSION AND POLICY RECOMMENDATIONS

The concept of sustainable development has spread during the 90s in scientific research both locally and planetary. All this research agrees that the achievement of sustainable development depends on the respect of four essential principles: equity between nations and generations, the equilibrium of the economic situation and the protection of the environment.

On this basis, several economists and scientists believe that the diffusion of technological innovation is a basic means to ensure sustainable development in the agricultural sector.

To verify this effectiveness, we tested the effects of technological innovation on the agricultural sector in the three Maghreb countries (Tunisia, Morocco and Algeria) for a period from 1997 to 2010 by a model of simultaneous equations, as well as their ability or non to achieving the objectives of sustainable development in agriculture sector.

The estimation results show that mechanization used by Maghrebin farmers is unsustainable. For this it's unable to achieve the sustainable development objectives in the agricultural sector of Maghreb countries. The mechanized agricultural land use may lead to reduced fertility and increased pollution.

A recent study done by CEMA (2014) indicates that there are 12 types of agricultural mechanization in the world. The weak type is used by developing countries, particularly Africa. It can be concluded that the poor quality of mechanization used by Maghreb countries to impact the agricultural sector sustainability.

Our findings have important policy recommendations for Maghreb countries.

First, the government support for funding and Development: the Maghreb Farmers need for state subsidies to buy sustainable agricultural machines with good quality. They also need the development of their rural areas by building infrastructure to attract investors to invest in the agriculture sector.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Secondly, improve training in the rural middle, especially how to operate farm machinery: the workforce in the agricultural sector of the Maghreb countries is not qualified because of their limited education level. The majority of labor worked in agriculture is the farming population.

Third, the development of environmental protection strategy and implementation in the rural middle, for example, the payment of fees for people that generate negative externalities in the rural areas.

Chapter 2
Practice of Green Marketıng Activities in the Organic Agricultural Sector in Turkey

Veysel Asoğlu
Harran Unıversıty, Turkey

Halil İbrahim Şengün
Dicle University, Turkey

ABSTRACT

Requests and needs are not static in a growing and changing world. On the contrary, they can develop and change with the effect of both environmental and internal factors. Green marketing is the request of social civilization. One of the effects of this growing interest in environmental markets in Turkey and the rest of the world can be seen in the move towards organic agriculture. The main purposes of this study are to define organic agriculture as described by environmental marketers and as practised in the agricultural sector, and to explore the current condition of organic agriculture in Turkey and the rest of the world. Subsequently, organic agriculture and the main problems in its related sectors will be discussed and suggestions for solutions will be given. Suggestions will be given that include political, as well as research and development and training programs that are related to improving organic agriculture and increasing organic exports.

INTRODUCTION

Sustainable agriculture involves the production of food products with sufficient and quality amounts and with appropriate costs. Besides, economic vitality of world agriculture involves protection of environment and natural agriculture resources and systems and practice that will develop welfare of population of the World. The most important fact which should be examined about sustainability in Turkey is agricultural activities and the subject of organic agriculture. Because, agriculture is the starting point which we define as prime production of food chain. Therefore, organic agricultural activities in Turkey will be tried to be examined in the study and problems faced will be put forward and solution ways will be discussed.

GREEN MARKETING

Although environmental issues affect human activities and whole human health, the number of science fields dealing with environmental issues are pretty few. The more the interest of society towards natural environment increases, the more businesses should review their internal policies in order for them to be able to fulfill the requests of society. Green Marketing takes places in the literature with different names such as ecological marketing, environmental marketing, sustainable marketing and conservationist marketing and etc. All of these concepts take reviewing marketing programs to be applied in meeting requests and needs of consumer with conservationist approach as a basis (Shehu, 2010).

Marketers haandcompiled process of change of green marketing definitions in time. According to this, development process of green marketing in time can be stated as below;

At firstly, Henion and Wilson (1976) emphasized the necessity of that all marketing activities in environmentalist marketing should become remedy for the causes of environmental problems and should bring awareness. Recently, İslamoğlu (2013) defined green marketing as "businesses' determining their marketing strategies, programs in a way that will protect and develop natural environment and applying them."

It is stated by financial communities that green marketing involved in marketing literature in a seminar, the subject of which was ecological marketing, American Marketing Union organized in the USA in 1975 for the first time (Erbaşlar, 2007; Ay & Ecevit, 2005).

As Ottman (1993) informed, green marketing is a work strategy which examines positive and negative sides of pollution, energy consumption and consumption of exhaustible resources, which aims at long-term profitability within the perception of responsibility in meeting the needs of society and consumers (Alagöz, 2008). It may be stated that green marketing has arisen from societal marketing with its one aspect. Societal Marketing is a marketing approach which aims at not only satisfying only its customers but also considering the expectations of society (Pezikoğlu, 2012).

Green Marketing is an approach which has been advancing by becoming more and more powerful since 1980s as a new marketing strategy which has double-sided (producer-consumer) interaction and compulsivity. Besides, green marketing means a process which renews itself continuously. It is observed that green marketing has become different conceptually in time. According to this, "ecological marketing, which involves all marketing activities which causes environmental problems and which will become solution to these environmental problems, and which showed up with phrases of recycling, ozone-friend and etc." comprises the first stage. The second stage is "green-environmentalist marketing". The third stage is stated as "sustainable-green marketing". Undoubtedly, development of environmental marketing has had some effects on marketing in the last 10 years. It is known that giant companies such as IBM, McDonalds and BT and etc. force their suppliers to show higher eco-performance by using their purchasing power in their hands. And it is seen that they control these works with green supervising. (Pezikoğlu, 2008).

SUSTAINABLE AGRICULTURE AND ORGANIC AGRICULTURE: TRADES AND SUBSIDIES

Sustainable agriculture is related to agricultural dimension of sustainable development. In sustainable agriculture, it is essential that in addition to that natural resources should be protected in the long run,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

agricultural structure where agricultural technologies which do not harm environment should be formed. Synthetic production inputs are used without supervision in a number of countries in the world. And at the same time, intense (conventional or intensive) agricultural production are being carried out without thinking negative results that cultivation techniques and technologies form. Nowadays, these practices has started to get attention as much as waste industry or urban pollutions with their characteristic of creating danger of life which may reach human via their effects on deformation of natural balance and also all creatures. Because of this, in sustainable agriculture, techniques that have not lost their naturality yet have had necessity. Here, using inputs which are not natural such as pesticides, synthetic fertilizers and etc. should be avoided and organic agricultural techniques meeting with health and environmental standards play a key role. Organic agriculture which bear importance in terms of reflection of sustainable agriculture to practice has started to constitute a necessity together with the development of environment awareness especially in recent years. In addition to this, products chosen in order to know and protect some agricultural products in especially European Union (EU) countries are registered in sustainable agriculture perception (Turhan, 2005).

Sustainable agriculture are being tried to be carried out with different systems in a number of countries round the World. Products produced by using this method and system are among the green products. HACCP (Hazard Analysis and Critical Control Point), ISO (International Organization for Standardization) series, organic and good agricultural practices confront us as green marketing products. (Albayrak et al., 2010).

Organic Agriculture is one of the systems of sustainable agriculture. However, Organic Agriculture has specific principles and practices in the process from the production of products on the field to their marketing (Demiryürek, 2011).

Sustainable aspects of organic agriculture within sustainable agriculture concept can be summarized as below:

- Avoiding earth and water pollution, even if it is low, as a result of choice and application of natural chemicals applied compatible with ecological environment and designing an agricultural production system which may be within ecological environment,
- Having formed a new system in terms of economic sectors, actors within conventional system being able to be within this commercial system.
- Producer's Adopting production methods protecting environment in rural areas,
- Distributing risk by having activity which has any other market network and price within agricultural activities carried out on the basis of businesses,
- Because work power need is higher, preventing unemployment and, being positive for businesses whose work power is intense,
- Being in the market as a new product which is just in the beginning of product life cycle, having become a trademark, and being able to form organic label at the national level.

As against the aspects mentioned above, criteria which should be taken into consideration in order to examine organic agriculture with regard to sustainability of agriculture can be classified as:

- Food safety and guarantee,
- Sufficiency and continuity in business income,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Continuity of employment in rural areas,
- Rural welfare (Pezikoğlu & Yavuz, 2006).

When the literature is examined, there are a number of definitions about the concept of organic agriculture. However, because there is no common definition which is agreed generally, it brings together some discussions and differences of opinion. Here will be given a definition whose framework has been drawn up technically by USA Agriculture Department (USDA). According to this "organic agriculture is a production system which forbids use of fertilizers with synthetic content, pesticides, growth regulators or which avoids them to a large extent. Organic agriculture systems depend on processes of product alternation, plant residues, animal fertilizer, legume, green fertilizing, organic farm waste and control of biological pests in so far as possible in order to cultivate the soil, protect the productivity, to provide plant foodstuff, to control pests, weeds and diseases (Anonymous, 1980).

Lampkin (1990) emphasized sustainability advantages of organic agriculture and defined organic agriculture as an agricultural approach aiming at the purpose of forming an integrated agricultural system which is environmentally, socially and economically sustainable. He emphasized that dependence on out-of-farm inputs should be reduced whether they have chemical or organic roots.

As a result of long-term studies, the definition of organic agriculture was approved by International Organic Agricultural Movement Federation (IFOAM) in Italy in 2008. According to this; "Organic Agriculture is a production system which sustains soil, ecosystem and human health. The system depends on ecological processes, biological diversity and cycles which have been adapted local conditions. Organic agriculture brings traditions, innovations and science together in order to be beneficial to the environment in which it is lived, to generalize fair relation and a better life quality for all related parties" (Anonymous, 2009).

In the efforts of increasing especially agricultural lands and water resources in the world in recent years, more and more difficulties are being met. Environmental effects such as oil erosion and air pollution have slowed down the increase of agricultural lands in the world, even they have brought it just to the point of stop. Not being able to cultivate the lands which have suffered from erosion seriously, and the lands' being used in out-of-agriculture areas such as buildings and factories cause millions of hectares of lands to be lost every year. While some countries such as Brazil, Israel and etc. are forming new agricultural lands by rehabilitating deprived lands in terms of productivity, other countries such as Turkey, China etc. convert 1. class agricultural lands into other usage areas. As a result of all of these, the amount of agricultural lands per person reduces in both Turkey and the World (Rehber and Çetin, 1999). On one side, the world population is increasing and on the other side decrease in cultivated lands is seen as an important problem. Developed and developing countries began to try to take precautions against all of these threats and started studies related to this subject in 1950s (Turhan, 2005).

Studies, which continued separately until 1970s, gathered movements of organic agriculture all round the world under a common roof in 1972. With the foundation of IFOAM which aims at directing development of the movement healthily, protecting required standards and methods, conveying all developments to its members and farmers, this gathering gained a different dimension. Really, practices of production standards which have been combined and/or have become adapted, aiming at production of organic foodstuff all round the world, are quite important for growing organic agricultural land and organic product markets to develop more. Harmonizing rules and every country's organizing its own regulations commonly is necessary in order to remove the difficulties of trade of organic products (İpek & Çil, 2010).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is known that organic agriculture started for the first time in EU and USA and then spread to other countries. There are total 37.2 million hectares of organic agriculture land (including transition process areas) in the world. In today's world, 1,2% of agricultural land cultivated in the world is organic agricultural land. (Eryılmaz et al.,2015; Emir & Demiryürek, 2015; Willer & Klicher, 2011). Nowadays, organic agriculture is becoming a sector whose market volume and consumption demand are increasing more and more all round the world. It gets attention that developed countries start to be in the position of consumer and developing countries start to be in the position of producer.

One of the most important driving power at the back of organic agriculture is that organic products are more reliable than conventionals with regard to chemical use and residue problem and that the number of consumers believing this is increasing. It is a fact that organic agriculture reduces toxic chemicals, prevents the use of Genetically Modified Organisms (GMO) definitely, reduces food additives and colorant use, on the other hand, increases beneficial minerals and foodstuff, beneficial oil acids and antioxidants. In addition to this, organic products it is mentioned that organic products have the potential to reduce the risk of formation of cancer, coronary heart diseases, allergy and hypermobility problem in children. A number of studies showing comparative benefits of organic food and forage in terms of health have been conducted. There are claims that organic products are more superior than products produced with other alternatives in terms of safety nutrition content and value. Especially, expectation that vegetables and fruit produced via organic way will be more beneficial than conventionals in terms of health is common (Rehber & Pezikoğlu, 2013). While up to 500 additives are permitted in conventional food production, the number of additives permitted in organic production is only about 30 (Heaton, 2002).

Countries making organic agricultural production preferred starting from usually conventional products of their countries in the transition towards production all round the world. For example, the first products produced organically are tea in India, milk and dairies in Denmark, meat and meat products in Argentina, banana in central America and Africa countries, date palm, olive oil in Tunisia, dried and fruit with hard shell (İpek & Çil, 2010).

While a fast production decrease is the point in question at first in the transition towards organic agriculture when compared to conventional agriculture, production level approaches to the previous level with precautions taken afterwards. While giving up using synthetic inputs causes productivity decrease, it provides important cost savings. In an evaluation made, while gross yield with the rate of 6-17% is the point in question in transition towards organic agriculture in plant production, because of decrease in costs, net income loss is said to be about 13% at most. Even if organic agriculture seems to be financially less advantageous than conventional agriculture, especially in the long run, it is actually more superior with economic contributions in the way of protecting environment and natural balance. Consumer income in the long run is very important in sustainable agriculture and so in organic agriculture (Turhan, 2005).

In World Trade Organization (WTO) organizations, agriculture has been involved within globalization. In WTO agreement, opinion of market mechanisms' directing agricultural production and change by purging agricultural policies of state intervention and social dimension has been agreed. However, because of welfare differences between rural communities, some privileges have been granted in certain subjects in agriculture. According to this, internal supports are examined in 3 parts, Red Box, Blue Box and Green Box. Green Box includes supports from which any discount is not requested in internal supports. Organic agriculture is assessed within this box. By the same token, direct income support payments are within this scope and direct income support payments made to organic agriculture does not get limited by WTO. FAO grants supports to organic agriculture and similar environment-focused

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

agricultural systems. Principles and standards of organic agriculture was defined by Codex Allimentarius (Pezikoğlu & Yavuz, 2006).

Before mentioning supports given to organic agriculture in Turkey, it is beneficial to mention their examples in the world briefly;

Organic agriculture have been conducted under the control of the state in the USA. Organic Agricultural Producers are supported with advance payments or payment conveniences for especially certification.

In Latin America, organic action generally has developed with its own effort. There is no state which provide support or economic help directly. As an exception, the state has published interministy organic plan in order to encourage organic production, research, marketing and trade in Brazil. In Bolivia, an action plan has been created in order to support development of organic production and to establish national control system.

EU Countries, which own more than 50% of organic food market, is also in the position of the biggest foreign purchaser of the world. Organic agriculture has located in the center of agricultural policy of the Union with Common Agricultural Policy (CAP), which took effect on 1 January 2005. With reforms made in common agricultural policy, agricultural subsidy policy has changed completely. According to this, protection of environment, food safety, animal and plant health and sustainable use of agricultural land are predicted with new regulations. In addition, both regulations related to agriculture-environment relations and various regulations dealt with within the scope of environment policies, and national programs which each country member of EU has developed according to their own conditions contributes for organic agriculture to be directed. Farmers in all EU countries gets support within the scope of agricultural environment programs. State supports aimed at organic agriculture in different EU countries are as follows;

The United Kingdom (UK) has given the biggest environmental priority to sensitive regions. Depending on the structure of land, farmers are granted previous period supports paid in the last 5 years in this country. In Germany, development of organic agriculture was supported by forbidding chemicals from 1989 to 1992. There are a number of different applications about the support granted to organic agriculture resulting from federal structure. Different programs are applied in each one of states in order to support farmers dealing with organic agriculture and participation conditions to these programs show differences. Annual subsidies are granted to farmers dealing with organic agriculture in vegetable production per hectare in Belgium and finance of two research centers which have been established for organic agriculture is provided. In Denmark, the government supports organic agriculture projects and grants subsidies per hectare. Although Danish Farmers are involuntary about transition towards organic agriculture, transition towards organic agriculture has been considerably enabled as a result of government policies and market pressures. In Italy, supports granted to organic agriculture are used like direct income support in some regions. Tax applications to pesticides are started in order to create financial resources in order to be used in development of organic market. In addition, campaigns of awareness-raising of the population are being carried out. In Netherlands, various precautions have been taken in order to increase production and consumption of organic agriculture according to policy called "Organic Market in order to Win". The purpose of legal regulations aimed at farmers making organic production in Netherlands is to increase sustainable investments in agriculture (Anonymous, 2012).

Because of fewness of studies in which organic agricultural trade and state supports are told together in developing states before in the literature, current condition in Turkey, insufficiencies, support elements which are and should be provided to organic agriculture will be examined in the study afterwards.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

In a study that Eryılmaz et al. (2015) conducted, according to results of the research made in certain provinces of Turkey, among the reasons that consumption of organic agriculture and food products is low are highness of prices and knowledge insufficiency. Increasing demand for organic agriculture and food products is important with regard to sustainability of production. Therefore, organic producers who want to continue their existence in the sector and who want to follow the development in the world should turn towards the perception of consumer-focused marketing.

According to Armağan and Özdoğan (2015), in Aydın province consumers prefer organic food products which they qualify as healthy and delicious more as their income level and education level increases. 30,4% of consumers stated that they could pay more to organic chicken and 30,4% of those to organic eggs.

According to results of researches that Akgüngör and et al. (2010) conducted on the people living in urban areas of İstanbul and İzmir provinces, the reasons for consumers to prefer organic products are that their nutrition values are higher and their health risks are lower. Consumers do not perceive organic food products more expensive than conventional equals and they are voluntary to pay up to 36% more to organic labeled and certificated products.

According to Akın et al. (2010), in Niğde province, families under the age of 40, whose income levels are over 1000, with one or two children and especially women consumers within this group are more sensitive about organic food subject than the groups having other socio-demographic characteristics.

According to a research that Dağıstan and et al. (2010) made on consumers living in the center of Hatay Province, 57% of consumers consumed at least one organic agriculture and food product. Knowledge deficit and price highness (70%) are among the leading reasons for consumers' not consuming organic products.

Sarıkaya (2007) determined in his research that the organic product groups which consumers, living in Ankara and İstanbul where organic agriculture and food product market intensifies, buy most are vegetables, fruit and drinks because they are easily found and their product ranges are wide.

Aydın (2011) found out that 7,81% of consumers living in urban areas of Samsun province regularly consume organic products and that knowledge deficit, with 43,22%, is in the first place.

According to Gündüz and Bayramoğlu (2011), 81% of families living in Samsun province agree to pay more for organic chicken. It was determined that monthly family income, education level of family head, monthly chicken consumption, organic food consumption and opinion of consumers related to risks conventional chicken bear in terms of health have effect on payment desire.

Ergin and Özsaçmacı (2011) found out in their study where he researched main reasons for consumers' buying organic product in İstanbul and Ankara provinces that thoughts that organic foods are more healthy, tasty, fresh and environment-friendly are dominant when compared to their conventional alternatives according to findings obtained.

As Erılmaz et al. (2015) stated in their compilation study they conducted, It was determined that markets of organic agriculture and food products intensifies in different parts of Turkey especially in big provinces such as İstanbul, Ankara and İzmir. It was seen that consumers' habit of purchasing organic agriculture and food products is not common in Turkey in general. Among the main reasons for this condition are that consumers do not have sufficient knowledge about organic production and they regard prices as high.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In a study Hassan et al. (2009) conducted, education was found to be the first of effective factors in the formation of consumer attitude and behavior in EU countries against organic food and agricultural products. Because, it is seen that organic agriculture and food products are preferred more by those whose education levels are higher.

In a study Urena et al. (2008) conducted, it was found out that another effective factor in the consumption of organic agriculture and food products is gender. According to findings, although tendencies of women consumers towards buying organic products are higher than men, their wills to pay to these products are lower.

In a research Kızılaslan and Olgun (2012) made, they found out that organic agriculture land and the number of producers are increasing more and more and on the other hand, Turkey cannot use the potential it has about organic agriculture sufficiently.

Gülse Bal et al. (2006) determined in a study conducted in Tokat province that 90% of consumers may pay more to reliable food.

In an organic product demand research conducted by Koç et al. (2001) in the center of Ankara, the rate of voluntary consumers to pay 50% and %100 price difference without reducing their consumption was determined to be 24,2 for tomatoes and 16% for cucumbers (Koç et al., 2001).

In a study Karahan Uysal et al. (2010) conducted, although the most important fact defining organic product is "logo", it is thought that Turkish consumers do not have sufficient information about it. In a study conducted on organic product consumers in İzmir and Ankara, it was determined that knowledge levels of consumers about organic product logos and standards are low and on the other hand, trust in logos is above average.

In a research made by Pezikoğlu (2004), price difference Turkish consumers are ready to pay for organic product was found to be about 2%.

In a research made by Demiryürek (2004), economic factors (especially premium price and market guarantee) were found out to be the most effective motivation element in transition of producers towards organic production in Turkey.

In another research made by Demiryürek (2011), a number of suggestions were made aimed at policies, research and development and training programs related to developing organic agriculture in Turkey and increasing our organic product export.

In a research Bahrs(2004) made, he stated that subsidies should be also supported with tax incentives.

According to findings they obtained in a research Azak and Miran (2015) made in İzmir province, Turkey, they stated that if supports that will increase the number of organic producers are made, the number of producers and consumers will increase, this will increase supply and may be able to balance product prices. State and municipalities should give supports that will reduce the costs of especially sellers, for example, paying transportation costs may prevent product prices from increasing. By increasing market places, opportunity of marketing their products easily should be given to producers, and it should be targeted to reach more consumers.

In a study Lotter (2003) conducted, the aspect of organic agriculture's being a system which provide important benefits to public about reducing environmental costs was emphasized. In the study was also stated the necessity of transferring high costs in transition towards organic agriculture from farmer and organic product customer to public.

ORGANIC AGRICULTURE TRADES AND SUBSIDIES IN TURKEY

Issues, Controversies, Problems

One of agricultural effects of sustainable and green marketing is seen in the shape of turning towards organic agriculture in Turkey and in the world. Organic agriculture practices is becoming widespread not only in developed countries but also in developing countries. This condition has become clear with increasing importance the consumers especially in developed countries give to their health and protecting environment. In parallel with this, organic food market is developing especially in Europe, America and Oceania. Demand for organic products which are not produced in developed countries has caused international trade to develop. So, developing countries whose ecology is suitable for organic agriculture have become organic product producers and exporters in order to be able to meet demands coming from developed countries. With this aspect, organic agriculture is a very valuable element whose importance in Turkish trade is increasing fast (Rehber & Turhan, 2001; Demiryürek, 2011; İpek & Çil, 2010)

Organic agriculture in Turkey started in the direction of demand of European importers and with export of sultanas and dried figs in Aegean Region for the first time in mid-80s and spread all round Turkey from here. Although farmers led the development of organic agriculture in the countries where organic agriculture started, European private organic agriculture companies played an active role in promotion of organic agriculture and adopting it to farmers in Turkey. That is, whereas Europe and in the USA realized bottom-up starting from producer (supply-based), top-bottom structuring of organic agriculture from companies dealing with organic agriculture towards producer (demand-based) is the point in Turkey (Kizilaslan & Olgun, 2012; Demiryürek, 2004; 2011).

Organic products started to gain importance commercially all round the world in 1990s. It became necessity for a national legislation on organic product which came to the fore in those years in Turkey which organizes all stages of organic agricultural activities from production to marketing to be created. In this direction, "Legislation on Production of Herbal and Animal Products" was enacted in 1994. With this legislation, organic agricultural activities were started to be carried out in Turkey for the first time under the supervision of Food, Agriculture and Livestock Ministry (FALM) and within rules determined. Later years, the legislation mentioned was modified in order to comply with changes in EU legislation together with developments lived in the sector and "Legislation on Principles and Practice of Organic Agriculture" was published in 2002.

By considering increasing importance of Organic Agriculture, "Organic Agriculture Law" No:5262 involving provisions of production, consumption and supervision of organic products was published in order to form a ground to penal sanctions and duties and responsibilities of the parties and to strengthen legal regulations made with the legislation in this field. "Legislation on Principles and Practice of Organic Agriculture" which was prepared by depending on this law took effect in 2005. In the direction of demands and needs coming from the sector, changes were made 3 times. At last, Council Regulation No:834/2007 and Council Directive No: 889/2008 were put into practice instead of Council regulation No: 2092/91, and national legislation was brought into conformity with European Union Legislation and was published in 2010. Besides, organic Agriculture Units were formed within 81 Province directorates of the Ministry in order to carry out activities related to organic agriculture. Duties and authorities of those to work in this unit were determined with Communique No: 2005/1. The Communique mentioned was revised as communiques, No: 2009/1 and 2011/4 (Anonymous, 2012).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

There are 42 accredited institutions for certification procedures of organic agricultural producers in Turkey as of 2016. The number of producer businesses having legal entity authorized by these institutions is 1106 (Anonymous, 2016b).

As specified in Table 1, organic agriculture has shown important developments year by year in every sense from the number of products to the number of producers, from total production land to total production amount.

As specified in Table 2, Turkey exported organic fig and fig products the most in 2014 (21.626.691 $). Afterwards nut and nut products (17.046.378 $) and sultanas (13.557.823 $) come.

As seen in Table 3, Turkey exported the most to Germany (19.248.646 $), the USA (19.053.760 $) and France (8.507.402 $) respectively. It is seen that the countries mentioned are developed countries as stated in previous sections.

As specified in Table 4, the first three of organic product import of Turkey the most in the basis of amount are baby food and drink, sultanas and composte (Plum, fig, apricot, peach, cherry)

In addition to general agricultural supports to producers performing organic agriculture, supports of 70 TL/da for vegetable-fruit, 10 TL/da for field crops will be granted in Turkey in 2015 with the decision of Board of Ministers No: 2015/7495 published in Official Gazette on 8 April 2015 and No: 29320. Support payments to be made to producers who practice ranching, to beekepers and to those who produce water products based on kinds are shown in Table 5.

Official documents from which supports related to organic agriculture in Turkey are taken as a reference are as follows;

- Communique on making payment of herbal production support (Communique No: 2015/21).
- Communique on making payment of support to organic ranching and organic water product cultivation (Communique No: 2015/31).

Table 1. Organic agricultural production data in Turkey in terms of years (including transition period)

Years	The number of products	The number of farmers	Land cultivated (ha)	Natural gathering land (ha)	Total Production land (ha)	Production Amount (ton)
2002	150	12.428	57.365	32.462	89.827	310.125
2003	179	14.798	73.368	40.253	113.621	323.981
2004	174	12.751	108.598	100.975	209.573	377.616
2005	205	14.401	93.134	110.677	203.811	421.934
2006	203	14.256	100.275	92.514	192.789	458.095
2007	201	16.276	124.263	50.020	174.283	568.128
2008	247	14.926	109.387	57.496	166.883	530.224
2009	212	35.565	325.831	175.810	501.641	983.715

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Investment management credit with low interest Decision of Board of Minsters (2014/7201 published in official gazette dated 21.01.2015 and No: 29244).
- Decision of Board of Minsters No:2015/8299 published in official gazette dated 16.12.2015 and no: 29564 on Having Investment and Management Credit with low interest for agricultural production used by TR Ziraat Bankası A.Ş. and Agricultural Credit Cooperatives.

Briefly, under the light of documents above, supports granted to organic agriculture in Turkey can be summarized in four main items.

- Land based support payment.
- Product based supports in Organic ranching.
- Having Investment and Management Credit with low interest for agricultural production used by TR Ziraat Bankası A.Ş. and Agricultural Credit Cooperatives (In 2016, the opportunity of credit use with 5.000.000 TL credit top limit with 50% discount from the rate of current interest rate has been provided).
- Support payments which are made to farmers who sign grant agreement and who participate in Protection of Agricultural Land with Environmental Purpose by FALM in order to protect soil and water quality in agricultural land, for the sustainability of renewable natural resources and taking required cultural precautions aimed at reducing negative effects of intensive agricultural activities are being made. Within this scope, 135 TL/da payment is being made to 3.category environment-friendly agricultural techniques and cultural practices (Anonymous, 2012).

In addition to these supports:

- Vegetable market tax are being taken within the scope of "The law on Regulating trade of vegetables and Fruit from raw, semi-products or products and other goods which have sufficient supply and demand depth having organic agriculture certificates".
- Within the scope of Communique on Supporting Environmental Costs, costs of certificate and analysis of organic products aimed at export. Expenditures of Certification and lab analysis (per certificate and/or analysis) are supported with the rate of 50% and up to 25.000 USD.
- Treasure lands are leased for 49 years to investments who undertake to make organic agriculture investment with the amount in TL equals to 10 million USD at least and employ 10 people at least for 10 years within the scope of the project. Entrepreneurs making organic product export benefit from export refund payments within the limits predicted.
- In addition, 600 TL support payment are being made to producers utilizing agricultural publishing and consultancy services. In order to agricultural entrepreneurs to be able to benefit from this support, they should be registered to farmer's registry and/or greenhouse, water products, beekeeping, sheep-goad registry system (Anonymous, 2012).

SOLUTIONS AND RECOMMENDATIONS

In order to create a difference in the market and enlarging marketing opportunities of countries in terms of global competition, first of all strategies about green marketing, developing conventional and organic

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

product potential, e-trade's, which has various advantages, becoming widespread and supports', given aimed at e-trade and marketing, becoming widespread in the dimension of farmers are needed. Using values and products especially specific to Turkey is important on the point of view of Turkey.

When organic product production and export data of Turkey are examined, it is seen that it has not used the potential it has sufficiently and efficiently. But Turkey, whose climate and soil conditions are already suitable for agriculture, is an appropriate country for organic agriculture system because it has lots of biological and genetic diversity. In this case, organic production level should be increased much more and in addition to this it should be encouraged more.

In order for environment-friendly organic agriculture to settle as a sustainable and preferred agricultural system, producers should be motivated, encouraged to this system, and in addition they should be enabled to get more profit than conventional agriculture. Otherwise, producers will not adopt and continue this system especially, when it is considered that income is low in organic agriculture, producers need to be supported especially in transition period.

In addition, supports granted to organic agriculture by the state should be increased and conversion of producers to organic agriculture should be encouraged. Research, training and publishings related to organic agriculture should be generalized by the state, private sector and NGOs. As a result of this, it is thought that both the incomes of producers increase and important amount of contribution will be provided to the economy of the country.

In developed and especially developing countries, some problems in both technical and economic sense are faced in transition towards organic agriculture. One of the most important of these is deficiency of technical knowledge and personnel related to the subject. Organic product raising techniques are a system which needs special knowledge and technology at each stage from production of product, even from preparing soil to collecting, processing, and packaging and distribution stages and which bring a number of rules together with it. Provided that Farmers and industrialist advance their technical knowledge and skills continuously, organic agriculture will be able to develop. Because of this, if expert personnel is added to support items to be granted by the state, it should be enlarged in a way that it will include salary and insurance Premium.

There are some differences in two items within production cost in organic agriculture when compared to other systems. One of these is the cost of certification and the other is the need of increasing work power. This additional work power need may be thought to be employment booster from the point of businesses whose family work power is high. But, it causes foreign work power need to increase in other businesses and to cause work power cost to increase. On the other hand, certification cost causes negativeness for both types of businesses. This condition does not leave any other choice other than contracted production for small businesses. In order to remove problems showing up at the marketing stage of organic products produced, contracted cultivation concept comes to the forefront here. Thanks to this, both producers market their products they have produced easily and industrialists gain the guarantee of obtaining raw material required with the quality and amount they request.

Target for the next a couple of years should be determined and market share and growth rates should be followed according to this. Contact offices that will give consumers information about it should be formed. Questions and problems of producers should be removed via these offices, required applications for incentives should be able to be made. Because it is known that Province directorates of Food, Agriculture and Livestock ministry are dealing with intensive bureaucracy and personnel problems, it is obligatory for a separate organization structure for organic agriculture to be established. In addition

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to this, agricultural engineers who will carry out consultancy for organic agriculture should be trained and assessed separately.

It is targeted for the energy used in transportation by consuming products produced in organic agriculture domestically. Nevertheless, products are sent to different parts of the world and it is observed that it has a similar structuring to conventional product trade. Therefore, classic supports as well as logistic supports should be provided.

Certification and branding in organic products' opening to world market are among indispensable works. Producers should be supported and their costs should be covered for these.

Although some deficiencies are generally in policies of developing countries related to organic agriculture, the advantages that they have should be remembered. In organic agriculture, there is no need for big investments for irrigation, energy and outside inputs. But investment is needed in order to make production by giving importance to especially trainings and researches. Additional supports for these should be provided to universities and research institutes. R&D activities conducted by public and private sector institutions related to organic agriculture is limited although they have increased with the efforts of some university research institutions in recent years. R&D works in organic agriculture should be supported continuously. One of the most important steps to be taken is that more agricultural (especially as aimed at organic agriculture) R&D activities should be encouraged in Technoparks which continue their activities under the coordination of universities and which are established in some parts of Turkey.

Technics and technologies used in organic agriculture are acceptable indicators in terms of green marketing with current condition. So, it is not necessary for new environmental systems with more cost as in conventional production systems to be formed. However, following new technologies produced on this subject may be useful for differentiation of organic producers and for being favored in the market more. It is significantly important to consider differences the business is within in the use of new technologies in organic agriculture. The new technology produced should be examined thoroughly with regard to location of the business, species produced, kind and business capital and should be adopted according to this. Especially as new packaging technologies, compostable packages, reduced production materials or those that may be used with different purposes, technological systems which increase the efficiency in water and energy use during production process and recycling involve techniques and technologies that may form differences depending on business and that may be used in organic agriculture within green marketing perception. In order them to be able to follow the technologies which improves fast in these matters, limits of supports of current technological renewing and capacity increasing applied to SMEs should be enlarged in a way that will be valid for organic agriculture producers.

Although export of organic agriculture products in Turkey is increasing more and more, the share of the country in organic agriculture and food products market is too low. Especially, supply of organic agriculture and food products in North American and European countries cannot meet demand increase in these markets. Therefore, these markets present a good opportunity for developing countries whose ecology and infrastructure is suitable for organic agricultural production and export like Turkey. Unfortunately, organic products which are exported as raw material without being processed such as dried fruit, nut, peanut and field corps and etc. mean loss in potential export revenues. In this sense, consultancy and technical support should be provided to producers in order for them to produce processed production not raw material. So added values will have stayed within the country.

Because of limited works of non-governmental organizations (NGO) with local quality, organic agriculture and food market in Turkey is far from reaching the level intentioned and targeted. Besides, deficiency of cooperation between public, private sector and NGO's and that there is no knowledge

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

sharing network confront us as another critical question. The numbers of producer cooperatives and organizations formed by producers' making organic production coming together is limited. Because they cannot get sufficient incentives from governments, they cannot defend their rights against private sector sufficiently and they cannot play an effective role in organic agriculture and food product market.

FALM should apply suitable incentive instruments and polices via especially organic producer unions, NGOs or private companies or directly to producers in order to ease transition process of producers towards organic production via financial incentives such as credit with low interest, premium price, cheap organic input and marketing guarantee. Similarly, FALM should support organic producer organizations via research, training and publishing activities.

Organic agriculture should be encouraged via public and private institutions with pilot projects in places whose ecology is suitable for organic agriculture in order for organic agriculture to be adopted and become widespread. In addition to organic herbal production at which we are good, special importance should be given to organic animal production which is too limited in order to increase export potential of Turkey in the world's market of organic agriculture and food where a great completion are lived and required encouragement precautions should be taken in order for it to improve.

In addition to organic marketing companies working as aimed at export, especially local organic producer unions should be supported financially by the government. In order for organic production and domestic market of organic food to improve, process of organic production, control, certification and marketing which are complex should be eased via required legal regulations.

In recent years, Conformity of the legislation of our country to the works done in order to simplify organic agriculture legislation in EU should be enabled. Works aimed at increasing consumer awareness about organic agriculture and food products via works of raising awareness of consumers should be increased. Turkish organic agriculture sector should be coordinated with the help of a high council to be formed and cooperation should be increased between related institutions.

Data aimed at organic production and export should be gathered single-handedly, a reliable database should be formed and results should be published officially. Works of product branding and labeling which are wrong like "Natural", "village product", "without fertilizer", "without pesticides" organic agriculture and food product or which are used to mislead consumers and which causes concept confusion should be terminated legally. In order to increase consumer trust in organic products, project management, and control and certification process of organic products should be brought into conformity with international Organic Agriculture and food legislation and standards.

Organic agricultural production works should be integrated with ecologic agricultural tourism services within the country and local practices should open to international ecotourism field. In addition to this, trade of organic products other than organic agriculture and food products (such as organic cosmetics, textile, wood, tree and local handcraft products etc.), production processes which do not pollute environment and which are compatible with ecology should be encouraged.

FUTURE RESEARCH DIRECTIONS

The most important subject emphasized usually in the studies where Organic agriculture in Turkey is examined is that Eastern and Southeastern parts of Turkey are very suitable for organic agriculture. But, Eastern and Southeastern parts of Turkey are also the most problematic geography of Turkey socio-economically. Because of terrorism lived for years, these regions are in the last places of regional

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

development ranking. In addition, the provinces in this region are in the last places of economic and social criteria such as education, employment and growth. It is a reality which is known and accepted by everyone that supports, subsidies and donations granted in these regions are not used efficiently and effectively at desired level.

Because of terrorist activities, which have increased recently, the number of investors coming are very limited even if the region is the place where investments are encouraged the most. As in all kinds of investments, the most important factor for people who want to make investment in organic agriculture is the feeling of security. Therefore, in addition to supports and incentives granted, formation of atmosphere of security and stability in especially Eastern-Southeastern region should be primary goal.

One of the most important ways of being able to give the required feeling of security to investors and getting rid of deadlock stated above is to bring Government Business Enterprises (GBE) which were carried out as an effective policy in a period to the agenda again with the occasion of organic agriculture investments.

The state can collect private enterprises and entrepreneurs in the GBEs within by controlling supervision mechanism and administrative mechanisms. In the structure of GBEs are partnership structures which are established between private sector and the public in general. So, investors who feel the support of public on their back can make investments more comfortably and securely. This model was applied in Kibbutz farms in Israel and gave positive results. Similar structures may be formed in Turkey. Local people can carry out organic agricultural activities jointly on their own land or on treasure land by working in coordination with the state. With this occasion, wrong use of supports and subsidies granted may be avoided. This system will be an important argument in the solution of unemployment which is one of the biggest problems in especially Eastern and Southeastern Region of Turkey. In the periods ahead, researchers may concentrate on this subject. And benefit of probable organic agriculture GBEs that will be formed may be discussed.

CONCLUSION

In recent years, the greatest agricultural successes are to be found in being able to realize production increases by reducing negative environmental conditions. This is only made possible by using sustainable and environmentally friendly methods in agricultural production. Green Marketing practices bring an agenda of activities aimed at increasing the use of organic methods in the agricultural sector.

Communities around the world are becoming increasingly aware of the environment and its effect on human health. As this awareness increases, the demand for organic products will also increase. As the production of organic produce rapidly increases around the world, this will cause competition between developing countries in the international market. Turkey is in a position to be one of the most important countries with a say in the global market for organic produce, if it can activate its potential in this field with timely interventions.

When Organic Agriculture becomes economically viable, it can generate new employment opportunities and can reveal the new organic products of input giants. It also protects the environment, meets the quality demands of consumers, generates alternatives with regard to rural welfare, and provides increased added value with new products. In terms of sustainability, although organic agriculture has its weaknesses and strengths, its greatest strength can be summarized as the continuity of soil and water resources, thus

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

protecting and maintaining the continuity of agricultural production. In terms of protecting soil resources, it is important to prevent agricultural land from being used for purposes other than agriculture.

Rich biological diversity, relatively clean ecological areas, plant species that are resistant to diseases and pests, and low levels of chemical input are among the main advantages that would come with the development of organic agriculture in Turkey and other developing countries. Therefore, Turkey has great potential to develop and produce a number of products (though not some tropical fruit) because of its ecology, geographical and topographical structure, and various climate characteristics. In addition, the agricultural production system in Turkey is spread over a very large area. Compared to industrialized countries, Turkey's use of chemical input per unit area of agriculture is very low. As a result, there is no intensive pollution in its agricultural land, especially in the Eastern part of Turkey, where the transition towards organic agriculture would be easier than in industrialized regions. Therefore, Turkey can avoid the environmental problems associated with intensive chemical input in agriculture, which is a problem in a number of developed countries. On the other hand, rural employment can be helped by increasing the organic production of labor-intensive products with high added value.

As a result, the development of organic agriculture in Turkey should be accelerated, together with:

- The financial support of governments for types and figures increasing.
- Producer and consumer training.
- Universities and research institutions' increasing their R&D activities.
- The continuous informing the public with visual and written media tools.
- The publishing of agricultural and research studies Cooperation with the private sector and NGOs.

Chapter 3
Rights of Nature to Protect Human Rights in Times of Environmental Crisis

Susana Borràs
Rovira i Virgili University, Spain

ABSTRACT

The well-being of humans and nature are inextricably linked. Nature is particularly mistreated in light of its characterization as merely "property" to be bought, sold, and ultimately degraded for profit. Reinforcing this misperception is the fact that modern environmental laws themselves implicitly accept this claim of "nature as property." They legalize nature's destruction by dictating how much of the environment can be exploited and degraded, rather than as an integral ecological partner with its own rights to exist and thrive. Instead, we need laws grounded in the inherent rights of natural world to exist, thrive, and evolve. The article focuses on the transition from the 'right to the environment' to a biocentric approach constructed around 'rights of nature.' This transition is evident in various new legal instruments, which serve as models for legal systems that can steer us towards more robust and effective environmental laws.

I. INTRODUCTION: FACING NEW CHALLENGES ON ENVIRONMENTAL PROTECTION[1]

The possibility to recognize and protect the Rights of the Nature is, with no doubt, a brand new approach in the field of environmental law. Traditionally, legal systems have considered nature as a "property", as an object over which human rights have been recognized and protected. Moreover, the promotion of laws and contracts to guarantee the property rights of individuals, corporations and any other legal entities as subjects of rightshave been common. The consequence, therefore, is that environmental laws and regulations, despite their preventive approach, have been developed over the last years in a way that recognize and legalize environmental harm. The amount of pollution and degradation allowed in the environment has been regulated within the legal framework and in some cases foresee the potential for environmental degradation.

Therefore, the human rights approach would offer a chance to protect the environment, conceiving it as a necessary dimension to enhance the most fundamental human rights. Certainly, the recognition ofindividual rightsin relation tothe environmenthas had a significantinfluence at supranational level. However, in general, the level of recognition of a human right to an adequate environment has not been without controversy: first of all, the protection of the environment through the configuration of a human right to an adequate environment rather than imposing obligations to protect the environment has no positive impact on the conservation of natural resources; secondly, the recognition of the protection of the environment is not really an individual right, but a programmatic norm lacking forcibility and, therefore, not required to the State (Bedoya, 2006).

Differently, a new approach is emerging, the recognition of the rights of nature, which imply a holistic approach to all ways of life, including all ecosystems. In recent years, a series of normativeprecedents have surfaced, which recognize nature has certain rightsas a legal subject and holder of rights. These precedentscontribute, together with greater sensitivity to the environment, to areorientation ofhow to protect the environment, considering the Earth as the center where life takes place. Therefore, the rights of nature are recognized as a holistic concept comprising all kinds of life and their ecosystems.

Through this perspective, called "biocentrism", Nature is not an object of protection anymore, but a real subject of rights, with fundamental rights as any other subject has, for example the right to exist, to survive and to maintain and regenerate vital cycles. The implication of this recognition is that human beings have the legal authority and responsibility to enforce these rights on behalf of nature. This concept is based on humans as part of life on earth having to live within its ecological limits, rather than being the center of environmental protection as the "anthropocentric" approach proposes.

Recognizing the rights of nature, Ecuador, Bolivia and a growing number of communities in the United States are basing their environmental protection policies on the premise that nature has inalienable rights, as have human beings. This premise is a radical but natural move away from the assumption that nature is a property under the rule of human law. Certainly, this view is a departure from Western culture and the development model which promotes the destruction of environment and life: climate change, disappearance of natural areas, indiscriminate surface felling of trees, desertification of new territories, dumping of toxic substances from industries into rivers, seas or lakes, oil slicks caused by ships and endless actions of a system that appears to legitimize environmental damage. This article, tracks the change in approach from anthropocentric to biocentric, which allows for an evolution in the legal protection of the environment: from human rights to the rights of nature. This new vision of environmental protection and how it is introduced into the different regulatory systems and its implementation is analyzed, including the recent trend in attributing a greater role to human responsibility in environmental protection. The article also discusses these new regulatory precedents, which undoubtedly mark an evolution in environmental law, both nationally and internationally. This new way ofprotecting the environment, due to the awareness of events, has led to the adoption of legislative measures on environmental law aimed at achieving an environmental policy more consistent with the conservation of natural resources, and establishing offenses andsanctions pointing more to the responsibility of those human beings who damaged nature. Nature meets its obligation to support life while humans increasingly take advantage of natural resources, causing irreversible environmental damage. This article explores how this recognition involves a number of issues to be resolved, as to who is able to claim these rights (on behalf of Nature) and how to make the legal system defend them.

II. THE ENVIRONMENTAL PROTECTION THROUGH HUMAN RIGHTS APPROACH

The traditional perspective to protect the environment has been "anthropogenic" based on the idea that a healthy environment is inherent for the dignity of every person. This concept necessarily takes for granted other human rights, including the right to life and human development. The indivisibility and interdependence exerted by the right to environment on the other human rights is evident: it strengthens and extends the meaning of already secured rights or rights, which, like the right to environment, are in the process of being set up. For example, the right to environment reinforces the content of the right to life, that is, a right to a dignified life in environmentally suitable conditions to promote healthy human development.

The fact that there is interdependence between environmental rights and other fundamental rights has actually divided the doctrine, in the sense that few understand that the right to environment reinforces the content of other rights and what should be done is to integrate environmental aspects into the definition of other human rights.In this respect, there is a need to recognize a right to an indivisible and substantive environment, being the reflection of social demand to live in a decent and ecologically suitable environment, where the person can develop in harmony with nature (Déjeant-Pons, 1994).

The existence of a growing social concern about the state of the environment and scientific alarm alerting us to the serious consequences of economic growth without limits requires the need for environmental protection through the adoption of international legal measures as well as regional and national ones.

The Universal Declaration of Human Rights of 1948 (UN, 1948), although being a document that does not explicitly relate to environment, is the first legal basis on which they could settle the right to an adequate environment. Article 25 states that "everyone has the right to a standard of living adequate for himself and his family, health and well-being ...". Subsequently, the International Covenant on Civil and Political Rights (UN, 1966a) and the International Covenant on Economic, Social and Cultural Rights (UN, 1966b), both of 1966, indirectly refer to the right to a healthy environment, relative to the right to life, as Article 6 of the International Covenant on Civil and Political Rights states by the express provisions the need to improve the environment as one of the requirements for the proper development of the individual. For example, Article 11 of the International Covenant on Economic, Social and Cultural Rights, when it recognizes the right of all people to an adequate standard of living and to the continuous improvement of living conditions; or Article 6 of the International Covenant on Civil and Political Rights, when a reference to the universal right to life is made.

In this regard, the Human Rights Committee has stated:

The term 'the right to life is inherent in the human person' cannot be understood in a restrictive manner (...) the protection of this right requires the adoption of positive measures by States. In this respect, the Committee considers it appropriate that States take all possible measures to reduce infant mortality and increase life expectancy, especially adopting measures to eliminate malnutrition and epidemics. (UN Human Rights Committee, 1982)

Therefore, the right environment is not a result of social development but *a prius* for human existence. Logically, suitable environment precedes the law itself: without a suitable environment, there are no humans, no society, no law…(Gormley, 1990, p. 97).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The first written suggestion that there should be a human right to a healthy environment came from Rachel Carsonin her book *Silent Spring*, published in 1962:

If the Bill of Rights contains no guarantees that a citizen shall be secure against lethal poisons distributed either by private individuals or by public officials, it is surely only because our forefathers, despite their considerable wisdom and foresight, could conceive of no such problem. (Carson, 1962, pp. 12-3)

But the first formal recognition of the right to environment occurs in the United Nations Declaration on the Human Environment, Stockholm, 1972 (U.N. GAOR, 1972), which states in Principle I that the person has the fundamental right to freedom, equality and the enjoyment of "satisfactory living conditions in an environment whose quality allows him to live with dignity and welfare", and has a solemn obligation, in return for this right, "... to protect and improve the environment for present and future generations.". This principle states that in addition to the rights for first and second generations, man has a "fundamental right" to enjoy adequate living conditions in an environment the quality of which allowsdignity oflifeand well-being, that is to say, a life, which will enhance the rights of future generations. This idea is expressed in the Preamble to the Declaration, paragraphs 1 and 2, stating that "the two aspects of human, natural and built environment are essential to human well-being and to the enjoyment of fundamental human rights, including the right to life", adding later that "the protection and improvement of human environment is a major issue which affects the well-being of peoples and economic development throughout the world, (...), and the duty of all governments". Despite this express recognition in an international document, the Declaration does not provide the necessary control mechanisms to make them effective and also is a non-legally binding document. From the substantive content of human rightspoint of view, after the 1972 Stockholm Declaration there has been a major trend in national legal orders towards recognising the environment –often at a constitutional level–as a specific right with different characteristics, depending on the political context and legal traditions of each country.

In similar terms, Article 1 of the Charter of Environmental Rights and Obligations of Individual, Groups and Organizations, adopted in Geneva in 1991, provides that: "All the Human Beings Have the basic right to an environment adequate for their health and well-being and the responsibility to protect the environment for the benefit of present and future generations". Subsequently, the World Commission on Environment and Development UN proposed as a legal principle: "All human beings have the fundamental right to an environment adequate for their health and welfare" (UNEP, 1987). Similarly, in 1990, in its Resolution 45/94, the General Assembly adopted a milder version of this formulation: "Everyone has the right to live in an environment adequate for their health and welfare."(UN, 1990). The Rio Declaration on Environment and Development of 1992 (UN, 1992) consolidated this trend by pointing out in the first Principle that all human beings are at the centre of concerns for sustainable development and are entitled to a healthy and productive life in harmony with nature. However, this Principle of the Rio Declaration loses firmness in relation to the provisions of the Stockholm Declaration, and as with the Stockholm Declaration, no accurate means exist to enforce the principles of the Declaration. Despite these shortcomings, both the Stockholm Declaration and the Rio assume an important role in the recognition of environmental problems and are a step in the development of international environmental law. In later lectures on Sustainable Development in Johannesburg in 2002 and Rio de Janeiro in 2012, it was possible to proclaim the right to a healthy environment.

Parallel to these developments in the recognition of the human right to environment, in the field of the Economic and Social Council (ECOSOC) of the United Nations, the Sub-Commission on Prevention of

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Discrimination and Protection of Minorities, under the Commission on Human Rights, has carried out important work. This has covered the harmful effects of the illicit movement and dumping of dangerous and toxic waste and products on the enjoyment of human rights, as well as the issue of human rights and the environment, through the work of the special Rapporteur Mme. Fatma Zohra Ksentini. This special Rapporteur carried out work in relation to the issues of dangerous products and waste dating back to 1989. As a result, the Subcommittee (coming out of the Sub-Commission on Prevention of Discrimination and Protection of Minorities)[2] concludes that the information available to them on human rights and environment, including "Environmental Perspective to the Year 2000 and after", justified the need for a study of the environment and its relationship with human rights (UN, 1989). Following the studies conducted in 1994 Mme. Ksentini presented a final report in which a concept of human rights and the environment is much closer to Principle I of the Stockholm Declaration of 1972 than the Principle I of the 1992 Rio Declaration.[3] The main conclusion of this report is that there has been a change in environmental law to provide the right to a healthy and decent environment. This right is part of the existing international law and has the capacity for immediate implementation through bodies dedicated to the protection of human rights. According to this report, the substantive elements of environmental rights include the right to development, life, and health and have procedural aspects such as public participation and access to effective national solutions. Attached to this report, there is the draft of the Declaration of Principles on Human Rights and the Environment, an overview of consultations with NGOs between 1990 and 1994, and a summary of national legislation and practices compiled by the Special Rapporteur based on the responses received from 67 governments.

Despite the important content of this document, there has been no attempt to complete this project, neither by the General Assembly nor by the Human Rights Commission nor the Economic and Social Council. Only the United Nations General Assembly in its Resolution 45/1994, adopted on December 14 1990, states that everyone has the right to live in an environment adequate to ensure their health and well-being. Similar expressions are found in various multilateral treaties dedicated to environmental protection, such as the Convention on Biological Diversity, 1992; the 1992 United Nations Framework Convention on Climate Change; the United Nations Convention to Combat Desertification in Those Countries Experiencing Serious Drought and/or Desertification, particularly in Africa, 1994; and Convention 169 of the International Labour Organization on Indigenous and Tribal Peoples in Independent Countries 1989. It is also necessary to add that the Institute of International Law, in its 68th session in Strasbourg in 1997, stated in Article 2 of its Resolution n. 1 of September 41997 "... every human being has the right to live in a healthy environment" (IDI, 1998).

Moreover, the 7th Goal of the Millennium Development Goals was about ensuring environmental sustainability, including the incorporation of the principles of sustainable development into countries' policies and programmes to reverse the loss of environmental resources (UN, 2000). Later, in 2007, the UN General Assembly adopted the UN Declaration on the Rights of Indigenous Peoples, which in article 29 proclaims "Indigenous peoples have the right to the conservation and protection of the environment..." (UN, 2007).

In March 2012, based on several other resolutions related to human rights and the environment and human rights and climate change, the Human Rights Council during its 19th session, established by Resolution 19/10, the mandate of the human rights and the environment (HRC, 2012a), which aims, among other things, to study human rights obligations related to the enjoyment of a safe, clean, healthy and sustainableenvironment, promoting best practices regarding the use of human rights in the formulation of environmental policies.[4] In the first report of December 22 2012 on the issue of human rights

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

obligations related to the enjoyment of a safe, clean, healthy and sustainableenvironment, states and others concerned are urged to remember that the lack of a full understanding of the contents of all the human rights obligations related to the environment should not be interpreted as that such obligations do not exist (HRC, 2012b).

In June 2012, at the UN Conference on Sustainable Development, States renewed their commitment to "the promotion of economically, socially and environmentally sustainable future for our planet and for present and future generations" (UN, 2012), without asserting the real right for humans to a healthy and safety environment. In general, linking human rights with the environment creates a rights-based approach to environmental protection that places the people harmed by environmental degradation at its center, but leaves the environment undermined to people needs.

III. HUMAN RIGHTS PROTECTION WITHOUT PROTECTING NATURE?

The formal recognition of a universal right to an adequate environment faces a number of obstacles, which have led to a sector denying its existence. In part because this right departs from the utilitarian and anthropocentric perspective, which has allowed the existing formal recognition of such right, but it has not been enough to protect nature, biodiversity and even the human health.

The major obstacles have been the traditional notion of state sovereignty, the lack of legally binding instruments and the unenforceability of this right due to the legal uncertainty of the protected object and the legitimacy of the holders. This leads to an absence of effective means for its defense and implementation of its protection. However, this has not prevented the protection of the environment, as part of the contents of a new human right by various international instruments. While it is true that currently there is no legally binding international instrument declaring a human right to the environment for the implementation of other fundamental rights.

The recognition of this right, however, can be sensed in the existing international consensus to protect the environment for the benefit of humans. However, a suitable and quality environment does not presuppose respect and guarantee of human rights.

The idea is well-established in international law that States should take measures to ensure respect for and protection of the environment as essential to the fulfillment of human rights (Lewis, 2012, p. 36). Considering that a suitable environment is a necessary component of human rights is also a priority for the competent bodies of the United Nations on the matter. As of 2012, 177 of the world's 193 UN member nations recognize this right through their constitution, environmental legislation, court decisions, or ratification of an international agreement, among these, some subnational governments recognize the right to a healthy environment, including six American states, five Canadian provinces or territories, and a growing number of cities. One of the biggest obstacles to the recognition of this right lies in state sovereignty; that is, the set of powers, which a state exercises exclusively on their territory recognized by the international order. Currently the only existing limit on the sovereign exercise of the functions of environmental management and imposed by international law is to manage the environment in a way that other States are not disadvantaged by the misuse of the natural resources. This question is contained in Principle 21 of the Stockholm Declaration, which states:

In accordance with the UN Charter and the principles of international law, States have the sovereign right to exploit their own resources pursuant to their own environmental policy and the obligation to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ensure that the activities carried out within their jurisdiction or control do not cause damage to the environment of other States or of areas beyond national jurisdiction. (UN, 1972)

Also, the Rio Declaration in Principle 2 (UN, 1992) reproduces the provisions of Principle 21 of the Stockholm Declaration.

Another obstacle to the recognition and realization of the right to the environment, which is already been referred to above, is the absence of a legally binding international instrument that explicitly recognizes this right. Some authors such as Makarewicz understand that documents like the Declaration of Stockholm or Rio constitute a generally accepted interpretation of the notion of human rights contained in the United Nations Charter (Makarewicz, 1986, p. 81). Handl and others (1995, p. 287) state that even if in some state practices this right does not separately exist, those states understand the right to environment is implied in inalienable rights, which cannot be knocked down, but in practice, this is not the case related to the right to environment. Nevertheless, within the limitations of economic and social rulings, the right to environment gets stronger.

Despite the "soft law" character of the international instruments, which recognize the right to environment, this right is inalienable qualifying; while the environmental degradation threatens the survival of humankind. Moreover, the flexible nature of existing instruments in this area can provide the further development of legally binding instruments, because "…when new values emerge, they need first to be so formulated as to pave the way for future developments in the form of binding instruments." (Kiss, Cançado Trindade, 1995, p. 287). In fact, the various aforementioned international instruments reflect the willingness to recognize the human right to the environment both for environmental protection and to ensure human survival. In this sense, perhaps the only way to articulate a human right to the environment is through the recognition of the existence of an international tradition generated by a constant and repeated international legal practice, along with the willingness to conceive this human right to a healthy environment (Lee, 2000, pp. 308-09). Lee states that consecutive unreserved reinforcement of this right in different non-binding documents constitutes an evidence of a comprehensive and consistent practice of States in the international arena. This practice can contribute to the final creation of a right to a proper and healthy environment as a principle of customary international law.

Another present difficulty in the recognition of the right to the environment is the inability to exercise the right to environment properly before the court because of the indecisive nature of the legal concept of "environment" and the lack of procedural mechanisms to invoke its protection.

These obstacles prevent full recognition of a right, which is still in formation, but its implementation can be promoted by establishing mechanisms such as information, participation, resources and education to influence the political will of the states and enable a human right to the environment to be legally binding. Legal systems seem to ignore the current social impulse, which recognizes the right to environment only acknowledging the legal status of other human rights. This clearly reflects which difficulties international human rights theory poses for the introduction of ecological limitations into international human rights law. In some sense, because the anthropocentric perspective, which is also the case for traditional western view of development and progress, centers on humans and it implies that humans are separate from Nature; in short, Nature is just a basket of resources that humans must take advantage of to feed economic growth (Gudynas, 2011, p. 262).

Based on the idea that the anthropocentric, a human right to environment is required to protect the most vulnerable people to the impacts of environmental degradation, but this view should to be combined with a complementary approach to protect the environment with the protection of human rights.

IV. TOWARDS THE PROTECTION OF NATURE

In current legal systems, our living Earth is perceived as an object without rights. Yet fictitious entities, such as corporations, are granted rights similar to those of humans without reciprocal and enforceable responsibilities and accountability. Since the existing environmental and human right laws are not enough to protect nature, biodiversity and human health, the destruction of our Earth continues, and without redress. Therefore, another approach to environmental protection is required. The so-called "biocentric approach", developed mainly by mega-diverse countries and developing with indigenous populations, offers a different world view raising the "anthropogenic" to recognize and protect nature as having rights and as a legal entity. This possibility is certainly a novel perspective on environmental law, as it departs from the above-mentioned perspective. As already discussed, traditionally legal systems have regarded nature as "property", an object on which to develop and protect rights. The most common has been the promotion of laws and contracts to protect the property rights of individuals, corporations and other legal entities, such as legal subjects. The consequence is that the laws and regulations on environmental protection, which have mushroomed in recent times, despite emphasizing the preventive orientation, actually legalize environmental damage by regulating how much pollution or destruction of nature may occur in the context of the law. Even the recognition of the human right to the environment or the environmental dimension of the human rights has not been sufficient to ensure the protection of the environment and the welfare of the people. This approach is not free of criticism, in the opinion of Bosselmann (2001, p. 108):

[…] in the long term the existence of an environmental human right could be seen as self-contradictory. A better option is the development of all human rights in a manner, which demonstrates that humanity is an integral part of the biosphere, that nature has an intrinsic value, and that humanity has obligations toward nature. In short, ecological limitations, together with corollary obligations should be part of the rights discourse.

The recognition of the rights of nature is an integral holistic view of all lifestyles comprising all ecosystems. Through this perspective, nature is no longer protected, but a subject of protection rights granted to nature in all forms of life, has the right to exist, persist, maintain and regenerate its vital cycles. The counterpart to this recognition means that humans have the legal authority and responsibility to enforce these rights on behalf of nature. This conception is based on humans as part of life on earth and living within ecological limits and therefore as Caldwell has observed: "Humanity has no extraordinary moral claim or rights over the natural world." (1972, pp. 236).

The "biocentric" view arises from the severity of the environmental status and the threat on natural ecosystems. The conception "biocentrism" is based on the idea that humans are part of nature and that nature conservation is, above all, a duty of human beings: both must coexist for the perfect organic balance of the planet (Lanza & Berman, 2009). According to this argument, any form of life is important to the balance of nature (Emmenegger & Tschentscher, 1994, pp. 545-92).

The idea that nature possesses inalienable rights akin to human rights has gone from a strictly theoretical concept to the basis for policy changes in several countries. To recognize the rights of nature Ecuador in its constitution, Bolivia in its legislation, and a growing number of communities in the United States, are basing their environmental protection systems on the premise that nature has inalienable rights, as do humans. This premise is radical but natural, emerging as a reaction to "anthropogenic" forces that

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

subordinate the environmental protection to the interests and / or human needs, reducing nature to a mere property, under the rule of law (Galeano, 2008).

1. Changing the Approaches to Protect the Nature

Following this other perspective of environmental protection, one of the first cases in which the rights of nature appear was the historic case of environmental law on the redwoods of California (*Sierra Club v. Morton*) in 1972, where the excessive corporate profit motives aimed to turn the habitat of huge old trees into an amusement park. It created a legal battle in which judges and academics questioned whether the trees should be entitled to a judicial proceeding (Pelizzon, 2011, pp. 6-12). In his dissenting opinion, Judge William O. Douglas argued that "inanimate objects" should legitimately to sue before the courts:

The critical question of "standing" would be simplified and also put neatly in focus if we fashioned a federal rule that allowed environmental issues to be litigated before federal agencies or federal courts in the name of the inanimate object about to be despoiled, defaced, or invaded by roads and bulldozers and where injury is the subject of public outrage. Contemporary public concern for protecting nature's ecological equilibrium should lead to the conferral of standing upon environmental objects to sue for their own preservation. This suit would therefore be more properly labeled as Mineral King v. Morton. (Sierra Club v. Morton, pp. 742-43)

Douglas continued:

Inanimate objects are sometimes parties in litigation. A ship has a legal personality, a fiction found useful for maritime purposes. The corporation sole—a creature of ecclesiastical law—is an acceptable adversary and large fortunes ride on its cases.... So it should be as respects valleys, alpine meadows, rivers, lakes, estuaries, beaches, ridges, groves of trees, swampland, or even air that feels the destructive pressures of modern technology and modern life. The river, for example, is the living symbol of all the life it sustains or nourishes—fish, aquatic insects, water ouzels, otter, fisher, deer, elk, bear, and all other animals, including man, who are dependent on it or who enjoy it for its sight, its sound, or its life. The river as plaintiff speaks for the ecological unit of life that is part of it. (Sierra Club v. Morton, p. 743)

As Berry (2014) explains, every being in the Earth Community has three rights: the right to be, the right to habitat, and the right to fulfil its role in the ever-renewing processes of the Earth community. This same reflection, led several authors from around the world to address this issue (Frazier Nash, 1989; Hanna et al., 1996; Boyle, 2006; Harding, 2007; Cameron, 2007). To mention a few: Stone (1972; 2010) in the United States, Godofredo Stutzin (1984, 2002) in Chile, or Cormac Cullinan (2002, 2008 and 2011) in South Africa.

A few years later, in 1982, over one hundred member states of the General Assembly of the United Nations adopted the World Charter for Nature, which states that "Humanity is a part of nature and life depends on the uninterrupted functioning of natural systems which ensure the supply of energy and nutrients" and provides a set of principles to be considered by man in their procedures with respect to the environment (UN, 1982). In this sense, the article establishes the duty of every person to act in accordance with the provisions of the Charter and to ensure the objectives set out in the Charter. This document recognizes the intrinsic value of nature and human beings aspart of nature, and it calls for humans to be

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

guided by a moral code of conduct that does not compromise the integrity of those other ecosystems or species with which they coexist. It also regulates that human activity must be developed according to the earth limits and processes, and according with the common equity and the precautionary principle. The Charter states, "Humanity is part of nature and life depends on the uninterrupted functioning natural systems that are sources of energy and nutrients. Every form of life is unique, warranting respect regardless of its worth to human beings and other living things for recognition; man must be guided by a moral code of action". Ashby (1978, pp. 82-5) asserts that no one can predict the full consequences of tinkering with any part of an ecosystem. Even the non-living environment has properties without which life as we know it would be inconceivable. Consequently, the author continues, "the rights of nature" must be protected by law.

Regarding the nature of Rights, Thomas Berry (Bell, 2003) explains that:

1. All rights are role-specific or species-specific, and limited. Rivers have river rights. Birds have bird rights. Insects have insect rights. Humans have human rights. Difference in rights is qualitative, not quantitative. The rights of an insect would be of no value to a tree or a fish. 2. Human rights do not cancel out the rights of other modes of being to exist in their natural state. Human property rights are not absolute.

According to Stone (1972, p. 489), one of the strengths of regarding natural objects as bearers of rights, Stone contends, is that it would reflect a fundamental shift away from the current view that nature exists for men.

In 2000, a group of non-governmental organizations and movements adopted the Earth Charter, which "seeks to inspire in all peoples a sense of global interdependence and shared responsibility for the welfare of the human family, the greater community of life and future generations" (Earth Charter, 2000). Four pillars of sustainability are:

1. Respect and care for the community of life;
2. Ecological integrity,
3. Social and economic justice, and
4. Democracy, Nonviolence and Peace, and sixteen other principles.

The Charter also recognizes the role of traditional, cultural and spiritual knowledge of indigenous peoples, non-discrimination and self-determination. Although this document is not legally binding, its principles are considered of universal relevance.

In 2009, Polly Higgins, a lawyer and activist in the UK, started a campaign calling on the United Nations to adapt a law recognizing the mass destruction of ecosystems a crime against international peace, that is, as an 'ecocide'.[5] Ecocide is defined as "The extensive destruction, damage to or loss of ecosystem(s) of a given territory, whether by human agency or by other causes, to such an extent that peaceful enjoyment by the inhabitants of that territory has been severely diminished" (Higgins et al., 2013, pp. 251-66). Founded on the duty to care for the planet, this crime against peace would be strict liability and *erga omnes*: which means compulsory for all, even those States who are not subscribed to the International Criminal Court (ICC). Mining, extraction of fossil fuels and deforestation could be classified as ecocide according to the "Eradicating ecocide campaign", which is a law against ecocide to be fully implemented in 2020.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Thus, over 10 countries have already recognized a form of ecocide in their national laws, including Georgia, Kyrgyzstan, Russia and Vietnam. In 2011, The Hamilton Group and held a mock trial in the Supreme Court of the United Kingdom to test the proposed crime of ecocide.[6] A process of restorative justice[7] was followed in 2012 from a fictitious company and victims including Earth (the voice of the Gaia Foundation), indigenous peoples and future generations. Since January 2014, in Europe, more than 112,000 people signed a petition through the European Citizen's Initiative for a European Directive on ecocide.[8]

In 2014, a coalition including End Ecocide in Europe, the European Network of Environmental Prosecutors, Globe EU and Green Cross International, launched a campaign in the European Parliament calling for the establishment of a Criminal Court on the Environment and Health, both at the European and International level with legal penalties for environmental damage. Once a crime of ecocide is recognized, the Criminal Court may allow an application through the Charter of Brussels, which would create a separate court. The Charter of Brussels has been opened to signatures since September 2014.[9]

In addition to this initiative of "ecocide" on April 22, 2010, World Day of Mother Earth, participants at the World People's Conference on Climate Change and the rights of nature developed and adopted the Universal Declaration of Rights of Mother Earth (People's Conference on Climate Change and the Rights of Mother Earth, 2010). This Declaration acknowledges Mother Earth as a living being with rights, including the rights to life, to existence and continues its vital cycles and processes free from any human interference. Even in 2012 the UN Conference Rio + 20 the need to live in harmony with nature has been recognized and in paragraph 39 of the Resolution of the General Assembly of the United Nations, "The Future We Want" refers to some countries recognize the "Rights of Nature" (UN GAOR, 2012), when asserts that:

39. We recognize that planet Earth and its ecosystems are our home and that "Mother Earth" is a common expression in a number of countries and regions, and we note that some countries recognize the rights of nature in the context of the promotion of sustainable development. We are convinced that in order to achieve a just balance among the economic, social and environmental needs of present and future generations, it is necessary to promote harmony with nature.

Peter Roderick, a lawyer also from the UK, proposed in 2011 a "Draft Declaration on Planetary boundaries"[10], in order to recognize and respect the Earth system processes that sustain life and promote responsibility to safeguard these processes of serious or irreversible harm. The Declaration is based on research conducted by Rockström (2009) and published in Nature in 2009 holding that there are 9 Earth-critical processes and associated thresholds that we must live within in order to avoid irreversible damage to our planet Earth and. According to this research, three of these boundaries have been breached: climate change; biodiversity and the nitrogen cycle. In this vein, in 2013, the Planetary Boundaries Initiative, a legal think tank, presented a petition for the adoption of an agreement on the protection of land system before the Open Ended Working Group of the United Nations on Sustainable Development Goals (ODS), as the main global priority to the goals of sustainable development after 2015.[11]

These are just some examples of international trends, mostly from academia and social movements, claiming environmental protection through the recognition of the legal personality of nature. This "biocentric" approach, as discussed below, has been reflected in some significant changes, legally speaking, and they deserve some attention. All demonstrate that in practice, recognising Rights of Nature is not difficult.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. Recognising the Rights of Nature

Among the protective laws of nature, at the oldest constitutional level is the Weimar Constitution of 1919. It has the reputation, together with the 1917 Constitution of Querétaro, of being one of the pioneers in incorporating social rights in the constitution. However, the Weimar Constitution is the first to protect nature. It provides in Article 150 that "Nature enjoys the protection and aid of the State". Despite this precedent, constitutions of the time did not include issues of nature protection and the human right to nature, including even the Universal Declaration of Human rights in 1948.

This is due to a lack of awareness about environmental damage. The first constitutions in the Americas are totally unaware of the existence of living beings other than human beings. The emphasis was on recognizing property rights related to land, water and nature.

During the 1980's and 1990's there is a wave of reforms in environmental legal frameworks in almost all South American countries, recognizing so-called third generation rights, incorporating related environmental issues, from the perspective of human rights.

Few charters on environmental protection contain the perspective on rights of and duties to nature (Boyd, 2012). The Constitutions of Colombia (1991) and Bolivia (in the 2002 reforms) provided that "all persons have the right to enjoy an ecologically balanced healthy environment" and the rights mentioned future generations. Environmental Law No. 1333, April 27 1992 (Bolivia, 1992) was a regulatory precedent recognizing the right to a healthy environment for people and living things in Bolivian legislation. In the Constitution of Peru, there is no right in itself, but an obligation of regulation. In Ecuador's Constitution, coded in 1984 "the right to live in a pollution-free environment and the states' obligation to promote the conservation of nature" is introduced. In 1998, the precautionary principal and the right for an individual to take an action to protect the environment is recognized. In 2007, Venezuela's Constitution recognizes the right and duty of each generation to protect and maintain the environment for its benefit and the future world. Everyone has to enjoy individually and collectively a live and a secure, healthy and ecologically balanced environment.

Significantly, after 89 years of Weimar, both the new Constitutions of the Plurinational State of Bolivia adopted in 2009, alongside the Ecuadorian Constitution from September 2008 included content in their respective sections, recognizing the rights of indigenous peoples and rights of all citizens to a healthy and balanced environment (Acosta & Martínez, 2009). In the Previous Constitution of Bolivia the right to a healthy environment was recognized so that individuals and communities of present and future generations, and other living beings could develop normally and securely. In particular, in Articles 33 and 34, the Magna Carta expresses the real rights of the population, and of the future generations of that country, to enjoy a healthy environment, protected and balanced, granting any person, either individually or on behalf of the communities, the power to take legal action in defence of the right to environment.

Both the Ecuadorian (2008) and Bolivian (2009) Constitutions mention nature, but while the Ecuadorian respects it as a living being with which on has to live in order to manage "living well", the Bolivian Constitution considers nature as a helpless and a vulnerable object requiring state protection (Cofre Lagos, 2006). However, in this case, nature always appears in the context of ancestral knowledge, acquired through an intense co-existence with nature itself. The text also diverges radically on another point. Bolivia's Constitution sees the industrialization of nature as a goal; whereas in the Ecuadorian case nature is presented as a subject of rights for the first time. The Bolivian text ends up creating a link between nature and modernity through progress, while the Ecuadorian Constitution breaks away from this perspective with a biocentric turn. It states that there must be a dynamic relationship between

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

society, the state, and the market, but balanced and in harmony with nature; granting nature inalienable rights and thus making it a subject of law (Zaffaroni, 2010; De Prada García, 2014).[12]

The Plurinational State Constitution of Bolivia, in Article 381, declares that the State shall protect all genetic resources and micro-organisms found in the ecosystem of the territory, as well as the knowledge associated with their use and exploitation.

Article 382 says the State has power and duty for defence, recovery, protection and reparation of biological material coming from natural resources, ancestral knowledge, and other ways originating within the territory.

Article 387 states that the law will regulate the protection and use of forest species of socio-economic, cultural and ecological relevance, giving special importance to the protection of coca, establishing that the State protects the nature and ancestral coca as a cultural heritage, a renewable natural resource of biodiversity, and as a factor of social unity (Article 384).

In the two constitutions, particularly in the Bolivian case, indigenous people have incorporated their demands to build plurinational states to represent them and their cultural values, expressed in the "Vivir Bien" ("living well" or "Suma Qamaña" in Aymara). In the Bolivian legislation this meant Nature qualified as a "Subject of Rights" – a truly normative leap.

In the Ecuador's Case "Buen Vivir" ("Living Well" or in Quechua "Sumak Kawsay"). In Chapter 7, Article 71 provides that Nature, or "Pachamama", where live occurs and is reproduced, has the right to integral respect for its existence, maintenance and regeneration of its live cycles, structure, functions and evolutionary process.

The indigenous worldview is reflected in the Bolivian Constitution in its preamble

In ancient times mountains arose, rivers spread out from one place to another, lakes were formed. Our Amazonia, our swamps, our highlands and our plains and valleys were covered with greenery and flowers. We populated this sacred Mother Earth with different faces, and since that time we have understood the plurality that exists in all things and in our diversity as human beings and cultures. Thus, our peoples were formed, and we never knew racism until we were subjected to it during the terrible times of colonialism.

Everything had its place, and humans and nature co-existed in harmony. The preamble reflects a dialogue from the past, in the present, saying that since time immemorial plurality and diversity are respected. It refers to the natural environment and land, as well as Mother Earth, in which original context various indigenous peoples emerged. Harmony was broken by colonization, introducing racism and altering the order in which indigenous people lived (Caudillo Félix, 2010).

It was not until 2010 that Bolivia adopted the first legislative package in the world in which the ancient indigenous conception of nature as a living being entered, giving nature equal rights to humans. Specifically the laws are: Law No. 071 of the rights of Mother Earth (2010) and Framework Act No. 300 of Mother Earth and Integral Development of Good Living (2012). Even though these laws are mostly abstract, their existence helps elevate a debate about the relationship between people and nature. In particular, the Law on the Rights of Mother Earth endorses some guiding principles, including the "common good", not multiculturalism and commodification of nature, and requires the state and citizens to respect the rights of the Earth. Under the Act, companies and individuals may be responsible for causing environmental damage and responsible for its repair. The Act also provides for an Ombudsman for Mother Earth to protect their interests.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

As fruit of these constitutional developments, on April 22 2009, the General Assembly of the United Nations, at its 63rd meeting, unanimously adopted the draft submitted by Evo Morales, the Bolivian President, stating that every April 22 is celebrated as International Day of Mother Earth (instead of the Day of Earth) (UN, 2009). Concluding the look at Ecuador and Bolivia's Constitutions, indigenous movements there have managed to incorporate their worldview, values and requirements within their constitutions (Wray, 2008).

However, it is considered that the only way to make the principles contained in the Magna Cartas effective is through daily struggles and processes of autonomy and self-management of their people. Previous political experiences have taught them the limitations of the system and the need to continue fighting for their collective rights, the establishment of a plurinational state, and an intercultural society that recognizes and respects indigenous peoples (Vargas, 2011, pp. 70-86).

In this regard, it is important to mention that in the United States of America, more than 24 towns and cities have implemented ordinances for the Rights of Nature (Kurth *et al.* 2012). One of the first legal instruments titled "Sewage Sludge Ordinance" was adopted in 2006 in Tamaqua Borough, Pennsylvania, which meant that corporations could not spread sewage sludge as fertilizer on farmland, even where the owner of the land consented. This Ordinance recognizes the rights of natural communities and ecosystems to exist and flourish, and recognized ecosystems as legal persons (s 7.6). Corporations may not interfere with the right of ecosystems to exist and flourish and Tamaqua residents can pursue actions on behalf of ecosystems. With this move, Tamaqua became the first US municipality to recognize the rights of nature and to enable residents to take action to vindicate those rights.

Another relevant example is Pittsburgh city ruling (2010, § 618.03), which prohibits companies drilling for natural gas in the city. This ordinance elevates the rights of individuals, the community and nature over corporate "rights" and thus becomes the first city in the USA to recognize the rights of nature as legally binding. By recognizing the rights of nature, ecosystems and communities against businesses and other levels of government, which can authorize such drilling, and by authorizing Pittsburgh residents to exercise those rights on behalf of threatened ecosystems, these ecosystems are effectively protected. Santa Monica (2013) also passed a ruling that elevates its right to enforce its Sustainable City Plan, including rights to clean air, water and soil, and the rights of nature above corporate entities' privileges and powers.

Since 2010, at least 18 Community Bills of Rights to ban natural gas drilling and hydraulic fracturing have been passed in municipalities in California, New York, New Hampshire, Maine, Maryland, Ohio, Pennsylvania and Virginia, and defeated in New Mexico.[13] Specifically, the Town Mountain Lake Park Ordinance on Natural Gas Extraction (2011); West Homestead, Pennsylvania Community Rights Gas Extraction Prohibition (2011); Town of Wales, New York Community Protection of Natural Resources (2011);[14] Baldwin, Pennsylvania Community Protection from Natural Gas Extraction Ordinance (2011); Wilkinsburg, Pennsylvania Community Protection from Natural Gas Drilling Ordinance (2011);[15] Forest Hills Borough's Community Rights and Protection from Natural Gas Exploitation Ordinance (2011); State College Borough's Community Bill of Rights Home Rule Charter Amendment (2011); Las Vegas, New Mexico's Community Water Rights and Local Self-Governance Ordinance (2013), amongst many others. These are the first communities in the U.S. to ban fracking, recognizing the rights of nature, and subordinating corporations to the people by popular vote.

Although these initiatives recognize rights of nature at the local level, it poses the question whether this recognition of nature's rights is ecologically valid (Rodrigues, 2014, pp. 170-84). Although the initiatives quoted above are local, policy development in the United States shows that attributing rights to nature is no exclusive to indigenous societies with a particular worldview. Western societies also promote

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

change in this direction, in response to new challenges that nature faces defenseless against the intense activity of large industrial corporations (Vermont Rights of Nature, 2012).

3. Protecting the Rights of Nature

Especially the indigenous, social movements have been the promoters of this new "biocentric" perspective, based on worldview, values and demands for the legal recognition of the rights of nature. However, it is necessary to analyze the effectiveness of these rights beyond formal legal recognition. In this sense, the practice has encompassed not only the protection of nature itself, but also the protection of the intangible and the spiritual, ensuring their preservation, and the protection of sacred sites and ancestral knowledge.

In certain cases, the formal recognition of the rights of Nature has implied the creation of institutional bodies and processes, such as Guardians for the Earth in Bolivia, and Ombudsman for Future Generations. In addition, many countries recognise locus standi/standing for the public to issue legal proceedings in the public interest (e.g. UNECE Aarhus Convention) - which could be expansively interpreted as including Nature, and even directly on behalf of Nature (e.g. Ecuadorian Constitution and local ordinances in the U.S.). These institutional tools can amplify the protection of the environment.

Regardless of the extent of rights granted to nature, it must rely on human representation to assert and defend these rights in a court of law (Donald Cameron, 2007). The first case of judicial enforcement of the rights of nature occurred in the year 2011 Action Protection, resolved on appeal by the Criminal Division of the Provincial Court of Loja (Wheeler versus Director de la Procuraduria General del Estado en Loja, 2011), presented by Richard Frederick Wheeler and Eleans Geer Huddle against the Provincial Government of Loja "for nature particularly in favor of the Vilcabamba river" over the works of the Vilcabamba-Quinara road expansion. The government project to build a highway without the required environmental impact studies, negatively affected the flow of the river causing floods and disrupted wildlife and the livelihoods of local communities. The court decision was issued on March 30, 2011 by the Provincial Court of Loja, which granted an injunction against the Provincial Government of Loja to stop violating the constitutional rights of the Vilcabama River to exist and to maintain its vital cycles, structure, functions and evolutionary processes (Daly, 2012, pp. 63-6). This is the first case of successful Nature Rights under Article 71 of the Ecuadorian Constitution (Wheeler versus Director de la Procuraduria General del Estado en Loja, 2011). The Chamber granted the motion, agreeing that "the action of protection is the only suitable and effective remedy to stop immediately and focused environmental damage" and applying the precautionary principle, the judges say "[...] "until such time it is objectively proven that no probable or certain danger exists over works carried out in a particular area producing contamination or environmental damage, it is the constitutional duty of judges to immediately pay attention to safeguarding and enforcing the legal protection of the rights of Nature, avoiding contamination by whatever means, or ensuring remedy. Note that with relation to the environment we shall consider not only certain damage, but also indications of possibility" [...]"(Wheeler versus Director de la Procuraduria General Del Estado en Loja, 2011, §5). Therefore, the Court confirmed the principle of precaution that until the government can show that the widening of the road would not affect nature; the presumption is to protect the rights of nature. The Court also endorsed the intergenerational principle, recognizing the importance of nature to protect the interests of present and future generations and ordered the government to submit environmental impact studies, develop a plan of rehabilitation and remediation, and publicly apologize for the start of construction of a road without the necessary environmental license (Smith, 2009; De Prada, 2014).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Chamber recalls that the Constitution "... unprecedented in the history of mankind, recognizing nature as a subject of rights [...]"; assumed as an obvious and indisputable fact the "importance of Nature", to the point that they consider "any argument about it is succinct and redundant", incorporating the decision that the idea that damage to it is "generational damage ", defined as" those which by their magnitude impact not only on the current generation but their effects will impact on future generations [...]" (Wheeler versus Director de la Procuraduria General del Estado en Loja, 2011, §7 and 8). In addition it modifies the burden of proof freeing the plaintiffs from proving damage, stating that it is the "[...] the plaintiffs did not have to prove potential damage. The Loja Provincial Government would have to provide evidence that the activity of opening a road neither affected nor would affect the environment in the future. It would be inadmissible to reject an action protecting Nature for the lack of prof presented, as in case of possible or assumed already caused environmental damage through pollution, the nonexistence of this damage should be proved not just by whoever is in a better position to do so but by the one who argues, ironically, that such damage does not exist"[...] " (Wheeler versus Director de la Procuraduria General del Estado en Loja, 2011, §10).

Despite the excitement surrounding this finding, which advocates recognition of nature as a subject of rights, the Board does not deny the possibility of the work, but states it should respect the "rights of nature" without specifying how they are violated. It merely repeats the Constitution "is violating the law of nature has to be fully respected its existence and the maintenance and regeneration of its vital cycles, structures, functions and evolutionary processes". In fact, all the reasoning is redirected towards the human right to a healthy environment. The action on behalf of the defense is of particular interest "[...] As regards the allegation that the people need [...] roads, indicates that: in case of conflict between two protected interests (sic) Constitution, the solution must be found in accordance with the legal elements which constitute the case and in light of the constitutional principles and values. This work is an essential function of interpretation by the constitutional court. But in this case there is nothing to ponder because there is no collision of constitutional rights or compromise of one of them, in that if the Vilcabamba-Quinara road is not enlarged, it complies with the constitutional rights of Nature. In any case, the interest of these populations in the road is lessened compared with the interest in a healthy environment that includes a larger number of people" (Wheeler versus Director de la Procuraduria General del Estado en Loja, 2011, §12). Accordingly, the judgment states that the Provincial Council is responsible for damages, ordering that environmental recommendations are welcome and "public apology for starting the construction of a road without the environmental licensing."

Also in Ecuador, on November 26, 2010, an international alliance of environmental activists[16] filed a lawsuit against British Petroleum (BP) in the Ecuadorian Constitutional Court, in defense of the rights of nature, which are recognized in the Ecuadorian Constitution 2008. In this sense, the Ecuadorian Constitution recognizes the right of nature to be restored and allows a citizen or group to present a case before the Constitutional Court of Ecuador for a violation occurring in a different country,which affects Earth as a whole. Instead of seeking financial compensation, the coalition calls on BP to disclose the data and information on the ecological destruction caused by the oil spill, and to restrain BP from mining oil underground as in the spill in the Gulf of Mexico disaster (Gaia Learning Centre, 2011).

Following this recognition of nature as a subject of rights, the Chief Justice in Belize ruled in 2010 that a reef is not owned, but is a living being that is part of the national heritage of Belize and cannot be sacrificed to the commercial interests (Supreme Court of Belize, A.D. 2009; Court of Appeal of Belize, A.D. 2011). The case is from January 13, 2009, when a cargo ship collided with Mesoamerican Reef, near Caye Glory in Belize, damaging 6,000 square meters of pristine reef. The Mesoamerican reef more

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

than 225 million years old, is the largest coral reef in the Atlantic Ocean and is home to over 60 species of coral reef fish and 500 other species. The Court considered the shipping company responsible and required it to pay $ 11 million Belize dollars ($ 5.5 million US Dollars), plus interest at 3% per year for environmental and ecological loss and the cost of restoration.

In this line, it is also interesting that from 1997, OxlajujAjpop, an organization of indigenous Mayan spiritual leaders, has been advocating for and developing a proposal for a Sacred Sites Act in consultation with indigenous communities. This bill is to ensure the recognition of sacred sites and territories and governance, access, use and conservation of communities. It has not yet been accepted by all members of Congress and government, but negotiations continue. OxlajujAjpop is also calling for a new Constitution and the legal reform that respects Mother Earth, ecosystems and indigenous territories, and a 'socially and legally' pluralistic state (National Conference of Ministers spirituality Maya of Guatemala, 2008).

Another interesting case is related to a group of international activists, who requested the opening of a trial in the Constitutional Court of Ecuador in 2010 referring to the right of nature and the right of sea further than the territory of Ecuador, to claim justice in the case of the Deepwater Horizon disaster, which is the famous British Petroleum oil spill in the Gulf of Mexico, in the name of the right of the sea.The claim challenged the usual jurisdiction territorial competence and mobilized new rights and visions which exist only in a few countries like Ecuador and Bolivia. This case illustrates how the traditional systems to demand compensation can be changed, in that the request can require a series of actions by the company BP, and not necessarily a direct financial compensation. For example, BP shall maintain the same quantity of oil underground as before the extraction, or use specific technical cleaning mechanisms, implying an economical sacrifice or a change in behaviour by the company, as a disincentive for repeating their actions, instead of simply a financial award. Such an example teaches an important although basic lesson: losses caused by environmental injustice go further than the money value. As far as possible justice should evolve, towards a diversity of values that can be incorporated into the sentencing systems in the court.

In 2012, the "Custodians of Sacred Natural Sites" Kenya, South Africa, Ethiopia and Uganda adopted a Common Declaration of African customary law for the Protection of Sacred Natural Sites in Nanyuki, Kenya (Custodian Meeting Nanyuki, 2012). The Declaration recognizes that sacred natural sites and territories are places of ecological, spiritual and cultural significance, where laws and ecosystem boundaries exist and must be respected. The Declaration provides important guidance on sacred natural sites which should be respected and prohibited for any activity, except necessary spiritual practices, and that the traditional systems of government, which communities hold should be recognized. Similarly, in New Zealand, following more than a century of petitions and legal action by local iwi (Maori tribal group), the Whanganui river in New Zealand was granted the legal status of a person under the name Te Awa Tupua. This legal victory means that the river now enjoys the same rights and responsibilities before the law as people and corporations and both the government and the Maori have been designated guardians to ensure that the river's rights are protected (Tutohu Whakatupua, 2012). This precedent-setting legal case is the first time the rights of a river have been guaranteed in this way, opening up exciting possibilities for protecting, and changing how we understand our relationship with, the natural world.

Apart from these cases, it is worthwhile mentioning that the first Permanent Court of Ethics was established on January 17 2014, for the Rights of Nature and Mother Earth, thanks to the Global Alliance for the Rights of Nature. Its inaugural meeting, attended by over 400 people, was held in Quito, Ecuador, the country which acknowledged these rights for the first time in its constitution. The Tribunal was chaired by Vandana Shiva. This first preliminary hearing was to determine eligibility for the award

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of rights of numerous acts of nature, including those affected by mining and commercial agriculture. The role of this Court is to promote the establishment of a future permanent court to contribute to the development of legislation that recognizes the rights of nature (Viale, Machado, & Acosta, 2014). The Court is held in different parts of the world, for example, in the negotiations on climate change (COP 20) in Lima in December 2014 (Larrea, 2013; Acosta, 2013).[17]

The initiative arose and was the expression of the coordinated action of a wide range of social movements and organizations from around the world, all moved by the desire to denounce the attacks, which Nature had suffered, and the suffering that comes from the past, systematically and with increasing intensity, in the name of "progress." This Court, a pioneer in the search for ways to build global justice against crimes against life, was established as a permanent platform to hear and judge cases of violation of the rights of Mother Earth that took place around the world.

In this first session of the Permanent Court of Ethical Rights of Nature included representatives from Australia, Switzerland, South Africa, USA, Spain, Canada, India, Romania, Bolivia, Argentina and England, Colombia, Germany, France, as well as Ecuador were included. After a full day session with presentations and discussions, the court took the unanimous decision to admit nine cases considered emblematic of the violation of the laws of Nature. Six spot cases were presented: pollution Chevron-Texaco (Ecuador); the threat to the Great Barrier reef due to coal mining (Australia); copper sky mining in the Cordillera del Condor reservoir case Mirador (Ecuador); cases of hydraulic fracturing (USA) and two cases on a global scale representing systemic violations of the rights of Mother Earth, involving genetically modified or transgenic organisms and climate change; and lastly the proposed oil drilling in Yasuní-ITT (Ecuador). During the Yasuní –ITT case, because of the immediate threads, and the convincing evidence the Tribunal agreed to establish a special Courtroom for this item, to consider the harassment of defenders of nature, including the people gathering signatures for a community consultation with which to put the brakes on the exploitation of crude in the Yasuní-ITT. It was also to consider the suspension of extraction activity in Block 31 and 43 (ITT), and carry out a general audit of all activities in the Yasuní National Park.

It was consistent that the Court of the Rights of Nature originates in Ecuador, the first country to recognize these rights in its constitution. It is ironic, however, that Ecuador has abandoned its leadership and its commitment to respect the rights of nature set out in its Constitution, which was overwhelmingly approved by the Ecuadorian people at the polls (Figueroa, 2011). The Government of Ecuador is currently promoting the expansion of oil production and large-scale mining threatening three million hectares of the Amazon forest remnants, while carrying out a systematic campaign against those individuals and organizations that defend the rights of Mother Earth protected by the Ecuadorian Constitution. The criminalization of popular resistance is undoubtedly the government tool to further expanding extraction: minerals, petroleum, biofuels, etc.

These cases illustrate to a greater or lesser extent, certain changes in the way of protecting the environment, moving away from the traditional anthropogenic perspective. Graduallysocialchanges areinfluencingthe evolution of the lawfor the benefit ofnature. Thesechanges respondto the attempt tostophumanizingnature and make the human beingresponsiblefor protectingthe environment. In some sense, history shows again that culture changes law and law in turn, broadly can change culture.

V. CONCLUSION

Environmental awareness generated by progressive degradation of the environment, from different areas has led to the call for a formal recognition of the importance of environmental protection for human well-being. However, the anthropocentric approach developed to protect human rights has shown that it is not enough to protect the environment. The traditional anthropocentricparadigm furthers dangerous ideas around the commodification and financialization of nature. So the new road for the biocentric perspective away from the Western model of development to a more holistic approach based on indigenous concepts such as "Living Well" or "Good living" and allowing for the development of the "right to a healthy environment" and "the rights of nature." The conception of an environmental dimension as an integral part of the realization of human rights has contributed to increased lack of care about environmental protection for the benefit of human welfare. The consequence has been the subordination of the well-being of ecosystems to satisfy human interests, not always respectful of natural cycles. Thus, the protection of nature through a human rights perspective has generated the dispersal of laws according to the subjective and fragmented interests of human groups.

The new focus on environmental protection, which has been discussed in this article, establishes a new relationship between humans and nature and harmony between the two, which should be preserved as a guarantee of nature's regeneration. It promotes the legal recognition of nature favouring the unification of laws throughout the different legislations by providing rules protecting the natural world with a common denominator, based on the needs of the biosphere. According to that, states must be required to prioritize the welfare of citizens and the natural world, developing public policies that promote sustainability and control of industries. The national economy should operate within the limits of nature. This certainly will not be an easy task. What may seem utopian is slowly becoming a reality in many countries. The key is to change policies and laws related to the environment, which simply encode pollution and destruction. The changes only will be succeeded, if such policies and laws recognize human rights as well as human responsibilities for a healthy and resilient Earth.

Despite the possible contradictions on a practical level, the emerging new regulations based on the biocentric approach at least raise the man's need to change the way it treats nature, but this new concept has not been widely translated into the world of laws and policies, or society in general. According to this concept, natural rights are not opposite to human rights: human rights are a subset of natural rights, because humans are a part of the nature.

The final idea is not the imposition of the biocentric view on the anthropocentric legal protection of the environment, but to change the way we conceive this protection: it is important to protect nature, but not under the blanket of protecting human interests. Social movements and even academic efforts should be made to invest in favour of the rights of nature and at least a new opportunity to preserve the environment and, of course, our welfare. Critically, therights of Nature framework provides a path through which people can re-learn respect for Mother Earth and for human rights.

KEY TERMS AND DEFINITIONS

Anthropocentric Approach: Viewpoint arguing that human beings are the central or most significant entities in the world.

Biocentrism: The view or belief that the rights and needs of humans are not more important than those of other living things are.

Ecocide: The extensive destruction, damage to or loss of ecosystem(s) of a given territory, whether by human agency or by other causes, to such an extent that peaceful enjoyment by the inhabitants of that territory has been severely diminished.

Environmental Law: The field of law that covers the protection of environment from a legal aspect; Human right to environment: is the enjoyment of everybody, without discrimination, to a safe, healthy and ecologically balanced environment.

Environmental Protection: Policies and procedures aimed at conserving the natural resources, preserving the current state of natural environment and, where possible, reversing its degradation.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Good Living (Buen Vivir): The Ecuadorian concept of *sumak kawsay*, meaning a full life in kichwa. It has emerged as a response to the traditional strategies for development and their negative environmental, social, or economic effects. It is an alternative concept of development that focuses on the attainment of the "good life" in a broad sense, only attainable within a community; a community that includes Nature.

Living Well (Vivir Bien): The Bolivian concept emanating from Latin America's indigenous peoples. The term translates as *sumaq kawsay* and *suma qamaña* in Quechua and Aymara, the two main indigenous languages of the Andes and it implies the creation of a new global relationship with nature and among human beings, expanding the rights to Mother Earth, setting ethical values and responsibilities of peoples with Mother Earth, the fulfillment of obligations of States, communities, and individuals with Mother Earth; and the protection of the environmental functions of Mother Earth as community-goods.

Mother Earth: A dynamic living system comprising an indivisible community of all living systems and living organisms, interrelated, interdependent and complementary, which share a common destiny.

Nature Rights: The recognition that our ecosystems – including trees, oceans, animals, mountains – have rights just as human beings have rights (nature in all its life forms has the right to exist, persist, maintain and regenerate its vital cycles).

Nature: All the animals, plants, rocks, etc. in the world and all the features, forces, and processes that happen or existindependently of people, such as the weather, the sea, mountains, the production of young animals or plants, and growth.

Rights of the Mother Earth: Mother Earth and all beings of which she is composed have the following inherent rights: the right to life and to exist; the right to be respected; the right to regenerate its bio-capacity and to continue its vital cycles and processes free from human disruptions; the right to maintain its identity and integrity as a distinct, self-regulating and interrelated being; the right to water as a source of life; the right to clean air; the right to integral health; the right to be free from contamination, pollution and toxic or radioactive waste; the right to not have its genetic structure modified or disrupted in a manner that threatens it integrity or vital and healthy functioning; the right to full and prompt restoration the violation of the rights caused by human activities; the right to a place and to play its role in Mother Earth for her harmonious functioning; the right to wellbeing and to live free from torture or cruel treatment by human beings.

ENDNOTES

[1] This chapter has been prepared under the DER2013-44009-P Project entitled"Del desarrollo sostenible a la justicia ambiental: hacia una matriz conceptual para lagobernanza global" (2014-2016), whose main researcher is Dr. Antoni Pigrau Solé.

[2] The Subcommission on the Promotion and Protection of Human Rights was established by a decision of the Commission on Human Rights of 10 Feb. 1947. Its former name was: Subcommission on Prevention of Discriminationand Protection of Minorities (renamedby ECOSOC decision 1999/256 of 27 July 1999).

[3] The Subcommittee commissioned Mme. Ksentini to develop a methodology for such a study. Two years later, Mme. Ksentini presented a preliminary report (E / CN.4 / Sub.2 / 1991/8, August 2, 1991). In this report, the provisions of several international and national human rights instruments relating to the environment, their relationship with other rights such as the rights of indigenous peoples and the right to development, the human rights violations and environmental degradation

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

are discussed and so are the environment, ecological rights and the implementation of environmental protection procedures. At the request of the Subcommittee, Mme. Ksentini presented two more reports, one in 1992 (E / CN.4 / Sub. 2/1992/7 on July 2, 1992 and Add.1) and another in 1993 (E / CN.4 / Sub.2 / 1993 / 7, July 26, 1993).

[4] Mr. John Knox was appointed in August 2012 for a period of three years, as the first Independent Expert on the issue of human rights obligations related to the enjoyment of a safe, clean, healthy and sustainableenvironment. His main tasks in accordance with Resolution 19/10, which established the mandate of the independent expert, inter alia, are the following: to study the human rights obligations related to the enjoyment of a safe, clean, healthy and sustainable environment, in consultation with relevant stakeholders; identify and promote best practices, and exchange opinions, in the performance of its obligations and commitments to support human rights, support and strengthen environmental policy, especially in the field of environmental protection; develop a compendium of best practices; make, within its mandate, recommendations that could contribute to achieving the Millennium Development Goals, in particular the Millennium Development Goal; and consider the results of the UN Conference on Sustainable Development (Rio +20), and provide a perspective of human rights monitoring processes.

In 2012 Kate Raworth proposed combiner understanding planetary boundaries to social boundaries, being essentially interdependent. In its report *A Safe and Just Space for Humanity: 'Can we live Within the donut'* integrates the study of Rockström and other '9 Processeses Earth-system' with "11 dimensions of human deprivation".

[12] The Ecuadorian constitutional text has three Articles where the following rights for nature are established: the Article 71 on the Nature, or *Pachamama*, where life is reproduced and occurs, has the right to integral respect for its existence and for the maintenance and regeneration of its life cycles, structure, functions and evolutionary processes. Article 72 refers that the Nature has the right to be restored. This restoration shall be apart from the obligation of the State and natural people or legal entities to compensate individuals and communities that depend on affected natural systems. In those cases of severe or permanent environmental impact, including those caused by the exploitation of non-renewable natural resources, the State shall establish the most effective mechanisms to achieve the restoration and shall adopt adequate measures to eliminate or mitigate

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

harmful environmental consequences. Article 73 states that the State shall apply preventive and restrictive measures on activities that might lead to the extinction of species, the destruction of ecosystems or the permanent alteration of natural cycles. The introduction of organisms and organic and inorganic material that might definitively alter the nation's genetic assets is forbidden.

[13] All these Ordinances were drafted in consultation with the Community Environmental Legal Defense Fund (CELDF). See http://celdf.org/resources-ordinances (accessed August 2, 2014).

[14] This amended another old Local Law 1 - 1993 known as "adoption of code", adopted by the Town Board of the Town of Wales on May 11, 1993, by adding a new chapter 162 known as the "protection of natural resources".

[15] Borough Council of Wilkinsburg, Allegheny County, Pennsylvania adopted ordinance number 28-70 that enacts an enforceable Local Bill of Rights, along with a prohibition on natural gas extraction to protect those rights.

[16] The group included Nnimmo Bassey from Nigeria and Vandana Shiva of India (both winners of the Right Livelihood Award), and other activists from Mexico, Peru and Ecuador, including the Chairman of the Constitutional Review Panel of Ecuador.

Chapter 4
The Impact of Kisan Call Centers on the Farming Sector

ABSTRACT

The Indian Agriculture has been an area with varied challenges. This sector is responsible for the growth rate and generating a per capita income. This sector generates a whopping 28% of the total GDP of India and over 15% of the total exports. The usage of Internet and phone technology can fill these gaps to a large extent. A continuous two way interaction among the farmers and agricultural scientists will ensure agricultural extension. A landmark step was taken on January 21, 2004 when the Department of Agriculture & Cooperation, launched Kisan Call Centers (KCC) with the help of the extensive telecom industry to deliver extension services to the farming community. The main purpose of these call centers is to answer the queries raised by the farmers in their local language, on continuous basis. At present the Kisan Call Centers are running from 14 locations all over India. In this chapter, we are trying to analyze how this strategy to help the farming community was introduced and how it is being implemented.

INTRODUCTION

The role of agriculture in India's socio-economic development is inherent since ancient times. Even today agriculture forms a significant part of the GDP and overall growth and sustainability of India. This sector provides employment to 51% of the total workforce, being the largest economic sector amongst others such as mining, tourism, retail, textile, industry and services. That being mentioned, the challenges before the agricultural practices in India are immense. It will not only benefit the overall economic progress of the country, but is also essential for the workforce of the nation, two thirds of which, directly or indirectly depends on the same. It contributes to around 27% of the GDP of India and somewhere around 13-16% of the exports. Still, the yields are not only lesser than expected, they are highly unstable and the gaps in technology transfer are much more intense as compared to those in areas that are irrigated.

Kisan call center is a Government of India initiative under the department of Agriculture and Cooperation. This initiative is primarily aimed towards assisting the farmer community for any issues or queries that they may have and also in training them to face the immense inevitable challenges. These knowledge centers are active throughout India providing services to farmers in terms of assistance and guidance in solving their problems in their regional local languages. Providing a structure to this entire operation of query handling involves effective use of technology, networking, a strong knowledge base, technically educated and informed staff. These call centers make use of an extensive telecommunication network, having a strong back end Management Information System to address the queries of farmers across the country, regarding agriculture practices and latest farming techniques. The scheme's objective is to serve the farming community spread over 5 lakh villages across the nation.

The need of the hour is to pay greater and more focused attention to information by extensively using the appropriate tools and technologies that help farmers cope up with the diverse challenges and learn new opportunities on a continuous basis. To capitalize on future export opportunities of agriculture products, the country needs to match global standards in terms of quality, stability and hygiene. Hence, the farmer should be aware and informed of the latest efficient agricultural practices.

The Kisan Call Center aims to fulfill the following:

- Fast and effective spreading of information
- Minimizing the gap between Farmer and Research Labs, agriculture universities, market, corporates
- On demand specific individual knowledge transfer and adequate facilitation
- Efficient use of the huge and complex telecom infrastructure

While the state of Kentucky, US is following GAP (Good Agricultural Practices) to ensure safety from post production deceases in the crops, and the GAP in Rome (Italy) are focused on setting up protocols and appropriate processes, the services provided by KCC are rather educational and informative in nature. They aim to educate the farmer with innovative and new technologies and techniques that should be implemented in order to yield better results.

Recently, to facilitate the queries of the farming community in an easier way, the Department of Agriculture and Cooperation has come up with an idea of Kisan SMS (Short Messaging Service) Portal. The users have to register and enroll themselves via a mobile number. Once registered, the user will receive regular updates about weather and agricultural alerts, absolutely free of cost. In this case, a farmer will be getting an SMS messages providing expert information and delivering services on his mobile from

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

agriculture scientists at various levels. The services cover diverse areas such as crop production and protection, animal husbandry, fisheries as well as dairying.

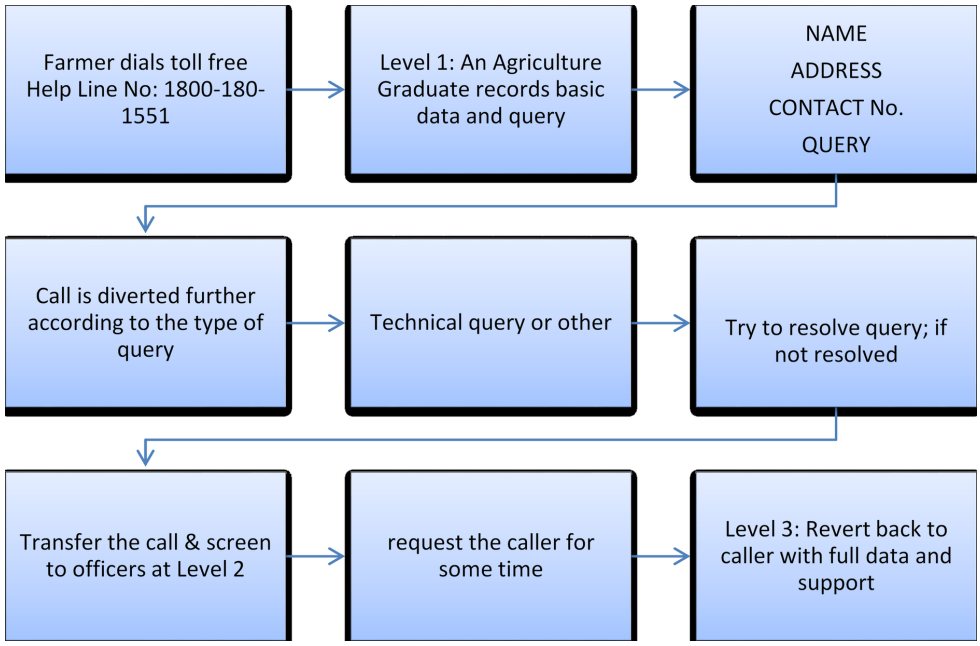
New types of information and services are expected to be included as the system progresses based on the different requirements of farmers. Some of these include:

1. Weather information including forecast
2. Alerts for farming related facts
3. Timely Information regarding disease/pests outbreaks
4. Technology related support for crop cultivation according to local conditions
5. Awareness of new crop variety
6. Market know how
7. Soil fertility reports

THEORETICAL FRAMEWORK

Here we describe the concept and structure of the implemented knowledge based service, also the infrastructure and technology involved in connecting the farmers with the personnel who address their individual queries in their local language. The steps for a typical calling procedure can be seen in Figure 1, below. Each call follows a pre-defined protocol and queries are addressed according to their nature by various levels of representatives, from agriculture graduates, postgraduates equipped with computer

Figure 1. Steps involved in a typical calling procedure
Source: National Institute of Agricultural Extension Management



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

systems, Subject Matter Specialists (SMSs) or Subject Matter Experts (SMEs) having sound technical knowledge, and various other but related scientists to promptly assist the farmers with their respective questions and doubts. This way these call centers provide extension services to the farmer community according to the nature of the problem. This is an opportunity for businesses with the existing extension services to grow their network further to help farmers in remote areas of the country adopt better practices.

When a KCC (Kisan Call Center) representative receives a call, he or she addresses the query based on their own knowledge and understanding. Also, the representative has access to a knowledge database containing FAQs, which is updated continuously with every incoming and outgoing call. The different type of calls can be identified as—

Technical Query:

- Crop Production
- Crop Protection
- Horticulture
- Agriculture
- Animal Husbandry
- Marketing

Others include:

- Admin related query
- Regarding Government Schemes
- Subsidy
- Seeds Positioning
- Gypsum, Fertilizers, Pesticides
- Credit and insurance

Farmers can provide feedback on the agriculture services provided by the government and the private sector; this helps in regular monitoring and improvement in services.

These call centers are generally a part of an organization like Research Stations, ATICs, Agriculture Colleges or are outsourced, as per the specific requirements. The objectives of such ATICs are the provision of a single and streamlines delivery system for the services and products to the kisans (farmers) and other FIGs as a continuous process of technology dissemination innovation. They also encourage the callers/users and facilitate them to provide their valuable feedback. The services offered by the call centers usually include customer support, multi-lingual direct assistance and other services. The senior agriculture scientists and experts in the government system are Nodal Officers.

The infrastructure of Kisan Call Centers is divided into three levels:

- **Level I:** A Call Center that is professionally managed including all the basic requirements for a stable network and smooth communication. The call center management dedicated for the KKC services maintains Local Area Network (LAN), Air Conditioning, equipment such as computers, headphones and an Uninterrupted Power Supply.
  Qualification representative: M.Sc. in Agriculture

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The major functions carried out by a Level I representative are being a first point of contact to the farmers, he attends the call with a welcoming message and takes the question down and feeds that into the computer by himself. The operator will be fluent in the local language and in most of the cases he is equipped to answer the question himself.

- **Level II:** A response center handling the services of Subject Matter Specialists for individual problem based query resolution. This contains upgraded and more robust technology setup as compared to Level I.
  Qualification of representative: PhD. In Agriculture, with 10-15 years of experience in relevant sector.
  The Level II representative holds certain responsibilities like answering the questions if the Level I representative couldn't answer the questions posed by the farmer. The Level II representatives comprises of the Subject Matter Specialists who stays at their respective places like educational institutions or the Govt. Offices. Depending on the expertise they hold the specific question will be forwarded to those persons. The expertise basically will be classified depending upon the crop or certain other parameters. In any case if the person is unavailable then there is a callback option where the question poser will be called back in mostly less than 72 hours.
- **Level III:** the Nodal Cell comprising of the Nodal Institutions is also fully equipped with the appropriate logistic support. The senior officers resolve queries and problems using software analysis tools.
  Qualification of manager: Masters in Agriculture, having 5-10 years of experience

For Level II and Level III support, agriculture agents are nominated from various institutions and organizations all over India. Proper training and induction is provided to the nominated graduates.

An important part of this organization is the Human Resource. The personnel attending calls need to possess basic skills to attend to farmers' calls effectively. Few skills identified are

- **Soft Skills**
  - Greeting and facilitation
  - Ability to speak using farmer's language
  - Usage of simple sentences and words
  - Patient listening
  - Probation of the details
  - Diagnosis of the query/problem raised by the farmer
  - Answering at the level of the farmer
- **Communication Skills**
  - Empathizing with the caller
  - Active listening
  - Commitment to assist the caller
  - Assertive responses
  - Relating with local or personal experiences, as need be
  - Polite replies
  - Subtle modulations or transitions in voice
  - Closing the calls with greetings as well

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Computer Operating Skills**
  - Basic know how of the mouse and the keyboard
  - Basic know how of the internet
  - Receiving and sending electronic mails

For successful implementation of any system there is always a need to monitor and review the regular performance using methods such as feedback from inside and outside the organization. Storing the data by Nodal Offices on a regular basis lays the foundation of such an extensive knowledge base. Analysis of the collected data takes place at these Nodal Institutions by specialist suitable for the job. The same Nodal Institutions are also responsible for documentation and reporting that help in creating consolidated courses of action for individual farmer's query.

OBJECTIVE

- Study of the concept and mechanism of operation.
- Understanding the ground level function of Kisan Call Centers.
- Analyzing the structure of the scheme.

RESEARCH DESIGN

Based on the learning and research, the elements of survey and data collection were inferred, by focusing on the planning, implementation and management of Kisan Call Centers. Certain Measurement indicators were identified to assess their performance and recommend opportunities for improvement. Parameters that were chosen include

- Number of daily calls received
- Agent quality
- Network sustainability
- Infrastructure
- Utility of software and technology
- Training

The expectations of the government and other stakeholders in the scheme were used to form an understanding about the size of the scheme. Some of the expectations from this scheme:

- Over 500 calls per day
- Technically sound personnel with good communication skills to resolve problems efficiently
- Smooth network quality and reliable connections
- Building regular Database
- Adequate infrastructure matching all technical requirements
- Simple User Interface of software
- Technical training to be continuously provided to representatives

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

A strong software tool that has been developed by Telecommunications Consultants India Ltd. (TCIL) supports Kisan Call Centers and ensures instant and continuous connectivity across the entire network. The Management Information System enables technical assistance to farmers and recording of queries to build a database, which is accessible all times to the KCC.

The database mainly consists of questions asked by farmers along with their answers. Report generation software is bought in use by the agriculture graduates having a user interface to generate reports based on specific parameters entered by the agents, according to the requirements of the concerned farmer. The filters used for scanning through database for generation of report are date, location, crop, problem etc. This data is made available over the Internet once the report is generated.

RESEARCH METHODOLOGY

Secondary data was gathered from various sources such as articles, journals and case studies from the Ministry of agriculture. This data was the basis of obtaining an in depth knowledge of the concept leading to a structure for the research.

Primary research was conducted involving site visit of KCC's nodal office in Ghaziabad. Information was gathered on the implementation and response of farmers towards the scheme. The objective of the primary research was to conduct analysis of data collected and inferring the grass root level implementation implications of the scheme. Further, identifying loopholes, if any and providing recommendations based on the learning and findings.

LITERATURE REVIEW

Maximizing the crop productivity is one of the major problems in a country like India where agriculture is the primary occupation. The crop productivity poses a huge problem pertaining to the amount spend on raising the crop and the amount a farmer can earn selling the crop in the market. One among the many reasons for not achieving the desired output is that the expert advice is not reaching the farmers on time. There is a lot of information gap between the research and actual practice. To bridge this gap, the research paper (P. Krishna Reddy and R. Ankaiah, 2005) mentions about a framework. According to the framework mentioned, each farmer will be equipped with Agricultural information dissemination system (AgrIDS) which is cost effective. This helps the farmers to cultivate with the help of both the crops related, location related experts.

The proposed framework mentions the integration of IT services, which grew rapidly over the last few decades, with agriculture. As it was mentioned that all the farmers will be made available, the AgrIDS system, so that the farmers can get the timely advise from the experts. It involves the pictures taken from the fields and then they will be transferred to the experts. They will have a look at those pictures and then will provide the advice analyzing them. The advice definitely will not be based on the received pictures alone but there are lot many details the experts, in their own area of expertise, will suggest the farmers which crops to elect and raise depending upon some of the major factors influencing the agriculture like rainfall, soil type, weather etc. Also financial experts suggest the farmers about the crops which possibly will have high demand in the international or the domestic market which will help the farmers to earn profits. Also production of certain crops in the country is rather scarce when the consumption is taken

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

into consideration so government can take steps into providing certain schemes that can motivate the farmers to raise that crop.

The research paper (P. Krishna Reddy and R. Ankaiah, 2005) also mentions about the drawbacks of the traditional system. At present the insights given to the farmers are in a generic and not specific to the certain farmers so for some the advice helps but a lot people might get affected either by not getting the desired productivity nor the profits. It does not cover all the farmers but only a few. There are numerous reasons some being the literacy levels, lack of awareness etc. The traditional process is just a one way process and if the farmers need more information on what they have been farming they couldn't get the information on time. The major drawback being unaccountability – number of advices given and the number of advices that are turned out to be useful. The proposed AgrIDS overcomes these drawbacks to a major extent.

The AgrIDS system will be using the data ware housing technologies, data mining techniques. Saving large amounts of data has become an easy task in the recent years. So all the queries that the system will receive in the form of either text or photos will be recorded along with the answers. This data being saved can be used in the future if the advice is requested for similar kind of problem by a farmer. In the present world extensive information is available online and there are many companies whose business model runs only on the data. With all of this enormous amount of data available it can be analysed and then refined so that the patterns can be drawn using the data mining techniques. Extrapolating the data available simulation models can be developed so that the future possibilities can be drawn from them. For all of this to happen the internet should be made available to all class of people where they can make use of the system proposed.

The system consists of various parts including farmers, coordinators, AEs and Agricultural information system where all of them are integrated using internet. The amount a farmer would invest in receiving the advices is substantially less by using this system. Amount of pesticides and fertilizers to be used for a crop can be moderated based on the actual requirement for high output. Because of lack of experience of the farmers they might not be using the adequate amounts of pesticides or the manure. So making this AgrIDS system available to the farmer, the money a person spends on the fertilizers will be saved substantially.

A research was taken up by a group of researchers from MSSRF (M.S Swaminathan Research Foundation) about the technical advancements in the field of crop husbandry that took place in the country pre – post independence periods and their implications. The research paper (R. Rukmani) mentions about the ICAR system which developed around 3000 hybrids and high yielding varieties related to various crops which promises more productivity and less prone to diseases. Some of these varieties were used in the country to witness a huge increase in the crop productivity. The statistics backs the fact that the growth rate in the 1990^{s} was less compared to 1980^{s} possible reason mentioned was because of the lack of the proactive decisions by the country in that time frame. Also the challenges faced by the government are the Intellectual property rights adoption and the assessment of advances in the biotechnology fields. The policies during the early decades after independence will have to see a significant change to meet the present changes in the field of the crop husbandry.

Considering both the research papers, (R. Rukmani) mentions about how the scientific technology totally shifted the face of agriculture to meet the growing demand and also mentions that some amends to the present policies are required to withstand the changes in this present world. This research paper (P. Krishna Reddy and R. Ankaiah, 2005) mentions about a framework consisting of AgrIDS that will help the farmers. While during the early decades when there was only a limited connectivity among the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

people, the state had taken steps to help farmers use the ICAR developed crop varieties (like Rice, Wheat and some Cereals) and it took decades for the crop productivity to reach to the current state. While taking into account the connectivity among people and the reach of any information in the present day, with advancements in the scientific development and integrating those with the IT models such as AgrIDS will definitely help the increase in the crop productivity.

Kisan call center have been one of the most pioneering initiatives by the Government of India. According to a report published in Asia Pulse, the Kisan call centers in India received 318,106 calls in total. These calls were from farmers who belonged to remote and tribal areas who sought solutions for their problems that varied from agriculture to animal husbandry. The Indian Society of Agricultural Professionals (ISAP) released this data. The ISAP is the organization that sponsors the functioning of the call centers. The article further stated that most of the queries originated from Shivouri and Shajapur districts in Madhya Pradesh. Also, the tribal areas over there also called up these centers to clear their doubts. The number of calls relating to agriculture crops were 173,274, while those about horticulture summed up to 93,299 and 12,802 were from the field of animal husbandry. Currently, the service has been made available from 6 AM to 10 PM, except for Sundays and gazetted holidays. The service is provided beyond these hours by an IVRS system.

There are fifteen subject specialists that are employed and available at the call centers in Madhya Pradesh who work in two shifts to ensure maximum time is available to cater to the queries of farmers. The Kisan call center here is managed and run by National Agricultural Development Project through a private public partnership. The Kisan call centers are equally effective when it comes to solving the problems of farmers in the hilly regions of Himachal Pradesh. A study conducted by Sharma and Singh in 2011 concentrated on two cash crops that are grown in the region, apple and tomato. These crops are grown in the high and medium hills of the state respectively. According to the study, the farmers who used the services of the calls center were more informed about their crops and benefitted from it. The productivity of crops of these farmers was much higher than those who did not used the services. It suggested that the farmers should be educated by the media and government about the call center so that farmers can grow their crops more effectively and scientifically.

Recently, the Government has collaborated with IFFCO Sanchar Limited for the restructuring of the KCC's. The new call centers would be state of the art and shall provide professional assistance as well as well technical innovations to the existing service network. These include call barging that will be handled by experts and officers of the government, video conferencing, dynamic monitoring of the working of the call centers. The books and reference material provided to the employees will also be upgraded to the latest editions of modern agricultural practices. The IKSL (IFFCO Kisan Sanchar Ltd.) has attempted to provide many innovation, interactive and engaging services for the farmers that subscribe to the KCCs. These services and its subscription is absolutely free of charge and includes benefits and activities like free voice messages on a daily basis to every subscriber, on his area of interest, call back facilities, mobile quizzes, common forums and focus groups. Their prime mission is to empower the rural section of the society and the farmers with high quality and germane services and information, through proper telecommunication and other communication channels.

84% of farmers were satisfied with the advice that they received from the call center personnel, as stated by the study conducted by Administrative Stall College of India in 2012. The study further revealed that the advice helped the farmers in efficiently managing their fertilizer and pesticide usage, which reduced the weeds, pests and diseases in crops. Moreover, this initiative is built and structured in a manner to accommodate continuous evaluations and monitoring, that would help the same to grow

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

in a more effective manner. After the research, it was also found that TNAU (Tamil-Nadu Agricultural University) formed Farmer's Associations – FIG (Farmer Interest Group) which is essentially an independent and self-managed group of farmers with common goals and interests. The members of this group pool in their resources, so that by uniting their resources, they can work towards the fulfilment of their common goals and objectives and share the consequential benefits.

DATA ANALYSIS

Nodal officers in Delhi and Ghaziabad aided in collection of data, to assess the performance and grass root level implementation of KKCs. The Scheme was launched at the time when BJP government was in power in India and the KKCs received recognition, showing good results and positive response from farmers.

The services provided through KCCs are monitored and reported by these Nodal offices. Although, the offices were equipped with all the facilities claimed by the government, a lackadaisical attitude was observed on our visits to the offices in New Delhi and Ghaziabad. All over the scheme has a total outreach to over 1500 villages and around 30 districts in 17 states of the country. This scheme has also provided employment to over 1800 BPL (Below Poverty Line) youth, living in rural India, by conducting training programs.

The knowledge base has grown immensely since the inception of these call centers. KCCs have enabled spread of knowledge amongst farmers and access to information easy by providing a proper channel supported by the government and private parties. States where the scheme has been most successful, like, Bhopal, Madhya Pradesh have KCCs running in Public Private Partnerships (PPP). A list of call centers across major states can be seen in Table 1.

RESULTS AND FINDINGS

The important findings from the project research are that Kisan Call Centers have:

- Transformed and impacted the lives of more than 1.25 lakh farmer families.
- Provided Specialized Training and job opportunities to over 1800 BPL youth.
- Promoted Entrepreneurial developments to bring in greater avenues for private ventures to agriculture graduates.
- The Bhopal KCC alone has answered up to 5 lakh queries during 2008-11.
- Made effective use of technology. A robust MIS system helps in advisory services and building knowledge base.
- Over 250 graduates, those have been certified as Crop Certified Advisor (CCA).
- Highest calls recorded for the vegetable growers, closely followed by food grain growers and fruit growers. 23.5 percent of the calls were recorded for the information about various diseases in the crops and 6.9 percent of the calls were related to animal husbandry.

SUGGESTIONS AND FUTURE IMPLICATIONS

The use of technology is critical to bridge the economic gap prevailing in the country, to stimulate growth by building individual capacity to generate value through learning the immense opportunities in agriculture and allied services. A shortcoming in the TOT (Transfer of Technology) model is a prominent challenge for the current private and public extension systems, however, the effective and efficient use of telecommunication channels, relevant technologies and internet, this gap can be bridged by a considerable extent.

After studying and analyzing the concept implemented by the government with the emergence of KCCs, we suggest that more private organizations should show participation in such initiatives, by forming alliances with the government and NGOs. In states where the scheme is to be launched, the mobile carrier partner companies can come up with initial promotional offers for farmers, such as distribution of registered sim cards to them. This would encourage the farmers, make life easier for them and spread greater awareness amongst them regarding KCCs.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Also, more importance should be given to courses like CCA (Crop Certified Advisor) and the youth, especially in the rural parts of the country, should be encouraged to pursue this as a career option.

Contemporary technology should be leveraged more effectively to facilitate growth. Promotional campaigns using mobile wagons and kiosks should effectively spread the scheme to untouched remote areas of the country.

KEY TERMS AND DEFINITIONS

AgrIDS: Agricultural information dissemination system, an online system proposed where the entire process of examining the crop and suggesting the productive steps by the specialists can be done online.

ATIC: Agricultural technology information Centre, a place where the information regarding the agriculture can be available.

GAP: Good Agricultural Practices, the best practices that can be adopted to attain the best possible output.

KCC: Kisan Call Center, a call center where farmers can get their queries regarding the agriculture can be answered.

PPP: Public Private Partnerships, a type of partnership where the public, private together is involved to raise the capital and be a part and owner of certain project.

SME: Subject Matter Experts, a part of the KCC where they would be answering the questions addressed to them to their best in order to resolve the farmer's queries.

TOT: Transfer of technology, where the use of technology among the stake holders.

Chapter 5
Fundamentals of Electrostatic Spraying:
Basic Concepts and Engineering Practices

Manoj Kumar Patel
Academy of Scientific and Innovative Research, India & CSIR-Central Scientific Instruments Organisation, India

Chirravoori Ghanshyam
CSIR-Central Scientific Instruments Organisation, India

ABSTRACT

The desired attributes of electrostatic spraying are uniform deposition onto both directly exposed or obscured crop surfaces which minimize the off-target losses of active ingredients to soil, water, atmosphere and provide more effective and economical pest control. This chapter presents an overview of electrostatic spraying technologies in the field of agriculture emphasizing the key role of advanced electrostatic instrumentation and chronicles the scientific innovations in the parlance of providing cost effective and reliable commercial systems along with an insight on the needs of future research perspectives and directives. It is aimed primarily at a familiarization with spraying concepts and engineering practices. This text is to bridge the knowledge and experience gap among researchers and technology developers and the people involved in electrostatic processes applied to agriculture and food processing. It will also introduce the engineering aspects of design and development of an electrostatic spraying nozzle for agricultural applications.

INTRODUCTION

Air-assisted electrostatic sprayers are advanced agri-instruments for efficient use of pesticides to agricultural crops, orchards, plants, trees etc. The electrostatic spraying technique is all about reducing the use of pesticide by increasing the efficiency and bio-efficacy. Bio-efficacy is a measure of the biological efficacy of an active ingredients of agro chemical such as insecticide etc. The methods used to perform the function of bioremediation are known as bioremediators. Electrostatic spraying is to be the one

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

among the available spraying techniques in precision agriculture and food processing. For example, the electrostatic spraying technique can be used for protective biomaterial coatings to fruits and vegetables for resistance towards microbial attacks, to enhance the transportation life, to control spoilage microorganisms, antimicrobial sprays for enhanced food safety etc. It is a method which reduces the environmental pollution by reducing contamination to soil as well as air. In totality, it reduces the chemical consumption which is used indiscriminately through conventional methods such as pedestal-mounted sprayers, the high pressure spray guns, the hand pressure swirl nozzles and the consecutive high volume spraying systems etc. The trans-disciplinary aspects of the embryonic field of electrostatic spraying have provided a major motivation to agricultural and food processing researchers for the development of novel techniques for spraying liquid pesticides to crops and orchards, protective coatings to food and food packaging, in addition to other applications of sprays to industrial, manufacturing and transportation, medical facilities and devices etc. This chapter is to be one among the motives behind the renewed curiosity in the usage of the electrostatics in liquid based spraying.

Although, organic measures for crop protection are being preferred, chemical intervention is still the fastest and most economical way for crop protection. However, due to lack of awareness and ignorance, pesticides are being used indiscriminately leading to side effects on human health and ecosystem. Electrostatic method of pesticide application reduces off-target drift, environmental pollution and human health risks and increases the bio-efficacy and mass transfer efficiency onto the biological surfaces of crops and trees with uniform back deposition. Law, (1978); Jia, Xue, Qui, & Wang, (2013) explained the design and development of induction based electrostatic sprayer for agricultural usage and evaluated the performance. So far, the equipment available in the market are uncontrolled in terms of spraying variability. Pesticide application control, targeted pesticide delivery and variable pesticide spraying are the key to improve operation quality, reduce chemical waste, environmental pollution and operational costs. This entices to develop a sensing mechanism which would discriminate between the presence and absence of pesticide application surfaces. He, Yan, & Chu, (2003) developed the automatic target detecting air-assisted electrostatic orchard sprayer. In this spraying system, the sensing mechanism is based on infrared proximity sensors which determine the presence and absence of target to be sprayed. Other than infrared proximity sensors, ultrasonic sensor mechanism is another substitute for target detection and canopy mapping. Sensory attributes stipulate a good approximation of target and canopy mapping for targeted delivery of pesticides to actual target. Automation and mechanization with respect to agricultural pesticide spraying is one of the naive research topics in the present scenario.

The last decade has witnessed the application of existing electrostatic techniques to various fields accompanied with rapid improvements of the spraying technology. Zhang, Srirama, & Mazumder, (2007) have worked on a new approach in signal processing and sampling which shows that electrostatic applications have gone beyond the earth and reached to Lunar and Mars missions. Space research needs electrostatics in dust and particle control. Mazumder et al., (2006); Hamid, & Atan, (2008); Ghayempour & Mortazavi, (2013); Khan, Maan, Schutyser, Schroën, & Boom, (2013) ; Zhang, Kobayashi, Uemura, & Nakajima, (2013) have shown the numerous applications of electrostatic spraying to various fields such as agriculture, medical, transportation, painting and industrial applications, though agriculture remained the main area of research during the last decade. Electrostatic application to agricultural pesticide spraying has revolutionized agriculture farming scenario by making advances and developments via off-target pest control to increase bio-efficacy and deposition efficiency. There is also an increase in deposition

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

efficiency by applying suitable charging techniques, better corrosion resistant material used in electrode design for spray charging and its insulation, liquid atomization methods, post processing of the spray by air assistance, automation of spray system and cost effective compact design and development for the layman in terms of easy-to-handle and simplicity of use. Developing an automated system for greenhouse spraying is the biggest challenge in the current scenario of research, since working environment inside the greenhouse is unbearable and dreadful due to the presence of increased level of humidity, carbon di-oxide and high temperature. Prolonged exposure of greenhouse workers to these conditions leads to a scratchy and hazardous work environment. Significant novel and innovative thoughts also came into existence; however, technical improvements and applications of the electrostatic spraying technique to various fields remain the main focus.

This chapter reviews the advances made in electrostatic pesticide spraying to agriculture and a brief description has also been made for the charge to mass determination, software like Fluent, CFD (Computational Fluid Dynamics) used in hydrodynamics and aerodynamics processes to simulate the electrostatic models with user defined functions and Deposit Scan to measure the percentage coverage, spray deposition rate and distribution of the charged droplets etc. It seeks to give a fundamental understanding of basics of electrostatic spraying to agriculture; along with the intricacies associated with the design and development of such high performance, efficient, efficacious modern advanced agri-instruments. In this chapter, innovative and technical concepts have been summarized and explained in detail that came into existence in electrostatic spraying along with the prevue of future perspectives and needs in the current scenario. However, before getting involved with the intricacies of electrostatic pesticide spraying, one may discuss the need for and applications of electrostatics in spraying.

Purpose of Pesticide Spraying

The use of pesticides to crops, orchards, plants and trees is among the most important pre-harvest facets of precision agriculture to protect the crops and for boosting the food production. Abhilash & Singh, (2009) discussed the importance of pesticides in the process of development of sustainable agriculture and shown that pesticides have become an important tool as a plant protection agent. However, exposure to pesticides both professionally and ecologically causes a number of human health concerns. The application of pesticides is one of the most frequently used methods to protect crops, orchards and trees against diseases and insects in agriculture. Off-target drift of pesticides is a term used for individuals droplets containing the full of life ingredients that are not lay down onto the target area, when spread-over crop protective pesticides to agricultural targets. The droplets most susceptible to off-target drift are usually smaller in size, less than 150μm in diameter (usually indicates the Volume Median Diameter, VMD) and effortlessly moved off the actual target area by wind, gravitational force or other agro-climatic, harsh and transient environmental conditions. The larger droplets settle down on the ground because of gravitational force. For example the conventional spraying statistics for grape growers shows that almost 60-70% of the pesticides have been lost via off-target drift and non-target deposition. Underside of the leaves and hidden areas remain untouched with the sprayed chemicals.

Efficient use of pesticides can protect and optimize the environment and natural resources, since the use of non-renewable pesticides and fertilizers is perhaps irretrievable, and encompasses an environment cost. Crop protection chemicals deposited in undesirable areas raised serious concerns caused by spray

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

drift, such as surface water contamination, damage to sensitive neighboring crops, health hazards for living individuals as well as masses and possible adulteration to the target and adjoining areas or possible over application within the target area. Off-target drift destruction can be managed by identifying and regulating the factors that affect it such as environmental conditions, equipment and methods used for liquid spraying etc., later being the most predominant factor to avoid such consequences.

Causes of Spray Drift

Managing spray drift improves pesticide bio-efficacy by guaranteeing that the correct amount of dose reaches at the target. Drift takes away the pesticide from the intended target, making it less effective, and deposits it where it is neither needed nor desired. There may be two kinds of drift in agricultural pesticide spraying:

- Finely divided spray drift is off-target movement of the spray particles.
- Vapor drift is the volatilization of the pesticide segments and their movements away from the actual target.

The pesticide then becomes an environmental pollutant in the off-target areas where it can injure susceptible vegetation, contaminate water, or damage wildlife. A number of variables underwrite to spray drift; these are predominantly due to the spray equipment system and meteorological factors:

- Droplet size and spray height.
- Operating speed, direction and wind velocity.
- Air temperature and humidity.
- Crop protection chemicals and carrier volumes.

Various officialdoms conduct rigorous distribution and drift testing. The reliable data is also very important when conducting drift experiments and it comes from independent testing agencies, such as Food and Environment Research Agency (FERA) in the United Kingdom, the Julius Kuhn Institute (JKI) in Germany and the Centre for Pesticide Application and Safety (CPAS) in Australia. Varieties and consumption of pesticides worldwide have been increasing dramatically as increased human population and crop production. In this process, misuse of pesticide becomes more and more serious, has resulted in heavy environmental pollution and health risk of living beings. Study shows that, even a fraction of percentage of efficiently sprayed protective pest by using advanced spraying equipment such as electrostatic nozzle, is sufficient for the desired biological target as compared to conventional methods.

The charged particle evaporation, droplet instability and its implications to agricultural spraying are justifiably explained and presented theoretically as well as experimentally by Law & Bowen, (1975). The surface energy condition can be drastically altered by the presence of unbound surface charge on an air-borne spray droplet. Evaporating droplet carries no charge as a result an increase in surface charge density is witnessed. This increase in charge per unit area cannot increase infinitesimally; approaches a critical level, called Raleigh limit of charge, at which the liquid surface ruptures and gives birth to small daughter droplets.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ELECTROSTATICS AND PESTICIDE SPRAYING: THEORETICAL CONCEPTS

Electrostatic force field application in agricultural spraying is a new technique to apply for the protective liquid pesticides and to reduce the off-target drift. It improves the efficiency of the system and bio-efficacy of the biological crops. For example, air-assisted electrostatic spraying, aerial electrostatic spraying system assembled in Helicopter and Tractors, are the modern systems used in agricultural pesticide spraying applications. In electrostatic spraying, finely divided droplets are charged by the application of high electrostatic potential to charging electrode. The system should work at lowest possible applied voltage so that it will work on low power consumption and hence the duration of the power supply. For efficient working of the system, ultimately one has to increase the charge to mass ratio at lower applied voltage as there is a trade off between applied potential and power consumption.

Electrostatic space charge and induced image charge forces enhance the uniformity of spray on the target surface, increase the transfer efficiency, bio-efficacy and adhesion. Electrostatic forces minimize the effect of gravitational force which is the main cause of spray drift and ground fall of the pesticide. The electrostatic forces levitate the charged droplets against the gravitational force; however levitation of the droplet depends upon the droplet diameter, surface tension, applied electric field and density of the liquid. The electrostatic spraying process is a very complex phenomenon which can be divided into three basic regions:

Hydro Electrodynamics

It mainly consists of liquid atomization and finely divided particulate matter charging. Liquid atomization can be achieved through centrifugal, pressure, air, hydraulic, pneumatic or electrostatic forces solely or by a combination of two or more of these forces. Chigier, (2007) showed the Challenges for future research in atomization and spray technology. Droplet charging methods include conduction, induction, tribo-electric, and corona charging; the induction charging is predominant in conductive liquid pesticide spraying.

Aerodynamics

It includes charged particles/droplets transport and charge retention. In the droplet transport region, aerodynamic, inertia, electrostatic and gravitational forces work together to determine the trajectories of the charged droplets.

Electrostatics

It mainly involves the actual spray deposition on the target; either it is conducting or non-conducting target. Electrostatic deposition onto a conductive target relies upon a displacement current to transfer electric charge onto or off the target to a degree appropriate for maintaining it at earth potential in the presence of the approaching charged-particulate cloud. In electrostatic spraying, it is assumed that the charged particulate matter is a slow moving phenomenon and therefore magnetic Lorentz force is negligible in comparison to electrostatic force.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In electrostatic pesticide spraying, the following fundamental phenomena are of great importance which have to be taken into consideration for the better understanding of the subject:

- Droplet charging methods.
- In-flight trajectory of charged droplet.
- Optimizing the deposition field and transient effects at deposition targets.
- Charge to mass evaluation and hence efficiency and efficacy of the spraying system.
- Understanding the drop size and its measurement.

Droplet Changing Methods

Research approaches to agricultural spray charging have been based upon several distinct principles. Maski & Durairaj, (2010) showed in their previous work that a major portion of the electrostatic pesticide spraying has been in the development of reliable means for droplet charging. Motion of a charged particle can be easily controlled by the electric force, which depends on the charging level. Therefore, it is desirable to charge the particle to as high as possible and the charged droplet must be acted upon by an electric field. Well known and field-proven methods for imparting the necessary and sufficient charge to pesticide spraying droplets are divided on the basis of conductivity of the liquid to be sprayed:

- Ionized-field droplet charging (for both types of conductive as well as non-conductive liquids).
- Electrostatic-induction droplet charging (only for conductive liquids).
- Direct contact charging (for non-conductive liquids).

Law, (1984) presented a thorough consideration of these charging techniques and pros and cons accompanying with each method, accentuating their applicability as dictated by the physical properties of the pesticide-liquid to be electrified. Each method of charging has advantages and disadvantages in terms of liquid conductivity to be electrified, the level of applied voltage, insulation from the rest of the associated device, power consumptions etc. Induction charging is the most predominant method of charge electrification to fine droplets in pesticide spraying.

Ionized Field Droplet Charging

In corona charging, a sharp electrode is held at a high potential resulting in a local electric field high enough to ionize the surrounding air. The positive charges in the ionized air are less mobile than the negative ones and so remain in the vicinity of the electrode long enough to be picked up by a passing liquid stream. It requires a high applied voltage ranging from few thousands to more than a hundred thousand volts, depending upon the geometry of the charging equipment. Either solid or liquid particles, of diameters larger than approximately 0.5 μm, travelling through this ionized-field region can acquire by ion attachment, a saturation charge dependent upon the particles dielectric constant, its surface area, and electrical characteristics of the corona discharge. Ionized-field charging theory has been well developed mathematically by Law, (1984) and can be used to calculate the net electrical charge imparted to an air-born particle as:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$q_p = f\left[1+2\frac{K-1}{K+2}\right]4\pi\varepsilon_o E_o r_p^2 \tag{1}$$

where K is the dielectric constant, f is the saturation factor, E_o is the applied electric field and r_p is the radius of the droplet. The fraction of the saturation charge actually attained by the particle depends upon the residence time, and the concentration and mobility of the ion in the charging field. For aqueous-based sprays (K=80) charged to half-saturation (i.e. f=5) in a typical corona-discharge nozzle, droplet charge in coulombs typically attains a value of:

$$q_p \simeq 6\pi\varepsilon_o E_o r_p^2 \tag{2}$$

With an associated charge to mass ratio of $\frac{q_p}{m_p} \simeq \left[\frac{9\varepsilon_0 E_0}{2\delta}\right]\frac{1}{r_p}$ C/kg, where δ represents the surface tension of liquid. While the ionized-field charging method is routinely used in a variety of commercial and industrial processes ranging from xerography to electrostatic precipitation, greater care must be exercised in properly designing the process into agricultural spray-charging devices, in order to maintain long-term charging reliability. Difficulties relate to the fragile nature of the exposed corona electrode, to the elevated ionizing voltage required (typically more than 15kV), and to the onset of reverse ionization from the passive electrode when inadvertently wetted or coated with resistive particles.

Induction Charging

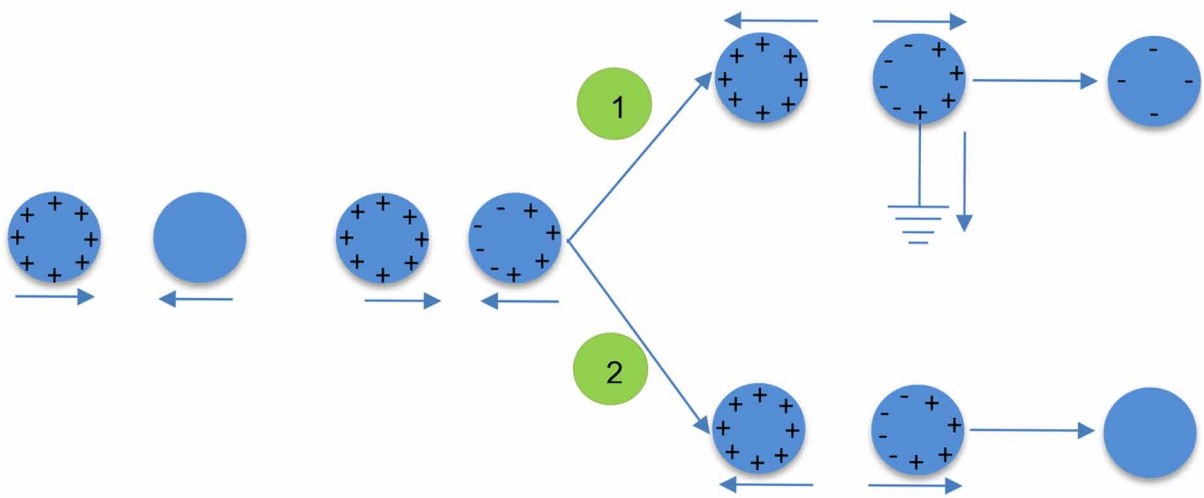
In 1980s, the work led by S. Edward Law at the University of Georgia, developed induction based spray-charging method meeting the engineering design requirements of robustness, simplicity, reliability, energy efficiency, and safety. The electrostatic-induction and the ionized-field spray charging methods are the ones widely used throughout many industrial processes. Agricultural charging based nozzle development has mainly relied upon the induction charging methods. This section presents a detailed consideration of induction spray-charging techniques, emphasizing their applicability as dictated by the physical properties of the pesticide-liquids to be electrified.

Spray liquid is normally electrically neutral. To charge a spray, the normal balance between positively charged protons and negatively charged electrons has to be disturbed so that spray droplets carry either a net positive charge or net negative charge. Droplets with same electrical sign (+ or -) repel while those with opposite charges attract.

Electrostatic induction has proved to be a very satisfactory alternative to the ionized-field method of charging spray droplets for agricultural pesticide applications. Figure 1 indicates the complete picture for understanding the induction charging phenomena. In this method, direct-transfer to the droplet-formation zone of a liquid jet results from electrostatic induction of electrons on to the continuous liquid jet and in order to maintain it at ground potential the presence of closely positioned induction electrode of positive polarity is required. Droplets, formed from the surface of this negatively-charged jet, will depart with net negative charge provided the droplet-formation zone remains subject to the inducing electric field acting between the non-ionizing electrode and the liquid jet.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Induction charging of finely divided particulate matter



Gauss's law indicates that maximum droplet charging should occur for the droplet-production zone located at the region which provides maximum field strength at the terminal surface of the liquid jet.

In induction charging of the spray droplets, two time constants are of importance:

1. Time constant of charge-transfer (τ)
2. Droplets formation time constant (t_f)

The level of droplet charge imparted by electrostatic induction depends upon the relative time rate of charge transfer to the droplet-formation zone, as compared with the time required for droplet formation. The charge-transfer capability by induction from a grounded metal nozzle through the issuing liquid jet depends upon the electrical as well mechanical properties of the continuous liquid jet.

The two most important properties of the liquid to be sprayed are:

1. Electrical properties such as conductivity, dielectric constant, permittivity etc.
2. Mechanical properties such as density, viscosity, surface tension etc.

For pesticides, the spray-liquid characteristic may be specified by the charge-transfer time constant, which is a function of the electrical conductivity (σ) and the dielectric constant (K) of the liquid as:

$$\tau = \left(K\varepsilon_0\right) / \sigma \tag{3}$$

If a duration of time t_f, characterizes formation of discrete droplets from the continuous jet, then spray liquids must satisfy the condition $\tau < t_f$, in order to satisfactorily charged by electrostatic induction process. In electrostatic spraying of pesticides, the conductivity of liquid to be sprayed is of inordinate significance and it is to be taken into consideration, when such a system is developed. The system must cover all the ranges of liquid based pesticides used as sprays.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Conduction Charging

In the case of charging by conduction, the DC electric supply is made by contact with the spraying liquid. In case of the conduction charging, the mechanical energy is used for dispersing the liquid into the droplets and the current that leaks to the power supply and assures a part of the electric energy for charging and accelerating the droplets. Both the mechanical energy and the electrical energy drive the charged drops to the target. The electrical energy depends on the nozzle current and the power supply voltage. Each droplet-charging method possesses its unique advantages as well as disadvantages in relation to technical and engineering requirements of vastly different pesticide-application situation encountered.

Droplet Charge Limit

The amount of charge that each individual drop can carry is limited. There is essentially two physical mechanisms limiting the charge that can be retained on the droplet surface, one is Rayleigh limit and other is Paschen limit. *Rayleigh limit:* In an electrostatic spraying process, as the droplets are charged by induction charging, the saturation charge is reached instantaneously. It takes a finite time for the particle to achieve this saturation charge. When the electrostatic force of repulsion is greater or equal to the attractive force due to surface tension, the droplets disrupt to smaller droplets and produce daughter droplets (Allah, 2002). The process results in a fine mist of highly charged droplets.

It has been shown that for dielectric drops in the presence of significant electric fields, particularly within spray plumes, the maximum charge a drop may hold is less than the Rayleigh limit of charge. The Maximum charge acquired during the induction charging process by a conducting sphere is limited by Rayleigh limit as shown in Equation (4) given by (Shrimpton, 2005):

$$q_{max} = \sqrt{64\pi^2\epsilon_0\delta r^3} \tag{4}$$

where, δ is the surface tension of the droplet and *r* is the radius of the droplet. *Paschen limit*: is another mechanism where the avalanche ionization process and localized electrical discharge can occur at the surface of a charged drop when, the drop charge exceeds the limit and that charge to mass ratio can be given by equation (5):

$$\frac{Q_p}{m_p} = \frac{12\varepsilon_o V_p}{\rho D^2}\ \text{C/kg} \tag{5}$$

where Q_p is the Paschen charge limit, m_p is the liquid mass flow rate, ρ is the density of liquid, D is the diameter of the droplet and V_p is the surface potential.

In-Flight Trajectory of Charged Particulate Matter

The maintenance of charge on electrified clouds of airborne spray enroute from charging nozzles to grounded-plant targets should be maintained. Once the droplets are charged sufficiently, the droplets have to traverse the distance to reach the actual target canopy. Common concern of electrostatic spraying is

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the exploitation of the most favorable force field for achieving the desired motion and the maintenance of droplet charge during the in-flight trajectory of the electrostatic spray. There is no ideal charge to mass ratio for spraying, however higher the ratio, the better is the efficiency of electrostatic spraying. Various studies reported different minimum level of charge to mass ratio i.e. 0.8, 1.2, 2.0 mC/kg etc. Laryea & No, (2004) have shown that these charge to mass ratio values can be used as references, recent studies have shown that these lower values result in an increased spray deposition on the target.

The change in charge to mass ratio is due to the existence of naturally-occurring free charge and electric fields of the earth's atmosphere. In normal air near the earth's surface, ionization by cosmic radiation and background radioactivity typically provide a charge creation rate c_i=1-7 ion pairs per cubic centimeter per second. The recombination coefficient α_i for these positive and negative ions is approximately $1.6*10^{-6} cm^3 sec^{-1}$. Since the rate of ionic recombination depends upon this coefficient as well as upon concentration (n_i) of both positive and negative species, the air's ion pair concentration is governed by the relation, $\frac{dn_i}{dt} = c_i - \alpha_i n_i^2$. Thus, a charged pesticide spray cloud will encounter some degree of neutralization by the following two actions: 1) traversing a region of ionized air; and 2) causing migration of oppositely charged air ions into the region of charged sprays. Spraying distance and its consequences on the performance of the nozzle has been discussed by Robson et al., (2013), at Federal University of Vicosa, Minas Gerais Universidade Federal de Vicosa, Vicosa- Minas Gerais and it has been concluded that for the liquid deposition, the electrostatic system was affected by the target orientation and spraying distance.

Optimizing the Deposition Field and Transient Effects at Deposition Targets

While inverse-square image-charge forces are significant for achieving deposition at millimeter droplet-to-target spacing, only the space-charge field is relevant for electrically driving charged droplets over greater distances within shielded plant canopies. Significant research effort has therefore been directed toward managing the space-charge electric field for enhanced target deposition. Findings have important practical implications regarding improved designs of portable, human-carried, electrostatic sprayers. A further strategy to enhance pesticide droplet deposition, under constraints limiting the dielectric breakdown of the space-charge field has been theoretically developed. In contrast to deposition benefits derived from surface-charge accumulation on plastic films under and above crops, charge buildup on the actual target plants must be avoided so that they will remain near ground potential. A target's inherent charge-relaxation time constant must accommodate this charge transfer i.e., displacement current to earth as charged conductive droplets impinge Law, (2001).

Charge to Mass Evaluation and Hence Efficiency and Efficacy of the Spraying System

The use of pesticides should be performed efficiently and judiciously to increase the bio-efficacy of the biological plants and trees, since its application without the appropriate technology can cause contamination of the soil and environment, leaving residues in food with an increased risk of farm workers' health. Numerous experimental tests have been conducted over the past quarter century which validate electrostatic crop-spraying technology as currently practiced by various field machines. Spray mass-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

transfer results by many researchers, both in the laboratory and the field; have generally verified 2-8 fold increase in target deposition, as well as improved spatial distribution on plant surfaces, greater deposition density, attributable to electrostatic forces.

Charge to mass ratio is a key term defining the performance of spray equipment in electrostatic spraying applications. Charge to mass ratio determination may vary as the field of application changes such as agricultural pesticide spraying, medical, powder coating and painting, however, the basics behind the measurement of charge to mass ratio is same. The effectiveness of various electrostatic applications depends directly or indirectly on this parameter. It is a critical measure that needs to be determined in order to accurately predict the behavior of a particle exposed to inertial, electrical and gravitational forces. A brief review has already been given by Toljic, Adamiak, & Castle, (2008) for the determination of particle charge to mass ratio distribution in electrostatic applications. Brown, (1997) divided charge to mass ratio measurement techniques into two categories. First, a static method of charge measurement, measures the amount of charge present in droplets directly. Second, the dynamic method for calculating the charge to mass ratio by observing the particle motion parameters in the presence of external electric field.

Static Method

In static method of charging, Ye, & Domnick, (2003) present a numerical method for the calculation of electric field with space charge in electrostatic powder coating with a corona spray gun and used a suction-type Faraday cup apparatus to measure the charge to mass ratio. An extended commercial Computational Fluid Dynamics (CFD) code was used for numerical simulations. Their calculated charge to mass profile based on Pauthenier theory showed a good agreement with the experiment for particles with radius less than 60μm. This is a good agreement with surface area theory. For particles with larger diameter, the experimental charge to mass values stayed constant which is in disagreement with theoretical knowledge. They conclude that this was probably due to the experimental uncertainty for the large particles. From the obtained results, it was evident that the sensitivity of this instrument decreased with increasing mean particle diameter.

In agricultural pesticide spraying the common mathematical method for measuring charge is based on charge to mass ratio that is characterized by measured spray current and mass flow rate.

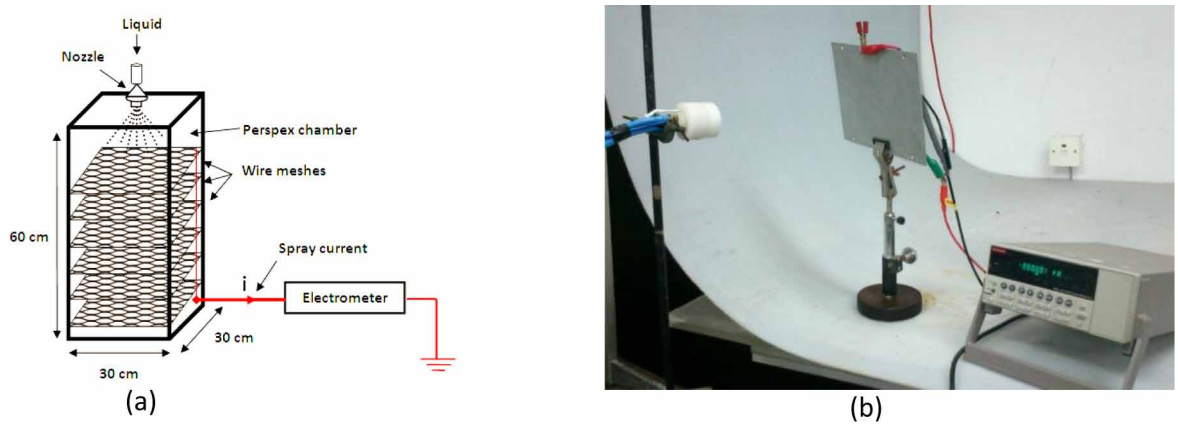
There are two methods of measuring the charge to mass ratio and hence performance of the spraying system:

- Faraday cage method
- Conductive plate method

In both the methods, the charged liquid spray was collected at a specific time and weighed. The spray current was divided by the mass flow rate to determine the charge to mass ratio. Both the performance measuring methods are nicely explained by Mamidi, Ghanshyam, Patel, & Kapur, (2013); Patel, Ghanshyam, & Kapur (2012b) in their previous research work conducted at CSIR-Central Scientific Instruments Organisation, INDIA. In these methods of charge to mass ratio measurement, the spray strikes onto the target, due to potential gradient the current flows and this current can be measured by an electrometer connected to the Faraday cage or conductive plate electrode as shown in Figure 2.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Common methods to measure the charge to mass ratio (a) Faraday cage (b) Conductive plate



Dynamic Method

The dynamic method for calculating the charge to mass ratio by observing the particle motion parameters in the presence of external electric field involves the Phase Doppler Anemometry (PDA) technique, a nonintrusive optical method for simultaneous measurement of the size as well as the velocity of spherical particles. Kulon, Malyan, & Balachandran, (2003) discussed that it is a noninvasive method of measurement of the charge level on a population of particles by combining the Phase Doppler Anemometry technique and high-resolution computer-controlled traversing system.

The principle of the Phase Doppler Anemometry (PDA) is based on light scattering from two-plane light beams incident on the particle. The intersecting coherent and polarized laser beams form a small measurement region of light and dark fringes within the spray. The phase shift between the signals from different detectors is proportional to the size of the spherical particle for reflection represented by Equation (6),

$$\Phi = \frac{2\pi d_p}{\lambda} \frac{\sin\theta \sin\varphi}{\sqrt{2\left(1-\cos\theta\ \cos\varphi\ \cos\psi\right)}} \tag{6}$$

where, λ is the wavelength of the laser light, d_p is the inter-planar distance, θ is the angle between the incoming laser beams, φ is the scattering angle and ψ is the elevation angle. The velocity measurement is based on the Doppler Effect. As a droplet passes through the measurement region it scatters light at a frequency based on its velocity normal to the fringes and its spacing. A receiving device measures the frequency of the scattering signal and the spacing of the fringes is determined based on the wavelength of the laser light and the angle between the beams. Knowing the Doppler frequency f_d, frequency of the scattered signal f_s and the spacing of the fringe d_f, the particle velocity v can be calculated as follows in Equation (7):

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$f_d = \frac{f_s + v}{d_f} = \frac{f_s + v2\sin \pi/2}{\lambda} \tag{7}$$

The PDA system was used to track the motion of charged particles in air in the presence of a dc electric field within the space between the parallel-plate electrodes. Charged particles exposed to the external electric field and situated in a viscous medium experience two types of force exerted on them: external electrical force and drag force as a result of a relative motion of a particle in the air. After the relaxation time, a particle attains mechanical equilibrium and reaches a steady state velocity relative to the medium.

Laser Velocity Meter (LDV), an important part of the Electronic Single Particle Aerodynamic Relaxation Time (ESPART) analyzer, is used extensively in non-invasive measurements of fluid flow, turbulence characteristics, and particle dynamics. ESPART analyzer can measure the statistical charge and size distribution of charged particulate simultaneously and it is widely used in industrial applications for the analysis of toner particles, drug powders, oil droplets, dust particles, pesticides charged particulate. In ESPART analyzer, the particle motion in an electric field is analyzed in noncontact manner using LDV or by image analysis. The ESPART analyzer is based on the motion of particles suspended in a gaseous medium when the particles are subjected to an external electric field. The measurements of size and charge of the particles, derived from their relative motion in the gaseous medium, are based on the assumption that the particle motion is within Stokes regime, which is valid only when the Reynolds number of the particles motion in less than 0.1. Some specifications of ESPART analyzer are:

Particle Charge Range

The ESPART analyzer can measure electrostatic charge on each particle in the range from zero to its saturation value, limited by many factors like breakdown strength of the surrounding medium, Rayleigh limit etc., with positive or negative polarity.

Particle Count Range

The maximum count rate will be limited to less than 500 counts per second when signal-to-noise ratio of the Doppler signal is high. At an excitation frequency higher than 2.0 kHz, the maximum count rate depends upon the minimum time required by signal and data processing circuitry for real-time size and charge analysis.

Particle Size Range

ESPART analyzers have been built based on both LDV measurements for small particles (diameter < 50μm) and with image analyzers for larger particles (20μm $<d_a<$100μm). ESPART analyzer is capable of measuring particle size and charge distributions in different atmospheric conditions.

Understanding the Drop Size and Its Measurement

Optical Image Analyzer

Among available methods of droplet size and to visualize the detailed time-resolved structure of electrospray, a simple and sophisticated system i.e. optical image analyzer can be used to study the different mode of spray with the increase in applied voltage and other parameters. A schematic of a typical optical image analyzer is shown in Figure 3. The measurement range of these instruments varies from 1µm with no definite upper bound restriction as the system optics determines the upper range. In such kind of measurements, a high speed camera is implemented to visualize the detailed time-resolved structure of electrospray. The measurement records the shadow images of the droplets by the high speed camera at fraction of micro second intervals. The size of the droplet is determined from the recorded images with the high-speed camera.

Deposit Scan

Zhu, Salyani, & Fox, (2011) developed a portable scanning system to measure the spray coverage and deposition quality feedback information, a system that could quickly evaluate spray deposit distribution and coverage area on deposit collectors such as water sensitive paper or Kromekote card. The system is integrated with a handheld business card scanner, deposit collector, a laptop or computer, and a custom-designed software package entitled "Deposit Scan". Deposit Scan also called ImageJ is a Java-based image-processing program used for the acquisition and analysis of images. It is developed by the National Institutes of Health (NIH), USA and is now available to open access. ImageJ can be used to measure an area and count number of spots in the user-defined areas or throughout the entire image. The shape of selected areas could be rectangular, elliptical, or irregular. It also quickly gives the deposits per centimeter square area of the image.

A Shift From Micro to Nano Scale Measurement

Stark, Zhang, Sharma, & Mazumder, (2008) developed a mathematical model using MATLAB/SIMULINK to measure the charged nanoparticle (particle size distribution ranges from 2 pm to 20 pm and charge to mass ranges from 2 to +24 pC/kg), a modification of the older ESPART analyzer that was restricted to measurement of sub-micron particles i.e. in printing industry applications, space applications, and in applications to distinguish between different types of bacteria. ESPART analyzer at present can measure nanoparticles, which requires measuring signals with a low SNR (Signal-to-Noise Ratio). Resolution of particle size relies heavily on the frequency of the exciting signal, which causes the particle to experience oscillatory motion. With an increase in the exciting frequency, smaller particles experience motion at high frequencies with greater changes. It can be inferred that a higher frequency exciting signal can be used to resolve smaller particle sizes at the limits of the light collection methods and devices such as silicon photodiodes and photomultiplier tubes. Amplitude of oscillation of the particle in the applied AC electric field charges up the particle. The magnitude of oscillation compared with the magnitude of the applied electric field gives the particle net charge.

FLUENT to Model Electrostatic Spraying Processes

The recent development of Computational Fluid Dynamics (CFD) software makes it possible to model the mechanical spraying process with ease. FLUENT is one of such powerful software tools to model the air flow in the continuous phase and the droplet motion in the discrete phase. However, it does not have a direct solution for the electrostatic field formed by the charged droplets. Fortunately, it offers user-defined functions (UDF) and user-defined scalars (UDS) as an extension to suit different needs for various applications.

Numerous studies have been carried out on the charged particle motion under electrostatic space-periodic field in crossed-field systems. In this study, changed particle trajectory was considered in crossed-field systems under periodical electrostatic distribution. Many parameters affect the process such as atomizing air pressure, liquid flow rate, nozzle-to-target distance, droplet size, charge to mass ratio, etc. The mechanical portion can be directly modeled with the computational fluid dynamics software. The droplet trajectories are computed under the discrete phase model. In this mode, the equation of motion is solved by the Lagrange approach where the droplets are tracked by the stochastic tracking (random walk) model in turbulent gas flow. The electrostatic force on the charged droplets due to space charge is incorporated into the FLUENT solver as a component of the droplet body force. The air flow and the droplet discrete phase can be directly modeled in FLUENT.

In practice, the Poisson equation of the electrostatic field is analogous to the general scalar transport equations within FLUENT. In this way, modeling of the electrostatic liquid spraying process can be performed solely by FLUENT without compiling a separate computer program to solve the Poisson field which calls for a vast amount of data exchange. The key of this technique is to find the space charge density for different charging models.

ELECTROSTATICS AND ITS APPLICATIONS TO AGRICULTURAL SPRAYING

The application of pesticides is one of the most frequently used methods to protect crops and trees against diseases and insects in agriculture and agricultural products for the sustainable agricultural development. Laryea & No, (2003) showed that more than 90% of the pesticides are applied as liquid sprays providing more accurate metering and on-site particle-size control but the sprays are highly drift-prone and it is mostly performed by using hydraulic and conventional spray nozzle systems, pedestal-mounted sprayers, high pressure spray guns, hand pressure swirl nozzles and the consecutive high volume sprayers. Sande et al., (2008) showed in their previous work that due to non-uniformity of droplet size and off-target drift, target deposition efficiencies less than 30% is very common in agricultural pesticide spraying. The work was mainly on different spraying techniques and how to optimize spray deposition and minimize spray drift. The smaller droplets are lost in airborne drifts and the larger ones are lost due to gravitational settling by the soil. Off-target drift, aerial spraying losses and uneven deposition are very common in pesticides application that leads to damage of non-target microorganisms, soil quality and environmental pollution. Further, Sayinci & Bastaban, (2011) also worked on spray distribution uniformity of different types of nozzles and discussed the parameters of spray deposition mainly for potato plant. Numerous scientists and researchers have been working on measurement and evaluation of off-target drifts and aerial spraying losses from the target.

Electrostatic force field applications to agricultural pesticide spraying is one of the most efficient and economic methods to protect the crops and trees from insects and diseases (Ru, Zheng, & Zhou, 2007a). Law, (1983) and his students have done a remarkable work in the development of electrostatic pesticide-spraying processes and prototyping devices at the University of Georgia from 1970 to the present-day's commercialization of the technology. Electrostatic technique in spraying has already been commercialized and being used in countries such as USA, China, South Korea etc. In developing countries such India, a small portion of the agriculture farming is being performed in large scale, however, the major chunk of farming is done in small scale. Therefore, the spray equipment available in the market are not viable to developing economies especially in Indian scenario. Mamidi, Ghanshyam, Patel, & Kapur, (2012) have highlighted that the demands of the spraying equipment are very much different in developing economies than developed economies, where the farming is carried out in large scale. On the other hand, earlier electrostatic spray systems are motorized and mounted on tractors, helicopters or any other vehicles because of the complexity and heaviness, bulky which lead to the economic burden to the small scale farmers. Literature shows that a large number of publications and patents are coming from developing economies in today's scenario and these publications are mostly based on simplifying the complex and sophisticated systems to small scale farming such as hand pressure based electrostatic nozzles.

The goal of pesticide spray application is not only the effective deposition onto the target, but also economical, available at the lowest cost. This means that in order to develop a technologically feasible and economically attractive system, more research at both the experimental and theoretical level is needed (Law, 1995). Even though many parameters are involved in an induction charge based electrostatic spray systems, all the investigations carried out thus far have demonstrated the intricacies of the electrostatic-spray phenomena (Ru, Zheng, & Zhou, 2007b). In this section, the different applications of electrostatics in agriculture spraying and related areas have been discussed in details.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Antimicrobial Sprays for Enhanced Food Safety

Antimicrobial agents are the biomaterials used to sanitize contact surfaces of the food production, processing and supply chain at various stages. The objective of the work 'Food Safety' at University of Georgia by Law and associates was to experimentally establish and control the mass-transfer efficiency and antimicrobial efficacy of the air-assisted induction charged electrostatic spraying process for spread over decontaminator liquids to various surface alignments and compositions commonly come across in food handling and processing operations specifically reconnoitering whether the lower volume of spray carrier liquid put down on the target surface would provide sufficient contact time for microbial cell death, as well as determining adequacy of target charge transfer for various electrically insulating versus conductive food-contact materials (Lyons, Harrison, & Law, 2011). They developed an air-exhausted biosafety chamber, an air-assisted induction charged electrostatic sprayer, commercially provided by Electrostatic Spraying Systems (ESS) Inc., was operated and compared to a conventional hydraulic-atomizing sprayer to determine mass transfer of active ingredient deposited onto the actual targets. Fluoroanalysis of AAIC (air-assisted induction-charged) electrostatic sprayer has given good agreement with theoretical considerations in terms of significant increase in deposition efficiency and surface sanitizing bio-efficacy. This provides backside deposition with greater efficiency and bio-efficacy. The deposition of active ingredients onto backside of the target was 29-times better than any conventional sprayer. However, in these kinds of microbial sanitizing techniques, it is to be noted that the sanitizing media should be biocompatible to food materials.

Postharvest Control of Fruits and Vegetables Spoilage Microorganisms

Maintaining the quality and desired sensory attributes of fruits and vegetables between farm and market is one among the major challenges. It is also called post-harvest treatment of biological commodities. This entices the application of waxes and water-loss barriers onto the surfaces of perishable food product. Law & Scherm, (2005) reported the development of an efficient electrostatic spray application method and processing-line prototype created specifically for postharvest protection of foodstuffs. They developed a prototype electrostatic sprayers unit utilizing an oscillating array of air-assisted induction-charging nozzles for postharvest treatment of fruits and vegetables on processing and packing lines. Example was the demonstration of prototype of Banana packing, a 1 m x 1 m shallow plastic tray containing 16-18 clusters of 5-7 bananas each is pushed along the process roller-line into the treatment chamber ejecting the previously treated tray of fruits. Experimental results of extensive evaluations of electrostatically applied protective sprays onto bananas for international shipment, where both microbiological and mass-transfer data document typically showed the 2-3 fold deposition improvements for food protection.

High Range Electrostatic Sprayers

To develop an electrostatic spraying system for high range spraying, such as defendable forest, shelter trees in urban areas, fast growth forest, field net forest and shelter trees on highways etc., is the current issue to be taken into considerations since performance of such systems deteriorate as the travel distance of charged droplets increases. Also greater the distance between the spray tip and the target area, the greater impact wind velocity can have on drift (Ru, Zheng, & Zhou, 2007c). Charge to mass ratio is one among the parameters which decide the performance and efficiency of electrostatic spraying systems,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a process of neutralization due to naturally occurring radioactive phenomena's in ambient atmosphere. It is also very important because in recent years, it has been observed that there are more and more tall trees in worldwide, as forest covering area become wider. Ru, Zheng, & Zhou, (2005) authenticated that to improve the effective spraying range; it should be considered such features of sprayers as spraying height and application efficiency. The work led by Zhou, Professor at the Nanjing Forestry University, China, designed and developed a system to apply liquid sprays to very high trees to control the forestry diseases. The high range spraying systems are commercialized recently and available in the market.

Aerial Spraying Systems

Based on the theoretical analysis and practical experiments and the requirements for the large area forest pest control and farming performed in large scale, Zhou, Ru, Shu, Zheng, & Zhu, (2008) developed an aerial electrostatic spraying system assembled on a helicopter, a hydraulically assisted flight control. The study addressed issues associated with inefficiencies in disease and pest control, including pesticide overuse, spraying difficulties and labor intensity. The spraying system includes electrostatic generator and two sets of nozzles. An electrostatic generator with two high-voltage power levels can output positive and negative high-voltage simultaneously and was used to deliver voltage of 24-36V into a high-voltage generator with output voltage of 10kV in common use and 20kV in maximum and mounted on the aircraft. On the basis of field tests and experimental results, it was observed that combining aerial spray technique with electrostatic spray technique, the invented aerial electrostatic spraying system applied in R44 was provided with scientific design, rational structure, convenient operation, high productivity and high efficiency and had no harmful effects to all the airborne equipment and instruments of R44. It was completely suitable for the safe flight and spraying of R44 helicopter. Electrostatic spraying, which accords with the demands of flight safety and spraying procedures; can evenly distribute droplets while reducing pesticide use that leads to environmental and soil pollution.

Equipment for Improved Deposition in Cotton

Air-assisted electrostatic and hydraulic sprayers have been developed in recent years to improve pesticide penetration and coverage within the plant canopy and to increase the efficiency and bio-efficacy of the biological surfaces of the crops and trees. These sprayers need to be evaluated to determine their effectiveness when compared with conventional sprayers. Sumner, Herzog, Sumner, Bader, & Mullinix, (2000) compared within-canopy penetration and leaf side coverage of spray materials applied using the following spray technologies: (a) air-assisted sprayer (b) over-the-top hydraulic nozzles plus drop nozzles (c) electrostatic air-assisted sprayer (d) over-the-top hydraulic nozzles; (e) over-the-top nozzles plus shielded drop. The results showed that the air-assist nozzles are better than hydraulic and other sprayers in term of coverage and penetration of the canopy of the plant.

Automatic Target Detection and Electrostatic Spraying

The recent work by Xiongkui, Aijun, Yajia, & Jianli, (2011) was based on an infrared sensor detection system to discriminate between the presence and absence of trees for which spray is not needed, when the detecting devices detect the target, an automatic control system activates the spraying system to spray toward the target. Similarly, when the automatic control system receives the signal of a gap between the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

trees from the "electronic eye", the spraying system shuts off. Infrared sensor detecting techniques have been adopted in automatic target detecting orchard sprayers to discern targets and control the spraying system automatically. The important engineering aspects to keep in mind while developing such systems, is the matching of the electrostatic spray nozzles and sensor actuation. The microcontroller response and response of different sensors should be matched because of the fast actuation of electromagnetic valves. The actuation of controlling devices should be matched for exact target detection along with sensitivity, accuracy etc. An infrared detector is utilized in the automatic target detection system along with electrostatic nozzle and air assistive fans. Multi-sensor fusion techniques can be utilized for this kind of spraying systems.

FUTURE RESEARCH DIRECTIVES IN ELECTROSTATIC PROCESSES APPLIED TO AGRICULTURE AND AGRICULTURAL RELATED AREAS

Real Time Monitoring and Pesticide Delivery

As the population is growing day by day, the demand of nutritious and healthy food is increasing. Therefore, there is a tremendous increase in green house farming to fulfill the demands of billions of people. In greenhouses, it is very difficult to work in the presence of high temperature, increased carbon dioxide and humidity level. Therefore, there is a possibility of automation and mechanization in agricultural pesticide spraying. The automation in pesticide spraying involves majorly three steps: sensor package to sense the target and to map the plant canopy (target detection and canopy mapping), data acquisition to calculate and store the data and the last is navigation to monitor the movement of an automated spraying system. By using sensory attributes, the pesticide dose can be decided as per requirement of the plant canopy and disease.

Pesticide application control and variable pesticide spraying is the key to improve operation quality, reduce chemical waste, environmental pollution and cut down the cost of production. Other factors which have to be considered in pesticide spraying are target detection, quantity and quality of spraying control, directionality of spray, efficient treatment with low pesticide doses, operator safety, ease of use and reliability, flexibility and economic and cost effective spray system.

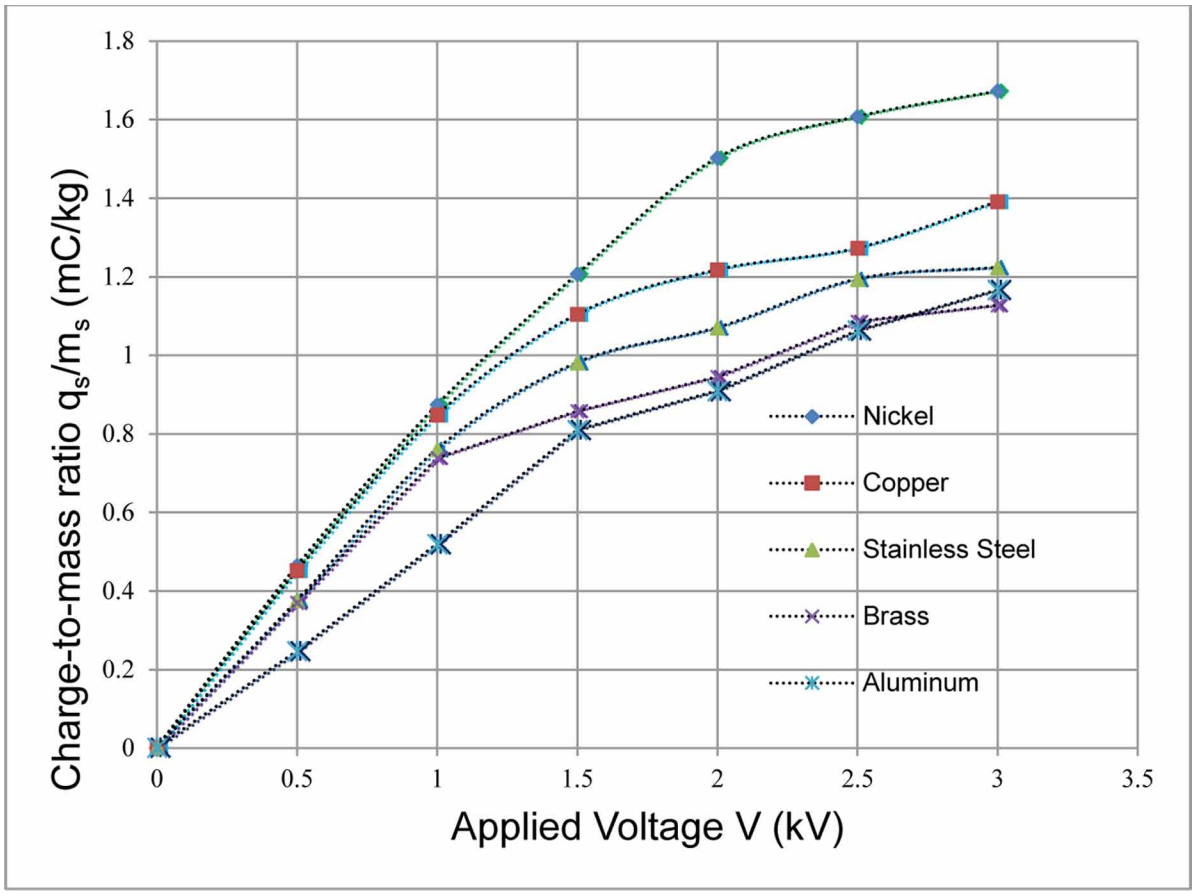
Characterization of Electrode Material for Spray Charging

Appropriate electrode material selection for spray charging and dimensional design and specifications are very important that need further study. Right electrode material and its insulation may enhance the chargeability of liquid sprays. So far the materials used as an electrode for spray charging were copper, brass and stainless steel. Recently nickel has been reported as a new electrode material for spray charging by Patel, Ghanshyam, Mamidi, Kapur, (2012a). Nickel increases the corrosion efficiency and enhances the performance of the system, since Nickel is assumed to be inert in standard temperature and pressure. This may enhance the charge to mass ratio and hence the performance of the electrostatic nozzle system.

Figure 4 shows the performance of the different material electrodes for spray charging in electrostatic spraying processes (Patel, Ghanshyam, Mamidi, Kapur, 2013). It shows that nickel (Ni) electrode has more spray current and hence the charge to mass ratio than rest of the electrodes because of availability of more electron surface density. Here the Fermi energy and work function of the charging electrode

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Charge to mass ratio for different material electrodes in spray charging



material are playing a key role. The performance and characterization of different electrode materials for spray charging is still a naive and unexplored area which requires furthers innovation in material synthesis to work at lower applied voltage for the same performance.

Electrostatic Sprays for Ratnagiri Mangoes to Enhance the Transportation life

Ratnagiri is the largest producer of quality mangoes such as Alphonso, Kesar etc. a Southern part of India. The life of the storage and transportation of these mangoes is about 7-10 days which is very short. The pest level on these varieties is reported by the European Union. This is because, pesticides are being used indiscriminately, affecting the export of perishable commodities, and as a result economic balance is affected. The European Union imposed a ban from May 1, 2014, on import of mangoes, after alleging to have found unwanted pests such as “non-European fruit flies” in some consignments. These mangoes are easily attacked by microbial and affected by ambient conditions. There is a possibility of electrostatic sprays or coatings on the surface of these mangoes to protect them from microbial attacks and ambient conditions and also to increase the self-life of transportation.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The electrostatically coated material on the surface of mangoes should be biocompatible so that it will not affect the human being and consumer of the products. The biomaterial should be soluble in water or other solvents so that it can be sprayed as liquid.

Protective Coatings to Apples for Resistance Towards Microbial Attacks

An excellent technique for applying protective thin coatings on fruits such as apples, to protect from microbial attacks has been proposed. Further improvements can be done by combining a processing and packaging line with the treatment chamber for automated online processing. An array of nozzles spraying different solutions can be used for applying simultaneous coatings such as waxes and fungicides. These electrostatically coated fruits are more resistive to the ambient conditions and can be stored for a long time.

Ultra High Electric Pulses to Preserve the Liquid Beverages/Foods

Technological advances in food processing industry have evolved various instruments, ranging from simple to complex equipment. These are either processing equipment or preserving equipment. Preservation of food item calls for new techniques, which involve various thermal and non-thermal methods. Pulsed Electric Field (PEF), which is a non-thermal method offers freshness, flavor and nutritional value and is used to improve the shelf-life of liquid food. In this technique, a short pulse is given to foodstuffs for a short duration for effective inactivation of microbes. Method of pulse generation is a still great concern of research, which needs further modifications and improvements. This generator may require power MOSFET, high voltage switching circuit, and microcontroller, to generate high voltage pulses of less than microsecond duration. The instrument should be equipped with data acquisition system and display system for proper and easy operation. Virtual Instrumentation could be used for data acquisition and control purposes.

Air-Assisted Electrostatic Nozzle for Variable Canopy Coverage

In the case of electrostatic spraying, the droplet size is normally in the range of 30-60μm or less and the droplets in this range are most susceptible to spray drift. The electrostatic repulsion among droplets is also the cause of spray drift. Presence of wind is another cause of spray drift and presently available sprayers cannot be used even in normal wind. It can be achieved by shielding the fine electrostatic spray from these harsh wind conditions. It may be simple mechanical means of shielding. The air-assistance forms an envelope around the spray to protect the finely generated charged particles. It also reduces the interaction of charged droplet cloud to naturally occurring charged ionic environment already present and hence applicable for higher range of spraying. The naturally occurring ions are present due the cosmic and radioactive activities. Air-assistance may provide virtual path to the finely divided charged droplets to reach actual target.

Automation in Switching ON/OFF of Power Supply

In the manual operation of the complex and sophisticated electrostatic sprayers, the probability of errors is very high, and calls for automation in the switching (ON/OFF) of the power supply to charge the small droplets in the design of the spraying nozzle systems. There should be an orderly and proper sequence

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to be followed from the different inputs for the efficient working of the electrostatic spraying nozzle system. A novel idea in the design of an automated circuit is to switch (ON/OFF) the high voltage power supply in electrostatic nozzle system, using the inherent property of water grounding, can be used. This can be achieved with the use of simple electronic and electrical components. Other way to achieve the goal is by using pneumadyne switch to control the high voltage power supply.

CONCLUSION

The aim of this chapter is to provide a basic understanding of an electrostatic spraying processes and the entry of charge to the liquid atomized as well as uniform deposition onto the surfaces of crops and orchards. This chapter has established a theoretical foundation for understanding the basics relying on electrostatic spraying, and relative effectiveness of the electrostatic forces. It emphasized the fundamentals behind the different charging mechanisms along with the charge retention and charge-loss phenomena and underlined the difficulties associated with each method, since it has always been a great challenge to inject the charge into the finely divided liquid droplets. The heart of the charge injection technique is being balance between hydrodynamics and electrodynamics, may generate flow instabilities which leads to turbulence. This requires co-design of the atomizer internal geometry from both hydrodynamics and electrical perspectives, the optimization of which leads to a maximum in the generated spray charge per unit volume contained by the spray.

This chapter links several research areas together to provide an integrated summary of the knowledge relevant to air-assisted electrostatic spraying and electrostatically assisted atomization of electrically conductive liquid specially an attention has been given to pesticide spraying. The emphasis of the review leans towards explanation of physics and description of experimental work, interactions between space charge gradient and electric field produced which in turn can generate instability throughout the bulk of the continuum. It also discussed the interaction between finely divided charged particulate matters and naturally occurring ions present in the atmosphere, leads to neutralization of the charged droplets and hence deteriorates the performance of the spraying system.

This chapter highlighted the various applications of electrostatic spraying to different fields of agriculture, engineering trends and food processing industry along with the future perspectives of the electrostatic spraying. Electrostatic spraying technique can be used for protective biomaterial coatings to fruits, vegetables and perishable food products for resistance towards microbial attacks, to enhance the transportation life, to control spoilage microorganisms, antimicrobial sprays for enhanced food safety etc. However, the biomaterial should be soluble in conducting liquids such as water and other liquid solvents. It is one among the bioremediators since it reduces the pesticide use and ensures the minimum residue level (MRL), an indication of pesticide residue in consumer commodities. Controlled and targeted delivery of pesticides is one of the current fields of interests in pesticide spraying, an automated system which is intelligent enough and trained properly to spray without interventions of human operator. Currently, the fabrication of electrostatically sprayed particles and liquid spray at industrial and user scale (e.g., ESS Technology, Inc.) is feasible. However, advanced research on electrostatic spraying techniques in the field of food processing and preservation is recommended to enable the applications workable at the industrial scale.

KEY TERMS AND DEFINITIONS

Bio-Efficacy: In agrochemical, bio-efficacy is a measure of the biological efficacy of an active ingredients of agrochemicals such as insecticide etc. Bio-efficacy of an insecticide is determined by the minimum dose required for maximum control of the disease. For an agrochemical, the bio-efficacy of an insecticide is determined by the minimum dose required for complete kill of the insects or diseases.

Charge to Mass Ratio: Experimentally the performance of the air-assisted electrostatic nozzle can be evaluated in terms of charge to mass ratio, which signifies the chargeability of the spray droplets by the charging electrode. It also signifies the efficiency and performance of the spraying system, higher the charge to mass ratio, better the performance. Charge to mass ratio depends on electrical and mechanical properties of the liquid as well as material of the charging electrode.

Electrode Material: The amount of charge present in the fine droplet depends on many parameters, the one is electrode material. Appropriate and suitable electrode material and its dimensional specifications may enhance the chargeability of finely divided particulate matter. Selection of electrode material for spray charging is as much important as other parameters such as electrical and mechanical properties of liquid to be sprayed. So far, most frequently used materials for electrode in electrostatic nozzle systems are nickel, copper, stainless steel and brass.

ESPART Analyzer: Electronic Single Particle Relaxation Time (ESPART) analyzer is an instrument which is used in many applications to determine both size and charge of micrometer sized particles in electrostatic spraying processes. ESPART analyzer consists of two major units: Laser Doppler Velocimeter (LDV) and particle relaxation apparatus which measures the velocity of a particle and aerodynamic diameter passing through the intersection of two coherent light sources, such as lasers and the signal processing unit, a simulation model for the ESPART analyzer to measure the time lag. The ESPART analyzer can measure the statistical distribution of particle size and charge in electrostatic spraying processes.

Faraday Cage: Faraday cage, a specially designed wire mess like structure which is called a cage, commonly used to collect the charged droplets coming out from the spraying system. The contact of the charge droplets onto the wire meshes of Faraday cage and transfer of the charge to the earth caused an electrical current which is detected by a microampere meter, the charged liquid spray is then collected at a specific time and weight. Then the spray current is divided by the mass flow rate to determine the charge to mass ratio.

Induction Charging: Induction charging is the most commonly used method to charge the finely divided particulate matter in electrostatic spraying processes. In electrostatic induction charging, direct charge-transfer to droplet formation zone of a liquid jet results from electrostatic induction of electrons on to the continuous jet and in order to maintain it at ground potential the presence of a closely positioned electrode of positive polarity is required. Induction electrification process reduces the chances of shock and hazardous to operators of the nozzle system.

In-Flight Trajectory: The path followed by the charged particulate matter in the presence of many forces including electrostatic force is called in-flight trajectory. Once the droplets have been charged inductively, the charged spray-cloud has to travel in a harsh and transient environment, and thus, a charged spray-cloud will encounter some degree of neutralization. The charged droplets are governed by many forces such as gravitational force, force due to surface tension, electrostatic forces, drag force etc.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Rayleigh Limit of Charge: A drop can hold a maximum charge, defined by the Rayleigh limit, or a limit defined by electrical breakdown strength. The maximum limits of charge that can charge mother droplet carry without rupture into the daughter droplets.

Volume Median Diameter: It also refers to average volumetric size or mean size. The Volume Median Diameter (VMD) refers to the midpoint droplet size, where half of the volume of spray is in droplets smaller, and half of the volume is in droplets larger than the mean. For example, A VMD ($DV_{0.5}$) of 50μm, indicates that half of the volume is in droplet sizes smaller than 50μm, and half the volume is in droplet sizes larger than 50μm.

Wraparound Effect: In electrostatic spraying, the pesticide deposits uniformly onto both directly exposed or obscured crop surfaces. The deposition of pesticide onto the backside of the crop surface is called wraparound effect. The wraparound effect occurs due to electrostatic phenomena takes place during the spraying.

Chapter 6
Aggressions of the Socio-Economic System on the Natural Capital

ABSTRACT

Nearly 250 million years ago, the Earth was shaken by the amplest extinction known so far, which led to the extinction of up to 96% of all the marine species, 70% of the vertebrate species, and almost all the insects. This extinction affected the whole range of biodiversity so much. Nature took almost 10 million years to recover after this event. Life was really in danger on our planet at that moment, due to the dismal conditions that were created, and the current research shows that these dire conditions continued to occur, in the natural environment, after that, triggering numerous outbreaks that occurred for five to six million years following the initial crisis, triggered by the carbon rise and the repeated shortages of oxygen, the increased warming and other such adverse effects, which, once initiated, were uncontrollable and had disastrous effects. When life returned to normal and, gradually, after several million years, a new beginning was possible, the significant elements that caused the disaster - global warming, acid rain - sound strangely familiar to us today.

MAN'S BELONGING TO NATURE

In time, for a very long period, nature in general, but especially forests, have been considered empty areas, some even hostile, which could become valuable only when the trees were turned into timber and/or the land freed (evidently, deforested) acquired a deforested land, acquired an agricultural use, or settlements or infrastructure elements were built on it.

Human perception and attitude to nature and its components is a key element for understanding the relations between nature, mankind and culture. This perception, aware or not, guides the attitude, the actions and the ecological footprint of different individuals, groups or cultures, on the environment in general and especially on nature. Yet, at the same time, this perception has consequences on man himself, directly influencing his mental and physical health.

Unfortunately, often science and, on these grounds, also education, tend to intellectualize, in the sense of complicating, the feeling of nature and implicitly man's relation to nature.

The genetic information related to man's ancestral belonging to nature comes back intuitively or culturally and produces feelings, often contradictory ones, in the relations between man and nature and even in relation to human naturalness.

In is almost unanimously acknowledged that the increase of the human population, accompanied by the growth of the needs for goods and services of the members of the different communities are the main drives of the human society's development, which determined the diversification, the improvement and the increased capacity of the means and technologies of access and use of the resources and services provided by the natural systems.

The concept of structural unity between biocenosis and the physical and chemical components of the area it occupies anticipated and actually substantiated the concept of "organization" in a given space, which is much more comprehensive and constitutes the backbone of the ecology theory. In this way, it has been possible to integrate the study of the populations in the study of the ecosystems - basic productive units.

The research carried out on the energetics of the ecosystems and, implicitly, on the energetics of the natural populations, highlighted the need to research the circulation of the mineral elements and, first of all, of carbon, nitrogen and phosphorus, to be able to explain the primary output dynamics.

From this new perspective, the bioindividuals, the populations or the species, interconnected in biocenoses, and also the structural entities resulting from their interaction with the abiotic environment, become integrated units, functioning based on cybernetic principles and self-regulable (Popescu C., 2008).

PRODUCTIVE CAPACITY AND CARRYING CAPACITY

This conceptual progress permitted to investigate and know the productive and carrying capacity of ecosystems or ecosystems complexes. Errors have also been committed, like those of the period 1960-1985, when, without a sufficiently consolidated basis, a series of sub disciplines were differentiated, such as: ecophysiology, ecotoxicology, biochemical ecology, biophysical ecology, agroecology, urban ecology, human ecology etc., which, operating each with many, often conflicting concepts, created confusions, undermining the coherence and credibility of ecology as a science.

During the same period, the theoretical basis of ecology was consolidated and completed with dynamic systems mathematics, attaining during the last two decennia of the 20th century the systemic conception that gave ecology the force and means necessary to perceive and interpret the physical and biological environment as a hierarchy of complex ecosystems, dynamically influencing one another. At the same time, the passage from the analythical method to systemic analysis allows identifying ecological systems as real entities and identifying, at the same time, ways of investigating them and of describing their behavior.

Systemic analysis supposes an integrated holistic approach both in the research and especially in the management of natural ecological systems and of those dominated by the human species.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

During the present stage, after the conceptual clarification of ecology as science of the ecological systems, an ample process of identification of the ecosystems organized in hierarchies, from simple to complex, also comprising anthropized systems, has been started, to be able to project and then develop support information systems and especially organize their integrated management.

This is how for us, forest administration people, understanding climate change as a direct effect of deforestation was unfortunately the first practical evidence of the accuracy of the systemic approach (Popescu C., 2008).

The many conflictual states created in the world in relation to the forests are caused by the fact that, unfortunately, people have understood too late that when forests vanish they do not lose only wood but first of all the effects of their first functions.

The very ample studies of the American researchers coordinated by professor Robert Constantza (University Professor of Sustainability in the Institute for Sustainable Solutions at Portland State University, 1997) demonstrate that the environmental services of the world's natural ecosystems go even over the world GDP and, under these conditions, during the last 200 years, about 3 billion hectares of forests have disappeared, namely almost half of the forests covering back then the Earth's land.

The increasing conflicts related to forests and forest lands and highlighting their implications on the political and managerial decision is part of the new arena delineated by the complex interaction between public processes and phenomena and between them and local ones, which are getting more numerous and call for solutions.

The topicality of the subject is also accentuated by the fact that, increasingly more, the relations citizen-administration will be defined by new directions and implications related to natural resource management, and only the integrated approach will be the one able to solve them competitively (Constantza, R., 1997).

The great ecological accidents, as well as the ecological crisis we are going through, are first of all due to the anthropocentric economic conception according to which plants, animals, forests, waters and ecological systems in general are important only to the extent to which they are the object of the interests of human communities.

The deeply negative effect of such an approach is that very few restrictions have been imposed on the way people deal with the environment in general and especially with forests. Practically, since times out of mind, and apparently even today here and there, in their relation with nature, the only limit of those people mastered by the desire of overexploitation of the natural resources has been only the result of their interplay with the interests of other individuals.

This is why the next step in the direction of a deeper approach was considered as "huge"; it is a step by which ethics has been extended to the analysis of all the areas and not just of those dominated by man. This is how the concept of "Earth ethics" was launched by the American forester and ecologist Aldo Leopold even since the middle of the 20th century.

Leopold's principles are today acknowledged by an increasing number of specialists in the theory of ecology and not just by them, as these principles have introduced new values:

- Nature and the environment have an intrinsic value, just as any value put in the service of man, or even in opposition to this
- Not just people and the projects put in their service carry value
- Something is correct when it tends to preserve the integrity, stability and beauty of the biotic community, and incorrect if, on the contrary, it has a different orientation

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Earth ethics simply extends the boundaries of the community, also including the soils, the water, the plants and the animals from all over the Earth
- The ethical community is therefore extended so that it overlaps the ecological community.

Starting from these concepts, the Norwegian Arnei Naess issued in 1978 the postulate according to which mankind is inseparable from nature. In other words, nature as a whole has moral value—not the human individuals or other living organisms, taken separately.

The conclusion of such an approach is that the environmental issues will be solvable only by those able to emit judgements of value, beyond the narrow limits of human interests.

GOODS AND SERVICE PRODUCTION

Continuing this logic, today, is unanimously accepted the thesis according to which "the goods and services production increase, in order to answer, on the one hand, the basic needs of the population, and, on the other hand, the increasing "desires" manifested in the developed countries have always been assured based on the absorption of matter and energy resources or services, assured by primary producers. In other words, it is admitted that the socio-economic system is strictly dependent on the energy performances of the natural and seminatural ecological systems.

Primary producers – the populations or species of plants and photosynthesizing and chemosynthesizing bacteria, concentrating solar energy and chemical energy, produce biomass that, after the decrease of their own consumption of energy, constitute an energy source for the heterotrophic species that are part of the structure of a biocenosis or human population.

Here, in Table 1, we see the gross primary production of the main ecological systems on our planet (Popescu C., 2008; Vădineanu, A. 1998).

Table 1. Gross primary production of the main ecological systems

Categories of Ecological Systems	Area ($10^6 km^2$)	PPB kcal/m^2/year	% of ecosphere PPB
Planetary ocean (depths > 200 m)	326	800	30
Desert and tundra	40		
Coastlines (altitude < 200 m)	34	4000	32
Grazing fields	42		
Coniferous forests	10		
Temperate forests	10		
Waters and wet temperate forests	5		
Traditionally managed agrosystems	10		
Estuaries, deltas, reefs	2	18000	38

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Therefore, natural and seminatural ecological systems produce biological resouces (concentrated energy) and recycle the raw matter needed by the biological production, using solar energy. The processes by which goods (renewable resources) and also services (water quality, soil formation and protection, carbon absorption and climate control etc.) are produced are relatively costly in point of energy, yet, solar energy, which is free, is the source covering these expenses. Consequently, it results that natural and seminatural ecological systems are the most efficient dissipative structures.

Dissipative structures accumulate, concentrate, transform and dissipate energy, the result being an increasingly complex organization, namely they behave antienthropically, and their main outcomes are the production of renewable resources and services.

It is precisely the increase of the organization degree and the productive capacity that are assured by the specific of biological systems, which are part and parcel of the ecological systems. It results, therefore, that natural and seminatural ecological systems are the only productive units and carrying units for life on the planet.

Unlike in them, in the systems transformed and controlled by man (agrosystems, farms, intensive aquaculture etc.), energy expenses are realized from considerable subsidies obtained by burning energy stocks concentrated in fossil fuels, constituted in time, via long geological processes.

The systems created by human populations (urban systems, industrial complexes), as energy are parasite systems, depending on the concentrated energy and raw matter stocked in natural systems.

Recycling raw matter needed by primary producers to absorb and concentrate solar energy in organic matter by photosynthesis, or chemosynthesis, is the most important ecological process on earth.

The recycling compartment, represented by the trophic structure of the biological systems, taken as parts of the ecological systems (beginning with biocenoses and ending with the biosphere) is closely interconnected with the elements of the hydrogeomorphological units (soil, lithosphere, water) forming the toposphere. In their turn, these components are interconnected by physical-chemical mechanisms and phenomena and constitute the support of the local, regional and global biogeochemical circuits.

The productivity of any ecological system depends on both the stock of macro and microelements available in the mass of water and sediments of acquatic systems, or in the soil and water of terrestrial systems, and on recycling speed of the respective stock by the ecological systems' biological elements.

Under these circumstances, the ecological systems availing themselves of relatively small stocks of macro and microelements, especially nitrogen and phosphorus, but having a very dynamic recycling system, realize great productivities of goods and services.

Such are the forests, the most productive biocenoses of our planet, which beside profitably using the lands that are poorest in micro and macroelements, often totally impossible to be used for other uses, provide fundamentally important services for the key components of the ecosphere, such as: lithosphere, hydrosphere or troposphere, namely they become carrying units of life.

It has been demonstrated in this way that the deterioration of the vegetal layer by deforestations and overgrazing, along with draining, damming, channaling, soil compaction through intensive agriculture have modified the amplest essential phenomenon on the planet: the water circuit in nature.

The development of the socio-economic system has been and will be dependent on the hydrological circuit, but it is regrettable that it is precisely many human activities that have significantly affected the key mechanisms of this circuit.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

EVALUATION OF THE RISK DETERMINED BY CLIMATE CHANGES

On Risk and Uncertainty

The consequences of most human activities are almost unforeseeable, because we often do not know the nature of these consequences. Here we have in view the extreme case of uncertainty regarding future events. As our knowledge improves we can express our uncertainty by the probability of occurrence of such consequences, namely we can transform our uncertainty into risk. Consequently, risk can be defined as measurable uncertainty.

Many ecological processes are, however, insufficiently understood so far, so that one cannot precisely foresee the impact of the economic activities on them and implicitly on the environmental components. One can understand and foresee the type of potential impact, but not its amplitude or the moment when it is going to occur. Particularly difficult is the anticipation of the possible impact of an event triggering a chain reaction. Irreversible effects, such as the disappearance of a species, damages on the ozone layer or landscape changes have become main concerns for the ecologists.

In order to face uncertainty, one can act in several ways:

- Stimulating investments in information
- Presenting eventual consequences and their probabilities of occurrence (evaluating risk)
- Carrying out analyses on the perceptions and preferences of the decision-maker and/or the public concerning the risk (the perception of risk and subjective preferences)
- Determining the rules regarding decision-making and investment strategies

Risk evaluation is the process by which uncertainty is turned into risk and answers questions such as:

- "How risky is the situation?"
- "What are the risks associated to the different ecological problems?"

Complementarily, risk management answers questions such as:

- "What should be done in this situation?"
- "What solutions can be found to reduce the risks associated to the various ecological problems?"

The aim of risk evaluation consists in analyzing and hierarchizing the risk levels associated to some ecological problems, based on the best information and scientific judgements available.

Ecological problems can represent a risk both for people, and for the ecosystems; they can also lead to the degradation of the quality of life. Each risk category is important and must be analyzed separately. For example, the heating of the atmosphere induces the heating of the waters, which has a negative impact not just on the biocenoses of the ecosystems, but also determines a loss of some recreational opportunities of the communities (diminishing the quality of life). For this reason, it is important to look at the ecological problems from all the perspectives: of the risks for human health, for the ecosystems, and for the quality of life.

Comparative Risk Evaluation (CRE) is also a useful tool for hierarchizing the priority actions in environmental protection. For this reason, the solving of the global environmental problems, such as

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

climate changes or irreversible biodiversity loss, has to be approached, if not simultaneously, at least according to the order of their priority.

CLIMATE CHANGE

Indices of the Impact of Climate Changes

The average air temperature worldwide has risen by 0.3-0.6o C since the end of the 19th century. In the year 1997 (the hottest year), the average temperature was 0.43 degrees higher than the average recorded during the period 1961-1990. Europe has been confirmed as matching the global trend, the 1990s being the hottest years. According to the estimates, the average temperatures of the year 2010 will be two degrees Celsius higher than those of the 1990s. At the same time, in Europe, it is estimated that the warming is going to be more significant in the northern than in the southern areas (Allan, D., 1994).

Global warming has been dilating the seas and oceans and accelerating the melting of the icecap. All these have led to an increase of the seas and oceans' level of 10-25 cm during the last 100 years. The estimates indicate the fact that in the year 2020, the sea level will be 50 cm higher than the level of the 1990s (with a variation ranging between 15 and 95 cm), the uncertainty degree being increased by the lack of knowledge regarding the contribution of the polar ice.

The increasing sea level can have consequences such as:

- Flooding and dislocating the marshy or low lands
- Increasing salinity in estuaries
- Deteriorating the potable water sources

From this perspective, the riskiest areas are deltas, beaches, islands and estuaries. In Europe, they include the coastlines of the Netherlands, Germany, the Balkan States, Ukraine, Russia and some Mediterranean deltas.

Coastal areas can also be affected in other ways than just by the rising of the sea level. For example, in the Netherlands, a 10% storm intensity rise, accompanied by changes in the wind direction, could bring more damage than a 60 cm sea level rise.

The cost of the adaptation and protection against a one-meter sea level rise has been estimated to US$12,300 million for the Netherlands, US$1,400 million for Poland and US$23,500 million for Germany.

Precipitations

In the Europe of the 20th century, the precipitations regime has been changing continually. Thus, precipitation quantities have grown, in general, in the Northern half of Europe and have decreased in its Southern half.

While in Northern Scandinavia, precipitations have increased by 5%, the southern parts of Italy and Greece have recorded, since the year 1900 till now, a decrease of about 5%.

All the attempts of modelling the climate modifications forecast an increase in the average annual precipitations; at the same time, global warming influences soil humidity, by accentuating water evaporation. The modelling of these processes suggests the fact that, in Europe, soil humidity is going to decrease.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hydrology and Water Resources

Even since the middle of the 19th century, the glaciers of the Alps have begun to "withdraw" (it is estimated that during the next hundred years, global warming will melt up to 95% of the glaciers of the Alps), which will influence the seasonal pattern of the river courses (Constantza, R., 1996). During the last decennia, their volume increased in Northern Europe, which agrees with the precipitations growth observed.

The climate change will probably accentuate the "hydrological stress" of some already sensitive European areas: the Mediterranean region, the Alps, Northern Scandinavia, the coastlines and central and Eastern Europe. The consequences of the hydrological cycle changes are hard to estimate; they include a possible increase in the frequency and intensity of flooding and a possible water quality decrease, by the infiltration of salty water in the underground water of the coastal areas.

Agriculture and Forest Ecosystems

The ecosystems' reaction to the changes of temperature, precipitations and soil humidity and of other factors that change along with the climate is hard to forecast.

The main impact on the species will be concretized in the modification of their geographic distribution. A one-degree Celsius rise of the annual average temperature is equivalent to a shift northwards of 200-300 km or in altitude of 150-200 m. A two-degree Celsius temperature rise in 50 years in Europe would lead to a shift of the climate zones northwards at a faster pace than the migration ability of most plant species. Moreover, in the alpine areas, the plants' location will be forced upwards, yet there may be no room available for their migration. Besides, the possibilities of migration in many parts of Europe are limited due to the intensity of the land use.

Climate change can have various effects on agriculture and forestry, namely on the plants' periods of growth and productivity. The growing variability of the climate can endanger certain crops due to the occurrence of late frosts. Some studies and especially simulation and modelling have shown that climate changes can trigger richer crops in large areas of Europe (Leopold, A., 1949).

CLIMATE CHANGE REASONS. MAIN GREENHOUSE GASES: EMISSION SOURCES, CONCENTRATIONS

Carbon Dioxide

The greatest anthropic source of CO2 is the burning of fossil fuels for the production of electricity, heat, in transports and industry. The natural ecosystems emit and absorb, by photosynthesis and respiration, large quantities of CO2.

In time, these processes have been balanced and have not given rise to extra emissions on either side. Human activities and the socio-economic system in general have disturbed, however, these balances, when they generated and as they continue to generate important supplementary net emissions. For example, by the destruction of the forests, carbon is freed, and this evil could be remedied, generating a significantly higher net absorptions, for example if deforested areas were reforested or if forests were allowed to reach greater ages and sizes.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

On a global level, the main CO2 sources are fossil fuel burning (77%), industrial processes such as cement production (2%) and modification of the land use (21%). In Europe, the contribution of these sources is slightly different: fossil fuel burning (98%), industrial processes (2%), while the land use can actually be a sponge absorbing 13% of the carbon dioxide emitted in Europe. At present, Europe generates 29% of the global carbon dioxide emissions.

CO2 emissions depend on the economic development degree of the different countries. Thus, the CO2 emissions level per GDP unit in the year 1994 shows that, excepting some parts of the former Yugoslavia and Albania, this indicator is considerably higher in Central and Eastern Europe (3.3 tons/US$) and in the new independent states (2.4 tons/US$), than in Western Europe. The numbers reflect the inefficient use of energy and the predominance of the heavy industry, consuming significant quantities of energy, in Eastern Europe.

Methane

The global anthropic emissions of methane total 375,000 tons/year, out of which 27% result from the use of fossil fuels. European emissions represent about 11% of this total. The main sources are: leaks from gas transport and distribution networks, coal extraction and agriculture - especially ruminants breeding and rice fields. Natural sources (e.g., marshes) contribute by about 20% to the global methane emissions.

Nitrogen Protoxide

The global anthropic emissions of N2O range between 3 and 8,000 tons/year. The existing uncertainties regarding the evaluation of these emissions results from the insufficient understanding of the processes involved and of their distribution around the globe. Worldwide, the greatest emissions are generated by the fertilization of the agricultural lands. In Central and Eastern Europe, N2O emissions in agriculture have decreased due to the reduction of the use of fertilizers; to a lesser extent, due to the restructuring process, the emissions coming from the industry have also recorded a decrease (the production of nitric acid and nylon).

Halogenated Gases

The emissions of halogenated gases, such as CFC, are rapidly decreasing due to their suppression according to the protocol of Montreal. Consequently, the emissions of replacing gases, especially HCFC and HFC, both greenhouse gases, have been growing. The data on these emissions are too limited to establish their evolution in time, yet their long-term remanence in the atmosphere and their high global warming potential, can increase their importance.

The contribution of greenhouse gases to global warming, and therefore their influence on the sea level, precipitations and ecosystems, depends on their concentration and period of remanence in the atmosphere and their efficiency in retaining radiations. For example, although CFCs are present in the atmosphere in very small concentrations, they are important because their period of remanence is around 100 years, and each molecule determines a greenhouse effect many times higher than one of CO2. To be able to compare the impact of various gases, the indicator called global warming potential relative to CO2 has been used, carbon dioxide being attributed the value one. The dimensions of this indicator depend on the time horizon considered. Examples of such values calculated for a period of 100 years are: 21 for CH4,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

310 for N2O and several hundred for halogenated compounds. The measurement units of these emissions, which take into account the values of the global warming potential are called equivalent (carbon).

Moreover, the tropospheric ozone can contribute to global warming, the estimates showing that they add 16% to the total effect caused by the anthropic greenhouse effect gases mentioned.

The aerosols, which can be emitted directly (primary aerosols), or formed in the atmosphere out of SO2, NO and NH (secondary aerosols), have a cooling effect, both directly, through the dispersion of the sunlight, and indirectly, by modifying the features of the clouds. The size of the cooling effect is not known for sure; it has been estimated that aerosols annihilate almost half of the warming triggered by greenhouse gases. However, unlike the main greenhouse gases, aerosols have a short period of remanence in the atmosphere. Their effect is therefore regional and short-term and appears especially over Europe, USA and China. As in Europe the level of SO2 and NO emissions is decreasing, the quantities of secondary aerosols generated are also decreasing, simultaneously to their cooling effect.

The great variations of the duration of remanence in the atmosphere of the various greenhouse gases shows a contribution in time to global warming that can vary from 20 to several thousand years. Consequently, there is a considerable temporal gap between the period when the emissions reduction takes place and the stabilization of their concentration in the atmosphere. Therefore, the actions undertaken today will need a long time to have some effect.

Global warming is not, however, the only effect that greenhouse gases can trigger. Thus, the actions meant to control the climate changes can have beneficial or negative side-effects on the environment:

- The reduction of CFC emissions meant to protect the stratospheric ozone also diminishes their greenhouse effect
- The decrease of the methane emissions meant to slow down the global warming phenomenon is concomitantly lowering the level of the tropospheric ozone
- The diminution of the SO2, NOX and NH3 emissions will reduce acidification

On the other hand, a side-effect will be the decreasing production of sulphate and nitrate aerosols, which have a regional cooling effect (Lester, R. Brown, et al., 1997).

OBJECTIVES AND POLICIES OF GREENHOUSE GASES REDUCTION

The Decision no. 406/2009/EC of the European Parliament and of the Council of 23 April 2009 regarding the effort of the Member States of reducing the greenhouse gas emissions so that they may respect the Community's commitments to reduce greenhouse gas emissions until 2020 is the central document regulating the position and the commitments of the EU States in relation to greenhouse gas emissions reduction.

The supreme objective of the UN Framework-Convention on Climate Change (UNFCCC), approved on behalf of the European Community by the Decision 94/69/EC of the Council JO L 33, 7.2.1994, p. 11, consists in the stabilization of greenhouse gas concentrations in the atmosphere at a level preventing any anthropogenic disturbance of the climate system (Popescu, C., 2011).

According to the opinion of the Community, expressed most recently especially by the European Council of March 2007, in order to be able to attain this objective, the global increase of the average annual temperature on the ground should not go over the preindustrial levels by more than 2°C, which

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

means that the world greenhouse gases emissions ought to be reduced, until 2050, by at least 50% compared to the levels recorded in 1990.

The Community's greenhouse gas emissions, regulated by the present decision, ought to continue to be reduced annually after 2020, as part of the Community's efforts of contributing to this global emissions reduction goal.

The developed countries, including the EU Member States, ought to continue to constitute an example, committing to reduce, until 2020, their greenhouse gas emissions by up to 30% compared to the levels recorded in 1990. They ought to realize the same thing in order to attain the collective goal of emissions reduction of 60% to 80% until the year 2050, compared to the levels recorded in 1990.

All the economic sectors ought to contribute to the realization of this emissions reduction goal, including the international transport by sea and the aviation sector. The aviation sector contributes to these reductions by its inclusion in the EU' emission quota trading system (henceforth called "Community system"). If, until 31 December 2011, no international agreement including the emissions coming from the international transportation by sea among its reduction goals is approved by the Member States in the framework of the International Maritime Organization or by the Community in UNFCCC, the Commission ought to submit a proposition coming into force until 2013 and including these emissions in the frame of the Community's commitment of emissions reduction. Such a proposition ought to reduce any negative impact on the Community's competitiveness, while considering the eventual benefits for the environment.

At the same time, in order to attain this objective, the European Council of March 2007 reiterated the community objective of reduction by 30% compared to the levels of 1990 of the greenhouse gas emissions until 2020, as a contribution to the conclusion of a global and comprehensive agreement for the period following the year 2012, on condition that other developed countries should also commit to realizing comparable emissions reductions, while the developing countries with a more advanced economy ought to contribute adequately, according to the responsibilities and capacities of each of them.

The European Council of March 2007 highlighted, at the same time, the Community's pledge of transforming Europe in a highly energy-efficient economy, with low greenhouse gases emissions, and decided that, until the conclusion of a global and comprehensive agreement for the period following the year 2012 and without affecting its position in the international negotiations, the Community takes on this firm and independent commitment of realizing a reduction of at least 20% compared to 1990 of the greenhouse gas emissions until the year 2020.

An improved energy-efficiency is an essential element for the accomplishment by the Member States of the present decision's demands. In this context, the Commission ought to closely monitor the progresses recorded in order to attain the objective of energy consumption reduction by 20% until 2020 and propose further actions in case of insufficient progress.

Directive 2003/87/CE

The Directive 2003/87/CE of the European Parliament and of the Council of 13 October 2003, instituting a greenhouse gas emissions trading system in the Community (JO L 275, 25.10.2003, p. 32) has created a greenhouse gas emissions trading system in the Community, which regulates certain sectors of the economy (Allan, D., 1994).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Paris 2015

The main objective of the conference is to sign a treaty by which all the participant countries will take on to reduce their polluting gas emissions. So far, the only document of this type was the Kyoto protocol, of 1997. Only a few industrialized countries have committed, however, to respect the provisions of this protocol. Meanwhile, these countries produce only 15% of the greenhouse gas emissions worldwide. Moreover, the Kyoto protocol expires in 2020.

Here are the main results of the final agreement of the Paris Climate Change Conference of December 2015:

- Limiting global warming to maximum 2 degrees Celsius compared to the average temperatures of the preindustrial epoch
- Checking all the commitments assumed by the signatory States every 5 years
- Financial help for developing countries, especially for those in the south, from the developed ones

The text of the agreement explicitly mentions a limitation of the global average temperature growth to up to maximum 2 degrees Celsius and a continuation of the efforts of lowering this increase limit down to maximum 1.5 degrees Celsius. The objective of 2 degrees Celsius, related to the preindustrial epoch, was established in 2009, in Copenhagen, and imposes a drastic reduction of the greenhouse gas emissions (GGE) and also energy saving measures and investments in renewable energies, as well as afforestation plans for large areas.

Numerous countries, especially Island States, which are the first threatened by the perspective of the rise of the planetary ocean, are in danger if average global temperatures rise by more than 1.5 degrees Celsius.

Out of the 195 States represented at the Conference of Paris, 186 announced measures meant to limit or reduce their greenhouse gas emissions until the horizon 2030. But even if these measures are respected perfectly, they would lead to an increase of the global average temperature of about 3 degrees Celsius.

To attain the objective of 2 degrees Celsius, the text proposes a peak of the greenhouse gas emissions as low as possible and the adoption, as fast as possible, of rapid pollution diminutions to attain a balance between the emissions resulted from anthropic activities and those that can be absorbed, a possible reference to the forests, but also to the new technologies meant to capture and store carbon dioxide.

One of the key provisions of the agreement refers to the constitution of a voluntary mechanism checking the respect of national commitments. Such a check-up will take place every 5 years and will "represent a continuation of the previous report". A first obligatory revision is to take place in 2025, after a collective action assessment foreseen for the year 2023. Meanwhile, a first discussion on the actions undertaken and the measures taken is foreseen for the year 2018.

The UN Climate Convention of 1992 introduced a strict distinction between the developed and the developing countries regarding the sharing of the obligations in this domain. Industrialized countries, such as the USA, want to fragment this clear separation line, and developing countries, such as India, refuse to accept the renunciation to this delineation in the name of their right to development and of the historical responsibility of the northern hemisphere for excessive pollution and climate changes.

Regarding the greenhouse gas emissions reduction, this "differentiation" remains active: the developed countries "need to be about to adopt objectives of polluting emissions reduction in absolute value",

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

while developing countries "must continue to improve their efforts" in the fight against global warming, according to their national situation.

Another important provision is that of granting financial aid to the countries of the austral hemisphere. In 2009, the developed countries promised they would discharge 100 billion dollars a year, starting with 2020, for funding climate policies in developing countries. The latter asked for a progressive increase of this sum and a greater clarity concerning the means of implementation of this provision.

On the other hand, the developed countries do not wish to bear these costs on their own and ask for contributions from countries in full economic expansion, such as China, South Chorea and Singapore or from the countries with rich oir reserves. The formula proposed is: "developed countries ought to assure financial resources to help developing countries" adapt to the effects of climate change and take measures to reduce their greenhouse gas emissions (Constantza, R., 1997).

THE PREMISES OF A NEW ENDEAVOR

In Paris, the participants have tried to conclude a new global climate treaty, entering into force in 2020. The 2009 Climate Summit of Copenhagen failed in a similar attempt. Experts like Christophe Balls are, however, more optimistic regarding the summit of Paris.

"Political will is much greater than in Copenhagen", as the political leader of the NGO German watch declared for DW. "Second, negotiations are more advanced than in Copenhagen. Third: the real world evolutions are much better than before Copenhagen. Last year, for example, the polluting emissions caused by energy production no longer increased, even though there was a little economic progress worldwide."

All the economy sectors ought to contribute to attaining a 20% reduction of the greenhouse gas emissions, compared to 1990, until the year 2020, in a cost-efficient way. Consequently, the Member States ought to implement further policies and measures in their effort of limiting even more the greenhouse gas emissions from other sources than those regulated by the Directive 2003/87/EC.

Each Member State's effort ought to be established in relation to the level of the greenhouse gas emissions recorded in the year 2005 nationally, which are under the influence of the present decision; this level ought to be adjusted to exclude the emissions in the atmosphere of the installations that existed in 2005 and which were included in the community system for the period 2006-2012. The annual level of emissions allocated for the period 2013-2020 expressed in tons of carbon dioxide equivalent ought to be established based on analyzed and verified data.

The Member Sates' emissions reduction efforts ought to rely on the principle of solidarity between the Member States and on the need of a sustainable economic growth throughout the territory of the Community, considering the Member States' GDP per capita. The Member States recording, at present, a relatively low level of the GDP per capita and, consequently, important expectations regarding the increase of their GDP, ought to be authorized to increase their greenhouse gas emissions level in relation to 2005, but also to limit this growth so as to contribute to respecting the independent commitment of Community emissions reduction. The Member States recording, at present, a relatively high level of their GDP per capita ought to reduce their greenhouse gas emissions levels in relation to 2005.

To be able to continue to assure an equitable distribution of the Member States' efforts of contributing to the implementation of the Community's independent emissions reduction commitment, no Member State should be obliged to reduce its greenhouse gas emissions until 2020 by more than 20% compared to the levels recorded in 2005, nor should it be authorized to increase its greenhouse gas emissions until

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2020 by more than 20% over the levels of 2005. The greenhouse gas emissions reduction ought to be attained in the period 2013-2020. Each Member State ought to be authorized to transfer from the following year a volume of up to 5% of its annual level of emissions allocated. When a Member State's emissions are lower than its annual level of emissions allocated, the respective Member State ought to be authorized to transfer to the following year the emissions reduction supplement.

To balance the Member States' emissions reduction costs differences, which would offer a greater geographic flexibility and at the same time improve the general efficiency of the costs incurred by the total community commitment, any Member State ought to have the possibility to transfer to other Member States a part of its annual level of emissions allocated. The transparency of these transfers ought to be assured by the notification of the Commission and by the recording of each transfer in the registers of both Member States involved. The respective transfers can be realized by a procedure convenient for both parties, including by tender, by market intermediaries acting as agents, or by means of a bilateral agreement.

The European Union ought to record a significant reduction of its greenhouse gas emissions. The use of credits coming from project activities ought to be limited, in order to complete the internal actions. The Union renews its pledge to continually improve its Clean Development Mechanism (CDM) and will try to improve it via adequate international procedures. It is important for the credits coming from the project activities used by the Member States to represent real, supplementary and permanent, verifiable emissions reductions, to present net advantages for sustainable development and no significant negative impact on the social or environmental level. The Member States, at the same time, ought to report on the qualitative criteria they apply for the use of such credits.

To grant the Member States a certain flexibility in the accomplishment of their pledges, to promote the sustainable development of third countries, especially of developing countries, and to offer security to investors, the Community ought to continue to recognize a certain number of credits from greenhouse gas emissions reduction projects undertaken in third countries before the adoption of a future international agreement on climate change (henceforth called "the international climate change agreement"). The Member States ought to make sure that the national policies of acquisition of these credits facilitate an equitable geographic distribution of the projects, especially by the increase of the Certificate Reduction Emissions (CER) ratio bought from the Least Developed Countries (LDC) and from Small Island Developing States (SIDS) and the conclusion of an international climate change agreement.

Consequently, the Member States ought to use the greenhouse gas emissions reduction credits granted for reduction realized during the period 2008-2012 and resulting from types of projects eligible for use in the community system during the respective period. At the same time, the Member States should be able to use greenhouse gas emissions reduction credits for the reductions realized after the period 2008-2012, resulting from projects recorded in the period 2008-2012 and from types of projects eligible for use in the community system during the respective period.

In the least developed countries, a very small number of CDM projects have been implemented. Considering the support given by the Community to the equitable distribution of CDM projects, including by means of the Global Climate Change Alliance, established by the Communication of the Commission of 18 September 2007 entitled "Building a global climate change alliance between the European Union and poor developing countries most vulnerable to climate change", it would be good to guarantee the acceptance of the credits coming from projects launched after the period 2008-2012 in the least developed countries, for types of projects eligible to be used in the community system during the period

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2008-2012. Such an acceptance ought to continue until 2020 or until the date of the conclusion of an agreement with the Community, if this date comes earlier than 2020.

To assure a greater flexibility to the Member States and to promote the developing countries' sustainable development, the Member States ought to be able to use supplementary credits coming from projects based on agreements concluded by the Community with third countries. In the absence of an international climate change agreement, establishing the quantity attributed to the developed countries, Joint Implementation (JI) projects cannot continue after 2012. The greenhouse gas emissions reduction credits resulting from these projects could continue to be recognized, however, in the framework of agreements with third countries.

The Member States' continual capacity of using credits in the framework of CDM is important, contributing to the assurance of a market for the respective credits after 2012. In order to assure such a market and new greenhouse gas emissions reductions in the Community, encouraging, in this way, the realization of the community goals in the domain of energy from renewable sources, energy efficiency, safe energy provision, innovation and competitiveness, it is proposed to authorize an annual use, by the Member States, of the credits coming from greenhouse gas emissions reduction projects carried out in third countries, within the limit of a volume representing 3% of the greenhouse gas emissions of each Member State non-regulated by the Directive 2003/87/CE in the year 2005, or undertaken in other Member States, until the adoption of an international climate change agreement.

The Member States ought to be authorized to transfer the unused part of this volume to other Member States. Certain Member States recording a negative limit or a positive limit of maximum 5%, according to the present decision, should be authorized to use, beside the above-mentioned credits, supplementary credits of 1% of their emissions checked in 2005 coming from projects undertaken in LDC and in SIDS, under the reserve of their respect of any of the four conditions foreseen in the present decision.

The present decision should not affect more stringent national objectives. If, to accomplish a more stringent objective, the Member States limit the greenhouse gas emissions level regulated by the present decision more than the obligations assumed based on the present decision, the limits imposed by the present decision regarding the use of greenhouse gas emissions reduction credits should not apply to the supplementary emissions reductions realized in order to attain the national objective.

The United Nations' Green Climate Fund has raised for the moment only US$ 2.3 billion, out of which one billion promised on Tuesday by France", as the Secretary-General of the United Nations declared in the conclusion of the reunion. This sum is far from the objective proposed, of 10 billion dollars until the end of this year, to reach 100 billion per year beginning with 2020.

The United Nations' high official also announced that private banks have pledged to issue green bonds worth 20 billion dollars and the insurers intend to "double their green investments" by 2015, reaching 82 billion dollars.

The American president called, from the summit's pulpit, to the conclusion of an "ambitious" agreement at the Conference of Paris of the end of 2015, promising that the United States will take on their part of contribution in "the urgent and increasing climate change threat".

In his turn, the French president affirmed that France will contribute with a billion dollars to the Green Fund, created in 2009 to aid developing countries in their efforts of facing climate change. Germany had announced, even since July 2015 a contribution of a billion dollars.

The Chinese Vice Premier declared that his country – one of the greatest polluters, along with India and the United States – "will collaborate with other states for the edification of a better future". He reaf-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

firmed, however, that the industrialized countries need to "respect their obligation to support, by their finance and technology, the developing countries".

China and India sent to the New York summit lower rank representatives, casting a shadow over this reunion, exceptional by the number and diversity of its participants: 120 heads of state or government, over 200 companies and numerous NGOs.

The reactions to the announcements of financial support from some countries were prudent. Oxfam-France appreciates that the billion announced by the president Hollande "is a first timid step that risks being insufficient"' and "there are many details still in suspense". Greenpeace considers that the announcement is "an important signal of support to the most vulnerable countries", yet regrets the fact that "the details remain unclear". The organization also regrets that "the Obama administration continues to allow the industry to prospect and exploit coal, oil and gas on public land".

According to a survey made by Chicago Council for Global Affairs and published on Tuesday, half of the Americans interviewed appreciate that the government does not make enough efforts in relation to climate change.

The Secretary-General of the United Nations, Ban Ki-Moon, who asked the participants to the opening of the summit to "demonstrate leadership", received support from the actor Leonardo DiCaprio, who took the floor and said that "clean air and a liveable climate are inalienable human rights" and that investing in renewable energies is "a good economic policy". DiCaprio, called by the UN "messenger of peace" for the climate, recommended the heads of state or government "to answer the greatest challenge of our existence with courage and honesty".

THE OBJECTIVE OF GLOBAL TEMPERATURE INCREASE OF JUST 2 DEGREES CELSIUS

Even if a new treaty is signed, including new climate protection measures, it is very likely to miss the objective of limiting global warming until the end of the century to just 2 degrees Celsius over the level previous to industrialization, although the international community had adopted this objective at the Cancun Climate Summit of 2010.

The consequences of a global warming of maximum 2 degrees Celsius are considered still moderate and controllable. The physicist Anders Levermann from the Postdam Institute for Climate Impact Research warns: "With increasing warming, some physical systems or ecosystems may be at risk. If we continue as we have begun, until the end of the century, our global temperature will be 5 degrees Celsius higher. This means the loss of most alpine glaciers. The Arctic Sea Ice will also disappear. Corals, determining for the existence of 600 million people worldwide, will also die."

According to the UN calculations, even if all the pollution reduction measures discussed were applied, the planet will grow warmer by 2.7 degrees Celsius until the end of the present century.

NEED FOR IMPROVEMENTS

Some States are asking that the summit of Paris ought to give birth to a process of revision and improvement of the climate goals every five years. The German chief-negotiator Karsten Sach is expecting tough

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

discussions on this topic. According to him, the EU would like the environment goals to begin to be reviewed already starting with 2020, while other countries, however, would like this process to begin later.

Controversial are also the regulations that ought to be adopted in this dynamic revision and improvement process. The head of German watch Bals draws the attention on the different calculation standards: "Some countries take into account the forests in their estimates; others do not." "The countries also have different factors regarding the polluting emissions for different fossil sources of energy."

EU negotiators are asking for more transparency on a global level, which bothers some, especially among the great emerging economies. "China and India are not the greatest friends of transparency and taking on responsibilities", says the speaker of the evangelical association "Brot für die Welt", Sabine Minninger.

NATURAL CAPITAL FROM THE PERSPECTIVE OF ECOLOGICAL ECONOMY

It has been demonstrated that what supports the sustainable development of the socio-economic system is the natural capital and biodiversity.

Practically, the natural capital of a country, region or of the planet, in general, is the network of ecological systems operating in a natural and semi natural regime and the anthropized systems, constructed through the transformation and simplification of the first two categories.

For this reason, renewable natural resources, including water and the soil, and non-renewable ones on the time scale at which the development assured by the natural capital elements is projected, are key factors of the economic system's production function and support of sustainable development.

Continuing this logic, the natural capital becomes part and parcel of the diversity of the ecological and biological systems and includes, beside the components operating in a natural regime, the human species, as part of the biosphere, together with their environment.

Therefore, natural capital has a certain productive capacity that has to be known by the economic activities' managers, in order to avoid overexploitation, namely a certain carrying capacity – an essential parameter, necessary in the process of dimensioning the anthropic pressure, namely of the human society, avoiding the degradation of the environment.

It logically results that, to guarantee a sustainable socio-economic development, it is absolutely necessary to assure the conservation of a diverse and balanced natural capital structure and a use of the resources and services produced by it within limits bearable for the natural capital components.

Beginning with the years 1970, when the Club of Rome began discussions on the limits of growth, for the first time, the issue of the need of modifying and transforming the economic growth model was brought up, in the sense that this growth cannot be unlimited.

A series of theories followed, concerning the concept of economic growth and the way of quantifying the degradation of the environment, differentiated by the theories that generated them:

The general economic theory interprets the natural capital either as a circulating monetary fund, or as a stock of technical means existing at a certain moment, which can be reproduced and diversified to support a goods and services flow necessary to development. The so large interpretation of the monetary capital in monetary and physical terms led to the conclusion according to which the natural capital might be a metaphor harder to quantify and use in designing an economic development model.

The neo-classic economic theory characterizes the economic systems as being designed and developed based on the principle of their independence to the environment, in the sense that the environment is not

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a factor limiting the development of the socio-economic system, because resources are renewable and can be assured endlessly, while the resulting wastes can be absorbed without restrictions. The theory was soon fought against and amended by its very supporters, as soon as they noticed that the deterioration of the environment is a reality, directly connected to the economic development. The supporters of a growth at all costs tried to argue that the resources provided by the natural ecosystems can be gradually replaced by those produced by the components of the environment created by man, based on the technological progress, namely the world can exist as well without natural resources.

In other words, a series of theories that had the gift of encouraging the economic development based on the maximization of the profit and on the relation demand-offer, tried to find arguments to support a development at all costs, going even up to modalities of substituting the natural capital. They supported either the direct substitution, when a component of the capital created can assure a service equivalent to that provided by the natural capital or an indirect one, generically defined as "efficient growth through technological progress".

The two modalities were impossible to defend except by a new approach – the systemic approach of the environment – which will be able to demonstrate that the environment is a hierarchy of simple systems or grouped systems that develop based on a stability hierarchy.

NATURAL CAPITAL FROM THE PERSPECTIVE OF SYSTEMIC ECOLOGY

The definition of the natural capital through the prism of the way the physical, chemical and biological environment is perceived, as representing the totality of the natural and semi natural ecological systems, permits a new approach of the ecological systems' management.

Natural ecological systems are, in this case, interpreted as self-regulatory systems with no or very limited direct anthropic influence (generally activities meant to meet the 1st order needs of the local population, research needs, and, more recently, ecotourism).

Semi natural ecological systems are represented by systems that, although bearing a direct anthropic influence (especially by the industrial exploitation of renewable resources), preserve their structural and functional features, by which they maintain themselves and develop themselves.

The basic feature of the natural and semi natural ecological features is that their productivity and stability does not require any supplementary input of energy produced in other systems.

The direct activities of exploitation of the resources from semi natural systems or of control of certain command factors, call for a current management process.

These ecological systems operating in a semi natural regime are represented by:

- Agro systems responsible for producing cereals, vegetables, fruits, technical and fodder plants
- Secondary forests or forest plantations for wood production
- Farms for the production of animal-based foods and raw matter for the leather industry, farms for aquaculture, in general, and for intensive fisheries, in particular
- Storage lakes created for the exploitation of the hydro energetic potential, renewable water source and exploitation of fishing potential etc.

The anthropic intervention is direct both during the stages of creation of these types of ecological systems by removing or totally eliminating the components of the natural ecosystems and affecting some

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

physical and chemical environments and especially the bio-geo-chemical mechanisms starting with the sawing or plantation stages, species improvement, fertilization, pests fight etc.

We shall underline the fact that the semi natural ecological systems produce resources and services, by concentrating the solar radiant energy and maximizing the density of the energy flow. For example, wet areas are ecological systems with intermediary position, between the terrestrial systems and the aquatic ones and characterized by their capacity to purify surface waters, due to mechanisms such as: periodically or permanently the soil is covered by hygrophyte species in which a specific fauna develops, able to recycle nutrients.

Practically, the natural capital is therefore made up of natural and semi natural ecological systems and anthropized ecological systems.

All systems making up the natural capital preserve the productive function of resources and services based on fundamental ecological processes. For this reason, the energy flow from the radiant solar energy which is free, and the recycling of nutrients—the fundamental mechanism for maintaining the bio-geo-chemical circuits – are defining elements of the natural capital structure.

At the same time, we consider that maintaining the spatio-temporal organization, the productive function, and controlling the dynamics of these ecological systems can be realized only if the human populations' direct and significant intervention is assured permanently and non-destructively.

Practically, anthropized systems are characterized by a strict dependence on the human populations' direct and complex intervention, associated to a flow of auxiliary energy, produced in other systems, such as those for energy conversion.

Consequently, one can state that these ecological systems have specific structural and functional features and, as a result, we can consider them an essential part of the socio-economic systems.

In essence, a third of all agrosystems, for instance, are intensive and super intensive production structures, calling for a very large auxiliary energy input, of up to 10 kcal/m^2/year. For this reason, such ecological systems are assimilated to anthropic capital components (built by human populations).

Finally, we consider this last category of ecological systems as representing natural capital (NC) components dominated and controlled by human populations and, consequently, one can state that these ecological systems are subordinated structurally and functionally to the socio-economic system's development strategies, actually proving that they are practically integrated in the socio-economic system (SES).

Moreover, we consider that the weight of this category of ecological systems increased exponentially during the last century, as the population and the 1st order needs of the members of the human societies increased, and the numerical growth of these systems is the result of a process of substitution of the natural and semi natural systems.

Therefore, we do not exclude the possibility of substituting, between certain limits, some components of the natural capital, by others, in order to increase productivity, yet the massive substitution of the ecosystems functioning in a natural and semi natural regime, producing for free renewable resources and services, by anthropized ones (super intensive cultures, urban centers, transportation infrastructure elements etc.), which cannot function except based on the significant increase of the energy flow produced in other systems is not allowed.

The comments on the so controversial issue concerning, on the one hand, the possibility and opportunity of substituting the natural capital components by components created by the human populations, and on the other hand, the obligatory need to guarantee complementariness, must lead to the conclusion that, always, the normal progress is towards the harmonization of the spatial relations and the matter and energy flows circulating between the natural capital and the socio-economic system.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

We reiterate the fact that all the components in a natural and semi natural regime and the anthropized ones are dissipative systems, maintaining and maximizing the energy flows and recycling raw matter, producing resources and services.

Thus, all the ecological systems are dynamic on large geological time scales and develop by going through different growth stages, depending on which they produce resources and services. It logically results that on ecological and geological time scales (over 100 000 years), all resources are renewable.

Practically, however, the socio-economic systems' management is based on strategies emitted for much smaller time scales (5-15 years); in this case, their management cannot be operated based on a comparison to the scales at which resources are renewable.

For this reason, in the category of renewable resources we cannot include anything else but the vegetal and animal biomass, most soil and water reserves and partially the mineral resources usable as building materials, for example.

Ores and fossil fuels (coal, oil, gas) have a replacement time of the order of hundreds of thousands or millions of years, which determines their inclusion in the category of non-renewable resources.

Managerially, the distinction between renewable and non-renewable resources is extremely important, as it leads to the conclusion that renewable resources need strategies meant to preserve their functional integrity and the productivity of the natural capital components, maintaining the exploitation rate under or very close to the rate at which these resources are produced or regenerated (Lester, R. Brown, et al., 1997).

For non-renewable resources, however, flexible strategies are needed, involving measures limiting the exploitation rates, identifying alternative sources and especially, technical measures of bio-geo-chemical recycling of the products obtained and of the residues.

One of the essential features of the natural capital, almost always neglected, is its structural and functional diversity.

The presentation of the problems up to this stage is giving us the possibility to highlight the structural and functional aspects of the ecological systems, which are actually arguments in the substantiation of the new model of socio-economic development: sustainable development.

Thus, Sustainable Development does not suppose only the need to maintain the natural capital as ratio over a critical level, but supposes especially the need for it to preserve a maximum level of structural and functional heterogeneity, on which long-term development opportunities will actually depend.

Thus, the issue of preserving biological and ecological diversity is not a collateral problem representing just a small defect for the political decision factor, but is the very issue of preserving the natural capital as development support and sustainability guarantee.

The last 3-4 decennia of the past century were marked, incomparably more than any other period in the history of mankind, by the evident process of deterioration of the perceptible environment, via the toxic, often lethal effects, of the by-products and final products resulted from the processes of the socio-economic system. These products have come together and have become concentrated in the major compartments of the environment (troposphere, lithosphere, hydrosphere) and have affected the taxonomic hierarchy of the biosphere, degrading at the same time the abiotic environment.

The reactions to the tendencies of degrading the environment by damaging anthropic activities have diversified as the effects were seized, assessed and linked to a series of concrete human activities.

Consequently, actions delimiting the pollution effects, and, very recently, actions meant to diminish and prevent pollution, have been designed and have increased in diversity.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Compared to the alarmingly growing tendency of the process of elimination of various plant and animal species, a phenomenon generating the worrying narrowing of biodiversity, the answer was mainly actions of identification of the vulnerable and endangered species and the elaboration of special protection programmes.

At the same time, for endangered habitats, the answer was ecological reconstruction actions, consequently also avoiding the elimination process.

The real process of erosion of biological diversity following the aggressions of the socio-economic systems could not be stopped by sectorial protection actions regarding certain species or the reconstruction of some endangered habits. For this reason, organisms such as E.U. or U.N. have found themselves obliged to adopt regional or global conventions on biodiversity protection, climate change, reducing greenhouse emissions etc.

Two mentions are needed, helping us to make a distinction between biodiversity in a broad sense and in a restrained sense, the latter being promoted by those supporting a "development at all costs":

- For a long time, this concept designated only the richness of species without taking into account the diversity of the structural and functional units of the abiotic environment.
- The socio-economic systems, which include a great diversity of the social, cultural and patrimonial capital, were not taken into account when biodiversity was discussed.

BIODIVERSITY AND ECOSYSTEM SERVICES AS FUNDAMENTS OF SUSTAINABLE DEVELOPMENT

While in its broad sense the concept of biodiversity includes the totality of the organized units constituting the natural capital, including the human species and the totality of the capital created by them, it results that the syntagm "diversity of the ecological and biological systems" would be more adequate for the concept of biodiversity in a broad sense.

Diversity needs to be analyzed and quantified at least on four distinct levels

- Of the species and species hierarchy
- Of every development level along the hierarchic line
- Of each system with supraindividual organization
- Of each genetic structure (Popescu C., 2003)

Consequently, biodiversity conservation ought to be designed and realized based on strategies, programmes and methods, pursuing on the one hand a sustainable use, namely within the limits of the carrying capacity of the natural capital components, and, on the other hand, a management of the development of the socio-economic system, namely of the capital created by the human populations.

Therefore, the diversity of the biological and ecological systems ought to be analyzed at least on these levels:

- Diversity as support of life
- Diversity of the biological systems in the species' hierarchy
- Diversity of the genetic structure of the population and of the species, including of Homo sapiens

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Ethno-cultural diversity of the socio-economic systems

The extension and operationalization of the biodiversity concept was necessary given the numerous attempts of reducing the diverse biodiversity forms, by supporting new ecosystem degradation techniques.

Governmental experts, as well as those of important financial organisms, still have the tendency, even to this day, of interpreting biodiversity restrictively, stating that affecting the environment is a natural process of technological development, and the solution is possible by new developments.

We need to mention that the 2002 Johannesburg meeting is a proof that the political decision factors have understood that they need to give up on speculative arguments and have seen themselves obliged to adopt, at least formally, clear measures meant to prevent environmental degradation.

Political decision factors and managers have had to admit that important for long-term development is the creation of the conditions needed for a sustainable development and implicitly for preserving biodiversity.

The large recognition of this need has been supported at least by the following arguments:

- The effort for preserving biodiversity cannot focus only on the ecological systems, arguing that they would integrate almost all the species, of which the great majority are unknown.
- It is equally necessary to preserve the habitats assuring the complex ecological-fundamental processes, and, naturally, to avoid the elimination of certain species.

Out of the total of about 50,000,000 species existing on Terra, over 90% are invertebrate species (fungi, bacteria), not yet studied, whose salvation would not be needed, since their contributions to the functioning of the ecological systems have not been quantified yet.

Conserving or maintaining the structural-functional integrity within the stability domain of a given natural or semi natural ecological system involves, to the same extent, maintaining the trajectory of the abiotic compartments' dynamics and the dynamics of the biotic compartments' trajectory, but also the interactions between them.

Thus, the term interconnectivity is introduced, representing the necessity of permanent intercommunication of the components, in the sense of support of life, one for the other.

When analyzing the development of each ecological system as a complex long-term process, the general tendency is to assure the mechanisms by which the number of species or populations can increase, without considering the necessity that, within them, specializations and interactions need to intervene, able to intensify the environmental services, such as maximizing the energy flow, recycling nutrients, and regulation, balance and stability mechanisms etc.

The result of such a process appears, therefore, in the extension of the stability domain on a spatial level, while the analysis on a time scale specific to large systems would be obligatory.

Therefore, one cannot at all speak about the existence of useless species within a complex model, but in different growth stages, the functioning of the ecosystem relies successively on some or the other of the species comprised in the taxonomic hierarchy.

Consequently, even though, at the same time, not all the elements composing the ecosystem on the spatio-temporal scale of analysis are equally important, each species has its distinct role.

It logically results that to preserve the ecological structures on the level of the national and macro regional complexes, one has to take into account the maintaining of a mosaic of natural and semi natural systems, to include all the types of ecosystems and preserve at least half of their surface. The conserva-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion of the ecological systems therefore involves their interconnectivity, assured via natural corridors or, where they do not exist, the technological and ecological reconstruction of such corridors is needed (Popescu C., 2003).

The connectivity of the natural and semi natural systems is an essential condition for the dispersion of the species within their area, for their movement, for the directions of the new gradients modified given the climate change, the consideration of the elements highlighted having to be done in fact by operative policies and strategies, on each State or State Union level.

The European Council established, on the occasion of the environmental ministers' summit of Sofia, in 1996, that on the level of Europe it is necessary to create a European network of ecological systems interconnected through management programmes, comprising the conservation of the natural and semi natural systems specific of their different European regions, the reconstruction of some endangered habitats, the rehabilitation of certain ecosystems and their reconnection, and special programmes of sustainable management for the anthropized systems.

All these are necessary since the biological systems' diversity actually holds a huge genetic fund (an immense genetic information bank), a fund assuring, on the one hand, the natural process of species dynamics and, on the other hand, information for the technological research concerning the correct dynamics of the anthropized systems and the correction of their trajectories, imitating nature.

Very recently, the syntagm bioindustrial development has emerged, in the sense of avoiding the negative tendencies generated by the idea that man masters nature. It is acknowledged in this way that the anthropic factor, though being the command subsystem, is part and parcel of the ecosystem.

Moreover, during the last decennium, there emerged the idea of creating a complementariness between the high-performance industries of the developed countries and the diversity of the genetic resources of the underdeveloped countries, in the sense that by the "Convention on Biodiversity" the developed states are obliged to return at least 20-25% of the profits obtained by exploiting the genetic patrimony to the underdeveloped countries.

These financial resources would have the role of funding the increase of the territories called "protected areas", namely precisely of preserving this invaluable genetic patrimony, the main support of life on our planet.

Chapter 7
Appropriate Extension Methodologies for Agricultural Development in Emerging Economies

B. S. Famuyiwa

ABSTRACT

Over two-thirds of the world's poorest people are located in rural areas and engaged primarily in agriculture and agricultural-related activities for their livelihood. Therefore, the future of most underdeveloped and developing nations depends on agriculture. Most African Countries have agricultural dependent economies that are hinged to rain-fed agriculture and based on smallholdings. These countries are referred to as countries with emerging economies and characterized as having low to middle per capita income and represent 20% of the world's economies. This chapter discusses; concepts of agricultural extension methodologies assessed from past to present, appropriating extension methodologies to encourage agricultural development, identifying roles of agricultural extension activities in agricultural development and factors influencing the choice of appropriate extension methodologies in emerging economies. It concludes with the constraints to sustainable agricultural development and extension methodologies which if removed will have the potential for progression towards economy development. Developing countries should fashion a sustainable extension system that will be socially acceptable and culturally compatible, economically viable and environmentally friendly.

INTRODUCTION

More than two-thirds of the poorest of the poor populations of the world are located in rural areas and derive their livelihood from the rural environment. More than 70% of such people in developing nations are engaged in agriculture and agricultural-related activities. Therefore, the future of most underdeveloped and developing nations depends on agriculture. Most African nations have agricultural dependent economies that are hinged to rain-fed agriculture and based on smallholdings. The smallholders depend mostly on traditional tools which, though easily maintained, are energy sapping and make agricultural production laborious. Many of the innovations that are developed by researchers, especially in the universities and research institutes, are wasting away on their shelves. Agricultural Extension agencies that are tasked with disseminating the developed innovations, are either moribund, the innovations/technologies have not been transferred to them or innovations are inappropriate. In some instances, scientists are not ready to release their innovations because they think that the extension agencies that disseminate the innovation to farmers will take their glory. All ofthese contribute to continued poverty among farmers.

Extension is a service or system which assists farm people, through educational procedures, in improving farming methods and techniques, increasing production efficiency and income, bettering their levels of living and lifting the social and educational standards of rural life (Maunder,1973). Agricultural extension can be defined simply as the transfer of useful information from a source to the farmers or rural dwellers. Swanson et al. (1997) defined agricultural extension as the extending of relevant agricultural information to people. Piercell and Anderson (1997) defined agricultural extension as a process of assisting farmers to be aware and adopt improved technology from reliable sources to enhance production efficiency, income, and welfare of farmers. The main goal of agricultural extension is to improve the socio – economic condition of farmers and rural dwellers. As a discipline, it finds itself articulating appropriate knowledge and decision-making capacity to determine how factors of production can be best utilized to improve the standard of living of rural dwellers through appropriate extension methodologies (Famuyiwa, 2013).

The general objectives of extension are to:

1. Assist farmers to discover and analyze their problems and identify their felt needs.
2. Develop leadership among farmers and help them in organizing groups to solve their problems.
3. Disseminate research information of economic and practical importance in a way farmers would be able to understand and use.
4. Assist farmers in mobilizing and utilizing the resources which they have and to identify what they need from outside.
5. Collect and transmit feedback information for solving management problems.

Agricultural extension, therefore, provides the indispensable elements that farmers need to improve their agricultural activities. This has made agricultural extension to be a crucial input in agricultural development, especially in Nigeria.

Most developing nations of the world especially in Africa have implemented various agricultural extension methodologies. Most of the methodologies are transferred from a country where it has been successfully implemented, to other countries regardless of the farming system and culture of the country. In addition, some funding agencies also sponsor and fund agricultural extension methodologies in developing countries. As soon as the funding ceases, the project also ceases. A good example is Agricultural

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Development Project (ADP) which was jointly funded by the World Bank, Federal and State governments in Nigeria. The ADP operated the Training and Visit (T&V) agricultural extension approach in Nigeria. This project was implemented between 1985 and 1995. But, after the cessation of the World Bank counterpart funding in 1995, technology delivery by the ADP progressively declined to the extent that State's ADPs found it difficult to pay salaries and to provide funding for other operating transaction costs (Agwu &Chukwuone 2005). This decline in the World Bank funding according to Havnevik et al. (2007) was not limited to Nigeria, it was part of the Structural Adjustment Policy of the Bank that adversely affected Africa. Though successes were recorded during the implementation of the project, it was not economically viable. If developing nations could create sustainable technologies, these would support their systems over a long period.

In the light of this, developing countries should fashion a sustainable extension system that will be socially acceptable and culturally compatible, economically viable and environmentally friendly. It has been discovered that most agricultural extension approaches and methodologies that were borrowed or sponsored by external agencies in developing countries did not involve farmers in a participatory process. Any sustainable agricultural extension approach or methodology to be adopted in developing countries, must guard against the above mentioned issues if rapid growth in agriculture is to be delivered and to enhance food security.

It might be useful at this point to differentiate between the terms 'approaches' and 'methods' in agricultural extension as used in this chapter.

Approaches: An approach in agricultural extension connotes the way or avenue to get things done. It can also be seen as the manner in which a problem is solved. Anandajayasekeramet al. (2002) referred to the concept "approach" as the "essence of agricultural extension system". They added further that "approach is the style of action within a system and embodies the philosophy of the system". In an agricultural extension system, an approach is the framework and structure of the system which serves as the pathway that guides in a program of action.

Method: This refers to the process and techniques used by extension agencies to get a task done. Examples include visits by extension agents to a group or a family, demonstration of skills to a group by extension agent and so on.

This chapter reviews the past and present agricultural extension approaches and methods. The understanding of these along with an in-depth view of their success and failures will assist in building appropriate and sustainable agricultural extension approaches and methods for the future. These will bring rapid development to the wellbeing of farm families, agriculture and the environment.

FACTORS INFLUENCING CHOICE OF APPROPRIATE EXTENSION METHODOLOGIES IN EMERGING ECONOMIES

Emerging economies are defined and characterized as economies having low to middle per capita income and represent 20% of the world economies. However, they can further be described as countries having low levels of human capital, high levels of poverty and under-nutrition, and high population growth rates. There are also the predominance of agriculture, low levels of industrialization, and urbanization but rapid rural-to-urban migration, dominance of informal sector, underdeveloped labor, financial, and other markets (Kumar, 2015 and Wikiversity, 2015).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

For easy dissemination and diffusion of innovation, some cogent factors have to be appropriately considered in choosing the method to be used among the array of methods available for extension activities. The majority of agricultural projects and programs that are extension based, fail or are moribund because some of these factors are not carefully considered.

Technological Applicability

Technology improvement is an indication of development. However, challenges are faced in the areas of applicability, adaptability, and acceptability into the system. Before now, dissemination of innovation was undertaken using a top-down approach which makes diffusion difficult and adoption almost impossible. The alternative Farmers' Participatory Approach (FPA), has so far yielded better results. This approach promotes the involvement of the target group, the farmers or the end-users, right from the conception of the idea through to the completion. This approach is being employed in National Fadama programs implemented in Nigeria. This approach empowers the target group to input their ideas for sustainable adoption of the innovation. The general aim is to see if the innovation fits into their felt needs.

Economic Feasibility

Economic feasibility of a method is very important for agricultural development. The final goal of development has to do with the cost effectiveness of the method and its approach. A sustainable method is the one that is market and farmer driven; meeting the needs of consumers and profitable to the farmers. In the case of technology or innovation to be adopted by farmers, it will only be appropriate if it adds to the income of farmers, either by cost reduction or by yield increase.

Another area of economic feasibility advanced by Campbell and Barker (1998) asks the question: Do farmers have financial resources to implement the innovation, in order to derive the benefit that will accrue? In the case of drying cocoa beans, this has been a very serious problem in developing countries that produce 75% of the world cocoa. Does the individual farmer have the financial capability to buy a Simona dryer, which was developed as an alternative and useful method for drying cocoa beans in humid areas?

Environmental Safety

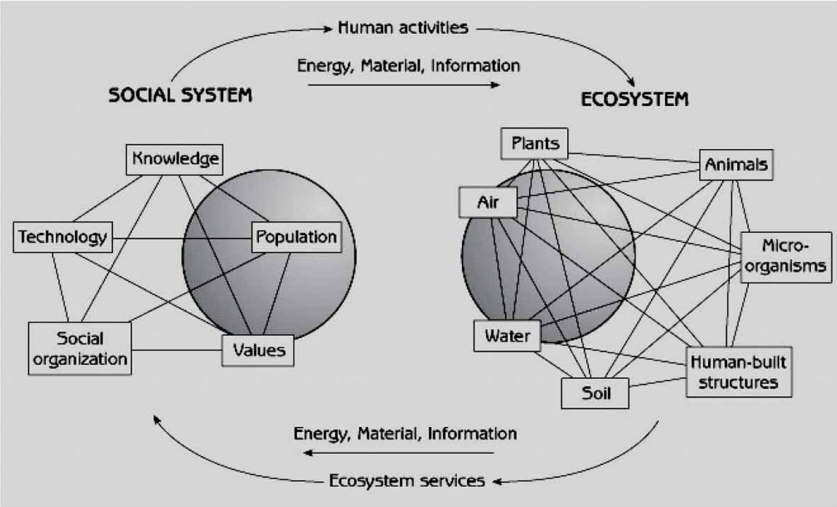
There are inter dependencies in the systems that make up an environment; the social system and the ecosystem (Marten, 2009) as shown in Figure 1. These two systems interact with each other and they both transmit energy, materials and information to each other. The social system is represented as the human activities, while the ecosystem is made of biotic and abiotic organisms. These interactions need to be guided through appropriate methods to enhance environmental safety.

Serious environmental issues have developed in emerging economies because of farmers' low income, high population, and high illiteracy level. Indiscriminate use of pesticides and other chemicals on the farm have been identified by different studies (Sosan and Akingbohungbe, 2009; Ogunjimi and Farinde, 2012 and Famuyiwa, Torimiro, and Adesoji, 2013). The diagram below as described shows the interaction between environmental elements; social system and ecosystem.

Technology in the social system brought about the use of pesticides for the control of pests on cocoa farms. Farmers, because of lack of knowledge on the use of pesticides or their anxiety to increase yields,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Interaction of the human social system with the ecosystem (Marten, 2009)



tended towards the indiscriminate use of pesticides. The indiscriminate use of chemical/pesticides which is a human activity from the social system consequently pollute the ecosystem and brings about chemical residue in farm products like cocoa beans that are made into chocolate and consumed by human beings. These chemical residues have been identified as causative agents of diseases such as cancer.

The goal should, therefore, be to carefully design dissemination methods of non-pesticide procedures or organic farming approaches to increase farmers' yield and the marketability of their farm produce.

Socially Acceptable

A social system is an interrelationship between the linkages that exist among all the elements of a society namely; individuals, groups, and institutions that make these elements form a whole. Since these elements are knitted together, moving the society from the status of developing to developed, will require methods that will be acceptable to them. However, introducing a paradigm shift needs a well-designed methodology to achieve acceptability.

Culturally Acceptable

The cultural system is located within the larger society or the social system. It is defined as interrelationship of six elements namely; traditions and norms; language; arts and literature; religion and belief systems; forms of government; and economic systems. Agricultural productivity that leads to development depends largely on how knowledge is adequately managed, shared and applied. Early theorists emphasized that behavioral change among farmers is a prerequisite of the agricultural modernization process. Hence, in order to achieve development in emerging economies, the method of dissemination and appropriate diffusion of innovation need to be carefully chosen. No matter how beautiful an innovation is, if it is not culturally acceptable the required adoption level will not be attained. This factor is highly considered in designing extension programs.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sustainably Suitable

Sustainability is the ability to undertake a project or process using the present resources, without compromising the future resources. ICCO (2008), posited that practices of cocoa farming should be considered as sustainable in terms of economic, environmental and social. However, the United Nations (2015) in its meeting (25^{th} – 27^{th} September 2015) deliberated on 17 points Sustainable Development Goals (SDGs) by member countries, the majority of which are emerging economies. The goals SDGs discussed include the issues of;

1. No poverty
2. Zero hunger
3. Good health and well-being
4. Quality education
5. Gender equality
6. Clean water and sanitation
7. Affordable and economic growth
8. Decent work and economic growth
9. Industry, innovation, and infrastructure
10. Reduced inequalities
11. Sustainable cities and communities
12. Responsible consumption and production
13. Climate action
14. Life below water
15. Life on land
16. Peace, justice and strong institutions
17. Partnerships for the goals

Audience Configuration

A proper understanding of the audience is another key factor in program development. Messages need to be specific as audiences are also specific. There is divergence in culture, gender, education and access to resources. The International Food Policy Research Institute (IFPRI, 2011), identified that gender relations are culture and context specific. It was specifically stated that addressing gender issues is one of the most effective ways of achieving development and reducing poverty in the society.

Content Relevance

The content flow between research and farmers is termed “information”; information about methods, innovation or advice. Information to meet the competitiveness of the stakeholders in agricultural development has to be content-specific to achieve desired sustainable economic growth. Studies according to Adedeji et al. (2013), and Mwangi and Kariuki, (2015), showed that the adoption rate of most technological innovations disseminated in emerging economies is low. The majority of these failures (low adoption rates) are attributed to inappropriate methods of extension delivery of the technology; innovations are not economically feasible, socially acceptable, technologically adaptive, culturally compatible, environ-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

mentally compliable and hence the innovations are not sustainably practiced. Technology in isolation, without regular guidelines by the extension professionals and the use of appropriate methodologies, cannot help in enhancing the productivity of any economy. Hence, it has to be content relevant to the specific environment where it is to be promoted.

Role of the Agricultural Extension in Agricultural Development

The role of agricultural extension in the past was to transfer new technologies from researchers to farmers. This role has not been able to meet the developmental challenges in developing countries.This is because most of the technologies disseminated to farmers have not been able to solve farmers' production problems. Agricultural extension's role in the recent past in most developing countries was seen to help farmers make their own decisions. Extension only increases the number of options from where the farmers can choose and also highlights the consequences of each option. At this point, it is the role of extension to answer questions that may arise when the knowledge of the farmers is limited. In a way, extension still guides in decision making.

Agricultural extension promotes and enhances the learning process among farmers. Farmers have many avenues by which they can learn. For example, people say, 'experience is the best teacher'. Farmers learn from their past experiences, from neighbours, from extension demonstrations as well as discussions with other experienced farmers. Agricultural extension must assist farmers in this learning process. Farmers are known to be knowledgeable in their area of production; extension should not look down on the farmers, but should be able to also learn from the farmers.

For extension to achieve its own set objectives, it is important to do what other agencies have left undone. For example, extension should include sources for agricultural inputs as well as marketing information in their programs or activities. It will be a waste of time and effort for an extension agent to introduce the use of fertilizer to a group of farmers who do not know the source of the input, fertilizer. Also, it will not be helpful for both the extension agent and the farmer to have a bountiful harvest without a market for the harvest. Providing guidance to the farmers in this regard would afford credibility to the extension agent and hasten the economic development of the farmers. Extension may also assist in supervising the appropriate use of loan/ credit and ensuring regulation adherence.The approach of the Cocoa Research Institute of Nigeria (CRIN) in solving coffee farmers' problems is designed as market and farmer driven approach to change farmers' attitude towards coffee cultivation. When farmers' problems are addressed with effective solutions, it is always easy to adopt innovations.

It has been observed that valuable local knowledge and resources are underutilized. Extension should harness the knowledge of 'indigenous' and rural people that are often termed as 'primitive' or 'unscientific', then pass them to researchers to transform and improve. This is important because what the farmers know and believe can develop them.

Appropriateness and Selection of Extension Methodologies for Agricultural Development

Extension is an ongoing process of getting useful information to people and then assisting those people to acquire the necessary knowledge, attitudes and skills (ASK) to utilize this information or technology for the purpose of improving their quality of life. The term, 'agricultural extension', narrows the focus

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and defines the area to which the extension process is applied. Without extension, the farmers would lack access to the support and services required to improve their livelihoods and other productive activities.

Extension is not concerned directly with generating knowledge. This is done in specialized institutions such as agricultural research centres, agricultural colleges, and Universities of agriculture.

Researchers neither have the time nor are they equipped and trained for the job of ascertaining from the farmers their field problems and of persuading farmers to adopt technologies. Similarly, it is not always practical for the farmers to visit the research stations and obtain first-hand information. Thus, there is a need for an agency that could interpret the findings of research to the farmers and to carry the problems of the farmers to researchers for solutions. This process is guided and supported by Extension Agents of the extension agency who work at the field levels and have direct contact with farmers and their families. The task of extension personnel is bringing scientific knowledge to farm families in the farms and homes. The objective of the task is to improve the efficiency of agriculture.

AGRICULTURAL EXTENSION SYSTEMS/ APPROACHES IN NIGERIA

A number of systems have been developed and applied in the process of agricultural development through various programs and projects with extension outfits in Nigeria. The extension system/approaches are categorized into two:

1. General Clientele Approach: These include a variety of approaches such as
    a. Ministry-based general extension
    b. Training and visit extension (T&V)
    c. Integrated (Project) approach
    d. University-based extension
2. Selected Clientele Approach: These include:
    a. Commodity based extension
    b. Commercial extension service
    c. Client-based and client-controlled extension

In an attempt to realize the expectations of increase in food production for the teeming population, successive governments in Nigeria have, at one time or the other, put in place many agricultural policies and programs as well as projects. Such programs that were implemented include, as shown in Box 1.

Box 1.

The National Accelerated Food Production Programme (NAFPP, 1972); First generation Integrated Agricultural Development Projects (1st generation ADPs, 1975); Operation Feed the Nation (OFN, 1976); River Basin Development Authorities (RBDAs, 1976); National Committee on Green Revolution (NCGR, 1979); the World Bank Assisted Agricultural Development Projects (2nd generation ADPs, 1986); Better Life Programme (BLP, 1989); National Agricultural Land Development Authority (NALDA, 1991); Family Support Programme (FSP, 1992); Family Economic Advancement Programme (FEAP, 1997); Fadama Development Programme (FDP, 1982); National Special Programme on Food Security (NSPFS, 1994) and the Poverty Eradication Programme (PEP) since 1999. Other efforts of note are the involvement of young school leavers and graduates in agricultural production through programs such as Farm Settlement Scheme (FSS, 1957); National Directorate of Employment (NDE, 1986); School to Land and Back to Land programme (SLBLP, 1985), National Economic Empowerment and Development Strategy (NEEDS, 2004) and recently the Farmer fields School (FFS) and Growth Enhancement Scheme (GES) under the Agricultural Transformation Agenda (ATA) (Olaniyi, 2010).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

All these programs and projects were targeted at enhancing food security and improving the standard of living of farmers through the use of various agricultural extension approaches and methodologies.

Extension Methods Incorporated in Various Agricultural Development Programs in Nigeria

Successes recorded in Nigeria in relation to agricultural development, could be traced to the implementation of agricultural programs with extension components and coupled with the selection of appropriate extension methodologies. Agricultural Extension has two dimensions (a) Educational and (b) Communicational. Both of these dimensions must be incorporated into agricultural development programs to achieve successful results.

The *educational dimension* involves the change agent (extension worker) attempting to build human capacity through the use of effective teaching methods to improve knowledge and develop the skills of the clientele (farmer) along with acquiring knowledge on improved practices to enhance production and marketing activities (Williams et al.1981). The purpose of education is for immediate action or to solve a problem, hence it is different from the formal education.

The *communicational dimension***:** This involves dissemination of information to the clientele on new technologies or innovations. It also involves exchange of ideas that could provide the basis for research or feedback on the use of previous innovations. Therefore, extension is involved in dissemination of useful information using the appropriate methods.

With various extension approaches, the choice of the communication channel or method generally depends on the number and location of the target audience and the time available for communication. The extension methods are categorized into: individual methods, group methods, and mass methods. Each of these methods has both advantages and limitations. The extension agent has to choose a particular appropriate method or combination of methods according to the needs of the situation. Let us now look at different extension methods in detail and their importance for small farmers in developing countries.

Individual Methods

Individual methods, also known as face-to-face methods, are the most universally used extension methods in both developed and developing countries especially in Nigeria. The extension agent meets the farmer at home or on the farm and discusses issues of mutual interest, giving the farmer both information and advice. The atmosphere of the meeting is usually informal and relaxed, and the farmer is able to benefit from the agent's individual attention. Individual meetings are probably the most important aspect of all extension work and are invaluable for building confidence between the agent and the farmer.

Learning is very much an individual process and, although group methods enable the agent to reach a greater number of farmers, personal contact and the individual attention of the extension agent are important supports for a farmer. The personal influence of the extension worker can be a critical factor in helping a farmer through difficult decisions, and can also be instrumental in getting the farmer to participate in extension activities. A farmer is often likely to listen to the advice given by the extension agent and will be grateful for this individual attention.

The individual contact method between the extension agent and the farmer may take a number of forms. These include:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Farm and Home Visits

Farm and home visits are the most common form of personal contact between the agent and the farmer and often constitute over 50% of the agent's extension activities. Because they take up so much of the agent's time, it is important to be clear about the purpose of such visits and to plan them carefully. Farm and home visits can: familiarize the extension agent with the farmer and family; enable provision of specific advice or information to the farmer; build up the agent's knowledge of the area, and of the type of problems which farmers face; permit explanation of a new recommended practice or follow up and observe results to date; arouse general interest among the farmers and stimulate their involvement in extension activities.

The following are involved in Farm and home visits.

1. **Planning for the Visit:** This include: extension agent makes an appointment with farmers if possible, decide the purpose of the visit; review previous records and information; prepare specialized subject matter that might be required; and schedule the visit into the overall work plan.
2. **Making the Visit:**
    - Be punctual for the visit.
    - Greet the farmer and family.
    - Praise the farmer's work.
    - Encourage the farmer to explain and discuss any problems.
    - Provide any technical or other information required.
    - Record the details of the visit.
    - Plan with the farmer the time and purpose of the next meeting.
3. **Recording and Follow-Up:** The purpose of farm and home visit will be lost if its content and conclusion are not recorded and no follow-up action taken. Therefore, record the purpose of the visits and decision resulting from visit; arrange for any follow-up information or advice to be sent and schedule the next visit to the farmer.

Advantages and Limitations of Farm and Visits

Farm and home visits are perhaps the single most important aspect of the agent's work in terms of establishing rapport with the farmers in their area and of building the trust and confidence that are vital to the success of their work. However, farm visits take up a lot of time and only a few farmers can be reached. Farm visits are, therefore, a costly extension method and for this reason they must be carefully thought out and planned. The visits must make an impact and must lead to positive agricultural development if they are to justify their cost. Finally, the agent should beware of visiting some farmers repeatedly. This would not only severely limit the range of activities, but could also arouse the resentment of other farmers who might feel excluded.

When is the methodology for personal contact used? It is worthy to note that individual methods are useful when there is sufficient time or in the slow periods of farming. Also, when the farm family is operating as a production unit.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Office Calls

Along with the extension agent visiting the farmer, it is expected that from time to time the farmer will visit the agent in the office. Such a visit is often a reflection of the interest which the agent may have aroused among the local farmers. The more confidence local farmers have in an extension agent, the more likely they are to visit the extension office. Such office visits are less time consuming for the extension worker, and offer some of the advantages of a farm visit. While no extension agent would wish to be overwhelmed by such visits every day, farmers should be encouraged to drop in, if it is convenient, for them to make the exchange of visits two-way. As with farm visits, office visits similarly have to be prepared. Although the agent may not know when a farmer is likely to drop in, the extension office can be arranged in such a way that the visitor feels at ease and can understand the activities of the office.

Telephone Calls

The deployment of information and communication technology in extension delivery service makes the use of mobile telephones relevant. Telephone calls and office visits serve a similar purpose. It is improbable that the extension worker will deal with many of the farmers in the area (if at all) by telephone. If the telephone is used, however, it should not be for long discussions but for passing on specific advice or information. Whatever the reason, it is important for the agent to speak clearly, to note the main points discussed and to enter them on the farmer's record.

Group Methods of Extension

The extension agent should consider the use of the group approach in work with farmers. The use of groups in extension has become more common over the past decade, and indeed, a number of new ideas have emerged about how groups may be used most effectively. For example, the widespread Small Farmer Development Programme (SFDP) in Southeast Asia was based upon group methods and has produced two manuals which detail the approach of group extension work. Furthermore, in Latin America, work with extension groups in Brazil and Colombia has shown the usefulness to extension of the formation of extension groups, and how these groups can support extension activity. Empirical evidence shows that a group of 5–7 members usually works best for achieving optimum productivity and participation. However, due to cost constraints, normally a group is formed comprising around 20–25 members. Some situations, such as microcredit, input acquisition, and marketing, may demand a larger group for initiatives to be cost effective. Various projects indicate that optimum membership ranges between 20 and 50 people, but groups of less than 20 farmers can also function well as reported by Sanginga et al. (2001), and Pretty, (2003). It is worthy to note that as with any social unit, conflicts within groups may arise. What matters most is how conflict is managed (Anandajayasekeram et al. 2008). Conflict, depending on the types, may be harmful or beneficial to the group. Generally, it is poor management of conflicts that weakens groups as it may lead to dissatisfaction of members, withdrawal or total collapse of the group. This is also applicable to extension work in many countries of the world.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Advantages of Group Methods

It has been seen that individual extension methods can be costly both terms of time and scarce extension resources, and that they reach only a limited number of people. There is also the danger that too much emphasis upon individuals can lead to undue concentration on progressive farmers to the detriment of the poorer farmers. The group method has advantages in the following aspects.

Coverage

The group method offers the possibility of greater extension coverage, and is therefore more cost-effective. Using the group method, the extension worker can reach more farmers and in this way make contact with many more farmers who have had no previous contact with extension activities.

Learning Environment

Extension groups offer a more reflective learning environment in which the farmers can listen, discuss and decide upon their involvement in the extension activity. The support of the group helps an individual farmer to make decisions and determine a course of action. The group creates a supportive atmosphere, and individual farmers can gain greater self-confidence by joining others to discuss new ideas and try out new practices.

Action

The group method brings together farmers with similar problems. Often, these problems demand concerted action (tackling the erosion of a hillside, for example), and such action can be taken more effectively by a group rather than by an individual, who may be overwhelmed by the enormity of certain problems.

Types of Group Extension Methods

Group Meetings

Calling the members of a group or the inhabitants of a local community together for a meeting is the most common group extension method. Although there may be an air of informality about such meetings, they will nevertheless need to be carefully thought out and planned. The group or community meeting is a useful educational forum where the agent and farmers can come together, and ideas can be openly discussed and analyzed. The agent may have information about a new government policy, or agricultural idea or practice. The agent will want to introduce this new information, to seek the opinions of community members and gain their support for extension activities. Indeed, there are a whole range of objectives for such community or group meetings:

Planning the Meeting

There are two important decisions to make regarding the time and location. A date and time for the meeting must be decided and announced. The time should be convenient to all concerned and should

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Forms of group meetings in agricultural extension systems in developing economies

Types/ Form of Group Meetings	Description	Purpose
Information meetings	The agent calls the group or community together to communicate specific new information which is thought will benefit them and upon which their advice is sought.	Review a particular problem, suggest a number of solutions and decide upon a course of action.
Special interest meetings	Topics of specific interest to a particular group of people (e.g., horticulture, bee keeping, or dairy farming) are presented and discussed in detail at a level relevant to those participating.	Discuss specific issues that are related to particular interest group based on their needs.
General community meetings.	Men, women and young people of a community are invited to attend and discuss issues of general community interest. It is important to hold such general meetings occasionally so as to avoid any community group feeling that it is excluded from extension activities. Whatever the case, however, the agent should only call a meeting if it can be useful. If farmers feel that their time has been wasted in coming to a meeting, they may refuse to come to subsequent meetings and thus frustrate the agent's work. The agent should make careful preparations and check a number of important arrangements which will be necessary to ensure a successful meeting.	Mainly for the purpose of general community interests especially as the situation demands..
Smaller meeting	Smaller meetings are more likely to meet the specific needs of those who attend. When plans are to be made or decisions taken, a small number of representatives will usually achieve more than a large gathering of all community members. On other occasions, it will be important for the meeting to be open to as many people as possible.	Ad-hoc committee to proffer solutions to a particular problem for a group of people.
Lecture and Discussion	A lecture or talk allows the agent (or other speaker) to convey a detailed, well-prepared message to the audience on a specific issue; for example, a new piece of technology, can be presented in this way, and illustrated by visual aids. It should be remembered, however, that the lecture is a particularly tedious approach to meetings and care must be taken to ensure that the audience will not get bored. Alternatively, in a discussion, many people are able to express points of view and ask questions. Discussions may be completely open and unstructured, or based on a prepared agenda of discussion points.	Presentation and deliberation of specific issues.
Formal Meeting	A formal meeting, with a chairperson, agenda and written record of proceedings. The chairperson keeps the meeting to the central issues, and the decisions of the meeting are recorded accurately so that they cannot be disputed later.	Appropriate when specific business/ issues has to be dealt with or decisions are to be reached for a particular group of people.
Informal Meeting	In an informal meeting, people feel free to express their own point of view and less dominated by the structure and formality of the proceedings. However, an open, unstructured discussion, although it allows all to participate, may result in a few people dominating the proceedings.	The same as for formal meeting

Source: Oakley & Garforth (1997)

avoid clashes with other events or activities. The meeting-place should be well-known, easy to access and appropriate for the form of meeting. The meeting-place should also be comfortable and have the necessary facilities. An extension agent should never hold a meeting at midday, on a very hot day, in the open sun. Such a meeting could be disastrous, as well as cause considerable discomfort.

After the above two issues have been considered, it may be useful for the agent to draw up a list of other arrangements to be made in preparation for the meeting. Such a check-list could include:

- Publicity for the meeting
- Seating arrangements

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Audio-visual equipment and material, or other educational aids
- Agenda, and order of events
- Guest speakers or other specialists who will contribute to the meeting
- Chairperson to take charge of the meeting; should be elected by the community
- Refreshments for speakers and, where necessary, other participants.

Conducting the Meeting

Even the most carefully prepared meeting can fail if it is not conducted in the right manner. While the above arrangements are important, the way the actual meeting proceeds will determine whether it will be a success or not. The agent must be conscious that interaction is with adults who do not want to sit for hours listening to a speaker talk endlessly. The agent should try to vary the agenda of the meeting: for example, a short talk, accompanied by visual aids, followed by comments and questions.

Variety of content, as well as a chance for the farmers to participate, will be important. In addition, the meeting must not extend too long. One-and-a-half hours are probably sufficient for a group or community meeting. It is better to have a highly productive, short meeting than one which rambles and loses effect.

The agent's role in the meeting should also respond to the circumstances. The agent should encourage the community to appoint a chairperson and should allow the chairperson to conduct business. The agent's role should be to inform and support, but not to dominate the meeting. Furthermore, the meeting should not resemble a class-room with the agent as teacher and the farmers as pupils. The agent should make every effort to ensure that during the proceedings the community members feel that it is their meeting and that they have a role.

As a guide to the proceedings of the meeting, the agent should keep the following points in mind. Start the meeting on time, then welcome community members and special guests, explain the purpose of the meeting and the programme to be followed, and begin the programme. Later, the agent should encourage questions and discussion, and be prepared to summarize the main points and note important decisions. The meeting should be closed with thanks to all concerned.

As the most commonly used form of group extension method, the group or community meeting will be most effective if carefully thought out and planned. After each meeting, the agent should make a brief record of the proceedings and the principal decisions taken and should also take any prompt follow-up action that has been decided.

Demonstrations

Farmers like to see how a new idea works, and also what effect it can have on increasing their production. Both purposes can be achieved by means of a farm demonstration. A good, practical demonstration is an invaluable method in extension work. The demonstration is a particularly powerful method to use with farmers who do not read easily. A demonstration will give such farmers the opportunity to observe, at first hand, the differences between a recommended new crop practice and traditional practices. The strength of the demonstration should lie in its simplicity and its ability to present the farmers with concrete results.

There are two principal types of demonstration used by extension agents - method demonstration and result demonstration.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Method Demonstration

Method demonstrations show and explain to farmers detailed procedures for implementing a technology. In the method demonstration, the farmer is shown step by step how, for example, to plant seeds in line, to use a mechanical duster to control insects, or to 'top' tobacco. The agent will probably be dealing with farmers who have already accepted the particular practice being demonstrated, but who now want to know how to do it themselves.

The main advantage of the method demonstration is that the extension agent can explain simple farming skills to a large number of people, thus increasing the impact of extension work. Moreover, as farmers are able to participate, there is a greater chance that they will benefit from the demonstration than if they were passively hearing it in a lecture.

The main limitation of a method demonstration is that, if there are too many farmers present, only a few get a chance to see, hear and do. The agent must be conscious that the demonstration is a learning experience and prepare the event accordingly. It is also vital that the demonstration be well thought out and competently conducted.

Result Demonstration

The main purpose of a result demonstration is to show local farmers that a particular new recommendation is applicable and beneficial under local conditions. Comparison is the important element in a result demonstration, for example, comparison: between using compost and no compost, between poor seed and selected seed, or between use of fertilizer and no fertilizer. "Seeing is believing" is an age-old expression, but one appropriate to a result demonstration. Until a farmer has actually seen the results of, for example, the application of a fertilizer, he will not be convinced by the agent's recommendation. By showing tangible results of a new practice recommended by the extension service, the agent can help to create confidence among the farmers and can greatly encourage them to try the practice themselves.

A result demonstration is an ideal way to present to farmers a comparison between traditional and new practices. It can also help to establish confidence in more scientific farming methods and increase the farmers' confidence in ideas originating from research stations. It shows proof of the value of a new practice. A result demonstration is also a useful tool that an agent can use to establish confidence among farmers in a new area.

Its major limitation is that it takes a long time to come to fruition and is thus a costly use of extension resources. If, in the end, for whatever reason, the new practice should fail, it could have disastrous consequences. Often such failures (for example, because of lack of rain) are outside the control of the agent.

Both method and result demonstrations are extension activities that require a lot of thought, careful planning and efficient execution. Although the two demonstrations differ somewhat in their purposes, they share a lot of common points and, in terms of their preparation and execution, they can be considered together.

Basic Principles for Demonstrations

Before the agent begins to plan and prepare for a demonstration, clarity about a number of key points will guide preparation and handling of the demonstration.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Participation. Where possible, demonstrations should be carried out on local farms with farmers' participation rather than on an extension plot or research station. Farmers will have more confidence if a demonstration is held on a neighbour's land, or if a new practice is shown by a fellow farmer, than if it is carried out by agents on extension's land. The more the local farmers can be involved in the whole process of a demonstration, the greater will be their self-confidence and readiness to learn.

Simplicity. Simple, clear-cut demonstrations of a single practice or new idea will be far more effective than ambitious and over-complex demonstrations that demand too much of the farmer. It is better to proceed step by step with a number of demonstrations than to try do to everything at once.

Learning.The demonstration is a learning environment and should be conducted in such a way that the farmers do in fact learn. A demonstration is a type of class-room, and the agent must be conscious of classroom requirements in terms of space, time, equipment and the teaching method to use.

Preparation. An extension agent should never contemplate holding a demonstration without careful planning and preparation. A demonstration hastily given could have disastrous consequences.

Planning the Demonstration

When the agent decides that a demonstration would be useful, time should be dedicated to planning and preparing for it. In this respect, a number of questions should be considered.

- What is the objective of the demonstration?
- Why is the demonstration the most suitable extension method?
- What would be the usefulness of the new idea to be demonstrated?
- When should the demonstration be held? When is the most convenient date and time both for the farmers and in terms of the application of the new idea?
- Where is the demonstration to be held? Which suitable location is the most convenient for the farmers?

The agent should work out in some detail answers to the above questions before proceeding any further. It is very important that the reasons for the demonstration be appropriate and clearly understood and that there is a realistic expectation that the demonstration will be of benefit to the farmers involved.

Preparing the Demonstration

The more carefully the agent can prepare all the details of the demonstration, the greater the likelihood that it will run smoothly. The following are the key areas of preparation.

1. Consult the local people and seek their help and advice in the preparation of the demonstration.
2. Prepare a detailed plan of the demonstration, the main issues to be covered, the sequence of events, the resources needed and the contributions required from other people.
3. Collect information and material available on the new idea or practice to be demonstrated, and make sure that the topic is familiar and that questions can be answered.
4. Check that all the support material is ready (for example, audio-visual aids, implements).
5. Select those farmers who will take part in the demonstration and brief them on the outline of events.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. Ensure that the demonstration has been publicized and that the farmers know exactly when and where it is to take place.
7. Visit the demonstration site beforehand to make sure that all is in order and that the site is appropriate.

Supervising the Demonstration

During the demonstration, the agent's role should be to supervise but not to dominate. Actively support the farmer who may be assisting in the demonstration, and encourage the others to participate as much as they can. The agent should be keen to ensure that all those present benefit from the demonstration. During the demonstration, therefore, the agent should:

Welcome the participants, make them feel at ease and ensure that they have all they require to benefit fully from the demonstration.

Explain the purpose of the demonstration, what is hoped to be achieved, and outline the various stages to be followed. Distribute any literature or other material which was prepared as a guide for the participants.

Conduct the demonstration in person or be ready to help the demonstrator farmer. Proceed at a pace the farmers can follow, and be prepared to repeat explanations or answer questions from participants. Emphasize key points and explain the practice step by step in simple words. In a method demonstration, ensure that all those who wish to do so, have a chance to practice the technique themselves.

Summarize the main issues or points which have arisen, encourage questions from the farmers and make sure that the participants have had every opportunity to try out or examine the practice being demonstrated.

Conclude the demonstration with a vote of thanks to all concerned, and with a few comments about any follow-up activities planned.

Follow-Up

It is important that any interest generated, or decisions taken at the demonstration be followed through. Farmers will feel let down if the agent does not do so. This follow-up will be useful for the agent as well. Demonstrations can often result in good contacts with local farmers, and the agent may be able to enlist their support for future activities. It is also important that the agent reflect upon the demonstration and evaluate its effectiveness. The agent should, therefore, write a report and prepare a record of the demonstration, noting the names of the participants, the effect achieved and personal impressions of the usefulness of the demonstration.

Field Days

Field days are usually opportunities to hold method or result demonstrations on a slightly larger scale, and are usually run in a more informal and less highly structured manner. The purpose is often to introduce a new idea and a new crop, and to stimulate the interest of as many farmers as possible. Experimental stations or other government centers may be used for field days, but it is more usual and profitable for them to be held on the land of a local farmer. There is a greater chance of making an impact if the field day is held on a farmer's land, and if the farmer plays a part in running it and explaining the purpose. Field days can range in size from a small group to annual events attracting hundreds of farmers. Since

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the aim is a general introduction to some new idea, there is less need to be concerned about limiting the numbers. The extension agent's role on the field day is to support the farmer on whose land it is being held, to offer general guidance to ensure that things run smoothly and to be available to answer questions and queries. It is probably better not to over-organize the field day but to try to create an atmosphere in which visiting farmers can inspect, inquire, question and generally get to know what is available. Although the agent will try to encourage an open and informal atmosphere for the field day, there is still a considerable amount of preparation needed to ensure that it runs well. The issues which the agent must consider are very similar to those noted under demonstrations and will not be repeated here. It may be useful, however, to bear a few additional points in mind.

- ***Limit*** the numbers to the capacity of the field, to avoid overcrowding.
- ***Ensure*** a good layout of field-day activities, with easy access and facility of movement around the field.
- ***Encourage*** the demonstrator farmer to take most of the initiative; give support but do not take over the field day.
- ***Provide*** suitably large visual material and also, if necessary, a loudspeaker, to ensure that all can hear. Check that extension literature and other material are available for information.
- ***Conclude*** the field day by bringing all the participants together, reviewing the day's proceedings and the main items seen and discussed, and explain any future relevant extension activities. A field day is a day out for farmers and is often a welcome relief from their daily hard work. The agent should, therefore, provide an interesting and well-presented exhibition, suitable refreshments and points of rest, and generally create an atmosphere in which the farmers will feel at ease and will be eager to know what is going on.

Tours

Farmers like to visit farms in other districts to see how they operate, what they grow and what kinds of problems the farmers there are facing. A tour is a series of field demonstrations on different farms, or at different centres, and can often attract a lot of interest from local farmers. The tour should give local farmers a chance to see how other farmers cultivate their land, and to exchange ideas and experiences with them. It is important, therefore, that the area to be visited be in some way similar agriculturally to that of the visiting farmers.

As with all other forms of extension, tours have to be well thought out, planned, prepared and conducted. The five stages of; determining the objective, planning the content, preparing the arrangements, conducting the tour and arranging for appropriate follow-up, will be a guide to the extension agent. However, it may be useful to add these points:

- ***Visit*** the area first to become familiar with local conditions, the farms to be visited, the route and road conditions
- ***Limit*** the tour to what is possible. It is better to do a short tour in which visitors can have a good look at local farms than to arrange an ambitious tour and be pressed for time. Don't tire the visitors out.
- ***Encourage*** the host farmers to do all the explaining and to take charge of the tour.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- ***Arrange*** for food and drink during the tour
- ***Conclude*** the tour with a short summary of the main events and note any comments or conclusions.

A field tour is an ideal method of involving farmers and of stimulating genuine interest in extension activities. It is also very useful in bringing farmers together to discuss common problems, and to gain useful experience of other areas.

Advantages of Group Methods (Based on the Experience of the Authors)

1. Enables Extension Agent to have face-to-face contact with a larger number of people at the same time.
2. Enables the Extension Agent to reach a selected part of the target group.
3. Facilitates sharing of knowledge and experience and thereby strengthen learning of the group members.
4. Reaches relatively large number of people, also offers more opportunities for interaction and feedback.
5. Satisfies the basic urge of people for social contacts.
6. Motivates people to accept change due to group influence. More effective than mass method in stimulating action. Less expensive than individual method owing to wider number of people reached at a time (Refer to Table 2).

Limitations of Group Methods

1. Wide diversity in the interest of group members may create a difficult learning situation.
2. Holding the meeting may be regarded as an objective itself.
3. Vested interests, power groups and village factions may hinder free interaction and decision making by group members.

Mass Methods

When Are Mass Methods Used in Extension?

Mass methods are used to

- Provide farmers with new awareness and draw their attention to certain new technology.
- Sharing experiences among successful farmers to other farmers in the community.

In this method, the Extension Agent communicates with a vast and heterogeneous range of people, without taking into consideration their individual and group identity. The method is used when a large and widely dispersed audience is to be communicated within a short time. There may be a few communicators and Subject Matter Specialists involved. The size of the audience may vary depending on the technique used.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Advantages

1. Suitable for creating general awareness among people.
2. Helps in transferring knowledge and, forming and changing opinions.
3. Large number of people may be communicated within a short time.
4. Facilitates quick communication in times of emergency.
5. Reinforces previous learning.
6. Cost effective due to large coverage.

Limitations

1. Less intensive method.
2. Little scope for personal contact with the audience.
3. Little opportunity for interaction with and amongst the audience.
4. Generalized recommendations hinder their application by individuals.
5. Little control over the responses of audience.
6. Difficulty in getting feedback information and evaluation of results.

CONSTRAINTS TO SUSTAINABLE AGRICULTURAL DEVELOPMENT AND EXTENSION METHODOLOGIES

Emerging countries are usually faced with constraints which are consequences of the factors that identified them as developing countries as earlier highlighted. More importantly, the 17 Sustainable Development Goals of the United Nations can only be achieved if the majority of the constraints are concertedly

Table 2. Summary of extension methods used in developing countries: Characteristics and functions

Characteristics	Individual Methods (Farm and Home visits, telephone calls, office calls)	Demonstrations (Method and Result)	Mass Media (radio, Television, Newspapers, Magazine, Bulletins)	Group Methods (group meetings, Lectures)
Creating Awareness of Innovation	0	0	XXX	0
Creating Awareness of own problems	XXX	XX	0	XXX
Knowledge transfer	XXX	XX	XXX	XXX
Behavioral change	0	0	0	XXX
Activating Learning processes	XXX	XX	0	XXX
Cost per farmer reached	AAA	AA	A	AA

(Van den Ban and Hawkins 2002)

0 --- Indicates Unsuitable X----The number of crosses indicates suitability

A ---- The number of As indicates level of cost incurred.

N.B. The points outlined in the Table 2 are based on research results (Olaniyi et al. 2006; Chaudhry et al. 2006; Cho and Boland, 2004) rather than the ordinary impression and opinions of individuals.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

attended to by member countries. Conclusively, the way forward to solving the challenges facing the emerging countries will only be attained through the Sustainable Development Goals which are embedded in the issues stated below. These are the major constraints jointly summarized by the authors based on their experiences and studies; affecting extension activities in Nigeria.

1. **Lack of Strategic Planning that Indicates Future Directions:** Madukwe (2008) in his Professorial inaugural lecture describes agricultural extension in Nigeria as 'practice without policy'. This situation makes it difficult for extensionists to operate effectively since the majority of their activities are not legislated.
2. **Inadequate Monitoring and Evaluation Systems:** Effective monitoring and evaluation bring about performance and early indication of deviation from program objectives. The majority of federal and state agricultural programs such as ADP, OFN, Green Revolution, NAFPP and RBDAs became moribund due to lack of effective monitoring and evaluation.
3. **Top-Heavy, Bureaucratic Procedures:** A lot of bureaucratic bottle necks and red tape entangle activities by delaying, while waiting on instructions that may not come at the right time
4. **Insufficient Resources for Effective Implementation of Priority Research:** Resources in the form of capital, equipment and humans are either, insufficient, inadequate or are not released to meet timeliness of priority research. Agricultural projects are time and season specific, so that efforts should be made by agricultural policy makers to be conscious of the importance of time and season
5. **Lack of Effective External Linkages:** A perfect linkage system involving the research-extension-farmers, results in solving pressing issues in the agricultural sector. The Nigeria story has a linkage system called Weak research-extension-farmers-inputs-linkage system which needs effective performance of all the stakeholders in the linkage system for better coordination.
6. **Inward Looking Attitude:** For progressive performance of agriculture in developing countries, all stakeholders along the agricultural value chain must demonstrate effective attitudes in every stage of agricultural production in which they operate.
7. **Lack of a Culture of Evaluation of Performance:**The majority of projects die within a short period, because of lack of evaluation to improve performance. The problem of not having performance indicators to evaluate, before commencement of a project leads to project failure.
8. **Decreasing Investors' Confidence:** Decreasing attitude of the investors sets in when researchers work more on basic research rather than applied research. On this note the targets of researchers and investors are at variance. While some researchers concentrate on basic research for self-aggrandizement and publication recognition, investors are interested in problem solving research that can address their needs; which is applied research. This brings about low private sector participation in research activities
9. **Policy:** Without a well-defined Agricultural policy by the Federal Government, Agricultural practices in the country looks like a journey without a destination
10. **Infrastructural**
    a. Equipment. There is inadequate modern equipment to work with.
    b. A good Research environments needs stable electricity, regular water supply and uninterrupted internet services

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

11. **Information Dissemination**: Extension plays important roles in creating innovation platform conducive for establishing an interactive linkage between research and End-Users (Roling, 1997). However, this unit is faced with many challenges in performing this role
    a. Lack of modern equipment to disseminate information
    b. Insufficient manpower to meet the increasing End-Users requests
12. **End-Users – Challenges faced by Research Institute are;**
    a. Poor participation and cooperation of End-Users in research activities
    b. Lack of adequate stakeholders participation and responsiveness
13. **Inadequate Training for Extension Agents:** There is need for on-the-job training of extensionists to bring about better job performance. The majority of the extensionists never attended on-the-job training. Extensionists should be exposed to the use of Geographical Information System (GIS), web Social Media for development, photographic and video equipment and open broadcast van, to mention few. All these will put value to extension work and make dissemination easy. More importantly, there is need to note that at every point of diffusion level, there are specific skills and approach in the use of equipment to facilitate adoption.

CONCLUSION

This chapter discussed several concepts of agricultural extension methodologies assessed from past to present and actions taken to make extension methodologies more appropriate to encourage agricultural development. It also identified roles of agricultural extension activities in agricultural development and the factors influencing the choice of appropriate extension methodologies in emerging economies. It concluded with the advice that developing countries should fashion a sustainable extension system that will be socially acceptable and culturally compatible, economically viable and environmentally friendly. Such an extension system will help hasten agricultural development in emerging economies.

Chapter 8
Agropreneurship Among Gen Y in Malaysia:
The Role of Academic Institutions

Asliza Yusoff

ABSTRACT

Despite great concerns regarding food security and the need to maintain a continuous food supply for an ever-increasing population, the agriculture sector remains an unattractive employment option, especially among younger generations. The big question is, "who should play a greater role in giving this sector young talents that are needed for successful agriculture and how it should it be acquired? Research has shown that this sector is dominated by an aging community of farmers who lack the innovative skills that is needed for running a new and modern agricultural industry. This chapter provides a brief overview of the importance of the agriculture sector and agropreneurship and is followed by why the involvement of the Gen Y segment is crucial for the growth and development of this sector. Since the basis for agropreneurship development among today's youth is based on training and inculcating an agropreneurship work culture at the university level, the authors proposed roles an academic institution could play in instilling positive an agropreneurial attitude among Gen Y graduates.

AGRICULTURE SECTOR AND WHY IT MATTERS?

In many parts of developing world, agriculture production is recognized as a strategy to improve a nation's standard of living, particularly to increase income, reduce hunger, and contribute to the improvement of other measures of well-being (Owens, Hoddinott, & Kinsey, 2003). Agriculture is also acknowledged to contribute significantly to economic growth in many countries (Bairwa, Lakra, Kushwaha, Meena, &

Kumar, 2014; Diao, Hazell, Resnick, & Thurlow, 2007; Razak et al., 2015). Furthermore, agricultural growth is seen as precursor to the industrial revolutions that spread across the temperate world, from England in the mid-18th century to Japan in the late 19th century. Higher agricultural productivity that generates an agricultural surplus open to partial taxation and is used to finance industrial development as well as enabling lower food prices for the masses underpinned the success stories of industrial and structural transformation.

Agriculture also plays a substantial role in providing employment opportunity and poverty reduction. It accounts for 32 percent of total employment globally and 39 percent of employment in developing countries of Asia and the Pacific (International Labour Office, 2014). The sector has been acknowledged to be a major contributor to poverty reduction, as is found in countries such as Brazil, Cameroon, Chile, Costa Rica, Dominican Republic, Egypt, Mali, Mexico, Nicaragua, Panama, Tunisia and, not forgotten, Malaysia (Cervantes-Godoy & Dewbre, 2010) among others in Asia and the Pacific (International Labour Office, 2014; Kuldilok, Dawson, & Lingard, 2013). Similar scenario is also seen in many developed countries such as the United States, the United Kingdom, Japan, and Australia, where agriculture sector does not only play a significant role in contributing the countries' food supplies but also provides other benefits such as improved physical and mental health, improved aesthetics, community building, employment opportunities, improved local land prices, and etc. (Mok et al., 2014).

On reflection, agriculture today is no longer a sector for poor people only. For instance, Thailand has gained its competitive advantage by dominating world exports of canned tuna with a market share of around 40 percent, which is at least four times higher than any other exporter (Kuldilok et al., 2013). Many other developing countries have benefited from agriculture not only to have sufficient food to maintain normal health for a growing population but also to increase the nation's economic standing (Bairwa et al., 2014; Diao et al., 2007; Razak et al., 2015). There seems to be no compelling reason to argue for the economically inferior state of agriculture sector in shaping the country's economic condition. With agribusiness' increasing technological sophistication, as is found in developed countries, agriculture can appeal to younger generations.

OVERVIEW OF AGRICULTURE SECTOR IN MALAYSIA

For many years, agriculture sector has been standing high as the backbone of Malaysian economy through the production of agricultural products for domestic consumption and also as the earner of foreign exchange (Abu Dardak, 2015). Agriculture plays an important role in the development of the Malaysia's economy including providing employment opportunity, uplifting the income of the populations and ensuring national food security (Siwar, Yasar, Ghazali, & Mohd Idris, 2013). Since its independence in 1957, agriculture has become a significant contributor to Malaysia's economy. For example, agriculture has contributed 38 percent of the country's GDP in 1960 as compared to 9 percent contributed by the manufacturing sector in the same year. In mid-1980s however, agriculture contribution to GDP has declined significantly due to the slow growth in the production of commodity and fluctuations in agricultural commodity prices (Selamat & Nasir, 2013). The declining trend keeps on continuing for decades. Even though it went up to 10.09 percent in 2010, it went back down for years after (Malaysian Department of Statistics, 2016). Despite this unstable trend faced by Malaysia, the country has observed an increased in total agriculture value added from RM18.7 billion in 2000 to RM21.6 billion in 2005. Albeit the performance of Malaysian economy experienced a rapid growth where the GDP has increased from RM11.8

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

billion in 1970 to RM751.5 billion in 2012, the contribution of agriculture sector showed a declining trend since 1970 (30.8 percent) to 2012 (7.3 percent) (Abu Dardak, 2015; Malaysian Department of Statistics, 2016). Although its contribution increased to 3.0 in 2014 but it has decreased by 4.7 percent during the first quarter of the following year (Bank Negara Malaysia, 2015; Ministry of Finance, 2013).

The agriculture sector in Malaysia is an area where employment opportunity is offered to the population. In 1960, this sector contributed 60 percent of total employment in the country. The contribution however dropped in 2000 and 2005, where total employment contributed by the agriculture sector accounted only 15.3 and 12.9 percent, respectively. In 2010, agriculture, forestry and fishing has made up 13.3 percent of country's total employment and has provided employment for 11.1 million people in Malaysia (Jala, 2013, September 30). Even though its contribution to the country's total employment has been decreasing, the agriculture sector in Malaysia still continues to be a major contributor to the development of the country's economy (Selamat & Nasir, 2013). Because of this, the Malaysian government takes a serious attitude toward the decline in employment potential, where a total of RM6 billion is allocated for the agriculture sector in the 2014 national budget. Despite the growth in the services sector, which has taken over the manufacturing sector as the main contributor to the country's economic growth, the agriculture sector is not going to be ignored because it is the main source of income for many for farmers, fishermen and agro-based industries.

Recently there has been renewed interest in the agriculture sector as people begin to understand that the sector plays a crucial role in providing food and reducing the nation's poverty level, especially in rural areas. Against this background observation, the notion of sustainable agricultural development in relation to national food security and a continuous food supply is quickly gaining importance because the government has outlined it in the country's New Economic Model (NEM). A country's resourcefulness in developing its agricultural sector is an indication of its ability to provide sufficient food for its population. According to the Economic Planning Unit (EPU), agriculture consists of producing industrial and food commodities that include crops (plantation and food), horticulture (olericulture, pomology, floriculture, nursery crop culture and landscape horticulture), aquaculture (marine and freshwater), and livestock husbandry. In conjunction with the NEM, which has striven to reduce poverty among 40 percent Malaysians who earn less than RM1500 a month, agriculture and the agro-based sectors are seen to have potentials in realizing the government plan.

In Malaysia, agriculture stands as the third pillar of the country's economy and follows behind the service and manufacturing sectors (Selamat & Nasir, 2013). Entrepreneurship, on the other hand, is acknowledged as one of the best strategies for the development of economic growth for a country and is a useful tool to sustaining a country's competitiveness in today's increasing trend of globalization. This is because it indirectly creates political and social stability through the creation of job opportunities and initiates innovations that lead to technological change and productivity growth (Ahmad, Wan Yusoff, Mf Noor, & Ramin, 2012; Lim, Lee & Cheng, 2010). Therefore, an integration of both has given birth to the concept of 'agropreneurship', a new and promising dimension of the agriculture sector. Research findings show that agropreneurship has a profound impact on growth and survival (Baron & Shane, 2008; Poornima, 2009; Verhees, Kuipers, & Klopcic, 2011), not only on the individual, but also on the society and country altogether. The development of agropreneurship also contributes to the growth of small and medium-sized enterprises (SMEs) through the creation of small and medium-sized agro-based enterprises (SMAEs). Given the significant role played by SMEs in making a substantial contribution to the global economic growth (Jutla, Bodorik, & Dhaliwal, 2002), the development of agropreneurship is a worthy subject to be examined.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Comparing agriculture sector in Malaysia to that of the neighbouring countries such as Thailand, Vietnam and Indonesia, the agriculture sector's contribution to the Malaysian economy is still relatively low and lags behind these regional peers in percentage contribution to GDP due to lack of scale, production-driven farming and low-value products (Ramachandaran, 2010). For example, according to a report by the World Bank, agricultural contribution to the country's GDP in Thailand, Vietnam and Indonesia was 10.5 percent, 17.7 percent and 13.3 percent respectively. However, in Malaysia, the sector's contribution to the country's GDP in the same year was 8.9 percent only. This highlights that Malaysia need to strive hard to be at least at par with its closest neighbours.

Therefore, in view of the growing world population, it is imperative that sustainable agriculture and food security and nutrition be part of the new sustainable development agenda in 2016 and beyond. A way to achieve this plan is by encouraging Malaysians, especially the younger generation, to venture into agropreneurship business activities. With full and strong support from the government, the agriculture industry in Malaysia, with its enormous prospects and prosperous business potential, creates a large and attractive chance for entrepreneurs (D'Silva, Mohamad Shaffril, Uli, & Abu Samah, 2009). Slowly, Malaysians have immense investment prospects with quick and high returns in agropreneurship business activities (Abdullah & Naem Sulaiman, 2013).

AGROPRENEURSHIP: THE NEW DIMENSION IN AGRICULTURE SECTOR

The concept of agropreneurship, is gradually getting attention in both agriculture and entrepreneurship areas of study, especially in redefining new and modern agriculture. Recent studies show that agropreneurship as a concept and practice is not wishful thinking and exageration: it has a profound impact on business growth and survival (Verhees et al., 2011). According to Nagalakshmi and Sudhakar (2013):

Agricultural companies increasingly have to adapt to the vagaries of the market, changing consumer habits, enhanced environmental regulations, new requirements for product quality, chain management, food safety, sustainability, and so on. These changes have cleared the way for new entrants, innovation, and portfolio entrepreneurship.

This have conclusively shown that the emergence of the free market economies globally has resulted in the development of a new spirit of enterprise "Agropreneurship" and the increased individual need for responsibility for running their own businesses (Alex, 2011).

The concept of agropreneurship is being promoted to encourage setting up of enterprises related to the farm sector in the effort to modernise the agriculture sector. There are various definitions of agropreneurship in the literature. An early definition by Ahmed, Hasan, and Haneef (2011) refers to agropreneurship as an employment strategy that leads to economic self-sufficiency of rural people. Nagalakshmi and Sudhakar (2013), on the other hand, define agropreneurship as sustainable, community-oriented, and directly marketed agriculture. A more recent definition by Bairwa et al. (2014) indicates that agropreneurship is a profitable marriage between agriculture and entrepreneurship which turns a farm into an agribusiness establishment in agriculture and allied sectors. Similarly Azer, Mohamad, Abdullah, and Mustapha (2014) describe agropreneurs as individuals who involve the agricultural aspects into business. Agropreneurship could also be understood as the classification of all activities where farmers adjust a free market economy as entrepreneurial (Soumiya Devi, 2015). Despite the various definitions

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

given to explain agropreneurship, the authors did agree on one aspect, which is that agropreneurship involves activities of producing, distributing and marketing of agricultural products to generate income and contribute to a sustainable community.

Agropreneurship is indeed seen to contribute at both individual and national levels. At the individual level, agropreneurship contributes to improving performance of an individual by reducing one's poverty level as a result of employment opportunity creation and allowing creativity and innovativeness to exist in meeting consumer demands (Bairwa et al., 2014; Nagalakshmi & Sudhakar, 2013; Osikabor, Adesope, Ibrahim, Babayemi, & Olatunji, 2011). At the national level on the other hand, agropreneurship has the power to improve economic viability (Osikabor et al., 2011) and to make agriculture a more attractive and profitable venture that contributes largely to national income by providing direct employment and income to the large, lower socioeconomic strata of society (Bairwa et al., 2014). Agropreneurship is now viewed to be an important agent of rural economic development (Mohd Yusof & Raja Abd Rahman, 2007). Agropreneurship's importance has also captured the attention of the country's important parties with the rise of the concept, 'agriculture is business' (Rezai, Mohamed, & Shamsuddin, 2011). With this concept, people in Malaysia are encouraged to become agropreneurs, not only to create wealth for themselves, but at the same time to contribute to the sustainability of society. This shows that communities also believe that agropreneurship indeed plays a significant role in contributing towards national economic growth and individual well-being. Therefore, future agropreneurs should be groomed, especially among youth.

THE IMPORTANCE OF AGROPRENEURSHIP IN ECONOMIC GROWTH AND DEVELOPMENT

Department of Statistics Malaysia revealed that in 2013, 76 percent of active companies in the agricultural sector were SMEs through the establishment of SMAEs. This shows that the success of agricultural projects depends largely on the success of SME's operation. Based on the findings, it is reported that SMEs and SMAEs play a significant role in and make substantial contributions toward national economies. This is evidenced by reports that 80 percent of global economic growth is attributable to SMEs (Jutla et al., 2002). In 2013, SMAEs drove 3 percent and 2.1 percent of Malaysian SME GDP growth and the country's overall GDP growth, respectively (SME Annual Report 2013/2014). Undoubtedly, agropreneurship activities play a significant role in contributing to the country's economic development by contributing to the supplies of food, job opportunities for people, earnings from exports and have also become major suppliers for agro-based industries (Hassan, Shaffril, Azril, Abu Hassan, & D'Silva, 2009; Okezie & Baharuddin, 2012; Siwar et al., 2013).

Even though the agriculture sector has recorded a more moderate growth (National SME Development Council, 2013), the country still expects the sector to improve, and this was supported by the higher output of crude palm oil from the maturing of new trees as well as being supported by food commodities, especially livestock and vegetables. The Third Industrial Master Plan (IMP3) highlights the need to push small entrepreneurs to become major players in agropreneurship and agro-based business activities with potential areas in resource based manufacturing SMAEs, such as herbal and traditional medicines, palm oil-based products, and food and beverages, including convenience foods for the halal market (Ministry of International Trade and Industry, 2006). Agro-based activities such as the agro-processing sector, which includes not only agro-related industries but also distribution services and trading activities, would roughly account for more than one-third of the GDP of Indonesia, Chile, Brazil and Thailand, and between

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

20 and 25 percent of GDP in sub-Saharan countries. The entire food system, including the production of primary goods and commodities, marketing and retailing, accounts for more than 50 percent of the GDP in developing countries (Jaffee, Kopicki, Labaste, & Christie, 2003). Furthermore, in developed countries such as in the United States of America (USA), agropreneurship activities contributes 13 times more to GDP than pure agricultural activities (Jaffee et al., 2003).

Due to the world's concerns about food security and continuous food supplies for people, agropreneurship has greatly captured the attention of multi-lateral organizations, policy makers and civil society (Food and Agriculture Organization of the United Nations, 2009). Hence, agropreneurship is a mechanism that provides an off-farm link in agrofood value chains. It supplies valuable inputs such as innovative information to the farm sector and at the same time connects the farm sector to the final consumers via the handling, processing, transportation, marketing, and distribution of agricultural products. These connections show strong cooperation between agropreneurship business activities and the performance of the agriculture sector. Indeed, vigorous agropreneurship business activities could encourage tremendous growth of this sector. At the same time, strong connection between agropreneurship and smallholders opens opportunity for the community to live a better life because it contributes to employment generation, poverty reduction and human resource development (Ahmed et al., 2011).

Agriculture today is no longer a sector for poor people only. Instead, given full and active supports from the government, it is now a sector where chances exist for businesses to prosper (D'Silva, Mohamad Shaffril, Uli, & Abu Samah, 2010). Hence, this offers significant opportunities for entrepreneurs to take advantage of opportunities and generate wealth. In fact, the focus of agropreneurship development is not only for the purpose of food security. Its importance also covers the transfer of knowledge, skills, techniques, expertise to the rest of the population via job creation and employment opportunity.

AGROPRENEURSHIP DEVELOPMENT IN MALAYSIA

Since the third era of industrialisation that took place between 1990 and 2005, it is only until recently that the focus on agropreneurship has started to regain momentum in Malaysia. Agropreneurship is now viewed to be an important agent for rural economic development (Mohd Yusof & Raja Abd Rahman, 2007). Because of that, the 9th Malaysian Plan outlined an RM 511.9 million budget allocation that aimed to produce 260,928 agropreneurs (Mohamed, Rezai, & Shamsudin, 2011). In this national development plan, the government placed great emphasis on the enrichment of the modern agriculture sector, outlining the way forward for it and to reenergize the sector to become one of the main contributors to the country's economic growth. The plan not only covers the commercial and biotechnology aspects of agriculture, but also on agriculture as a business. Consequently, small agricultural entrepreneurs in the country need to be pushed forward to become major players in SMAEs, as outlined in the Third Industrial Master Plan (IMP3). Based on the SME Annual Report 2012/2013, SMAEs that are run by agropreneurs rank number four of overall SMEs in this country. Table 1 summarizes the Malaysian SME establishment, as compared to other sectors in 2011. Even though SMAEs represent only 1 percent of the overall SME establishment in Malaysia, its contribution to GDP is still significant. As of 2012, SMAEs contribute 3.3 percent to Malaysia's GDP (Malaysian Department of Statistics, 2016).

In Malaysia, agropreneurship is becoming increasingly important. It offers opportunities for generating revenue and creating a future that straightforward subsistence farming often struggles to provide. In the 2003, the Ministry of Agriculture and Agro-Based Industry allocated and spent RM500 million on

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Number of SME establishments by sector

Sector	Micro	Small	Medium	Total SME
Manufacturing	21,619	13,934	2,308	37,861
Services	462,420	106,061	12,504	580,985
Agriculture	3,775	1,941	992	6,708
Construction	8,587	6,725	3,971	19,238
Mining & Quarrying	57	126	116	299

Source: Economic / SMEs Census 2011 by Department of Statistics, Malaysia.

entrepreneurial development programs with aims to transform traditional farmers to visionary agropreneurs (Abdul Halim, Alias, Che Hamid, & Zakaria, 2011). Government's effort to promote agropreneurship did not just stopped there. The effort to promote modern agriculture and agropreneurship was also led by government agencies such as Department of Agriculture in collaboration with government linked companies (GLCs), such as Khazanah Nasional Berhad's subsidiary, Blue Archipelago. Realizing that agropreneurship is a very important activity among SMAEs specifically and its contribution to SMEs generally, the National Food Security Policy (FSP), which was approaching its expiration in 2011, was finally extended. Furthermore, the Fourth National Agricultural Policy (NAP4), a policy under which RM5.6 billion was allocated for agricultural development, was also executed in the same year (Adnan, 2011).

Moving forward, the government's support for agropreneurship and SMAEs was also clearly outlined in the national policies and development plans, such as Economic Transformation Program (ETP, 2011-2020), IMP3 (2006-2020), 10th Malaysian Plan (10MP) and SME Masterplan (2012-2020). In order to translate SME development strategy into reality, the National SME Development Council (NSDC) was established in 2004 to provide strategic direction for government policies on SME development and to ensure coordination and effectiveness of government programs. One of the key initiatives developed by NSDC is the National SME Development Blueprint, an annual action plan for SME development. Two types of government support for the development for agropreneurship and SMAEs are financial and non-financial support. Included under the first category are property loans, working capital and grants that are channelled through the Agro Bank with aims to provide agropreneurs a continuous working capital via overdraft facility. With the purpose to strengthen SMEs, the government has launched a Shariah-compliant SME Financing Fund of RM2 billion. The scheme is currently managed by 13 Islamic banks with the government providing a 2 percent profit rebate. Another initiative to assist agropreneurs with the capacity and potential to sustain their businesses is the SME Revitalisation Fund. The government also established an RM10 million SME Emergency Fund to assist SMEs that are affected by natural disasters. This fund channels soft loans up to a maximum of RM100 thousand to affected SMEs through the Small and Medium Enterprise Corporation Malaysia (SME Corp. Malaysia) and the Malaysian Industrial Development Finance Berhad (MIDF). On the other hand, the latter category (non-financial) of support includes advisory, marketing, management, networking, research and development and technical support.

Equally important, various government agencies such as Palm Oil Research Institute of Malaysia (PORIM), Rubber Research Institute of Malaysia (RRIM), Malaysia Cocoa Board (MCB), Malaysia Agricultural Research & Development Institute (MARDI), Forest Research Institute Malaysia (FRIM)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

have also participated by expressing their support and commitment to grow agropreneurs and SMAEs to be economic champions by conducting research and development (R&D), activities in agriculture and providing agricultural training programs. Agencies like the Federal Agricultural Marketing Authority (FAMA) on the other hand, plays its role in securing market base and looking for market potential for local produce, particularly fruits and vegetables, as well as internationally promoting horticultural products such as fruits and flowers.

In order to promote the involvement of youth in producing modern agriculture and promoting the growth of agropreneurship, the government introduced the My *Kampung* My Future (MKMF) program. Huge amounts of funding were allocated for the success of this program with a goal of generating future agropreneurs. Today, as one of the government's effort to reduce graduate unemployment, RM50 million was allocated under the Graduate Entrepreneurship Fund, which is managed by SME Bank. The fund provides soft loans of up to RM500 thousand at an annual interest rate of 4 percent. To show that the government is very serious about building local agriculture industry, the sum of RM6 billion was allocated to implement high value-added and commercially-viable agriculture programs that requires human capital input from the youth sector ("Budget 2014: Support for SME plans," 2013). In order to further instil interest towards agriculture among the young segment and also to grow young agropreneurs with high income, the government has established the Young Agropreneur Unit through the aspirations of the Minister of Agriculture in September 2013. Mainly targeted for individuals under the age of 40, the aim of this program is to assist and encourage agropreneurship business activities among this group by involving in agricultural activities such as crops, livestock, fisheries, marketing, technology and innovation, as well as special projects such as agro-tourism and agro-based industry. Additionally, the implementation of this program is hoped to facilitate in shifting youth's paradigm towards this sector whereby the government is focussing in changing the traditional held belief regarding negative perception of agriculture sector.

As innovativeness was proven as being impacted by education (Yusoff, Ahmad, & Abdul Halim, 2016), the Agriculture Youth Entrepreneur Incubation Programme (AYEIP) with an aim to provide education, training and practices intended for youth who are interested in agriculture field was developed. The programme outlines provide agriculture coaching and offer a 'hands-on' experience on farming knowledge. The AYEIP programme was conducted in the Department of Agriculture (DOA) in four centres across the country. The programme was developed particularly for young (18-35 years old) agriculture institute graduates, university graduates, youth and any general Malaysian citizen, and police retiree or pension army personnel. The incubation consists of eight months full time programme which was fully funded by Malaysian government under the Ninth Malaysian Plan. At the end of the incubation programme, participants who passed stringent training together with good entrepreneurial qualities will be granted with a space for starting agropreneurship business activities.

Furthermore, to enhance youth agriculture interest and entrepreneurial skills, various activities and programs were provided by the Malaysian government through its agricultural departments. such as trainings that covers various business aspects that include production, marketing, advertising and promotion (Performance Management and Delivery Unit, 2010). The Malaysian Agriculture, Horticulture and Agro-tourism (MAHA), through its active promotion of agricultural products with its motto "Agriculture is business", was also one of the government's initiatives that opened important opportunities for youth to get ideas to create new products (Performance Management and Delivery Unit, 2010).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Finally, the government through its Ministry of Higher Education (MOHE) strives to assist SMEs in expanding their business through the introduction of Public-Private Research Network (PPRN) programme. Demand-Driven Innovation Project by PPRN endeavours to identify entrepreneurs with technological problems and researchers with viable research-based solution. Under PPRN programme, entrepreneurs who face difficulties in their venture could join the PPRN programme and begin describing their problems. In responding to that, PPRN subsequently develop a team of experts and scientists in the area to readily develop new technologies and taking appropriate action to assist in solving the entrepreneur's problem. Besides helping the entrepreneurs, this approach also aims to develop close cooperation between academics and entrepreneurs in producing innovative, high quality, competitive and unique products. Furthermore, in order to solve the problem, the entrepreneurs will be provided with a grant. A fund up to RM50,000 for every problem solved with the cooperation of entrepreneurs and academics will be granted.

AGROPRENEURSHIP SUPPORT THROUGH EDUCATION

Becoming an agropreneur is not a career path to be undertaken lightly. Agropreneurs have to prepare themselves to take calculated risks, be creative, innovative and resourceful, ready to put in long hours of hard work, cope with stress, and weather the bleak periods as well as the good ones. Realizing these needs, an agropreneur incubator program was established. It is a six-month course developed and aims to produce more agropreneurs with exposure to the realities of the entrepreneurial world who are confident and competitive. Agropreneurship training and education is actually not something new in Malaysia. Indeed, agropreneurship education: which is embedded in entrepreneurship education in Malaysia, began as early as lower secondary level in high school when the Integrated Living Skills (ILS) curriculum was introduced in 1991 (Mohamed, Rezai, Shamsudin, & Mahmud, 2012). Later when the students moved to the upper secondary level, students may choose subjects that relates to entrepreneurship such as Commerce as an elective course. At a much higher level, entrepreneurship education is even more emphasis. Through its Basic Student Entrepreneurial Program (BSEP) that started in 2003 and with early participation from 19 local and one private higher education institutions, the government aims to provide training to final year students who are interested in becoming entrepreneurs.

Subsequently, agropreneurship education and training in producing skilful agricultural talents cannot be given any less attention. Realizing the contribution of agriculture to the country's economic growth, the Malaysian government has been promoting both formal and informal agropreneurship education. For example, agropreneurship education has been promoted as early as primary school for children where most primary schools in the country encourage their students to sell foods during the *Canteen Day,* an entrepreneurship day of which students sell things during school hours. Other examples of government efforts to promote agropreneurship education can also be seen in common activities offered by various organizations, along with the formal entrepreneurship education offered at higher education institutions such as conferences, seminars, short courses and training on agropreneurship. Furthermore, realizing the importance of agropreneurship, the Malaysian government through its public and private universities and colleges has put in several academic programs and training at tertiary level to cultivate graduate feasibility and desirability for agropreneurship. At the university level, programs are typically offered by faculty of agro-based industries, faculty of agriculture or faculty of applied science.

WHY FUTURE GENERATION NEEDS TO CONCENTRATE ON AGROPRENEURSHIP?

In Malaysia, Chan, Selvadurai, and Hamid (2009) have raised concerns and highlighted the issue of small number of young entrepreneurs. According to the authors, the involvement of youth in entrepreneurship in Malaysia is not up to the expected level despite the huge efforts put forth by the government. The same issue was highlighted by Mohammad Nor, Nik Mohd Masdek, and Maidin (2015). The authors stressed that participation of youth in entrepreneurial activities was very low. Indeed, the growth percentage of entrepreneurs in Malaysia (youth and elderly) did not even exceed 26 percent (Mohammad Nor et al., 2015). Supporting this claim, a survey conducted by the Ministry of Education (MOE) in Malaysia revealed that among 22,016 working graduates, only 2.8 percent is self- employed and only 1.4 percent of 11,313 diploma holders are self-employed (Zainal Abidin and Irsyad, 2012).

Furthermore, a few of previous researchers have expressed their concern regarding youth unemployment in Malaysia (Abu Samah, D'Silva, Shaffril, & Uli, 2011; Mohammad Nor et al., 2015; Shamsuddin, Mohmad Isa, Aziz, Mohamed Mahfol, & Alagari, 2013). According to Abu Samah et al. (2011), the unemployment rate among youth was 4 percent in 2011. The rate kept on going up where in 2015, the youth unemployment rate was reported to be around 10 percent (Ministry of Finance, 2016; Mohammad Nor et al., 2015). Additionally, the current report by the Ministry of Finance showed that up to 40 percent of the total unemployed in Malaysia are youth especially the university graduates (Ministry of Finance, 2016). Furthermore, the report revealed that over 90 percent of those unemployed are aged between 15-29 years old.

Given this unfavourable situation, many researchers have called for agropreneurship activities as an approach in dealing with the overwhelming rate of youth unemployment as well as to increase the number of graduate entrepreneurs (Abdullah & Naem Sulaiman, 2013; Abdullah, Abu Samah, & Othman, 2012; Hock-Eam, Ahmad, & Jan, 2015; Mohammad Nor et al., 2015). Besides that, it was found that majority of graduate entrepreneurs were involved in wholesale and retail trade; services, real estate activities, and the manufacturing sectors (Hock-Eam et al., 2015). Hence, there is an urgent call for the involvement of young entrepreneurs to enhance and strengthen the agriculture sector in Malaysia via agropreneurship activities (Abdullah & Naem Sulaiman, 2013; Abdullah et al., 2012; D'Silva et al., 2009, 2010). Therefore, given the issue of small number of young entrepreneurs and an overwhelming rate of graduate unemployment in Malaysia, it is imperative for future generation to concentrate on agropreneurship as one of the tools to cater these issues.

THE CHALLENGE: GEN Y INVOLVEMENT IN AGROPRENEURSHIP

With the surge of interest in sustainable development, agropreneurship has now been earmarked as an important business activity for the country's economic development. However, the development of modern agriculture and agropreneurship endeavours will not be a success without an involvement of the young people, especially the Gen Y segment. Because of this, the Malaysian government endeavours to develop agropreneurial skills among this population. The local government has also placed great emphasis on encouraging and motivating them to become agropreneurs with the objectives of ensuring increasing and continuous supplies of food for the nation as well as decreasing the youth unemployment rate (Abdullah, Abu Samah & Othman, 2012; D'Silva et al., 2009). This can be seen through government highlights

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the Third Industrial Master Plan (IMP3) to push small agropreneurs to become major players in the agro-based industries (Ministry of International Trade and Industry, 2006).

Yet, despite the considerable critical attention that was paid to the issue of food security and continuous food supplies in the country, Malaysians relatively show a lack of interest in agriculture sector when, compared to other sectors, only 11.8 percent of country's total employment comes from the agriculture sector (Abdullah et al., 2012). At the same time, the country is also facing the issue of an ageing agricultural community. The Performance Management and Delivery Unit (2010) reported that the average age of paddy farmers is above 60 years and 40 percent of fruit farmers are above 55 years of age. Supporting this report, a major finding in agriculture also showed that over 66 percent of people in agriculture are over 50 years old where the young are not interested and do not want to be involved in agriculture perhaps due to the view of low profitability held on this sector (Alam, Siwar, Murad, Molla, & Toriman, 2010; Jala, 2013, September 30; Zainal Abiddin & Irsyad, 2012). Later findings also showed the same phenomenon. It was revealed that 45 percent of farmers in Malaysia are 55 years old and above and this situation has caused retardation in production improvement (Abdullah & Abu Samah, 2014; Che Abdullah & Mustapha, 2009; Siwar, Idris, Yasar, & MOrshed, 2014). This phenomenon highlights that the agriculture sector in Malaysia is experiencing a shortage of young agricultural talent (Zainal Abiddin & Irsyad, 2012). Additionally, Movahedi, Latifi, and Sayyar (2013) emphasized that agropreneurship activities in Malaysia suffer from a lack of educated and skilful workforce and entrepreneurial spirit due to aging agricultural community. Until today, the issue of youth involvement in agriculture remains a big question mark. Their involvement in agropreneurship activities is still discouraging where young agropreneurs (aged 18 to 40 years) accounts for only 26 percent of all agricultural community (Abdullah et al., 2012). This figure is still far below despite the strong encouragement from the local government.

Notwithstanding the huge efforts put forth by the government, the involvement of youth in entrepreneurship in this country is still not up to the expected level (Chan et al., 2009). Possibly due to the instability of the agriculture sector, the youth in this country are more inclined to work in the manufacturing sector because they believe the sector brings them a better image, higher income and more advanced urban infrastructure (Che Abdullah & Mustapha, 2009). The great challenge therefore is to see how to get Malaysian youth, specifically the Gen Y segment, to venture into agriculture given the stigma associated with agriculture and farming. Researchers have expressed their concern regarding youth unemployment and suggesting venturing in agropreneurship and become agriculture self-employed as one of the solution (Abdullah & Naem Sulaiman, 2013; Abdullah et al., 2012). Hence, there is an urgent call for the involvement of young entrepreneurs to enhance and strengthen the agriculture sector in Malaysia via agropreneurship business activities (Abdullah & Naem Sulaiman, 2013; Abdullah et al., 2012; D'Silva et al., 2009, 2010).

WHY GEN Y INVOLVEMENT IN AGROPRENEURSHIP IS IMPERATIVE

Considering the significant role played by SMAEs in developing the country, Malaysian Gen Y are encouraged to become agropreneurs to meet both new career opportunities and also to ensure an increase and continuous supply of foods in the future (Abdullah et al., 2012; Zahrom, 2012, December 13). Besides its objective to enhance income distribution and reduce the nation's poverty level, many countries nowadays are gearing toward producing young entrepreneurs that possess many optimistic characteristics as one of the solutions to decrease the youth unemployment rate (Abdullah et al., 2012; D'Silva et al.,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2009). Together with fast growing current technology and innovation, the agriculture sector definitely demands fresh and innovative ideas from the young segment, especially those with agropreneurship education, knowledge and skills.

Equally important, as SME Masterplan 2012-2020 outlines it's vision to develop globally competitive SMEs across all sectors that enhance wealth creation and contribute to the social well-being, the Malaysian Prime Minister encouraged high investment in youth as he believes "…the youth of today are an asset… who will take Malaysia to greater heights". Approximately, 38 percent of the Malaysian population consists of youth (SME Master Plan 2012-2020). In the same way, it has been suggested to create a "productive society" especially among the young population (those between the age of 18 to 40 years old) (Ahmad, Ramayah, & Tuan Muda, 2013). Agropreneurship activities should be cultivated among the young people because as individuals get older, they become less willing to invest time in activities that do not produce quick returns, including starting a new business (Lévesque & Minniti, 2006). In addition, the productivity level among this population must be kept high in order to spur economic growth and thus energize entrepreneurial spirit that drive first generation entrepreneurs (Ahmad et al., 2013).

Globally, the Gen Y population totals approximately 70 million, which is double the size of Gen X (Hewlett, Sherbin, & Sumberg, 2009). In Malaysia, Gen Y accounts for 40 percent of the country's total population and is the fastest growing segment of the workforce today. Even though there exists a contrary view that ageing or the third-age entrepreneurs (those between the age of 50 to 64) possess high working experience, know-how, and great financial means for entrepreneurship (Baucus & Human, 1994; Singh & DeNoble, 2003), and hence are better off in their entrepreneurial pursuits, the Gen Y cohort is more appropriate to be the key to drive a sustainable economy of long term growth that a nation can depend on because they are characterized by many optimistic values needed by agropreneurs in today's modern agriculture environment, such as being technology savvy, independent, self-reliant, entrepreneurial thinkers, well-educated, confident, passionate, upbeat, ambitious, result-oriented and socially conscious with high integrity (Geyzel, 2009; Martin, 2005; Sox, Kline, & Crews, 2014), as well as vibrant, energetic and high productivity (Joseph, Adanma, & Chinonso, 2012; Onwumere & Ukpebor, 2011). Evidence from the United States of America by the Kauffman Foundation (2012) reveals that 29.4 percent of entrepreneurs were 20 to 34 years old, and roughly 160,000 start-ups a month were led by Gen Y in 2011. Similarly, Pugh (2014) reports that more than half of Gen Y (54 percent) either want to start a business or have already started one. Thus, the Gen Y segment is the best candidate to venture in agropreneurship in order to realize the government plan in creating agriculture as a promising economic sector for the country's development. Based on those arguments, agropreneurship venturing among the Gen Y agropreneurs has recently grown in importance and is seen to be a practical concern to be investigated further in future research.

PROMOTING GEN Y AGROPRENEURSHIP: THE ROLE OF ACADEMIC INSTITUTIONS

It has been discussed extensively in the entrepreneurship literature that entrepreneurship is indeed a discipline of traits that can both be learned and taught (Vanevenhoven, 2013). Relying on the assumption that "entrepreneurs can be made", it is the role of academic institutions to take initiatives to promote agropreneurship among graduates by offering agropreneurship courses and programs and also via agropreneurship support mechanisms. Academic institutions emerged as a place where 'critical tools'

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

for the development of future entrepreneurs are offered. The 'critical tools' here implies all efforts the institutions take in contributing to the development of future entrepreneurs. Furthermore, young agropreneurs have been postulated to have the risk taking and innovative attributes in undertaking a business enterprise (Mohamed et al., 2012; Zainal Abiddin & Irsyad, 2012). Therefore academic institutions are expected to produce young talents who are confident, motivated, proactive, innovative, take up entrepreneurship challenges as well as have a substantial skills to work in a team (Sánchez, 2013). The engines of agropreneurship development among youth are based in training and inculcating agropreneurship work culture (Mohamed et al., 2012) during their study at the university. Therefore, the role of academic institutions is paramount, as it is a centre that make contribution to the development of agropreneurship by creating an extent of business opportunities and equipping students with innovative business skills (Mohamed et al., 2012).

Specifically, in order to promote youth agropreneurship from academic institution perspective, the following suggestions are put forth.

1. **Stimulate Awareness and Positive Agropreneurial Attitude:** Firstly, academic institutions should stimulate students' awareness and form a mental picture and experience of the viability of agropreneurship as a career choice via formal agropreneurship courses and programs. Agropreneurship education must appear to enable students to acquire a set of knowledge and skills needed for successful performance along the entrepreneurial process (Matlay, 2008). This set of skills can facilitate future agropreneurs, especially for opportunity discovery and as well as promoting agroepreneurship desirability and feasibility and thus increase the formation of intention to become self-employed (Peterman & Kennedy, 2003; Saeed, Yousafzai, Yani-De-Soriano, & Muffatto, 2015; Solesvik, Westhead, & Matlay, 2014). Furthermore, young agropreneurs are postulated to have the risk-taking and innovative attributes needed in undertaking a business enterprise (Mohamed et al., 2012; Zainal Abiddin & Irsyad, 2012). Therefore, students who are supplied with agroepreneurship education and were enrolled in agroepreneurship courses are expected to be confident, motivated, proactive, innovative, and willing to face agroepreneurship challenges, as well as have the substantial skills to work in a team (Sánchez, 2013). Students who have participated in agropreneurship education are expected to be more entrepreneurially oriented, thus having a higher intention to become agropreneurs. This can be achieved by formulating detailed and meaningful curriculum and content that leads to students' adoption of appropriate attitudes that will cultivate their interest and desire in learning activities as well as developing their skills and competencies (Heinonen, 2007; Muhammad, Ismail, & Eh Rak, 2013).
2. **Provide Agropreneurship Education via a More Holistic Approach:** Secondly, academic institutions should provide agropreneurship education at the individual level with emphasis on the interaction between young agropreneurs and opportunity. It is true that developing positive attitude toward a certain behaviour is necessary, but positive attitude alone is insufficient. Students also need to be assured that the behaviour is feasible to achieve in real world (Baden & Parkes, 2013; Florin, Karri, & Rossiter, 2007). Notwithstanding positive outcomes derived from implementation of the entrepreneurship education programs that were reported, some however showed a contradictory discovery. Surprisingly, entrepreneurship education was found to exhibit negative outcomes too. For instance, students who engage in entrepreneurship education were found to show a somewhat declination in their intention to become entrepreneurs despite the significant positive effect on their self-assessed entrepreneurial skills (von Graevenitz, Harhoff, & Weber, 2010). This, possi-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

bly, is due to individuals' learning dissimilarities as students learn at different rates, have different motivations, start with different bases of knowledge and experience, and have access to different resource networks (Vanevenhoven, 2013). Therefore, what academic institutions could do is to pay more attention to finer variables such as pedagogical methods. In educating future agropreneurs, academic institutions could look at how individual interaction with the agropreneurship environment is emphasised. This approach is known as experiential learning. This technique is acknowledged to have the capability in producing entrepreneurs just the way it produces other people, such as professionals (Dhliwayo, 2008). Furthermore, in a different research setting, experiential learning in agricultural economics was revealed to be superior than traditional classroom learning (Parcell & Sykuta, 2003). An implementation of agropreneurship education with the presence of experiential learning in a supportive environment could affect students' perception of agropreneurship feasibility by allowing them to see themselves to be real agropreneurs. Rather than just learning theory, experiential learning is about action and thus it unlocks one's capabilities (Jennings & Wargnier, 2010) and give opportunities to students to see themselves as real entrepreneurs rather than pretending to be one (Vincett & Farlow, 2008). Experiential learning as an approach of discovery learning was acknowledged to have an ability to create the right learning atmosphere, allow articulations and interactions of ideas, offers synergistic learning among different participants and creates new meanings on students' knowledge, skills and experience (Smith, Collins, & Hannon, 2006) Additionally, Moore, Boyd, and Dooley (2010) indicated that true learning is the product of experiences which students collect throughout their learning process, as well as its evaluation and reflection.

3. **Create Large Agropreneurship Business Opportunities:** At the same time, agropreneurship education should also be tailored to contribute to the development of agropreneurship by creating large business opportunities (Mohamed et al., 2012). Hence, academic institutions could offer action-based agropreneurial programs. This is necessary for an acquisition of higher quality and quantity of education, relevance and current real-life experience from the external resources, network acquisition, and the availability of role models that can contribute to the movement of actual business start-up (Rasmussen & Sørheim, 2006). The reason for this is because effective entrepreneurial development programs must be based in a real work setting, encompassing a "learning-by-doing' element through outside classroom activities such as internships, so that the learning outcomes can be better implemented (Dhliwayo, 2008; Henry, Hill, & Leitch, 2005). Accordingly, academic institutions should extend their programs by offering more experiential programs such as internships to provide students with some exposure on the actual entrepreneurship environment as they learn on the ground (Vanevenhoven, 2013). Besides that, real-life agropreneurship exposure can also be gained by allowing students to be trained by real agropreneurs who had encountered challenges, or even failure, during their enterprise founding journey (Kuratko, 2005). Agropreneurship education offered should allow students to be actively involved in real business opportunity because it could lead to a birth of an enterprise (Rasmussen & Sørheim, 2006). Through action-based agropreneurial programs, future agropreneurs as the experiential learners are able to establish multiple set of skills that are cognitive, emotional and physical and in which the learning experience is heightened while at the same time developing capabilities to solve real-world problems (Baden & Parkes, 2013). Experiential learning through internship or trial firms may develop relevant entrepreneurial skills and enhance the feasibility and desirability to become entrepreneurs (Davey, Plewa, & Struwig, 2011).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. **Instil the Sense of Agropreneurship Desirability and Feasibility:** Next, offer opportunities for students to view agropreneurship more feasibly and desirably. Since an academic institution is the place where students formally acquire necessary entrepreneurial abilities and skills and systematically learn how to become successful agropreneurs, such institutions are also the right and best place in providing students with training and experiences to embark on an entrepreneurial career (Ghazali, Ibrahim, & Zainol, 2012), it should also be the place where students turn for support needed for initial agropreneurship venture creation. According to Ismail et al. (2013), the development of early entrepreneurial competencies is a significant result of the entrepreneurial role played by the educational institutions. Indeed, both the academic institutions and their instructors (i.e. professors) are important institutional key players in promoting entrepreneurial spirit, cultivating entrepreneurial capabilities and inspiring self-employment among the students through innovative programs and a research oriented culture (Ismail & Ahmad, 2013; Rae & Woodier-Harries, 2013; Souitaris, Zerbinati, & Al-Laham, 2007). Furthermore, students' intentions to become entrepreneurs was evidenced to positively and significantly relate with academic institutions environments (Md Rasli, Khan, Malekifar, & Jabeen, 2013; Trucker & Selcuk, 2009). In fact, many business enterprises, particularly in the developing world such as Malaysia, have been initiated at academic institutions (Ghazali et al., 2012). The supportive environment of an academic institution could lead to entrepreneurship development, particularly in intensifying students' entrepreneurial intention. The possibility of students to become self-employed is more likely to increase if the institutions provide adequate education and aspiration. By furnishing an entrepreneurially supportive environment and infrastructure, academic institutions are actually playing a part in increasing students' perceived self-efficacy and their involvement in entrepreneurial activities (Hashemi, Hosseini, & Rezvanfar, 2012) and thus changing students' perception on entrepreneurship feasibility.

Youth agropreneurial aspirations may be hindered due to inadequate preparation, such as insufficient business knowledge and lack of risk taking preparation. Because of this, agropreneurship may not be seen to be feasible or even desirable to students. In fact, stronger entrepreneurial promotion by academic institutions is needed by students to assist their enterprise foundation process (Venesaar, Kallaste, & Küttim, 2014). One way to supply adequate preparation to students is by fostering a supportive institutional environment, such as supplying resources like initial capital for business creation, inclusion of role models, and giving one-to-one support. With regard to a developing country such as Malaysia, academic institutions are expected by students to be supportive by providing networks, workshops, idea development for starting a business and entrepreneurship focus projects (Davey et al., 2011). These types of supports may increase students' confidence levels to take risk and thus initiate the new venture creation.

5. **Play an Active Role in Connecting Gen Y to the Network Circle:** Finally, since performing agropreneurial activities and founding an agropreneurship business cannot be done in isolation (Rutten & Boekema, 2007), academic institution should become an agent for networking development between students and potential suppliers, customers and capital providers. Indeed, it was found that the unavailability of social network and lack of resources were hurdles to entrepreneurship (Sandhu, Sidique, & Riaz, 2011) and contribute to hiccups along the agropreneurial process. Nascent agropreneurship businesses cannot be realized unless agropreneurs are able to acquire those resources (Sesen, 2013). In order for agropreneurs to successfully operate their business, the importance of resources available to them and knowledge is undeniable. Networks can be

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a source of necessary resources needed to start an entrepreneurial behavior (Fernández-Pérez, Alonso-Galicia, del Mar Fuentes-Fuentes, & Rodriguez-Ariza, 2014; Gutiérrez & Pérez, 2010; Najib & Kiminami, 2011; Quan, 2012; Rampersad, Troshani, & Plewa, 2012; Sequeira, Mueller, & Mcgee, 2007; Sesen, 2013; Slotte-Kock & Coviello, 2010), such as information regarding the applicable laws, necessary permits, reference, potential sources of financing and emotional support to provide agropreneurs with distinctive resources and knowledge (Sequeira et al., 2007). Valuable, distinctive and unique key resources supplied by networks improve the effectiveness of entrepreneurs (Slotte-Kock & Coviello, 2010) by greatly allowing them to experience positive outcomes as distinctive and unique resources contribute to greater and remarkable returns (Chiu & Lee, 2007; Rutten & Boekema, 2007). Since becoming an agropreneur, and also other kinds of entrepreneurs, they are challenged with limited resources (Sequeira et al., 2007) and uncertainty, encouragement, information, support, and access to key resources provided by networks greatly influence students' intention to become agropreneurs in a favorable manner. Agropreneurs who are capable of developing meaningful networking are entrepreneurs that gain rewards from networking, which enable them to make decisions quickly, build confidence, save lots of valuable time and necessary cost as well as learn greatly from the experiences of others (Liñán & Santos, 2007; Rampersad et al., 2012; Sequeira et al., 2007). At the initial state of the agropreneurship venture creation process, potential agropreneurs can benefit from networking in at least two ways. First, agropreneurs can make use of networks to recognize business opportunities and chances. Second, being surrounded by networking allows agropreneurs to get access to resources that can range from financial to human such as skilled labours. Therefore, an academic institution that is actively involved in arranging and introducing the students to the appropriate network circle will minimize the hiccups in the agropreneurship process. Academic institutions should take proactive actions to closely link students with potential business and social networks, which may be accomplished by conducting a seminar and providing focus group development with real world entrepreneurs, capital providers, and motivators.

CONCLUSION

In summary, the development of Gen Y creating a future that traditional subsistence farming often struggles to provide. Since an individual spends almost 18 years in getting formal education with 7 seven years at the tertiary level, an academic institution is undoubtedly a very salient agent in producing young agropreneurs. Academic institutions should pay more attention to what they could offer to develop more young agropreneurs by contributing to the development of integrated entrepreneurial skills, capabilities and competencies. With adequate agropreneurship education coupled with extensive agropreneurship supports programs received, it is believed to help Gen Y graduates to nourish creativity and innovation, especially in developing a novel agropreneurship product and useful ideas. Future research in agropreneurship area should focus on the impact of Gen Ys' skills and competencies developed by academic institution, and it is used along the agropreneurial business creation process as well as how these accumulated assets could impact the business performance. Another dimension that future research could focus is on the benefits the Gen Y could get from the network circle created by the academic institution in assisting the development of agropreneurhsip business activities among this unique cohort.

KEY TERMS AND DEFINITIONS

Academic Institutions: Higher educational institutions dedicated to education and research, which grants academic degrees the students.

Academic Institution Agropreneurship Support: The tangible and intangible assistance provided by the academic institution in fostering agropreneurship business activities among students including concept development support and perceived business development support.

Agriculture: The broad field that includes efforts of farming, planting, fisheries, and downstream agro-based and agro-processing industries. In Malaysia, agriculture involves plantation and food crops, horticulture, aquaculture, livestock husbandry and all other related activities.

Agropreneurship: Entrepreneurship activities practised by individuals who own goals to create wealth by applying innovative skills within the agriculture industry.

Agropreneurship Education: Formal pedagogical agribusiness programmes or process of education for agropreneurial attitude and skills which involves certain personal agropreneurial qualities.

Gen Y: Young people who were born between 1977 and 2000. Also known as Millennials, Nexters or the Nexus Generation, or Echo-Boomer.

Graduate Entrepreneurship: Entrepreneurship business activities that are run and managed by graduates who have graduated from higher education institutions.

Chapter 9
Application of Information Communication Technologies for Agricultural Development Through Extension Services: A Review

L. K. Mabe
North-West University – Mafikeng, South Africa

O. I. Oladele
North-West University – Mafikeng, South Africa

ABSTRACT

This chapter outlines the role that Information Communication Technologies (ICT) play in the global context and in Africa, agricultural extension and Agricultural development. The role of and use of ICT by extension officers, the trends of ICT in agricultural information management, how ICT bridge the digital divide as well as the types of ICT tools used by extension officers such as radio, television, computers and internet. It also gives the perspective about the factors that influences use of ICT by extension officers which are seen as playing an important role human development.

INTRODUCTION

ICT and the Global Context

According to Roy (2005), the use of Information Communication Technologies is expanding rapidly. ICTs comprise of a diverse set of technological tools and resources to create, disseminate, sore and manage data and information. Traditional ICT tools such as television, radio and telephone have proven their effectiveness in promoting development in marginalized areas. The emergence of computers, the internet

and wireless communication technology, along with powerful software for processing and integrating text, sound and video into electronic media comprise modern ICTs. The spread of the global electronic network of computers popularity referred to as the internet and wireless telephony has generated an unprecedented global flow of information, product, capital and ideas. Furthermore Adesope, Asiabaka and Agumagu (2007), states that the advent of the computer gave a new direction to the information and communication technology industry. This is evident in the use of technologies such as electronic mail (e-mail), electronic commerce (e-commerce) and more recently mobile phone, which Salihu (2000) referred to as Palm assistant, because of its palm-size nature. Information communication technologies such as electronic mail and electronic conferencing provide scientists, administrators and information staff with rapid and reliable communication, while increasing productivity and decreasing communication costs by reducing the physical means of communication channels (Kerrigan, Lindsey & Novak, 1994).

ICT and Africa

Agriculture has and will be the backbone of the African economy contributing to the livelihoods of rural communities. The prospects of African globalization cannot be separated from the nature of its historical incorporation in the world economy, the ensuing commodity based export structure, unequal terms of trade and declining position in the world economy. Globalization demands driven re-casting critical questions on the role of state and NGO's to steer economic development through the use of ICTs. In Africa, most farming communities rely on the public Agricultural Extension services for technical farming advice and information. Information communication Technology can be the instrument for stimulating the growth and by ushering in unique forms of national and transnational exchange relationships between producers and consumers, for instance, the scope of widening markets, profitability and investments and the choice of diverse range products, services and facilities (Roy, 2005).

Africa, like the rest of the world, needs to attain the United Nation's Millennium Development Goals (MDGs) and the World Food Summit (WFS) goals to reduce the number of hungry people from 790 million to 400 million by 2015. To reduce poverty by 50% by 2015, the African economies need to grow at 7% per annum. Another target requires that a national strategy for sustainable development be in place in every country to ensure the reversal of current trends in the loss of environmental resources at both national and global levels by 2015. Several factors are responsible for the numerous challenges facing the continent. First, there has been underinvestment in the rural areas. Inadequate access to markets and unfair market conditions also continue to be major stumbling blocks. These challenges, coupled with the crippling impact of limited access to advanced technologies, weak infrastructure, high production and transport costs, present the image of a continent that will be poverty stricken for many years to come (ECA, 2005).

Richardson (1997) points out that ICTs are considered to be drivers of change for rural and agricultural development, as they are efficient tools for reaching rural and remote communities and for improving agricultural productivity. Due to this factor, ICTs can speed up the extension of development services in areas that include healthcare, education and agriculture. Furthermore, ICTs can be instrumental in strengthening partnerships and in providing a framework for shared learning. It is not surprising, therefore, that ICTs have led to increased use of a networked information environment and the development of platforms for better sharing and exchange of information and knowledge (Van Audenhove, 2003).

ICTs, Agricultural Extension, and Agricultural Development

Agricultural Extension and advisory services in the field of agricultural development has seen many changes in the past decades. The first trend is the change in philosophy and rationale behind extension services towards more participatory approaches and participatory technology development (PTD), a shift has been made in thinking about the role of extension services in broader information and knowledge sharing processes (Leeuwis, 2004). A second trend in extension services, situated at a less conceptual level and a more professional level, seems to be the development towards 'extension-plus' which means that extension and advisory services plays an expanded role because extension has long been primarily associated with 'transferring technologies to farmers' (Sulaiman, 2003).

According to Munyua (2008), Information and knowledge play a central role in rural agricultural development. In describing the role of women and men in agricultural and rural development, information and knowledge are essential if women and men are to respond to opportunities and major challenges of the coming century. In emphasizing the role of information and knowledge, information and knowledge is described as prime productive resources. The Food and Agriculture Organization of the United Nations (2000) advances a corresponding view to this perspective in its assertion that "information and knowledge play a key role in ensuring food security and sustainable development". World Bank (2002, cited in IICD 2006), also takes the position that "information and communication technologies are a key input for economic development and growth".

Munyua (2008) states that Africa has a cumulative body of agricultural information and knowledge, know-how and practices that need to be shared continent-wide and applied for improved livelihoods and sustainable development. Although there is a lot of information relevant to small-scale farmers, this is scattered and hard to find. Most of the institutions implementing initiatives on ICTs and small-scale agriculture in Africa have developed local agricultural information and knowledge resources in English, and in some cases, in local languages. Bertolini (2004) notes that most farmers in Africa rely on intermediaries such as nongovernmental organizations (NGOs), extensionists and producer organizations to access and exchange information on innovations in crop varieties, pest management, soil fertility, weather forecasting and irrigation among others. Wider access to such information and in a more cost effective manner ought to be given priority.

There seems to be recognition that extension should merge with, or at least should incorporate, other fields such as improved access to markets, research, advice, credit, infrastructure, farmer organization development and business development services. "Research and extension strategies should emerge out of a broader livelihood analysis organized through a wider consultative exercise." Next to these developments in fundamental thinking in the academic and professional worlds, a third global economic trend from public services to private services can be identified. Although, for instance in India, the state Department of Agriculture (DoA) continues to dominate extension provisions, initiatives towards privatization and public-private partnerships do exist (Sulaiman, 2003).

Effective agricultural development requires access to information on all aspects of agricultural production, processing and marketing and it seems likely that if anything this need is increasing (Jones, 1997). ICT is already showing the potential to play an important role in the delivery of this information to this sector in both developed and developing countries. In most cases the base technology is universal, rather than being specific to agriculture, and hence usage evolves from existing designs and practices (Zijp, 1994).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The agricultural communications industry will change in the future because the agricultural industry itself is changing dramatically. There is more information but perhaps less knowledge than ever before in agriculture and that is a huge opportunity for extension officers. At the same time, the emergence of the internet as a communications medium, as well as the convergence of many other traditional communications vehicles like print, radio, television and database marketing, has a direct impact on extension officers approach their jobs (Boone, Meisenbach & Tucker, 2000).

According to Boone et al. (2000) today agriculture holds a unique position in society. As more and more of the world's population moves from rural to urban areas, agriculture as a way of life is changing. Although its role in food production has not changed, however, and more and more of the world's food production is centered on agriculture with fewer and fewer people engaged in production farming. The gap between rural and urban society has narrowed. Media and popular culture have changed the way that farmers work, live and interact with other parts of society. Depending on the commodity in which a farmer specializes, information and technology is critical for efficiency and fiscal success. Technology is not limited entirely to the production aspects of agriculture. Farmers, as has much of society have adopted personal computers technologies into their farm operations; therefore computer technology is built into most equipment in use on farms today. Specialty crops and specialty farming operations are also tied into advanced technology.

Role of ICTs in the Extension Service

Information and communicative technologies are key enablers of globalization. They allow for the efficient and cost-effective flow of information, products, people and capital across national and regional boundaries. ICT is not a panacea for rural development problems, but it has the potential to help the rural poor to leaping some of the traditional barriers to development, by improving access to information, expanding the market base, enhancing employment opportunities and making government services work better (Swanson & Rajalathi, 2010).

According to Leeuwis (2004),the conventional method of training and information dissemination through the extension channel has been based on cascade model: master trainers are trained, they in turn train the trainers who go to the field to conducting training of extension officers / workers; extension agents carry information to the final recipients. This model has obvious disadvantages such as loss of information, degradation of quality of training, long lead times and high costs. In fact, the lead time of such a training cycle is so long that by the time one training cycle is completed, the second is overdue. There is therefore a great need to speed up the extension process and enhance its quality. It is in this area where the use of ICTs amongst extension officers plays an important role and with the Participatory Programme Extension Approach, the gap that exists in the information flow between the end users will be addressed.

Effective ICTs strategies must provide the basic infrastructure for connectivity and access, develop human capacity, offer affordable demand-driven ICT services and involve local stakeholders and beneficiaries in project design and implementation. Liberalization of the telecommunications sector can dramatically expand connectivity and reduce costs, but the strategic government investment or regulatory measures are needed in disadvantaged areas where the private sector does not provide services. Community- based telecenters offer a way of providing affordable access to ICT services in rural areas and this will assist agricultural extension officers to disseminate required farming information that will increase the agricultural productivity (van Veldhuiven, et al, 1997).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The diffusion of ICTs is fundamental to enable developed and developing countries to stimulate socio-economic development and usher in structural change. The term digital divide has been coined to capture the bias in the patterns of access to ICT in terms of the levels of use on the internet (region, sector, socio-economic group), the ownership of computers or public facilities, and the availability of telecommunications (telephone lines), the nature of use (e-mail, using the World Wide Web), and the institutions (public and private) offering ICT facilities (Roy, 2005)

ICTs are in addition are considered to be drivers of change for rural and agricultural development as they are efficient tools for reaching rural and remote communities and for improving agricultural productivity. Due to this factor, ICTs can speed up the extension of development services in areas that include healthcare, education and agriculture. Furthermore, they can be instrumental in strengthening partnerships and in providing a framework for shared learning (Richardson, 1997).

Uses of ICT's by the Extension Service

The ICT sector as a whole (telecommunications, broadcasting, computer hardware and software, and related technologies) has emerged as a strategically important sector driving social and economic change. The paradigms shift in development concept towards participation and sustainability coupled with revolutions in the information and communication technology has provided opportunities for extension and rural communities to move into the information age. Extensive review of literatures in agricultural development showed that there is a direct relationship between research and the utilization of research findings. This is a strong linkage complimented by flawless information flow enhanced by the effective use of ICT by the extension services significantly boost agricultural production and improve rural livelihoods in developing countries. Front line extension workers, who are the direct link between farmers and other actors in the agricultural knowledge and information system, are well positioned to make use of ICT to access expert knowledge or other types of information that could facilitate the accomplishment of their day-to-day activities (Aboh, 2008).

The important role played by agricultural extension services in providing linkages and support to agricultural research information and technology transfer for farmers and farming communities has been crucial to agricultural success. Strong criticism of public agricultural extension services has circulated in recent years. This criticism is due to agricultural extension top-down approach, which has been supply- driven, technically weak, patronizing, and catering only to large farmers and providing insufficient coverage of and contacts with farmers (FAO,2004).

IFAD (2002) reached the conclusion that extension services in Africa have failed to address the needs of small-scale farmers. In another study, Richardson (2006) argues that agricultural extension services that provide agricultural information do not work effectively in Africa. These shortfalls may be due to changes in the extension process that have resulted in the shift to the facilitation and brokerage of information, communication and advocacy services. This range of services, meant to improve rural livelihoods, can benefit from the applications of ICTs. It has been found for instance that the technologies could be used to restructure extension services. For example, they can be used to disseminate information and advisory services to farmers to improve their efficiency. More specifically, agricultural information on input supply, use, product marketing, and value addition could be transmitted through ICTs, thus cutting down the number of visitations by extension workers. ICTs could also free time for extension workers if greater use is made of telecentres and other public access points.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is true that public extension services unfortunately have been ineffective in reaching farmers and farming communities with information and technologies needed to ensure food security and sustainable development. Farmers have managed to obtain information from other sources where agricultural extension services have been insufficient. These preferred sources include other farmers, private sector agricultural marketing and sales providers (of seeds, fertilizers and agrochemicals) or from NGOs and civil society organizations. There is substantial literature providing evidence to this fact. What is clear from many studies, however, is the continued need for information by farmers and farm communities- thus necessitating continued improvement in ways and means to provide the extension support that farmers and farm communities require and demand.

According to FAO, (2004) given the reality of an interconnected world, the recent trend currently confronting agricultural extension globally are also manifesting regionally and nationally. These include the responses to the effects of globalization, privatization, increasing commercialization of agriculture, increased democratization and participation, environmental degradation, increasing incidences of natural disasters, improved communications including the availability of information technology, the need to address the HIV/AIDS epidemic, preferences for multidisciplinary approaches and holistic development and criticism of extension itself. The faces of globalization and privatization on extension, for instance, are probably most pronounced in the highly competitive, market – driven orientation of agribusiness. However, most extension services are ill prepared to deal with the changes due to extension agents' lack of knowledge and skills in those areas.

The twin challenge for developing country agriculture, then, is to harness the power of ICTs to compete in complex and rapidly- changing regional and global markets while empowering poor smallholders with information and communication assets and services that can increase their productivity and income and protect their food security and livelihood.

New technologies, new applications and new business modes and their wider availability and affordability are enabling widespread innovation in addressing the needs of the poor farmer and farming communities. The uses of ICTs are driving changes in agriculture that make it even more urgent to understand their potential and pitfalls. The dramatic and rapid expansion in global information and communications networks in the past decade, and the concomitant proliferation of new information and communication devices, applications, services and business models pose significant new opportunities and new challenges for developing subsistence agriculture and for rural poor populations. Globalised food markets have both opened new market opportunities for developing country agriculture and created new risks and volatility, including new challenges to food security, and risks of marginalization from agricultural value chains that increasingly depend on technical sophistication for speed, customization and food safety.

Agriculture Technology Dissemination

According to (Nagasri, 2000; Aizaki, Nakashima, Ujie, Takeshita & Tahara, 2010), all agricultural extension and farmer programs face major challenges which are ensuring cost effective outreach, designing solutions tailored to needs of individual farmers and cultivating an image that is farmer friendly. Any change in technology, the economic impact of ICT occurs through improvements in efficiency and increasing productivity. This can take place in different ways including improving efficiency in resource allocation, reducing transaction costs, and technical improvements that result in an outward shifting of the production function. In particular, through the provision of information from a source that is relative affordable, accessible and broadly available, ICT can contribute to the reduction of uncertainty in activi-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ties and transactions, reduce the extent to which markets are thin, missing or incomplete, and reduce the extent to which information asymmetries can be exploited by the relatively informed to extract rent when transacting with the relatively uninformed.

Most of the farming communities, particularly in the rural areas, do not have access to the huge knowledge base acquired by agricultural extension centers and businesses. ICT can provide vital access to information, markets by connecting the rural poor and marginalized to the worlds information resources and opportunities. The inequality in opportunities presented by ICTs is widest between commercial and subsistence farmers, urban and rural groups, rich and poor, men and women, and the educated and uneducated. Despite this, ICTs use in rural areas is increasing, such as the internet and cell phones and the individual, community ad national benefits they bring by making information available at the fingertips are forever emerging. A productive sector depends on a fruitful and fair interaction between the diverse actors-communication and information flows are critical to this process. The technology and socioeconomic context of the farmers determines the selection of ICT in terms of content, media and form of communication.

According to FAO (2006), there are numerous instances where improved production and market information is important to farmers who are often a particularly vulnerable group. These might include extension and research on adoption of new crop varieties, mechanization, pests and weed control, processing and the care of livestock. A further observation was made by FAO (2006) that, technology and what can be accomplished with it has implications for rural communities and producers of all sizes, whether these are larger commercial producers who need to understand global market situations that affect them or subsistence producers concerned with local input markets. This is particularly relevant in the agriculture sector which is an activity that is often highly dependent on externally determined requirements. Government, parastatals and private sector agri-business frequently regulate commercial agricultural production by placing requirements on quality, safety, logistical arrangements and even quotas. Inputs to the agricultural sector may be similarly affected, including seed, fertilizers, pesticides and herbicides as well as livestock feed and veterinary services (FAO, 2006).

The development of agricultural producers can be enhanced by using ICT is though what is known as site-specific management, also called precision agriculture. This refers to a knowledge intensive management strategy that involves the application of information technology to crop production. The literature provides many examples of ICT applications in this domain, including uses in the application of chemical samples, application of fertilizers, application of herbicides, application of liquid fertilizers, application of pesticides, and so forth, as well as activities for efficient resource management such as livestock movement regulations (FAO, 2006).

Farmer Education

According to FAO (2004) strengthening and upgrading rural education and training is a sure means for addressing the knowledge, skills and information gaps that currently exist for farmers as well as extension agents. Today's farmers seem to be more innovative and extension services have become laggards. The important role that rural education institutions can play in this is vital and will require policy changes and commitment and support by governments, donors and communities, as rural schools and institutions are often given lower priority compared to urban institutions and are thus under - resourced and underutilized. Strengthening of education's linkages with extension is a needed component.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Extension personnel are unable to creatively respond to the change taking place in the environment and remain duplication and tradition bound. Farmers need dynamic information relating to agricultural rural development. There is presently a gap between farm families need by way of generic and dynamic information in what the conventional extension agencies are able to provide. Therefore, to satisfy the need s of farmers and farming communities, information and communicative technologies would be very effective. ICTs can play a major role in updating the farming community by ensuring information flow through agri-websites, enabling the industry to take an updated, uniform database of farming practices to the individual villages, with the data customized to individual agro-climatic zones (Bhatnagar & Schware, 2000; Acker & Gasperini, 2008).

There is potential to bring about transformation in agriculture, through the enhancement of education and research. Perhaps the most straight-forward way in which this can occur is through the conventional agricultural extension system. Traditional Training and Visit extension is a comparatively costly approach requiring the preparation, printing and dissemination of training material, large numbers of trained extension officers who carry the messages to be conveyed, and the risk that messages may become distorted when they are eventually conveyed. Extension officers who are connected through ICT will be better able to update their knowledge on a continuous basis than in the past, avoiding the criticism that the information provided by these services is often irrelevant or out-of-date. This approach does not require any ICT capacity on the part of the farmer, and as a result, may be relatively simple to implement in many countries. However when farmers are digitally literate a range of new opportunities become available.

According to FAO (2006), ICT can be used for agricultural research surveys and censuses completing a 'virtuous circle' of information exchange and can also be used to build what have been termed Knowledge Digital Libraries which can include the collection of indigenous knowledge about crops and cultivation practices specific to local contexts. Through participatory research strategies that place farmer's and communities at the centre of the research process, a network for small scale development projects can foster the exchange of information, experiences, expertise and solutions to technical problems and adapt the often generic nature of information accessed by ICT to local conditions. Such appropriately supported ICT strategies have the potential to enhance access to information and information technologies as well as access to channels and other modes of communication.

Prize Realization

The benefits of using ICTs can be broadly categorized as personal and commercial. On the personal front ICTs can be used to enable farmers to keep in touch with their relatives and friends whereas commercially, farmers can use them to obtain information on the prices of agricultural inputs and marketing their products. Most farmers sell their produce to middlemen or in the nearest markets where the middlemen decide on price. The farmers have virtually no interaction with the buyer nor do they know the prices ruling at nearby markets. By making commodity prices and market information on a real time basis available on the internet, the farming community can be provided with choices that they lack today. This will ensure better price realization and stimulate a drive towards better productivity. The role of extension services becomes increasingly important in ensuring that the use of ICTs is more relevant and effective.

Furthermore the use of ICTs amongst extension officers can also enormously benefit farmers who grow cash crops by providing forecasted information on future process of commodities. This will prevent the tendency of farmers to jump a decision on the basis of ruling price levels and later discover that the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

process have crashed when they are ready to sell their produce at the end of the season. Information on likely future process of commodities can avert this disaster to a large extent (Nagasri, 2000)

According to Rivera and Sulaiman (2009) in India, Reuters Market Light provides information on market prices, weather conditions, agricultural policy news, and tips on farming cycles via SMS to fee-paying subscribers in India. Information can be personalized based on the type of crop, region of the country, and local language. The service employs a staff of 300 full-time content professionals to provide news and data on more than 250 crop types, 1,000 markets, and weather forecasts for 2,500 locations.

Back-Up Services

An important task in the process of development is that of carrying information on the latest agricultural concern to rural areas. It is not sufficient for extension officers to provide farmers exhaustive information through web portals, their specific queries have to be replied though on-line chats, they have to be provided with early warning systems regarding pest onset and weather forecasts to their local areas. Digital data storage appeared on the scene much later than long distance communication. While telephones and telegraphs revolutionized the transfer of information, traditional analog methods like pen and paper were still considered sufficient enough to keep track of production. Bookkeeping had become an art by then, and farmers simply did not have enough time to learn the ins and out of computerization.

However, as the volume of information increased dramatically over the years, the limitations of old methods became increasingly clear. They first became apparent in central organizations like Ministries of Agriculture which had to keep track of production on an exceedingly vast scale and maintain the information indefinitely. The vulnerability of paper and the massive amounts of record to track meant that digital storage quickly went from being a novelty to a necessity. The use of ICTs amongst extension officers will attract large number of farmers; lot of new industries interested in providing services like transportation ad mechanized farm operations like pest control will get created (Gurstein, 2000).

Enhancing Agricultural Production

Swanson and Rajalahati (2010) reported that most countries have somewhat similar agricultural extension systems, but most systems differ in terms of their respective management structure, including how extension priorities are set, how extension programs are planned and by whom, and how extension programs are actually organized and implemented. Farmers especially emerging ones often face threats from soils, drought, erosion and pests. Key areas where ICTs can help improve this is by providing up to date information about pest and disease control, early warning systems, new varieties, new ways to optimize production and regulations for quality control.

Capacity Building and Empowerment

The meaning of the term capacity building seems to vary according to the user, but there seems to be no doubt that ICTs are capable of helping to achieve it. There are many definitions, but they all carry the same theme concerning developing an organization's or individual's core skills and capabilities to help them achieve their development goals. This definition suits the context of ICTs as it assumes knowledge of the existence of development goals, without which ICTs are unlikely to be of much value (Marker, McNamara & Wallace, 2002).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is widely accepted today that the information society is going to lead the knowledge society where individuals as well as institutions are valued and judged according to what they know and how much they know. The farming population needs new knowledge and new skills to understand, to feel at ease with, to take advantage of, to benefit from, and to operate ICTs efficiently. The sped of change of ICTs means that acquisition of this new knowledge and skills needed to operate ICTs is becoming a never ending process.

Marker et al. (2002), further states that capacity building also relates to the accumulation of social capital, which refers to those features of social organization such as networks, norms, and social trust that facilitate coordination and cooperation for mutual benefit and establishing networks for mutual benefit that can be nurtured and extended through the use of ICTs. ICTs can help create and sustain online and offline networks that introduce and interconnect people who are working toward similar goals. Many NGOs can use ICTs as an advocacy tool to champion their courses.

ICTs can be used strengthen communities and farmer organization to strengthen their own capacities and better represent their constituencies when negotiating input and output prices, land claims, resource rights and infrastructure projects. Rural communities are able to interact with others via the use of ICTs which reduces social isolation that they would otherwise be facing. Besides, ICTs are able to make processes like law-making and land title approvals more transparent (FAO, 2004).

In the past senior subject-matter specialists were needed to provide technical support to field extension staff about key crops, livestock, fisheries, and other commodity areas. In the future, it may be possible to make more of this technical and marketing information available electronically to the field extension staff, given the complexity of problems being addressed. The goal should be to enhance the capacity of the field extension staff to make available a wide range of technical and market information to the different group of farmers being served, especially small-scale men and women farmers through the use of ICTs (Swanson et. al, 2010).

According to Flor and Hazelman (2004) in Thailand, it is mandatory for the field extension staff of the DOAE to undergo training on Basic Computer Applications and Web Tools. The DOAE ICT Center conducts both training courses on a regular basis. However, secondary data from the 2001 UNDP Human Development Report reveal that computer literacy in the rural areas is still quite low. Generally, Thai extension workers are computer literate and proficient in using the World Wide Web. Their role may go beyond plain users but as contributors to and developers of online knowledge products. Thus, training programs on Web technologies (i.e., Web writing, html, and interface design) might be in order.

Knowledge Base

A knowledge base is a portal –type application that can centralize many major sources of information into one searchable reference library. The sources of information could include government websites, universities, document archives, the Internet, economic reports, historical data and others. The information may have different security levels depending on who is looking at the information, but in general would be open to browsing or searching by topics and keywords. Internet information would be filtered and categorized for more accurate and valuable results. Information in the knowledge base include: technology, seeds, livestock, veterinarian resources, best farming practices and natural language sources (Richardson, 2006).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

AGRICULTURE KNOWLEDGE MANAGEMENT

Knowledge sharing, exchanging and dissemination are elements in a broader theme which is knowledge management. The central purpose of knowledge management is to transform information and intellectual assets into enduring value. The basic idea is to strengthen, improve and propel the organizations by using the wealth of information and knowledge that organizations and its members collectively possess. It has been pointed out that a large part of knowledge is not explicit but tacit. This is true for knowledge in agriculture where a lot of good practices are transferred without being well documented in books, papers or extension documents. To manage the knowledge properly, ICTs are needed. In effect, there are many information technologies that can be used for knowledge management (Said, Rafea, El-Beltagy & Hassan, 2009).

Content management system in its wider sense including data bases and multimedia, *is* the core technology of information and knowledge management. This technology can be used in different applications: Building a national agriculture research information system (NARIS) which needs to include research outcomes, projects, institutions and researchers in every country, and a regional research information system that works as a portal for all the NARIS. An example NARIS has been developed at the agriculture research center in Egypt, developing an information system of indigenous agricultural practices can enable researchers to examine this knowledge and decide on its usefulness for sustainable development. Such a system will also keep this knowledge for future generations before it disappears as a result of advanced technologies, developing an information system recording matured technologies that on a trial basis have proven successful and success stories that have achieved economic growth will strengthen the interaction between inventors and innovators. This will lead to an innovation-driven economic growth paradigm, storing and retrieving images, videotapes and audiotapes related to different agricultural activities (Said et al. 2009).

Said, et al. (2009) further states that geographic information systems (GIS) are needed to store databases about natural resources with a graphical user interface that enables users to access these data easily using geographical maps. Furthermore decision support system techniques are needed in many applications such as simulating and modeling methods can be used to build computer systems that can model and simulate the effect of different agricultural production policies on the economy and the environment to help top management make decisions, using expert systems technology to improve crop management and track its effect on conserving natural resources is elaborated in This technology may also be appropriate for keeping indigenous knowledge. Expediting the expert systems development by generating agriculture specific tools to overcome the well-known problem of knowledge acquisition and enhancing the explanation capabilities of expert systems developed for agriculture.

Agricultural Information Needs

The effectiveness of information transfer process depends on the effectiveness of the communication system through which the transfer is to take place, and that, in turn, depends on whether the target audience has access to the medium and can understand the message which it conveys (Feather,1994). In light of the constraints of human and financial resources and geographical distances, the media and ICT are being promoted as valuable tools in the delivery of extension information. Increasingly, ICT is being regarded as a tool for sustainable development and poverty reduction. The extent and rate of change now occurring in the development of ICTs have opened the way for significant change in crop production

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

management, agricultural decision-making and information dissemination. The farmers may depend on extension personnel to get the proper advice to cultivate the crop. The information needed relate to different schemes, crops, technologies, seeds, fertilizers, pesticides, availability of fertilizers, seedlings, biopesticides, soil fertility, pest and disease diagnosis and many more.

The agricultural marketing information is essential for farmers to increase their profits. Information such as price details of seeds, fertilizers, pesticides and availability of these products in the market enables the farmer to take decision in choosing right seed, fertilizer and pesticide required for the better farming. The vital information that flows from the agricultural policy maker's desk, such as fixation of procurement price, procurement targets and policy relating to exports helps to farmers to get maximum profits.

In India, Reuters Market Light provides information on market prices, weather conditions, agricultural policy news, and tips on farming cycles via SMS to fee-paying subscribers. Information can be personalized based on the type of crop, region of the country, and local language. The service employs a staff of 300 full-time content professionals to provide news and data on more than 250 crop types, 1,000 markets, and weather forecasts for 2,500 locations (Rivera & Sulaiman, 2009).

The delivery of information, technical advice and agricultural skills training for farmers rests with national extension services. However, in the Pacific extension activities are typically given a low priority. Extension work continues to face challenges because of the scarcity in human, financial and physical resources. The need 'to do more for less' is a realty, and partnering with the media can help enhance extension services (SPC, 2011).

Agriculture Support

Research suggests that increasing agricultural productivity benefits the poor and landless through increased employment opportunities. As the vast majorities of poor people lives in rural areas and derive their livelihoods directly or indirectly from agriculture, support for farming is a high priority for rural development. ICTs can deliver useful information to farmers in the form of crop care and animal husbandry, fertilizer and feedstock inputs, drought mitigation, pest control, irrigation, weather forecasting, seed sourcing and market prices. Other uses of ICTs can benefit farmers, enabling them to participate in advocacy and co-operative activities.

Vulnerable and Marginalized Groups

According to Marker et al. (2002), women in developing countries particularly, face difficulties in using ICTs, as they tend to be poorer, face greater social constraints and are less likely to be educated or literate than men. They are likely to use ICTs in different ways, and have different information requirements, to men. Women are less likely to be able to pay for access to ICTs, either because of an absolute lack of funds or because they lack control of household expenditure. Constraints on women's time or their movement outside of the home can also reduce their ability to access technologies. Such groups usually require special assistance and attention in order to benefit from programmes that are targeted at poor people.

Munyua (2000) further notes that, in any farming system it is important to recognize the various roles of men, women, youth, and children. Women in rural areas have very little access to information. They are mostly poor, illiterate, and unable to afford even the very most basic forms of ICTs, such as radios and telephones. Nevertheless, rural women actively seek and disseminate information. So ICTs

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

must be appropriate to enable women to gain access to information efficiently and cost-effectively. Gender considerations have, however, not received the attention they deserve in the design and use of information services or in the application of ICTs. Therefore the types of information required to meet the needs women express, to determine the information gaps, and to select the ICTs and services to best close these gaps must be identified.

The lack of reliable and comprehensive information for rural female farmers is a major hindrance to agricultural development. They require information on agricultural inputs; market prices; transportation systems; product potential; new environmentally sound production techniques and practices; new agricultural technologies; new markets; food processing and preservation; decision-making processes; the resource base; trade laws; and trends in food production, demand, and processing. Women also need to exchange indigenous knowledge. However, most available local information is packaged in a raw form and therefore difficult to access or use .The situation is compounded because women do not know where to find this information. Moreover, current mass media and communication systems have not been used to maximum effect in development. Information should be accessible to female farmers at selected sites, with various ICTs to facilitate easy access to relevant information and information exchange to meet the information needs of rural female farmers (Munyua, 2000).

Trends in Agricultural Information Management

According to Ballantyne (2009), the world of agricultural information and communication is changing, as agricultural innovators become active creators and managers of information and knowledge and information managers become innovators. These effort calls for greater investment in knowledge creation, information access, and the wider use of information technologies. There is an exploration on what the renewed interest might mean for information and communication specialists working in agricultural environment. Starting from an "innovation systems" perspective which looks across the agricultural information for development landscape and highlighting some items on the agenda of information and communication specialists working area. The widening recognition of the value of farmers knowledge, growing used of information and communication information and communication technologies to enable different agricultural development activities, concerns to ensure that public investment result in public goods whose benefits can travel, related efforts to ensure that agricultural content is open and accessible, the discovery and increasing use of a 'social' web, and some emerging new roles for agricultural library information and information centers to meet changing demands.

Virtual Community

Satyanarayana, Reddy, Balasubramani, Sharma, and Bhaskar (2008) defines a virtual community, e-community or online community as a group of people that primarily interact via communication media such as letters, telephone, email or usenet rather than face to face. If the mechanism is a computer network, it is called an online community. Virtual and online communities have also become a supplemental form of communication between people who know each other primarily in real life. Many means are used in social software separately or in combination, including chartrooms and forums that use voice, video and/ or text.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Virtual Information Networks

A number of virtual information networks with the objective of linking agricultural institutions for facilitating better access to information resources have been initiated successfully. While some of these network agricultural institutions within a country, link to agricultural institutions around the globe.

Agriculture Network Information Center

Agriculture Network Information Center (AgNIC) is an Internet based network of public and private agricultural libraries and information centers, coordinated by the National Agriculture Library (NAL), USA. The network aims to provide global access to agricultural information. AgNIC Members represent 40 land-grant universities and other national and international partners including universities and research institutions, government agencies, and a non-profit organization. Through its website the network provides access to a network of electronic sources on research and teaching in agriculture, food, renewable natural resources, forestry, and physical and social sciences. AgNIC is a distributed discipline-oriented source of agricultural information in electronic form on the Internet. The goals are to: identify major collections of agriculture-related information; provide mechanisms to facilitate access/ retrieval from these information resources; create mechanisms to encourage organizations to collaborate in creating/ using AgNIC. AgNIC partners select important information sources for inclusion in the system (Satyanarayana et al. 2008).

Services include: Resource database with web sites, image collections, lists of publications, documents, databases, and other resources; Calendar of events which includes meetings, seminars, national and international symposia and conferences, conventions, and workshops in agricultural and related sciences; News items; Specialized Services – such as Plant Disease Announcements; discussions on emerging plant diseases around the world; Expertise where specialists respond to individual questions. There are partnerships between libraries and United States Department of Agriculture (USDA) Cooperative Extension programs; between libraries and academic departments within colleges; between states and between technologists and librarians. Member participants take responsibility for small segments of agricultural information and develop Web sites and reference services in their specific subject areas. Nearly all participating AgNIC institutions have developed partnering relationships with a variety of internal and external institutions, groups, and agencies to develop content and tools for their respective Web sites.

Agricultural Libraries Network

The Agricultural Libraries Network (AGLINET) coordinated by the Food and Agriculture Organization of the United Nation (FAO), is a world-wide, voluntary network of international agricultural libraries with regional/country coverage and other comprehensive or specialized subject resource collections. All member libraries provide, upon request, access to the literature originating in the country or region or for a given specialization. AGLINET aims at combining resources for mutual and rational use through delivery of primary documents, by means of inter library loan provision of reproductions, bibliographic information; with appropriate regional and subject specialization. Member libraries include Agricultural libraries of national or regional importance with comprehensive collections and strong regional cover-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

age; Libraries in special subject fields within the broad domain of agriculture with worldwide coverage. AGLINET Network members include Libraries from Argentina, Australia, Belarus, Belgium, Benin, Botswana, Brazil, Bulgaria, Brazil, Canada, China Costa Rica, Czech republic, Denmark, Egypt, Estonia, Ethiopia, Finland, France, Germany, Hungary, India, Indonesia, Italy, Japan, Jordan, Kenya, Korea, Latvia, Lithuania, Malawi, Malaysia, Mexico, Netherlands, Nigeria, Norway Philippines, Poland Portugal, Russia, Slovenia, South Korea, Sprain, Sri Lanka, Sweden Syria, Thailand, UK, Uruguay, USA, West Indies and Zambia (Satyanarayana et al. 2008).

International Information System for Agricultural Sciences and Technology

The Food and Agriculture Organization (FAO) of the United Nations initiated agricultural information networking through AGRIS. Established in 1974, AGRIS facilitates information exchange and brings together world literature dealing with all aspects of agriculture and related subjects. AGRIS is a cooperative system in which 240 national, international and intergovernmental centers in participating countries input references to the literature produced within their countries and draw on the information provided by the other participants. The new vision of AGRIS, in response to the needs includes: a decentralized approach with greater emphasis on national partnerships, improved linkages between the AGRIS network and other FAO initiatives; focus on management of documents in agricultural science and technology in full text; information about activities, organizations, and people in agricultural science and technology (FAO, 2006).

Agrigate

Coordinated by the National Library of Australia is a project of the libraries of the Universities of Melbourne, Adelaide and Queensland, and the Commonwealth Scientific and Industrial Research Organization (CSIRO) in Australia. This is a subject information gateway for resources, both online and offline, in agricultural research. The purpose is to support the identification and dissemination of quality research materials selected by an editorial review process consisting of members of the agricultural research community. The content covers agriculture and related areas of value to the Australian agricultural research community. The resources selected have been reviewed by subject specialist librarians. The majority of resources identified in the database are available online.

AGROWEB CEE Network

Satyanarayana et al. (2008) states that AGROWEB CEE network has been established by organizations and individuals involved in agricultural and rural development in Central and Eastern Europe. This collaborative network is maintained by representatives of participating countries, and facilitated by International Association of Agricultural Information Specialists (IAALD) and FAO. Twenty-five countries from the Balkan region, New Independent States, Baltic States, Caucasus region, Central Asia, and European Union are participating in the network. National web pages have been established as portals for the countries in the region, which provide access to information about agriculture-related institutions - ministries, libraries, information centre's, universities, research centre's, NGOs, agro-marketing organizations and other organizations. The Agro Web national portals provide Internet links,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to these national institutions and to other relevant national web sites. In addition to the national portal pages, cross-cutting subject areas have been identified and a number of thematic sectors of the network are being coordinated by regional focal points.

Asia-Pacific Association of Agricultural Research Institutions (APAARI)

Information exchange among the Asia-Pacific national agricultural research systems is one of the primary objectives of the Asia-Pacific Agricultural Research Information System (APARIS). Components of APARIS include Management Information System (MIS) Tools viz.: Regional Research Networks (RRN) Database, NARS Database, etc.; information on regional events; access to scientific publications generated by agricultural research in the region; electronic Forums to facilitate dialogue among stakeholders of Agricultural Research for Development (ARD) in the region on issues of strategic importance; gateway/portal service - portal to RRNs, websites of NARS Institutions in the Asia/Pacific region, web-enabled information on key topics/themes of ARD; Knowledge Networks on ARD in the APAARI region; information dissemination through APAARI web site and publications. The web site has linkages to various national, regional and international institutions, networks, and other organizations (Satyanarayana et al. 2008).

The Consultative Group on International Agricultural Research

According to FAO (2006), The Consultative Group on International Agricultural Research (CGlAR) is a research network of fifteen international agricultural research centers. The 15 centers supported by the CGIAR are independent institutions, each with its own charter, international board of trustees, director general, and staff. The institutions are Africa Rice Center (WARDA), Biodiversity International, Centro Internacional de Agricultura Tropical (CIAT), Center for International Forestry Research (CIFOR), International Maize and Wheat Improvement centre (CIMMYT), International Potato center (CIP), International Center for Agricultural Research in the Dry Areas (ICARDA), International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), International Food Policy Research Institute (IFPRI), International Institute of Tropical Agriculture (IITA), International Livestock Research Institute (ILRI), International Rice Research Institute (IRRI), International Water Management Institute (IWMI), World Agro-forestry Center (ICRAF) and World Fish Center (WFC).

Thirteen of the 15 CGIAR Centers are located in developing countries and the knowledge gathered is shared and disseminated across the world. The CGIAR website gives access to a Virtual Information Center and Library. One can tap into agricultural information databases, including online libraries of the CGIAR Centers and the Core Collection Database. The CG Library gives access to databases and e-journals and facility to go directly to the full text of publications. One can search CGIAR libraries/ other agricultural libraries/by specific topics. The Virtual Information Center provides information on various topics mentioning the source against each topic. Each institutional library is the source for/ and responsible for providing information on specific subject areas viz.,: Agriculture in the Dry Areas- ICARDA library; Agriculture in semi arid tropics- ICRISAT library; Agro-forestry- ICRAF library; Aquaculture and fisheries -WFC library; Food policy- IFPRI library, Agricultural biodiversity – IPGRI library; Water Management-IWMI library; Wheat - CIMMYT library(FAO,2006).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

DAINet: German Agricultural Information Network

The German Agricultural Information Network (DAINet) is a catalogue of Internet sources in the field of nutrition, agriculture and forestry. DAINet was established in 1995 to guide people interested in subject specific information to sources on the Internet. DAINet has about 7,500 references to information sources and about 800 web links to agriculture-related organizations. Three sections cover, 'information', 'service' and 'dialogue'. The 'information section' organized by subjects, structures worldwide existing agricultural information under 'subject fields', 'user groups' and 'topics'. The 19 'subject fields' cover various topics of agriculture. The division into five user groups caters to the specific needs of farmers, economists, scientists, educators and journalists. The 'service section' is structured according to types of data. The 'dialog section' is used for professional communication through Internet. 'Information' and 'service' sections offer links to databases and web pages and also give access to newsgroups and mailing lists (Satyanarayana et al. 2008).

ELIN: Entomology Library and Information Network

According to Satyanarayana et al. (2008), the ELIN project hosted by the Natural History Museum, London, aims to establish a global Entomology Library and Information Network to provide entomologists with a co-ordinated and structured electronic information resource including a gateway to a wide range of entomological information. A mailing list was launched in 1998 and has over 100 members from libraries and information centre's from around the world, which has encouraged international communication between specialists working with entomological information. The ELIN project provides up-to-date, detailed information about entomological libraries around the world. ICTs.

Information Network on Post-Harvest Operations

Information Network on Post-Harvest Operations (INPhO) is an FAO databank project of the Post-Harvest Management Group. It is an international collaborative effort by the FAO, GTZ and CIRAD which aims to support the collection and dissemination of information on proven technologies and products in post-harvest systems. Components of the network include a comprehensive collection of information on post-harvest issues, communication/interactive services; links with other databases. The website includes full text documents of training and technical publications, country profiles, crop profiles (main focus is on cereals and grains, fruits and vegetables, oil seeds, roots and tubers). Recipients of this information include people working in the agricultural production and marketing sector viz., producers, researchers, policy makers, private investors and donors (FAO, 2006).

Philippine Agricultural Libraries and Information Services Network

Philippine Agricultural Libraries and Information Services Network (PhilAgriNet) aims to create and maintain a central electronic database of Philippine technical agricultural literature and make this accessible to agricultural scientists worldwide. Membership is open to agricultural institutions. The database intends to cover all technical publications on agriculture, generated by member institutions, both published and unpublished, and written in any language or dialect, regardless of format. Affiliation is open

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to libraries of Government agencies and corporations engaged in agricultural research; state colleges and universities, whose curriculum includes agriculture and independent or private agricultural agencies.

Virtual Extension Research Communication Network (VERCON)

Virtual Extension and Research Communication Network (VERCON) established by FAO aims to use the potential of the Internet and apply it to strengthening and enabling linkages among the research and extension components of the national agricultural knowledge and information system. VERCON aims at improving linkages between and within agricultural research and extension institutions through human and technological components. The human component is a network of staff of research and extension institutions, faculty of agricultural education, NGO workers, in some cases agro producers committed to strengthening collaboration, communicating, sharing information and supporting improved agricultural production. In order to link the human component there is the technological component, which allows members of the network to communicate and develop, share, store and retrieve information (FAO, 2006).

Network members can engage in two-way horizontal communication to address problems, discuss solutions and coordinate local, regional and national agricultural activities. An illustration of how VERCON functions: A farmer visits an extension office with an insect that is causing heavy damage to his cotton crop. The extension worker identifies the insect by consulting a database of digital photographs of various cotton pests that have been photographed in the area and scanned. Using a chat room, a number of integrated pest management specialists are consulted simultaneously about how to accurately identify and control the pest. Relevant information is quickly compiled from research results, pest distribution maps, publications and the photo file into a Fact sheet using a template. A message with the fact sheet attached is sent to all extension officers in the region, warning about the presence of the pest and providing recommended integrated pest management measures. This is communicated to farmers through IPM farmer field schools, facilitated by extension.

In 2000, the Virtual Extension and Research Communication Network (VERCON) project was funded by the FAO Technical Cooperation Program (TCP) to develop a Web-based information system to strengthen the link between research and extension. The Egyptian Government established a pilot VERCON to support research and extension interaction and the flow of information between research, extension and farmers in Egypt. This network has been extended to include other stakeholders, and other services through a project funded by Italian Debt Swap Program and executed by FAO in collaboration with Central Laboratory for Agricultural Expert Systems (CLAES). Several expert systems have been made available on this network in addition. In collaboration with other stakeholders, CLAES has developed three regional expert systems for wheat, faba and barley. Furthermore CLAES also developed the National Agricultural Research Management Information System (NARIMS) through a project funded by FAO/TCP (FAO, 2003).

Web-Based Information Service for Agricultural Research for Development

Web-Based Information Service for Agricultural Research for Development (WISARD) is a web-based information platform that provides searchable information on experts, organizations, outputs and projects in the fields of ARD, Natural Resource Management (NRM) and Sustainable Development (SD) from the mid-nineties till date. The system can be used at organization, network, national and international levels. WISARD allows decentralized data input and management through focal points at organization,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

network or national level. A module has been added for depositing outputs of research and another is under development for 'Technologies and Best Practices'. Present partners include among others, CGIAR, IPM-Europe, and Rice-Wheat Consortium for the Indo-Gangetic Plains, FAO, donor agencies, international and national NGOs and European agencies and national agricultural research systems of India, Pakistan, Nepal and Bangladesh.

Bridging the Digital Divide with Technology

The emergence of digital divide lies in the acknowledgement of the existence of an environment that sustains, unequal and unaffordable access to digital and network resources; enormous disparities in the ICT endowment/infrastructure and the lack of suitable local digital content. Digital divide cuts across international borders and goes beyond the gap between developed and developing nations to include the unequal participation of women, youth and marginalized communities, as well as the lack of local culture and content. The concept applied to reflect the disparity in access to information that is growing within nations, namely, between the rich and poor and between urban and rural communities. In recent years, as ICTs have become a more important part of the global information economy, more attention has been given to the gap in access to ICTs between developed and developing nations, and also within countries (Alao, 2010).

E-Agriculture

The FAO defines e-Agriculture as an emerging field in the intersection of agriculture informatics, agricultural development and entrepreneurship, referring to agricultural services, technology dissemination and information delivered or enhanced through the Internet and related technologies. More specifically, it involves the conceptualization, design, development, evaluation and application of new (innovative) ways to use existing or emerging information and communication technologies (ICTs)" (FAO 2006). E-Agriculture is intended to promote the integration of agricultural stakeholders and technology with multimedia, knowledge and culture, and aims to improve communication and learning processes.

According to FAO (2006) e-Agriculture is an emerging field focusing on the enhancement of agricultural and rural development through improved information and communication processes. E-Agriculture also addresses the 8th Millennium Development Goal, and the target to make available the benefits of new technologies, especially information and communication technologies to the fight against poverty. More specifically, e-Agriculture involves the conceptualization of design, development, evaluation and application of innovative ways to use information and communicative technologies in the rural domain, with a primary focus on agriculture. All stakeholders of agriculture industry need information and knowledge about the phases of agriculture, for example: water management, fertilizer application, food safety and food marketing and how to manage them efficiently. Any system applied for getting information and knowledge for making decisions in any industry should deliver accurate, complete, concise information in time or on time. The information provided by the systems must be in user friendly form, easy to access, cost effective and well protected from unauthorized accesses. ICTs can play a significant role in maintaining the above mentioned properties of information.

The World Summit on the Information Society (WSIS) Plan of Action emphasizes two key areas on e-Agriculture, namely:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Ensuring the systematic dissemination of information using ICTs on agriculture, animal husbandry, fisheries, forestry and food in order to produce ready access to comprehensive, up-to-date and detailed knowledge and information, particularly in rural areas.
- Establishing public-private partnerships that seek to maximise the use of ICTs as tools to improve production, marketing and food safety standards (FAO 2006).

Electronic Publishing in Agriculture

Satyanarayana et al. (2008) states that Electronic Publishing (e-Publishing) is quickly becoming an important part of publishing mainstream. Recent innovations in this area have made it possible to publish on the information super highway. E-document can be accessed at the computer. It makes much easier for readers to search the information. It is very quick and easy for a reader to browse the table of the contents of previous issues, to jump directly to a particular section of a document or even particular section of an article. E-Publishing (EP) difference lies in the new levels of value it provides through features not possible in traditional media. EP products may differ to an even greater degree than print products. Nevertheless, there are some common features to distinguish EP from print Publishing in terms of value to end-users.

Satyanarayana et al. (2008) further states that EP products create additional value for the user with regard to following three dimensions: content availability, content transparency and interactivity and content format. Content availability means that EP products can be delivered and accessed with more independence of time and place than can be traditional print products and that their delivery is less limited with regard to quantity. Content availability includes: time of delivery - available any time; location of delivery - consumption anywhere; amount of information - end of traditional boundaries imposed by paper volume and price. Content transparency and interactivity refers to new tools and opportunities concerning information navigation The main features are: Interactivity- contextual hyperlinks open new dimensions of information retrieval and lead to new types of information behavior: browsing, etc. the possibility to integrate content and services; and search tools across one or thousands of documents - interactive information processing.

For example, Electronic Publishing in Agriculture in India, The Directorate of Information and Publications of Agriculture, (DIPA), New Delhi, is the official publication wing of the ICAR through which the research and other activities are revealed to the world. DIPA brings out a variety of publications in English and Hindi languages for the use of scientists, researchers, students, policy planners, extension personnel, farmers and the general public. The e-publications of DIPA include - "Handbook of Horticulture", ICAR Research Projects Information – Research Project Files (RPF) Database, ICAR Vision 2020 Document etc. Some other important institutions bringing out e-publications in Agriculture in India include, National Institute of Agricultural Extension Management (NIAEM), Indian Agricultural Research Institute (IARI), New Delhi, Indian Farmers Fertilizer Cooperative Limited (IFFCO), Krishak Bharati Co-operative Limited (KRIBHCO), National Bank for Agricultural and Rural Development (NABARD) National Agricultural Co-operative Marketing Federation of India Ltd. (NAFED) Indian Agricultural Statistics Research Institute (IASRI), and State Agriculture Universities of Tamilnadu, Uttarakhand, Punjab, Haryana and Andhra Pradesh. Two major open universities namely Indira Gandhi National Open University (IGNOU), Delhi and Yeshwantrao Chavan Maharashtra Open University (YCMOU), Nashik and National Institute of Agricultural Extension Management, MANAGE, have taken open and distance

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

learning in Agriculture on a national scale, and all these institutions are in the process of bringing out a number of e-publications in Agriculture (Satyanarayana et al. 2008).

E- Commerce

Harris (2004) indicates that m-commerce using wireless mobile phones and PDAs to sell goods and services has been growing rapidly. It is the case however, that most countries cannot make payments online due to national ICT policies, security risks and inadequate infrastructure such as low bandwidth to support e-commerce. Other bottlenecks have been created by inadequate skills to use e-commerce, the legal status of e-mail communication and the high telecommunication costs. Not surprisingly therefore, in Africa, e-commerce has been insignificant in the agricultural sector. Thus, a number of transactions have to be conducted off-line (Tregurtha & Vink 2002). Some of the reasons given for not adopting e-commerce include: lack of applicability and little incentive to change business models when returns are not clear; poor trust in e-transactions; privacy considerations; shortage of ICT-skilled labour (Qiang, Clarke & Halewood, 2006).

The findings of a survey on e-commerce that was conducted in South Africa there are a number of challenges to using e-commerce such as: the need for face-to-face interaction; data privacy and security issues; hesitance of customers to use the technology; inadequate staff with e-commerce expertise; costs of implementing e-commerce; unwillingness to make organisational changes; low levels of Internet usage; non-supportive business laws; inadequate legal protection (Qiang et al, 2006).

Types of ICT Tools Used by Extension Service

Increasing diversity and complexity of global agriculture, and the seed of global innovation in ITC tools, services and business models, requires in turn a flexible approach to policies and investment choices that focuses not on 'choosing winners' among ICT options but on maximizing conditions for local innovation and creative public –private partnerships to expand ICT access and services. According to Obayelu and Ogunlade (2006), ICTs consist of various collections of resources and technical tools that are used for connecting, spreading, storing and managing information. ICT represents the collection of hardware and software that is used for producing, preparing, transferring and storing data via devices such as computers, radios, televisions, etc., and it includes an extensive scope of traditional and modern media.

In general, ICTs can be classified into three groups: New ICTs: This group consists of computers, satellites, one-on-one connections, wireless phones (mobile), the internet, e-mail, the web, internet services, video conferences, CD-ROMs, personal computers (PC), distance control systems, informational-geographical systems, global positioning systems (GPS), electronic cameras, databases, etc. The hidden concept behind these technologies is that they are not automatically considered to be new, but their common and inexpensive availability has resulted in them being regarded as new; Old ICTs: This group consists of radios, televisions, telephones, telegraphs, audio and video cassettes, films and slides. This group of technologies have been used for several decades; Very Old ICTs: These groups of technologies have been used for several centuries and includes newspapers, books, photo albums, posters, theater, human interactions, markets and plays (Obayelu & Ogunlade,2006).

According to FAO (2006), combining traditional information and dissemination methods with new forms of extension of extension delivery will promote information access by farmers and farming communities. The ICT tools that have great potential for use in agricultural extension include radio,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

television, telephone (GSM), the web, search engines, packet digital assistants, cameras, video, email, computer, contact data bases and system, CD-ROM, DVD, current awareness, group ware, rural radio, etc. regardless of the tool, the focus must be on the people who will use the technologies and the content rather than the technologies themselves. Farmers depend on multiple sources of information and technologies. In most societies, face- to- face contact is still the preferred mode of communication. Given the large populations to be served by extension agents and the dispersed and distant locations, face-to-face communication is not always possible and thus to combine strategies and communication channels to include traditional information sources, such as radio, print, video and television, together with new forms of delivery such as through ICT.

Rivera and Sulaiman (2009) states that different approaches to delivering farm extension services via ICT channels in a sustainable (i.e. without on-going donor support, although often with government support) and scalable ways (i.e., to reach tens of thousands or millions of farmers) have been identified. Often, more "high tech" ICT channels such as mobile phone services are combined with an older ICT channel, like radio, that has been used well for many years in sub-Saharan Africa and for decades in the US and elsewhere. Strengthening the use of ICT to close the gap between those who have access to extension services and those who do not, along with the strategies use of traditional media, is an opportunity that needs to be harnessed. Use of ICTs is now increasingly available and becoming more affordable. Linking ICT tools and other traditional mediums is also advocated, with choices dependent upon the local situation and realities. ICT provide information access and networking, which are two areas where the current extension systems are weak- between research and extension and between extension and farmers.

According to Lie (2006) the renewed interest in ICTs for agricultural development is remarkable and triggers the question: "What is the difference between the classic mass media attempts and the 'new' attempts to use ICTs as instruments for bringing about change?" The first thing that seems to be different relates to the shift in paradigmatic thinking about change and development in general and the role of ICTs in development in particular. This change is often framed under the heading 'from modernization to multiplicity'. The new paradigm emphasizes non-linear bottom-up perspectives and local cultural relevance. The second thing that seems to be different and is more specific is that the new ICTs, such as internet and mobile phones are not only and primarily used to reach the masses as the mass media were supposed to do. The new ICTs can also cater for small and specific audiences, which opens up possibilities for sharing more relevant and even tailor made information.

As the mass media mainly aimed at national development, the new ICTs can also be appropriate instruments for aiming at local, community levels. The implementation of any technology needs to be participatory and sustainable in its very nature. Although difficult to implement, the new ICTs have the potential of becoming a more democratic medium than traditional media such as national television that is often operating in a national power driven environment. So, an important difference between then and now seems to lie in the possibilities of the technology itself. The possibilities of the ICTs have changed towards more flexibility as it is related to speed, convergence of media forms; interactivity and specificity (Lie, 2006).

Furthermore, Lie (2006) states that in the area of 'agricultural extension systems' or 'agricultural knowledge and information systems' (AKIS) one of the changes taking place is the integration of new information and communication technologies. The mainstream focus of bringing ICTs to rural areas seems to be lying on (multi-purpose) telecentres or information kiosks as they are called in India. Two mainstream ICTs in the debates seem to be the use of the internet (including email) and the use of mobile phones, although mobile phones seem to get far less attention. Besides these two 'new' ICTs, radio

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

remains one of the most important communication and information technologies for rural areas, but also the overall paradigmatic thinking about agricultural extension has changed.

The present systems no longer think in terms of 'adoption and diffusion of innovations', but talk about 'agricultural knowledge and information systems', emphasizing social learning and negotiation, participation and interactivity, the sharing——instead of transmissions——of all kinds of knowledges, knowledge markets and networks and continuous change. Within this paradigm shift from 'extension' to 'communication for change' in the agricultural sector, there is also a growing recognition of the importance of cooperation and integration of the natural sciences and the social sciences, in case of the communication sciences. Without intrinsic trans disciplinary cooperation, ICTs would only have a limited chance of being successful in an appropriate and sustainable way (Lie, 2006).

Radio

Radio has achieved impressive results in the delivery of useful information to farmer and farming communities. One of its strengths is its umbiquity. For example, a recent survey of 15 villages in Nepal found radios in every village, with farmers listening to them while working in their fields. Another survey of 21,000 farmers enrolled in radio-backed farm forums in Zambia found that 90 percent found radio programmes relevant and more than 50 percent credited the programmes and forums with increasing their crop yields (Dodds, 1999).

Community radio projects have indicated how extension officers and farming communities can use ICTs tools appropriate for their own purposes. For example, in Nepal, two-community radio stations were established, radio Lumbini in Manigram in western Nepal and Radio Madan Pokhara in Palpa District. Village development committee of the communities held a license and a community group holds the other. Both services have proven to be very popular. Ownership of radio receivers in the coverage areas has shown an increase of 68 percent in the use of community radio station for agricultural information. Programmes include valuable development messages; the Kothmale community radio station in Sri Lanka *p*rovides an interface between smallholder farmers in remote regions. In daily agricultural programmes presenters accepts requests for information from community members and browse the Internet live in response to listeners' requests, the information accessed is explained, and communities are enabled to develop their own websites which are then hosted on the station's server and searches the internet for answers, which it then broadcasts on air (UNDP-APDIP, 2004).

For example, in Ghana the community radio station provides agricultural programmes intended to develop and assist farmers in accessing information about the agricultural practices. Agricultural programmes are prepared by community radio extension officers who visit communities to discuss problems and priorities and record discussions with local experts. They enable smallholder farmers to hear people within their own communities discuss the issues in their local languages. *Arid Lands Information Network-East Africa (ALIN-EA), partnered* with World Space Foundation, ALIN-EA uses digital satellite radio broadcasting to provide Web-based information for smallholder farmers in Ethiopia, Kenya, Tanzania and Uganda. In Kenya, Mali Shambani is a weekly hour-long radio program featuring agricultural news and responding to the business and market access needs of small, rural farmers. The program covers a wide range of topics, including market prices and trends, farming techniques, weather and seasonal issues, financing opportunities, inputs, land use, and quality standards. Each program also offers an interactive call-in component where farmers are given the opportunity to pose agricultural questions to a panel of experts either via phone or SMS (FACET, 2010). Furthermore, Rivera and Sulaiman

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(2009) states that, Farmer Voice Radio (FVR) is a radio extension service currently operating in Kenya, Malawi, Tanzania, Mali, Ghana and Zambia that targets smallholder farmers. FVR's radio extension agents pro-vide regular, on-site extension support to a small group of pre-selected farmers, which are then documented and broadcast via radio.

Television, Videocassette, VCD, and DVD

The UNDP-APDIP (2004) reports that television (TV) is commonly cited as having considerable development potential. It provides programmes with moving pictures and sounds otherwise unavailable to smallholders, using standardized and readily available technologies. Television programmes can be pre-recorded or live and interactive (with smallholders calling in), although the latter may have to be asynchronous over greater distances and different time zones. Television programmes can now be Internet streamed. Videocassettes, VCDs and DVDs can be shared between individuals, families and community groups for self-paced learning. Production and material rights acquisition costs can be high and time consuming to maintain.

There are examples that exist of television usage for agricultural educational purposes. The most notable example of TV used for agricultural development and growth comes from China with its TV University and agricultural TV station. In Viet Nam, two universities in the Mekong Delta Region work with the local TV station to broadcast weekly farmers' workshops that are watched by millions of farmers and rural communities (UNDP-APDIP, 2004). Similarly, the South African Broadcasting Cooperation (SABC) broadcast a multidisciplinary Agricultural TV programme in partnership with the Department of Rural Development and Land Reform. The Agri TV program broadcast information related to agriculture, rural development and land reform. It also aims to inform and keep up to date with the latest developments and trends, while educating by means of practical information on topics ranging form vegetable production, animal health to irrigation technology.

Video and Digital Video Cameras

Video and digital video cameras are emerging as important ICT tools for extension services. Rural smallholders can visually record and communicate problems to subject specialists. Digital photographs and video clips can be distributed and exchanged online through email or instant messaging, or by regular mail, enabling interactive and collaborative problem solving. Use of these applications should grow as costs reduce, and as digital video and operating systems become more standardized and available. Commonwealth of Learning Media Empowerment (COLME), highlighted that in Ghana and the Caribbean, working with in-country agencies, COLME identifies rural community needs and trains extension workers in shooting and editing videos using local content. The tapes and/or broadcasts serve large numbers of farmers, thus offsetting reducing extension services. The programme provides training in literacy for smallholders and women in Ghana, and in agribusiness and environmental sustainability in the Caribbean. For example in India, Digital Green disseminates targeted agricultural information via digital media to small-scale and marginal farmers. The system includes a digital video database that is produced for farmers by farmers. Participating villages are provided with a TV, DVD player and camcorder operated by local NGO staff and managed by farmers, along with DVDs that are shipped to the village. Nightly viewings are set up on a rotating basis around different areas of the village for small groups of 10 to 20 farmers (Rivera & Sulaiman, 2009; FACET, 2010).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Telephone

In many countries, access to the telephone system is a vital element that government's attempts to implement various policies to offer affordable telephone service but unfortunately some countries lack sufficient telephone lines. In Bangladesh, the Grameen Bank, a village-based micro-finance organization leases Grameen hand phones or cellular mobile phones to successful farmers and community members, this practice has delivered significant benefits to the farmers and rural community dwellers. The phones are mostly used for exchanging price, business and health related information. They have generated information flows that have resulted in better prices for outputs and inputs, easier job searches, reduced mortality rates for livestock and poultry, and better returns on foreign-exchange transactions. Phone owners also earn additional income from providing phone services to others in the community and rural people account for one-fourth of all the phone calls made (Bayes, Von Braun & Akhter, 1999). Bayes et. al (1999) further indicates that for rural communities in general, phones offer additional non-economic benefits such as improved law enforcement, reduced inequality, more rapid and effective communication during disasters and stronger kinship bonding. Furthermore these telephones have perceptible and positive effects on the empowerment and social status of phone-leasing women and their households.

The United Nations Development Programme (Asia-Pacific Development Information Programme, 2004) in collaboration with the Government of India conducted a study on China and found that villages that had telephones as the most basic communications technology, experienced declines in the purchase price of various agricultural commodities and lower future price variability. It also noted that the average prices of agricultural commodities were higher in villages with telephones than in villages without telephones. Vegetable growers said that access to telephones helped them to make more appropriate production decisions, and users of agricultural inputs benefited from a smoother and more reliable supply. Better information also improved some sellers' perception of their bargaining position vis-à-vis traders or intermediaries (UNDP, 2004). Village telephones facilitated job searches, access to emergency medical care and the ability to deal with natural disasters; lowered mortality rates for livestock thanks to more timely advice from extension workers; and improved rates in foreign-exchange transactions (Eggleston, Jensen, & Zeckhauser, 2002). In Nigeria the telephone use in extension delivery even with the recent launch and explosion of the global system of mobile (GSM) as a dividend of democracy is non-existent to very insignificant. The serious limitation of access to reliable telephone lines makes even ordinary intra-and inter-organizational networking for agricultural information exchange a harrowing and frustrating experience (Arokoyo, 2010)

Cell Phones

According to Rivera and Sulaiman (2009) there are currently a wide variety of approaches being tried to use cell phone networks to enhance extension services. Few have managed to scale to millions of farmers and it is not clear yet due to the paucity of research and the relatively short time periods of the implementations which approaches have the most impact. Clearly, a variety of approaches (or combinations of approaches) may prove successful. The approaches are varying in several ways: whether text or voice is used and, for text, if searches or queries are made via SMS or more advanced data queries which require a more capable and expensive phone hand-set or whether farmers use the mobile phone services directly or via a mediator such as a farm extension worker.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Whether cell phones enable one or two-way communication, whether farmers or intermediaries are "pull" information where farmers initiate the query, or information is "pushed" to the farmer or intermediary via a text message, a voice phone call or voicemail. This capability to enable two-way exchanges (synchronous or a synchronous) is an important enhancement to farm extension service delivery because it allows the service deliverers to receive frequent feedback regarding the most important information for farmers and how well they understand the information being delivered to them (Rivera & Sulaiman, 2009). In the Pacific, mobile phones offer another potential for extension workers, with estimates of up to 50% of Pacific Islanders having access to mobile phones. Mobile phones could help extension workers disseminate information on crop pricing or pests and diseases to farmers. In Tonga, a pilot exercise is underway using mobile phones to link farmers and extension officers. The United Nations Conference on Trade and Development (UNCTAD) is helping develop an efficient market information system and a user-friendly platform to disseminate information via mobile phones. UNCTAD supports the establishment of a regional information hub that would be based at SPC (http://www.spc.int/lrd/index.php).

Public Address Systems

Public address systems (PAS) commonly found in China and Vietnam are used to deliver public information, announcements and daily news. A community in VietNam is planning to augment its PAS, by connecting it to the internet so as to obtain useful information for broadcasting (UNDP, 2004). Public address systems which are localized are more popular than the radio which is technically simpler and less expensive. However, research on less developed communities suggests that the telephone and radio remain the most important to provide direct access to ICT tools for changing the lives of the farmers and rural people (Heeks, 1999).

Computers and the Internet

According to Aboh (2008), the use of computers and Internet as ICT tool will help extension officers to analyze data, write scientific papers, prepare plan of work, draw budgets, produce curricula and handouts and reach out to farmers easily. The Internet has grown to be the world's most important communication medium. It is a reasonably inexpensive, fast, two-way medium and a powerful tool for storage, retrieval, and dissemination of information. It is also good for publishing. The Internet can introduce new information resources and open new communication channels for rural farmers. Extension officers can send the document through which could serve as a subject of demote in an internet discussion group, and they could be placed on a website for viewing .Computer is a group of integrated parts that have the common purpose of performing the given operations and can be defined broadly as any of a class of man-made devices or systems that can modify data in some meaningful way whereas the internet is a loose amalgam of computer networks connecting thousands of sites and millions of users all over the world (FACET, 2010).

Asia-Pacific Development Information Programme (APDIP) conducted by UNDP (2004) in collaboration with the Government of India, APDIP on computers and the internet are commonly made available to rural communities in the form of community-based telecentres. Telecentres provide shared access to computers and the internet and is the only realistic means of doing things for rural communities. Although telecentres come in many guises, with the two key elements being public access and a development orientation. This characteristic distinguishes telecentres from internet or cyber cafes.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Internet cafe or cyber cafe is a place where people can get connected to the Internet while eating or have a cup of coffee using publicly accessible computer. While the main activity in the cyber cafe is the Internet, such as email, newsgroup and web site surfing, other applications usually available are office suite to type document, spreadsheet, games, such as online games and other utilities such as printing service, scanning and digital photo service. Alao (2010) indicates that cyber cafes can be a useful device in fostering development through ICTs, but the difference is crucial, because development-oriented telecentres embody the principle of providing access for a purpose and that of implementing a development agenda. To achieve this development objective, telecentres perform community outreach services in order to determine the types of information used to foster development activities. Computer literate telecentres staff acts as intermediaries between farmers and rural community members who may not be familiar with ICTs and the information services that they require.

According to UNDP-APDIP (2004) telecentres can provide a range of ICT-based services from which they can earn an income, such as telephone use and faxing, photocopying and printing, email and word processing. This helps with financial self-sustainability, which telecentres are often required to attain, although some argue that rural people should not pay ICT based development services provided as a public service, rather like libraries. The results of experiments with telecentres mixed functions have demonstrated considerable benefits for their target audiences; others are struggling with fragile connectivity and uncertain communities and very few have achieved self-financing sustainability. With Kiosks, telecentres and knowledge centers', rural farmers acquire skills to improve their products better by making them appeal to local and global markets. They have the access to promote their products, handle simple transactions such as orders, and seek opinions to make decisions for their own development.

Telecentres and knowledge centers" have a relative positive impact on rural communities in terms of promoting development, political awareness and social change (UNDP, 2004). For example, the International Rice Research Institute (IRRI) provides a comprehensive resource links with the IRRI Rice Web through the *Rice Knowledge Bank*, which provides information on practices in the field; research findings; technology transfer methods and support skills; training materials; statistics and other data; a discussion area; and access to other agricultural sites. In Kenya, the farmers helpline operated by KenCall, a for-profit call center, is a real-time call center service staffed by agricultural experts that provides agricultural information, advice and support to small holder farmers over the phone, using voice and voice call-back to farmers, not SMS. The service has received funding from GSMA and the Rockefeller Foundation (FACET, 2010).

SIMputers

According to Lie (2006) the Simputer is a low cost portable alternative to PCs, by which the benefits of IT can reach the common man. Simputers are handheld computers similar to personal digital assistants (PDA). However, they are fitted with SIM cards for data transmission and reception. Simputers may be used by an extension worker to provide pricing and market information to farmers received from a central server located in the dzongkhag. The Simputer itself is invented, developed and produced in India. It has a special role in the third world because it ensures that illiteracy is no longer a barrier to handling a computer. The key to bridging the digital divide is to have shared devices that permit truly simple and natural user interfaces based on sight, touch and audio. The Simputer meets these demands through a browser for the Information Markup Language (IML). IML has been created to provide a uniform ex-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

perience to users and to allow rapid development of solutions on any platform. This ICT has been tested successfully in Thailand by the Bank for Agriculture and Agricultural Cooperatives.

By being inexpensive, portable, running on the open source operating system Linux, having network (including internet) facilities, having text-to-speech facilities, being able to run on three AAA batteries, and being robust, the original idea was that it could be capable of playing a role in closing the digital divide. The Simputer was intended to be 'an access device for the masses' and aimed at farmer communities in rural areas. Critiques have been skeptical about these intended target groups. Technical issues as well as economic and socio-cultural issues remain unclear. There were power problems, sales and production costs problems, but also, only a few projects have been recorded that actually use the Simputer in rural change projects.

Bridging the digital divide by using the Simputer that runs on Linux, means introducing ICTs and providing infrastructure (wireless or connected to desktops). From an end-user perspective, open source software is not always an interesting option. Although it is possible to do basic text editing and to work with a spreadsheet on the Simputer, it is not comparable with the major Desktop/notebook applications (Lie, 2006). In July 2003, it was reported that 600 Simputers had been sold and 1,500 to 2,000 Encore Simputer machines were out in the market in September 2003 (Ganapati, 2003). According to Fonseca & Pal "there is limited evidence of end-user consumer purchases in rural India." The only information that seems to be available on existing projects that use the Simputer is the information that is provided by PicoPeta, one of the organizations involved in the manufacture of the Simputer (I4D, 2004). These projects involve fields such as spot billing in electricity metering and micro financing in Karnataka, India. With the coming of the new Amida model of the Simputer in April 2004, the market also seems to have shifted a little bit to the urban rich and urban young who cannot afford to buy an expensive PDA, but can afford to buy a Simputer. For them the Simputer could be an interesting alternative as the price is more interesting. This shift in markets is emphasized by the way the Simputer is advertised (Lie, 2006).

Intranet

These processes link rural radio stations with each other and with the internet. A team of communication experts specifically trained for information gathering and dissemination on the internet, by adapting information to the local context, radio scripting and interviewing techniques, manages the network of stations thus facilitating external as well as location specific information.

Web-Based Information and Learning Resources

Web-based "learning objects"-individual, self-contained and often customizable information or instructional packages with text, images, animations or movie clips-are rapidly growing in number and availability. They allow farmers and rural communities to pursue their own learning routes and interests, but there are issues of cost, computer literacy and Internet access. Smallholders also have to be able to plan and manage their own learning, discriminate between reliable and dubious source material, and draw their own conclusions from the available resources. Program developers must be capable of using advanced authoring tools to customize courses to individual needs, while achieving economies of scale by designing for large learning groups.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

CD-ROM and DVD-ROM

Compact Disc-Read Only Memory (CD-ROM) and Digital Versatile Disc or Digital Video Disc- Read Only Memory (DVD-ROM) are ICT tools with storage medium that, together with a microcomputer, offers rapid access to a very large volume of data, including text, audio, graphics, animation, slides and video in computer-accessible learning and demonstration documents. They are considerably cheaper to mail than print material, but farmers and smallholders must have access to computers and printers and be able to afford the connection, printing and other costs. They are also interactive and provide farmer and extension feedback. Programs can be multimedia, combining text, sound, graphics and video, and can provide simulations, tests and other active learning tasks (Zijp, 1994).

Agricultural development depends on rural communities and farmers having access to information they need and can use effectively. Yet poor communications systems make transmitting timely, accurate information to agricultural extension agents, health workers, and others, a difficult task. Smallholder farmers must be computer literate, or helped in using the technology and computer access is an issue, but mobile computing with laptop and notebook computers is a promising solution for low-income countries (Zijp, 1994). According to Zijp, (1994) CD-ROM is used across all sectors, including agriculture, natural resource management, medicine and social sciences. Most applications involve storage of large amounts of material which can be easily retrieved. CD-ROMs can provide ready access to a vast amount of information on local pests and plant diseases, which can be used to support decision making in cop management and integrated pest management, thereby increasing productivity and reducing the environmental impact of agriculture. They can also delver crop protection information efficiently and effectively to extension agents and other intermediaries, as well as to farmers themselves. For example, CTA- EU selected agricultural information services in Cameroon, Kenya, Mali, Papua New Guinea, Trinidad and Tobago, Western Samoa, Zaire, Zambia and Zimbabwe to participate in a pilot project aimed at improving national self- sufficiency in the dissemination of scientific agricultural information and to introduce computer technology in developing country information services in order to encourage the production of local databases.

Organizations which disseminate scientific agricultural information, such as ministerial libraries, universities and regional development centers, were provided with the necessary CD- ROM equipment and commercially available databases. Up to two weeks of onsite training were given as well. Six to twelve months after installation, evaluation of the project found that the equipment had been used 50 percent of the time for CD-ROM application and the remaining time was put toward word processing, local databases, inputting into international databases and online access to remote databases (Zijp, 1994).

GIS/Decision Support Systems

According to Munyua (2008) Geographical Information System (GIS) is an information technology that links activities in the field and the office, and allows for comparisons between different types of agricultural data. It helps to establish relationships between data sets and is important in the production of maps as well as charts that present results in visual form. In addition, the spatial variability that it captures allows for unique handling of certain locations. It also helps in the analysis of post harvest variation in crop yield measures. This is done by analysing yields of previous years to guide future management decisions. The GIS details include maps and additional information associated with coordinates and time, and these are all linked in a computer database that could be analysed further. In general, a GIS technology provides

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a holistic view of the production system and helps make precision agriculture practical and useful even for small-scale farmers. GIS accounts for its significance in the following initiatives:

In Kenya, the International Livestock Research Institute (ILRI) has used the GIS technology and remote sensing in its Small Dairy Project. It has also employed the technology to map fences in its livestock-wildlife ecosystem initiative; furthermore, the Kenya Agricultural Commodity Exchange (KACE) plans to use a GIS in the near future to develop commodity patterns and seasonal patterns. The information obtained can then be used to produce a map of the country, depicting the seasonality of different crops, the nature of what is being produced and their geographical coverage, among others. In some cases, the data will help in the estimation of supplies and expectations, apart from assisting in the selection of markets before harvesting and in the provision of dispersion distribution and productivity patterns. Finally, the forecasting of supplies and market potential that the technology makes possible is viewed as critical by KACE in its preparation of export plans and local market sales. DrumNet in Kenya plans to apply GIS and has acquired GPS technology to help map out where farmers are located, the collection points, and easy ways of accessing transportation, cell phone accessibility, roads and cell phone connectivity, among others. The International Small Group and Tree Planting Alliance (TIST) is training farmers in Kenya and Uganda in community-based reforestation projects to use PDAs and Global Positioning System (GPS) technology to gather reforestation data, which is then uploaded to an online database (Munyua, 2008).

Munyua (2008) further indicates that in South Africa, the GenARDIS project has used GIS applications in natural resources management in the Roiboos tea lands and in exploring the spatial dynamics of gender in rural areas.

Mobile Mapping

Mobile mapping is a concept and system with the ability to collect field data, including unique geospatial time tags and attributes, for integrating into/updating a GIS. Mobile mapping essentially remembers what has been recorded, when it was recorded and where it was recorded, and allows for addition or expansion of the stored data. Thus, mobile mapping provides the freedom to collect data anytime, anywhere and in any manner (GIS Development 2006).

Factors Influencing Use of ICT by Extension Officers

Agricultural Extension systems in most developing countries are under – funded and have had mixed effects. Much of the extension information has been found to be out of date, irrelevant and not applicable to small farmers needs, leaving such farmers with the very little information or resources to improve their productivity. ICT helps the extension system in re- orientating itself towards the overall agricultural development of small production systems. With the appropriate knowledge small- scale producers can even have a competitive edge over larger operations. When knowledge is harnessed by strong organizations of small producers, strategic planning can be used to provide members with at least- cost inputs, better storage facilities, improved transportation links and collective negotiations with buyers (Amutha, 2010).

Extension services combine educational methodologies such as farmer field schools and demonstration plots as well as advice from extension agents. They include the dual challenges of informing farmers

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

as well as keeping extension agents themselves well trained with access to back up experts for tough problems. They are delivered by public and private entities via extension agents. National ministries of agriculture have hundreds and sometimes thousands of extension agents, and large buyers often have their own private agent networks. Still farmers often go years without having direct contact with an extension agent. To increase access to these critical services, both public and private provider shave been using a variety of delivery "channels," such as radio, print media and, increasingly, ICT-enabled channels, some of which are often combined. Mo-bile phone networks are the ICT channel most often used, given the recent dramatic increase in access to such networks, even in rural areas, and affordability even for the poor (Rivera & Sulaiman, 2009).

The information and communication intensity of global agriculture has increased dramatically, as globally – traded commodities and the demand of a growing global middle class for higher value-added, more diversified food products necessitate more time –urgent and contextualized information about crop varieties, supporting technologies, market trends, trading partners and the competition. Poor smallholder farmers face an increased risk of being left et the "bottom of the value chain", seeking to earn income from commodity crops that are increasingly volatile in price while being faced with substantial information disadvantages (impediments and costs imposed in part by physical isolation, weak infrastructure and asymmetric access) that continue to limit their leverage at market and their ability to innovate in response to changing demand.

Some prior studies have demonstrated that demographic and characteristic background such as age, gender, ethnicity, marital status, level of education, prior experiences with computers and the Internet influence the ICT and or e-Learning adoption. Agricultural extension depends to a large extent on information exchange between and among farmers on the one hand, and a broad range of other actors on the other, has been identified as one area in which ICTs can have a particularly significant impact. There is growing recognition that farmers and members of rural communities have needs for information and appropriate learning methods that are not being met. In the midst of this change, extensionists are grappling with the question of how best to harness ICTs to improve rural livelihoods. Meera et al (2004) had noted that as a result of the emerging new paradigm of agricultural development, old ways of delivering important services to citizens are being challenged; traditional societies are also being transformed into knowledge societies all over the world.

Age of Extension Officers

Flor and Hazelman (2004) states that in Indonesia most extension workers based in the local governments are beyond 40 years old and awaiting retirement. They belong to the old school of information and communication. A training course that covers design, development and utilization of information and communication media by agricultural extension workers is required. Although this course would include sessions on digital multimedia production, it should likewise incorporate interfaces with conventional and traditional media as well as alternative last mile linkage strategies. In Indonesia, there are eight thousand researchers compared to 35 thousand extension workers, most of who are now under the payroll of local governments. It is mentioned that innovative agricultural technologies are housed in the AIATs which now carry part of the agricultural extension burden. However, the AIATs are staffed by researchers and not by extension workers.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Gender Composition of Extension Officers

About 94 percent of agricultural extension agents worldwide are male, multiple studies have reported problems with male extensionists delivering services only to men, or focusing narrowly on traditional roles when delivering programmes to women (FAO, 2006). A holistic approach to agricultural extension today goes beyond technology transfer for major crop and livestock production systems. It also includes goals for human capital development, in terms of enhancing the management and technical skills of farm households relating to production and postharvest handling of high-value crops, livestock and fisheries, sustainable natural resource management, family health and nutrition, and leadership and organizational skills, in addition to social capital development, that is, organizing producer groups (Swanson 2008). As tools embedded within existing social and gender relations, information and communication technologies (ICTs) are perceived, used, and appropriated in ways that are subject to asymmetries in power, privilege, opportunity, and choice.

Several studies including the CTA-sponsored one on rural women's access to public and private extension services have revealed that the village level extension agent is the most effective source of information for farmers but certainly not the most efficient in terms of cost and coverage (Arokoyo, 2010). According to FAO, (2006) the number of female extension officers has increased, although their representation continues to remain extremely low, ranging from 3.1% of the extension staff to 22%. While increased number of women agents does not necessarily guarantee that more women farmers will be reached. Several reports indicate that female extension agents are more inclined to contact female farmers and are more likely to address issues of concern to them, such as subsistence production and household food security. At the same time, women farmers may be more inclined to attend a demonstration when a woman gives it. The situation is still similar in South Africa. The agricultural sector in the Northwest Province is clearly a male dominated sector with more than 80% of the labour force being males. According to the Gender Focal Points, 2003 the total number of extension officers in the department was 939, with the total number of males being 602 (64%) as compared for women 337 (36%)(Mabe, 2005). Modern ICT including internet and web technology is needed to make these systems available regionally and globally. Accessing information communication technologies will bring a wealth of information to all agriculture stakeholders including women farmers in rural and urban areas and will help in overcoming the existing digital divide.

Education Level and Years of Experience of Extension Officers

Adesope et al. (2007) revealed that there was a significant but negative relationship with information technology needed. This implies that the higher the educational qualification the less the information technologies needed and the lower the educational qualification the more the information technologies needed. It is possible that respondents with higher qualifications may have too many responsibilities to grapple with, hence may not have the time to appreciate more need for Information technologies. Agricultural extension has the ability to solve many of the challenges that agriculture is facing, but it needs to be made attractive. Indeed, the nature of agricultural extension itself is challenging since it involves working with the farming community (which is not easy as we need to understand rural life and human behavior), have a good knowledge on agriculture (pest and disease management, market prices and opportunities, other stakeholders in agriculture and their role etc.) and have specific skills (good communication skills, listening skills, be a trainer and learner at the same time etc.).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Access to Allocated Vehicle for Extension Work

Given the problems that extension agents face in facilitating direct contact with farmer clients and with researchers due to the physical distances involved and the lack of transportation needed for their mobility, the application of ICT offers excellent possibilities. Utilizing ICT for strengthening research-extension-farmer linkages must, however, move from pilot testing phases to integration into research-extension systems and beyond the urban focus. Major factors to also address include the creation of an enabling environment, development of infrastructure, development of software and information content, making ICT sustainable, building capacities, combining its use with traditional media and learning from success stories (APO, 2002).

Average Distance Between Extension Officer and Clients

Given the problems that extension agent's face in facilitating direct contact with farmer clients and with researchers due to the physical distances involved and the lack of transportation needed for their mobility, the application of ICT offers excellent possibilities. Utilizing ICT for strengthening research –extension-farmer linkages must, however, move from pilot testing phases to integration into research- extension systems and beyond the urban focus. Major factors to also address include the creation of an enabling environment, development of infrastructure, development of software and information content, making ICT sustainable, building capacities, combining its use with traditional media and learning form success stories (FAO, 2006). Mmbengeni and Mokoka (2002) indicated that extensionists in Limpopo Province, South Africa experience a serious lack of transport during the execution of their day-to-day duties. This constraint has a direct influence on the ability of extensionists to reach farmers on a regular basis, on the ability of extensionists to facilitate communities and the provision of transport for farmers during farmers-day and training events.

Number of Farmers Covered by Extension Officers

Several studies including the CTA-sponsored one on rural women's access to public and private extension services (Arokoyo, Chikwendu & Ogunbameru, 2002) have revealed that the village level extension agent is the most effective source of information for farmers but certainly not the most efficient in terms of cost and coverage. At the inception of the state-wide ADPs in 1980 the extension agent: Farmer (EA: Farmer), ratio ranged "between" 1:2000 to 1:3000. This was expected to come down to "between" 1:800 to 1:1000 by the project completion date and the withdrawal of World Bank support. This target was never achieved. A recent field survey by NAERLS and PCU (2002) showed that the EA: Farmer ratio was "between" 1:848, in Ogun State in the South- West Ecological Zone to 1:1650 in Katsina State in the North-West Ecological Zone. This is similar to the finding by Arokoyo et al (2002), of ratio of "between" 1:1000 and 1:2000 in the public extension service, and worse for the women-in-agriculture program, which was found to have several extension blocks expected to be filled by female extension agents, vacant. It is clear therefore, that no matter however effective, extension delivery through the village extension agent can neither be efficient nor cost-effective for a developing country like Nigeria, with a population of about 150.00 million, majority of who are involved in agriculture (70 – 80 percent) and illiterate. The Extension Service therefore must be appropriately supported with the use of ICTs (Arokoyo, 2010).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

According to Glendenning et al, (2010) in India, the extension staff of the DoA operates at the district and block levels, which are administrative subdivisions. A block is a subdivision of a district. The numbers and capacity of the staff vary greatly throughout the country, but it is well acknowledged that staff numbers are low. The ratio of staff to farmers varies widely across the country with 1:300 in Kerala and 1:2,000 in Rajasthan. In Ghana the ratio of extension workers to farmers is estimated to be 1 to 2000, but in recent years the number of agricultural extension workers has been going down, while the numbers of farmers is growing. This means the role of the extension workers in the dissemination of knowledge within rural communities is diminishing. The use of ICTs to support the work of the Extension Officers might be beneficial for the development of the agricultural sector (Akkermans, 2010).

In agriculture extension service and the Veterinary services Units play a major role in improving agricultural production. To ensure their effective operation, the district has been delineated into 22 operational areas. Currently there are 13 extension officers in the district giving an extension officer farmers ration of 1: 5000, which is high compared with the acceptable ratio of 1: 400. This indicates that the district has a serious problem as far as the number of extension officers in concerned. A survey of the extension service unit reveals that, the unit faces a number of problems, which have inhibited its ability to reach farmers effectively which include: poor condition of roads leading to some farming communities, inadequate means of transport, delays in the payment of staff allowance, extensive coverage areas for field officers, high extension officer farmer ratio, lack of motivation for field staff.

In Papua New Guinea, the extension officer to farmer disparity points to challenges in delivering information. The extension farmer ratio is one extension officer per 3,600 people, and in some parts of the northern Solomon Islands this ratio is 1 per 14,000. For medium size islands such as Samoa and Tonga, the ratio is closer to 1 per 800 people. Extension work is further hampered by a lack of transport, or lack of fuel for transport.

Contact With Farmers

According to Asian Productivity Organization (2002) given the complex nature of agriculture and the challenges being faced, the use of multidisciplinary approaches involving a mix of specializations is becoming more and more the norm in addressing information delivery today. Technical specialists along with social scientists and communications and information specialists are combining expertise to address farmers' and farming communities' problems and needs. Studies have shown that farmers depend on multiple sources for information and technologies. In most societies, face-to-face contact is still the preferred mode of communication. Given the large populations to be served by extension and the dispersed and distant locations, face-to-face communication is not always possible and thus needs to combine strategies and communication channels to include traditional information sources, such as radio, print, video and television, together with new forms of delivery such as through ICT.

Due to the limited number of extension workers, farmers are using the phone to seek advisory services. Extension information can also be shared through a website. In addition, PDAs could be used to collect and disseminate critical agricultural information that farmers need. The shift to these technologies would cut down face-to-face contacts drastically and reduce telecommunication and transport costs. Farmers would, however, require training and a change of attitude to be able to access the ICT driven information and advisory services. Of importance is the fact that the applications of ICTs in extension services would provide for more content diversification and ensure a wider reach. In India for instance,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the e-choupal model has made it possible to reach farmers through public access centres that include telecentres, knowledge centres and access points (Munyua, 2008).

Area Covered by Extension Officers

Several research studies conducted on extension organizations have revealed that the delivery of goods is effective when the grass roots extension worker covers a small area of jurisdiction with multiple purposes or broad basing. The existing system of large jurisdiction, each with a narrow range of activities, is less effective. Broad basing agricultural extension activities, developing farming system research and extension, having location specific modules of research and extension, and promoting market extension, sustainable agricultural development, and participatory research are some of the numerous areas where ICT can play an important role. However, broad basing requires grass roots workers to be at the cutting edge of extension and master of many trades, which is not really possible. The emergence of such knowledge workers will result in the realization of the much talked about bottom-up, demand driven technology generation, assessment, refinement and transfer. ICTs can help by enabling extension worker gather, store, retrieve and disseminate a broad range of information needed by farmers, thus transforming them from extension workers into knowledge workers. ICT has many potential applications in agricultural extension. It can bring new information services to rural areas where farmers, as users, will have much greater control than before over current information channel. Access to such new information sources is a crucial requirement for the sustainable developing of farming systems. If extension agents will effectively and efficiently use ICT, it will make their work easier and moreover, facilitates their information delivery and after extension services (Amutha, 2010).

Effect of E-Readiness of Extension Officers

Swatman (2006) clarify that e readiness is defined as being prepared mentally or physically for some experience or action. In terms of e-Learning, Borotis and Poulymenakou (2004) defined e-Learning readiness as the mental or physical readiness of an organization for some e-Learning experience or action. According to Arokoyo (2010) most of the nation's agricultural research and extension system (NARES) members now have computers for information and data management, most of the computers have neither telephone nor internet access. Even ordinary email access becomes a big deal for a whole national Research Institute. The low computer literacy level of the managers and staff makes the ICT-readiness of the system very low. Kauffman and Kumar (2005) introduce three stages of diffusion of ICT at the country level of analysis are the ICT readiness stage, the ICT intensity stage and the ICT impact stage. In the first stage of ICT readiness, they argue that when the technology is new to a country or a region, the readiness of its people to adopt it is a crucial issue. On the other hand, Kaur and Abas (2004) noted that ICT readiness assessment allows one to design comprehensive e-Learning strategies and effectively implement ICT goals. Hence, generally ICT readiness assessments help a country's leaders to measure and plan for ICT integration, focus their efforts and identify areas where further attention is required (Krull, 2003).

FAO (2006) stated that several studies have revealed that lack of access to information hampers the performance of extension activities. In most cases, it was found that extensionists have little or no access to sources of agricultural information. Although most extensionists are aware of the large amount

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of information available on the internet, they do not have access to internet facilities causing constraints not only in terms of access to information, but also in terms of communication (i.e. e-mail).

Constraints Faced by Extension Officers

According to Raabe (2008), information flow within the public sector moves linearly, with content focusing on the transfer of technology for increasing crop production. A wider definition of agricultural extension, beyond improving crop productivity, has not been embraced. Information flow is supply-driven and not needs-based or area-specific so farmers see the quality of the information provided by the public extension staff as a major shortcoming. This is due to the static and inflexible nature of the organization, where a top-down hierarchical approach continues. Sulaiman, (2003) further states that access to extension is also an issue, because of the low level of outreach by public extension services. This is partly due to the public staff being overburdened with implementing state and centralized schemes, which are also not easily modified to suit local needs and conditions.

There are also insufficient funds for operational costs, training, and capacity development, which limits the activities and continual development of the extension staff. Sulaiman, Hall, and Suresh (2005) indicate that of the required 1.3 million to 1.5 million extension personnel, there are only about 100,000 on the job. At the state level, the various line departments have been criticized for working in isolation, with weak linkages and rare partnerships, which limits information flow.

Furthermore, the research–extension link has been criticized for not absorbing or using feedback from farmers and extension staff. Extension personnel and farmers are passive actors, and scientists have limited exposure to field realities. The various components of the public-sector extension system suffer from duplication of programs, without convergence. While Agricultural Technology Management Agency (ATMA) is pushed as the platform through which the multiple agencies can converge, the implementation difficulties are proving too great for effective integration, with shortages of both personnel and funds (Glendenning, Babu & Asenso-Okyere, 2010).

Effects of ICT Use on Information Access by Extension Officers

Information has been identified as one of the resources required for the improvement of agricultural production (Aina, 1995). It is said to be a resource that must be acquired and used in order to make an informed decision. Those who possess appropriate and timely information will make a more rational decision than those without. The various agricultural information users populations can be categorized as policy makers and planners; researchers; extension staff; educators and students; agro-based industries and services staff; and farmers. It was also observed that each of the sectors mentioned above contribute directly to the improvement of agriculture hence relevant information provided to each category of these user populations will contribute positively to the development of agriculture in Africa. Information is the potential ingredient for the advancement of agriculture. Without information the agricultural sector may degenerate into extinction. Information provides the basis for scientific innovations in agriculture. Agricultural information has been defined as all published or unpublished knowledge on all aspects of agriculture.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Application of ICT in Other Countries

The applications of ICT for agriculture were reviewed in this section with specific examples from countries in Africa, Asia and Europe.

India

The e- Choupal and Satcom were reviewed form India. Swanson and Rajalahati (2010) reported that e-Choupal (which means gathering place in Hindi) and a profitable rural transformation initiative in India, is a web based information and procurement tools for Indian farmers that places computers with internet access in rural farming communities to have access to information and an e-commerce hub. e-Choupal was developed by the private sector in India, and has enabled farmers from selected parts of the country to gain access to up- to- date price and marketing information, as well as to engage in online sales of agricultural products and online purchases of inputs. This privately financed ICT system is owned and managed by ITC Limited and it currently has over 10,000 eChoupal sites where farmers regularly engage in online sales and purchases on a fee – for- service basis. Given the success of this system, the Government of India is now establishing similar common service centers (CSC) whereby rural people and other parts of the country can gain access to similar technical and marketing information, including online transactions. Currently, there are 6,500 functioning CSC's and the plan is to scale this number up to 100,000 CSC's serving the 638,000 rural villages across India. In addition, some block-level extension offices that received World Bank support also have PC's with Internet access: therefore, farmers in these areas cam also gain access eChoupal and other technical and market information.

The e-choupals serves as both a social gathering place for exchange of information which delivers real-time information and customized knowledge to improve farmer's decision-making ability, thereby better aligning farm output to market demands; securing better quality, productivity and improved price discovery. This model helps to aggregate demand in the nature of a virtual producers' co-operative, in this process facilitating access to higher quality farm inputs at lower costs for farmers. The e-choupal initiative also creates a direct marketing channel, eliminating wasteful intermediation and multiple handling, thus reducing transaction costs and making logistics efficient.

This system has also catalyzed the rural transformation that has helped to alleviate rural isolation, create more transparency for farmers, and improve their productivity and income. e-Choupal has helped to empower farmers in India with real time information on weather and prices so that they can insulate themselves from unpredictable climatic conditions and price fluctuations at markets.

Bhatnagar and Schware (2000) also reported that India was amongst the first countries to explore the use of Satellite Communication technology (Satcom) to support development and today its space efforts are recognized the world over for their wide spectrum of application relevant to societal benefit. Satcom offers the unique capability of being able to simultaneously reach out to large numbers spread over large distances even in the remotest corners of the country. It is a very strong tool to support development education. Satcom has been used both in broadcast mode as well as an interactive mode to reach out to rural audiences at large, and to conduct training programmes for extension staff as well as rural population who are participating in the implementation of development actives.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sri Lanka

The Department of Agriculture is presently moving towards introducing electronic media for dissemination of information to extension agents as well as farmers. Cyber Extension is one such initiative where farmers could make use of e-mail and the internet facilities to access information and communicate, particularly with the Department of Agriculture (DOA) to get advice and assistance to solve their farming problems. Furthermore the Audio –visual Center of the DOA has initiated a toll-free telephone service for the farmers to directly contact agricultural researchers for obtaining advice to their problems. This service is becoming popular among farmers but publicity has to be given to reap the full of benefit of it (Mudannayake, 2006).

China

According to Ke and Zhang (1999), subsistence farmers do not need to interact significantly with people beyond their own families. Yet in raising output above the subsistence level, communication is important. Despite low levels of ICT in rural China, studies have shown that ICT, including the telephone and internet have positive impacts on farm households in terms of industrial patterns, market expansion, sale and supply channels, education and healthcare. For example, duck farmers in the Hubei province now sell their ducks directly to customers through a telephone order system. With access to telephones, the potential exists to eliminate intermediaries who do not add value to products. Furthermore in Haikou village in the suburbs of the city of Wuhan is well known for producing balsam pears. Although farmers had bumper harvests for years prior to installing telephones, they did not profit from them because local intermediaries had forced prices down. After the installation of telephones in 1998, farmers were able to contact vegetable dealers in their neighboring province and sell their products at much higher prices. This experience led to the installation of 41 telephones in this village within two months. Agricultural universities and research institutes have become pioneers in providing internet- based-education for farmers. The Capital Farmer Network (www.capitalfarmer,net) is a popular web site that specializes in agricultural technology and provides free online seminars to farmers on new agricultural techniques. Lack of internet infrastructure, however, means that few farmers benefit from these services (Ke & Zhang, 1999).

Ireland

According to Acker and Gasperini (2008) the use of ICT has improved safety of animals in Ireland, in 2001, the foot and mouth crisis in Surrey brought back memories of the fears to many Irish farmers, but on this occasion ICT has been able to provide them with some reassurances. The very fact that Northern Ireland can prove that no animals from Surrey have entered it in recent times shows that the benefits of ICT in action. All cattle entering the island of Ireland, on both sides of the border, are tracked and monitored with software used to trace their movement.

A major cattle movement is operated through a monitoring system which is a great help in ensuring safety, as it ensures traceability of cattle from birth to death. ICT is enabling both government and industry to reassure all stakeholders be they consumer of farmer that agricultural products in Ireland are safe to use. The department of Agriculture plans to roll out the monitoring system to cover the movement of ll animals by the end of 2008.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Israel

According to Gelb et al (2008), the collaborative contribution of extension and research to Israel's agricultural productivity and profitability dates back to the late 19th century. It facilitated technological innovation in agriculture, transfer of information, training of farmers and sector connectivity. These were in effect a dictate of continuous deteriorating agricultural terms of trade, crippling water shortages and severe climate and soil constraints. The Israeli Extension Services (IES) strategic decision to adopt Information and Communication Technologies significantly enhanced Extension's capabilities and scope of activities. ICT empowered extension's ability to develop, introduce and adopt innovative agricultural technologies and collaborate with research and international partners. Adoption of ICT as one instance of technological innovation dramatically improved the transfer and management of information, production chain efficiencies and integration within and with the agricultural sector. These were and are critical Israeli Extension success factors enabling research, services and farmers' ability to sustain a profitable, thriving agriculture sector. The use of ICTs contributed to rural viability and a model for adoption of technological innovation.

Burkina Faso

According to Munyua (2008) the Business Intelligence Trade Points model in Burkina Faso is used in the agro-business sector to address the socio-economic exclusion of small-scale farmers. The project collects and disseminates market information for local producers and facilitates trading through e-commerce which is growing gradually.

Egypt

In 1987, officials at the Egyptian Ministry of Agriculture and land reclamation recognized expert systems as an appropriate technology for speeding development in the agricultural sector. To realize this technology, in 1989, the ministry initiated the Expert Systems for Improved Crop Management Project (ESICM) in conjunction with the Food and Agriculture Organization of the United Nations (FAO) and the UNDP. The project began in mid-1989 and the CLAES joined the Agricultural Research Center (ARC) in 1991. Through the development, implementation and evaluation of knowledge-based decision support systems, CLAES is helping farmers throughout Egypt optimize the use of resources and maximize food production. A dozen expert systems have been developed for horticulture and field crop management (Rafea, 1999).

Jamaica

RU Network in Jamaica is a pilot project of the Caribbean Agricultural Advisory Service (CAIS), which uses "Information Cafés" with internet connection to exchange knowledge and experience between rural communities, researches and extension services. It provides CD-ROM based information and printers, scanners, digital cameras and audio recorders for capturing, storing and distributing local information.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Mauritius

In Mauritius, there is a mobile service used in Agricultural Extension is the "SMS Disease Alert" by the Agricultural Research and Extension Unit (AREU). This service is about sending SMS to registered planters when there is a disease outbreak on a particular crop. The service is beneficial to the planters as they can take precautions to prevent the disease to affect their crops.

Rwanda

In Rwanda the Sustainable Partnership for Rural Enterprise Agricultural Development (SPREAD) programme is using ICTs to sell coffee internationally and to monitor the international coffee auction through an innovative partnership that links SPREAD, Texas &M University and Michigan State University. This trading model facilitates direct access to new markets and was instrumental in introducing international quality standards on coffee auctions via the Internet (Munyua, 2008).

Senegal

Manobi project uses cell phones with wireless access protocol (WAP) and short messaging service (SMS) technology to provide members of Senegalese fishing communities, and fruit and vegetable grower farming communities, with up to date weather and market price information. The goal of users is to secure higher prices from middlemen and improve the timing of entry to markets when demand is high and supply is low. Users are also able to reduce spoilage by locating buyers while goods are still fresh. The project has also contributed to the expansion of mobile telephone infrastructure in targeted towns. The service integrates a variety of existing technologies, including voice telephone, web and personal data assistants (PDAs) to create a real time data and information processing network (Batchelor, Evangelista, Hearn, Sugden & Webb, 2003).

South Africa

According to Bua news (2010) Limpopo Department of Agriculture, budgeted R6 million in 2010 financial to install technology –based information systems that will enable extension officers to provide relevant and accurate information to farmers' instantly. The Department of Agriculture introduced the e- Agriculture project, which aimed at improving emerging farmers' access to information and markets through the use of information communication technologies such as internet and SMS messages. Since the e-Agriculture project was launched in October 2010, 215 farmers and 16 extension officers have been trained in basic ICT skills using Digital Doorways, which are robust computer stations with multiple screens that provide internet access to rural communities.

Uganda

Information and Communication Technology has a role to play in any country's development. Like other countries' Uganda has recognized the potential and enabling elements of information and communication technologies as a tool for social and economic development. Although there has not been a comprehensive

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

survey of human resources in ICT in Uganda, it is fairly obvious that various levels of skills are required and the existing training institutions are meeting some of the training needs. There is a need to assess the national requirement for ICT skills, establish how much is available and then determine the best strategy of meeting the appropriate ICT skills requirement. Communication is one of the basic human rights and access to communication channels should not be left entirely to market forces. This creates a situation of information dualism, with a minority urban information rich and the rural majority being information poor. Conducive environment for investments in communication infrastructure should be prompted to narrow the information gap between the urban and rural areas (Ministry of Works, Housing and Communications, 2003).

Zambia

Agriculture is the economic backbone for many Zambians especially in the rural areas: as such it plays an important role in the social and economic development of the country Kasonde (2009). According to the National Information and Communication (ICT) Policy, the Zambian government has committed itself in making sure that ICTs are integrated in the agricultural sector reform process in order to contribute to the social and economic revival of the country. This will be achieved by working closely with the local community so that they develop human capacity to manage and maintain ICT equipment, create integrated agricultural information systems on agro technologies and techniques, pricing and market information, for all agro products in order to provide strategic information for farmers, governments and other stakeholders at national, provincial and districts level. ICTs should be undertaken to create awareness campaigns for all types of farmers in the use of traditional and new ICT tools at all levels, develop and promote ICT skills development among agricultural extension workers and farmers, develop a monitoring and evaluation system for the conversation and sustainable utilization of natural resources in agricultural production systems.

Zimbabwe

Gudza (2010) notes that podcasting has been adopted as a media to disseminate agricultural information amongst rural farmers. This is an innovative way of using ICTs to disseminate information to those areas that have limited road networks and poor communication infrastructure. Podcasts are being used as an alternative to distribute audio and video content particularly on the internet. Podcasting project has already taken off in Mbire district and it can help to transform the lives of small scale farmers despite of lack of electricity and poor communications. Traditionally the agricultural extension officers who work under Agricultural Research Extension Service (AREX) would provide agricultural information to farmers orally and through brochures, posters and pamphlets even though the local people did not have an input in the development of the content. However with podcasting the local people are able to develop their own content because the concept is dependent upon people, technology and content.

According to Gudza (2010) the podcasts' are in local or indigenous languages and all stakeholders collaborate to develop the podcasts. Theses podcasts will have information covering a variety of themes on crop and livestock production and management. The podcasts are played on MP3 players which are powered by rechargeable batteries. These podcasts are indispensible tools in disseminating knowledge on agriculture to disadvantaged farmers. This project is collaboration between government,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

non-governmental organizations like practical action and local community leaders. The project has made the farmers more knowledgeable and it has helped them to generate and share knowledge that improves productivity through using ICTs.

Sudan

Golder, an international company, has been working with ASBNACO - a Sudan-based company that manages the Agadi Farm and the Arab Authority for Agricultural Investment and Development (AAAID), to introduce commercial mechanised farming. As part of this project, the GPS and the GIS technology have been introduced to help improve farm productivity while conserving the environment. This has been achieved through an acquired auto-steer tractor, fitted with a GPS satellite guidance system that controls tractor steering. PA has helped to cut down planting time on the Agadi farm by 60%, compared with the time taken for a similar task in two previous seasons.

Spatial yield monitoring, using GPS field monitors have also been installed in combine harvesters to monitor yield variations within each field and produce yield maps so that farmers can identify high and low productivity areas on their farms. The maps also guide fertilizer, seed and agro-chemical applications. Controlled traffic farming (CTF) has also been introduced in the project, using GPS-based self-steering tractors that limit movements of tractors to selected rows within a field to reduce soil compaction and erosion. In addition to these changes, a GIS-based farming information and management system is in the process of being developed, while plans are underway to introduce infra-red photography and Variable Rate Application (VRA) technology. These systems and technology would help to identify weed infestations, water stress, and crop pest outbreak areas and make it possible to select appropriate chemical applications, thus reducing the wastage normally associated with conventional blanket spraying. It has been observed that VRA enables the efficient use of fertilizers, chemicals and seed based on the analyses of previous seasons' production and the chemical content of soils. Furthermore, it also prevents unnecessary groundwater contamination (AAAID, 2006).

Key challenges faced by the Agadi Farm include the need to ensure reliable operation and maintenance of highly specialized equipment under harsh and remote conditions; demands associated with providing training in the use of GPS equipment and GIS software for local technicians; intricacies associated with assessing the adoption of precision farming systems or their integration into current practices. It is anticipated that the wide acceptance of PA in Africa will enable the potential of PA to be fully exploited. However, the technology requires adequate funding for high-tech farming applications, which is beyond the financial reach of small scale farmers as individuals (AAAID, 2006).

Factors Influencing Application of Information Communication Technology in Agricultural Extension Services

The theoretical framework explores research on the use of ICT by extension officers in different parts of the world. This is the view of establishing a conjectural link between several variables have been used to determine ICT use, constraints to and effect of e- readiness among extension officers. Ahmadpour, Mirdamadi, Hosseini and Chizari (2010), noted that variables such as age, gender, education level, the number of farmers covered by extension officers, number of years of experience as an extension officer, e readiness, access to allocated vehicle for extension work, and studying for a higher degree have impact

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

on the use of ICT's by extension officers.Using descriptive statistics and (Binary) Logistic model, Ndag, Sanusi and Aigbekan (2008) found that the proportion respondents who did not have the requisite knowledge on computer use was slightly higher the North-central (57.14%) than in the South-west (55.71%). Age and ownership of a personal computer (PC) were significant factors ($p< 0.1$) determining the probability of ICT use to search for information by respondents in North-central Nigeria.

Hosseini, Niknam and Chizari (2009) categorized factors influencing ICT use by extension officers into six namely: organizational, technical, financial, social, regulatory and human challenges, ordered by their impact. Based on the findings, organisational challenges are the most important issue. Technical challenges are always potentially troublesome in the application of ICT's. Bheenick et al.., (2003) and Schimtz (2003) stated, for extension organization, in order to fulfill its function, has to overcome technical challenges along with human, regulatory, financial and social challenges as main constraints to apply ICTs. The findings about financial challenges is in accordance with those of Khan (2001); Kushner et. al., (2004) and Stribhadung (2006) which shows that cost of buying and maintaining the system would have effect on the application of ICT. The importance's of technical factors have been pointed out by several authors as Barajars et al. (2000), Surry (2002), Bheenick et al. (2003), Ebadi (2005), and Castels (1996). The findings also reflect an important fact that positive attitude and knowledge and skills of experts directly impacts the application of ICT. This is in corroborating with the findings of Lynch (2001). The results of the study pointed out to this fact that, there was relationship between social factors and application of ICT by the extension service in Iran. The findings are in accordance with studies by Sullivan (2000), Samak (2006), and Tyan (2003). ICTs have tremendous potential in Iran and it is evident now that ICT's will change the way people live, work and learn. In this regard, agricultural extension has the opportunity to harness the effective use of ICTs.

Adesope, Asiabaka and Agumagu (2007), examined the effect of personal characteristics of Extension managers and supervisors on their information technology needs in the Niger delta area of Nigeria. The result showed that there is no significant difference in the Information Technology needs of both categories of respondents. Findings also revealed that number of associations belonged to, educational qualification, training, category of organization were the personal characteristics that significantly influenced information technologies needed by extension managers and supervisors. Lashgarara, Mirdamadi and Hosseini (2010), noted that Information and communications technologies (ICTs) represent an important strategy that can be used in attaining food security in Iran. The results showed that, according to the experts' point of view, the situation of food security in rural Iranian households was medium, but that ICTs could play an important role in improving the situation. The results further showed that increasing food production, transferring of new methods and technologies, improving interactions and communications, providing information about cultivation and harvest, facilitators and content of old technologies account for 71% of the variance of the food availability of rural Iranian households. Moreover, the path analysis technique demonstrated that the improvement of interactions and communications had the greatest influence on determining the casual model of improving the food availability of rural Iranian households.

Aboh (2008) noted and examined the frequency of ICT tools usage by agricultural extension agents in Imo State, Nigeria. Findings of the study revealed that only mobile phone and computer were frequently used by respondents. Though ICT tools were not frequently used for extension services and this has grave implications for agricultural development. Based on the findings of the study, the following recommendations were made: there should be adequate provision of computers for all the extension agents. Adequate provision should be made for the maintenance of the ICT facilities and systems, provi-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

sion should be made in providing training programme for the extension agents in order to update their knowledge on the latest and new information technology, government to establish policy programme as means of bridging the digital divide, creating digital opportunity for various users of extension services in the country. ICT enabled extension service must be able to define its key stakeholders and audience and jointly determine their needs.

Purnomo and Lee (2010) noted that in Indonesia, the perception of agricultural extension officers', readiness and barriers towards implementation of ICT programme, the assessment model of e-LRS to measure the readiness of ICT programme implementation. The first finding reveals that they perceived that three out of the four factors of readiness as positive. The e-LRS assessment revealed that they perceived farmer readiness as lowest and thus considered it as a barrier. Also, the technological and organizational cultures were also seen as the main barriers of ICT programme implementation, and demographic variables such as regency and age, must also be considered when ICT programmes are implemented.

Oladele, (2011) compared the effect of Information Communication Technology on Agricultural Information access among researchers, extension agents, and farmers in South Western Nigeria, and noted that a significant difference in the effect of ICT on agricultural information access among researchers, extension agents, and farmers . The study concluded that access to agricultural information through ICT will continue to improve, since perceptions are overtly positive among researchers, extension agents, and farmers. Agwu, Uche-Mba and Akinnagbe (2008) ascertained that the level of usage as well as constraints to the use of information communication technologies (ICTs) among major stakeholders in the agricultural development process in Abia and Enugu States of Nigeria. The findings indicate that majority of researchers; extension workers and farmers had high, moderate and low knowledge levels of available ICTs, respectively. Out of 24 information communication technologies researchers utilized more ICT than extension officers and farmers. The study revealed major constraints to the use of ICTs to include lack of sufficiently trained computer personnel, lack of confidence in operating modern ICTs, erratic and fluctuating power supply, poor finance, lack of internet access in the rural areas and high cost of ICTs hard and software's, among others. The study concludes with the need to have a National Agricultural Extension Policy on the use of ICTs with major emphasis on access, availability and use.

Akparo, Okon and Inyang, (2007) analysed constraints affecting the utilization of Information and Communication Technologies (ICT) for agricultural extension activities by agricultural extension officers in Nigeria's Niger Delta Region. The findings revealed important specific constraints which include: poor ICT infrastructure development, high cost of broadcast equipment, high charges for radio/ television presentations, high cost of access/interconnectivity and electricity power problems. The use of Factor Analysis aided to crystallize identified constraints into three factors of 'poor enabling environment', 'lack of accesses and 'dissemination of unrelated information'. Adebayo and Adesope (2007) examined awareness, access and utilization of ICT among female researchers and female extensionists in South Eastern Nigeria. Information collected showed that female researchers and female extensionists are aware of ICT; both categories of respondents know how to access Internet on their own, but do not have adequate access to IT. The types of ICT needed by female researchers and female extensionists include; World Wide Web, Electronic Mail, Electronic Spreadsheet, Word Processing, CD-ROM, Use of Projector, Use of computer, Web Design, Chartroom. Salau and Saingbe (2008) indicated that in Nigeria researchers had greater access and utilization to ICT facilities than extension workers. The level of education positively influenced the level of utilization of ICTs while years of working experience had negative influence. The key problems militating against the use of ICTs in the area were poor access to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ICT facilities, lack of computer knowledge, low income and poor power supply. It was recommended that agricultural organizations should install all necessary ICT facilities in their establishments and provide training opportunities for their staff. Constant power supply to both urban and rural communities should be considered a fundamental human right and treated as such.

Chapter 10
Strategic Positioning of Turkey Agricultural Products on the Agricultural World Market

Hamadoun Sidibe
Université de Moncton, Canada

ABSTRACT

Applying a strategic management perspective, particularly the BCG tool, this chapter demonstrates that the agricultural products exported by Turkey are distributed unevenly on the four cells of the global agricultural markets matrix: almost of its products (236 products or 85.20% of its portfolio) are Question Marks, two products are a Star, one product is a Cash cow, and 38 products are Dogs. Such a situation creates important strategic choices for the leaders of the country and for its businesses. None of Turkey top ten exports were among the top ten growers in the world. Turkey is world export leader in ten products, but these products are not the world most growing markets, and the country should increase its relative market share in some of its ten top exports, and also consider developing organic product segments, and eliminate tobacco products in its portfolio.

INTRODUCTION

The Republic of Turkey is one of the fastest growing economies in the world, and has become increasingly intertwined with a global economy. In this global economy, agriculture is very important, as we have witnessed during the global food crisis and the large disputes in the World Trade Organization (WTO) negotiations at the Doha Round and beyond. These resulted in a split between the members of developed and developing countries over the large agricultural subsidies maintained by the richer countries and the industrial subsidies enforced by the developing countries. Despite these disputes, one main agreement made during the WTO negotiations in Doha was the need to eliminate restrictions and distortions in the world agricultural markets.

In Turkey, agriculture is a key sector for jobs and is one of extreme importance in the economy of the country. According to recent data from the FAOSTAT (2014), and the World Bank (2104), agriculture

utilizes more people than industry in Turkey. Agriculture accounted for 30.40% of the nation's total jobs in 2013. That proportion was even higher for female employment at exactly 52.52% in the same year and indeed is the main source of employment for women there. In response to the opening of and better access to global markets, this chapter addresses the following question: What products should Turkey choose to export to the world markets?

This chapter adopts a strategic management perspective. Application of strategic management and planning is necessary to analyze the current and future position of an enterprise for two fundamental dimensions before developing the strategies of that enterprise or organization; namely: (1) the forces of the external environment that determine the industry trend and the opportunities of the market as well as its threats; and (2) the internal competencies of the enterprise that will determine the potential of the unique competitive leadership which the enterprise can mobilize to establish a commercial superiority against competitors. The strategies chosen must balance the external opportunities and any threats with their own internal strengths, and weaknesses.

The main objective of this study is as follows: Considering the world demand of agricultural products and Turkey's competitive position, what strategies (or what agricultural products) must the country adopt or choose? To answer this question, this chapter adopts the business portfolio analysis approach developed by the Boston Consulting Group (BCG). The growth rate of agricultural products that Turkey exports to the world, the ratio of the total exports of Turkey by agricultural product to the total exports of the world leader of that product, and the share of the exports of each agricultural product of Turkey in terms of the total exports of agricultural products by Turkey are used to measure the three dimensions of the BCG matrix.

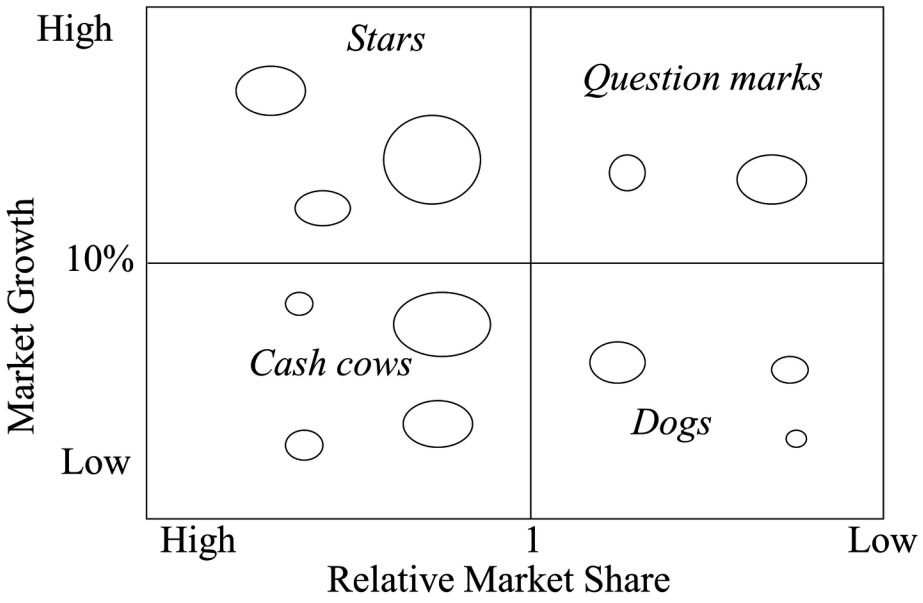
The chapter is organized into six main sections: Introduction, Literature Review, Application of the BCG model to the world markets for agricultural products with Turkey as a center for decision-making in terms of that nation's portfolio of world exportable agricultural products, Methodology, Results, Conclusions and the limitations of the study and suggestions for future research. The study duplicates the previous research conducted on West African countries by Sidibe (2011, 2012). The chapter will benefit scholars, scholar-practitioners, business executives, and undergraduate/graduate business and economics students as reference material because it links theory to application.

LITERATURE REVIEW: PORTFOLIO ANALYSIS AND THE BCG MATRIX

This analysis of the BCG matrix follows the presentation of Sidibe (2011) who borrows mainly from Hax & Majluf (1984). Applying the BCG view, an enterprise is a portfolio of business units or firms (SBU for Strategic Business Units), and every unit makes a contribution unique to the growth and profitability of the whole. Still, the units do remain largely independent, and their strategic directions thus need to be approached in a distinctive way. The main objectives of the enterprise are recognized as being both growth and profitability. The BCG developed a growth-market share matrix in which each unit is represented on a grid of four cells (see Figure 1). The horizontal axis corresponds to the relative market share of a business unit (measured by a log of the ratio of the sales of the unit to the sales of its main competitor) to characterize the strength of the enterprise in a specific sector of activity. The vertical axis indicates market growth, representing the attractiveness of the market in which the unit operates (as measured by the growth rate of that market). The area of each circle is proportional to the total sales produced by that particular unit and measures the contributions of every unit to the total sales of the entire enterprise.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The BCG matrix



Each axis is divided into two parts. In the market growth dimension, the cut-off between strong and weak growth was fixed initially by the BCG at 10%. However, Hax & Majluf (1984) recommended choosing either industry average growth or a measure of general economy growth, such as GNP growth, or a weighted average growth rate of each sector of activity or the growth target of the enterprise as the cut-off. When the business units lie above the cut-off, they are in an embryonic phase of growth; if they are below the cut-off, they are in the maturity or aging phases of business activity. When an industry grows rapidly, one can penetrate the market aggressively and increase market share considerably without necessarily eroding the sales of its competitors. On the other hand, in a mature or aging industry it is not possible to earn market share without decreasing the sales of competitors (Hax & Majluf, 1984: 129; Sidibe, 2011: 33).

To separate the units by their high and low internal strengths, the BCG chose (in its initial proposition) a relative market share of 1.0. The higher the relative market share, the higher will be the competitive advantage of the enterprise, and the more it can exercise considerable dominance in the business. The strategic choices will depend on the location of the units in that matrix. The *Stars* are the units localized in the upper left corner of the matrix. These are very attractive units (high market growth) in which the enterprise has a strong competitive position (high relative market share). They generate a lot of cash and require a considerable influx of cash at the same time if the enterprise wants to sustain its competitive strength quickly in this increasing market. Consequently, the excess final fund contributed to the headquarters or the deficit required from the headquarters is relatively low. The goal of the *Stars* is to increase or maintain their market shares. *Cash Cows* are units that bring an abundant amount of funds to the organization as they have a very high competitive strength in a low market growth situation. Their positive cash flow can be used to sustain the development of other units in the enterprise if the allocation of resources is centralized. Therefore, the strategic choice is to maintain their market shares.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

*Question Mark*s are large, untapped opportunities which are very attractive because of their high growth rate of the market in which they exist. However, the enterprise does not have a significant presence in the corresponding market. Therefore, it is necessary to decide to identify selectively among those products that can be promoted with success to attain a leader position (*Stars*) (Hax & Majluf, 1984: pp. 132-133). The decisions regarding them are to increase the market share of some, harvest (looking to short-term cash flow without too much concern for the long-term), and divest from others. *Dogs* are units that operate in low market growth and are dominated by their competition. Therefore, they are less attractive and are weak. The small amount of cash they generate serves to maintain their operations. If any recovery of the situation is not close at hand, then the logical strategy is to either harvest or divest. In summary, the strategic choices for the units are: Increase market share (for some *Stars,* and some *Question Marks),* maintain market share (for some *Stars,* and for some *Cash Cows*), harvest (for some *Question Marks,* and for some *Dogs*), and divest (for some *Question Marks,* and for some *Dogs*).

STRATEGIC POSITIONING OF TURKISH AGRICULTURAL PRODUCTS ON THE WORLD MARKET

This section of the chapter delineates the research methodology and presents the results analysis and discussion.

1. Methodology

The research methodology for this project is based on the methodology used in an earlier paper as indicated. The data for the present research derived from FAOSTAT, the statistics database of the FAO, which is the most complete, and up-to-date database of all the free online databases for international organizations in the United Nations system used in our research. FAOSTAT3 data for year 2011, the latest available, was collected in October, November, and December of 2014. FAOSTAT3 is the newest and updated database of FAOSTAT.

a. The Data Collection

The data come from the FAOSTAT3 database, and the data collection from the FAOSTAT3 database proceeded very precisely. FAOSTAT has changed the structure of its database, so it is different from the one used by previous research. The new database is FAOSTAT3, so in this research, a period of experimentation was necessary to learn and understand its structure and the precise functionality of the different forms of downloading as well as the compatibility of the downloaded forms with the software the authors used in this chapter. FAOSTAT3 contains many sub-databases, among which are two that were relevant to our study: **Crops and livestock products,** and **Live animals**.

The Crops and livestock products database was accessed first to deliver its results as Exports into the CSV format, as well as the database labeled Live animals first as the total World export for each product and then as each country export for each product. The CSV format files were then transformed into Excel files. Combining the downloaded data from these two databases provided precise data for the full agricultural sector - crops and livestock products (469 aggregated and non-aggregated products),

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and live animals (24 aggregated and non-aggregated products)– for a total of 493 aggregated and non-aggregated products (of which 413 were non-aggregated products) for 203 countries. To avoid a double count, only **the 413 non-aggregated products** were used in the analysis. In summary, Turkey exports for 2011 and then 2010 were sorted so as to measure the growth rate of these exports and also measure the exports of the world competitors of Turkey for 2011 so as to measure the relative market share of each agricultural export from Turkey for that year. After the data collection, this chapter per the authors then calculated the variables for those measurements as discussed below.

b. Measurement of the Variables

Three fundamental variables exist in the model for the BCG (see section PORTFOLIO ANALYSIS: THE BCG MATRIX): Market growth rate of each business unit or product, relative market share of each business unit or product, and the contribution of each business unit or product to the total sales of that enterprise. For market growth rate, we calculated the growth rate of the world export value in US dollars for each agricultural product exported by Turkey from 2010 to 2011 for this chapter per the authors who formulated that variable and did so as follows:

$$\varphi_{it} = (X_{it} - X_{it-1}) * 100 / X_{it-1}$$

φ_{it} = the growth rate of the world export of the agricultural product i exported by Turkey in 2011
X_{it} = the world export of agricultural product i exported by Turkey in 2011
X_{it-1} = the world export of agricultural product i exported by Turkey in 2010
$i = 1 \ldots 250 \ldots 413$

The cut-off between high growth and low growth was fixed at 3.5%, a growth rate of real GDP the International Monetary Fund (IMF) World Economic Outlook (WEO) released on April, 2014 as the projection for Turkey for 2019 (IMF, 2014b: p. 184). The latest data from the IMF Country Report Turkey 2014 Article IV Consultation-Staff Report released on December 5, 2014, prepared by a staff team from the IMF, projected for Turkey a 3.4% average growth rate in real GDP from 2014-2019 (IMF, 2014a: p. 29), while the average growth rate of real GDP for the past 10 years (2003-2013) was 5%.

The cut-off at 10% recommended initially by the BCG seemed coercive because of fluid tensions in the world markets in general, and the agricultural markets in particular as they related to the negotiations within the WTO and in particular due to the tensions between North and South countries, the tensions between the USA and the European Union regarding agriculture, **and the much lower growth of actual, past, and future real GDP for Turkey**. For the actual year 2013, the growth rate for the real GDP for Turkey was 4.1% (IMF, 2014a: p. 29) or 4.3% (IMF, 2014b: p. 184). In the past, the average annual real GDP growth rate from 1996-2005 was 4.3% (IMF, 2014b: p. 184), and from 2003-2013, it was 5.0% (IMF, 2014a: p. 29). From these data, the authors calculated that the average annual real GDP growth over the past 18 years (1996-2013) was 4.65%. All of these figures fall below the rate of 10% recommended initially by the BCG, in less than half.

To obtain the relative market share, the relative market share of each agricultural export value in US dollars for Turkey for year 2011 was measured by calculating the log natural of the ratio for the export

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

value in US dollars of each agricultural product exported by Turkey to the export value in US dollars for the world export leader for each product exported by Turkey. If Turkey were the world leader, then the denominator would refer to the exports of the world's second exporter. We formulated this variable as follows:

$$\tau_{i.t=}\ln(x_{i.t} /\max x_{ijt})$$

$\tau_{i.t}$ = relative market share of product *i* exported by Turkey for 2011
$x_{i.t}$= the export in value of product *i* exported by Turkey for 2011
x_{ijt}= the export in value of product *i* by country *j* for 2011

Thus, max $x_{ijt}$is the export in value of world export leader for product *i* exported by Turkey for the year 2011. If Turkey was the world leader, the denominator would refer to the exports of the world's second exporter.

The cut-off between products of high and low relative market share was fixed at 1 as recommended by the BCG. The contribution of each product to the total sales of the enterprise was estimated by the share of the export of each agricultural product as it related to the total agricultural exports of Turkey. In other words, that measure was the percentage of the exports of each agricultural product in terms of the total of agricultural exports of Turkey. That contribution was formulated as follows:

$$\rho_{i.t} = (x_{i.t}/x_{..t})*100$$

$\rho_{i.t}$= share of the export of product *i*to the total agricultural exports of Turkey for 2011
$x_{i.t}$= the export in value of product *i* exported by Turkey for 2011
$x_{..t}$= total agricultural exports of Turkey for 2011

c. The Data Analysis

To analyze the collected data, the three variables above were calculated using EXCEL and then transferred to SPSS where the diagram for the matrix was drawn, using the Graph Interactive Scatterplot function by improving the visualization of the contribution of each product. This contribution is represented by the ranking of the products based on their share to the total agricultural exports of Turkey for 2011, ranging from 1 to 277 where 1 is the top export of Turkey, and 277 the last export. In addition, the product name was abbreviated to have each displayed in the graph. Multiple experiments were necessary to achieve the best result.

RESULTS AND DISCUSSION

In terms of these results, the authors analyze and present successively the range of agricultural products exported by Turkey in 2011, the contribution of each agricultural product to total the country's agricultural exports, the growth of the world's agricultural exports, the competitive position of Turkey on the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

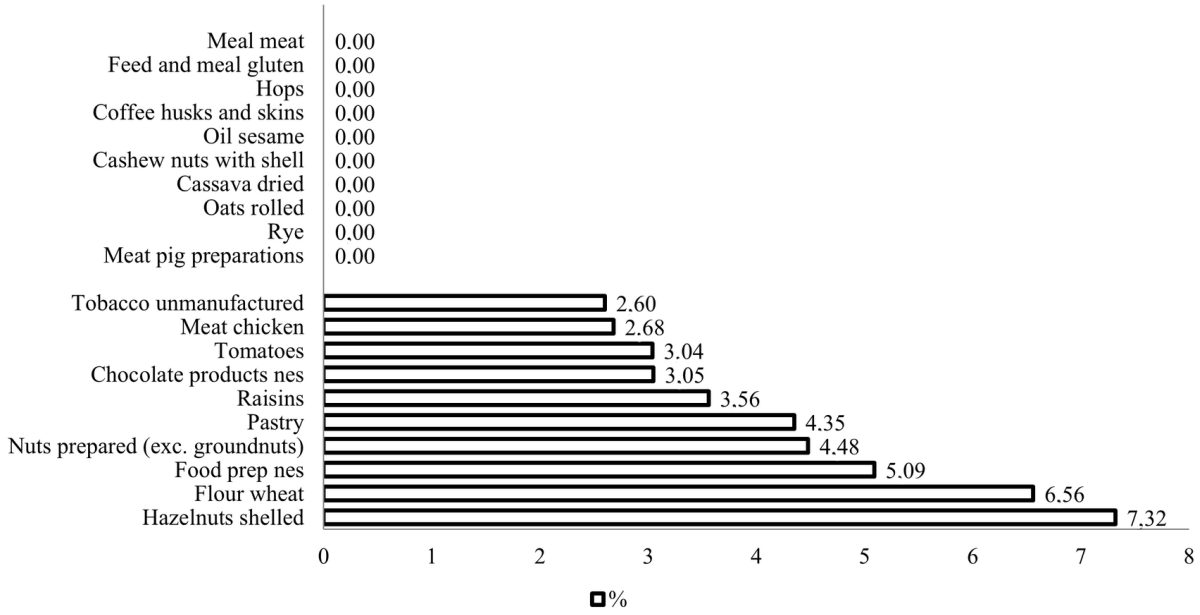
world market for agricultural products (by analyzing the relative market share held by the agricultural exports of Turkey), the positioning of the products exported by Turkey in the strategic matrix, the strategic choices for each product, and then a dynamic discussion of the analysis.

1. Agricultural Exports for Turkey in 2011

The total exports of all agricultural products from Turkey in 2011 totaled US**$14,228, 600,000**, thus accounting for 1.73% of the GDP or 10.55% of Total Merchandise Trade or 103.49% of total agricultural imports. It consisted of 333 agricultural products worldwide (Crops and Livestock products, and Live animals) of which only 56 products (or 16.82%) were marginal exports (below US$1,000 in export value). Those products whose export was less than US$1000 are not listed in the FAOSTAT3 databank and have zero value. Therefore, for Turkey a total of **277 products generated an export of US$1,000 or more** (see Figure 2 and Table 1 for more details) and are analyzed in this chapter.

The total export of these **277 products** accounted for 95.62% of the total exports of the entire agricultural sector (Crop and livestock products, and Live Animals). These products were essentially dominated by Hazelnuts shelled which accounted for 7.32% of the total agricultural exports of the country (see Figure 2). **The five top (main) agricultural exports for Turkey were**, therefore successively, Hazelnuts shelled, Flour wheat, Food prep nes, Nuts prepared (excluding groundnuts), and Pastry. These five top products accounted for 27.77% of the country's total agricultural exports in 2011. **Out of the 277 agricultural products exported, the top 10 represented 42.72% of the total**. Among the top 10 products, Figure 2 shows a relatively equal distribution between the two top products and the three next and the five next others. In comparison to previous research, Turkey is less dependent on small number agricultural exports than are West African countries where Sidibe (2011) found that Cotton lint accounted for 74% of Burkina Faso's total agricultural exports in 2008.

Figure 2. Agricultural exports for Turkey in 2011, share of top ten, and last ten products



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

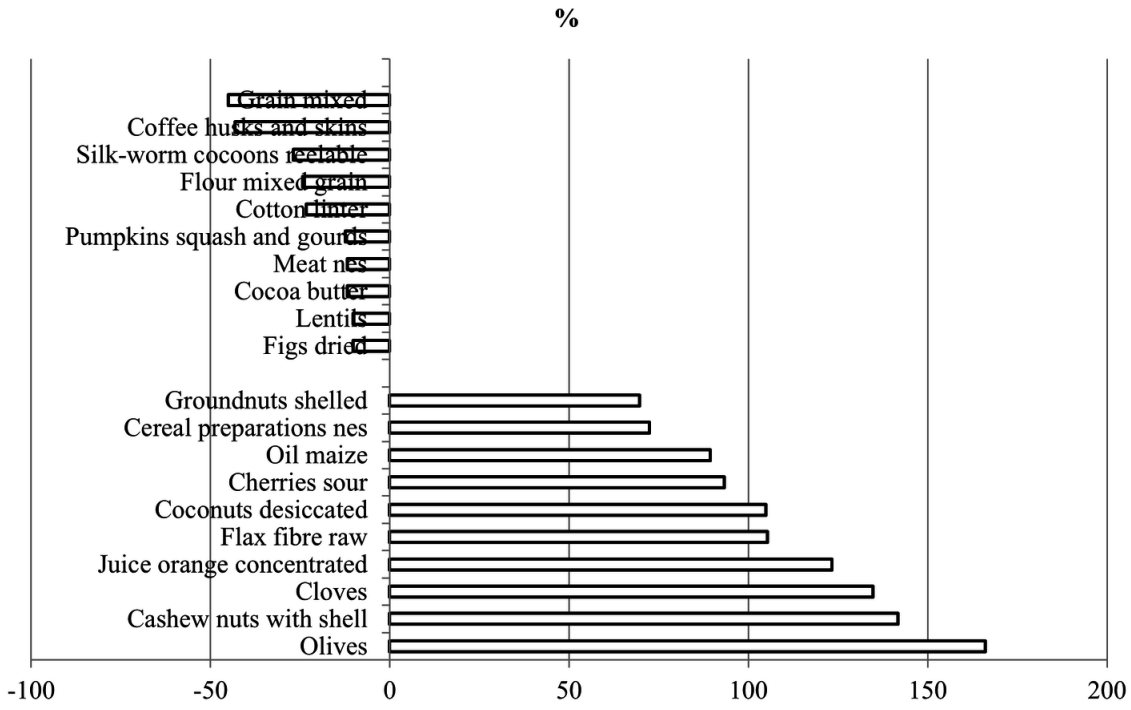
2. Growth of World Agricultural Markets

The World Export of Agricultural Products grew significantly during 2010-2011, indeed at a rate of 21.66%, which is higher than the World Total Merchandise Trade (world exports of all economic sectors for all countries, which totaled just 19.87%). In this general context, the world agricultural markets for Turkey enjoyed excellent growth, even for some its main export products. The world market for the agricultural products exported by Turkey also grew significantly during the 2010-2011 period (see Figure 3 and Table 2 for more details)

The growth rates for the world in 2011 were very high (maximum 166.14%), and almost all products had positive growth rates (251 products out of 277 or 90.61%). The other 26 products out of the catalogued 277 products or 9.39% had a negative growth rate for that same period. A total of 108 products (or 39% of the total) had a growth rate higher than the total world trade growth rate (21.66%), and nearly three-quarters (74%) enjoyed a 2-digit growth rate. Indeed, the growth rate of 78% for the listed products was higher than the growth rate for the entire real GDP for Turkey in 2011 at 8.8% according to the IMF (2014a: p. 29). Further, the growth rate for 85.92% for the products (238 products out of 277) was higher than the target for 2019 (3.5%) as noted in the above section).

The growth in the world agricultural markets for Turkey's Top 10 exports was positive and ranged from 1.39% to 41.65% for that year. Of the Top 10 exports from Turkey, eight products (namely Hazelnuts shelled, Flour wheat, Food prep nes, Nuts prepared (exc. groundnuts), Pastry, Raisins, Chocolate products nes, and Meat chicken) enjoyed a 2-digit growth rate, while Turkey's top two exports (namely Hazelnuts shelled, Flour wheat) had growth rates higher than the world growth rate for that same period

Figure 3. Growth of the world agricultural markets for Turkey, 2011: The top ten, and the last ten



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(respectively -24.92%, and 41.65%). Only two products from Turkey'stop ten exports had growth rates below the target for 2019 (3.5%). The world's top ten growth products were Olives, Cashew nuts with shell, Cloves, Juice orange concentrated, Flax fibre raw, Coconuts desiccated, Cherries sour, Oil maize, Cereal preparations nes, and Groundnuts shelled.

None of the top ten exports from Turkey were among the Top 10 growers in the world. The main 10 exports of Turkey were not from the world's highest growing markets. Among these world growing markets, the best Turkey export position was Olives which is Turkey 235th export. Turkey exports in these Top 10 growers in the world were marginal, accounting for only 0.95% of the total agricultural exports for the country (US$134,734,000 / US$14, 228,600,000 = 0.95%). In general, Turkey's main exports are **not** part of the world's most growing markets.

Generally, one can conclude from a review of these statistics for 2010-2011 that the business opportunities for Turkey are good if one considers the growth rate in the world markets for the products that Turkey exports. It is evident that 78% of the products exported by Turkey are in markets whose growth rates are higher than the growth rate for the GDP of Turkey in 2011 (8.8%), while the growth rate of 85.92% of these export products is higher than the GDP target for 2019 (3.5%). Additionally, nearly half of the products exported by Turkey (39%) are to markets where the growth rates are higher than the growth rate of overall world trade for 2011 (21.66%). Thus, the government of Turkey and the country's business sector should take advantage of or capitalize on these identified opportunities while also taking into account the country's overall world competitive position. However, none of the Top 10 exports from Turkey were among these Top 10 growth products in the world. Thus, the main 10 exports of Turkey were not to the world's greatest growing markets as previously stated.

To capitalize on these world opportunities, Turkey must substantially increase the exports of some of its marginal exported products**;** namely, Olives, Cashew nuts with shell, Cloves, Juice orange concentrated, Flax fibre raw, Coconuts desiccated, Cherries sour, Oil maize, Cereal preparations nes, and Groundnuts shelled - which are the world's greatest growing products. In addition, none of its Top 10 exports had a negative global growth in 2010-2011.

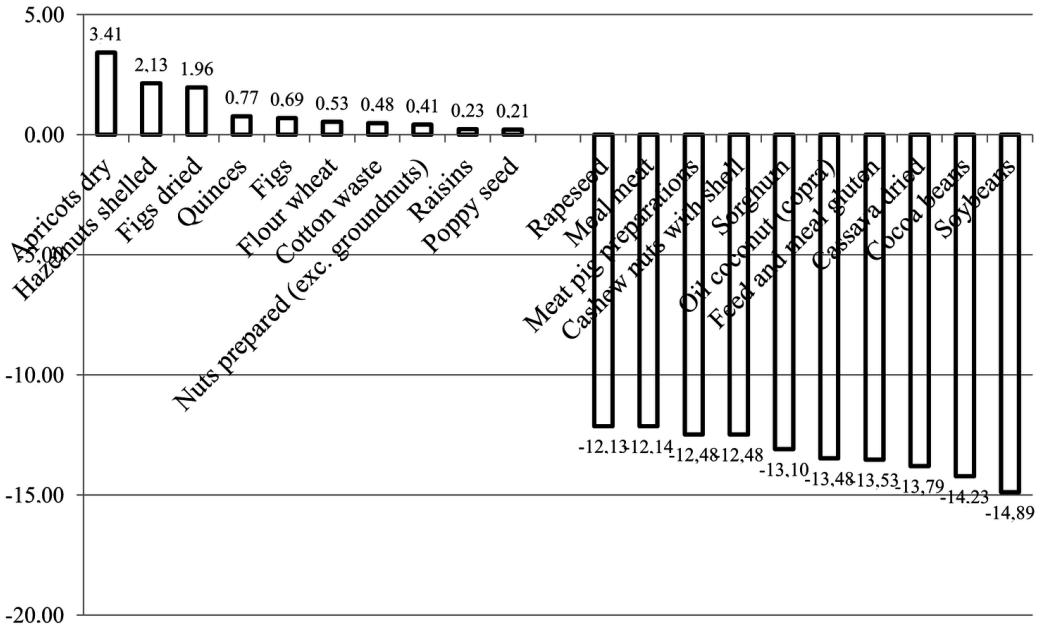
3. Competitive Position of Turkey on the World Market for Agricultural Products: Relative Market Share for Turkey Agricultural Exports

Figure 4 demonstrates that Turkey is the world leader in 10 products: Apricots dry, Hazelnuts shelled, Figs dried, Quinces, Figs, Flour wheat, Cotton waste, Nuts prepared (excluding groundnuts), Raisins, and Poppy seed. For the three first products (Apricots dry, Hazelnuts shelled, and Figs dried), Turkey totally dominated its competitors. Their relative market shares – strengths relative to their main world competitors – are very high and higher than 1. The most competitive product for Turkey (Apricots dry) garnered 3,026.98% of its world main competitor in 2011, Germany. Its second competitive product (Hazelnuts shelled) garnered 843.46% of its world main competitor, Georgia, and the third competitive product (Figs dried) garnered 712% of its world main competitor, the USA. Some of the main exported products for Turkey in terms of value are also products where Turkey holds a better competitive position in the world. They are among the top ten export products that hold a stronger relative market share.

Regarding the Top 10 export products of the country, four (Hazelnuts shelled, Flour wheat, Nuts prepared (excluding groundnuts), and Raisins) are also products for which Turkey also holds a better competitive position in the world. For example, the main export (Hazelnuts shelled) is the country's

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Relative market share for Turkey agricultural exports, 2011



second competitive product (garnering 843.46% of its world main competitor, Georgia). The second main export (Flour wheat) is the country's sixth competitive product (garnering 169.36% of its world main competitor, Kazakhstan), and the fourth export (Nuts prepared (excluding groundnuts)) is the country's eighth competitive product (garnering 150% of its world main competitor, the USA). The sixth main export (Raisins) is the country's 9th competitive product (garnering only 125.76% of its world main competitor, the USA).

The other six of the Top 10 exports are not among the top ten competitive products. For example, the third export product (Food prep nes) is the country's 43d competitive product (garnering only 12.10% of its world main competitor, the United States). The fifth export product (Pastry) is the country's 31st competitive product (garnering only 18.74% of its world main competitor, Germany). The seventh export product (Chocolate products nes) is the country's 48th competitive product (garnering only 11.35% of its world main competitor, Germany). The eighth export product (Tomatoes) is the country's 27th competitive product (garnering only 20.66% of its world main competitor, Mexico). The ninth export product (Meat chicken) is the country's 73rd competitive product (garnering only 5.39% of its world main competitor, Brazil). Finally, the tenth export product (Tobacco unmanufactured) is the country's 42rd competitive product (garnering only 12.83% of its world main competitor, Brazil). Also, we observed that the eleventh main export (Apricots dry) is the country's first competitive product (garnering 3,026.98% of its world main competitor, Germany).

Therefore, Turkey should increase its relative market share (for some of its ten top exports) if it wants to become more competitive and an important player in the world agricultural markets or form useful alliances with other countries. It has a good competitive position in some products, but these products are not the world's highest growing markets.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

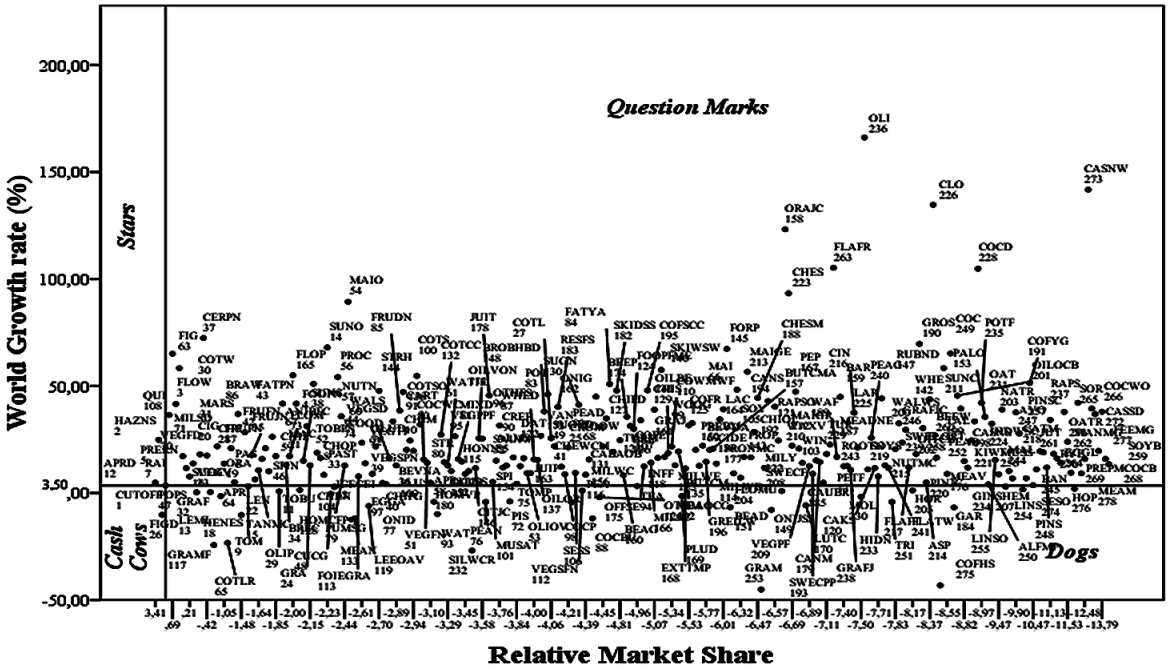
4. Positioning of Agricultural Products Exported by Turkey on the World Growth-Relative Market Share Matrix

Figure 5 shows the positions of the agricultural products exported by Turkey on the matrix framed by two main variables: Growth rates for world exports of agricultural products, and the relative market share for the agricultural products exported by Turkey. The visual reveals that the agricultural products exported by Turkey are unevenly distributed in the four cells of the matrix (the BCG), while almost all of its products are *Question Marks* (236 products or 85.20% of its portfolio). Two products (Hazelnuts shelled «HAZNS», and Apricots dry «APRD») are a *Star,* one product (Figs dried «FIGD») is a *Cash Cow, and* 38 products (or 13.72% of its portfolio) are *Dogs*. This situation creates problems that relate to major strategic choices for the country's leaders and its business sector. This chapter will discuss strategic choices for the Top 10 products in terms of the export receipts for Turkey or, in other words, the country's dominant export products based on the matrix categories.

a. The Stars

Two products (Hazelnuts shelled «HAZNS in Figure 4», and Apricots dry «APRD») are *Stars.* They are the most competitive products for Turkey and thus its strongest products with 2.13 and 3.41 in terms of

Figure 5. Positioning Turkey agricultural products in the world markets, 2011



Note: 277 products are plotted. For the top-ten and least-ten products, each product in the coordinates is represented by a code and a number. The number indicated the product rank in total exports of all agricultural products from Turkey in 2011, i.e. 1 = top export, 2 = the second position, 3 = third position, and so on.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

relative market shares, and world growth rates that reach 24.92%, and 4.84%, respectively. Turkey is the world's leading exporter of these products. Its Hazelnuts shelled exports in 2011 reached US$1,041,430,000, or 8.43 times that of its most important competitor, Georgia. As noted earlier, Hazelnuts shelled is the first export (the top export) of Turkey, and the country is the world leader for this product. Furthermore, Hazelnuts account for 7.32% of the country's total agricultural export value. With this product enjoying an excellent world growth rate of 24.92%, a reasonable strategy would be to increase this export or at least maintain its current position. For Apricot dry, the exports totaled US$360,907,000, or 30.26 times that of its most important competitor, Germany. However, it accounted for 2.54% of the country's total agricultural export value (rank 11), and a slow world growth rate of 4.84%. Even with this slow world growth rate, a reasonable strategy would be to increase this export or at least maintain its current position, in hopes that world growth will increase.

b. The Cash Cows

One product (Figs dried «FIGD») is a *Cash Cow*. It is the third competitive product for Turkey, with 1.96 as relative market share, but with a negative world growth rate (-10.18%). Turkey is the world's leading exporter of this product. It exported US$151,546,000 in 2011, or 7.12 times that of its most important competitor, the USA. Although Turkey is the world leader in this product, it again marginally accounted for only 1.07% of the country's total agricultural export value, ranking 25 out of 277 exported products. If its world growth rate increases substantially, Figs dried can be considered a *Star*. It will not likely become a *Dog* in the near future because Turkey already holds a big market share. Its export of the product is much higher than its most important competitor (7.12 times). Therefore, a logical strategy would be to increase the export of the product or at least maintain its current position for Figs dried.

c. The Dogs

A total of 38 agricultural products (i.e., 13.72% of the products exported) were situated in the *Dogs* cell. These have low market shares in markets that are growing slowly or even decreasing. This weak market share jeopardizes these types of products when facing bigger competitors. The BCG perspective is that these products are big losers; they are less attractive in terms of market growth, and they are weak compared to their world competitors. If there is no legitimate reason to expect any recovery in the near future, the logical strategy is to harvest or divest them. The basic objective for harvesting a dog is to increase short-term cash return without much concern for long-term impact and then sell these products to earn cash needed by the *Question Marks*.

A total of 13 products made up the *Dogs* cell (i.e., 34.21% of that cell) – Tea, Tomatoes, Ginger, Chestnut, Hops, Papayas, Tobacco unmanufactured, Horses, Vegetables fresh nes, Flour mustard, Olives preserved, Grapefruit (including pomelos), and Lemons and limes – are in markets which are growing slowly, but have some positive growth rate. The other 25 products in that cell (i.e., 65.79% of the cell) were in markets that are decreasing (have a negative growth rate). If the overall world growth rate increases substantially, these products may become *Question Marks,* but never *Stars* because their market shares are very small.

The five least competitive products (ascending) among the *Dogs* were Hops, Papayas, Ginger, Garlic, and Coffee husks and skins. Hops were the least competitive. For example, the world leader in Hops, Germany, exported US$173,261,000 in 2011 while Turkey exported only US$1,000; in other words,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Germany exported 173,261 times that of Turkey. Following the same line of reasoning, Mexico, the world leader in Papayas exported US$46,264,000 in 2011, while Turkey exported only US$2,000; in other words, Mexico exported 23,132 times that of Turkey. For Ginger, the China mainland is the leader and exported US$409,484,000, while Turkey exported only US$29,000, or in other words, the China mainland exported 14,120 times Turkey's exports of Ginger.

Garlic's world leader, the China mainland, exported US$2,068,290,000, while Turkey exported only US$336,000, or in other words, the China mainland exported 6,155 times Turkey's exports of Garlic. For Coffee husks and skins, the United Republic of Tanzania was the leader and exported US$5,031,000, while Turkey exported only US$1,000, or in other words, Tanzania exported 5,031 times Turkey's exports of Coffee husks and skins. Facing such large and strong competitors, the government and the business sector of Turkey has few meaningful choices. A reasonable strategy would be harvesting or divesting or moving toward organic production and export of the named products.

Two products from the Top 10 exports for Turkey were in the *Dogs* group, namely Tomatoes («TOM»), and Tobacco unmanufactured («TOBU»). Regarding world growth and relative market share, Tomatoes are in a better position than Tobacco unmanufactured; we recall that Tomatoes is the eighth export of Turkey, and Tobacco unmanufactured is its tenth export. For example, the world leader in Tomatoes, Mexico, exported US$2,093,140,000 in 2011, while Turkey exported only US$432,461,000; in other words, Mexico exported 21 times that of Turkey, the world growth being 3.04%. Following the same line of reasoning, Brazil, the world leader in Tobacco unmanufactured, exported US$2,878,610,000, while Turkey exported only US$369,464,000, meaning Brazil had 7.8 times Turkey's exports of Tobacco unmanufactured, the world growth being 1.39%.

Divesting Tomatoes would not be acceptable, considering that it is a product that is consumed daily, so there is always a fear of dependence on other countries; further, the product is perishable (and weather is thus a factor). If tomato production is suited well to natural conditions (i.e., soil and climate) of the country, Turkey could move toward a more focused strategy that benefits organic segments tomatoes (with organic being a positive trend). For Tobacco unmanufactured, based on the negative impact of cigarettes on health according to the World Health Organization [WHO](2013, p. 8), these tobacco products should be divested (or abandoned). Divesting (abandoning) these products could free up resources that could then be used to increase the market share of products whose relative market share will increase as discussed and recommended above, and also solve a health issue. The WHO Report on the Global Tobacco Epidemic (2013) stated the following facts and warnings:

The WHO Framework Convention on Tobacco Control (WHO FCTC) recognizes the substantial harm caused by tobacco use and the critical need to prevent it. Tobacco kills approximately 6 million people and causes more than half a trillion dollars of economic damage each year. Tobacco will kill as many as 1 billion people this century if the WHO FCTC is not implemented rapidly (p. 8).

The report continues by stating that "*Complete bans are needed to counteract the effects of tobacco advertising, promotion and sponsorship...*[and]*Bans must completely cover all types of tobacco advertising, promotion and sponsorship*" (p. 26, p. 30) With the documented worldwide will to reduce the demand for tobacco led by the WHO, the practical and logical strategy for Turkey is to divest of or abandon all tobacco and tobacco-related products.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

d. The Question Marks

This is the large portfolio in Turkey as 85.20% of the export portfolio for Turkey, or 236 products out of 277, rest in the *Question Marks* cell. These products enjoy strong world market growth (their growth rate exceeded Turkey's GDP 2019 target growth), but they face much greater world competition. **Seven of the Top 10 Turkish exports are in this category**: Flour wheat, Food prep nes, Nuts prepared (exc. groundnuts), Pastry, Raisins, Chocolate products nes, and Meat chicken. They enjoy a 2-digit world growth. It seems unreasonable to divest them; however, because their importance in terms of the country's exports their world growth rates, and the possibilities to tap new niches. So, a logical strategy for these seven products would be to increase their market share to bring them in a *Star* position, and/or to move toward a more focused strategy that serves organic segments. Thus, it becomes necessary to invest in these seven of the Top 10 exports products from Turkey.

Among the *Question Marks* products, the ten products which have a better competitive position or better strength relative to their global competitors include: Quinces, Figs, Flour wheat, Cotton waste, Nuts prepared (excluding groundnuts), Raisins, Poppy seed, Vegetables in vinegar, Vegetables fresh or dried products nes, and Cereal preparations nes. For these products (particularly for the first seven in which Turkey is the leader), if the country increases its exports, these products would become *Stars*. The logical strategic decision for these products would be to increase their market share and move toward a more focused strategy that serves organic segments. Thus, it is advisable to invest in these ten products as well.

The five least competitive products in descending order which were *Question Marks* include: Oil coconut (copra), Feed and meal gluten, Cassava dried, Cocoa beans, and Soybeans; soybeans were the least competitive. For example, the world leader in soybeans, the USA, exported US$17,563,900,000 in 2011, while Turkey exported only US$6, 000; in other words, the USA exported 2,927,317 times that of Turkey. Following the same line of reasoning, Côte d'Ivoire, the world leader in Cocoa beans, exported US$3,029,180,000, while Turkey exported only US$2,000, meaning Côte d'Ivoire had 1,514,590 times Turkey's exports of Cocoa beans.

For Cassava dried, Thailand is the leader and exported US$978,593,000, while Turkey exported only US$1,000, meaning Thailand exported 978,593 times Turkey's exports of Cassava dried. Feed and meal gluten world leader, the USA, exported US$754,089,000, while Turkey exported only US$1,000; therefore, the USA exported 754,089 times Turkey's exports of Feed and meal gluten. For Oil coconut (copra), the Philippines was the leader and exported US$1,425,450,000, while Turkey exported only US$2,000, or the Philippines exported 712,725 times Turkey's exports of Oil coconut (copra). Facing these large and strong competitors, the government and the business sector of Turkey do not have a meaningful choice. However, the country could try to enter the organic segment for these products, as they were traditionally organic, and animals there are traditionally raised in a natural environment. At the same time, the country could increase the daily protein intake of its own diet by making this choice.

Another *Question Mark* product which could be abandoned is Tobacco products nes (even the world growth rate is only 21.70%, and the relative market share -2.69), because according to the WHO (2013), cigarettes have a negative impact on health, and tobacco products kill nearly 6 million people thus causing hundreds of billions of dollars of economic damage worldwide each year. In the *2013 Report on the Global Tobacco Epidemic,* the WHO introduced stronger measures to help countries worldwide reduce their demand for tobacco (WHO, 2013 p. 8). Therefore, the practical and logical strategy for Turkey

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

is to divest all tobacco and tobacco-related products. Divesting these products could free up resources which could be used to increase the market share of products whose relative market share will increase as already recommended.

CONCLUSION

Turkey exports a broad range of agricultural products, 277 products all told in 2011. The growth of all agricultural exports from Turkey (20.58%) was below, but still close to that of, agricultural exports worldwide (21.66%). In other words, Turkey cornered the world market, but not at the same speed as its competitors. However, that world growth was also unevenly distributed among the export portfolio for Turkey: The maximum growth rate was 166.14%, most products (90.61%) did have positive growth rates, and the other 9.39% posted a negative growth rate; nearly three-quarters (74%) enjoyed a 2-digit growth rate, and 78% of the listed products had a growth rate higher than the real GDP for Turkey in 2011 (8.8%).

Furthermore, the growth rate of 85.92% of these export products was higher that the target for 2019 (3.5%). The growth of the world agricultural markets for Turkey's Top 10 exports was positive and ranged from 1.39% to 41.65% for that year. Of the Top 10 exports from Turkey, eight products (Hazelnuts shelled, Flour wheat, Food prep nes, Nuts prepared (excluding groundnuts), Pastry, Raisins, Chocolate products nes, and Meat chicken) enjoyed a 2-digit growth rate, while Turkey's top two exports (Hazelnuts shelled, Flour wheat) had growth rates higher than the world growth rate for that same period (successively -24.92%, and 41.65%).

Only two products from Turkey's Top 10 exports had growth rates below the target for 2019 (3.5%). None of the Top 10 exports from Turkey were among the Top 10 growers in the world. The main ten exports of Turkey are not part of the world most growing markets. Among these world growing markets, the best Turkey export position is Olives which is Turkey's 235th export. Turkey exports in the Top 10 growers in the world are marginal, accounting for only 0.95% of the total agricultural exports from the country. In general, Turkey's main exports are not found to be in the world's greatest growing markets.

However, Turkey is the world leader in ten products: Apricots dry, Hazelnuts shelled, Figs dried, Quinces, Figs, Flour wheat, Cotton waste, Nuts prepared (excluding groundnuts), Raisins, and Poppy seed. For the three first products (Apricots dry, Hazelnuts shelled, Figs dried), Turkey totally dominated its competitors; their relative market shares – their strengths relative to their main world competitors – are higher than 1. The most competitive product for Turkey is Apricots dry, while the second competitive product is Hazelnuts shelled. Regarding the Top 10 export products for the country, four (Hazelnuts shelled, Flour wheat, Nuts prepared (excluding groundnuts), and Raisins)) are also the products where Turkey holds a better competitive position in the world.

For example, the main export (Hazelnuts shelled) is the country's second most competitive product (garnering 843.46% of its world main competitor, Georgia). The second main export (Flour wheat) is the country's sixth competitive product (garnering 169.36% of its world main competitor, Kazakhstan), and the fourth export (Nuts prepared (excluding groundnuts)) is the country's eighth competitive product (garnering 150% of its world main competitor, the USA). The sixth main export (Raisins) is the country's 9th competitive product (garnering only 125.76% of its world main competitor, the USA). Therefore, Turkey should increase its relative market share (in some of its Top 10 exports) if it wants to be more

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

competitive and an important player on the world agricultural markets or alternatively, form useful alliances with other countries. Turkey has a good competitive position in some products, but these products are not the world fastest growing markets.

The agricultural products exported by Turkey are distributed unevenly on the four cells of the matrix (of the BCG), and almost all of its products are *Question Marks*: Two products are a *Star,* 1 product is a *Cash cow,* 38 products are *Dogs,* and 236 products (85.20% of its portfolio) are *Question Marks*. This situation creates important strategic choices for the leaders of the country and for businesses. The logical strategic choices for the country now are the following:

• Increase the market shares of the following *Question Marks* products: Flour wheat, Food prep nes, Nuts prepared (excluding groundnuts), Pastry, Raisins, Chocolate products nes, and Meat chicken (seven of the Top 10 exports of Turkey are in this category), Quinces, Figs, Flour wheat, Cotton waste, Nuts prepared (exc. groundnuts), Raisins, Poppy seed, Vegetables in vinegar, Vegetables fresh or dried products nes, Cereal preparations nes (these ten products have a better competitive position in this category), Oil coconut (copra), Feed and meal gluten, Cassava dried, Cocoa beans, Soybeans (these products hold the least competitive position in this category, so increase their share by entering organic segments), and the following *Cash Cows* – Figs dried.

- Maintain the market share of the *Cash Cows* – Figs dried.
- Divest or abandon the following *Dogs* products – Tobacco unmanufactured, *Question Marks* products – Tobacco products nes.

Move toward new organic product segments for the following *Dogs* products – Hops, Papayas, Ginger, Garlic, and Coffee husks and skins, Tomatoes, *Question Marks* products – Oil coconut (copra), Feed and meal gluten, Cassava dried, Cocoa beans, Soybeans. Considering the new passion that the developed or industrialized countries have for organic food, Turkey should choose a focus strategy for their products that will satisfy the growth of this very specific organic food market.

This chapter stresses certain limitations for this research, particularly those related to its static nature. The study examined the internal strength (relative market share) of Turkey for only 2011, and the growth rates of world agricultural markets for only one short period (2010-2011). A more dynamic approach would bring better insight and also further precise strategies to evaluate. This study also did not examine the destinations of the agricultural products exported by Turkey and the consumers (intermediate and ultimate or final consumers) of these exported products. Future research should take account of and examine these specific factors and integrate those results with the results offered here.

Chapter 11
Stakeholder Agriculture:
Innovation From Farm to Store

Alexandros Antonaras
University of Nicosia, Cyprus

Alexandros Kostopoulos
CSR Hellas, Greece

ABSTRACT

The shift in agricultural production and agribusiness may be a solution in reducing unemployment and particularly that of young people which is dramatically high in several European countries that are experiencing the negative consequences of the recent global financial crisis that led to a dramatic decline in their GDP per capita and has affected all sectors of economic activity, including agriculture. The overall scope of this chapter is to present an Agricultural Entrepreneurship and Social Innovation Framework that can lead to a new business model with social aspects, contribute to the economic growth and sustainability and hence combat the phenomenon of unemployment and poverty in rural areas that have been seriously affected by the recent financial crisis.

INTRODUCTION

According to UN Global Compact (2016), the world's population is expected to grow to nine billion by 2050 and demand on global food systems intensifies every day, while businesses will be critical partners in designing and delivering effective, scalable and practical solutions for food security and sustainable agriculture. Every actor along the agriculture supply chain, including farmers, traders, retailers, investors and consumers have a role to play in advancing food security protecting the environment and ensuring economic opportunity.

Globally recognized organizations like the UN Global Compact have already ranked sustainable agribusiness among their top priority issues. In this context, in 2014, the Food and Agriculture Business (FAB) Principles were launched by UN Global Compact as a voluntary framework to advance the positive impact businesses can have in the food and agriculture space and engage in principle-based collaboration with the UN, governments, civil society and other stakeholders.

Focusing on European countries, five decades after the founding of the EU and the implementation of a Common Agricultural Policy, the rural structures of each Member State continue to vary considerably. The main reasons for this variation are the different economic and social-political progress achieved in each member state and the different geographical and climatic data. Thus, for each country the agricultural sector represents a different proportion of their overall economy and contributing differently to the national GDP, employment rates and foreign trade as well as the overall cost of living of the population.

Countries experiencing the negative consequences of the recent economic crisis, of the recent years such as Greece, Cyprus, Spain and Portugal show a dramatic decline in GDP per capita, which has affected all sectors of economic activity including agriculture. In parallel, the agricultural sector in these countries has traditionally been of significant importance to their economies, representing a main economic activity and employment opportunity of a large part of their population, and was relatively higher as a percentage of their GDPs compared to the EU average. It is worth to mention that between 2005 and 2008, the employment rate in the EU, at ages 20-64, rose and reached 70.3%. The trend reversed from 2009 and employment returned to 2006 level at 69%. The following five years employment in EU declined further with an average employment level at 66%, making it very difficult to reach the European target of 75% by 2020 (Eurostat, 2015).

The current lack of sufficient employment opportunities in urban areas, as well as several other obstacles together deepened further youth unemployment in the agricultural sector creating continuous instability guiding to social exclusion and finally poverty. Moreover, farmers have nowadays weak cooperatives leading to the development of individual farming culture that does not support at least a minimum standardization level of their products or farming processes. In addition, the majority of them face overexposure to the financial institutions having difficulties to pay back their loans and as a consequence secure further funding for their future production needs. The limited farming knowledge and absence of formal agricultural training creates further barriers for young people entering the farming sector.,

The shift in agricultural production and agribusiness may be a solution in reducing unemployment and particularly that of young people, which according to the ILO's (2016) World Employment, Social Outlook, in the counties mentioned above it increases continuously and remains dramatically high. To enable such a shift, people, especially young, should be encouraged to remain or return to rural areas and supported to enter the field of agricultural production, which seems to be able to ensure a fair income and provide a chance to young people to build their future with dignity.

There is an urgent need to change the existing and problematic reality. This can be done with the participation of as many as possible players of the production. The creation and support of collective economic rural activities in the form of new, highly-equity cooperatives in the context of social enterprises can create economies of scale and enhance the development of commercial agricultural products by the farmers themselves. These social forms of collective representation bodies and the establishment of regional agricultural chambers can further support rural entrepreneurship, for producers to work together as entrepreneurs. The comprehensive training for farmers arises as a basic need and attending a training course on the "Primary production" can help to de-demonize her.

In addition, the development of an effective network of applied agricultural research to serve farmers in cooperation with the academic community, as well as farming in experimental fields using innovative agricultural applications can contribute to the reversal of the age distribution of farmers. At the same time, the provision of financial support through traditional tools and the development of additional tools of social and solidarity economy, the protection of agricultural means of production, the targeted land

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

use, and the rational use of water may result in the long-term growth of domestic self-sufficiency rate and the development of a National Rural Policy that would be feasible to implement.

Recognizing the need to change the above situation, this chapter presents and analyses the theoretical concept of an innovative approach that has been successfully implemented by a multinational company,(and is briefly presented later in the case study), with the involvement of different stakeholders, including representatives of the primary sector (farmers / producers), secondary (retail, manufacturing) and tertiary sector (banking, transport etc.), in an effort to: [a] secure farmers' income through contractual farming, [b] provide appropriate training to farmers, [c] help securing financial assistance for them provided by financial institutions that undertake the guarantee on behalf of them, [d] support the upgrading of technical means and utilities in order to obtain a higher yield per hectare of production, and [e] develop the appropriate channels to put into the market "unique" products in response to the continuously changing demands of increasingly socially sensitized consumers.

The overall scope of this chapter would be to develop an Agricultural Entrepreneurship and Social Innovation Framework (AgrESIF) that can lead to a new business model with the social aspects and contribute to the economic growth and sustainability, and hence combat the phenomenon of unemployment and poverty in rural areas that have been seriously affected by the financial crisis over the last years. The conceptual Framework links four different forces which shape the potential of an AgrESI project and determine its success and effectiveness, namely the relative global trends, the needs of the rural community, the consumers' behavioral trends and the support available by the responsible corporations, taking into account parameters such as stakeholder expectations, micro-financing needs, international initiatives and the set of entrepreneurial skills required.

GLOBAL TRENDS

Sustainable Farming

Farming sustainably means growing crops and livestock in ways that meet three objectives simultaneously, those of i) economic stability and profit, ii) social benefits to the small farm holders, their families and the local community, and iii) environmental conservation. According to Food and Agriculture Organization of the United Nations (FAO, 2014f) sustainable agriculture depends on a whole-system approach whose overall goal is the continuing health of the land and people, in respect to the Principles of Sustainable Farming. Therefore, sustainable farming concentrates on long-term solutions to problems instead of short-term treatment of symptoms.

More analytically, sustainable farming requires economic sustainability, meaning that the small farm entrepreneurs and/or enterprises are consistently profitable from year to year, the family savings or net worth is consistently going up, while the family debt, where occurs, is consistently going down. Also purchase cost of off-farm feed and fertilizer is decreasing and in some cases reliance on customer payments is decreasing.

On the other hand, social sustainability means that more money circulates within the local economy as the small farmers support other businesses and families in the community. The number of rural families is holding steady or potentially is going up (ATTRA, 2003). Consequently, low skilled young people take over their parents' farms and continue farming as well as highly skilled college graduates with studies in relative fields to agribusiness return to the community after graduation.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Also, environmental sustainability, according to the Millennium Ecosystem Assessment (2005) means that agriculture can be treated as ecosystem management of complex interactions among soil, water, air, plants, animals, climate and people, with the ability to integrate all these factors into a production system that is appropriate for the environment, and as described before, the people, and the economic conditions where the farm is located.

A successful transition from traditional to sustainable farming depends on the farmer's careful monitoring both of progress towards the goals set and of the overall health of the system. Planning and monitoring are particularly important in sustainable agriculture, which relies on natural systems to replace some of the work done by input products like fertilizer and pesticides (ATTRA, 2003). Constant support as the ability to evaluate and re-plan farming procedure according to protocols is vital to the farmer who wishes to farm more sustainably. This transition process should be linked with global trends and international initiatives in order to produce concrete improvements to all stakeholders and mostly to future generations.

The 2030 Agenda for Sustainable Development

Our planet faces multiple and complex challenges in the 21st century. The world's population is expected to grow to nine billion by 2050 and demand on global food systems intensifies every day (UN Global Compact, 2016). 2015 was an important year for the future of agriculture and development. A new set of global Sustainable Development Goals, now on known as "SDGs", will shape the next 15 years of policies, programs and funding (Farming First, 2015). More specifically, on 25 September 2015, the 193 Member States of the United Nations adopted the 2030 Agenda with its Sustainable Development Goals (SDGs), a set of 17 aspirational objectives with 169 targets and many more sub-targets expected to guide the actions of governments, international agencies, civil society and other institutions over the next 15 years (2016-2030).

These ambitious 17 Goals of the 2030 Agenda is a global vision for people, for the planet and for long-term prosperity. They integrate the three dimensions of sustainable development – economic, social and environmental, while at the same time no one goal is separate from the others, and all calls for comprehensive and participatory approaches.

The 2030 Agenda for Sustainable Development is as relevant to developed as it is to developing nations and it charts a plan for the future – shifting the world onto a sustainable and resilient course and leading to transformation. Also, the new 2030 Agenda commits the international community to act together to achieve the Goals and transform our world for today's and future generations.

Agriculture and SDGs

Industrialization drove workers from the fields to the factories with the promise of better opportunities and higher living standards. In employment terms, agriculture accounts for approximately 36% of the global workforce and falling, although the figures mask huge disparities between developed and developing countries (ILO, 2013). For example, according to World Bank (2014) data, in 2010, only around 2% of the US working population was engaged in agriculture, while in India the percentage was approximately 50% and over 80% in Sub-Saharan Africa (including related rural enterprises).

Reaching the SDG targets simply will not be possible without a strong and sustainable agricultural sector (Farming First, 2015). More than any other sector, agriculture is the common thread which holds

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the 17 SDGs together. Specifically, Sustainable Development Goal #2 calls to: "end hunger, achieve food security and improved nutrition and promote sustainable agriculture." To fulfill this goal, the United Nations has identified a series of specific targets (see 2.1-2.5), as well as the means of implementation (see 2.a-2.c) for reaching them.

Specific target 2.1 aims by 2030, to end hunger and to ensure access by all people, in particular the poor and people in vulnerable situations, including infants, to safe, nutritious and sufficient food all year round. Tackling hunger is not only about boosting food production; it's also about increasing incomes and strengthening markets so that people can access food, even if a crisis prevents them from growing enough themselves (United Nations, 2015).

Specific target 2.2 aims by 2030, to end all forms of malnutrition, including achieving, by 2025, the internationally agreed targets on stunting and wasting in children under 5 years of age, and address the nutritional needs of adolescent girls, pregnant and lactating women and older persons (United Nations, 2015).

According to the Farming First plan, (a coalition of multi-stakeholder organizations developed as a joint call to action in response to the global challenges posed at the 2009 United Nations Commission on Sustainable Development), agriculture can play an important role to address malnutrition in three ways:

1. Biofortified foods, such as vitamin-A enriched rice or sweet potatoes, are bred to have higher amounts of micronutrients and can help provide essential vitamins and minerals;
2. Micronutrient-enriched fertilizers improve soil fertility, helping to support higher yields of more nutritious food and can combat micronutrient deficiencies in humans;
3. Improved agronomic practices can also help, for instance, crop rotation and conservation tillage by encouraging food diversity and preventing nutrient depletion of soils.

Specific target 2.3 aims by 2030, to double the agricultural productivity and incomes of small-scale food producers, in particular women, indigenous peoples, family farmers, pastoralists and fishers, including through secure and equal access to land, other productive resources and inputs, knowledge, financial services, markets and opportunities for value added and non-farm employment (United Nations, 2015).

Agricultural development is inextricably linked to economic growth that benefits the poor. In fact, the World Bank (2016) has estimated that agricultural development is about two to four times more effective in raising incomes among poorer than growth from any sector (and up to 11 times more effective in sub-Saharan Africa). Also, increased productivity, when coupled with better access to markets, can help address hunger directly at the farm level or provide sufficient additional income to buy food at the market. Boosting rural incomes and ensuring ample employment means looking at economic opportunities across the entire rural value chain, from farmers and input suppliers to value-added processing and services, such as transporting and marketing of food (Farming First, 2015).

Specific target 2.4 aims by 2030, to ensure sustainable food production systems and implement resilient agricultural practices that increase productivity and production, that help maintain ecosystems, that strengthen capacity for adaptation to climate change, extreme weather, drought, flooding and other disasters and that progressively improve land and soil quality (United Nations, 2015).

Agriculture is more vulnerable to climate change than any other sector. A warming climate could reduce crop yields by more than 25%, according to the. Agriculture and land use change are also responsible for between 19–29% of global greenhouse gas emissions (United Nations, 2015). But the sector can also help to substantially mitigate against future greenhouse emissions, especially by increasing

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

productivity of land already under cultivation and thus reducing deforestation. A higher price of carbon can help incentivize agriculture's mitigation potential. More productive farms also tend to use less water per unit of crop produced. Innovations such as drip irrigation can also improve agriculture's water use efficiency while still supporting higher productivity.

Reducing food waste is another area which can improve the sustainability and resilience of the agricultural sector. A recent report by WRAP (2015) estimated that one third of all food produced is never consumed, at a total cost as much as $400 billion a year and 3.3 billion metric tons of greenhouse gases being released annually, about 7% of the total emissions. Reducing food waste by 50% globally could save $300 billion a year by 2030 and could feed as many as a billion people. By 2030, this consumer, food waste could cost as much as $600 billion a year, unless we act now to address this problem (Reuters US, 2015).

Specific target 2.5 aims by 2030, to maintain the genetic diversity of seeds, cultivated plants and farmed and domesticated animals and their related wild species, including through soundly managed and diversified seed and plant banks at national, regional and international levels, and promote access to and fair and equitable sharing of benefits arising from the utilization of genetic resources and associated traditional knowledge, as internationally agreed (United Nations, 2015).

Increasing agricultural productivity means that we can produce the food our global population needs while keeping as much other land as natural habitat where biodiversity can flourish (instead of using land more extensively for agricultural and biodiversity simultaneously). Smallholder farmers play a key role, as they hold as much as 75% of the global seed diversity in staple food crops, with the rest being held in gene banks. Urgent action will be needed, since as much as 10% of the biodiversity seen in 2000 may be lost by the year 2030, resulting from land lost to infrastructure as well as from agriculture and climate impacts (EurekAlert, 2015).

More than just its direct impact on hunger and malnutrition, global food system and agriculture are also linked to many global trends and consequently too many of the 17 SDGs.

SDG #1 aims to "end poverty in all its forms everywhere"(UNSDKP, 2015). Growth in agriculture is at least twice more effective in reducing poverty than from any other sector, taking into account that rural people represent the largest segment of the world's extreme poor by far contain more than 70% of the total (Farming First, 2015).

SDG #4 aims to "ensure inclusive and equitable quality education and promote lifelong learning opportunities for all"(UNSDKP, 2015). Agriculture extensions enable farmers to access to the skills, tools, inputs and knowledge they need to thrive. Investment in agricultural extension services yields 80% annual rates of return and can help farmers to double their crop yields(Farming First, 2015).

SDG #5 aims to "achieve gender equality and empower all women and girls" (UNSDKP, 2015). Women produce over half the food globally, so bridging this gap could reduce global hunger by as much as 17% according to Farming First plan. Given equal access to recourses as men, women would achieve the same yield levels, boosting total agricultural output in developing countries by 2½ - 4%. This additional yield could reduce the total number of undernourished people in the world by 100-150m or 12-17%(Farming First, 2015).

SDG #6 aims to "ensure the availability and sustainable management of water and sanitation for all" (UNSDKP, 2015). By 2030, global water demand will increase more than 50%, with agriculture alone requiring more than what can be sustained to feed the world even before domestic and industrial needs are met(Farming First, 2015).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

SDG #7 aims to "ensure access to affordable, reliable, sustainable and modern energy for all" (UNSDKP, 2015). By 2030, energy demand is expected to increase as much as 50%, driven mostly by developing world demand. Crops are more likely to be diverted for use as biofuels, doubling or even tripling as a proportion of total use(Farming First, 2015).

SDG #8 aims to "promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all" (UNSDKP, 2015). Agriculture is an engine of pro-poor economic growth in rural areas. Entrepreneurship across the rural and food sectors can generate employment and growth. More specifically, according to the data from Farming First plan, 85% of farmers are small holders, who have less than two hectares of land. Also, 43% of the agricultural laborforce in developing countries are women. Moreover, 70% of the youth aged 15-24 in sub-Saharan Africa and south Asia live in rural areas, and they are twice as likely as adults to be unemployed(Farming First, 2015).

SDG #12 aims to "ensure sustainable consumption and production patterns" (UNSDKP, 2015). Nowadays around one third of the food produced is wasted. At the same time average per capita consumption is expected to grow through 2030, despite population increases (Farming First, 2015).

SDG #13 aims to "take urgent action to combat climate change and its impacts" (UNSDKP, 2015). By 2030 agriculture's carbon mitigation potential could reach as much as 7,5% of total global emissions, depending on the price of carbon and adoption of agricultural productivity measures (Farming First, 2015).

SDG #15 aims to "protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss" (UNSDKP, 2015). Improving the efficiency of farmland can help meet world's growing consumption demand while minimizing the loss of natural habitats and forests for additional cultivation (Farming First, 2015).

As derived from the above, there are significant interactions between SDGs.Staying with the food SDG example, a commonly discussed set of interactions lies in the "nexus" between food, water and energy (Weitz et al. 2014). More specifically, vital for agriculture, water is also required for energy production in cooling thermal power plants and generating hydropower.In addition, energy is required for water pumping and irrigation systems and at the same time water is needed for irrigating agriculture. Finally, according to the ICSU (2016), there are also competing resource requirements, forexample; food production may compete with bioenergy production for the same land or water. All these factors create an active debate in the coming years upon solution space in terms of governance measures or technological options that could transform negative interactions into more positive ones.

LOCAL RURAL COMMUNITY NEEDS

It is widely agreed that in order to avert future food crises, agricultural productivity must be increased in ways that are sustainable, resilient and conducive to rural development and poverty reduction. While the world's cultivated land areas have grown by 12 per cent over the past 50 years, agricultural production has roughly tripled owing to significant increases in the yields of major crops (FAO, 2009).

At the same time, much of the agricultural expansion has been at the expense of forests: between 2000 and 2010, 13 million hectares of forests were lost each year through conversion to other land uses (FAO, 2010). However, forests are crucial for sustainable agriculture as they protect soils, regulate water flows, serve as gene pools and maintain a healthy climate. As a result, agriculture productivity growth is slowing down in many parts of the world.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Family farmers produce at least 56 per cent of all agricultural production worldwide (FAO, 2014a). With supportive, stable policies and greater participation in policy processes, smallholder farmers can respond positively to policy and market opportunities. To realize the full potential of smallholder agriculture, there is a need to remove the constraints that limit its investment capacity. Responsible investments in agriculture are a top priority from the perspective of both donors and recipients (FAO, 2014b).

The first objective is to support investments by smallholders themselves, but their capacity to do so depends on other related investments in collective action, in public goods and supportive rural infrastructure (UNSG, 2014). Secondly, investment in agricultural knowledge, science and technology can contribute to substantial increases in agricultural production over time. Increases in productivity can also contribute to a net increase in global food availability per person and general food security (FAO, 2011).

Also, according to FAO's (Food and Agriculture Organisation of the United Nations) publication under the title "Deep Roots" on the occasion of the appointment of 2014 as International Year of Family Farming (FAO, 2014c), with the expertise of companies and brands that often are the main customers of smallholder farmers and resources of several indirect partners, such as creditors or distributors of their products, smallholder farmers can be supported to achieve better yields, reduce their losses after the harvest, and improve the quality of their staple crops (FAO, 2014d).

Moreover, efforts to gather and share lessons on effective approaches to connect smallholder farmers with markets in a sustainable way and share them widely with stakeholders, as well as investment in smallholder farmers capacity-building are considered necessary for agricultural development in local rural areas (WFP, 2015).

Furthermore, post-harvest handling, storage and transportation of the products, should be reexamined in order to obtain yield sustainable results and boosting local and even national food security over the long term (FAO, 2013).

Generally, investments in infrastructure work better if they support the models of production and markets that are appropriate to smallholder farmers and, furthermore, these investments would need to be bolstered by measures to secure tenure rights (USAID, 2014).

CONSUMERS' BEHAVIORAL TRENDS

During the last decades, a new model of consumption can be seen mostly in wealthy capitalist nations around the world (Lewis & Potter, 2011). Ethical consumption has become an umbrella term covering a wide range of concerns from animal welfare, labor standards and human rights to questions of health and wellbeing and environmental and community sustainability (NRI, 2001).

One of the first polls for the issue by Global Market Insite across 17 countries, including the USA, Australia, Japan, China, India and various European countries, found that 54 per cent of online consumers would be prepared to pay more for organic, environmentally friendly, or Fair Trade products (Horne et all, 2016).

On the one hand, negative modes of campaigning such as boycotts emerged in the nineteenth century continued as global brand-based activism into the twentieth, and on the other hand the shift in the consumer behavior with the development of the general idea of combining ethics and shopping that become

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a mainstream concept especially in developed countries, guide to the conclusion that if consumers cared about moral issues, then companies and brands that did the right thing would have a larger market share.

Especially for agricultural products ethical consumers purchase those products that minimises social and/or environmental damage, while avoiding products deemed to have a negative impact on society or the environment. But most importantly consumers across the globe are growing increasingly concerned about the origins of the food they eat. Interest in the food safety, local food economy, environmental impacts, and the complexity of the entire food supply chain, has led to the creation of new categories and labels to differentiate food products, such as "bio", "ethical" or "green" (AAFC, 2013)

These developments in consumer behavior can be seen as opportunities for companies, but also farmers as ethical products are expected to see increased demand in the near future as environmental awareness amongst consumers continues to grow. This trend is expected to be seen in nearly all product categories and will have a significant impact on the food sector, as already organic items seeing particularly increased demand (AAFC, 2013).

Within the ethical foods market, manufacturers need to earn customer trust through transparency and wider recognized labels that will promote on a larger scale the overall potential benefits of these products.

Organic foods that were once reserved for niche markets are now becoming more mainstream and with increased exposure and competition. Due to increasing demand and growing availability, unit prices for organic food are expected to decline over the next couple of years, giving the consumer more buying power and subsequently boosting sales(AAFC, 2013).

Fair trade is an alternative approach to conventional trade and is based on a partnership between producers and consumers. Fair trade can make a difference helping producers build sustainable livelihoods, diversify their businesses, and even reinvigorate entire sectors of production (Fairtrade, 2014).

Products that are marked as 'fair-trade' are gaining popularity among today's consumers, although not as quickly as some other ethical food categories, although consumer demand for low prices is seen as a persistent obstacle to market growth by fair trade producers(AAFC, 2013).

At the same time there is a strong need for consumer education regarding ethical products. The lack of international standards, limited product availability in most cases and falsified or inconsistently defined claims happen in the past have created an overall mistrust of ethical labels, so companies and brands will have to invest in earning again consumers' trust by bringing transparency and traceability characteristics of their products. Consistent, clear, and commonly adopted definitions for claims such as "sustainable", "ethical", "fair trade", "carbon neutral" or "social product" would reduce consumer skepticism and increase market potential. According to OECD (2008) study on best Practices in developed countries members of the organization, consumer education as to what these labels represent would also empower consumers to choose products that address the issues of most importance to them.

Last but not least consumer education should also focus on reduction of food losses and waste. Given that many smallholder farmers in developing countries live on the verge of food insecurity, a reduction in food losses in those countries could have an immediate and significant impact on their livelihoods. According to FAO (2014e), if food losses and waste could be halved, the required increase of food available to feed the world population by 2050 would only need to be 25 per cent, and not 60 per cent as currently projected. Considering its nature and causes, halving food losses and waste could be a feasible target based on technical, economic, environmental and social considerations.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

RESPONSIBLE CORPORATIONS' INITIATIVES AND SUPPORT

The last few decades of globalisation have generated unprecedented growth but also unprecedented levels of inequality. According to Oxfam's (2014) estimates, one percent (1%) of the world's population will soon own more wealth than the other 99% and the richest 85 people on the planet as much as the poorest half of humanity.

With citizens nowadays demanding responsible business behavior from all kinds of organizations corporations and their leaders (Antonaras et al, 2011) are accountable not only for their specific responsibilities in terms of consultation, impact assessments, benefits and grievance mechanisms but also in relation to wider approach on sustainable development. Galinski argued that having a moral compass leads to more effective business practices — whether in building sales, retaining employees, or reducing litigation and regulation costs (as sited in Antonaras& Memtsa, 2009). It is clear that there is some sort of a relationship between business ethics and business success, or better sustainable excellence (Antonaras& Memtsa, 2009).

In this direction, the 2030 Agenda for SDGs expect both direct and indirect contribution from the business. Direct, through financing and partnering on SDG related projects (e.g. infrastructure) where business will be called upon to invest more in developing countries, or in poor rural areas in developed countries. Indirectly, through an increase of business activity emphasizing on equitable economic growth as a driver for development implies a significant global expansion in the private sector itself. Developing countries as well as rural areas of developed countries need businesses to create more jobs, move people out of poverty and contribute to local problems and needs.

The SDGs clearly prioritize both employment and development. For the agriculture sector this is a long-term balance endeavor with the use of the benefits of agricultural technology and mechanization for greater efficiency on the one hand, while on the other make efforts to avoid potential losses in employment that will affect smallholder farmers and their families.

AGRICULTURAL ENTREPRENEURSHIP AND SOCIAL INNOVATION FRAMEWORK

Taking into consideration all the above forces, a theoretical framework on developing Agricultural Entrepreneurship and Social Innovation (AgrESI) projects (or even businesses) is presented in an effort to provide a simplified model approach and positively influence interested parties in getting involved in such projects. The conceptual framework links the four different forces which shape the potential of an AgrESI project and determine its success and effectiveness, namely the global trends, the needs of the rural community, the consumers' behavioral trends and the support available by the responsible corporations.

It seems that these forces contribute significant input in designing an AgrESI project that will assist people in rural areas to participate in entrepreneurial initiatives, enable organizations to align their CSR related activities to the needs of this vulnerable group taking into account the changing trends in consumer behavior and attempting to respond to the global trends for sustainability as they are expressed, among others, through the 2030 SDGs.

The framework also takes into consideration several other factors such as: the stakeholders expectations and the willingness of responsible corporations to support an AgrESI project, the entrepreneurial

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

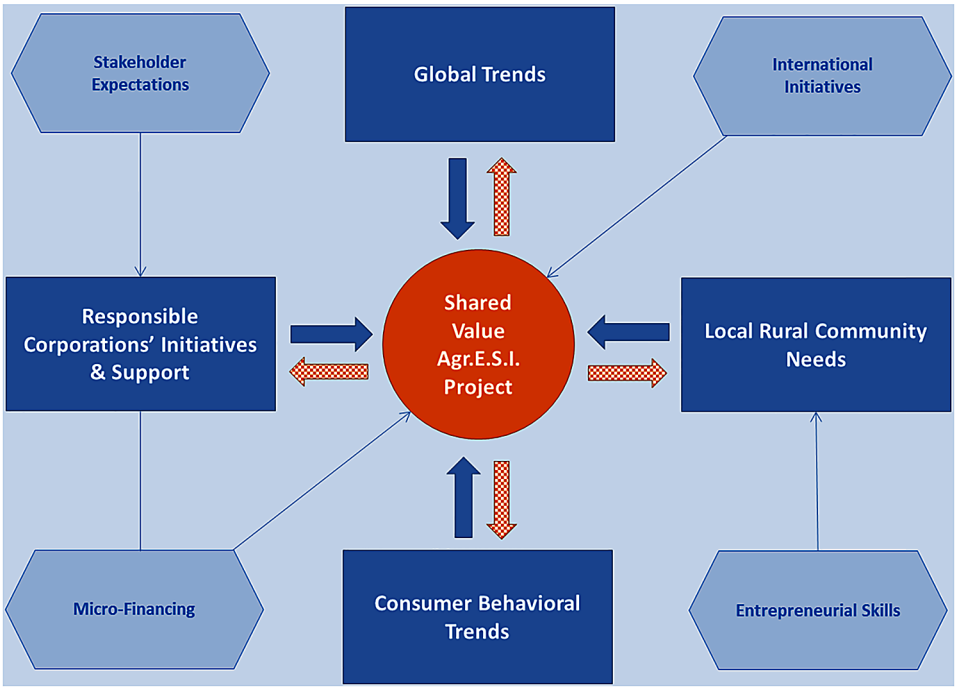
skills needed by the people in rural communities in order to ultimately manage the new agri-business, the experiences from similar international initiatives, and the need for micro-financing in order for the new agribusiness to grow and emerge into a sustainable businesses.

Figure 1 below graphically depicts the theoretical framework for agricultural entrepreneurship and social innovation.

The checkerboard arrows indicate that once an AgrESI project is effectively designed and implemented it will soon return value back to the four forces of the framework, in other words it creates shared value. The organizations involved may receive back part of their investment as dividends from their participation in the new agribusiness and benefit from the increased social value that their participation in the AgrESI project will create. Consumers will receive better and high quality products as a result of their preference and demand for products that comply with strict social and environmental criteria. The local rural community will receive the direct value resulting from the new workplaces that will be developed for the local people as a result of the AgrESI projects. Finally, the implementation of AgrESI projects will gradually shape the national trends for sustainable development which in their turn will influence the relative European and international trends.

As explained, the successful initiation of an AgrESI project needs to ensure that stakeholders' expectations are managed, appropriate support, both financial and in kind, is available, and people involved acquiring the necessary entrepreneurial skills and utilize the experiences from similar international initiatives. The significance and importance of these parameters for an AgrESI project are explained below.

Figure 1. Agricultural Entrepreneurship and Social Innovation Framework (AgrESIF)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Stakeholder Expectations

The adoption of CSR by enterprises is an ongoing process of learning and change. The key issue is to realize their role in the modern socioeconomic environment and to mobilize in adopting CSR initiatives which will assist them in taking a preventative approach to new developments and the new market requirements.

In order to do business sustainably, companies musthave good knowledge and strengthen their reflexes towards all the actors around their sphere of activity. Identifying their stakeholdersis the first step, followed by a second which is to prioritize them, so as to identify therelevancy of their modes of interaction and the relative risks. This practical approach is a core part of CSRpolicies.

Stakeholders whether they act as individuals or groups of individuals they have an impact on the one hand or they are affected on the other by the activities,products or services of a company.Stakeholders cover a wide variety of actors, such as employees and their representatives; customers and consumers; public authorities; national and local communities; Governments, professional organizations, public and international organizations; civil society and NGOs; suppliers and the wider supply chain; media and press; investors and rating agencies; the wider financial community and others.

According to CSR Europe's (2008) Toolbox for Proactive Stakeholder engagement, community involvement and development, promote communication and positive relations between a company and local stakeholders. It facilitates acceptance of corporate activities by the local population. It creates the base and opportunities for synergieswith local decision-makers, who become more positive to support the company in case of difficulty, thus facilitating the long-term sustainability of its activities within the country. In certain delicate contexts, it also tends to reduce incidents and tension, thus preventing provocation and security risks.

A main stakeholder group of a food and agriculture corporation are the small farm holders that act at the same time both as suppliers offering their products, but also at the same time as members of the local community that offers to the corporation the "social license to operate".

When farmers act as a group of individuals and part of the local rural community face sometimes problem to communicate or express their wishes exposingdemands as a shopping list where they ask everything and anything. Businesses have a duty therefore not only to listen, but several times to train local communities in the dialogue process. Also, small farm holders and family farmers, both women and men are the main investors in their own rural community and play a vital role in the sustainability of the community itself but also in the sustainability ofthe food value chain and systems.

Moreover, organizationsrepresenting farmers and their families should strengthen the capacity of those they represent to invest responsibly through provision of assistance in order for farmers to gain improved access to inputs, extension, advisory, specialized financial services, specific education, dedicated training, and access to final consumersthrough retailers including supermarkets.

Equally, according to the CFS's (2014) Principles for Responsible Investment in Agriculture and Food Systems, corporations involved in agriculture and food systems are encouraged to inform and communicate with other stakeholders, conduct due diligence before engaging in new arrangements, conduct equitable and transparent transactions, and support efforts to track the supply chain.

Furthermore, according to the above mentioned Principles processors, retailers, distributors, input suppliers, and marketers are encouraged to inform and educate consumers about the sustainability of products and services and respect national safety and consumer protection regulations. Enterprises in-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

volved in the marketing of food products are encouraged to promote the consumption of food which is balanced, safe, nutritious, diverse, and culturally acceptable, which in the context of this document is understood as food that corresponds to individual and collective consumer demand and preferences, in line with national and international law, as applicable.

Last but not least the role of workers in agriculture and food systems is vital.Workers and their organizations play a key role in promoting and implementing decent work, thereby contributing to efforts towards sustainable and inclusive economic development.

Finally, consumer organizations can contribute to the implementation of a new sustainable oriented agreement in the agriculture and food systems by informing and educating consumers about products, farmers, companies and other players about the followed methods with them towards a safer food system that will be able to feed also future generations with dignity.

Entrepreneurial Skills

As mentioned above, the successful implementation of an AgrESI project requires the involved people in rural communities to acquire the appropriate entrepreneurial skills in order to ultimately manage the new agribusiness. People in many rural areas, especially young people, are not only lacking farming and agricultural knowledge and experience, but also lack entrepreneurial and business skills. Potential agribusiness entrepreneurs need to develop a set of skills that will enable them to identify a problem, develop a solution and provide evidence of value for that solution. Therefore, they need to possess appropriate entrepreneurial skills including observation and experimentation skills, creativity and critical thinking skills, communication skills, integration and problem solving skills. In addition, they need to demonstrate commitment against the initiative itself and the other stakeholders involved in the AgrESI project initiative.

According to the Entrepreneurial Learning Initiative (2016)an entrepreneurial mindset can empower ordinary people to accomplish extraordinary things. It can empower people from all walks of life, from every background, culture and discipline. And the implications of entrepreneurial mindset, education reach far beyond enterprise creation.

Entrepreneurship is a mindset that can empower ordinary people to accomplish the extraordinary. Entrepreneurial success does not require revolutionary new ideas (Taulbert& Schoeniger, 2010) but the appropriate skills. After all, entrepreneurs come in all shapes and sizes and their impact extends far beyond the creation of new ventures. Policy makers from the White House to the World Economic Forum have begun to recognize the power of entrepreneurial thinking in all aspects of our increasingly interconnected, globalized societies, including the public, private, academic, and non-profit sectors.

So the challenge for any AGrESI project is to ensure that people to be involved in the new agribusiness initiative should acquire this entrepreneurial mindset. This can be done in cooperation with universities and business incubators that possess the knowledge and the resources to transfer it to the people in the rural areas.

Micro-Financing or In-Kind Support

The majority of the world's population is poor, subsisting on $2-3 per day. Although, according to the UNDP (2009), over 500 million of the world's poor are economically active earning their livelihoods

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

by being self-employed or by working in farms and microenterprises. Poor people constitute the vast majority of the population in most developing countries. Moreover, an overwhelming number of the poor around the world continue to lack access to basic financial services. In the contrary, developed countries despite the global economic crises that increase dramatically financial inequalities and the amount of poor, continues to seemicrofinance as a marginal financial product with high risk. In order to achieve its full potential of reaching a large number of the poor, microfinance should become an integral part of the financial sector. According to the Key Principles of Microfinancing launched by CGAP (the Consultative Group to Assist the Poor) (2004) financial sustainability is necessary to reach significant numbers of poor people, while sustainablemicrofinancing is about building permanent local financial institutions.

A study of IFAD (2010) describes ways that lack of formal credit affects rural poverty and encourages indigenous financial arrangements to take the place of missing formal finance. Limited access to credit is linked to low technology, agricultural production systems and to people working as an unpaid family labor rather than in self- or wage employment (Meyer, 2011).

Microfinance could be seen as a sustainable mean of poverty alleviation leading to lasting, sustainable development.This development should also be a holistic one covering all aspects of livelihood of small entrepreneurs including small farm holders. From the economic aspect a small amount of financial support in a form of loan helps reduce desperation and anxiety while at the same time allows farmers to make more effective investment choices. Having a limited, butstable income, they can then begin savings with cultivating costs and looking forward to expand their business and eventually becoming more financially secure. From the social aspect microfinancing could help the entire local rural community if the support is given as a program that brings farmers together in groups, enabling them to support each other. Cooperation and trust within the groups strengthens over time and can lead to improved decision making in the wider community. At the same time, for each farmer as an individualto receive a small financial support through a small loan is not just an economic or financial transaction. It is a significant personal moment where each farmer is trusted again and feel valued for his/her family and for the wider community. Also, microfinancing can produce a multiplier effect as in several cases, receivers of small loans become more eager to provide small loans to others especially within their local community.

Given the limited availability of agricultural credit, marketing arrangements that integrate financial services help smallholder farmers participate in markets. Supermarkets, input supply companies and traders often offer inputs on credit as a way to develop preferred supplier relationships with small farmers (Meyer, 2011).Other innovative approaches for supporting individual farmers shouldnot be limited only to financial microloans but also extend to other kinds of support taking into account and assessingeach farmer's needs, character, standard of living, educational level, financial status, repayment capacity, and personal values and vision.

In more detail, individual support could be provided to farmers by other players in the wider value chain by linking them to suppliers with high-quality seeds and fertilizers and negotiating prices on their behalf. Another kind of support could be the provision of formal and informal education in good farming practicesand crop-specific training,provided by experienced and expert agriculturists and relative scientists. Also, providing smallholder farmers with necessary funds to pay the required tuition fees for their children in order to acquire the necessary agricultural education and return back home, could also be seen as an overall investment with high level of long-term return.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Additionally, a way of support could be to link farmers with buyers,assisting them through packaging, labeling and traceabilitytechnology in orderto obtain better market prices. Technology is also a vital success factor. Supportingsmallholder farmers with technological equipment may result to increased efficiency and cost reduction through field-based data collection and proactive management of meteorological changes. Furthermore, empowering women to participate in the farm work through support and on the job training to strengthen their ability to participate in income generation and to better protect their families against loss from unforeseen events as small harvests or bad weather conditions.

Finally, assistance either financial through micro loans either in kind through support can be the solution for smallholder farmers in order to improve their lives of themselves and their families, under the provision that farmers are not bound by unilateral contracts.

International Initiatives

Small scale farmers need support to ensure they are not perpetuating the kinds of practices the SDGs seek to eliminate: as child labor, exploitation of girls and women, or use of forced labour, issues covered by the 10 Principles of the UN Global Compact that is followed in a voluntary basis by thousands of companies lots of them involved with the agriculture sector.

UN Global Compact is the world's largest voluntary corporate sustainability initiative. It was launched in 2000, as a call to companies around the world to align their strategies and operations with universal principles on human rights, labor, environment and anti-corruption, and take actions that advance societal goals. On May 13th, 2014 the UN Global Compact launched the Food and Agriculture Business (FAB) Principles (2014), following a two-year consultation process with over 1,000 businesses, UN agencies and civil society organizations engaged in agriculture, food and nutrition systems. The six FAB Principles aim to help realize sustainable development and empower businesses to contribute to the post-2015 development agenda. The principles were introduced in Rome, Italy, on 13 May 2014.

The Principles respond to calls from the UN Conference on Sustainable Development (UNCSD, or Rio+20) for sustainable development of food production through increasing local investments in a responsible way, reducing waste and the use of water in supply chains and ensuring access to local and global markets. The FAB Principles are the first set of global voluntary business principles ofthe food and agriculture sector, and are designed to serve as umbrella principles that complement existing initiatives on agriculture and food sustainability.

UN Global Compact (2014) business participants in the food and agriculture sector are invited to take an additional, voluntary step to embrace a set of Food and Agriculture Business Principles (see Table 1) and report annually on their progress.

The Principles are aimed at companies in food and agriculture sector wanting to act responsibly and could be followed by all farmers and agribusinesses – regardless of size, crop or location – as a principle-based commitment and as a framework to show their overall orientation toward corporate sustainability.

Also in 2011, the OECD Declaration on International Investment and Multinational Enterprises, known as OECD Guidelines, that provide an open and transparent international investment environment to encourage the positive contribution of multinational enterprises (MNEs) towards economic and social progress, were revised.The OECD Guidelines are the most comprehensive set of government-backed recommendations on what constitutes responsible business conduct (RBC). They cover nine major areas

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Food and agriculture business principles

Principle	Requirement
Aim for Food Security, Health and Nutrition	Businesses should support food and agriculture systems that optimize production and minimize waste, to provide nutrition and promote health for all people.
Be Environmentally Responsible	Businesses should support sustainable intensification of food systems to meet global needs by managing agriculture, livestock, fisheries and forestry responsibly. They should protect and enhance the environment.
Ensure Economic Viability and Share Value	Businesses should create, deliver and share value across the entire food and agriculture chain from farmers to consumers.
Respect Human Rights, Create Decent Work and Help Communities to Thrive	Businesses should respect the rights of farmers, workers and consumers. They should improve livelihoods, promote and provide equal opportunities.
Encourage Good Governance and Accountability	Businesses should behave legally and responsibly by respecting land and natural resource rights, avoiding corruption, being transparent about activities and recognizing their impacts.
Promote Access and Transfer of Knowledge, Skills and Technology	Businesses should promote access to information, knowledge and skills for more sustainable food and agricultural systems.

of RBC: information disclosure, human rights, employment and industrial relations, environment, bribery and corruption, consumer interests, science and technology, competition, and taxation. (OECD, 2015). Large corporations in the area of food and agriculture should take into account these principles when cooperate in the global environment, especially through their supply chains in rural areas of developing countries.

In addition, the Committee on World Food Security (CFS) endorsed on 15 October 2014 at its 41st session the Principles for Responsible Investment in Agriculture and Food Systems, known as CFS-RAI Principles (2014). The principles contain ten core principles related to: food security and nutrition; sustainable and inclusive economic development and poverty eradication; gender equality and women's empowerment; youth; tenure of land, fisheries, and forests and access to water; sustainable management of natural resources; cultural heritage, traditional knowledge, diversity and innovation; safe and healthy agriculture; inclusive and transparent governance structures, processes, and grievance mechanisms; impacts and accountability. An additional section describes the roles and responsibilities of stakeholders.

The objective of the Principles is to promote responsible investment in agriculture and food systems that contribute to food security and nutrition, thus supporting the progressive realization of the right to adequate food in the context of national food security (CFS, 2014).

All the above mentioned volunteer frameworks and principles are addressed to corporations that accept the concept and principles of CSR and recognize the vital role of sustainable development. CSR has a twofold importance. It relates both to their stand-alone / autonomous operation and contribution to the social and natural environment in which they operate, and to their relationship with larger businesses whose suppliers, subcontractors or associates they are. As a result of this twofold importance is that in most cases businesses as part of wider value chains are invited by major clients to operate under specific frameworks and to adopt CSR initiatives to ensure their existing cooperation.

The main aim of businesses operate in the food and agriculture sector is being able to evaluate their priorities and risks and incorporate CSR principles into their own policies, strategies and everyday way of work and thus capitalize on the advantages this approach could bring both in terms of improved competitiveness and maintain sustainable in the future.

THE McCAIN CASE

The Company

Founded by farmers, McCain became a global business, operating under three core values: authenticity, commitment and trust that guide its behavior and business interactions. McCain builds close, long-term relationships with local farmers – some of them are suppliers for three generations – in several markets that operates. McCain focus on Good Food, Good People and Good Business, setting standards for all its operations. Company's involvement is mostly driven, locally and managed by the individual regions, so the support can take many forms such as transfer of knowledge and expertise to growers, donation of products and services, sponsorships that inspire broad participation towards worthwhile goals and, sometimes, direct financial support.

The company supports social business and in 2013 McCain signed an alliance with Nobel Peace Prize Laureate, Muhammad Yunus, to kick-start the 'Campo Vivo' project. This was the first South American joint venture between a multinational company and the Yunus Social Business and the project's aim is to improve the quality of life of Colombian farmers. Campo Vivo benefits underprivileged farming families in Colombia who face many challenges. Some lack the necessary land or resources to produce crops and many farmers have been displaced by the armed conflict in the country. By providing education and support services via the Campo Vivo Cultivation Center of Excellence, the project helps them to successfully develop commercially viable potato, carrot and pea farming businesses in a fair and sustainable way (McCain, 2016).

In addition to local community support, the company funds The McCain Foundation – a philanthropic organization, largely supporting initiatives in the Atlantic provinces of Canada where McCain Foods was founded. The McCain Foundation has five areas of support; arts & culture, community projects, health & wellness, education and environment.

"Karpos Frontidas": An Initiative for Social Product Creation

In 2013, McCain decided to enrich its Corporate Social Responsibility strategy with new innovative approaches and initiated a consultation process with key stakeholders in three European countries (Germany, Greece and Poland) in order to choose the country from which it would start its efforts based on the conclusions of the open dialogue with its stakeholders.

The result of the stakeholder dialogue conducted in the three countries led to the launch of an ambitious intervention in Greece in order to assist local rural farmers to overcome the difficult economic situation in the country, due to the global financial crisis, and in an effort to help them remain at their places, and continue to support their families, local society and country at large.

As a result of that stakeholder engagement process (see: AgrESI - Stakeholder expectations), in 2015, McCain in collaboration with CSR HELLAS –a Greek non-for-profit business driven network for the development of business responsibility and sustainability – created a unique product in the category of fresh vegetables, and especially potatoes. Through this initiative, McCain aims to support Greek small farmers and unemployed young people who returned back to their birthplaces as a result of the high-level of unemployment rates in the cities, in order to get involved with the cultivation of fresh potatoes. "Karpos Frontidas" project is the first pilot step essential for the multiplication of the approach in other

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

products, regions and countries. It also acts as a consumers' awareness approach in order to buy responsibly, yet sustainably.

The project initiates a new relationship between the company and poor farmers living under the poverty line. McCain safeguards the income of farmers through contractual agreements while at the same time is trying to equip them with entrepreneurial skills (see: AgrESI -Entrepreneurial skills)in order to develop the appropriate entrepreneurial mindset.It also provides training, technical means and farming know-how(see: AgrESI - Micro-financing or in-kind support) so as small farmers cultivate potatoes of high quality, as well as gain access to the market under the label of a new social product that has been grown according to the principles of sustainable agriculture (see: AgrESI -International initiatives).

Also, taking into consideration that the new product is grown with special care for the environment and the consumer needs and demands (see: AgrESI -Consumers' behavioral trends), and that it secures a better income for the farmers, this product aims to become the first Social Product in the market of fresh vegetables originated by Greek small poor and underprivileged farmers.

Several other businesses operating within the context of CSR and in order to safeguard their sustainability (see: AgrESI -Responsible corporations' initiatives and support),were invited to cooperate with McCain for the successful implementation of the project. Primarily, as mentioned before McCain (2016b) has the project coordination, while CSR HELLAS acts as consultant on socioeconomic issues. Program integration obtains partially the support of a global ethical investment fund, well known for its support of Greek people and organizations of wider civil society during last years' financial crisis. The provided support from the foundation aimed at strengthening organizations that exhibit strong leadership and sound project management and that can bring considerable, enduring and positive social influences and changes at large.

Furthermore, one of the largest financial institutions in Greece provides financial support (see: AgrESI -Support through Micro-financing or in Kind) to farmers through a new product (credit card) specially designed for small farm holders. With this credit card farmers have the ability to buy their products such as crops, fertilizers, etc. necessary for their farming while McCain safeguards for those micro credits to the bank.

Moreover, McCain through its long-term cooperation with academic institutions offering agriculture education provides training and expertise to farmers, developing special cultivating protocols dedicated to the specific land and farmer's needs. The cooperation with the academic community is continuous through elaboration of research with national or regional scope to determine the investment criteria by region, such as farmer's income, social factors, unemployment rates and analysis of soil ingredients. Also, McCain's business partners offer to small farmers persistence audits of active substances and special discounted rates to the supply of their products, while agronomists and consultants oversee and support farmers (see: Local rural community needs).Furthermore, McCain invests towards renovation and modernization of existing infrastructure for the selection process and packaging, in collaboration with farmers themselves. Last but not least one of the most important services McCain offer to farmers is access to market through its traditional channels of distribution, in order the final product reach consumers. The final product which is a bag of 3 kg of potatoes provides traceability data available to consumers through the use of new technology applications.

In conclusion, the program aimed to tackle poverty and social exclusion through partnership and constructive engagement between businesses and smallholder farmers in disadvantaged rural communities. The programme was designed to meet the four goals below.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Goal 1: Promote awareness, knowledge and uptake of the notion of "Sustainable agriculture", "Farming Sustainability" and "Social Product".
Goal 2: Increase access to formal and informal educational, recreational and business cultural development activities and resources.
Goal 3: Increase smallholder farmers' work readiness, employment prospects and income increase.
Goal 4: Promote active engagement with policy, practice and decision making processes on matters affecting agricultural but also commercial issues.

The main aim of the proposed approach is the gradual withdrawal of McCain as the main supporter of the initiative and the emergence of a self-managed model in which farmers/producers will themselves be involved in the process as the main stakeholders and shareholders of a new agribusiness.

Finally, McCain's initiative is directly aligned with the Sustainable Development Goals (see: Global Trends) and more specifically with Goal#2 that among others "promotes sustainable agriculture"; Goal#8 that "promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all"; Goal#12 that "ensures sustainable consumption and production patterns" and Goal#17 that "strengthen the means of implementation and revitalize the global partnership for sustainable development".

FUTURE RESEARCH DIRECTIONS

Although the above case study shows that such projects can be successfully designed and implemented, further work is required in order to analyze the various parameters from the different stakeholders' perspective. In addition, the possibility to design more similar initiatives can be explored by investigating the intentions of corporations that are actively involved in CSR activities and try to identify if these organizations are more likely to support such projects. Socially responsible companies can be identified through CSR Networks operating in many European countries and a quantitative / qualitative survey may be conducted in order to investigate the interest as well as the ability of such organizations to adopt or join respective social innovation programs, which can lead to clear benefits for both the companies themselves and the society at large. At the same time the survey can capture the groups of potential beneficiaries and stakeholders based on the sector of activity of each company concerned.

CONCLUSION

This chapter presented a conceptual framework to enable the development and implementation of Agricultural Entrepreneurship and Social Innovation projects or even enterprises. This new business model which contains various social aspects, can contribute to the economic growth and sustainability and hence combat the phenomenon of unemployment and poverty in rural areas that have been seriously affected by the recent financial crisis in many European countries. An actual case study of such a project was presented describing how a private initiative involving different stakeholders can produce mutual benefits and create social value, and therefore justifying the proposed framework.

Several factors were explained in this chapter, some of which can be seen as innovative approaches to traditional practices, while the development of a clear framework of collaboration among various

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

stakeholders may result in overall improvements in the farming sector. Briefly summarized, farmer's continuous training on modern farming techniques and available technologies should be integrated in their every-day work in order to improve received knowledge and further enrich their skills, keeping focus as well on the development of entrepreneurial perspective. At the same time, communication becomes a high priority for farmers in order to maintain exposure of their products. So, the development of a common communication strategy among farmers from a specific area that cultivate the same product could be seen as an innovative approach for reaching final consumers through appropriate messages that underline the unique characteristics of the product, inform about the adoption of internationally accepted Principles and farming guidelines, and increase overall transparency and traceability.

Moreover, reinforcement of agriculture sector through appropriate financial support could contribute to better promotion and acquaintance of the consumer with the end product, its background and the goals it represents, such as solidarity, fighting youth unemployment, etc. The adoption of regular and systematic communication between all identified stakeholders through effective channels, so that everyone is informed about recent developments, current difficulties and possible opportunities, can be perceived as a prerequisite for the success of the process and as an enhancement of transparency among partners. Social media is a new era for the farming sector that require enrichment regarding farming processes and new technologies that can keep stakeholders, mostly consumers, inform about all dimensions and innovations covered by the agribusiness program, including soil analyses, weather forecasts, safe transportation and storage, etc. In other words, there is a necessity for raising awareness among the consumers regarding branded agricultural products from small farmers, that respect at all stages of the value chain the principles of responsible entrepreneurship and contribute justifiably and transparently to the selling price. Finally, through the appropriate stakeholder engagement and by linking the product to its origin, history, and way of grow, farmers could create the story of the product that accompanies it from farm to store!

Chapter 12
Striking a Perfect Fit in Leadership Style for Effective Farmer Training in Botswana

Flora M. Tladi
University of Botswana, Botswana

ABSTRACT

Botswana since pre-independence days prides itself with decades of experience in development planning supported by structural frameworks comprising networks of institutions at central government and village levels responsible for leadership and coordination of affairs. Unfortunately when problems arise, development planners focus on the structural frameworks alone disregarding the leadership powering development planning at different structural levels and diverse stakeholder dynamics at play. Therefore, re-structuring is always the common solution even though not necessarily the best intervention. The trend is noted with farmer training whose program organization has for 79 years undergone cycles of re-structuring. The chapter argues for a holistic evaluation approach to always check the fit between the leadership style and whether the power processes at the different structural levels are in synch. The chapter advocates for well aligned leadership style with structural frameworks and recommends a leadership style that can be a perfect fit for effective farmer training.

CASE BACKGROUND

The general view of leadership is that of a process through which employees are influenced to work willingly towards achieving organisational goals. Leaders at all levels in the organisation use the influencing process to communicate ideas and gain acceptance of them, inspire followers to support and implement the ideas through change. Once supportive interpersonal relationships develop between leaders and followers, organisations are sure to succeed in realizing their missions (Du Toit et al., 2011).

Leadership style actually anchors on the influencing process and therefore affects communication, employee morale and their input to improving work processes, setting of goals, productivity, and the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

whole organisation's effectiveness. Leadership style is a critical facilitator in the achievement of organizational goals, at the same time enabling personal growth and development. Characteristics such as trust, reputation to deliver on promises, having satisfied customers, ability to attract and keep talented employees, being result-oriented, having output exceeding that of competitors, adaptability to change, and informative performance management systems describe effective organizations (Root lll, 2014; Singh et al. 2008).

In the case of farmer training, the organization of concern is historically that of agricultural extension whose services are a common feature of administrative structures of change in rural areas. Leadership is an essential process in the organization of agricultural extension. In fact, the mandate of extension is educational leadership and change (Khalil et al. 2008; Morse et al. 2006).Agricultural extension services in partnership with farmers are responsible for directing development programs and change in rural areas. The purpose of the services is mainly to develop farmer training programs that will not only increase local food, but also increase farmer income and the sustainability of agricultural practices. This is to ensure that farmers have the most current information on how to grow food efficiently and economically; they must have knowledge of new techniques and technologies above all to increase their level of productivity (Rosegrant & Cline, 2003).

An extension approach that succeeds in providing the right training and therefore, increased food production exists when the right fit of leadership style is maintained throughout program planning and implementation. This is the leadership style that accommodates change and promotes collaborative action by multiple and diverse groups such as farmers who are key to successful operation of an extension system (Morse et al. 2006). Other forces that need factoring into the leadership process are globalization, its challenges, and impact on the role of agricultural extension (Karbasioun et al. 2007; Toness, 2001). The leadership style therefore, should cultivate an environment enabling extension systems to operate like learning organizations in response to inevitable changes in their work environments (Ladwig & Rohs, 2000). Learning organizations respond timely to work changes and they are quick to learn, adapt, and change accordingly (Noe, 2010).

Botswana since pre-independence days prides itself with decades of experience in development planning guided by structural frameworks comprising networks of institutions at central government, district, and village (grass-root) levels. However, when problems arise development planners tend to focus on the institutions and structural frameworks alone and not the prevailing leadership processes as well. Re-structuring alone without focus on whether the leadership is congruent with structures in place is always seen as the solution even though not necessarily the best. This chapter therefore, discusses the institutions, emergent structural frameworks and leadership processes which have over time supported farmer training in Botswana. This is to review the structures and the leadership in order to determine the leadership style that can best align with the institutional frameworks in place for effective farmer training and successful implementation of development programs at the grass-root level. Firstly, the chapter discusses the concept of leadership in relation to farmer training. The chapter then provides an overview on farmer training, the institutions offering training, organizational and leadership structures. Secondly, the chapter reviews the institutional networks and leadership processes that have governed and supported farmer training overtime and constraints. In conclusion, the chapter recommends a leadership style that can be a perfect fit for more improved farmer training in Botswana.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCEPT OF LEADERSHIP

The concept of leadership is big and its complexity is compounded by the diverse contexts in which it is practiced and the many interpretations. When exploring leadership, it is also important to separate the term from that of leader because often what a leader does is not necessarily what leadership is (Scouller, 2011). According to Scouller (2011, para. 6), a leader is a person who "leads a particular group at a particular time". His or her purpose is to ensure that there is leadership in the group or organization. Leadership is a process and this means that it comprises several tasks, activities, and a series of choices different leaders make when defining and achieving a goal. Leadership is performed by leaders acting at different times in different situations. The leader's responsibility is to ensure therefore, that there is appropriate leadership at all times and it is not necessarily performed by the one designated as leader (Scouller, 2011; Adair, 1983). As revealed in the literature, we can find leadership in every purposeful endeavour of any scale that requires organized effort towards achievement of goals: work, play, adventure, program, project, and personal life. The managerial view of leadership defines it in the context of work as the process during which an individual with supervisory responsibility influences employees to work willingly towards the achievement of organizational goals (Du Toit et al. 2010). Scouller (2011) provides a definition of leadership that is more encompassing to contexts that are not work-specific when he said it is a three-stage process that involves (1) setting a purpose and direction which inspires people to combine and work towards willingly; (2), paying attention to the means, pace, and quality of progress towards the aim; and (3), upholding group unity and individual effectiveness throughout.

Leadership models, philosophies, and styles provide a theoretical framework that simplifies the concept of leadership. They show that the thinking behind leadership even though offering different perspectives is overlapping and compatible. For instance, while a leadership model gives ideas on how to lead effectively or become a leader, a leadership philosophy comprises value-based ideas and prescribes the sources of the leader's power and how he or she must act. A leadership style is a description of the behaviour of a real-life leader (Leadership Theories). In this chapter leadership style is seen as broad-based and an integral part of a model: it refers to a process that can be used to learn, teach, apply and adapt leadership: a set of behaviours that enable people to lead effectively and at the same time, grow as leaders. This concept of leadership style borrows from Scouller's (2011) three-stage process of leadership: setting a purpose, direction, and inspiring people to combine and work towards it willingly; paying attention to the means, pace, and quality of progress towards the purpose; and upholding group unity and individual effectiveness throughout: coordination.

Historically, three groups of leadership models define effective leadership and are the foundation to many such as John Adair's (1983) Action-Centered Leadership model and the Scouller's (2011) Three Levels of Leadership (3P-public, private, and personal) model. The models are the Trait-Based, Behavioural Ideals, and Situational-Contingency models. The theory behind the trait-based model is that leaders are born and cannot be made and that certain traits make effective leaders. The behavioural ideals models focus on what researchers identified and believe are behaviours of effective leaders; while, the situational-contingency models their theory is on the idea that leaders' behaviour must vary according to the circumstances they are facing and that leaders can change their behaviour at will to meet differing circumstances (Scouller, 2011).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Five critical elements constitute the leadership process. These are ((a), authority, being the right to give commands and demand action from followers; (b), power, comprising the ability of a leader to influence the behaviour of followers; (c), responsibility, is the obligation the leader has to perform the required activities to achieve organizational goals;(d), delegation, the leader assigning responsibility and authority to followers, giving them new tasks to perform; and (e), accountability, is about the leader taking stock and evaluating how well followers meet their responsibilities. According to Du Toit et al. (2011), strong leaders influence followers because they have power that allows them to exercise their authority fully. Therefore, power gives the leader leverage to influence others towards achieving organizational goals.

Leadership style describes the behaviour of real life leaders. Leadership style is an observed classification of behaviour of people in leadership. Unlike leadership philosophy, a leadership style does not prescribe behaviour type for leaders but merely reflects what exists as observable behaviour of leaders in action: that is, how best leaders exercise their authority, use position or personal power to influence others, and how individuals perform (Leadership Theories). Three leadership styles, authoritarian, participative, and 'delegative' popularized by Lewin (1939) present distinct modes of behaviour by leaders and followers. Authoritarian leadership style has leaders behaving like autocrats or dictators and more likely to use position and coercive power in their dealings with followers. Authoritarian leaders make decisions without much consultation with others; they hand out pre-determined goals, methods, and deadlines. Participative leadership style in which leaders consult, participate in group work, accept advice from colleagues, and then make final decisions is also referred to as democratic leadership style. 'Delegative' or Laissez-Faire leadership style, often seen as a no-leadership-process has the leader delegating responsibility for results to followers with groups setting goals, deciding on work methods, roles, and setting own pace of work. This leadership works better when followers share the same vision for the organization and its strategic direction as the leader and if he or she trusts the followers (Leadership Theories).

According to the literature, leadership can be found in every purposeful action of any scale that requires organized effort towards achievement of goals. No one single ideal approach to leading exists because organizational cultures and circumstances vary. Leadership styles provide a framework or guide and should not be taken as straight-jacketed behaviour expected of leaders. The leader's personality, personal goals, and relationship with followers strongly influence his or her leadership style (Singh et al. 2008). As the situational-contingency theory advises, the leaders' behaviour must be flexible and therefore, vary according to the circumstances they are facing (Scouller, 2011). This is to create and maintain a goal-achievement supportive organizational culture (Schein, 1985).

LEADERSHIP AND FARMER TRAINING

A better and practical approach to understanding leadership is to focus on a particular framework or an organization (Gupta, 2009). In the case of farmer training, agricultural extension systems provide such frameworks. Agricultural extension is a transformational system based on education, communication, and rural development. Its major purpose is to provide educational leadership and change among rural communities or farmers. Agricultural extension operates within a knowledge system that includes agricultural research in a process integrating farmers, agricultural educators, scientists, and extension agents. As revealed in the literature, the process and the many actors imply several levels of power and diverse leadership behaviour. The farmers' position in the knowledge system as the main target and beneficiary

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

places them between research and extension. Extension agents become a critical communication link between the system, research and farmers. This makes the agents critical role players in the effectiveness of farmer training and the knowledge system as a whole (Khalil et al. 2008; Morse et al. 2006). Extension agents, actually have two main work roles with differing areas of responsibility that require leadership competencies. These are the work roles of (1), knowledge, communication, innovation and, (2), educator, facilitator, and catalyst (FAO, 2001).

Extension Agent's Role of Knowledge, Communication, and Innovation

In the role of knowledge, communication and innovation, the agent's responsibility is to train farmers: arm them with knowledge and information for decision making about particular innovations. The extension agents are conveyors of technical knowledge; they are trainers, teachers, and instructors of the farmers in the use of the very knowledge. Depending on the approach used by the local extension system, the agents will also have technical knowledge, information or technology packages to promote among the farmers.

To communicate extension messages successfully to farmers and engage them in learning and discovery, agents have to break through barriers of rural isolation and understand the values, customs, indigenous knowledge systems and the meanings that affirm the identity of farmers as members of a community whose culture will influence their decision to adopt new practices. In this approach, extension work is highly structured and follows rigidly existing government policies and programs of rural development (Daskon & Binns, 2009; Schwieder, 1993 in Morse et al. 2006).

Extension Agent's Role of Education, Facilitator, and Catalyst

The work role of educator, facilitator and catalyst, deviates a little from that of technology transfer. Technology transfer model is a linear model and often criticized for being a top-down extension approach and in Botswana, the reason for many problems of technology adoption and low farm yields (Acquah, 2003). Extension agents assume the role of educator, facilitator, trainer and catalyst in the transformation of farmers' lives. The agents follow a more participatory extension approach that recognizes multiple sources of innovation, interdependence of technology development and the farmer as an equal partner in the process (Sulaiman et al. 2006). In this role extension agents concern themselves more with the farmer's personal development and less with pushing programs and specific targets. The agents' task is to support and encourage farmers' initiative, helping them to gain confidence, organize themselves, participate more in extension activities and solve their own problems.

FARMER TRAINING IN BOTSWANA

Agricultural extension has been the main provider of farmer training in Botswana for over 79 years. The extension system originated in 1926 with dairy farming specific messages until 1935 when its mandate became all agriculture inclusive with programs targeting small scale traditional agricultural production systems (Hobb, 1985). Farmer education and training programs were implemented through methods such as individual farm visits, process and result demonstrations, farm walks, and media such as radio, posters, pamphlets. Extension agents organized short courses at rural training centres. The first rural training centre, the Denman Rural Training Centre (DRTC) located in Sebele, 10 km north of Gaborone,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the capital city began operating in 1967. Currently, there are five rural training centres in Botswana. The Rural Training Centres operate under the direction and leadership of Centre Principals and subject-matter specialists (Sebadieta, 2006).

Several extension approaches over the years, changed one after the other always as an attempt to find appropriate methods for improving national farmer training programs; for example, the Cooperative Demonstration Plot Scheme (CDPS) in 1947, marked the first farmer education activities of a formerly established agricultural extension system in the country. The CDPS emphasized on-farm demonstrations as the major training method. Extension agents set up demonstration plots on farmers' fields to ensure a wider training coverage and improved transfer of technologies among farmers (Lever, 1970). In 1962, the Pupil Farmer Scheme (PFS), an approach based on a concept borrowed from Zimbabwe replaced the CDPS (Lever, 1970). In the PFS extension approach, one agent worked with and focused extension education programs on 15 to 25 farmers. Individual farmers or a household had to own a plough, draught oxen, a de-bushed and de-stumped field To qualify as a pupil farmer and register with the training program. Once in the program, as the pupil farmer's skills acquisition progressed and production methods improved, he or she was promoted and graduated to progressive, improved, and then master farmer level (Baker, 1988).

Similar to the CDPS, the PFS was selective with limited coverage: farmers who were not registered with the scheme were not getting any extension advice; while, the expectation was for all farmers to access the training programs by a public extension system. Other problems faced by the PFS extension methods were lack of coordination, inadequate supervision of staff, lack of equipment, poor transportation, poor housing (Willet, 1981).

Extension service reviews by consultancy agencies such as the Ford Foundation (1972/73), Chambers and Feldmann (1973), and Chambers (1977) were commissioned by the Botswana Government still in a quest for better extension methods that reached all farmers, increasing coverage, improved training effectiveness, and agricultural production (Odell 1978). As a result, many strategies were used to improve extension program implementation. The Integrated Rural Development Program (IRDP) replaced the PFS and then the Accelerated Rural Development Program (ARDP), followed in 1973 to 1976 (Mrema, 1995). In 1980s, Farming Systems Research Extension (FSR/E) Approach, promoted by FAO then was introduced together with inputs programs supporting farmers such as Arable Land Development Project (ALDEP), Accelerated Rainfed Arable Project (ARAP) and Agricultural Technology Improvement Project (ATIP).

Farming Systems Research Extension approach (FSR/E) was implemented through four projects: Farming Systems in the Southern Region (FSSR), Agricultural Development Ngamiland Project (ADNP), Molapo Development Project (MDP), and the Agricultural Technology Improvement Project (ATIP) as the fourth in 1983. The projects tested technologies recommended by research on farmers' fields and found them inappropriate, unworkable, and requiring modification. The FSR/E did not have significant impact on agricultural production; it did however, succeed in (a), testing and developing relevant technologies for small farmers with limited resources, (b) improving linkages with research, extension, and other institutions, (c) improving farmer confidence in research and extension, (d) skills development among subject specialists and extension workers in the Ministry of Agriculture (MoA), and (e), developing research infrastructure in the countrywide.

The FSR/E faced several challenges such as (a), the severe drought conditions in 1982 to 1987, (b) impact by the approach in the target was limited compared to the amount of resources used, (c) the size of expatriate staff, the level of their training and access to resources as compared to that of the local

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

research staff of the MoA caused disparities and competition between the two groups, (d) lack of access to trained personnel who were willing to work in remote areas where most FSR/E projects were located, (e) difficult coordination of project activities administered by different departments of MoA and other government ministries, (f) lack of funds to support the FSR/E and other development programs, and (g), timing of the FSR/E, institutionalization of the approach into the MoA too early (Frankenberger & Mitawa, 1988). The added constraints became the spending of lots of money on subsidies; a major part of agricultural extension service occupied with taking the subsidies to farmers, and therefore a diversion by extension from its mission as extension workers spent most of their time distributing inputs, preparing payment of subsidies, and assessing farmer applications and not much on education and training (Mrema, 1995).

Following a major review of the agricultural sector in 1989-90, a new agricultural policy focusing on training for household food security as opposed to national food self-sufficiency was adopted in 1991. The policy emphasized relevant agricultural extension programs targeting farmers' needs. At the same time as the new policy on agriculture was formulated, The Ministry of Agriculture (MoA) underwent a major reorganization through the Organizational and Methods (O&M) study of the Government Departments. This led to the split of the former Department of Field Services and the establishment of two parallel agricultural extension systems in the Ministry and regions: one system provided livestock production and health training, and the other crop production and forestry.

In 2006 Cabinet approved yet another restructuring of the MoA that was carried out by O&M. The restructuring took into consideration a number of recommendations from the First National Conference on Agricultural Extension (1995) including (a) the separation of the Department of Animal Health and Production and (b) renaming one the Department of Veterinary Services and the other, the department of Animal Production. The two departments are presently under the Deputy Permanent Secretary, Technical Services. Farmer education and training combined into one unified service under six Regional Agricultural Coordinators at regions and coordinators reporting to the Deputy Permanent Secretary (Support Services). Other departments which were renamed were the Division of Agricultural and Statistics as the Division of Research and Statistics; the Department of Crop Production and Forestry became the Department of Crop Production. Another new department was that of Agricultural Business Promotions; while, the Department of Agricultural Research was retained without change. Another major re-structuring activity was the establishment of a coordinating unit of agricultural extension under the Deputy Permanent Secretary's Office (Support Services). This meant that functions under Crops and Horticulture, Animal Production, Farmer Education, Animal Health, Agribusiness Promotion and Conservation of Agricultural Resources were to be coordinated by one department: Extension Service Coordination Department assuming the role of unifying force among all stakeholders in farmer training.

ORGANIZATIONAL AND LEADERSHIP STRUCTURES

Several institutions coordinate, monitor, and evaluate activities of agricultural and non-agricultural (rural extension) extension at the Central government (Ministry), region, district and village or grass-root levels. The Rural Extension Coordinating Council (RECC), whose main mandate is to promote team work, ensure efficient use of resources, improvement of standards by Government Ministries involved in planning for development at the village level is a structure at the Ministry level. The Council (RECC) was established in 1982 and consists of a team of Heads of Extension Departments at ministry level.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Principals of Rural Training Centres, Agricultural College, and other institutions such as Cooperatives, Public Health, and Wild Life and Tourism involved in development-related training are members of the RECC. The Council is chaired by the Coordinator of Rural Development and meets every four months to ensure continued exchange of information on extension programs, monitoring and evaluation of all rural development plans. The RECC has a sub-committee on training that advises the Council on matters of training for extension agents and the relevance of the programs. The Sub-RECC for training promotes research, evaluation and coordinates training programs.

At the district level, the District Extension Teams (DET), a sub-committee of the District Development Committee (DDC), has a membership of Heads of Extension Departments. The DET includes the District Officer Extension, District Adult Education Officer, and District Agricultural Officer. The DDC guides and supports policy implementation at the district level by the DET; while the DETs interpret policy for the Village Extension Teams (VETs), guides, and monitors VETs activities at the village level. The DETs, VETs, the Farmers Committee (FC) and Village Development Committee (VDC) coordinate implementation of extension programs at the district and village levels. The DETs strengthen planning and monitoring systems by VETs: they monitor the implementation of VET activities, promote communication among extension staff for coordinated and integrated programs and efficient use of resources.

The VETs comprise extension workers from different extension departments at the village level and help villagers to prepare and implement the village plan. The VETs are communication links between the village and district; while the mandate of the VDCs set by a Presidential Directive in 1968 is to mobilize community members and other institutions for development action. The VDC serves as a link between village leaders, politicians, and district authorities to increase the flow of development information, identify needs and develop plans for their villages. They are the main institution responsible for coordinating development programs in the village. Other coordinating institutions include Parents and Teachers Association (PTA), Village Health Committee (VHC), Social Welfare Committee (SFC), and Community Based Organizations (CBOs) (District Planning Handbook Draft, 2008).

At the village level the other link in farmer training are extension agents, technical staff popularly referred to as agricultural demonstrators (ADs) who work directly with farmers to implement extension education programs. Farmers need continued learning to acquire new skills, knowledge and information in order to improve their farming and other productive activities. The work roles of AD's as extension agents put the officers in leadership positions and their leadership styles therefore affect the farmers they train, others with whom they work, especially those at the village level, and attainment of extension goals (Khalil, et al. 2008). Hence as revealed by the needs assessment study (2009) of the University of Botswana Centre for Continuing Education, Public Education Section ADs need training in leadership to improve their skills.

Two groups of institutions provide the framework that guide extension program implementation and farmer training as conducted by the AD's at the grass-root or village level. The traditional institutions comprise of chieftaincy, chiefs, headmen or headwomen, and their deputies. This group is referred to as traditional because of its pre-colonial origin. The other groups of institutions referred to as modern institutions were created after Botswana's independence (in 1966). The institutions include the VDC, the Village Extension VET, FC, and PTA (District Planning Handbook Draft, 2008). The institutions at the village level represent different levels of power and leadership processes that the AD's must understand; they need to appreciate the importance of the leaders and their support in making farmer education and training more effective. The extension management must therefore determine the strengths of the structural frameworks in relation to the diverse leadership styles presented by the two types of institutions,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and the power types at play as brought about by chiefs, headmen/headwomen, religious leaders, and political leaders. Extension management must also recognize the amount of influence the leadership dynamics have within the rural communities at the same time, positioning of AD's in supportive and enabling leadership environments by the Ministry of Agriculture (MoA) is essential to enable them to play their role well in effective farmer education (Hart, 2006: Morse et al. 2006).

BEST FIT LEADERSHIP STYLE FOR MORE EFFECTIVE FARMER TRAINING

According to Hart (2006), great lessons and benefits for extension can be gained from tribal leadership styles and practice; especially when extension leaders need to make tough decisions about currently facing extension systems. These are essential decisions about best approaches and strategies for implementing educational programs, relevance of the programs to the needs of farmers, prevailing economic and market forces, globalization and climate change. He describes tribal leadership as a process during which the leader "mentors, shares leadership, develops leadership for others, builds consensus, leads by example, allows other people to take the lead, gives other people the opportunity to be in their position, and is the last one to eat at a meal" (para. 6). This sounds more like servant leadership described by Greenleaf (1977) as a self-sacrificing leadership where the leader serves followers, always striving to make a positive difference to their benefit. The servant leaders are strong in listening, motivation, empathy, self-awareness, healing, persuasion, conceptualization, foresight, stewardship, and commitment to other people's development and community spirit (Leadership Theories).

Morse et al. (2006), on the other hand, suggest a catalytic or public leadership for adoption by extension systems that are re-organizing to address a new role change and power shift dictated by globalization. Luke (1998, p. 33) defined catalytic leadership as a "trans-organizational leadership process" that focuses attention on mobilizing diverse group of individuals and agencies to address a particular public problem. The leadership "evokes collaboration and concerted action among diverse and often competing groups toward a shared outcome". Public or catalytic leadership style is participatory and congruent with the educational mission of extension; extension agents act as catalysts in the communities. As implied by the definition of 'catalyst', extension agents will act more like a chemical reaction where "a substance usually used in small amounts relative to the reactants modifies and increases the rate of a reaction without being consumed in the process". In this type of scenario, what is needed is "a different mind-set", a different way of thinking about leadership or what it means to be an extension agency, rather than simply providing content, the extension system must also facilitate process or group development: processes where community members work together, create a vision, and make a difference. Clearly, this shows that successful farmer education and training programs require leadership styles that fit well into the structural frameworks already created, recognize the leadership at the different institution levels of extension organization, keeps the processes in synch and allows power sharing (Crosby & Bryson, 2005).

Catalytic/Public leaders have four primary tasks to achieve: firstly, raising awareness in the community, inviting stakeholders to encourage appreciation of problems and issues. Secondly, public leadership task is to form working groups to address common problems. The leader convenes meetings and uses knowledge, personal contacts, networks, and knowledge of stakeholder interests to motivate everyone in the work groups to participate. Thirdly, the task of the catalytic leader is to create strategies: the leader opens up guided discussion and gets interested parties talking around a particular issue to stimulate creation of strategies. Fourthly, the catalytic leader's task is that of 'sustaining action': the leader tries to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

maintain momentum among work groups, identifying talent, re-enforcing cooperative behaviour among groups, motivating them to stay focused on goal achievement. Catalytic leadership skill requirements are similar to those of extension work. For instance, some of the skills that training of extension agents should provide include group dynamics and formation, analysis and diagnosis, initiative, and communication which use the same principles as the public leadership skill of strategic thinking, group facilitation, and networking (Morse et al. 2006; FAO, Guide to Extension Training).

Other leadership styles that are recommended presently are those able to facilitate a transition of extension to a learning organization such as transformational leadership (Ladewig & Rohs, 2000). Transformational leaders value personal growth and individual development. They appeal to higher needs and values of followers, inspire them with new possibilities in order to raise their level of confidence, conviction and desire to achieve a common, moral purpose. Transformational leadership occurs when one or more people engage with others in such a way that leaders and followers raise one another to higher levels of motivation and morality (Burns, 1978). This leadership fits well with extension systems currently as the systems attempt to respond to the many changes impacting extension operations. In coping with changes in extension work, the systems must encourage a learning culture among stakeholders at all levels to acquire the leadership competence necessary to transform (Petterson, 1998 in Ladewig & Rohs, 2000).

Singh et al. (2008) in their study of effects of motivational training program on the development of leadership styles in agricultural scientists and extension agents revealed a high preference for participatory, motivating, and empowering leadership styles. The results revealed the need for a leadership process of a complimentary nature, combining more than one group of leadership behaviours and competencies. This confirms Scouller's (2011, para. 7) statement when he said that "leadership is a process, with which there may be different leaders acting at different times in different situations"; the formal leader's purpose therefore, would be to ensure that there is leadership at all times. This is the situation in Botswana: the case of formal, traditional, and informal leadership institutions that drive extension programs especially at the village level.

Another leadership style that can improve relevance of extension presently is one that borrows aspects of the Scouller's 3P model. The leadership model combines the strengths of traditional leadership theories to offer a more integrated approach described in the catalytic (Morse et al. 2006), tribal (Hart, 2006) transformational, and learning organization (Ladewig & Rohs, 2000) models. The 3P model comprises of three levels of leadership: central to the process is the personal and third level of leadership; public (first) and private (second) levels of leadership which deal with outer behaviours. Public leadership is about the actions or behaviours involved when a leader needs to influence two or more or more people simultaneously; while the private leadership level is about behaviour required to influence individuals, one by one. Scouller (2011) outlined four dimensions of leadership which he says represent public and private leadership and what leaders should be doing to influence people in groups or individually. The dimensions are:

- Shared group motivating purpose or vision;
- Action, progress and results;
- Collective unity or team spirit; and,
- Individual selection and motivation.

The personal leadership emphasizes a person's leadership presence built around one's knowledge, skills, beliefs, emotions, and unconscious habits. As observed by Scouller (2011), central to leadership

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

is the leader's "self-awareness", his /her progress toward self-mastery and technical competence, and sense of connection with those around him/her. The inner core is the source and represents a leader's outer leadership effectiveness. There are three performance areas for the personal leadership level:

- Leader developing his/her technical knowledge and skills;
- Growing the right attitude toward other people; and,
- Leader working on his/her psychological self-mastery.

The main argument in Scouller's leadership model is that: (1), self-mastery by the leader is key to growing his/her leadership presence; that is, building trusting relationships with followers and being flexible to accommodate change, while remaining authentic; (2), personal leadership is the most powerful of the three levels of leadership and can be instrumental in making extension agents more effective in executing their duties. The main criticism of the 3P model of leadership is that it may be difficult to use as a guide to self-development without a professional coach or psychologist as self-mastery is a deeply-psychological concept. Extension can take care of the issue by offering regular in-service training and engage psychologists in adult education to train the agents and the supervisors; after training, the agents and supervisors will coach farmers and other agents.

CONCLUSION AND RECOMMENDATIONS

The chapter discussed extension in Botswana, constraints and strengths as the system promoted its mandate to provide farmer education and training; the institutions and structural frameworks which supported farmer training over 79 years were reviewed. The chapter questions the many re-structuring exercises used to intervene whenever extension program implementation problems arose without due regard for the leadership processes which are part of the structural frameworks created to promote farmer education. A holistic evaluation approach is recommended for more targeted and inclusive interventions that can help determine the perfect leadership style fit for more effective farmer training in Botswana.

Literature on leadership and extension revealed several leadership styles with potential for promoting effective farmer training. These include:

- Tribal leadership style recommended by Hart, (2006) especially when extension leaders need to make tough decisions about current global issues facing extension systems. Actually, sustainable community development is successfully achieved when such local leadership is formally recognized through formal tools measures such as government extension policy (Ozor & Nwankwo, 2008).
- Catalytic or public leadership, because the skill required to successfully practice the leadership are similar to those of extension work. These are skills such as group dynamics and formation, analysis and diagnosis, initiative, communication, and strategic thinking (Morse et al. 2006).
- Transformational leadership (Ladewig & Rohs, 2000), will facilitate a transition of extension to becoming a learning organization because transformational leaders value personal growth and individual development. Transformational leadership fits well with extension systems currently

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to enable well targeted response to the many changes impacting on their operations. Extension systems must cultivate a learning culture among all stakeholders to acquire transformational leadership competencies (Patterson, 1998).

- The 3P Leadership model by Scouller (2011) is another leadership style for improving extension relevance; it borrows aspects of the 3P model. The third level of leadership in the 3P model, the personal leadership is the most central to leadership styles recommended for extension: it emphasizes a person's leadership presence built around one's knowledge, skills, beliefs, emotions, and unconscious habits. The personal level represents the inner core which is the source of a leader's outer leadership effectiveness. The leadership model actually combines strengths of the traditional leadership theories and uses them to offer a more integrated approach described in the catalytic, transformational leadership, and learning organization (Ladewig & Rohs, 2000) models.
- In conclusion, the leadership model that provides the perfect fitting leadership style for effective farmer education and training in Botswana is one that adopts and combines principles of leadership as presented by the 3P model in the three levels of leadership. This is because the leadership model combines strengths of the leadership styles recommended in the literature as the best for re-aligning extension missions worldwide.

KEY TERMS AND DEFINITIONS

Agricultural Extension: Extension and agricultural extension used inter-changeably; extension used to mostly when referring to agricultural extension. Extension purpose is to develop farmer training programs; support local food production, increase farmer income. Extension services, with farmers direct development programs and change in rural areas.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Extension Agents: Formally educated and trained professionals; they serve as a critical link in all extension activities. They link government with the people at the rural community level to bring about change. Their job places them in multiple roles of conveyors of technical knowledge, teacher, educator, facilitator, motivator, consultant, administrator, organizer, arbitrator, advocate, friend, as well as catalyst, motivator, activist, and leader.

Extension Approach: An organizational structure, providing the style of action for the system: leadership, allocation of resources, equipment, facilities; framework for program planning and implementation; and framework of linkages to guide interactions with other organizations.

Farmer Education and Training: Providing knowledge and skills through educational and training programs and at the same time, communicating to the farmers; providing information particular technologies and innovations from agricultural research.

Formal Leaders: Hold recognized positions of authority; appointed by someone in higher authority; others inherit the leadership position.

Informal Leaders: Do not hold any particular position of authority; often not easy to identify; people respected by others because they have an attractive personality or personal presence; there are knowledgeable and make good decisions; team leaders.

Leadership Style: A set of behaviours used by leaders as they perform activities to achieve pre-set goals.

Traditional Leadership: Shared leadership; organized by the clan system, guided and sustained by elders of a clan through teaching of tradition, values, culture, and language of a particular tribe.

Chapter 13
Rebirth of a Program via Community, Industry, and Philanthropic Support

Cathleen Brandi Ruch
Lake Region State College, USA

ABSTRACT

In 2002, Lake Region State College closed their "Agricultural Farm Business Management" program, due to low enrollment and lack of interest. However considering that agriculture is one of the leading economic developers in North Dakota, Lake Region State College (LRSC) leaders and the community felt this might have been a premature closing, and decided to look at other agriculture workforce initiatives, considering ways to revitalize the agriculture workforce and its needs. This was an ambitious goal considering how rural LRSC is, with roughly 2000 in student matriculation in a given year. Before looking at reinventing, or "rebirthing" the ag program, challenges and steps needed to be addressed and employed. The following chapter will provide a case study on how LRSC leaders, its community, and the alignment of philanthropic support was able to revitalize or "rebirth" the agriculture program to the new cutting edge of Precision Agriculture.

INTRODUCTION

The fiscal relationship between higher education and its respective state has been eroding for a number of years. In fact, according to Mortenson (2004) there have been huge cuts with state appropriated funding for higher education in the last two and a half decades. In FY 2004, states appropriated $60.3 billion for operations, and this was down from FY2003 at $61.5 billion, and down from FY 2002 at $62.8 billion (p. 3). In fact, since 1978, state appropriated funding has declined by 40%. There are many factors that contribute to this nationwide decline for state funding, the biggest factor has been contributed to the economic recessions noted in the last 25 years, and two-year institutions are not immune to this decline in funding (Weerts & Ronca, 2006, p. 936).

The first and oldest community college was Joliet Junior College, founded in 1901 in Illinois. Community colleges then flourished nationally in the 1960's with 457 active campuses. Community colleges historically focused on liberal arts, however, during the depression took a more pragmatic turn, offering job-training programs in order to offset widespread unemployment (Community Colleges Past and Present, 2015). Two-year institutions are known to be 'open enrollment' and serve a range of students (Thelin, 2004). Local funds primarily funded and supported two-year institutions at 94 percent, however was soon to be insufficient, and other revenue streams were mainstreamed- state revenue, tuition and fees, federal funds, and gifts and grants. In the 70's came the awareness that public funding was not going to be sufficient for community colleges to meet their missions (Strauss, 2001).

Today, community colleges enroll nearly half the nation's undergraduate students (Worth & Smith, 1993) and funded primarily from state, local government, and student fees (p. 347). When it comes to fundraising, rarely see the "megagifts" at the two-year institution that four-year institutions have come to know and count on for philanthropic giving. However, reported by the "$70 Million Gift to Help California Students" (cited in Ramano, Gallagher, & Shugart, 2010) in 2008 a $70 million donation was presented to a community college system, to assist scholarships for California's 109 two-year colleges. However the gift was focused on scholarships, and as reported by Gose (cited in Ramano, Gallagher, & Shugart, 2010), "most community college donations are earmarked for scholarships" (p. 59). Additionally, in the 2014 CASE Survey of Community College Foundations (Paradise, 2015) reported that when it comes to a comprehensive or capital campaign, 80 percent of surveyed participants cited scholarships as the top destination (p. 27).

Two-year institutions are divided and recognized by three different types of demographics, categorized by the Carnegie Classifications of Institutions of Higher Education™. Carnegie defines community colleges by *service areas*; rural, suburban, and urban. This type of classification was set in place to demonstrate that nearly all public community colleges are place-based institutions, with geographic service delivery areas defined by state statute, regulation, or custom (Hardy & Katsinas, 2007, p.6). The Carnegie Foundation for the Advancement of Teaching (as cited from Hardy & Katsinas, 2007) defined that *serving*, whether the student is from an urban, suburban, or rural areas, depends on the physical location of that campus.

When it comes to fundraising, two-year institutions are not viewed the same, despite what service area they serve, and rural community colleges face the greatest budgetary strain. In fact, according to one study provided by Katsinas, Tollefson, & Reamey (2007), reported "rural community colleges lacked access to a good stream of local support" (p.4). For example when it comes to alumni and future support, students who attend two-year and matriculate to a four-year institution transfer their alumni loyalties, and later become donors to that four-year institution (Worth & Smith, 1993). Additionally, Worth and Smith (1993) further reported that since two-year institutions are program based and not research focused have constraints on where and what kinds of foundations and donors to solicit. In fact, a survey provided by The Marts & Lundy reported to *The Chronical for Philanthropy* (Daniels, 2015) that fifty-one percent of the large gifts to higher education went to university hospital centers and health programs, up from 41 percent in 2013. John Cash, Marts & Lundy's chairman said that "Instead of being driven by a sense of loyalty to their alma mater, Mr. Cash said, many of his clients prefer to give to institutions that are on the cusp of big breakthroughs."…"Donors are giving their big gifts to support research," he says. "They're much more opportunistic. They're not building buildings and creating monuments to themselves" (Daniels, 2015; https://philanthropy.com/article/Mega-Gifts-on-the-Rise-at/227955). Comparing prestigious and well-known four year agricultural institutions, such as Purdue where gifts are provided by the Bill

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and Melinda Gates Foundation (Austin, 2011), two-year institutions cannot compete, and therefor need to look at other avenues. Therefor to assist with philanthropy and fundraising, two-year institutions align themselves with the workforce, as is their mission, and solicit gifts supporting their unique programs and industry. To assist in this process, community college foundations have learned to align themselves to philanthropic opportunities via their foundation boards. In fact, Paradise (2015) reported in a CASE whitepaper that community college boards are composed of 98 percent of business and industry.

Reinventing a program in higher education, especially one that needs to be tied to a rural community presents a myriad of programs and challenges. However, such efforts have become necessary. A case study of a recent program reconstructed at a rural community college is presented. It will highlight the needed outreach nature of a close alignment of philanthropy, community, and higher education. By way of example will be a case study of the reinvented traditional agriculture program to the new cutting edge of Precision Agriculture.

Precision Agriculture (Precision Ag) is the combination of agriculture and technology. In the agriculture arena, the demand on farmers to continuously produce more food, fiber, and fuel for this world has made it imperative to become more efficient. In turn this need for efficiency has prompted the adoption of various forms of precision agriculture technologies. The use of precision agriculture technologies is the tool to allow farmers to manage small areas, and treat these areas uniquely in regards to their individual characteristics. Technology allows for the collection of immense amounts of data that assists in making necessary management decisions. The demand does support a workforce with these new skills.

The precision ag industry was very new and cutting edge. Initial research provided by key leaders at Lake Region State College (LRSC) indicated that there was not another institution regionally or nationally undertaking this type of workforce and developing a viable accredited program. However, the question was how to get industry to support this program, when there was no other model regionally, nationally or internationally? How much industry and community interest was there to support this type of program? Without proof that there was going to be a return on investment, and the fact that Lake Region State College (institution that housed the program) had initially closed their "Agricultural Farm Business Management" program, local industry was not interested in committing funding. Where was the revenue going to be generated from in order to implement and sustain this program? Other revenue would have to be considered and applied for, such as statewide grants that supported equipment and program funding.

The following chapter will discuss the following: 1) data collected in order to support a new and cutting edge workforce program, 2) local community funding committed in order to support the program, 3) overview of the Trade Adjustment Assistance Community College and Career Training federal grant, which required local support, that launched the program 4) other statewide grant funding that was used to support the program, such as the Workforce Enhancement Grant (North Dakota Department of Commerce), and 5) what the current efforts in place from the community in order to continue to provide support.

BACKGROUND: TRENDS IN REGARDS TO HIGHER EDUCATION AND THE WORKFORCE

Two-year institutions are recognized as a vital backbone in economic and workforce development (Bailey & Kienzal, 1999, p. 1), especially in rural locations. Push for two-year institutions to work with specific industries and offer content-specific courses or programs continues (Zinser, 2003, p. 1). Business leaders

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

continue to voice their disapproval regarding higher education not producing the necessary workforce. With this kind of censure, two-year institutions eliminate programs that are not closely related to workforce. Fain (2014) reported that the two-year system, Louisiana Community and Technical College, made large programmatic cuts in recent years as state appropriated funding went from 70 percent to 30 percent. The system eliminated close to 700 programs, which were not closely tied to workforce needs. For example, the system cut its cosmetology program, since it no longer supported a workforce need (p. 2).

These funding cuts not only took place in Louisiana, but nationally. In the article, *Signs of hope for state funding* (2014, November 20), it was reported that during the last recession, 11 states had higher education funding cuts of more than 30 percent. Other states had decreases between 20 and 30 percent.

The trend of cutting higher ed programs not closely tied to workforce is not just a response to the last recession, but has been taking place many years. State appropriated funding has dwindled, and institutions of higher education, especially the two-year institutions, have had to align themselves closer to the workforce. Lake Region State College (LRSC) had to make the same type of cut in the early 2000's, and closed their "Agricultural Farm Business Management" program since it was not seeing student enrollment or retention. Like many institutions (two or four-year) looking to cut and save state appropriated funding, the closing of the program seemed like a logical strategy. However, in a state where agriculture is one of its prime economic developments, the community and agriculture industry of Devils Lake questioned the decision of discontinuing the program. Leaders and stakeholders revisited the closed program, and considered a bold move of reinventing the closed program, constructing and launching a new program, which would be tightly coupled with the community and local workforce industry.

REBIRTH OF A PROGRAM

In 2005, LRSC leaders and stakeholders revisited the agricultural program, to consider if there was a way to reinvent the ag program, providing a new prospective in the industry. After researching the agricultural needs statewide and nationally, it was concluded that agriculture was seeing considerable workforce needs within *Precision Agriculture*. In fact, precision agricultural careers continue to expand in occupational diversity and are numerically increasing as reported by the US Bureau of Labor Statistics in the Ag Leader Insights Magazine (2014, Spring), "employment opportunities will increase by more than 29 percent and create more than 100,000 new jobs by 2020" (p. 8).

Precision ag technology has been evolving since 1995 (Greene, 2011). Producers within the central regions of the U.S. recently reported in communication that 92 percent use one or more precision agriculture technologies, and have had such technology on their farm for an average of 5 years. Sixty percent plan to increase use of such technology within the next two years, and the majority of producers turn to their local agricultural implement dealer for information assistance when acquiring, installing, servicing such technology (P. Gunderson, personal communication, 2011).

Regionally and locally, precision agricultural was also considered a workforce need since approximately 32,000 farms/ranches are located in North Dakota however, of that number 3,000 are "limited resources", 5,000 are "retirement farms/ranches", and 8,100 are "residential lifestyle farms/ranches." These farms/ranches generated at least $250,000 or more in sales annually, and the children of these agricultural enterprises would be targeted as potential students for the program (U.S. Censes of Agriculture, 2007, Table 64). This in turn concluded that this new agricultural program could potentially

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

impact a constituent of 29,000. This was a significant finding for a small regional institution, averaging an enrollment of 2,000 comprised of traditional and non-traditional students.

ISSUES, CONTROVERSIES, PROBLEMS: THE CLOSING OF ONE PROGRAM AND THE REBIRTH OF ANOTHER…CAN IT BE DONE AND RECEIVE LOCAL PHILANTHROPIC SUPPORT?

The Dakota Precision Ag Center (DPAC), Center of Excellence, was first created under the auspices of the ND Governor's Center of Excellence grant initiative in 2006. It was one of the first Centers to initiate research and job creation activity.

It was a long road before DPAC became to fruition. After the writing, and funded Center of Excellence (COE) grant, the program was underway. Answer Farms, an agricultural research facility, was recruited to assist DPAC in assessing current precision agriculture technology on local farms. The plan involved recruiting local farmers and producers from the cohort of adult farm management trainees directly involved in LRSC's Adult Farm Management program. With this selection, leaders of the DPAC program would be able to do research on farms, discovering which 'precision technology' was effective in order to base the reinvented agriculture degree program, Applied Associates of Science in Precision Agriculture. However resistance form the local agricultural community was encountered since LRSC had previously closed its agriculture training program- Agriculture Farm Business Management. Workforce and the local community was apprehensive in providing resources or assistance to an institution that closed a program that was providing much needed education and training in a field that was one of leading economic drivers of the state- agriculture.

Meetings and renewing relationships led by DPAC and LRSC leaders of local agricultural producers, establishing that once the newly reinvented ag program was in place, and successful, it would not be closed. However, only 3 (three) ag producers was willing for DPAC to use plots of their land for research, finding out what 'precision technology' was going to be the most needed and used as training and educational platforms for future precision ag students.

While three producers vested into the research and program was a good start, it was hardly the indication needed to ensure that the local community and workforce was vested into the DPAC program. An endeavor of this magnitude was going to need a vested community and workforce in order to build and sustain the program, which was going to need vast amount of equipment and other expenditures to get the program reinvented and launched. More research would have to be deployed, demonstrating need and sustainability before the ag workforce and local community would once again support an ag program at a small rural two-year institution.

Data Collected in Order to Support a New and Cutting Edge Workforce Program

According to the site, Bureau of Labor Statistics (North Dakota) North Dakota is the most rural of all the states, with farms covering more than 90 percent of the land with a strong economy and a low unemployment rate which stands at 2.8 percent, the lowest in the country (Bureau of Labor Statistics-North Dakota, 2015). During the country's most recent economic downturn where many states had few jobs,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

North Dakota was creating jobs and hiring. In fact, the state added 21,300 new jobs since 2005 earning a top position in the nation for growth (Murphy, 2010, p.116).

Considering North Dakota has such a high farm population, it could be concluded that the economic impact of a reinvented cutting edge agriculture program was within scope. However, intense research was deployed since the institution already had low enrollment numbers in past agriculture training programs which led to the closing of the program. This, in turn, produced a cautious local agriculture workforce and an institution needing a 'sound investment' before commitments would be forthcoming. Additionally, when it came to sustaining this type of program, other implications needed to be addressed; 1) any educational program in this arena will not be successful unless the target audience, agriculture producers, are directly involved in its design and 2) agricultural industries must possess economic clout, both locally and regionally in order to provide support.

In response, DPAC and LRSC leaders provided research in support for a new agriculture program in precision ag and the following key points were addressed; 1) what type of precision ag training was needed; 2) earnings for future employment; and 3) what were current industry economic profits in order to support future employees. In 2010, the following data was collected via surveys provided by the North Dakota Implement Dealers Association (NDIDA). They surveyed and compiled the following data:

- There are 126 retail farm equipment dealerships in North Dakota
- Annual total retail sales of new and used farm machinery and repair parts in North Dakota is over $495 million
- Over 3,120 people statewide are employed by retail farm equipment dealership.
- The average dealership employee earns over $43,000 per year
- The average annual payroll per dealership is over $1.1 million
- Dealership payroll statewide is over $132 million annually
- Dealer payroll comprises 12% of ND's total retail payroll
- Dealers statewide pay over $17.5 million in payroll takes and employee benefits annually (NDIDA, 2010)

Based on preliminary research, the need and support for a new agriculture workforce seemed promising, however, more in-depth research needed to be deployed. LRSC and DPAC leaders with specific questions created a survey in order to understand what the needs are from farmers, producers, and other ag workforce to build a successful program. Seventy-eight producers and dealerships responded to a survey conducted through the North Dakota Agriculture Association, which included the following inquiries:

1. Estimate the number of employees you will be hiring in the next 5 years who will specialize in precision farming technology.
2. How many new employees will you be hiring in the next 5 years that need basic precision ag knowledge but won't necessarily specialize in it?
3. Where would you expect future employees to receive training in technical areas of precision ag?
4. Where would you expect future employees to receive training in consultation of precision ag?
5. Where would you expect future employees to receive training in agronomics, businesses management, and soft skills?

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Results from the survey included in Table 1 indicated that precision ag skills and knowledge would be a necessary and required skillset of 187 new employees across the next 5 years in North Dakota. Table 2 indicated that an additional 272 job openings in agribusinesses will require basic precision agriculture skillset. Table 1 and 2 combined indicated 459 jobs would be added where individuals could benefit from precision ag training. Additionally, results concluded that ag industries were looking towards and expecting state colleges to step up and provide the necessary training.

For survey question 3, "Where would you expect future employees to receive training in technical areas of Precision ag?" Table 3 indicated that 58 percent said college courses, however 92 percent responded with *industry sponsored* – which was not a surprising result considering the lack of a program locally or regionally that could support this type of program.

Survey question 4, "Where would you expect future employees to receive training in consultation of precision ag?" Results from Table 4 indicated 73.3 percent in favor of *industry sponsored* however the second strongest response was *formal training (college courses)* with 64.5 percent.

Survey question 5, "Where would you expect future employees to receive training in agronomics, businesses management, and soft skills?" The results from Table 5 indicated employees would be get-

Table 1. Estimate the number of employees you will be hiring in the next 5 years who will specialize in precision farming technology. (Data source: DCTOA (c). N.D. (Skipped Question)	2	

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ting their training from the *formal training (college courses)* at 86.8 percent, and *industry sponsored* was second, with 40.8 percent.

Quantitative responses were also captured from equipment dealers, which said that, "The guys on staff right now in the state (N.D.) are not up to date on knowledge of precision agriculture." Some dealerships indicated that, "No employee is currently trained in precision agriculture technology" (P. Gunderson, personal communication, 2011).

Another industry leader indicated the following in an interview:

INTERVIEW WITH INDUSTRY LEADER

We need you (the Techs and Universities) to be bringing the next

…generation of precision worker to the workforce. There are not enough hours in the day to try to train people on the go, it usually takes a year to get them up to speed. To have them come in the door with the basic skills and knowledge, priceless. Additionally, the following statement was captured during an interview with a local N.D. agricultural cooperative, I don't know what I'm going to do; my guys aren't training, none of the other guys are out other (n=5) locations are training to use this stuff either. (Company name) doesn't provide the training, a local precision ag firm doesn't provide the training, but they want a special pricing agreement in exchange for providing the training, and we don't have any other source for training. You guys at Lake Region know how to do this stuff…why aren't you involved in training statewide for us? Every ag co-op in the state is in the same shape we are (P. Gunderson, personal communication, 2011).

DPAC and LRSC leaders disseminated qualitative and quantitative data and concluded that a precision ag program needed to be started and implemented at LRSC. However, 'wanting' and 'needing' this type of program was not going to get the program off the ground without local philanthropic support.

Local Community Funding Committed in Order to Support the Program

Devils Lake resides beside the largest natural body of water in North Dakota. The lake covers more than 160,000 acres, and has earned the reputation of being the "Perch Capital of the World." The city consists of 8,000 people, with 500 businesses (Devils Lake North Dakota, 2015, p. 20), which includes the necessary businesses to support the program. At least six ag businesses located in or around the city proper, including CASE-IH, John Deere, and Butler-Cat®. The state of ND houses the largest CASE-IH agricultural dealer network in the world, and the largest John Deere agricultural dealer network in the U.S. Hence, its agricultural implement dealer networks were not only poised to recruit and place large numbers of precision agriculture technicians, those networks also were capable of providing paid internships and other training opportunities in partnership with LRSC and DPAC.

With the need established within the workforce, the next step was to find and solicit local community support and funding. Considering the program was not up and implemented, and the institution could not prove the program would be viable with producing the workforce needed, funding from the community was going to be a challenge. As noted by Milliron & Browning (2003) that compared to four-year institutions, community colleges are relatively new to 'high stakes' fundraising (p. 90), and LRSC is no

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

exception. LRSC was not known as an institution to solicit and receive large donations, or 'megagifts'; and with little validity that the program would work, soliciting donations needed to provide sustainability was going to be a challenge. Philanthropy for the program was going to have to come in the way of 'gifts in kind' via local industry; and few local industries were interested in supplying 'gift-in-kind' to assist in the development of the program. High Plains Equipment (HPE) of Devils Lake, N.D. had 27 employees and is the CaseIH Agricultural/AFS-Advanced Farming Systems™ / Borgaults ®/ Unverferth ® farm machinery dealer in the Devils Lake area. HPE had recently moved to a new location and constructed an ultra-modern facility. DPAC leaders developed a relationship convincing HPE that DPAC was poised to train the next generation of precision ag employees, however needed a viable building to implement the program. LRSC could not house the program on its campus since it did not have the necessary space needed. With the newly formed relationship in place, HPE provided complete access and use of their 4,480 square foot building 1 mile north of the LRSC campus for instructional and staff purposes and part of the 6,160 square foot shop space for student hands on training. Additional facility space would also provide for faculty and staff.

Farming is a risky business, considering a good yield (how much money a crop produces) could produce a huge return on investment or a below par yield could potentially bankrupt a farmer, its family, and future family for life. With such high risks involved, producers and farmers rely on accurate input from the land and the equipment they invest. Understanding and correctly interpreting the technologies used in precision ag, (this goes beyond the use and mechanical upkeep of a tractor or combine), was critical. DPAC leaders built and reinvented a program not only around the basic upkeep and maintenance of ag equipment, but the advanced technologies used in order to farm efficiently- and thus developing an Associate of Applied Science in Precision Ag. DPAC leaders looked outside of the scope of the 'basic equipment needs' of the program, and started talking and achieving buy-in from other industries where technologies would be utilized to achieve the precision in agriculture. Two local industries where cultivated to provide 'gift-in-kind' with access to software critical to the development and implementation of the precision ag program.

A local industry was approached to provide satellite remote sensing, which provides inferred mapping. Inferred mapping is a valuable tool when providing insight to a farmer's yield. When inferred pictures are captured, developed and stitched together to form a complete picture of a field, it can indicate the best and most profitable yield while assessing problems within the field itself, such as lack of nutrients and water. Again, in the high risk life of farming, every square inch of a field needs to be scrutinized and evaluated for yield production consistencies and inconsistencies.

Additional support was solicited from a company that built and sold Unmanned Aerial Vehicles (UAV). Gift-in-kind was provided in the purchase of UAVs in order to provide training for DPAC students in the flying and accessing inferred pictures (inside the Center). Like satellite remote sensing, UAVs can provide inferred photos that can assist producers and farmers with the necessary understanding of what their yield is or is not producing in the way of food. Without understanding and having training on these types of technologies, graduates of the program would be handicapped to assist farmers and producers when assessing fields and overall profit of their yield.

Additional support came from local industries from Butler-Cat®, John Deere®, FarmWorks Software®, and other high tech industries - each one providing gift-in-kind, from the use of high-tech precision ag equipment, to accessing needed software. All support provided an imperative need and support to implementing the program and providing necessary job training to future DPAC students.

Overview of the Trade Adjustment Assistance Community College and Career Training Federal Grant, Which Required Local Support

What ultimately launched the Dakota Precision Ag Center (DPAC) was seed funding from the Trade Adjustment Assistance Community College and Career Training (TAACCCT) grant. According to the Department of Labor- TAACCCT website, in 2010, President Barack Obama signed the Health Care and Education Reconciliation Act, which included $2 billion over four years to fund the TAACCCT grant program (DOL, 2010). The TAACCCT grant program, funded through the Department of Labor and partnered with the Department of Education, was implemented to "assist community colleges and other institutions of higher education with funds to expand and improve their ability to deliver education and career training programs. Training programs are geared for individuals to complete their education in two years or less, and focused on workers who are eligible for training under the TAA for Workers program" (DOL, 2010).

The TAACCCT grant was written and submitted by DPAC leaders in the spring of 2012, and awarded the following fall. The grant project was entitled Training Precision Agriculture Technicians (TPAT) and was geared to create career pathways through coursework and training through technology in precision agriculture. The project's major purpose was to deliver training and assistance to TAA-impacted workers, unemployed Veterans, unemployed and underemployed persons seeking to increase their skills for new and higher-paying jobs in the state of North Dakota. Lake Region State College would support and provide online learning and personalized instruction. Through competency based skill assessments, use of cognitive tutors, and developmental educational services, students would have the ability to accelerate progress for certifications and degrees.

The grant was developed to fiscally launch the precision ag program, which also solidified more community and local workforce support. In order to submit the grant, DPAC leaders had to ensure that the support from the institution and the community was in place. While data supported the need to re-invent the closed agriculture program, the federal government was not going to fund LRSC and DPAC $2.9million dollars in funding unless the local community and workforce were supporting the effort. With diligence, and the building of the foundation for the program over the last few years, the community and institution was ready to move forward behind the grant. A partnership was created with Job Service North Dakota (JSND), the State agency that administers the TAA for Workers program. DPAC had solicited and sustained a network of agriculture industry employers and businesses and created The Council of Consultants. In 2012-2013 The Council of Consultants consisted of 5 (five) individuals from implement dealerships, agronomy firms, and precision agricultural consulting firms, providing recommendations for curriculum development and technical, job skill-set banking, post-training assessment, on the job training opportunity, and resources such as precision technology test equipment and job opportunities. Today, with a membership of 15 (fifteen), the Council has expanded to a Board of Directors, composed of agricultural implement dealership management-level staff, precision agriculture software vendors, agronomists, crop consultants, producers, and agricultural cooperative representatives who provide overall training and research program advice and linkage to employees.

After a year of funding from the TAACCCT grant, the TPAT program at the Dakota Precision Agriculture Center (DPAC) had met and surpassed its expectations and was seeing success as a statewide, regional, and international program, providing services to students from Montana, Iowa, South Dakota, Michigan and Canada. In its first year of launching the program (2013), the program had enrolled 29 (twenty-nine) students and 27 (twenty-seven) completed their first year.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

These key ingredients were needed in order to land the funding and launch the Precision Ag program. However, initial seed money can only reinvent and launch the program, more work needed to be deployed in order for the program to survive the next phase and reach sustainability.

Other Statewide Grant Funding That Was Used to Support the Program, Such as the Workforce Enhancement Grant (North Dakota Department of Commerce)

Seed money from the TAACCCT grant assisted in the launching of the precision ag program, however other local and statewide funding needed to be solicited considering program's needs were expensive, and $2.9 million in federal funding was not going to be able to cover all the initial costs.

DPAC leaders looked at the state for the next round of funding, which included the Workforce Enhancement Grant (WEG), administered through the North Dakota Department of Commerce. The Workforce Enhancement Grant Program provides funding for a demand driven response to workforce training needs for the five (Bismarck State College, Bottineau College, Lake Region State College, North Dakota State College of Science, and Williston State College) two-year institutions in North Dakota.

DPAC leaders knew that this program needed to be more than just a training program for those wishing to achieve an associates degree. The WEG was constructed not only to help supplement the program fiscally, but also provide another vital need; DPAC needed to provide outreach and training to those already in the precision ag business by providing workshops and training opportunities for local constituents. This, in turn, would start to bridge the gap towards producers and local ag workforce who were skeptical in providing necessary verbal or financial support for the program, and creating long term partnerships.

Again, through survey efforts provided by LRSC and DPAC leaders, identified necessary workforce skills that ag producers, farmers, and other ag businesses were lacking. In fact, identified that some agricultural equipment dealers, grain merchandising services, and independent agronomists/precision agriculture consultants needed necessary basic skills to manage farms in this high tech age of precision ag. Through Workforce Enhancement Grant funding, DPAC leaders constructed training needs in basic computer skills, basic precision agriculture, enhanced electronics skills, and customer relation skills. Grant funded efforts was able to provide DPAC leaders extended outreach and educational outreach to 55 (fifty-five) farmers in need of assistance and refresher classes in precision ag. This also continued to rebuild the torn relationships among the local workforce within farmers and producers.

What Are the Current Efforts in Place From the Community in Order to Continue to Provide Support?

The collaboration among institutions that is facilitated by consortia is a vital lever for transformational change—the type of change that will enable colleges and universities to not just survive but to prosper. (Forcier, 2011, p. 1)

CHANGE, COLLABORATION, AND CONSORTIA

Change, collaboration, and consortia – 3 C's - have become the watchwords of contemporary higher education. The one element that state and federal policymakers, major foundations (Lumina, Kresge,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Gates, and others), and government agencies all share is the firm belief that higher education must change in order to remain effective. One increasingly common strategy to promote such transformation is an intense focus on collaboration between and among institutions, including the creation of consortia arrangements. Indeed, in many cases, collaboration and/or the formation of consortia are now requisite for the receipt of external funding. (Krotseng & Ruch, 2013, p.18)

Identifying and connecting with natural partners is the first step in developing long-lasting collaborations. (Krotseng & Ruch, 2013, p. 19)

DPAC was successful with the Workforce Enhancement Grant, providing educational outreach to farmers in need of assistance and refresher classes in precision ag. However, this was local, and DPAC wanted to move beyond the regional borders and provide this type of educational outreach statewide with a mobile training lab. This type of large-scale training was beyond the limits of the current program, and was time to employ the next phase to build support for the DPAC program. DPAC leaders knew that in order to provide change the next obvious step was collaboration building towards consortia. DPAC leaders looked towards their natural partner to collaborate with which was TrainND Northeast. TrainND is part of the North Dakota Workforce Training System, which provides and delivers training where the business needs it.

In collaboration with TrainND, DPAC leaders assisted in writing the Career Technical Education (CTE) grant in order to support workforce training in precision ag with a mobile training lab. With this collaboration, DPAC and TrainND would be able to offer non-credit workforce training developed specifically for the agricultural industry statewide. Small Business Computer Skills, GIS Systems, Basic Precision Agriculture, Enhanced Electronic Skills, Introduction to Welding, and Service to Customer Communication Skills will be available to producers, implement technicians, equipment operators, and other agriculture employees. Grant efforts would enable collaborative partners to purchase and equip a mobile high-tech training laboratory that will enable the delivery of precision agriculture technology training to the rural areas in the state of North Dakota.

SOLUTIONS AND RECOMMENDATIONS

The birth or rebirth of a program takes time, research, investment of a community, solicitation and commitment of the industry who will support it, extramural funding, and then collaboration of partnerships. The rebirth of the ag program took 8 years, troubleshooting and learning 'best practices.' The following take-away(s) could provide rural higher education institutions through philanthropy and other promising strategies ways to birth or rebirth a program tied to the community and workforce.

1. Research. Know the program you are trying to birth or rebirth. Talk with those in the industry. Ensure there is a need, and support for the program. You do not want to be a program that gets funded and implemented, only to have to close the program down in two-years, and to become another statistic like the ones stated at the start of the chapter. Some other items to consider:
    a. Is this a program your local constituents want? Talk with those who are involved and not involved in the industry and get their perspectives.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

   b. Do not stay local when it comes to researching the proposed program. Go outside the area to ensure this is a program needed locally, regionally and statewide. Once support has been provided locally, efforts will be needed outside the area for continued support and build sustainability.
   c. Enlist the support of your local legislature. Securing funding and support in the state, whether through political actions or statewide grants, is another vital way to build sustainability.
2. Start looking at external support. Federal grants are a good place, especially in the Department of Labor (DOL) or the US Department of Education. The current US federal administration is geared towards workforce development, and now is the time to capitalize on it. Current research and articles provided via the DOL indicates that this is a focus that will not be going away anytime in the near future.

   Also, look at statewide grants that support career and workforce developments, such as your CTE (Career Tech and Education) grants. Most states have these types of grants in place, or pools of money institutions can apply and compete for.
3. Continue to work with local workforce as programmatic activities are solidified. Develop a steering committee comprised of those who are vested either financially (workforce), legislatively (state), and who can provide guidance and extramural support.
4. And according to Krotseng & Ruch (2013), if you have not already considered or initiated collaborations with key partners or other like-minded institutions – start now. This is not a trend that will fade; it is becoming the norm to qualify for grants and extramural funding from federal, corporate, and private foundation sources. Begin today to identify potential partners and solidify productive alignments in preparation for the next major grant opportunity (Krotseng & Ruch, 2013, p. 19).

FUTURE DIRECTIONS AND RESEARCH TO BE CONSIDERED

Tight coupling between workforce and higher education is not a fad, and is becoming more of an emerging trend. As institutions continue to look for ways to develop or rebirth a program, whether in small rural locations or in an urban setting, this chapter speaks to all types of institutions and leaders, i.e. administration, faculty, legislatively, community and local workforce. Philanthropy and higher education is now an 'all hands on deck' practice, were everyone from the President down the chain of an institution is a fundraiser of some sort. No one is immune or not included in the process. All are involved with cultivating relationships. According to Ashford (2015, January, 5), "Rural colleges face plenty of challenges, such as a smaller pool of donors and fewer large corporations and wealthy donors nearby, but they actually have some advantages" reported Rich Gross, a consultant hired by the Danville Community College foundation. Such as being a "critical component in the community's workforce development, economic development, healthcare and quality of life," Gross reported (Ashford, 2015). LRSC DPAC leaders considered the 'community's workforce development' when rebirthing the program, Precision Ag. Furthermore, these are the areas a rural community college should focus on when it comes to cultivating relationships and building philanthropic donations- whether developing or rebirthing a program, building endowments, etc.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

Rural institutions and community philanthropy support, while difficult to obtain, is the future of institutions of higher education to gain financial stability. However, key stakeholders and leaders should not dive into the process serendipitously. As this chapter demonstrated, steps and other issues need to be considered before moving forward. Again, data collection is vital; and most institutions rely heavily on data collection in order to make changes or decipher directions or missions. In the process of collecting data via quantum methods, do not forget qualitative; discussing and talking with local constituents, obtaining their ideas, thoughts and opinions is also important to knowing what is going to be sustainable in the way of programs. The development and sustainability of the Dakota Precision Ag Center was not developed, built and implemented overnight, or with little understanding of the workforce, community needs and philanthropic opportunities. Building workforce relationships, which provided the necessary foundation for the program, in order to achieve 'gifts-in-kind' in the way of expensive agriculture equipment, and internship and employment opportunities for graduating students.

However, when building or 'rebirthing' a program, rural or urban, leaders and key stakeholders need to look 'outside' there borders, and think of other ways to bring in funding for support; such as federal and statewide grants which align with efforts. Also, working with local legislative representatives, aligning with their efforts is another necessary process.

And last, for future sustainability, collaboration and consortium with natural partners with similar visions and missions is key- especially for rural institutions. The sharing and collaboration of resources demonstrates the commitment needed to ensure future sustainability.

KEY TERMS AND DEFINITIONS

Agricultural Producers or Producers: Another word for farmer.

Answer Farms: An agricultural research facility located near Fort Dodge, Iowa.

Career Tech Education Grant: North Dakota grant administered via the Career Technical Education department for the development and support of workforce enhancement.

Dakota Precision Ag Center: One of Lake Region State College's programs, which houses the Associates of Applied Science in Precision Ag.

Lake Region State College: Two-year higher education institution located in Devils Lake, North Dakota.

Precision Agriculture: This is the combination of agriculture and technology.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Trade Adjustment Assistance Community College Career Training Grant: Federal grant that was signed by President Barack Obama, and administered by the Department of Labor and Department of Education, in order to assist two-year and other higher education institutions in the development and expansion of education and career training programs.

Unmanned Aerial Vehicles (UAV): This is also known as a Drone, which is an unpiloted aerial vehicle.

Workforce Enhancement Grant: Grant administered via the North Dakota Department of Commerce in the development and support of workforce enhancement.

Chapter 14
Impact on Agricultural Sustainability of Maghreb Countries:
An Empirical Analysis by 3SLS

Rachida Khaled
University of Sousse, Tunisia

ABSTRACT

This paper is aimed at making the diffusion of the technological innovation and their role in affecting the agricultural sector in the three-sided (social, economic and environmental), a hand, it can participate to resolve problems of the agricultural sector: the effects of the climatic changes, the farming exodus and the migration and the problems of poverty. The theoretically and empirically studies analyze the mechanical innovation role in improving agricultural sustainability through the impact of mechanization on agricultural productivity, CO2 emission and demographic growth for a panel of three Maghreb countries (Algeria, Morocco and Tunisia) during the period 1999-2012. By using simultaneous equations, the authors' finding that mechanical innovation cannot achieve the purpose of sustainable development in the agriculture sector in the Maghreb countries through the negative impact of mechanization and research and development on agricultural productivity.

INTRODUCTION

The agriculture is a sector which plays a crucial role in the enhancement of territories, since this sector contributes to the increased growth of the country, nourishes all living things, but meeting a sustainability problem especially in developing countries. Agriculture is introduced into the sustainable development plan to improve and modernize this sector for agriculture called 'environmentally responsible' (Ambroise et al, 1998).

At the beginning of the seventy years, agriculture has found its place in political debate through the exposure of these issues such as: the mode of production productivist, environmental degradation, political and institutional structures etc.

This is a great debate that is open to the world in all commissions and United Nations organizations that is related to sustainable agriculture to set new targets for renewable and sustainable development.

This debate based on the work of UN member states, seeks to combine a consensus around vital of a new human world politics, fair and concerned with protecting the environment.

The birth of this new concept "political ecology" began to spread in the world where some developed countries were changing their mode of production by the substitution of industrial processes of physical or chemical to biological processes. For example, with the use of nitrates substituting nitrogen fixation by bacteria as herbicides and pesticides will have been replaced with natural antagonists of weeds and insect pests (Estevez et al, 1999).

The Sustainable increase in agricultural yields each time was not achieved without the destructive effects of the environment. The transition from conventional mode to sustainable ways of agriculture has formed a long journey that has supported both socioeconomic and environmental terms.

On this basis, in the early ninety, the concept of sustainable agriculture began to appear officially. This new agriculture aims to protect resources in agriculture (soil, water, energy ...) and stimulating the biological process that is the basis of stability by the mastery of pests and weeds (Estevez et al, 1999) and find a quick way to balance the three aspects already mentioned in the economic, social and environmental occurrence and in the agricultural sector.

Although the word sustainability was popularized by the spread of the concept of sustainable development (Delchet, 2004), the term sustainable agriculture and sustainable society have been discussed in the North American continent (The limits to growth, Meadows and al, 1972). On this basis, the author has initiated a debate on the production-growth and its environmental and social consequences in a period characterized by an energy crisis. Since then, the concept of sustainable agriculture has been distributed increasingly in all environmental debates.

While the question of whether technological innovation, particularly the mechanization improves or prevents the agricultural sustainability opens the door to the birth of several economic and political debates, there are little theoretical and empirical studies on the factors of development and economic durability of irrigation system in Maghreb countries.

The objective of this paper is to make up the void in the literature and make an in-depth analysis the sustainability agriculture sector of the Maghreb countries in order to identify their socioeconomic and environmental factors.

To better understand what leads the mechanization effect on the Maghreb agriculture sustainability, we browse in these paper three types of factors, social, economic and environmental. The scope of our study covered 3 Maghreb countries during the 1999-2012 periods. We utilized an econometric methodology based on the 3SLS.

Our results show that the mechanical innovation, research and development cannot achieve the sustainable development purpose in the agricultural sector of the Maghreb country in particular economic efficiency.

The rest of the paper is organized as follows. Section 2 furnishes a brief literature review of the impact of technological innovation in the agricultural sustainability. Section 3 presents the trend of agriculture and mechanization in the Maghreb countries. Section 4 shows the data and the adopted econometric

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

methodology. The empirical results are obtained and interpreted in section 5. The rest of the paper is devoted to the presentation of some solutions, policy implications, suggestions and conclusion.

Technological Innovation and Sustainable Development: A Brief Literature Review

Major prior studies related to the present paper include Alani (2012), Blazy and al (2011), Esposti (2002), Van Rijn and al (2012), Feder and al (1993), Ruttan (1974), Khaled and al (2014, 2016). These studies focus on the effects of technological innovation such as mechanization, on the development of agricultural sustainability in developed and developing countries.

The concept of "innovation" is developed by the neoclassical approach as Adam Smith, David Ricardo, Marx etc. and improved by the Austrian school as Joseph Schumpeter. Technological innovation is defined as the set of innovations that induce transformation or a disruption of resources and methods of production, organization of work, products and markets, economic structures.

Schumpeter distinguished five types of innovation such as product innovation (production of a new product, process innovation (new method of production), discovered a new source of raw materials or energy, commercial innovation and new types of organizations (Dubouloz, 2006).

The neoclassical school indicates that the technological innovation and technological progress are factor that enhances the production quantities of capital and labor unchanged. This is an unexplained residue like manna falling from heaven. While Schumpeter explains that technological innovation is the engine of economic development.

Several authors analyze the impact of mechanical innovation and their role in the development of agricultural sustainability. For example, Alani (2012) shows that the improving agricultural productivity is linked with technical progress, he argues their work by a theoretical model derived from a production function type Cobb–Douglas to measure the impact of technological innovation and the productivity on economic growth in Uganda. He found that as technological innovation enhances economic growth. While the labor and capital productivity has reduced economic growth. He explains this result by the low productivity of the workforce who prefers leisure than work.

Fadavi et al (2010) analyzed the impact of mechanization on production through a survey of a diverse swatch contains 80 apple growers in Iran. They have obtained results as mechanization could not vary significantly because of the increased labor and energy cost during the harvesting operation. According to these authors, the agricultural mechanization is a destruction source of the land and natural resources.

Blazy et al (2011) indicate that, the improvement in agricultural production based on the reduction of pesticide use and renovation of soil fertility in the fight against weed, provide the nitrogen to the soil without insecticides increases in numbers, each of this way has led to technological innovation. According to the authors the innovations also have different effects on the net operating income and the productivity. The implementation of some innovating method in the agricultural sectors based on environmental, social and economic conditions.

Blazy et al (2011) conducted a survey on conventional farmers and organic banana farmers to have the most efficient technology adopted in the French Antilles (Guadeloupe and Martinique). They are found as a result that mechanization will be a source of sustainability in the production of organic banana due to its negative impacts on the environment.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recent research shows that agricultural development is improving by the technological innovation, but whereas the durability can affect positively or negatively by the mechanization as it explains Khaled and al (2016) in his empirical analysis that is founded on the OLS modeling.

The innovation in agriculture and rural enterprise comes from whatever source (formal or informal) of new modes in the production and organization of agricultural activity.

The rural populations have a human capital integrating essential sources of knowledge and new procedures through their knowledge and modes of organization.

Good solutions found by small farmers themselves are a necessary source for enhancing agricultural productivity of developing countries.

Poole (2006) explains that, the mechanism and the level of research and innovation in the formal agricultural system have increased in the eighteenth and nineteenth century later has the use of scientific methods in relatively advanced economies (quoted by Khaled et al, 2016).

The R&D preferences in agriculture were encouraged during the last century by the government, which led to the birth of the formal national research systems in advanced and developing countries and the creation of organism's international research.

The green revolution is represented as a result of public research or as a classic example of a method giving land ownership to the farmer.

At this point, we can say that innovation is constituted by various researches and it can be spread through different distribution procedures by economic historical, political, institutional and climate contexts. In recent years, the increasing advances in technology led to the creation of technology platforms such as information and communication technology (ICT) and biotechnology (Khaled et al, 2016).

EVALUATION OF SOCIOECONOMIC AND ENVIRONMENTAL FACTORS

Energy

The farming surroundings and the agricultural sectors endure mediocrity of the infrastructure and the lack of information. These two difficulties cause the reduction of the outputs of the agricultural production and the decrease of the level of employment in this sector, what conducted to the apparition of poverty in these surroundings (Khaled et al, 2016).

For solving these problems, it is necessary to encourage the investment in the energy since he/it is considered like means of enhancing the life quality for rural populations, while being based on the technologies, in particular of information and the communication.

The lack of infrastructure and high costs are often explained by the lack of rural energy associated with various social, economic and political difficulties.

The energy is necessary to reinforce the nonagricultural farming economy directly and the agricultural farming economy indirectly.

The current price of oil and its derivatives can release hazardous effects that affect various areas such as air pollution, sea pollution that led to the decline the marine resources and soil pollution and thus to reduce the fertility of agricultural land and subsequently to lower yields and lower employment in this sector, Which encourages migration from rural to industrial or other services.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Energy supply associated with conventional technologies in rural areas can be more expensive. The social and environmental benefits of the development of services based on energy sources other than oil are viable.

We must invest in the energy sectors other than oil for environmental and economic reasons, such as wind and solar energy, which are technically feasible for local markets in rural areas.

Poverty Reduction

The project " objectives of the millennium for the development " (OMD) defined real strategies to avoid poverty while improving the investments in the infrastructure and the human capital in the farming surroundings, what permits to improve the agricultural sector by a qualified manpower, as well as the increase of production following the increase of the transportation means and thereafter a growth of the outputs and a reduction of poverty in the background farming, while motivating the equality between the sexes and the protection of the environment (Khaled et al, 2016).

The project of the OMD includes the science, the technology and the innovation and permits to apply the knowledge to the development.

The difficulties faced by developing countries in innovation are not related to the creation of new knowledge, but the effective use of existing techniques.

The System of Supermarkets

The impact of the international proliferation of large series on food retail sectors was generally analyzed for developing countries and also in several other regions such as Latin America, Central and Eastern Europe, sub-Saharan Africa and Asia (Khaled et al, 2016).

In developing countries, to reason at a time of demand bound to the tendency of the local life forms and to the big international business entry, the food systems are quickly going to be complex. In Tunisia the international supermarket entry is increasing with the time the sample Carrefour Market that has developed in most regions of Tunisia.

However, the international supermarket is a novelty that ensures the sale of food products, such as fresh produce, namely fruits, vegetables, meat and fish, which promotes the growth of production in the two sectors agriculture and fisheries.

So the international supermarket is an innovation that improves several areas such as fisheries and agriculture, and for industry.

Khaled et al (2016) indicates that, the international supermarket system offers the advantages that are the development of the employment in these stores and in their specific supply chains, an overall increase in the quality of food coming from the technology transfer and commercial uses of farmers.

National supermarkets are represented as major suppliers and demanders of local products, in the less advanced countries. These companies run into relationship marketing and ensure the root of supply series. This new business model is distinguished by low margins and high quality, creating new opportunities and new challenges for providers, such as self-service sales, healthy environments, indicating prices, the aggressive marketing and the promotions are henceforth the strategic norm (Cadilhom et al, 2006).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The development of monopsony system and economies of scale associated with the production, the basis of the standards and the organization rule and multiplication of knowledge to make, transmission of the markets that explains the situation of the small agriculturists of the difficult zones that is outside of these markets.

Agricultural Evolution in the Maghreb Country

The Maghreb region includes richest country in oil and gas (Libya, Algeria) and countries whose resources are very limited compared to their populations (Tunisia, Morocco and especially Mauritania) throughout the region of Africa north (Khaled et al, 2016).

To solve this problem of limited natural resources, many economic and political leaders put agriculture in question. For all the Maghreb countries, the agricultural sector remains of major importance in the economic, social and political level.

The sector must continue to achieve two strategic objectives: the protection of the development of basic agricultural products so-called strategic (cereals, milk, potatoes and sugar) and compensation for producers in the event of agricultural disasters.

Globally, on the basis of the green revolution goal, the success of these R&D should result increased the production volume of basic agricultural products, by increasing yields and agricultural productivity and lower the level of agricultural imports expensive and rarely by the degree of respect and apply the principles of sustainable development (Khaled et al, 2016).

So the use of new technologies such as cultural diversity or animal genetic material shows very contradictory results, with rising environmental costs (protection of forest areas and backgrounds, the use of mechanization on fragile soils with increased erosion, ...) and the social costs (loss of a genetic heritage applied to the arid conditions, deterioration of the collective actions with the individual production motivations).

In some difficult areas, these new technologies do not find their place because of the lack of infrastructure for production and transport, and low participation in services such credits to finance the costly inputs.

Also applied research, partly in experimental research institutions overlooked the local expertise of the actors and the spread of this research was done at the expense of local knowledge which ensured a balance between the medium and the community.

In the arid media, the options distribution difficulties are in intensive systems, which have been frequently reduced for social reasons, such as non-rationality of producers or low level of education in marginal and disadvantaged areas, etc.

The basic consequence is the reduction of the actions to the destructive technical applications of the nature to restrict the environmental risks, in particular the risks of drought.

However, facing the demographic increase of the Maghreb countries, and in light of the urbanization and unemployment increases rates attached to the emigration from the marginal surroundings, of the pastoral zones deterioration, the increasing desertification problem, and the weak technological transfer of research in the difficult zones that correspond to more of 85% of the territory, the agricultural research was interested again controlled in the small and medium agricultural farmers of the arid and semi-arid zones, but this new orientation made itself it in a setting of liberalization, from the years 80, named pre – adjustment period.

Table 1. Summarize the tendency of socioeconomic and environmental factors such as the agriculture productivity, energy production, number of mechanization and the net income per capita in the three Maghreb countries in 2005 and 2010

Country	Agriculture Productivity		Energy Production		Number of Mechanization For 100 Square km		Net Income Per Capita	
	2005	**2010**	**2005**	**2010**	**2005**	**2010**	**2005**	**2010**
Algeria	8.221	9.0	166662.44	150524.713	128	141	10270	12630
Morocco	14.677	14.4	610.282	879.445	490	490	4710	6200
Tunisia	10.127	8.2	6681.4	8120.509	127	120	7360	9800

(WDI, 2014).

The above table measures the evolution of socioeconomic factors (agricultural productivity, number of mechanization and net revenue per capita) and the environmental factor (energy production) in the two years 2005 and 2010.

The table showed that, in Algeria, the all socioeconomic factors increase by against the environmental factor such as energy production is dropped. In Morocco, the number of mechanization remains constant during the years 2005-2010. While the net income per capita increases despite declining agricultural productivity and increases of energy production. In Tunisia, the number of mechanization has decreased, as well the agricultural productivity. While net revenues per capita and energy production have increased.

This table indicates that mechanization has evolved with the same sense of agricultural productivity and inversely to the energy production. This trend explains that mechanization is the motor of productivity (Feder et al, 1993) and production in Maghreb countries.

The Maghreb countries are characterized, in recent years, by the introduction of green and not productivist technologies, for this reason the number of mechanization is reduced as the case of Tunisia (Boughanmi 1995).

However, the adoption and dissemination of this model seem to be moving very slowly because mainly of its uniformity and lack of adaptation to regional diversity and heterogeneity of production systems in Maghreb countries. The biological and chemical technologies (improved seeds, chemical fertilizers) are basically neutral about the size of the operation and can be adopted by both large and small farmers, provided that an effective extension system, closely related research and near the farmer (Ruttan, 1985; Boughanmi 1995). The Tunisian experience related to extension remains too rigid administrative and involving little agricultural profession, despite some reforms in the direction of decentralization and coordination of extension programs.

Econometric Methodology and Data

The approach selected in this paper was to model the mechanical innovation impact on the agriculture sustainability in the Maghreb countries. Our initial intention was to cover all countries in the Maghreb, but given that some countries have not yet data of agricultural productivity (for example, Libya, Mauritania), the samples are included only 3 Maghreb countries: over the period of 1999-2012.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Data

Data were extracted from two sources, the data will be used for the measurement of variables are taken from the database of the World Development Indicators (WDI 2014) and food agriculture organization (FAO 2014).

Information related the expenses in research and development "R&D" (ERD), the expenses in information and communication technology "ICT" (EICT), the CO2 emission (CO2_E) and the demographic growth (DG) are collected from Worlds Development Indicators (World Bank, 2014). Other information related to agricultural productivity (AP), the mechanization, the Labor (L), the farming population (FP) is collected from food agriculture organization (FAO, 2014).

The dependent variables of interest are agriculture productivity, energy production and net income per capita.

The Variables

Our analysis founded on macroeconomic factors:

- **Agricultural Productivity (AP):** Agriculture in value added by the worker (% of GDP) (WDI, 2014). V. Ruttan (1974) indicates that the agricultural growth, improvement begins with the apparition of one sustained increase period in the total productivity via the use of new factors and new technologies; our technology is the system of irrigation (Khaled and al, 2014).
- **The Expenses in Research and Development (ERD):** Clark and Youngblood (1992) showed that the variable " technology ", as the expenses of the R&D changes the supple utilitarian shape with time is included in the specification of the function of profit, this variable permits to solve the problem of tendency of time (Thirtle and al, 1995). The R&D is the key of development and modernization of the agricultural sector (quoted by Khaled and al, 2016).

Even in the developed country, the agricultural systems of research meaningful are dedicated to testing and refined the innovations of the agriculturists and to test the adaptation of exotic exploitation varieties and the species of the animal (Ruttan, 1974).

- **The Expenses in Information and Communication Technology (EICT):** Permits to improve the sector by the diffusion of innovation to the world level and the diffusion of the R&D toward the producers and the consumers.

The ICT decreases the uncertainty of the producers concerning the bought input and of the consumers concerning the consumed product (Feder et al, 1993).

- **The Mechanization (M):** It is a very important technology to improve the outputs of producers. (Clay, 1982).
- **The labor (L):** Alani (2012) proved that the labor is considered as a technology that permits of replaced the machinery in some cases to keep the durability of the sector.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **The Farming Population (FP):** Himself the producers, the consumers and the manpower. The farming sociologist research has contributed to the diffusion efficiency of technology (Ruttan, 1974).
- **The CO2 Emission (CO2_E)**: Carbon dioxide emissions are those stemming from the burning of fossil fuels and the manufacture of cement. They include carbon dioxide produced during consumption of solid, liquid and gaseous fuels and flaring (WDI, 2014). This variable is defined by Soni and al (2013) as environmental determinant.
- **Demographic Growth (DG):** The population growth (annual %) corresponds to the exponential growth rate of the population in the middle of the year n-1 to n, expressed as a percentage. (WDI, 2014). SemihAkc-omak et al (2009) and Van Rijn and al (2012) indicates that, the demographic growth is a factor of social aspect.

Econometric Methodology

From a methodological viewpoint, we chose to value the involvement of the innovations technological to the durability and the growth of the agricultural sector based on the standard production function of Cobb - Douglas type (1928) improves by Dowricks and Rogers (2002) respecting the properties traditional neoclassical (Khaled and al, 2016).

$$Y = AK^{\alpha k}H^{\alpha h}L^{\beta} \text{ or } \beta = 1 - (\alpha_k + \alpha_h) \quad (1)$$

Where, Y is a dependent variable which is defined by agricultural productivity, CO2 emission and demographic growth. K, H, L and A are, respectively, the physical capital, the human capital, the labor that grows to the rate exogenous and constant " n ", the technical progress is neutral in the sense of Hicks (1932) and αk, α_h, β are the production elasticity's (Khaled et al, 2016).

However to evaluate the participation of mechanical innovation, we decomposed the stock of physical capital in two parts: the material, physical capital is the mechanization (M) and the immaterial physical capital is the expenses in the information and communication technology ICT (EICT).

The ERD is the investment in human capital, according to the theory of human capital (Nafiou, 2009).

The expenses in R&D (ERD) and the expenses in the technology of information and communication, ICT (EICT) are considered like an investment in the innovation (OECD, 1999).

The stock of the labor is decomposed into two parts: the labor in the agricultural sector (L) and the farming population (FP).

The goal of this paper is to examine the relationship between mechanical innovation and agricultural sustainability through the impact of mechanization on agricultural productivity, CO2 emission and demographic growth.

This relationship is measured by a simultaneous equations model (3SLS) extended as follows:

$$AP_{it} = \alpha + \beta_1(EICT)_{i,t} + \beta_2(M)_{i,t} + \beta_3(ERD)_{i,t} + \beta_4(L)_{i,t} + \beta_5(FP)_{i,t} + \beta_6(CO2_E)_{i,t} + \beta_7(DG)_{i,t} + \xi_{i,t} \quad (2)$$

$$CO2_E_{it} = \alpha + \beta_1(EICT)_{i,t} + \beta_2(M)_{i,t} + \beta_3(ERD)_{i,t} + \beta_4(L)_{i,t} + \beta_5(FP)_{i,t} + \beta_6(AP)_{i,t} + \beta_7(DG)_{i,t} + \xi_{i,t} \quad (3)$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$DG_{it} = \alpha + \beta_1(EICT)_{i,t} + \beta_2(M)_{i,t} + \beta_3(ERD)_{i,t} + \beta_4(L)_{i,t} + \beta_5(FP)_{i,t} + \beta_6(AP)_{i,t} + \beta_7(CO2_E)_{i,t} + \xi_{i,t} \quad (4)$$

$i = 1, 2,\ldots N, t = 1,2,\ldots Ti$

Where AP, CO2_E and DG are the dependent variables, are defined respectively as agricultural productivity, CO2 emission and demographic growth. The Independent variables are the expenses in research and development (ERD), the expenses in information and communication technology (EICT), the mechanization (M), the labor (L), and the farming population (FP).

Equation (2), allows measure the impact of mechanical innovation on economic sustainability through the effect of the mechanization (M) on the agriculture productivity (AP), as well as the spending of research and development (ERD) and spending of information and communication technology (EICT) impact.

Equation (3), allows examine the impact of mechanical innovation on environmental sustainability through the effect of the mechanization (M) on CO2 emission (CO2_E), as well as the spending of research and development (ERD) and spending of information and communication technology (EICT) impact.

Equation (4), examines the impact of mechanical innovation on social sustainability through the effect of the mechanization (M) on the demographic growth (DG), as well as the spending of research and development (ERD) and spending of information and communication technology (EICT) impact.

Our methodology is based on an estimate of the simultaneous equations model (3SLS), a sample of 3 Maghreb countries (Algeria, Morocco, Tunisia) and a measurement of the variables from the data for the countries will of 1999 until to 2012.

This simultaneous equations model is estimated by the generalized method of moments (GMM). Since generally, the results of GMM are robust.

RESULTS AND INTERPRETATION

Table 2 provides summary statistics on the variables.

Table 2. Descriptive statistics

Variable	Mean	Std. Dev	Min	Max
AP	12.04083	3.502358	6.68	20.223
ERD	.5452381	.331392	.07	1.5
EICT	4.497619	3.163703	1.5	14.5
L	6.506214	2.970074	2.3	10.9
FP	39.64065	4.713145	33.902	47.6508
M	5.632143	2.200882	2.45	8.1
CO2_E	2.215405	.717636	1.132	3.529

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2 shows that the average agricultural productivity, the entire sample is 2.437398%. The inter-individual variance (between) 0.0908%, while the intra individual variance (time) is equal to 0.0172%, in our case the inter-individual dimension (3 countries) is very important that the intra-individual dimension (17 years country) (0.0908%> 0.0172%). The same for the regression (3) and (4).

Table 3 summarized the results of three least squares (3SLS) models for the sample of the 3 Maghreb countries from 1999 to 2012.

The first column presents the effect of mechanization on economic sustainability through their impact on agricultural productivity. The second column indicates the effect of the mechanization on environmental sustainability through her effect in CO2 emission. The third column shows the impact of mechanization on social sustainability through her effect on demographic growth.

According to the regression (2), we show that, the variables: population growth (DE) and expenditure of R&D (ERD) are positive and significant at the 5% and 10% level. The variables: labor (L) and mechanization (M) are negative and significant at the 1% level. While the variables: expenditure of ICT (ECIT), farming population (FP) and a CO2 emission (CO2_E) are positive and not significant.

The above table (regression 2) shows that, where agricultural productivity (AP) increases by 1 percentage points, mechanization (M) decreases by 1.747371 percentage points and labor (L) decreases by 0.4338862 percentage points. By against, demographic growth (DG) rise by 3.887044 percentage points and R&D expenditure (ERD) increase by 2.011479 percentage. This result is similar to the study of Fadavi and al (2010) and Khaled et al (2016).

Table 3. The model estimation by the 3SLS method

Models	**(2)**	**(3)**	**(4)**
Variables	**AP**	**CO2_E**	**DG**
AP	---	.0213774 (0.386)	.0679745 (0.000)***
CO2_E	.8139869 (0.386)	---	.3073321 (0.010)***
DG	3.887044 (0.000)***	.4615501 (0.01)***	---
M	**-1.747371 (0.000)*** **	**.0752307 (0.000)*** **	**-.0032265 (0.962)**

EICT	.0069395 (0.936)	.0263234 (0.049)**	-.0141828 (0.206)
L	-.4338862 (0.000)***	.076319 (0.000)***	.0193965 (0.202)
FP	.1810303 (0.107)	.0436239 (0.013)**	-.028774 (0.057)*
Constant	9.928643 (0.106)	-3.26619 (0.000)	.9223143 (0.264)
Observations	42	42	42
R^2	0.9220	0.9524	0.6737

Note. — Panel estimations of the 3 Maghreb countries. The dependant variable is the agriculture productivity (AP), CO2 emission (CO2_E) and the demographic growth (DG). Variables in parentheses are at the significance level of 1% *, 5%** and 10%***.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

This negative impact of mechanization on the economic sustainability explains that the mechanization cannot achieve economic efficiency in the Maghreb countries due to the intensive use of mechanization in the sector, allowing deteriorate soil fertility over time and eventually lowers productivity and performance in the agricultural sector (Fadavi and al, 20101).

The variables: expenditure of ICT (ECIT), farming population (FP) and a CO2 emission (CO2_E) are not significant because the relationship is indirect with agricultural productivity. This relation is created through other factors such as labor, energy production, etc.

In the regression (3), we mark that, the variable expenditure on R&D (ERD) is negative and significant at the 5% level and the: expenditure on ICT (EICT), labor (L), farming population (FP), mechanization (M) and population growth (DG) are negative and significant at the 1% and 5% level. While the variable: agricultural productivity is positive, but not significant.

The above table indicates that, when CO2 emission (CO2_E) rises by 1 percentage points, mechanization (M) increases by 0.0752307 percentage points, labor (L) increases by 0.0752307 percentage points, demographic growth (DG) rise by .4615501 percentage points, communication and information technology expenditure (EICT) increase by 0.0263234 percentage points and farming population (FP) raises by 0.0436239 percentage points. However, R&D expenditure (ERD) drops by 0.3136046 percentage points.

According to the study of Kallivroussis et al (2002); Soni et al (2013), the use of mechanization in the agricultural exploitation causes diffusion of pollution in the soil and in the air as CO2 which leads eventually to the reduction of soil fertility, development of diseases in rural areas, etc.

The variable agricultural productivity is not significant because of its indirect relation with the issuance of CO2.

Regression (4), indicates that, Variables: expenditure of R&D (ERD) and rural population (FP) are negative and significant at the 5% and 10% and the variables: agricultural productivity (AP) and a CO2 emission (CO2_E) are positive and significant at 1%. While the variables: mechanization (M) and expenditure on ICT (EICT) are negative and not significant and variable labor (L) is positive but not insignificant.

The above table suggests that, demographic growth (DG) increases by 1 percentage points, the CO2 emission (CO2_E) rises by 0.3073321 percentage points and the agriculture productivity (AP) increases by 0.0679745 percentage points. Whereas, R&D expenditure (ERD) and farming population (FP) decreases respectively by 0.2275172 percentage points and 0.028774 percentage points.

The variables mechanization (M), expenditure of ICT (EICT) and labor (L) are not significant. These results explain the indirect relation between this factor and demographic growth.

According to the regression 2 and 3 analysis, mechanization (M) can affect negatively the demographic growth by diffusion of CO2 in the soil and air (regression 3) which subsequently leads to disease development and subsequently the reduction of population growth. The CO2 diffusion induces to soil degradation and subsequently the decline in productivity and production (regression 2) agricultural which causes the increasing undernourishment and decreased demographic growth.

Mechanization improves the purchasing power of Employers in the industrial sector such as an equipment manufacturing society, for against the rural population suffers from very high level of poverty. As he explains Timmer (1992), the agricultural sector is like a black box, it provides power to all the other sectors against it is not growing.

In the Maghreb countries, the mechanization affects negatively the environmental, economic and social sustainability's.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

According to the results of the simultaneous equations model (3SLS) estimation, we noticed that the workforce has a negative role in the functioning of agricultural machines (Ruttan, 1974). The regressions (2) show that the relationship between agricultural productivity and labor is negative (0.4338862).

Labor recruited in the agricultural sector of the Maghreb countries is unqualified. It is malfunctioning agricultural machinery and deteriorates the production by ecological footprint (Fersino et al, 2002).

The impact of mechanization on economic, social and environmental aspects is explained by the effect of labor on the three durability's. The workforce in agriculture of the Maghreb countries is unqualified. The lack of learning by doing in the agricultural sector prevents increasing performance and productivity through ecological footprint, poor use of fertilizers, spreading pollution and over-exploitation of water resources (Feder et al, 1993).

The result of the estimated regression 2 and 3 shows that the level of research and development have a negative impact on the environmental and social aspects through their impact on CO2 emission and demographic growth, this result can be interpreted by the novelty of the sustainable agriculture in the Maghreb countries, such as organic farming. These results are similar to studies of Esposti (2002), and Khaled et al (2016).

Biological research and development remains until today in the laboratories and has not yet applied to a field.

The information and communication technology (ICT) has a positive effect on environmental aspect, this result is explained by the introduction of new technology (mobile, internet, etc.) in rural areas and their participation in the agricultural sector through improved marketing of an agricultural product line, development and definition of sustainable agriculture concept and organic products in the Maghreb countries (Khaled et al, 2016).

The result of the estimated regression 3 indicates the farming population affects negatively the environmental aspect through their impact on CO2 emission.

The population increase in rural areas increases the pollution in the zone and increases the use of water resources, leading to over-exploitation of natural resources.

Mechanization used by Maghreb countries is not sustainable since it cannot achieve the sustainable development aims in the agricultural sector of the Maghreb countries.

RECOMMENDATION POLICY

The results of the model estimation 3SLS include policies of very important implications for producers and consumers of sustainable agriculture in the Maghreb countries are listed as follows:

1. The government support for funding and Development: The Maghreb Farmers need for state subsidies to buy sustainable agricultural machines with good quality. They also need the development of their rural areas by building infrastructure to attract investors to invest in the agriculture sector.
2. Improve training in the rural middle, especially how to operate farm machinery: the workforce in the agricultural sector of the Maghreb countries is not qualified because of their limited education level. The majority of labor worked in agriculture is the farming population.
3. The development of environmental protection strategy and implementation in the rural middle, for example, the payment of fees for people that generate negative externalities in the rural areas.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

SUGGESTION

In order to enhance the estimation model, this section suggests some recommendations for future studies. There are a few studies that examine the mechanical innovation and their role in determining the agricultural sustainability. Research on the innovation of sustainable agriculture, in recent years, begins to develop, but many questions remain unanswered or their answers are ambiguous. This section provides suggestions for future study. The empirical studies that are performed on innovation for sustainable agriculture focus on the Maghreb countries. Future studies on the mechanization factors and their impact on the agriculture sustainability could focus on a large sample of developing countries that exceeds 3 countries. This is to analyze the trend of impact method of sustainable and innovative culture on socioeconomic (the cost of production and transportation, the qualification of manpower, funding for agricultural sector), institutional, policies (agricultural sustainability policy) and biophysical (protection of natural resources) factors in these countries. The future studies should compare the level of development of sustainable agriculture in developed countries and developing countries.

CONCLUSION

The concept of sustainable development has spread during the 90s in scientific research both locally and planetary. All this research agrees that the achievement of sustainable development depends on the respect of three essential principles: equity between nations and generations, the equilibrium of the economic situation and the protection of the environment (Khaled et al, 2016).

On this basis, several economists and scientists believe that the diffusion of technological innovation is a basic means to ensure sustainable development in the agricultural sector.

To verify this effectiveness, we tested the effects of mechanical innovation on the agricultural sector in the three Maghreb countries (Tunisia, Morocco and Algeria) for a period from 1999 to 2012 by a model of simultaneous equations, as well as their ability or non to achieving the objectives of sustainable development in agriculture sector.

The estimation results show that mechanization used by Maghreb farmers is unsustainable. For this it's unable to achieve the sustainable development objectives in the agricultural sector of Maghreb countries. The mechanized agricultural land use may lead to reduced fertility and increased pollution. This result is similar to the study of Khaled and al (2016).

A recent study done by CEMA (2014) indicates that there are 12 types of agricultural mechanization in the world. The weak type is used by developing countries, particularly Africa. It can be concluded that the poor quality of mechanization used by Maghreb countries negatively affects the agricultural sector sustainability.

Chapter 15
Deployment of Wireless Sensor Networks for Soil Macronutrients Measurements in Farms

Daudi Samson Simbeye
Dar es Salaam Institute of Technology, Tanzania

ABSTRACT

Farmers need accurate information about soil nutrient content if they are to apply the correct amount of fertilizer. Farmers who do not practice regular soil tests are facing numerous difficulties such a lack of accurate statistical information for soil and crop management, increased costs for fertilizers, and environmental degradation. However, traditional laboratory testing is costly and laborious, taking up to three weeks to complete. This study presents a technology which integrated various elements into a portable in-field device that measures soil macronutrients of nitrogen (N), phosphorus (P) and potassium (K) and soil pH. Then it transmits the measured data wirelessly to remote base station for analysis, presentation and storage in real-time. Farmers can access the information from the base station server through their mobile phones. Firstly, the grower can use the test data to provide important indicators into the levels of nutrients in the soil which can be interpreted to stem over-use or under-use and efficiently manage their fertilizer application. Secondly, the system can decrease response time for the grower to implement alterations in the soil nutrient composition. And lastly, it can increase the awareness of precision agriculture, its benefits and usage amongst the average farmer. The results from this test provide important indicators into the levels of nutrients in the soil which can be interpreted to stem overuse or under-use. The grower can use the data compiled to efficiently manage their fertilizer application.

1. INTRODUCTION

All essential elements are by definition required for plant growth and completion of the plant life cycle from seed to seed. Some essential elements are needed in large quantities and others in much smaller quantities. However, from a practical standpoint, three of the six essential macronutrients are most often "managed" by the addition of fertilizers to soils, while the others are most often found in sufficient

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

quantities in most soils and no soil amendments are required to supply adequate quantities. From a management perspective only, the primary nutrients are Nitrogen (N), Phosphorus (P), and Potassium (K), because they are most often limiting from a crop production standpoint. All of the other essential macronutrient elements are secondary nutrients because they are rarely limiting, and more rarely added to soils as fertilizers (Amundson, Guo, & Gong, 2003; Brady & Weil, 2002).

Nitrogen is a part of all living cells and is a necessary part of all proteins, enzymes and metabolic processes involved in the synthesis and transfer of energy. It is a part of chlorophyll, the green pigment of the plant that is responsible for photosynthesis. It helps plants with rapid growth, increasing seed and fruit production and improving the quality of leaf and forage crops. Nitrogen often comes from fertilizer application and from the air (legumes get their N from the atmosphere, water or rainfall contributes very little nitrogen) (Schaetzl & Anderson, 2005).

Like nitrogen, phosphorus (P) is an essential part of the process of photosynthesis. It is involved in the formation of all oils, sugars, starches, etc. It helps with the transformation of solar energy into chemical energy, proper plant maturation, and withstanding stress. Phosphorus effects rapid growth, encourages blooming and root growth. Phosphorus often comes from fertilizer, bone meal, and superphosphate (Schaetzl & Anderson, 2005).

Potassium is absorbed by plants in larger amounts than any other mineral element except nitrogen and in some cases, calcium. It helps in the building of protein, photosynthesis, fruit quality and reduction of diseases. Potassium is supplied to plants by soil minerals, organic materials, and fertilizer (Schaetzl & Anderson, 2005; Silva & Uchida, 2000).

Deficiencies of nutrients in plants have various visual symptoms that are usually similar regardless of the species. The most common deficiency symptom is reduced growth, which is difficult to detect and diagnose at a glance. Other visual symptoms usually involve changes in coloration following a specific pattern, such as from the leaf tip down the midrib towards the base of the leaf or from the leaf margin toward the midrib, or between the veins of the leaf. Such symptoms may appear in new leaves or old leaves, indicating the phloem-mobility of the deficient nutrient and the ability of the plant to translocate existing stocks of the deficient nutrient (Havlin, Beaton, Tisdale, & Nelson, 2005; Hillel, 2004; Lutgen & Tarbuck, 2004).

With nitrogen deficiency, plants often have stunted growth; leaves develop a yellow color, which is a condition known as chlorosis. Since nitrogen is a mobile nutrient within the plant, nitrogen moves from older growth to new growth when deficient. As a result, nitrogen deficiencies first appear in older leaves. Since deficiency symptoms are sometimes difficult to diagnose, the location of the symptom (new or old growth) helps us determine which nutrient, if any, is deficient. When nitrogen is severely deficient, chlorotic leaves may die and fall off the plant (Silva & Uchida, 2000; Soil Survery Staff, 2007).

Plants often have overall stunting, particularly during the early stages of growth during phosphorus deficiency. Phosphorus is a mobile nutrient; and so, symptoms first appear in older growth. When deficient, older leaves develop a dark green to blue green color. In certain corn and grass species, older leaves may develop a purple coloration. Phosphorus deficiencies can cause poor fruit and seed development as well as delay crop maturity (Silva & Uchida, 2000; Soil Survery Staff, 2007).

Likewise, plants often experience stunted growth with potassium deficiency. Like nitrogen and phosphorus, potassium is a mobile nutrient. Older leaves may develop chlorosis along the margin, or edge, of leaves. Certain crops may have weaken stalks, which causes lodging (toppling over) (Silva & Uchida, 2000; Soil Survery Staff, 2007).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Soil pH is one of the most important soil properties that affect the availability of nutrients. Macronutrients tend to be less available in soils with low pH and more available in soils with high pH. Lime can be added to the soil to make it less sour (acid) and also supplies calcium and magnesium for plants to use. Lime also raises the pH to the desired range of 6.0 to 6.5. In this pH range, nutrients are more readily available to plants, and microbial populations in the soil increase. Microbes convert nitrogen and sulfur to forms that plants can use. Lime also enhances the physical properties of the soil that promote water and air movement (Silva & Uchida, 2000).

Growing concerns about environmental pollution by excessive use of fertilizers have led to increasing needs to monitor soil nutrients required for crop growth. Traditionally, such measurements have been carried out in a central laboratory, involving time-consuming sampling, transportation and storage steps. On-site monitoring of Nitrogen (N), Phosphorus (P) and Potassium (K) nutrients is preferable due to the potential for a higher density of measurements at a relatively low cost, allowing more efficient mapping of soil nutrient variability for variable–rate nutrient management. We need better soil information to solve pressing problems such as how to monitor the effects of climate change on soil, how to use precision agriculture for improving the sustainability and efficiency of food production and how to assess and remediate contaminated land (Kim, Sudduth, & Hummel, 2009).

The macronutrients (nitrogen, phosphorus and potassium) are managed and replaced as fertilizer on a crop-by-crop basis. They represent a significant input cost of food production both financially and environmentally. Excessive nitrogen fertilizer can subsequently leach soil nitrates into waterways and have direct consequences on human and environmental health and water quality (Rossel, Adamchuk, Sudduth, McKenzie, & Lobsey, 2011). Since no proven economical methods has been yet devised to effectively and efficiently allocate chemicals to meet crop needs, significant energy waste occurs in application of agriculture chemicals. Consequently chemicals and fertilizers are applied in uniform amount irrespective of local changes in soil chemical conditions (Mishra, Mapara, & Vyas, 2015). The solution to this problem can be the use of sensors capable of determining several analytes, such as soil macronutrients and pH, simultaneously. It would further reduce sample processing time, sample volume and reagent consumption. Integration of the multiple data streams available from such sensors might provide improved estimates of the individual analytes through its ability to quantify and factor out any cross-channel responses (Kim et al., 2009).

However, traditional variable rate methods used in soil sampling are time consuming, costly and not accurate. Thus, they fail in providing a true estimate of the nutrients soil needs. To obtain better crop response to inputs, a rapid, non-destructive, timely and cost-effective soil analysis are needed to enable site-specific fertilizer applications (Jimenez-Donaire, 2015). Inorganic fertilizers, in particular nitrogen-based fertilizers, have revolutionized agriculture. However, effective management of the amount of fertilizer used on land is becoming ever more important for many reasons including economic efficiency and for sustainable agricultural practices to preserve and enhance crop yields and avoid damage to the environment and to human health. In order to accurately supply the right amount of nutrient for crop growth it is important to know what nutrient reserves exist within the soil. Nitrogen is highly mobile and therefore needs to be monitored more regularly than phosphorus and potassium as these are more stable and changes in levels are slower. They also hope that the real-time information detected by the sensor and used to prescribe the application rate would optimize the overall economic or agronomic effect of the production input. The values obtained may not be as accurate as a laboratory test, but the high sampling density may increase the overall accuracy of the resulting soil nutrient or pH maps. Conventional soil testing methods, however, which combine soil sampling in the field and chemical analysis in the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

laboratory, are costly and time consuming, thereby limiting the number of samples analyzed in the field and making it difficult to characterize spatial variability in soil nutrient concentrations in an agricultural field (Schepers & Schlemmer, 1998; Artigas et al., 2001; Kim, Hummel, Sudduth, & Motavalli, 2007).

When soil test results are combined with information about the nutrients that are available to the various crops, a reliable basis for planning the fertility program can be established (Hoeft, Peck, & Boone, 1996). Soil nutrient monitoring can be used to reduce fertilizer and application costs, diagnose soil problems and evaluate crop performance and economic returns based on nutrient utilization. These applications have prompted the development of sensors to measure soil properties and complement the more conventional laboratory techniques used for their analyses (Rossel et al., 2011).

Wireless sensor network (WSN) devices are now widely used for real-time environmental monitoring as well as in agriculture, on ground that, they allow conditions to be monitored continuously and on a remote basis. They have proven to be powerful tools for monitoring short-term variations in these parameters particularly in agriculture. Wireless sensor network (WSN) monitoring schemes have the advantage of easy installation, convenient maintenance and cost effective. Moreover they are update, flexible as to information and inspection as compared to traditional wire monitoring system (Yoshikawa, Murata, Furuya, & Eguchi, 2007).

In this work, ZigBee wireless communication technology (IEEE 802.15.4) is preferred over other technologies for the development of wireless sensor network due to its low cost and low power consumption property (Simbeye, Zhao, & Yang, 2014; Simbeye & Yang, 2014). This paper proposes a real-time wireless sensor network system that enables sensor data to be delivered within time constraints so that appropriate observations can be made or actions taken. Obtaining these accurate real-time results in-situ allows growers to determine how much fertilizer their land actually needs, therefore saving of money through efficient application of fertilizer, ensuring that crops are not malnourished (disease management), which would result in wasted resources and capital and safeguarding the surrounding environment from harmful pollution. This research will provide farmers with constant monitoring of fields, tailored crop analysis and disease management, making information on the nutrient status of arable land easily accessible and available to the farmer anytime anywhere.

2. RELATED WORKS

Although traditional lab analyses provide accurate results, they neglect local spatial variation in macronutrient concentrations within a soil area. They usually involve either random, adaptive, or grid sampling techniques. In random sampling, soil cores are obtained randomly within the field. In adaptive sampling, prior information is used to select locations for soil core samples. In grid sampling, soil cores are collected from predetermined points in the field. None of these soil sampling practices has been recognized as the most effective (Adamchuk, Hummel, Morgan, & Upadhyaya, 2004). The chemical analyses required to create a precision fertilization scheme that accounts for such variation involves extremely intensive and complex laboratory testing that demand a lot of time and cost. In the past, many have viewed this technique as physically impractical and cost prohibitive over a large area of farmland. Furthermore, colorimetric methods hinder real-time information supply. Modern agriculture demands continuous information of chemical and physical soil parameters, which is not available with traditional techniques (Lemos et al., 2004; Mouazen, Maleki, De Baerdemaeker, & Ramon, 2007).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sensors provide quantitative results and can be more time and cost effective than conventional laboratory analyses. They are becoming smaller, faster, wireless and more accurate, energy efficient and intelligent (Rossel et al., 2011). A multi-parametric analytical system for measuring primary nutrients contents in cultivated soil was developed for on field analysis using the techniques as UV Spectroscopy. The authors analyzed soil propertie for accurately mapping various primary nutrients in the soil. Various soil samples were taken from cultivated farms at the agriculture college, Pune. The results were as the concentration of the primary nutrients (N, P and K) varies the maximum absorbance of soil sample also varies. However, some drawbacks include atmospheric and soil interference and the high cost of instruments. Soil fertility research has established measure of macronutrient concentrations in the soil that are enough for field crop production without further additions. For example, Magdoff, Ross, and Amadon (1984) suggested that soil with a residual nitrate level below 10 mg/kg would require a full-rate nitrogen application rate to achieve 100% corn yield goal. Residual nitrate levels above 30 mg/kg would require no additional fertilizer. Similarly, for corn production, soils having plant available phosphorus and exchangeable potassium levels of 27.5 mg/kg and 150 mg/kg, respectively, would be considered adequate to support crop production if the amounts removed by the crop each year were replaced.

Soil sensing techniques to assess this variability on-the-go has been developed by Sethuramasamyraja et al. (2008) as an alternative to tedious manual soil sampling and laboratory testing. The goal of this study was to evaluate an Agitated soil measurement (ASM) method for integrated on-the-go mapping of soil pH, soluble potassium and residual nitrate contents using ion-selective electrodes. To implement ASM, an integrated agitation chamber module (IACM) was developed and attached to a commercial soil pH mapping implement. In a field simulation test, neither precision nor accuracy errors obtained with ASM were lower than for a previously investigated direct soil measurement (DSM) method. Laboratory evaluation of the ASM method revealed substantially lower measurement errors and increased regression analysis r2 values when compared to the field simulation, indicating that the proposed ASM method retains the potential for improving on-the-go field mapping. However, for reduced electrode abuse and the ability to use less expensive half-cell ion-selective electrodes, physical implementation of ASM through the IACM did not bring substantial improvement over conventionally available DSM. This could be attributed to the design of the IACM and use of half-cell electrodes. The authors proposed further research to improve the design of the solution-based measuring equipment and to develop an algorithm integrating on-the-go measurements with other sources of spatial data for an improved decision-making process. However, difficulties encountered with current systems included a slower-than-desired and not completely reliable extraction process, electrodes of limited durability, and the need for frequent recalibration due to signal drift. The disadvantage of on-the-go sensors based on ion selective technology is that soil sampling and nutrient extraction are required, increasing the complexity of the system and the time required for a measurement.

Kim et al. (2013) presented an automated sensing of hydroponic macronutrients using a computer-controlled system with an array of iron-selective electrodes (ISEs). The study reported on development and evaluation of ISEs for direct measurement of macronutrients in recirculating hydroponic solutions. An ISEs array incorporating the selected membranes in combination with a computer-controlled measurement system was evaluated for the direct measurement of nitrate, potassium and calcium concentration in paprika hydroponic solutions. However, the tested calcium electrodes did not provide satisfactory results due to reduced sensitivity in the hydroponic solution. Moreover, signal drift and reduced accuracy over time are major concerns with an in-line management system based on continuous immersion of ISEs in a solution.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recently published research (Kapis & Ombeni, 2015), proposed a framework for deployment of easy to use wireless sensor networks for farm soil monitoring and control: a case study of horticulture farms in Pwani region Tanzania. The communication within the network (intra communication) was done through ZigBee module in the coordinator while analysis, interpretation, and transfer of information to farmers and remote server were done in the base station connected to the coordinator. In this framework data collected from the soil was analyzed in the local server in the field and sent to the remote farmer directly to their mobile phones cellular network in real time. Internet service was used to send information to the remote server in which farmers can still receive information even if the internet connection is not available. Much research has been done on deployment of WSN for different applications like precision agriculture and so forth. Some frameworks guidelines have been proposed. However, many of these frameworks are not complete and practical as they just mention only few technologies like routing protocols. For those few developed frameworks they do not lead to systems which can be easily used by users who are ICT illiterate and with little knowledge on horticulture sector (Kapis & Ombeni, 2015).

The scientific objectives of this study was first to create a technology which integrated various elements into a portable in-field permanent device that measures soil macronutrients of N, P and K and soil pH. Then it transmits the measured data wirelessly to remote base station for analysis, presentation and storage in real-time. Farmers can access the information from the base station server through their mobile phones. The grower can use the test data to provide important indicators into the levels of nutrients in the soil which can be interpreted to stem over-use or under-use and efficiently manage their fertilizer application. Secondly, to decrease response time for the grower to implement alterations in the soil nutrient composition. The waiting period for results of current methods of soil analysis is too long and does not allow the grower to identify problems arising from actual depletion or saturation of nutrients within the soil in time. This can result in crop diseases, yield loss, soil erosion and the loss of beneficial organisms contained in the soil. Lastly, to increase the awareness of precision agriculture, its benefits and usage amongst the average farmer. At present there is a science barrier in the agricultural community, where technological products in the market only cater for high-end users and are not feasible for the average farmer to purchase.

3. MATERIALS AND METHODS

A. Data Acquisition System

The data acquisition system was designed using the Nutri-Stat sensors based on innovative probes that are part porous ceramic and part PVC. The PVC encloses the electrochemical sensor, measuring approx. 4 x 3 cm, which contains four channels for each Ion-Selective Electrode (ISE). Water/Liquid that flows from the soil into the porous ceramic cup via a micro pump creates a vacuum in the cup. Once in the cup, the water is in contact with the sensor, enabling an ISE to take a nutrient reading; measuring NO3- (Nitrate), K+ (Potassium), PO4 3- (Phosphorus) and pH respectively. The four ISEs are housed in a novel lab-on-chip platform, using low temperature co-fired ceramics (LTCC) technology. These processes, performed inside the porous ceramic enclosure, allow it to be buried in the soil for an indefinite time without enduring damages. It is managed through a small LCD controller that also displays results. The sensors have the following range and accuracy: Nitrate range from 0 to 650mg/L ±5% F.S,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

phosphate range from 0 to 200mg/L ±10% F.S, potassium range from 0 to 800 mg/L ±5% F.S and pH range from 0.0 - 14.0 ±0.05% F.S.

Although the probe will be submerged in the soil, a controller above the soil monitors the whole testing process. The controller contains a battery operated LCD. When enough water is acquired in the probe from the soil, the controller starts a sequence, pumping the sample into the LTCC Lab-on-Chip, takes the readings and discards the sample into a waste collection cup. If a wash is required after the measurement, the controller starts the washing procedure and resets the equipment for another test. The hardware design mainly includes an AVR ATmega64 microcontroller (MCU) as a core control system and peripheral circuit design. The ATmega64 MCU has enhanced low-power AVR RISC architecture, data throughput up to 1MIPS/MHz, which can alleviate the contradiction between system power consumption and processing speed. The input analog signals from nitrate, potassium, phosphorus and pH sensors are digitized using analog to digital converter AD7705 chip and fed to the MCU. On one hand, the microcontroller performs computations and transmits the information to the personal computer (PC) in real-time through Zigbee wireless communication module for data analysis, processing and display. The coordinator node's responsibility is to receive data acquired from different sensors such as samples of dissolved oxygen, pH, temperature and water level, and send command in order to achieve human-computer visualization interface. The smart nodes need to communicate with the coordinator node to transmit measured data. The coordinator was interfaced with the monitoring base station through RS232 cable.

B. Monitoring Software

With the results from the data acquisition system in hand, the grower and/or crop consultant need to implement a number of decisions based on the final statistics. The measurement and control software for the base station was realized by LabWindows/CVI software development platform whereas the data acquisition control software was realized by ICCV.7 of AVR for better nutrient management. The user-interface provides features for the complete real time measurement, control, data processing, display result output, report printing and other functions. The main features include real-time measurement and display of nitrate, potassium, and phosphorus as well as soil pH. It realizes real-time acquisition and control of the precise timing and high speed sampling. The implementation of the test results should be real-time displayed in a variety of experimental curve display and can always switch observation and zoom, and save operation curve very conveniently. In addition, farmers can request measured information from the system at any time by querying a mobile code. Furthermore, the system can automatically calculate and generate test report of soil macronutrients and soil pH according to user needs. The implementation of the automatic calibration and easy to operate improves greatly the reliability of the system.

The LabWindows/CVI software delivers the versatile array of test definition, analysis and reporting capabilities required to address the evolving needs of advanced researchers, as well as the intuitive operator interface needed to establish and sustain standard, industry-compliant manufacturing quality testing. To ensure the function of the majority of the test sample material for testing, the system detects in real time the data sample to be uploaded to a computer. The computer system software supports a large number of test data processing to ensure that the detection system can detect a large number of data in real-time, secure transmission to the computer, communications interface between the computer system and USB communication ports (Simbeye & Yang, 2014). Based on virtual instrument technology, the system combined with computer technology and instrument technology, sampling the multi

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

input parameter signals and exporting the detailed control signal in the coordination with the hardware. Also, this software monitors and controls the applications process, hardware circuit, real-time sampling, data analysis and signal processing. According to measurement and control requirement, it generates the control signals on the basis of feedback control algorithm, expressing and exporting data, thus achieving a wide range of automatic test requirements and specific function.

The virtual instruments, that is, on to the general-purpose computer as the core hardware platform design is defined by the user. The test function is achieved by the test software with a computer system virtual instrument panel. Users can operate this computer via user-friendly graphical interface, as in the operation of their own customized as a traditional instrument. It takes full advantage of the unique computing, storage, playback, call display and intelligent features such as document management, while the traditional instruments of the specialized features and software of the control panel combine to make it blend with the computer. So they constitute a fully functional of computer resources from the exterior to the same traditional instruments, while use fully a new intelligent instrumentation system. LabWindows/CVI software features robust capabilities for interacting numerically and graphically with post-test data. With this operation one can get the most from test results with intuitive displays and flexible, interactive data plots and have full freedom to explore different scenarios by adding variables, calculations, tables or charts. Integrated analysis tools include movable markers, text and construction lines, and the ability to define the region of interest and easily zoom in for closer inspection. Multiple graphs of the same post-test data can even be contrasted simultaneously for deeper insight into parameter properties. The captured and analyzed information from the base station monitoring software was transferred to the server and user mobile phones using GPRS technology. The overall system architecture is shown in Figure 1.

Figure 1. Overall system architecture

4. RESULTS AND DISCUSSION

The system was validated by taking soil samples and extracted samples using soil macronutrients and pH sensors in several places and then running the system and analyzing the soil samples using real-time analysis and comparing the results. The results were very promising and can be used as a diagnostic tool or to identify trends through time. After analyzing the data obtained from the experiments, it could be observed that the levels of macronutrients nitrogen, phosphorus and potassium and soil pH were changing consistently not varying greatly from year to year. The values obtained for nitrogen in different soil samples were differing significantly among themselves, as depicted in Figure 2. As for the average contents of phosphorus and potassium, it was found that values were fluctuating in the range of ±50.0 and 107.0 mg/kg respectively (Figure 3 and 4).

Determining the nutrient concentrations for nitrogen, phosphorus, and potassium can reveal how a soil is functioning in regards to its intended use and how nutrients are cycling through the soil. A nutrient measurement provides an analysis of average nutrient concentration (mg/L) for all nutrients tested. In an agricultural setting, knowing the concentration of nutrients can help food producers know when to add fertilizer, how much to add, and which nutrients need supplemented and in what amount. Consistently high nitrogen soils, for instance, would be good for growing nitrogen-demanding crops such as soy and corn. High nitrogen levels are also particularly useful for non-flowering plants because nitrogen is required for any green part of plants. High nitrogen levels can suppress flowering however, if they remain higher than phosphorus levels. Phosphorus controls flowering in plants and is important to any plant production involving flowering or fruiting plants and phosphorus is often added to soils or directly to plants before and during flowering and fruiting life-cycle stages to increase agricultural yields in larger

crop size and increased amounts of fruit production per plant. Potassium is involved in catalyzing many chemical reactions required to support plant life including drought tolerance and moisture regulation. Low potassium soils will likely need to be irrigated if soil amendment is not possible. Nutrient concentration can also inform of nutrient deficiencies or surpluses that can be detrimental to plant growth. If a nutrient is too high, amendments can be performed to reduce a surplus, such as adding mulch or tilling the soil. If nutrients are too low to support plant production, fertilization can be used to add nutrients in an amount needed for a specific crop. Low nutrient soil may also have more applicable uses to land managers for recreational or developed (paved surfaces or building construction) spaces.

Table 1 shows the statistical performance of our system for soil macronutrients and pH measurement. The data analyzed I n computer at the field were sent to the farmer mobile phones through cellular network and to the remote server through internet. The ISE module was evaluated with respect to the pH response and the long-term stability. It could be shown, that the pH response of the system using the novel miniature reference electrode is equivalent to the response of a system using a more traditional reference electrode (Figure 5). The measured soil samples of farm are slightly alkaline ranging from 7.4-8. All the sites were carefully selected so as to include different soil types and different conditions. Soils tend to acidify over time, particularly when large applications of ammonium based fertilizers are used or there is a high proportion of legumes in the rotation. With this project, Farmers now have a tool that makes it easier for them to provide fertilizer in the field whilst adhering to the soil macronutrients levels. This tool also provides the farmer information about the uptake of nutrients by the crop itself hence giving the farmer information about the status of the plant. The results from this test provide important indicators into the levels of nutrients in the soil which can be interpreted to stem overuse or under-use. The grower can use the data compiled to efficiently manage their fertilizer application.

CONCLUSION

At a rate of growth of 2.7 percent per annum, the national average population growth rate ranks as one of the fastest in the world and translates to a net total of about 1.2 million people being added to the population annually. At this rate Tanzania's population is projected to reach 70.1 million in 2025 (Agwanda & Amani, 2014). There is an urgent need for sustainable agriculture to be reinforced as to meet the inadvertently increasing demands for produce. The Tanzanian government has already taken action in this regard, issuing a number of policies, directives and legislations related to sustainable agriculture. This study will contribute to these efforts by facilitating accurate and frequent soil testing and fertilization management. Such nutrient concentration homogeneity across the field will optimize the yield and the quality of the produce for the benefit of consumers, creating a positive impact on healthy foods and healthy eating in society. Optimal application of fertilizers will deliver benefits for the environment by reducing pollution.

Improved soil macronutrient sensing leading to potentially commercial products will require additional research and development efforts. Further efforts are needed to improve the durability of sensing systems under harsh conditions found in the field. We need a more robust database management system that would provide the backbone to the graphic user interface, able to handle networks of more than 100 nodes (500-1000 sensors). This database must be able to manage rapid computations and statistical analysis. These systems also need to be web-enabled, so that farmers can access sensor data with handheld devices in the field, using the same wireless networks that transmit the data to the office computer (server). The information can be processed onboard or relayed in its raw form over a short-range wireless network to a central access point which could comprise of a laptop or a personal digital assistant (PDA). The system can be employed to raise an alarm condition when a subject's vital signs exhibit unusual behavior. Any adverse change in a subject's status can then be signaled to the relevant parties'.

ABSTRACT

Climate change and wastewater control are one of the foremost demanding situations for Indian cities. Urbanization and unparalleled growth of cities across India continue to create immense pressure on land and water resources. This uncontrolled growth continues to produce growing volumes of wastewater. Climate change, impacts inclusive of, intense storm events in summer time or extended moist periods in wintry weather are quite visible in India. In urban and peri-urban areas, wastewater use for agriculture is an emerging precedence. Due to susceptible enforcement of regulatory, most of the wastewater generated is permitted off untreated/ partially treated. While many previous studies have checked out the global modifications and associated impacts of climatic variations on water resources, few have targeted at the evaluation of the particular effects and adaptation priorities for water systems in towns. Proper reuse of wastewater for irrigation will significantly lessen the shortage, offer a sustainable water source, improving farming productiveness, lessen pollution, generate livelihood potential for low earnings city households along with contributing to their each day food needs. There are tradeoffs which need to understand which includes problems to individual's health, and surroundings. Through suitable treatment methods, water users' cooperatives, policy shift and the introduction of market based approaches, treated wastewater use in agriculture can be enhanced and all associated risks can also be curtailed. This chapter focuses on use of treated urban wastewater and its management for agriculture in selected Indian cities.

INTRODUCTION

Urban wastewater management is a challenge for many developing countries including India. Rapid urbanization and unparalleled growth of cities across India continue to create immense pressure on land and water resources. This uncontrolled growth continues to produce growing volumes of wastewater. Due to weak enforcement of regulatory measures, most of the wastewater generated let off untreated/ partially treated. While many preceding research have checked out the global modifications and climate related variability on water sources, few have targeted at the assessment of the specific consequences and version priorities for water systems in cities. Proper reuse of wastewater in irrigation can significantly lessen water shortage, offer a sustainable source of water, improving agricultural productivity, lessen pollution, create livelihood potential for low earnings city households, put in to their each day food needs. Hence a needed focus to understand and review the wastewater supply and treatment for Indian cities is required. The variety of challenges associated with climate, water and cities are very pressing, which depends on its demography, economics and administrative potential. The urban wastewater use for irrigation is a growing global phenomenon. Such irrigation method can build livelihood opportunities and strengthen food security. But the major hurdle is to come up with the sensible, low-cost safeguards that do not hamper farmer's livelihoods and thus providing a useful resource in meeting food needs and supplying cheap produce to expanding towns. Through suitable treatment methods, water users' cooperatives, policy shift and the introduction of market based approaches, treated wastewater use in agriculture can be enhanced and all associated risks can also be curtailed. This chapter focuses on use of treated urban wastewater and its management for agriculture in selected Indian cities.

CHANGE IN CLIMATE AND ITS EFFECT ON WATER RESOURCES AND AGRICULTURE

Climate change as per the United Nations Framework Convention on Climate Change (UNFCCC) has been defined as, "a change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods". Increased emission from industrial sectors along with changed agricultural pattern combined with widespread deforestation has effected a change in the gaseous composition of earth's atmosphere (Table 1).

Table 1. Greenhouse gases in surroundings

Elements	CO_2	CFCs	CH_4	N_2O
Avg. concentration 100 years ago (ppbV)	290×10^3	0	900	270
Present concentration (ppbV) (2007)	380×10^3	3 to 5	1774	319
Proposed concentration in the year 2030 (ppbV)	400×10^3 500×10^3	3 to 6	2,800 to 3000	400 to 500
Atmospheric life (years)	5 to 200	75	9 to 15	114
Global warming ability years relative to CO_2	1	4750 to 10900	25	298

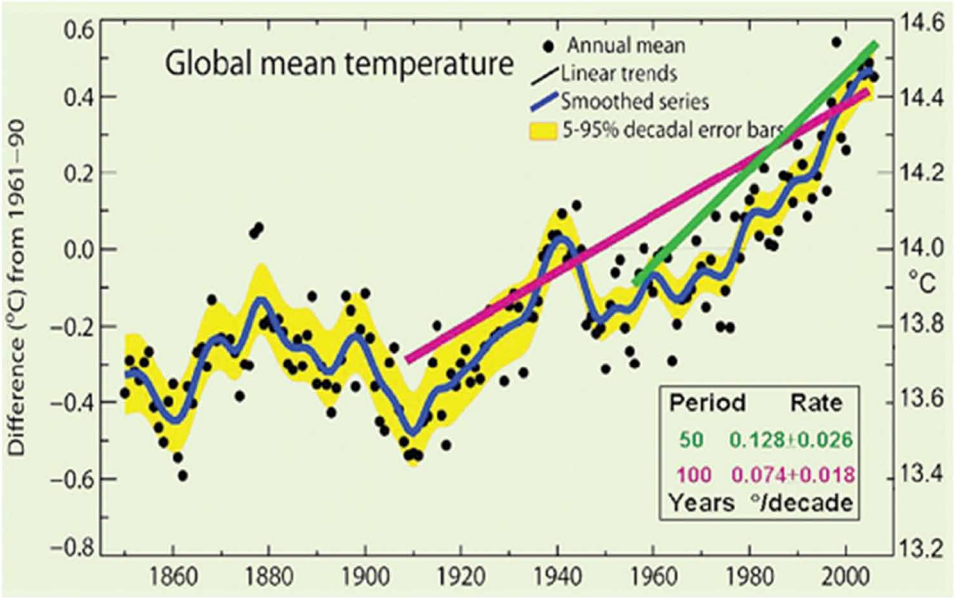
Source: IPCC (2007)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The global yearly mean temperature toward the end of the twentieth century, as an after effect of GHG aggregation in the climate, has expanded by 0.4–0.7 ºC over that recorded toward the end of the nineteenth century. The previous 50 years have demonstrated an expanding pattern in temperature @ 0.13 °C/decade, while the ascent in temperature amid the previous one and half decades has been much higher (Figure 1). The Inter-Governmental Panel on Climate Change (IPCC) has anticipated the temperature increment to be between 1.1 °C and 6.4 °C before the end of the 21st Century (IPCC, 2007). The worldwide temperature alteration is relied upon to prompt other local and worldwide changes in the atmosphere related parameters, for example, precipitation, soil dampness, and ocean level. Snow spread is additionally answered to be bit by bit diminishing.

Along these lines, coordinated endeavors are required for moderation and adjustment to decrease the helplessness of farming to the unfavorable effects of environmental change and making it stronger. With more than sixty percent of its populace subject to atmosphere touchy exercises, for example, farming, the effects of environmental change on horticulture accept huge significance for India. Environmental change projections made up to 2100 for India, demonstrate a general increment in temperature by 2-4°C combined with expansion in precipitation, particularly amid the rainstorm time frame. Mall et al. (2006) give a great audit of environmental change sway examines on Indian farming for the most part from physical effects point of view. The accessible proof shows critical drop in yields of essential grain crops like rice and wheat under environmental change conditions. Biomass and yield tend to decay with expanding temperature, as higher temperatures abbreviate crop length, upgrade breath and diminish time for radiation interference (Rawson, Gifford, & Condon, 1995). As yields in probably the most profitable areas of the world are drawing nearer a level or notwithstanding declining (Pathak et al., 2003), the possible impact of environmental change on harvest generation adds to the officially complex issue. It is a noteworthy test to assess the effect of rising temperature on product yield. Indian farming is profoundly

Figure 1. Trends in global temperature over the years
(IPCC, 2007)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

reliant on the onset, retreat and extent of rainstorm precipitation, especially in the downpour sustained territories of east, north-east and south India. Atmosphere modelers and IPCC records have anticipated conceivable outcomes of expanding variability in Asian Monsoon flow in a hotter world. Regardless of extension of range under watering system, dry spells, created by insufficient and uneven dispersion of precipitation, keep on being the most imperative climatic distortions, which impact the horticultural generation in India. The seriousness of a dry spell will be heightened in a hotter world. Extreme and incessant flooding because of environmental change would be a noteworthy issue in the Indian subcontinent. Soil temperature influences the rates of natural matter disintegration and arrival of supplements. At high temperatures, however supplement accessibility will increment in the short-term, over the long haul natural matter substance will reduce, bringing about a decrease in soil ripeness.

INDUSTRIAL AND MUNICIPAL WASTEWATER IN MAJOR CITIES

There is an extensive literature in context to industrial and municipal (sewage) wastewaters, its sources, volumes generated, wastewater characterization, impacts on life forms, legal norms and diverse treatment methods/strategies; however, most studies have not considered explicitly the implications of climate change for the delivery of water management objectives (Arnell et al., 2015; Gebrezgabher et al., 2015; Grit et al., 2015; McCarl et. al., 2015; Neumann et. al., 2015; Peirson et al., 2015; Zouboulis & Tolkou, 2015; Lewis, 2016; Valta et al., 2016). In the recent times, there have been research papers that are tackling the issues of industrial wastewaters treatment and management by novel methods, technology adoption, etc. taking climate change aspects into account (Itankar & Patil, 2015; Patil & Rao, 2015; Rao & Patil, 2015). For betterment of the class of life and improvement of productive competency of the people city water supply and sanitation are important basic needs. Also in many arid and semi-arid countries water is becoming an increasingly limited resource and planners are forced to consider any sources of water which might be used economically and effectively to promote further development. In urban areas, water is tapped for domestic use (78% of population has access to safe drinking water and 38% to sanitation as per CPCB 2009) and industrial uses from streams, rivers, lakes and wells. Municipal sewage is defined as "waste originating from a community; may be composed of domestic wastewaters and/or discharge from industry" and is major source of water pollution in India, particularly in and around large urban centers (Central Pollution Control Board, 2009). Almost 80% of the water supplied for domestic purposes, comes out as wastewater. In most of the cases wastewater is let out in the same form and it either gets soaked into the ground as a possible contaminant of ground water or is discharged into the natural sewage system ensuing in the contamination in downstream areas. According to the Central Pollution Control Board (CPCB, 2001) the Infrastructure Development Finance Corporation estimated that 73% of urban wastewater in India is untreated; with the increase in the drinking water supply to urban areas, the wastewater increases. Tables 2 shows the quantity of water requirement in future for various sectors whereas the Table 3 gives the sewage water generation from class I cities and Class II towns which also includes the upcoming smart cities as recently announced by the Government of India

If wastewater is not treated or disposed, it will create problem (Misra, 2014). It also poses great threat to the hydrology as well as water quality of natural water bodies. It is linked with a number of hazards, counting community's physical condition, agronomic, and ecological. Microbial health hazards are harsh in low and middle-income nations, which frequently involve the straight or indirect use of raw wastewater and/or impure waters from rivers to water edible-crops.

Source: A* National Council for Integrated Water Resource and Development (NCIWRD), B#Website of Ministry of Water Resources, Govt. of India, National.

The wastewater treatment requires an investment of US$65 billion which is ten times bigger than what is proposed by government (Kumar, 2003). India ranked as the 3rd largest user of untreated wastewater for agriculture in the world (Scott et al. 2010). In the year 2012, Israel and India used wastewater for agriculture to the tune of 64% and 24%, respectively (Grover, 2012). India will soon cross the 50:50 urban-rural population threshold and reach 750 million urban Indians by 2050 (Scott et al. 2010). A total of 38,254 million liters per day (MLD) of wastewater discharge in the year 2009 is projected to increase 120,000 MLD in 2051 (Planning Commission, 2012). There are various issues like treatment technology, different sizes of urban settlements and the land availability for setting-up treatment facilities. Mara (2009) suggests that the waste stabilization ponds (oxidation ponds, maturation ponds and duckweed ponds) can be appropriate for small towns having land availability. Afifi (2011) points for large urban settlements with land scarcity for the establishment of sewage treatment plants (STPs) and less demand for treated sewage for farm application, mechanical treatment systems viz. activated sludge process, trickling filter, up-flow anaerobic sludge blanket (UASB) and aerated pond are suitable to create good results.

OPPORTUNITIES AND CHALLENGES OF WASTEWATER RECLAMATION AND REUSE

Total municipal wastewater generated by Indian industries is 13,468 MLD out of which 60% is treated and the small and medium industries being major contributor to untreated wastewater. As it is known, that the industrial waste effluent is typically more poisonous thus the efforts for its use in agricultural needs to be focused mainly on municipal sewage for the predictable prospect. This difference is also seen in the research writing, which is filled with the studies on sewage-fed agriculture but barely the reuse of industrial wastewater for agriculture (although much investigation is being undertaken on water use competency in industries and on-site use by recycling).

The exception is industries producing comparatively less unhealthful effluent such as those within the food/beverage sector, for example breweries, sugar mills and fruit processing units. Data on brewery manufacturers shows that two million KL (Kilo Liters) of beer was consumed in India in 2012. According to the CPCB, about ten KL of effluent is generated per KL of beer created in India on an average which

Source: *Status of sewage in India(CUPS/61/2005-06)- Central Pollution Control Board* (http://www.sulabhenvis.nic.in/Database/STST_wastewater_2090.aspx)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

results in 20 million KL of effluent per year or about 55 MLD. It may seem that this is a small number but as per statistics the beer industry in India is experiencing growth in the coming future which invites a large amount of waste generation. In dry season or in the water scarce regions a small amount of reuse of wastewater can make difference. Thus these industries are more interested in wastewater reuse which has been seen in EU sponsored W4C project.

Most of the industries are practicing the reuse of wastewater in agriculture. Treated wastewater is being distributed by the SABMiller brewery in Andhra Pradesh for free of charge to local farmers. The treated effluent from the sugar mill is being sold by the Ugar Sugar Works in Karnataka at a cost of Rs. 3,000/ha to farmers. These are also generating the media coverage in positive way but the actual situation is more complicated. The main problematic issues are that there is no monitoring and of these practices. Most of the industries are situated in non urban areas.

State Pollution Control Boards (SPCBs) in India do not have the assets to check them continuously. Due to lack of any monitoring, there is no way to assure a certain quality of treated wastewater to farmers. Without technical studies it is not possible to state whether such wastewater reuse methods are having a negative effect on soils, crops or farmers' physical condition. In addition, farmers' needs frequently differ by season; for example, they would desire wastewater in the dry season stopping wastewater supply to farmers and putting more stress on reuse on-site and in-process. This may sometimes result into the evaporation of waste matter which can be energy serious and creates solid waste that needs removal.

An appropriate monitoring method can solve this crisis and help in agricultural reuse of wastewater from these industries. If an self-governing body can be set up containing of local agricultural extension officers, scientists from local universities, representatives from local farmers' and involvement of cooperative and industries, this committee can draw up official preparations and be able to check class and amount of wastewater delivered. Ideally, financial support for this should be shared justifiably among the various stakeholders; while the involved industry should cover a comparatively big share of financial support; if it is only industry sponsored there may be perceptions of disagreement of interest. Some primary steps are being taken in this way through the W4C project: ICRISAT is researching on SABMiller's wastewater reuse in Andhra Pradesh and the University of Agricultural Sciences, Dharwad is investigating on Ugar Sugar Works' wastewater reuse in Karnataka. The results of this beginning research will optimistically guide to testing with establishing a feasible model for checking agricultural reuse of water from the industries.

Use of wastewater in agriculture is a budding priority in India under water shortage. The influential issues are accountable for this are - growing water stress in a lot of areas of tier-I cities as well as tier-II cities; rising urbanization increasing wastewater flows connected with the growing water delivery and sewage; also more city households engaged in agricultural events, chiefly as foodstuff prices carry on to enlarge. The unforeseen consumption of raw wastewater helps to increasing risks to society, flora, and the surroundings. In these conditions, state administration is more and more worried to make wastewater reuse for agriculture an optimistic power for growth as component of their water resources management schemes, is about to be an major key region for development. The succeeding foremost messages look for to direct governments, practitioners, and stakeholders, water professionals, willing to construct and/or make stronger national as well as local capacities for protected wastewater irrigation.

A study of main issues concerned to wastewater irrigation can be stated by segregating cities into four heads by state of financial development, characterizes the variation of issues across cities in diverse steps of growth, depicts probable ways and prospect importance for developing wastewater handling. Correctly designed, managed and implemented, wastewater irrigation policies can give numerous paybacks that

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

accumulate in the agricultural, as well as environmental sectors. Facing such problems and benefits, cities looking better wastewater use for agriculture should follow the under mentioned objectives:

I. reduce danger for community health;
II. reduce surroundings risk;
III. advance livelihoods for city agriculturists; and
IV. put together wastewater as part of water resources management context

One or more combinations of these objectives can be followed by the city depending upon the economic growth (Table 4). As an example the cities with low income can put more concern on reducing microbial hazards to physical condition while developing the livelihoods of urban farmers, whereas on the other hand cities with medium and high income can give importance to reduce chemical and environmental hazards, mostly when they are stressed out with water, a complete collaboration of wastewater and the water resources management schemes.

Checking of Microbial Risk and Establishing Pathogen Decreasing Targets

The World Health Organization's "Guidelines on Wastewater Use in Agriculture" of 2006 focuses on a risk evaluation and organization approach which follows the Stockholm Framework. Following are the advancements:

1. Definition of bearable highest extra load of sickness;
2. To get bearable risks of infection;
3. To lay down health-based goals to reduce pathogen;
4. To decide how the necessary pathogen reductions can be achieved; and
5. To put in a scheme for confirmation monitoring.

The 2006 strategy provide nations at all level of growth with the way to sensibly take embattled steps to decrease health risks. Even when complete wastewater treatment is the solution, it presents a multi-barrier move toward shielding the health of farmers and consumers.

Table 4. Wastewater irrigation objectives in Indian Cities

Economic Development	Minimize Public Health Risk		Objective 2: Minimize Environmental Risk	Urban Agriculture and Improvement in Livelihood	Integration of Water Use in Wastewater Irrigation
	Microbial	Chemical			
Cities with low income	Vital	Short	Short	Vital	Short
Lower-middle income cites	Elevated	Emerging	Emerging	Elevated	Incipient
Upper-middle income cities	Elevated	Vital	vital	Elevated	Evolving
High-income non-OECD cities	Elevated	Elevated	Elevated	Short	Advanced

Gradually Apply Industrial Pre-Treatment and Control

To reduce the chemical risk and the desired function of the treatment set and wastewater irrigation policies the effluent generated from the industries discharging considerable amount of wastewater needs to be controlled. To confirm that the heavy metals, salts, organic toxins and other pollutant produced by industrial processes do not attain levels which may destroy pipes, slow down biological treatment processes, contain in the wastewater in large amount than the allowable for irrigation use or discharge in the surroundings or get collected in the sludge, thus limiting its reuse for this standards and discharging restrictions must be stated for the industries. The rising industrialization of city regions requires that chemical hazards of wastewater for irrigation be accounted, mainly through the preface, gradual execution, enforcement of industrial wastewater pre-treatment and manage programs.

Approach for Wastewater Use in Agriculture

Summers of 2016 in India, have brought the water scarcity issue at the forefront, thus making treated wastewater as the best commodity for trade for meeting industrial and irrigation needs of the cities. To make wastewater a viable resource governments investment and policies would inspire and encourage private sector to get involved through pedicle business models, (like the 2006 WHO tips). An approach to move from unstructured to structured wastewater use for irrigation and recognizing that dreams can't be met in a day or in single phase, the strategic plan have to be multi-phased and within an agreed and practical time-frame.

Resourceful Wastewater

The wastewater reuse system, establishment of equivalent authoritarian framework, and the execution of structured wastewater irrigation requires embedded use of agricultural wastewater inside the broader water property manage background. A quantity of integrated water property control thoughts should be accomplished, in particular: accept a multi- sectored method to water management in affiliation with river basin manage; inspire stakeholder participation and devolution of duty; promote non-public region involvement; and rent financial gadgets.

Wastewater Reuse Case Studies

Beneficial use of wastewater has been practiced in California since 1890s, when raw sewage was implemented on 'sewer farms'. Over a period of time there was a steady increase in the sewage utilization and by the year 1987, roughly 900 m3/d of municipal wastewater (7-8% of the production) was getting used for the various applications (California State Water Resources Control Board, 1990). Historically, agricultural use has dominated, and maintains to do so, but during the last decade reclaimed wastewater has been more and more used for landscape irrigation in urban regions and for groundwater recharge. Maximum of the reclaimed water (78%) is used inside the principal Valley and South Coastal regions of California. This has saved around 0.759 Mm3/d of clean water. In the period 1981 to 1987, the Ministry of Agriculture and Public Health, with assistance from the United Nations Development Program (UNDP), carried out studies designed to assess the effects of using treated wastewater and dried, digested sewage sludge on crop productivity and on the hygienic quality of crops and soil. Treated wastewaters

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and dried, digested sludge from the La Cherguia (Tunis) and Nabeul (SE4) activated sludge plants were used in the studies and irrigation with groundwater was used as a control. At La Soukra, tests were conducted on sorghum (*Sorghum vulgare*) and pepper (*Capsicum annuum*) using flood irrigation and furrow irrigation, respectively. Clementine and orange trees were irrigated at OuedSouhil (Nabeul). Use of treated wastewater and sewage sludge at the L. A. Soukra and Oued Souhil experimental stations, wherein the soils are alluvial and sandy-clayey to sandy, had no longer adversely affected the physical or bacterial best of the soils. The use of wastewater led to annual and perennial crop yields higher than yields produced via groundwater irrigation. Sewage sludge application increased the production of sorghum and pepper and resulted in the plants containing better concentrations of N, P and K and some minor factors (Fe, Zn and Cu). Untreated sewage has been used for decades to irrigate forestry tasks a long way from the inhabited areas of Kuwait. Effluent from the Giwan secondary sewage treatment plant became used to irrigate plantations on an experimental farm from 1956 (Agriculture Affairs and Fish Aassets Authority, Kuwait 1988). Use of raw sewage for irrigation within the Mezquital Valley of the Tula River Basin began in 1886 (Sanchez Duron 1988). But, it become now not until 1945 that the Ministry of Agriculture and Water assets installed the number 03 Mezquital Irrigation District to manage the distribution of wastewater from Mexico town for irrigation functions. Irrigation is important in this Irrigation District due to the fact rainfall is constrained and poorly allotted over the year, most falling between July and September. Sewage from Mexico town blended with variable proportions of surface water gathered in reservoirs in the basin has enabled farmers within the Mezquital Valley to provide agricultural produce for the capital city. The East Calcutta sewage fisheries are the biggest unmarried wastewater use machine regarding aqua-way of life inside the global. An historical account of the development of this gadget has been given by using Edwards (1985 and 1990). Ghosh (1984) offered the facts on the range of size and numbers of sewage fisheries in Calcutta as shown in desk 45. In 1945, the location of sewage-fed fish ponds become approximately 4628 ha, in a wetlands region of about 8000 ha, however the fish pond location have been reduced to about 3000 ha through 1987 because of city reclamation and conversion of fish ponds to rice paddies. Possession of the ponds is in the control of around 160 urban dwellers, who appoint almost 4000 households as fishermen, and there are several fishermens' cooperatives (Strauss & Blumenthal, 1989).

Consequences of Use of Wastewater

There are many winning wastewater use policies throughout the globe where nutrient reuse is a main benefit to the project (Pescod & Arar, 1988; FAO, 1992). Rarely, however, is a system laid out or intended on the base of nutrient recycling the main restraint to any wastewater use project is community health.

Depending on its composition, the treatment it has undergone, the extent to which it is irrigated and the regulations and principle guidelines under which it is being utilized, wastewater use in agriculture can be viewed as both a benefit, providing water and nutrients for the cultivation of crops and ensuring food supply to the cities, as well as a source of pollution, a threat affecting the health of users, consumers and the environment (Javier et al., 2013). Wastewater, especially domestic wastewater, contains pathogens which can cause disease spread when not managed properly. The survival of pathogens and how they infect a new host needs to be understood in developing a program to eliminate or minimize health risks. The primary objective of any wastewater use project must therefore be to minimize or eliminate potential health risks. As stated earlier, wastewater contains pathogenic microorganisms inclusive of bacteria, viruses, and parasites, which have the ability to reason disorder mainly, human parasites such

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

as protozoa and helminth eggs are of unique importance on this regard as they show to be most hard to eliminate by using treatment procedures and had been implicated in some of infectious gastrointestinal illnesses in both developed and growing nations (Hussain, Raschid, Hanjra, Marikar, & Hoek. 2002). However, in evaluating health impacts it must be remembered that it is the actual risk that make people fall ill that must be quantified and not the presence of pathogens in water. Whilst the potential risk may be quite high, the actual risk depends on many other factors. The use of untreated wastewater for irrigation, no doubt, poses a high risk to human health in all age groups. However, the degree of risk may vary among the various age groups. Untreated wastewater irrigation leads to relatively higher prevalence of Ascariasis infections with children (Cifuentes et al. 2000; Habbari et al., 2000), hookworm (Feenstra, Hussain, & Hoek, 2000). A lot of cities are facing key challenges in organizing the hazards linked with unrestrained wastewater irrigation, mainly water-shortage cities and low-income cities. Many have also begun to concentrate on those problems and progressed toward some degree of intended wastewater use in agriculture some with budding ways and others with definite plans. Each nation is sole, and experiences of other countries and cities can give some instruction as to how to get better wastewater irrigation practices. Cities can become accustomed to the techniques and schemes developed somewhere else to go with their own situation.

Development Partners

The support from the different organizations was sought by the cities for implementing their own ideas, skill development institutions, NGO's, etc. Many of the organizations have generated awareness among the people to avoid the usage of untreated wastewater. Most of them helped to maintain the cities with the secured wastewater irrigation and also selling of the same. Many volunteers are being motivated to offer more attention on this kind of initiative and add an asset to his/her nation. The different organizations that helped in the above context are - World Health Organization, The United Nations Development Program, International Development and Research Centre, International Water Management Institute, Resource Centre for Urban Agriculture and Forestry (RUAF), Water Partnership Program (WPP) to name a few.

BUSINESS MODEL FOR WASTEWATER REUSE IN AGRICULTURE

Fifty percent of the world's inhabitant's lives in urban areas and this is likely to reach two thirds by 2050. In many developing countries, urban populations are fraught with inefficient waste and used water management systems and these spill over into the environment, often with dire consequences. A walk through any Indian city would reveal open sewages and trash-filled drains. Moreover, rivers in many cities like Pune have turned in to veritable sewers. These cities have an immediate and urgent need for improved waste management and sanitation; however, the local authorities are neither financially nor managerially ready to meet the burgeoning challenge. Untreated wastewater inadvertently enters agricultural fields in India and is a prime reason for the spread of pathogens. However, for the entrepreneur urban waste presents a business opportunity and for municipal bodies this could be a potential market approach to solve an everyday urban problem. Due to India's monsoon based climate and consequent seasonality of its rivers, most parts receive their natural supply of fresh water only about four months in the year. In such a condition urban wastewater generated daily, turns out to be a resource which can bridge the supply gap. Wastewater, can be, in many cases a source of rich materials which can be re-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

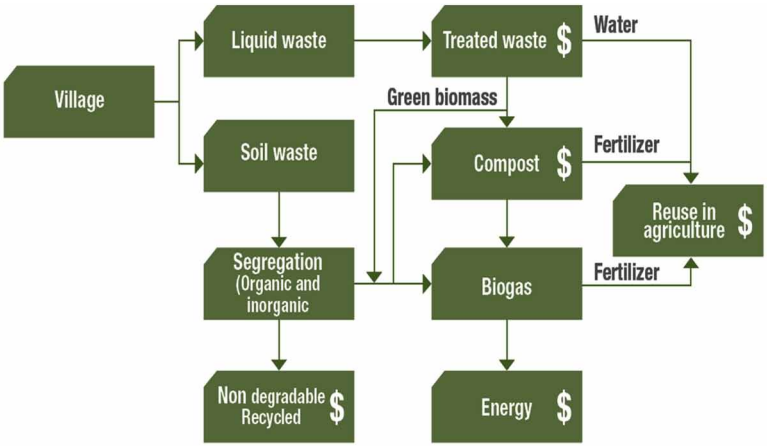
covered after some treatment. The nutrient value of domestic wastewater in agriculture is well studied but carries significant health risks. Involving the private sector in wastewater treatment and developing a business model can potentially turn this activity operationally efficient and distributionally effective.

The two major applications of urban wastewater, or used water, are in agriculture and in industry. Significant developments are seen in both cases, especially in arid regions of the world like Australia, Middle East and United States. Industry can safely use treated wastewater in a variety of applications like cooling system make-up water, boiler feed water, process water, wash down water and uses like site irrigation, fire protection, road cleaning. A successful example is seen in the mining industry, where an increasing number of mining companies are using reused water from residential or industrial areas (Workshop on industrial water reuse in the mining sector, 2013). In India, an example of urban wastewater use is seen in the city of Bangalore where it is used to recharge ground water sources. Urban wastewater is used for refilling exhausted irrigation tanks in rural neighborhoods and this in turn replenishes ground water levels. Such a depleted tank situated in Hoskotte in rural Bangalore receives excess water from an urban tank and serves as a storm water and wastewater reservoir throughout the year (Drechsel, Qadir, & Wichelns, 2015). Another ongoing project of the International Water Management Institute is being run with the objective of analyzing risk and opportunities of fecal sludge reuse in Indian agriculture. The project will examine options for optimizing private sector engagement in the valorization of fecal sludge and urine as agricultural inputs. The project focuses on the areas around the cities of Bangalore and Hubli-Dharwad in the State of Karnataka, but will also explore the scale of fecal sludge reuse across at least five other states within India. Of particular interest is private sector participation and search for scalable business models.

Similarly, for rural waste management, which is perhaps a problem of lesser proportion but similar consequences, the Decentralized Waste Management Systems model recommended by ICRISAT (ICRISAT, 2015) can be implemented through the green business model (Figure.2).

In African countries small-scale entrepreneurs are using human waste to make a profit. In Ghana, for instance, urban and peri-urban farmers use nutrient-rich sludge and wastewater to grow crops (International Water Management Institute, 2015). While this requires careful attention to health concerns,

Figure 2. Decentralized Waste Management Systems model recommended by ICRISAT
Source ICRISAT



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

they can be overcome by regulation and third party audits. Planners must ascertain that there are enough end-users for a waste product.

For assessing the viability of any urban or rural wastewater use projects, planners must evaluate two aspects of the proposed project. Economic justification – are the total benefits arising out of the project higher than the total costs? There is a high probability of economic justification for most Indian urban wastewater projects for a reason – the untreated wastewater finds its way to farms and ground water sources and poses a massive health hazard. This cost, while difficult to quantify, is nevertheless a real cost and one which must be factored in this evaluation.

Financial viability – who pays and how? This is not an easy challenge. The urban wastewater requires energy intensive technology for treatment while the output is valuable to agriculture and industry. Does the municipal authority pay for the treatment with the urban tax payer's money or must the beneficiaries of the treated water pay for it. Successful examples from several places in the world can be looked to find an effective and equitable way to manage the costs.

Arguments Favoring Private Sector Participation in Used Water Treatment

Studies and examples from other countries provide these compelling arguments, which are summarized below. Profit motive can lead to efficient operations, which is not possible when operations are undertaken by the local governing body. The introduction of a profit motive can lead to increasing the efficiency as compared to public management of the water system.

Private enterprises can get in managerial skills and capabilities which may not be available with local governing bodies. The private sector has improved managerial capabilities and sources of financing leading to better planning and control systems. Moreover, efficient operating and accounting procedures and effective distribution must be incorporated for securing profits.

Assurance of customer satisfaction is a strong influencer to efficient operations. This is a key objective of any business. Businesses run on customer satisfaction, while public authorities woefully lack this objective.

Lessons From Other Countries

Various countries have successfully used private partnerships to create sustainable business models in urban wastewater management. United Nations has worked with several African countries and developed economies in the European Union and has implemented models which seek business profits and social good. In these cases local bodies provide the services using a mixture of financing sources which suit local conditions. The public-private liasons (PPP) models with contractors can include management contracts, service contracts, leases, divestures concessions (build-operate-transfer), and public-private organizations (Hutton & Wood, 2013). In many nations, wastewater management service are not supported, low valued and rules (where they exist) may not be meticulously applied, thus cost revival may be difficult. Cost upturn options include creating business opportunities and economic instruments. Murray et al. (2011) have recommended that public-private liasons based on cost-recovery from the recycle of human waste could help to co-finance the sanitation/wastewater sector and to incentivize also, at the same time, promoting small and medium scale entrepreneurs. They put ahead four waste- based business models (involving aquaculture, biogas recovery, compost production and the use of fecal waste as an

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

industrial fuel) and they projected a number of competence indicators in order to permit a comparison between different reuse options and hence allow a monetary assessment to be made of different reuse business concepts.

Critical Success Factors for Successful Public-Private-Partnerships in Wastewater Treatment

A good number of works by experts and several winning examples demonstrate the usefulness of partnering with the private sector. But, these tie-ups are complex to design, to practice and function. Therefore, PPPs must be carefully checked in the background of the project, the social benefit and the concerned gains to be attended under various ways. Some of the critical factors for a successful PPP are discussed below.

1. **Availability of Market:** Private participation cannot be attractive where there is no prevailing demand. While it may seem that treated wastewater may be readily in demand, there have been cases where farmers have declined to use such water. This could be due to low awareness and may require government campaigns to promote its use.
2. **Multiple Stakeholder Benefit Objectives:** Profit is certainly the motive for private participation, however, it must be met with social benefits, which may not always be quantifiable. The stakeholder analysis often requires data and strong managerial capabilities to lay out the multiple benefits that the PPP must address.
3. **Competitive Procurement Process:** While this is a fundamental requirement of social projects, there have been instances where private companies, on the basis of technological uniqueness, have driven specifications to make the bidding process favorable to them.
4. **Thorough Risk Assessment:** Many studies have shown the local governing bodies to be ineffective to quantify project risks. On the other hand, some successful projects have employed the services of third party risk assessors. This could be an option when the local body lacks the required skills.
5. **Shared Authority and Responsibility:** Holding the private partner responsible for the outcome is effective when they have the required authorities in place. Where such authority has been lacking, the projects have encountered undue delays in the bureaucratic decision making processes.
6. **Social Support:** This is an essential condition to any public-private project. The society which stands to benefit from the project must have a buy-in of the project. In urban wastewater treatment projects, this includes the polluters and the beneficiaries of the treated water.

Lower-average-income nations (like Iran and Jordan), higher-center-profit nations (like Chile, Argentina, Mexico), and high-earnings nations (like Kuwait and Qatar) give best examples of the successful use of wastewater. It can be the examples that a major role in treatment of wastewater can be played by the private sector by providing private investments, design, build and operate the treatment plants so as to attain the standards for irrigation. Many water scarce nations practice the involvement of private sector for the same and use in irrigation has been practice in many water scarce countries.

A study by Ernst & Young indicates that the Indian water sector can require venture of around $130 billion between 2011 and 2030. Wastewater management, in particular, is emerging as a key thrust area. Currently, only 60% of industrial and 26% of domestic wastewater is treated in India. Metros and large cities are treating only about 30% while smaller cities treat a minuscule 3.7% of their wastewater. Wastewater treatment has been a largely neglected area because municipal bodies cannot charge water

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

users for the service. Thus, while municipal bodies often do get funding for wastewater treatment projects, operating and maintaining treatment plants is still a challenge. Recycling and reuse of wastewater has been encouraged by the Water Policy 2012. Industries in coming years may have to rely mostly on reuse of water for which recycled water can fetch a good price. A Chennai based company has bagged a project in Tuticorin from the Tamil Nadu government to set up a sewage treatment and solid waste treatment plant. The contract includes building the plant free, taking ownership and operating it. The treated water will be sold to industries which will bring in the revenues.

CONCLUSION

Climate change and wastewater control are one of the foremost demanding situations for Indian cities. Urbanization and unparalleled growth of cities across India continue to create immense pressure on land and water resources. This uncontrolled growth continues to produce growing volumes of wastewater. Climate change impacts inclusive of, intense storm events in summer time or extended moist periods in wintry weather are quite visible in India. In urban and peri-urban areas, wastewater use for agriculture is an emerging precedence. Due to susceptible enforcement of regulatory, most of the wastewater generated is permitted off untreated/ partially treated. While many previous studies have checked out the global modifications and associated impacts of climatic variations on water resources, few have targeted at the evaluation of the particular effects and adaptation priorities for water systems in towns. Proper reuse of wastewater for irrigation could significantly lessen water shortage and offer a sustainable source of water, improving agricultural productiveness, reduce pollution, and create livelihood possibilities for low earnings city households and contribute to their each day food needs. However, there are tradeoffs that need to be understood which includes risks to human health, and environment

The success stories from Israel and Chile indicates that for achieving secure and successful wastewater irrigation requires slow, steady and determined efforts on all fronts for several years. Learning from these examples Indian wastewater projects can create big opportunities for countering urbanization and helping economic development.

Possible solution to achieve this is to help municipal authorities to transport large volumes of water from long distances (150 km) which are a part of the rural agricultural system. During this process couple of hurdles gets created like over excessive fees of lifting water, river pollution and groundwater contamination. In every panorama, water augmentation must be considered at the side of special wastewater remedy strategies for multiple makes use of, and ought to be backed up with public policy and social incentives. This will surely guard the downstream customers and also offer financial benefits and help the surroundings offerings that constitute an imperative part of all varieties of lifestyles. A state and city wise approach for wastewater use in agriculture ought to seize the variety seen within the Indian context; this bottom up approach will identify nodal agencies for systematic data series and collection. Data collected can be effectively used for wastewater control plans thus preserving and reducing continued dispute between states for freshwater use .The reuse of wastewater generated will conserve groundwater, ecosystems, and reduce downstream affects thus helping in restoring livelihoods. However, wastewater treatment is crucial stages and hence should be designed to meet the requirements of end users, but these needs to be elaborated based on the wastewater supply at that location. Such sector based study can become a part of municipal improvement plan, making best use of wastewater generated in the towns. If wastewater is taken into consideration and included as a vital factor into national water plans

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and water cycles catchments, doubtlessly this will protect the downstream users and provide economic opportunities through alternative use of wastewater within towns.

The crude approach for India estimated that over 1.1 Mha of land can be irrigated using the available wastewater resource from different cities. Water can be collected through dedicated channels and infrastructure. Wastewater needs to be diluted with fresh water for its better usability,

Because dilution changes the water class, and estimations may require a exceptional modeling approach, technology driven systems like Remote Sensing and Geographical Information Systems (GIS) and unique mapping of drainage networks can offer better basic consequences which could help to investigate the nutrient loads leaving the metropolis. GIS-based mapping make land-use as part of their utility, to increase baselines, upon which future research may be modeled. Wastewater irrigation may be a dynamic system in the urban areas, and land-use patterns can exchange with development and socioeconomic exchange; consequently, to study techniques to capture this dynamism, spatially and temporally. Case studies confirmed that because of wastewater use farmers spent plenty less on inputs, and wherein the nutrient resources can be balanced the final results modified into more excessive exceptional (Delhi, Kanpur and Kolkata) in phrases of price monetary financial savings and economic returns. This become most effective primarily based on agricultural production, and a further holistic economic analysis desires to be completed to seize the personal advantages to the households and social benefits to the organizations. Wastewater agriculture is but no longer without horrible externalities, and fitness affects on farmers and clients are of huge state of affairs as mentioned above. From an Indian context more research are required in the regions of wastewater irrigated agriculture, health and food protection, and health economics, particularly at the farm and purchaser stages, to capture the diverse settings wherein the problems exist. Threat evaluation device like Quantitative Microbial chance evaluation (QMRA) and Quantitative Chemical chance evaluation (QCRA) may be used to evaluate the capability risk, which want to then be addressed via a couple of barrier approaches with fitness-based totally dreams for risk discount (WHO, 2006). In evaluation in India, greater emphasis wishes to be located on wastewater treatment processes that take away heavy metals, which seem to have a great deal better tiers than in maximum components of Africa (Raschid-Sally & Jayakody, 2008). Wastewater management and remedy cannot be planned in isolation. They should be a center a part of the strategic plans for water deliver and sanitation, irrigation and drainage, strength, and environmental offerings (World Bank, 2004). Moreover, it will become very essential to recall the ones additives in light of water availability for cities, and to highlight the need for continuous inter-sectoral communicate and action plans to address the ever-developing water demands (Global Economic Organization, 2010). Integration of water assets improvement with water services can provide greater help for agricultural water control. India being in recent times greater urban and peri-city than rural, it's time for safe wastewater.

Chapter 17
Sericulture Industry: A Bonanza to Strengthen Rural Population in India

P. J. Raju

ABSTRACT

India has a huge potential for sericulture development unlike other agro industries since sericulture is a unique agro-based industry comprising of several components such as mulberry cultivation, silkworm rearing, silk reeling and other connected activities. Each of these components appear to be independent but closely linked with one another having intricacies of their own. The major activities of these components comprises of mulberry food-plant cultivation to feed the silkworms which spin silk cocoons and reeling the cocoons for unwinding the silk filament for manufacturing silk goods, subjecting them to the process of degumming, bleaching, dyeing, weaving and printing. Thus sericulture industry provides employment to approximately 7.85 million in rural and semi urban areas in India. Of these, a sizeable number belongs to the economically weaker sections of the society, including women. In addition to this, India has the unique credibility of producing all the five known commercial silk viz., mulberry, tropical tasar, oak tasar, eri and muga of which muga with its golden yellow glitter is unique and prerogative of India. Though silk is a luxury item, it is produced by the rural populace and purchased by urban rich, causing money to flow from urban to rural. It also prevents rural people to migrate to urban areas. The United Nation's recent endeavor "Millennium Development Goals" has an eight point programme to make our earth more healthy wealthy and free from inequalities by 2015. Sericulture being a rural and women friendly business aligns well with many of these ideas which are explained in detail in the chapter.

INTRODUCTION

Father of the Nation, Mahatma Gandhi said that the "Real progress / development in India can be achieved only through village development programs". Rural development can be assured only by creating sustainable entrepreneurship with employment and income generation to the rural needy poor people. But most of the people are illiterate and the available resources are scarce and are not reaching the actual needy. Good number of schemes were planned and executed by different agencies in rural areas especially for the development of agriculture dependents. Eradication of poverty and unemployment are often attributed to the lack of "sustainable livelihood". A livelihood comprises the capabilities, assets (stores, resources, claims and accesses) and activities required for a means of living. A livelihood is sustainable which can cope with and recovers from stress and shocks, maintain and enhance its capabilities and assets and provide sustainable livelihood opportunities for the coming generation and which contributes net benefits to other livelihoods at the local and global levels and in the short and long term. The rural development has been a major factor of sustainable livelihood by using available resources, manpower and technology. The women and unemployed youths are to be taken as the driving force of any sustainable development in rural India. Strong rural urban linkages will not only help farmers stay back in villages pursuing profitable enterprises, it will also improve access to quality produce by urban consumers. It is noteworthy to mention the views of late Dr. A.P.J. Abdul Kalam, who has advocated his concept of PURA (Providing Urban facilities in Rural Areas).

Agriculture is the single largest livelihood source in Asian countries contributing to about 30 percent of the GDP and sericulture plays a vital role in it. There are certain evidences from various studies that more than 70% of the poor people live in rural area and the reduction of rural poverty continues to be a primary goal of the developing countries like in India. So far, various policies have been pursued to address this concern and among the major ones is rural employment creation. Sericulture is an agro-based labour intensive industry which provides gainful employment to the rural and unemployed youth and helps to uplift the socio-economic status of small and marginal farmers. It is therefore necessary to focus on a broader spectrum of the rural economy. The establishment of rural based agriculture enterprise like sericulture, in particular, could be very effective in creating new job opportunities and providing income for their livelihood. Being a rural agro-based labour intensive industry the Sericulture sector plays a vital role for checking the migration from rural to urban areas. Because of it multifarious advantages such as high employment potential, rural base, relatively low capital requirement, checking migration to urban areas, meeting raw material needs of the silk weaving industry and as such introduction of sericulture has been attempted in several countries but it could be sustained only in a few countries. Considering the merits of the sericulture industry for inclusive growth and the activities aligning with the Millennium Development Goals, the Government of India and the State Governments have taken up various developmental programmes for the development of sericulture and silk industry in India

Silk is the most elegant textile in the world and known as the "Queen of Textiles". On the other hand, it stands for livelihood opportunity for millions owing to high employment oriented, low capital intensive and remunerative in nature. The very nature of this industry with its rural based on-farm and off-farm activities and enormous employment generation potential has attracted the attention of policy makers to recognize the industry as one of the most appropriate avenues for socio-economic development of a largely agrarian economy like India.

Mulberry sericulture is a land based activity, which is labour intensive and provides good returns to the farmers. It has special significance for women as the silkworm rearing is done indoor is not physi-

Figure 1. Mulberry Garden

cally laborious and can be taken up along with other household activities. Mulberry sericulture has both agricultural components relating to mulberry plantation as well as industrial components relating to reeling, twisting and weaving. Because of demand of silk yarn and fabrics both within and outside the country, mulberry sericulture has promising market. Production of quality silk yarn within the country would help in reducing import of silk yarn from outside.

India continues to be the Second largest producer of silk in the World (Datta and Nanavaty, 2005). Among the four varieties of silk produced, as of 2012-13, Mulberry accounts for 79% (18715 MT), Tasar 7.3% (1729 MT), Eri 13.2% (3116 MT) and Muga 0.5% (119 MT) of the total raw silk production of 23,679 MT. This is against the production of 23060 MT Silk by end of XI Plan (2011-12) in the country. There has been a significant increase in raw silk production in 2013-14, as indicated in the Table 1.

Table 1. World raw silk production

Country/Year	2009	2010	2011	2012
China	84000	115000	104000	126000

Note: *Figures of India is for financial year April – March, Source:*www.inserco.org

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The world raw silk production was 1,52,868 MT in 2012. China leads the world with silk production of 1,26,000 MT or 82.41% of the produce. India is the second largest producer of silk in the world and has 15.49% share in global raw silk production. All the countries except China and India have been witnessing a declining trend in raw silk production in the last two decades.

PRODUCTION AND CONSUMPTION OF RAW SILK

Production of raw silk in India was 26,480 MT in 2013-14(p) of which, mulberry raw silk output aggregated to 19,476 MT (74%). The remaining 7,004 MT (26%) was *Vanya* silks. Mulberry sericulture is mainly practiced in five states namely, Karnataka, Andhra Pradesh, West Bengal, Tamil Nadu and Jammu & Kashmir which jointly account for about 96% of the total mulberry silk production in the country. As the consumption of raw silk (around 29,730 MT) exceeds the production, the additional requirement of around 3,500 MT of silk (particularly Bivoltine mulberry silk of international quality) is imported mainly from China.

RAW SILK IMPORTS

The quantity and value of raw silk imported from 2009-10 to 2013-14and for 2014-15 up to April-2014 are given Table 2.

Exports

The Indian silk goods are being exported to the traditional major markets like the USA and European countries and small markets of Asia Region. There was a slump in silk goods exports from the country from 2008-09 onwards due to melt down in the global economy and sharp depreciation in the value of Indian Rupee against US$. The silk goods export earnings decreased over the years due to global recession. The export earnings reduced in the subsequent years and reach Rs.2303.53 Cr. in 2012-13. However during 2013-14 export earnings increased by 5.28% compared to 2012-13 and reached Rs. 2425.16 crores. Export value of silk goods from 2009-10 to 2013-14 and for 2014-15 up to April-2014 is presented in Table 3.

Table 2. Raw silk imports

Year	Quantity (MT)	Value (Rs. in Crores)
2009-10	7338	933.70
2010-11	5820	927.59

*April-2014 to June-2014, p: provisional

The silk production has shown remarkable progress during the year 2013-14 in-spite of drought, un-seasonal rain, cyclone etc. The target set for the year has been fully achieved. At present, India produces 26,538 MT of raw silk of which the contribution of mulberry silk is 19,506 MT and non-mulberry silk, 7,032 MT. In India, various efforts could successfully tropicalize the bivoltine sericulture suiting to Indian conditions through different approaches such as R & D, synchronization of production process by putting in place an effective management system and incentive support at farmer's level to enhance production and quality. Sericulture industry provides employment to the persons in rural and semi-urban areas in India. Of these, a sizeable number of workers belong to the economically weaker sections of society, including women. India's share in global raw silk production is about 15% forming the second largest producer of mulberry silk. All the countries except China and India have been witnessing a declining trend in raw silk production in the last two decades. Japan was once a major producer of silk but has started abandoning sericulture due to industrialization. Mulberry sericulture is mainly practiced in five

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

states namely, Karnataka, Andhra Pradesh, West Bengal, Tamil Nadu and Jammu & Kashmir jointly account for the 96% of the total silk production in the country.

Silk produced in India is unique in its nature with diverse designs, unique craftsmanship, colour combinations, luster and heavily loaded with the ethnic style and nature of the community. Each region has its own traditional distinctive designs and weave and a market in terms of acceptance. Exquisite brocade fabrics of Banaras of Uttar Pradesh, Mysore silks of Karnataka, tie and dye and patola of Gujarat and Rajasthan, ikats from Odisha, Pochampalli from Telangana, Balucheri of Bengal and temple silks of Tamil Nadu are some pride creations of India.India has developed an international market for Indian silk goods by creating a niche market for the handloom silk having its own weaves, textures and design. India earned foreign exchange revenue of US $ 410.62 million through export of silk goods during 2013-14. Silk fabrics and readymade garments are the major items of the exports which accounts for about 95% of the total value of exports. The traditional major markets for Indian silk goods are the USA and European countries, UAE, Saudi Arabia, Hong Kong and Singapore. In India, there is a strong prospect for horizontal and vertical expansion to meet the increased domestic and export demand for silk products.

SERICULTURE IN ANDHRAPRADESH

Andhra Pradesh occupies 1st position in unit productivity and 2nd position in the country next to Karnataka in production of Silk. As a rural agro based industry, Sericulture has now expanded to almost all districts in the state. Ever since its introduction, it is playing a pivotal role in the development of rural economy of the state (Goel *et al*., 2003; Seshagiri *et al*., 2003). Andhra Pradesh produces all the four popular varieties of Silk worm cocoons namely Mulberry, Tasar, Eri and Muga. The state has got very strong and traditional weaving base with more than a lakh number of hand looms mostly concentrated in weaving pockets like Dharmavaram, Pochampally, Gadval, Patur, Peddapuram,Narayanpet, etc., In the last decade number of cotton weavers have taken to silk weaving in centers like Rayadurg and Proddatur because of better income in silk weaving. In Andhra Pradesh, Anantapur district stands on the top for having the largest mulberry acreage and high cocoon production. Presently sericulture is standing as main occupation of the farming community in the Rayalaseema region particularly in Anantapur and Chittoor districts by absorbing the rural labor giving direct and indirect employment to the other communities through Silk Reeling, Twisting, Dyeing, Weaving and Block printing, Sericulture industrial equipment and inputs manufacturers (Seshagiri and Ganapathi Rao, 2002). The Government of Andhra Pradesh has created a separate department and promoted the Sericulture industry both in On-farm and non-farm sectors through the launching of various schemes.

SERICULTURE ENTREPRENEURS AND THEIR CONSTRAINTS

Sericulture is not only a tradition but also a living culture in India. Sericulture is both an art and science of raising silkworms for silk production and ensuring the livelihood security with this enterprise and its related activities. However, the entrepreneurs are facing various challenges for their sustainability in the industry. Fair prices and timely availability of the quality inputs are the major constrains to the farmers and his knowledge base is influenced by the R & D support / Technical guidance by different agencies. At present, availability of skilled labour has become a thrust among the farming community in continu-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing in the sericulture enterprise. The prevailing environmental factors and socio-economic status also influences in the successful harvesting of the crops. Various other factors such as financial and other line departments support also play major role in the continuity of the entrepreneur in the industry. These factors influence the entrepreneur for continuation in the enterprise as indicated in Figure 2.Considering the need and constrains of the entrepreneurs, State Govt. of Andhra Pradesh supports them financially for various activities (Table 5).

Figure 2. Status of sericulture entrepreneur

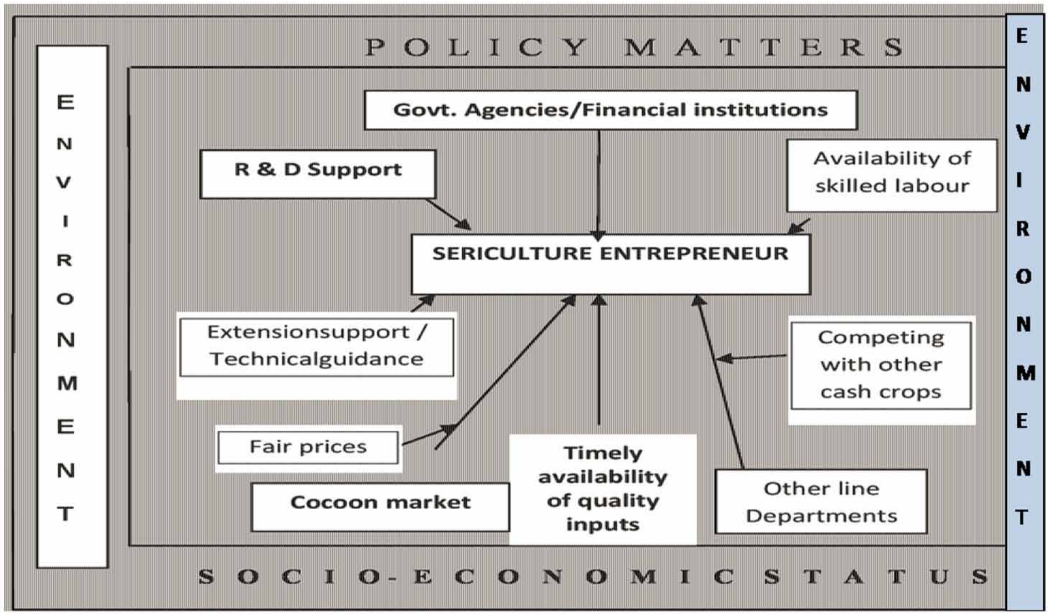

Table 5. Financial assistance

Sl. No.	Item / Activity	Amount (Rs.)
1	For raising Mulberry Garden in 1 acre	6,750.00
2	Construction of Rearing Shed	1,00,000.00
3	Rearing Equipment	37,500.00
4	Farm Mechanization	10,000.00
5	Irrigation facility per Ha. (Bore Well / Drip / Sprinkler)	37,500.00
6	Organic fertilizer like Neem Cake	5,000.00
7	Disinfectants	1,500.00
8	Construction of CRC & Equipment	2,50,000.00
9	Seri Poly Clinic	1,50,000.00
10	Construction of Verandah to a Rearing Shed	15,000.00
11	Production incentive for CB Silk (per Kg)	20.00
12	Production incentive for Bivoltine Silk (per Kg)	40.00

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

EMPLOYMENT POTENTIAL FOR RURAL PEOPLE

Silk industry is emerged as a major employment provider in the country which leads to poverty alleviation and inclusive development. 60 lakh persons are engaged in various sericulture activities in the country. It is estimated that Sericulture can generate employment @ 11 man days per kg of raw silk production (in on-farm and off-farm activities) throughout the year. This potential is par-excellence and no other industry generates this kind of employment, especially in rural areas, hence, sericulture is used as a tool for rural reconstruction. It is obvious that mulberry sericulture can be an effective tool in solving the problems of unemployment and poverty alleviation in the rural areas. Silk industry provides employment to 7.9 million people in the country. The labour force participation rate in silk industry is the highest in comparison to any other avocation in the country. Sericulture consists of two phases, one is mulberry cultivation which is basically agriculture in nature through which mulberry leaf, the food of the silkworm is produced and the other one is rearing of silkworms for cocoon production. The income per unit area is comparatively very high and this industry is having very good employment generation potential as the industry is involving mulberry cultivation, silkworm rearing, silk reeling, silk twisting, silk dyeing, silk weaving, silk garments manufacturing and allied activities like bamboo tray, chandrike making and sericulture carpentry. The economic advantages of sericulture industry lie in its high employment potential with low investment. It requires low gestation period and continues to yield for 15-16 years with little expenditure on maintenance. It gives higher returns, unlike other agricultural crops. Thus the industry plays a major role in women empowerment in particular and distribution of equity from rich to poor.

The very nature of the sericulture industry with its rural based on farm and off farm activities and enormous employment generation potential has attracted the attention of the policy makers. Further, the changes in employment and income opportunities in rural areas may be brought about by selecting a highly labour intensive and high income yielding cropping pattern and sericulture has been identified as one such sector which plays a vital role in generating gainful employment opportunities. Every acre of sericulture practiced under irrigated conditions had a potential to employ 247 men and 193 women round the year (Jayaram *et al*., 1998). They have also shown that the small scale mulberry farms provided ample scope for employment of owned family labour and suggested its potential to solve the problem of seasonal unemployment. To reverse the continuing decline in agriculture, restoring farmers confidence in farming and turnaround in rural – urban migration is crucial.

Figure 3. Rearing of silkworms

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Shoot rearing method of silkworms

Keeping in view the potentialities of the sector, Ministry of Agriculture, Govt. of India had earlier notified the inclusion of Sericulture activities up to the stage of cocoon production and silk yarn production in Agri-enterprises up to the stage of yarn production and marketing to be eligible under Rastriya Krishi Vikas Yojana (RKVY Schemes), which are State Plan programmes. Similarly, the Ministry of Rural Development (MORD), Govt. of India has also revised the guidelines of the MGNREGA scheme where in the benefits of the scheme can be availed by the small and marginal farmers for asset creation in their land towards irrigation facility, plantation, horticulture, land development etc. Since, majority of the Sericulture farmers come under the category of small and marginal farmers, the concerned department of Sericulture should get the desired work approved by the Gram Panchayat for inclusion under the project available for wage employment under MGNREGA (Mahatma Gandhi National Rural Employment Guarantee Act).

ENHANCING VILLAGE ECONOMIES FROM EVERY COMPONENT

The strategy for sustainable development adopted so far is required to be revisited keeping in view of the development in the silk industry. The interventions attempted so far are required to be made more focused for taking care of the aspirations of the youth on the short run. At the beginning of the new millennium, Millennium Development Goal (MDG) was adopted with a view to achieve certain goals and specific targets by 2015. Adhering to the MDG, the UN has incorporated some elements of the position taken by India and other developing countries such as that green economy should not result in creation of new green barriers like carbon tax, impose new conditions on aid and finance and increase dependence of the developing countries on rich nations for cleaner technologies. About 57% of the gross value of silk fabrics flows back to the cocoon growers with share of income to different groups 56.8% to cocoon grower, 6.8% to the reeler, 9.1% to the twister, 10.7% to the weaver, 16.6% to the trader. Thus, large chunk of income goes back to the villages from the cities.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

HIGH RETURN WITH LOW GESTATION

The new innovations of mulberry cultivation, silkworm rearing and improved hybrid silkworm seeds have brought an unparallel revolution in the silk industry of the Southern states in India. They do not call for any special heavy investment as the same are developed to suit the existing socio-economic conditions of the farm house-holds. The simplicity in adoption of these technologies and attractive income thereof have great appeal to the farmers with the result that sericulture is spreading fast in new areas covering practically almost all the districts of the Southern states. It is also helping in rapid transformation of the poor sericulture villages into reasonably prosperous rural areas. The new sericulture technologies are very much farmer oriented and have, in fact, transformed sericulture which used to be a subsidiary rural occupation in the past, into a full time highly remunerative agricultural activity better than any other cash crops. In view of the high employment potential and remunerative income generation, sericulture has come to be regarded as one of the important means of alleviating rural poverty and ushering in rural prosperity and is therefore, receiving due attention in rural development programmes both at the State and National levels (Kumaresan, 2011). In physical terms, the impact of sericulture research on the development of silk industry in the southern states has been very spectacular as evident from the quantum jump in productivity and expansion of the industry.

Keeping in view of the advantages of silk in promoting inclusive development, promotion of sericulture will continue to be an important factor in the coming days. Silk has been an inseparable part of Indian culture and tradition as no ritual is considered complete without silk apparel. In India, Sericulture is not only a tradition but also a living culture. The future of silk in the 21st century seems to be bright and its consumption is likely to rise despite its high prices. Sericulture is recommended as one of the most effective tools for rural development in general and poverty alleviation in particular. Sericulture is also recognized for its transfer of income from richer to poorer classes, use of marginal land without affecting food grains production and high export potential (Seshagiri and Ganapathi Rao, 2002). Till recently, sericulture was considered a subsidiary occupation but with the introduction of new technologies had led the industry to highly remunerative cash crop which inturn increasing the mulberry acerage. Mulberry takes only six months to grow for commencement of silkworm rearing. Mulberry once planted will go on supporting silkworm rearing year after year for 15-20 years depending on inputs and management provided. Five crops can be taken in one year under tropical conditions. By adopting stipulated package of practices, a farmer can attain net income levels up to Rs.30000 per acre per annum.

Several socio – economic studies have affirmed that the cost – benefit ratio is quite good in sericulture in comparison with other cash crops. Revenue is generated in silkworm rearing from the sale of cocoons which was Rs. 2,43,000/- acre / annum and the total cost of cocoon production including mulberry cultivation was estimated Rs. 1,81,313/-. The net returns were 61,753/- per acre per annum. Cost – benefit ratio was also calculated and worked out to be 1:1.50. It may be concluded that the revenue obtained from sericulture is fairly higher and its high profitability nature can be made known to the farmers and popularized through extension programmes. The details of the sericulture economics are given in Table 6.

FRIENDLY ENTERPRISE TO WOMEN

An empowered person is someone, who has the power to decide—to say, if they have land, 'Well, I can go farm, I can grow crops, I can plant seeds'—or if they have animals, to say, 'I can sell them without

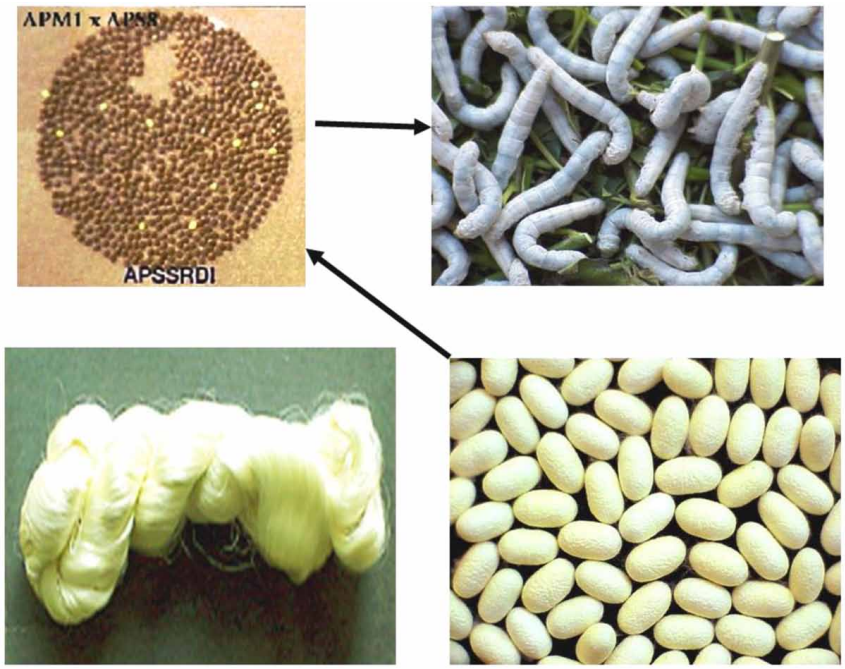
Figure 6. Different stages in end product (silk) production



going to ask permission' This is a person who has the power to decide about their things, their life, their actions.

People who are empowered 'see change in their lives'.

Under the globalization, privatization and liberalization, role of women is becoming more prominent and many of the industries women workers are preferred. As a result, the economic empowerment is getting accelerated and the gender concerns would be sorted out. Many of the studies undertaken proved that the sericulture and silk industry is an ideal tool for women empowerment and gender equality. The policy initiatives are focused towards promoting increased participation of women in sericulture. Several studies conducted on human resources involved in agriculture and an allied activity shows that the women form a major component of workforce. Considering their lions share in agriculture and allied activities as work force, both Central and State Governments have launched several women oriented HRD programmes, formation of women groups for improving their per capita productivity, bargaining power etc., through knowledge up-gradation and skill improvement. As a cottage industry, sericulture provides ample work for women in the rural areas particularly in silkworm rearing and reeling, while men work in the field. The involvement of women in different activities of sericulture is about 53 percent and their contribution in the on-farm activities is lower than that in post-cocoon activities. Being rural based, less specialized skill, mostly indoor activities, less physical energy, continuous job with frequent income, scope for utilizing several by-products for value addition and work is evenly spread over during the day which suits women for taking up sericulture.

Sericulture appears to be more suitable for women because of the advantages such as;

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Involves mostly indoor activities with low requirement of physical energy.
- Work is spread through out the day with sufficient gap and leisure time.
- Silkworm rearing demands delicacy and infant care, which are inherent qualities of women.
- Low level of technical skill and education are sufficient to carry out the work.
- Needs minimum investment with long life and short gestation period.
- Scope of utilization of several by-products for value addition and better earning.
- Provides job at door steps avoiding long travelling from dwelling places.

Sericulture being a high employment potential agro-based cottage industry provides congenial atmosphere for women employment. Series of activities involved in production of silk encompass both on-farm and non-farm activities. The major economic end products such as leaf, cocoon, raw silk, and fabric provide ample scope for employment of women as there are several independent and inter-dependent economic activities. Women contribute to less than 50 percent of the country's population and most of them are largely rural based, deriving their livelihood through agriculture and its allied enterprises. The women earn the money in agriculture either as a family member or wage earner. The women friendly enterprise like sericulture provides ample scope for women in the rural areas particularly in silkworm rearing and reeling while men work in the field. The various studies indicated that women involvement in sericulture is about 53 per cent.

"Feed the Future" supports the inclusion of poorer and more economically vulnerable populations in economic growth strategies in the agriculture sector in order to have a transformational effect on regional economies and restructure local production, distribution, and consumption patterns for long-term, sustainable development. Because women play a prominent role in agriculture and due to the persistent economic constraints they face, women's empowerment has become a main focus of Feed the Future. Empowering women is particularly important to achieving the Feed the Future objective of inclusive agriculture sector growth.. The concept of inclusive agriculture sector growth is broad and multidimensional. Women's empowerment in agriculture is an important component of that inclusive growth, and Feed the Future seeks to measure and monitor women's roles and engagement in numerous areas of the agriculture sector.

PERFECT ACTIVITY FOR WEAKER SECTIONS OF THE SOCIETY

Sericulture could be practiced even with very low land holding and the enterprise has the features of low gestation, high returns which makes sericulture an ideal programme for weaker sections of the society. Unemployment and poverty are the major challenges of the developing nations and it is necessary to generate productive employment on a large scale. In view of multifarious advantages of mulberry sericulture, it is considered as an effective tool for economic empowerment of the disadvantaged segments. Sericulture covers both land based activities relating to plantation as well as industrial activities like reeling, twisting and weaving. Its labour intensive nature provides a solution to the problems of seasonal unemployment and underemployment (Purushotham and Rama Mohan Rao, 2009). It is a farm based, labour intensive and commercially attractive economic activity falling under the cottage and small scale sector. It particularly suits rural based farmers, entrepreneurs and artisans as it requires low investment but with potential for relatively higher returns (Raju, 2006). It provides income and employment to the rural poor especially farmers with small land holdings and the marginalized and weaker sections of the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

society. Sericulture enterprise recognized for its low investment and quick and high returns which make it an ideal enterprise which fits well into the socio-economic factors of India.

Vanya silk sector which is mostly forest based is practiced in forest belts. The population involved are mostly tribal and socially backward communities in these areas who practice sericulture as a subsidiary occupation at household level. Vanya, the wild silks of India provide livelihood opportunities to tribal inhabitants and it is considered as an important tribal development programme. It provides gainful employment to the people of tribal community / weaker sections and helps to ensure sustainable economic growth of the region. Vast tracts of forest based tasar food plantations available in the country, if judiciously exploited for rearing tasar silkworms, can offer supplementary gainful employment for tribals. Sericulture can be practiced even with very low land holding. Three/Four acre of mulberry garden and silkworm rearing can support a family of three without hiring labour. Features such as low gestation, high returns make sericulture an ideal programme for weaker sections of the society.

FULFILLS EQUITY CONCERNS AMONG VILLAGE

Though silk is a luxury item, it is produced by poor rural people. Benefits of sectoral value-addition primarily accrue to rural households. As the end product is purchased by urban & urban rich and the money goes to rural poor. It helps to prevent migration of rural poor to urban areas. Benefits of sectoral value-addition primarily accrue to rural households.

In the Indian context, issues relating to sustainable development are somewhat more complex as it has to deal with multiple constraints typical to a developing country with a high population and relatively low natural resources. Unfulfilled expectation of the youth is at times leading to anger and anger leading to violence. These have in turn been affecting peace and implementation of development plans and programmes. To overcome such type of problems, providing of employment to rural youth through agriculture and its allied enterprises is one of the means to check them from anti-social activities. Further such type of policies will ensure sustenance of agriculture and its allied enterprises in the villages (Rajagopal Reddy *et al*., 1999)

ATTRACTING AND RETAINING YOUTH IN AGRICULTURE (ARYA):

Majority of Indians lives in villages and real progress is not possible, unless rural development takes place at a rapid pace. *Youth and agriculture are the twin pillars of sustainable* growth in the developing countries. For a healthy rural development, participation of entire population is very much essential. As the Indian social system is having bulk of educated and trained youth, conscious of their social responsibility and willing to render dedicated service to the community can play a pivotal role in rural development. Youth population in India in the age group of 15 – 35 years is around one third of the total population. Out of this total youth population, 20% of them constitute the urban sector while remaining 80% are from the rural side. But majority of the rural youth are living in an environment confronted with many problems including the sluggishness of the village life, economical & social insecurity, the village factions, illiteracy and limited work opportunity. The socio-economic development and prosperity of the country depends to a considerable extent on the type of youth the country possess as the rural youth

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

have abilities and capabilities to orient themselves to the main stream of the development process. The youth are considered as the backbone and cream of the nation.

Youth occupy an abiding place in moulding the future of any country, both socially and psychologically, Indian youth form a complex yet potential group which can be mobilized for nation building. The role of youth in transforming the face of Indian sericulture is very crucial [3]. It has been universally accepted that the attitude of an individual plays a crucial role in influencing his behavior. The youth as a vital section of the community have their share in the nations plans and programmes. The greatest potential of the solution to our problems lies in the guidance and training of rural youth to develop themselves into progressive farmers and enlightening citizens of India in the near future. The rural youth work is of great importance for rural development, since it teaches them the process of doing things together. In most of the developing countries, rural youth are growing very rapidly in numbers and will continue to do so in the future ahead. They are the vectors of new ideas and imbibe the necessary impatience and excitement needed to spur up all round development. During this period the youth undergo physiological and psychological changes that are more receptive to new ideas, ready to pay, take and willing to work under one roof. Hence there is a need to kindle their energies for fruitful purposes and develop them in the desired direction.

Directly or indirectly numbers of farm families are depending on Sericulture. The rural youth of both sexes involve because of their family and community background in farming and are active partners in various agricultural activities. Since youth are recognized as effective "agents of change" they can help in the process of dissemination and adoption of modern techniques and methods of sericulture and can take active part in the removal of resistance to innovations among rural people. Sericulture involves various aspects and among all these aspects farm youth are actively involved. They participate in most of the sericulture operations like field preparation, application of manures and fertilizers, inter cultivation, disinfection, feeding the silkworms etc. The greatest potential of the solution to our problems lies in the right guidance and training of the rural youth, who inturn would help the rural youth to develop themselves into progressive farmers and enlightened citizens of India in the near future. They are the nation builders of tomorrow and they are the carriers of the new ideas. They carry the necessary impatience and excitement needed to spur up all round development in the rural communities.

Globally, most young people (around 85%) live in the developing countries, where agriculture provides the main source of income and, therefore, it is vital that young people are brought to the mainstream of agriculture. But, in the recent past, retaining youth in agriculture has been identified as one of the major problems. Today's agriculture reflects a poor social image and hence, rural youth is moving towards urban sector for alternative and better opportunities. The future challenges are complex in nature and magnitude especially due to shrinking natural resources, declining profitability and adversaries of climate change. Obviously, these challenges are not only posing a threat to agriculture and food and nutrition, security but also creating wider socio-economic gaps within the society. Overall, the current agricultural policies do not provide attractive and sufficient avenues for engaging youth in agriculture.

Youth has the capability and capacity to make significant changes in agriculture but needs right policies and proper grooming. Many of them around the world are already making significant contributions to the Millennium Development Goals (MDGs), but their work needs to be acknowledged, recognized and strengthened. The past glory of "Green Revolution" was achieved due to policy support and infrastructure as well as human resource development of youth. There is an urgent need to involve youth in decision-making processes at all levels to reorient agricultural research for development. Each country needs to develop long-term, consensus-based and integrated youth policy, for which there is

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

a great need to share experiences at national, regional and global level. There is a high potential for cooperation among agri-stakeholders, particularly through networking of youth at different levels. The future of agriculture warrants impact oriented efforts at scale by involving youth to play a catalytic role in establishing 'Plough to Plate' chain. This depends on greater involvement of youth through effective networking for knowledge sharing and out scaling of innovations. It is through their active involvement that we can move forward to make agriculture an agri-business oriented profession which is very crucial for the prosperity of our farming communities.

To Fight Hunger, Inspire Youth

It is our responsibility to get young people excited about the challenge of feeding the world and then provide the opportunities to become the next generation of leaders. Shirking this responsibility of preparing today's youth for tomorrow is not an option. let's take time to understand the critical role of youth today in ensuring global food security tomorrow.

SERICULTURE INDUSTRY: SWOT ANALYSIS

Various survey reports of Sericulture indicated that, there exists lot of scope for empowerment of rural people through Sericulture. The SWOT analysis for the sericulture industry in the present scenario revealed the following which helps the policy makers for formulating various projects and for streamlining the industry for its sustainability in the long run.

STRENGTHS

- Traditional practice of the enterprise
- Well acceptance of the farming community
- Suitability of the industry for production of all type of silks
- Availability of man power, skills and appropriate technologies for sericulture
- The trend for demand of silk in the domestic market
- No dearth of skills in the weaving and processing sector
- Timely support of scientific fraternity in achieving the higher yields
- Support from the administration
- Water potential
- Eco-friendliness

WEAKNESSES

- Since sericulture is labour oriented industry which requires so much of manpower. In the present scenario the availability of the agriculture labour with operational skills is of great difficult.
- The variability of raw material quality due to small scale of production in the diversified environment.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Lack of participation from corporates in sericulture related activities.
- All the allied activites are not co-ordinated each other for their effective functioning.
- High production cost associated with poor quality.
- Volatility of the prices for the outcome of the industry production.
- Slow rate of adoption of improved technologies for higher yields with quality silk.
- Poor economy of the farming community.
- Poor mindset of traditional farmers.
- Non-availability of the certain inputs which is of major concern in certain parts of the sericulture practicing areas.
- Lack of awareness and initiatives.

OPPORTUNITIES

- Because of industrialization, the reduction in production of silk by traditional silk producing countries.
- Improvement of silkworm breeds using conventional and biotechnological tools.
- Promoting private participation in production activities through contract farming.
- Huge man power availability and abundant natural resources.
- Growing demand for Indian silk products in the Global market.
- Application of the products in the health and pharmaceuticals.
- Awareness on the utilization of byproducts of the industry.
- Improving trades under international free trade area.
- Large scope for exploitation of byproducts for producing important products of industrial importance.
- Emerging demand for the its industrial application in the other fields such as food and feed industries, cosmetics, etc.
- Support by the State and Central owned Departments of Sericulture.

THREATS

- Competition from other cash crops such as sugarcane, cotton, etc.
- Because of the globalization, the shifts in the tastes of the consumers.
- Continuous and heavy dependence on imported silk for exports. Any negative change in the importing policy will cause a so much of damage to the industry.
- Tropical stress of the State.
- Unexpected events like invasion of pests and diseases and etc.
- Fluctuations in the international prices and increased dumping of cheap raw material.
- The non consistency in the marketing strategy and lack of proper marketing support to sell the products of the producers.

In light of the above, Govt. of India and various state governments are implementing schemes in pre and post cocoon sector and few more schemes are in the pipeline for popularization of bivoltine seri-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

culture in particular and sericulture in general, farm to fabric concept to encourage corporate sector and women empowerment through sericulture. The sericulture industry achieved significant positive growth in terms of raw silk production and productivity in the recent years due to the improved technologies and through the wide extension network. The industry is having a large potential for the production of higher yields. The policy makers while formulating the projects, consideration may be given for the strength and opportunities of the sericulture industry which are explained above by keeping the track of weaknesses and threats of the industry. For the sustainability and flourishing of the sericulture industry with higher yields, the emphasis may be given to the assistance for establishment of Mulberry Kissan Nurseries, assistance to individual Sericulturists, Establishment of Chawki Rearing-cum- Input Service Centres, setting up of Disinfection Squad and Establishment of Silk Reeling Infrastructure. These five components are expected to complement each other and serve as a strong back bone by way of creating a congenial circumstance for wholesome development of the sericulture industry in the rural sector for their overall development to visualize the vision of Sericulture Department "*To achieve self sufficiency for meeting the domestic silk requirement leading to vibrant rural economy by creating employment and income generating opportunities which results in poverty reduction and also preventing rural to urban migration of the rural poor*".

SOCIO ECONOMIC EMPOWERMENT THROUGH HUMAN RESOURCE DEVELOPMENT

Science and Technology is used as an effective instrument for the overall development of the sericulture industry. Central Silk Board (CSB), Bangalore under the Ministry of Textiles, Govt. of India is the apex body for overall development of sericulture and silk industry in India. The functions assigned to the Board are to promote development of the silk industry by all appropriate measures like undertaking, assisting and encouraging scientific, technological and economic research, improvement of mulberry cultivation and production of quality raw silk. Indian sericulture is not only vast and widely dispersed but also multidisciplinary in nature involving silkworm seed sector, cocoon sector and post cocoon sector. The Central Silk Board, Bangalore is coordinating and implementing collaborative research activities in association with National level R&D Institutions, State Sericulture Research and Development Institutes and Universities for promoting research and development of appropriate technology towards attaining quality and productivity levels of Indian silk. Simultaneously, state owned research institutes like Karnataka State Sericulture Research and Development Institute (KSSRDI) and Andhra Pradesh State Sericulture Research and Development Institute (APSSRDI) are also functioning for the overall development of the sericulture industry in the country. Since inception of these institutes, the institutes are working for the development of highly productive and qualitatively superior silkworm hybrids suitable to tropical eco-climatic conditions of India. The research institutes are actively functioning for creating awareness to the farmers and technical staff of the department through periodic training programmes.

Under the project entitled "*Socio-economic empowerment of tribals through state-of-the–art technologies in Sericulture*" funded by Science and Society division of Dept. of Science & Technology, Govt. of India, a total of 150 "Soliga" tribals have been brought into mainstream sericulture through establishment of model trial farm to demonstrate integrated farm management system for sustainable

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

sericulture with the plantation of coffee and other cash crops including fruit yielding varieties along with mulberry trees. This concept of model tribal farm has greatly influence psyche of the tribals in taking up integrated farm management especially due to their small land holdings including their nomadic culture due to shifting cultivation.

As a sustainable economic activity favouring the rural poor in the unorganized sector, sericulture holds special promise for the women. Most of the sericulture rearing activities could be attended by the women while attending to their normal household activities. Sericulture is particularly useful for employment of women who are illiterate and can not go out of their homes due to various limitations / constraints. Involvement of women in various sericulture activities has increased their income level along with their confidence level. Sericulture enterprise assuring the women for their economic support which helped the industry to be recognized as a women friendly enterprise. This inturn helped the women community for their empowerment and gender related bias. Though women form major workforce in all income generating activities of silk production chain, appreciation for her involvement remained unrecognized. Several efforts were made to address the problems of women sericulturists recognizing the major role played by women in different activities. Several training programmes were organized exclusively for the development of women entrepreneurs in the local areas.

Realizing the importance of women in sericulture, various measures were undertaken by the different agencies for encouraging the women for their participation. In this direction, the Andhra Pradesh State Sericulture Research and Development Institute (APSSRDI) has made an attempt to train the women farmers in a project entitled "*Productivity improvement and economic empowerment of women in Andhra Pradesh through technological intervention and valuation in sericulture*" which was initiated by contacting women sericulturist's at different places in traditional sericulture areas of Anantapur districts and explained the objectives of project and its importance to acquire knowledge on practical technologies for overall productivity improvement through sericulture leading to their economic empowerment. Accordingly, the training programmes in organic cultivation practices (6 days duration) and silkworm rearing including pest and disease management (15 days duration) were initiated. The enthusiastic women sericulturists from Anantapur and Chittoor Districts of Andhra Pradesh were identified. The socio-economic status and other related data were collected individually from each trainee at the beginning of the programme.

Organic Cultivation of Mulberry

Four hundred and twenty seven women sericulturists belonging to Chittoor and Ananthapur districts of Andhra Pradesh were imparted practical training for 6 days in mulberry cultivation practices with thrust on organic farming techniques in thirty batches during the year 2006-2009. During the course of training, the trainees were taught, demonstrated and involved in carrying out various practical technologies like soil health measures through economical and effective organic cultivation practices like composting, vermi-compost, green manure crops & mulching, use of bio-fertilizers besides other package of practices in mulberry cultivation so as to obtain higher productivity with improved leaf quality. The ill effects of irrational use of chemical fertilizers were also demonstrated to the women trainees. Mulberry being a foliar crop, the need for INM (Integrated Nutritive Management) and IPM (Integrated Pest Management) measures were also demonstrated. The women trainees acquired knowledge on technical, agronomical practices of mulberry cultivation and evinced confidence over practicing the organic cultivation practices.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Silkworm Rearing and Pest Management

Three hundred and twenty six women sericulturists were trained in the important practical aspects of handling silkworm both at young and adult stages, disinfection, use of eco-friendly disinfectants, egg incubation and maintenance of hygiene etc. These necessities for silkworm rearing were demonstrated besides creating adequate awareness on the general mistakes being committed by them resulting in crop failures/poor performance. The new innovations like, use of eco-friendly disinfectants, cost effective rearing techniques like shoot rearing etc. were explained and demonstrated. The women sericulturists themselves were involved in the silkworm rearing and were made to understand the importance of disinfection and maintenance of hygiene in addition to the other requirements for successful cocoon crop harvests. The trainees were given timely suggestions to overcome the problems encountered by them as and when contacted. Further, a book in local language comprising of the practical technologies on mulberry cultivation and silkworm rearing aspects including pest and disease management which would serve as a ready-reckoner was provided to each of the trainees.

Andhra Pradesh State Sericulture Research and Development Institute (APSSRDI) has implemented aproject entitled "*Popularization of new silkworm hybrids and disinfectants among the sericulturists of Andhra Pradesh through technology demonstration and validation*" (funded by NABARD). Under this project a total of 300 farmers and most of them youth were trained in two phases. After successful completion of training programmes, the team of Scientists / Extension personnel has collected the information with prescribed questionnaire. During the personal visits, the resource persons have interacted with the trainees at their work site to obtain feedback of the training programme. The trainees expressed general satisfaction over the technical improvements in their sericultural activities after the training programme. In case of mulberry cultivation, the significant change that was observed was the application of bio-fertilizers, usage of recommended dose of fertilizers and vermicompost along with green manuring. The training in silkworm rearing including pest and disease management made the farmers to realize the importance of surface disinfection of silkworm eggs and also the disinfection of rearing house including hygiene maintenance during silkworm rearing. The chawki rearing concept, integrated pest management, self-mounting and shoot rearing reduced the workload or drudgery which inturn saved the money. Further they opined that the information on the input supply of various fertilizers, their ultimate impact on the quality leaf and the importance of high yielding mulberry variety helped them. In total, the information which is collected from the trainees was compiled and categorized such as sericulture profile, opinion about the training programme and their level of knowledge before and after the training programme.

Feedback from the Trainees

More than 90% of the trainees expressed their satisfaction towards the overall training programme and its usefulness for effective maintenance of sericulture enterprise. The trainees have strongly felt that the objectives of the training programme were quite clear and accordingly the day wise training schedule is well planned. Further they have felt that most of the resource persons have encouraged active interaction and participation during the training programme. About 95% of the trainees felt that, the training programme is quite useful since most of the activities were focused to reduce the drudgery in sericulture which is the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

need of the hour. All most all the trainees have felt that the content of the training programme was made easier to follow from illiterate to literate. The resource persons were well versed with sericulture since the experienced Scientists in their specialized field were invited. Some of the progressive farmers were also invited to share their experience with the trainees who have helped them to understand and correct their day to day sericulture activities. Most of the trainees felt that the facilities and the time allotted for the training programme was sufficient.

Knowledge Level of the Trainees After the Training Programme

The resource persons have collected the information about their sericulture knowledge level before and after the training programme and their view of the training programme is as follows.

1. Most of the trainees expressed that, they were aware of a few mulberry and silkworm hybrids but during the training, the sufficient knowledge has been gained particularly with regard to silkworm hybrids which have helped them to choose the silkworm hybrids based on the different seasons. Further knowledge on the input supply of various fertilizers, their ultimate impact on the quality leaf and importance of high yielding mulberry varieties helped them for harvesting successful crops.
2. Among the trainees, about 45% have expressed that they are effectively following the production of quality leaf through IPM and INM packages by eco-friendly approach, compost making, vermi compost and green manures and their effective utilization in raising quality mulberry gardens for silkworm rearing.
3. About 90% of the farmers have opined that before the training programme, they knew the importance of Chawki rearing but after the training much awareness has developed on the scientific method of rearing the chawki worms which in turn influence on the success of the silkworm rearing. After the training, a total of 30% are maintaining the separate chawki gardens with separate package and practices.
4. After the training programme, the knowledge on the new silkworm hybrids helped them for selection of particular silkworm hybrids and the knowledge on their special characteristic features helped them to harvest successful crops. With regard to disinfection practices, 70% of the trainees revealed that before the training programme they were having knowledge on the disinfection but after the training, the effective way of conducting disinfection programme enlightened them to ensure proper disinfection and to meet its purpose.
5. All the trainees opined that, the emphasis on the various important sericultural aspects during silkworm rearing such as moulting, resumption from moult and spinning care have enlightened them to ensure the required optimal conditions. Further the practice of sorting the defective cocoons before the marketing and their proper transportation helped them to obtain maximum price to their produce in the market.
6. The training programme has impacted much on their sericulture practices for carrying out better way which in turn has reflected in the increased cocoon yield of 5 to 7 kgs for 100 dfls besides stability in cocoon crops. Most significant impact of the training programme was that number of crops undertaken by them increased from 3 - 4 crops before training to 5 - 6 crops after the training lead to an increase in the overall income per year/acre.

Chapter 18
Design for Autonomy:
Water Resources in Ladakh

Carey Clouse
University of Massachusetts – Amherst, USA

ABSTRACT

This chapter describes one series of climate-adaptive design innovations found in Ladakh, north India. Five different water management techniques chart the region's unique and highly specialized response to water scarcity, and in so doing highlight important lessons for climate-adaptive planning elsewhere. In this case study, the dispersed, community-based water management strategies practiced in Ladakh suggest a level of design thinking that supports environmental stewardship, economic autonomy, cultural consciousness and social cohesion.

INTRODUCTION

In the face of global climate change, planners and designers can provide valuable expertise to communities in transition. Indeed, changing environmental conditions will necessitate new solutions for the mitigation and adaptation of infrastructural systems, human settlement patterns, and traditional ways of conceptualizing urban life. While the impacts of a changing climate are difficult to project and plan for, instability promises to become a common challenge of the Future City. In this environment, resilient, adaptive, and flexible designs for supporting human development suggest a way forward.

This chapter describes one series of climate-adaptive design innovations found in Ladakh, north India. Five different water management techniques chart the region's unique and highly specialized response to water scarcity, and in so doing highlight important lessons for climate-adaptive planning elsewhere. In this case study, the dispersed, community-based water management strategies practiced in Ladakh suggest a level of design thinking that supports environmental stewardship, economic autonomy, cultural consciousness and social cohesion.

While social capital rarely factors into the design of water infrastructure, it can have major policy and urban planning implications. This consideration is perhaps even more relevant in the tiny high-Himalayan villages of Ladakh, where the meltwater from glaciers and snowfields has always been treated as a

form of the commons. In this region, subsistence agriculture practices demand a level of collaboration not often felt in more urban settings, as meltwater must be equitably divided amongst landholders, and farmers must work together to direct, store, and disperse this precious resource.

In this context, top-down government-generated planning decisions tend to be out of touch with the largely invisible social, cultural and religious processes that guide most of the decision-making and daily activities throughout the region. Unlike the high authoritarian planning schemes that have characterized other Indian cities, the water management practices described in this paper have instead been developed in and for Ladakh: they are knit into the Ladakhi cultural and social fabric, and are inextricably rooted to the region's environmental context (Scott, 1998). As a result, these design solutions are finely-tuned to the individualized needs of each community, deployed on a case-by-case basis. Whereas larger, government-sponsored infrastructural projects might lack a regional understanding of materials, construction techniques, environmental conditions or social frameworks, these design solutions reflect the context and culture that they serve.

LADAKH: CLIMATE AND CONTEXT

Located within the state of Jammu and Kashmir, in the rain shadow of north India's Himalayan range, Ladakh is a rugged and dry mountain region. Environmental conditions could be considered both extreme and inhospitable, characterized by high altitude, low humidity, and extremely low precipitation. The region is referred to as a cold desert environment, with temperature fluctuations that range from -40C to 35C and scarce rainfall, between 50 and 300mm annually (Bhasin, 1992; Demenge, 2007).

Ladakh's mountainous terrain is sparsely populated, containing some of the highest inhabited villages on earth (Norberg-Hodge, 2000). More than fifty villages exist in the region, supporting populations of 100 to 1,500 people (District Statistics & Evaluation Office, 2013). Moreover, the trans-Himalayan mountain range has effectively cut the region off from the southern portion of the subcontinent, where the "forbidding climate, remoteness and inaccessibility (has) kept Ladakh isolated, except for traders, for centuries" (Mann, 1986, 3).

In this challenging environment, strong social and cultural traditions have effectively tethered people to the land, and to each other. According to scholar R.S. Mann, Ladakhi "people feel that their adaptation (to climate) alone made them survive whenever nature posed threat (sic) to their existence" (Mann, 1986, vi). While humans have effectively and sustainably flourished in this region for more than one thousand years, existing environmental pressures, coupled with unstable weather patterns caused by a warming climate, have brought about changes to age-old patterns of living in recent years (Mingle, 2015; Rizvi, 1998).

Agriculture in Ladakh

While the region remains relatively isolated today, Ladakh has witnessed many sweeping changes over the last four decades, particularly with the rise of tourism and an increasing number of employment opportunities in the local military and government sectors. According to scholar Mohammed Deen Darokhan, this shift has also caused a deterioration in the practice of ancient farming techniques and agricultural reliance overall. Darokhan regards agriculture as "the only sustainable way of life in Ladakh," and worries that villages could "lose the genetic material and cultivation techniques due to a neglect of farming"

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Darokhan, 1999, 79). Other scholars note that agriculture is inextricably tied to land stewardship and cultural survival, as the traditional agricultural lifestyle has supported many centuries of sustainable human settlement in the region (Norberg-Hodge, 2000; Rizvi, 1998).

While these demographic shifts have become even more marked in the intervening years, culturally, socially, and even economically, traditional agrarian values persist. Most Ladakhi villagers still practice a single integrated system of subsistence agriculture and have very few opportunities for economic participation (Crook & Ostmason, 1994; Gutschow & Mankelow, 2001; Norberg-Hodge, 2000). This is the outcome of many years of farming effort, as generations of farmers have worked with natural cycles "to green the desert and bring biological diversity" to an otherwise barren landscape (Darokhan, 1999, 78). Indeed, the lush green farmlands, thick stands of willow trees, and surprisingly fertile topsoil visible in an otherwise inhospitable desert environment represent many centuries of judicious land stewardship. (Figures 1 and 2 in the Appendix) Perhaps not surprisingly, this difficult agricultural environment also reinforces the value of traditional methods, where "the adoption of agricultural innovations is slow" (Mann, 1986, 173).

The primary crops grown in Ladakh are barley, wheat, buckwheat, millet, peas, mustard seed, apricots, and livestock fodder including alfalfa (Gutschow, 1997; Humbert-Droz & Dawa, 2004; Sagwal, 1991). While agricultural production continues to support subsistence households, some farmers have shifted to cash crops in response to the large presence of the Indian military and tourist industry and their demand for potatoes and vegetables (Tiwari & Gupta, 2007).

Water in Ladakh

In Ladakh, water is primarily used for two purposes: household activities and crop irrigation. Most villages supply household water from groundwater, rather than the surface meltwater used in agriculture. In these cases groundwater is drawn from wells (using hand pumps), mountain springs, or from those two sources via tanker trucks, which refill household barrels or tube wells (Akhtar 2013; Sudhalkar, 2010). While the challenges associated with groundwater depletion in this region are significant, household water use represents but a tiny fraction of the water volume needed to support farming and animal husbandry. As such, surface water management—the collection, retention, and dispersion of flowing meltwater from glaciers and snowfields above—has become a central planning concern of the Ladakhi village. Moreover, subsistence agricultural practices, and the elaborate system of irrigation associated with them, dominate the social, economic, and physical structures of village life (Gutschow, 1997; Norberg-Hodge, 2000).

Annual precipitation is limited, and most irrigation water comes from melting snowfields and glaciers in the northern part of the watershed (Akhtar 2013). While this region hosts the headwaters of the Indus River, water used for farming must be captured as it courses down the mountains from the high Himalayan glaciers to the river below. The floodplains of the river typically lack "viable arable land" and the idea of pumping water from rivers is, in this context, too difficult (Gutschow & Mankelow, 2003, 28). Instead, villages historically drape across the sides of mountains, opportunistically sited between the high glaciers above and the river below.

While the presence or absence of glacial meltwater may initially determine the location of a village, the resulting system of irrigation infrastructure depicts a far more intentional, sophisticated and laborious planning effort. Katiyar et al. note that "Without irrigation vegetable farming is out of the question in Ladakh," and indeed this practice has emerged as a means of contending with an otherwise inhospitable climate and landscape (2012, 312). According to Tibetan scholars, skillful irrigation was

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

present in this region in the 10th century, and in many cases early stone canal work has been improved upon for centuries (Bell, 1928).

In this climate and context, irrigation has become an elegant, efficient and equitable system in most villages, honed over many hundreds of years and kept in check by village politics and social norms. Professor and scholar Kim Gutschow describes the power dynamic created by this water management as "webs of water," which bind villagers to each other and to a communal decision making process (Gutschow 1997, 105). Sharing a single water source has led villagers to develop an advanced rotational system for water distribution as well as enduring practices for collective bargaining and oversight. In the summer months, fields might be watered every seven to ten days, depending on the crop and time of the season. If water ceases to flow at the end of the summer, everyone in the village will equally feel the effect of the drought.

Climate Change and Glaciers

According to the *Leh Handbook*, due to the region's "arctic desert condition and (the) scanty rainfall of the district, irrigation depends on the eternal glaciers" (District Statistics & Evaluation Office, 2012, 24). But glaciologists, climate scientists, and journalists agree that the glaciers appear to be eternal no more. New global weather patterns have caused large-scale changes to this landscape, resulting in an overall reduction of glacial mass across the Himalayan range. Journalist Jonathan Mingle notes that the state of "Jammu and Kashmir has lost 20 percent of its total glacial mass in the past six decades," (Mingle, 2015, 397) and cites a study of over 2,000 glaciers across the Indian Himalaya by India's Space Research Organization, which "determined that 75 percent are retreating, at an annual rate of 3.5 percent" (Mingle, 222).

A 2010 USAID report on the state of glaciers and hydrology in High Asia also explains that glacier melt is occurring, leading to impacts such as "too much water (floods), too little water (droughts/ increased aridity), or water at different times (more early in the growing season/less late in the growing season)" (Malone, 2010, 25). This is an acute problem for subsistence agricultural farmers, who rely on relatively stable weather and meltwater patterns to grow their traditional crops, and to determine when to sow, water, and harvest their fields. Unlike farmers working with electricity, pumps, and other advanced technologies, Ladakhi villagers lack access to the tools that could otherwise provide a relative safety net. Instead they have relied almost exclusively upon the glaciers high above their villages to act as a storage device for water over the course of the year.

As climate change impacts snowfall and glacial mass in the region, the water resources available to farmers appear to be shrinking (Grossman, 2105). The 2010 USAID report suggests that the drainages in this region should be addressed by "well-planned management, conservation, and efficient use of the water people currently have available to them" (Malone, 2010, 27). While one could argue that these suggestions have already guided water management practices in Ladakh for centuries, the development of new tools and techniques could help farmers plan for improved water security.

ADAPTIVE DESIGN SOLUTIONS FOR WATER MANAGEMENT

Historically, Ladakhi villlages have relied on low-tech, time-tested water management systems to funnel high glacial and snowfield meltwater down to croplands lower in the valley. The traditional canals,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

water diversion gates, and systems for equitable sharing, have, for centuries, effectively supported subsistence agricultural practices. As scholar Janet Rizvi notes, "The scantiness of rainfall makes Ladakhi agriculture totally dependent on irrigation; but all those sources that lie within the scope of traditional technology have been tapped (1998, 177). Indeed, many scholars suggest that Lakahi irrigation practices have already been fully optimized as a reponse to the arctic desert environment (Crook & Ostmanson, 1994; Norberg-Hodge, 2000; Rizvi 1998).

In recent years, however, the changing weather and diminishing glacial meltwater brought about by climate change has inspired improvisation on these traditional systems. In some instances, entire villages have moved to new waterside locations (Mingle, 2009). In other cases, villages have sought to improve their water management infrastructure with technical assistance from local NGOs and state government agencies. Several relatively new innovations have been adopted by Ladakhi villages, typically in the form of a design intervention that bolsters extant water infrastructure functioning.

These solutions have been developed and deployed on a case-by-case basis, often as a result of stakeholder involvement, using consensus decision-making and sweat-equity. As such, the numerous responses represent a family of design interventions that might be deployed as needed in a wide variety of water scarce environments. This body of adaptive management practices reinforce the systems already in place in Ladakh, and represent an effective small-scale planning solution for the social, cultural, environmental, economic and even religious implications of this place.

Artificial Glaciers

Artificial glaciers might be more accurately called ice dams, as they form large, layered pools of ice over the winter for spring and summer agricultural use. These large-scale landscape infrastructure projects efficiently store and manage glacial meltwater by exploiting annual freeze-thaw cycles and incorporating large storage reservoirs to contain glacial runoff (Ahmed, Higgins & Norphel, 2010). During periods of drought or when Ladakhi farmers otherwise wouldn't have access to meltwater (such as in the early spring), the artificial glaciers melt, releasing their ice stock in the form of irrigation water. The long, cascading pools are located between the high natural glaciers and the village croplands below, using gravity to move the water when farmers open regulating and diversion gates (Higgins, 2012; Norphel, 2010).

These glaciers have been placed above eight different villages in Ladakh, and range in size from a small number of pools at a single site to many dozens of reservoirs that extend over a mile in length. (Figures 3 and 4 in the Appendix) They are typically built using masonry walls with stone collected from the site and local labor, often through work parties organized by the Leh Nutrition Project (Clouse, 2014). In allowing farmers to collect water that is cascading down through the watershed during non-agricultural seasons (fall and winter), and save it for later use (spring and summer), the artificial glacier effectively increases the overall water supply available to farmers (Vince, 2009). Moreover, because these glacial pools serve the entire village and help to stretch the communal supply of water, they are collectively owned, managed, and operated by local farmers.

Ice Stupas

Ice stupas were designed by Sonam Wangchuck in 2014, as scalable ice towers that can store fall and winter water, as ice, for use during the following spring and summer. (Figure 5 in the Appendix) Much like the artificial glacier, ice stupas take advantage of annual freeze-thaw cycles, gravity-fed watersheds,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and placement between high glaciers and low croplands. Unlike artificial glaciers, however, the ice stupa requires the extensive use of pipes to funnel water through trenches and up to the spout of the stupa's crown, as well as regular maintenance throughout the winter, to move pipes as ice forms.

The ice stupa has several advantages to the artificial glacier. It can be endlessly replicated across a village landscape, unlike the glacier pools, which need to be located on specific slopes and solar aspects. It is scale-able, functioning equally well for small reserves of ice as it for a large, multi-story site. In this sense it is also something that individual farmers can develop on their own accord, rather than relying on the larger village buy-in needed to implement an artificial glacier system.

However, the ice stupa connects to the social, cultural and religious fabric of Ladakh in other ways. In built prototypes over the past two years, builders have purposefully worked with the imagery of the local stone *chorten*, or *stupa*, which serves as a religious icon and prayer site. The ice forms in a similar structural shape, referencing the sacred forms of the stupas that are already built in this landscape. To emphasize this connection, the team of builders invited monks from the nearby Phyang monastery to bless the stupa, and they strung Tibetan prayer flags across the ice mass. In this way, the project developers have helped to root the radical new design intervention within the extant religious, social and cultural vocabulary of the region.

Snow Barrier Bands

Snow barrier bands perform much like the snow fences found in other parts of the world. In Ladakh, they are long, linear masonry walls built at high mountain passes in the upper portion of a watershed. The walls are typically built from stone found on the site, and are usually 3' wide, stand up to 5' tall, and can be many hundreds of feet in length. Used alone or as a part of a larger series, they help to capture snow, hold it on site at the top of the watershed, and then release it in the form of meltwater in the late spring. (Figures 6-7 in the Appendix)

In Ladakh, many ancient villages have been built on the south side of mountain ranges, in order to take advantage of passive solar heating in cold winter months. However, the winter winds blow from south to north, effectively propelling scarce winter snow from the densely populated side of the mountain range to the uninhabited northern slope. Snow barrier bands serve to stop snow before it can tip from a south-facing drainage into a north-facing drainage, thereby increasing the amount of meltwater that will be available to farmers in populated areas.

Snow barrier bands are also derivatives of ancient local building vocabularies. They incorporate masonry walls, which constitute the vast majority of traditional Ladakhi construction, from houses and temples to animal enclosure, crop protection, and fences. Because they serve an entire watershed, whole villages will work together to construct and maintain them, even though they are placed at high mountain passes. In the case of the snow barrier bands built at Warila Pass in 2013, several hundred villagers actively collaborated on the build, which was held over the course of a week at an elevation of 17,500'.

Canals/Kuhls

Water infrastructure systems, such as the *kuhls* or the primary canals that direct meltwater to village croplands, have increased in size and scope over the past decade. Kuhls have been widened, improved with impervious membranes, regulator gates, and pipes, and stretched farther than traditional technolo-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

gies would have otherwise allowed. They now have been engineered to leap over ridges, cross highways, and exploit topography to carry water across many miles to towns outside of a particular drainage.

Kuhls help to address one of the major challenges for today's farmers: the inefficiency of traditional irrigation infrastructure. Ancient channels linking upper glaciers to low-lying fields have been carved out of the landscape over many hundreds of years; these are the mud, wooden, or stone lines carrying water along a path. These waterways lose a large amount of their volume to seepage; in one estimate 90% of the water routed above the village of Stongde, in the neighboring Zanskar valley, vanished before reaching fields (Crook and Ostmanson 1994). Newer, high- and medium-tech kuhls reinforce these crumbling old canals, improving water access by reducing losses due to seepage and poor engineering. (Figure 8 in the Appendix)

These new irrigation projects provide a much more efficient, and often large-scale approach, than pre-existing progenitors. However, the kuhls can still be considered relatively small-scale and supportive design interventions. While they have been built with funding from government agencies (such as the Watershed Development Agency), they often draw construction labor from adjacent villages. Moreover, kuhl construction reinforces traditional Ladakhi cultural and social frameworks, by hardening and improving existing water management systems that work within conventional agricultural concepts.

Zings

Zings are large water reservoirs, usually located just above croplands in order to store meltwater for agricultural use. The reservoirs are typically constructed from masonry or earth berms, and are then lined with concrete or mud. At the upper end they will feature a gravity-fed inlet, while the lower side will have a drain and overflow gate. Water diverted into the zings can be controlled, both to direct it in and to release it into the fields. Zings are connected to the source of the meltwater and to the fields below by the same canals that have historically supported irrigation practices in Ladakhi villages for centuries. (Figure 9 in the Appendix)

These small ponds have a limited capacity, so they cannot provide enormous stores of water. However, they do buy time, enabling farmers to irrigate fields according to their own schedule. For instance, when fields are on a rotation of a split night and day watering schedule, those who have a "night shift" can divert the water to a zing to hold it for use the following day (Gutschow, 1997). By storing water, even temporarily, above the sites where it will be used, the zings ensure that all of the water available to farmers during a season will be used, thus reducing waste.

WEIGHING THE BENEFITS

Unlike many other forward-thinking climate-adaptive design ideas, each of these five water harvesting and management solutions supports the existing agrarian lifestyles honed over centuries in Ladakhi villages. This is particularly relevant in a society where "agriculture is the backbone of every village economy, engaging up to 70% of the working force," and many Ladakhi villagers rely exclusively on local agriculture for their food supply (Pulselli & Pelliciardi, 2014, 347). Rather than reimagine the economic frameworks that will support village life in the years to come, these design interventions seek to improve the productivity of the existing system.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In assessing the economic implications of such interventions, one must first ask: Are they effective? Most hydrological models, especially those involving untested design interventions, are carried out over a series of years: indeed, one year would not adequately describe patterns or outlying factors. Current data on these five water management strategies lacks this long-term view, and several of the interventions described in this chapter lack even the most rudimentary modeling. Thus, it is still too early to be able to tell whether the interventions work as anticipated, and to what extent they improve water access for cold desert farmers.

Anecdotally, however, each of these five design interventions has been met with much interest and excitement from village farmers (Higgins, 2012). The low cost of implementation, across the board, and the relative flexibility of each of these strategies suggests radically-inclusive access for those who wish to employ these solutions. And in all cases, the water management strategies effectively improve or shore up existing systems, so they represent a relatively low-risk response to climate-change adaptation.

While traditional surface water irrigation has supported life for many hundreds of years, structural flaws are evident in the broader planning system. One of the most difficult planning challenges for Ladakhi villages is that current irrigation methods don't allow for population growth; the system assumes a fixed number of individuals or farms. With better health and life expectancy through access to new medical practices, and with the dissolution of the ancient practices of primogeniture and polyandry, the number of households in the region will likely continue to grow. Because the cultivable land in villages is fixed, individuals may need to seek employment elsewhere or import food for local consumption.

Likewise, the overall volume of water available in the watershed effectively places limits on the size and scale of an individual farmer's cropland; villagers must work together to develop an equitable division of irrigated fields. Ultimately, the volume of water coming from the high glaciers and seasonal snows may not be enough to support the crops grown below. After all, the intensive and highly productive agricultural practices of Ladakh rely heavily upon water resources, and are effectively limited by the region's supply of water.

CONCLUSION

In high mountain villages, the self-sufficiency and relative autonomy of groups have historically been prized survival traits. Small, independent villages act as distinct units, with villagers solving problems as they surface, working together to make decisions, and taking care of one another in times of need. The community-based water management framework implemented in Ladakh acknowledges that these villages have historically functioned as autonomous, self-governing populations, and seeks to reinforce age-old methods of group resilience.

Unlike the top-down planning solutions that may work well for large urbanizing populations, Ladakhi villages demand solutions that are site-specific, small, and dispersed. While broad, overarching schemes for infrastructure projects may be needed in large urban areas, in Ladakh these designs lack the physical, cultural, social, religious, and economic context that will ensure a proper fit.

The five new water management strategies for Ladakh provide a working example of the type of interventions that could work in other cold mountain environments. In suggesting a policy direction for the future, small, dispersed systems, responsive to local conditions, appear to be a promising way forward. In these examples the design intervention recognizes the relative autonomy of each village, both in terms of needs and opportunities; they engage stakeholders in the development of each system, from

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

construction to maintenance; they layer over existing water infrastructures to improve efficiency; and they are affordable, scalable solutions, accessible to rural farming villages. These designs suggest an approach to water management that offers co-benefits: interventions are rooted in the communities they serve, connected to the cultural, social and religious context, responsive to the climate and landscape, supportive of rural self-sufficiency and independence, and affordable due to their scale and size.

In many communities water is an invisible resource: not owned, managed or operated by users, perhaps not even a significant factor of the economic, religious, or social functioning of those sites. But in the high Himalaya, water is a form of the commons that is absolutely critical to group survival, and it is made visible by the clear relevance it has to daily life. The various techniques for water planning in this desert region help to illuminate some of the opportunities and challenges inherent to climate change adaptation. In so doing, these five different designs from the Indian Himalaya suggest a model for other water-constrained mountain communities. If, indeed, instability will become the chief characteristic of the Future City, water management solutions will likewise need to become flexible, scalable, layered and dispersed. Finally, in order to effectively deploy these varied approaches, pioneering solutions also must fit in. Climate-adaptive water management practices in Ladakhi villages demonstrate the importance of integrating new design interventions with existing irrigation systems, social fabric, environmental context, religious interest and cultural identity.

Chapter 19
Web Based Automatic Soil Chemical Contents Monitoring System

Samuel Dayo Okegbile

ABSTRACT

The need for finding new, more efficient and sustainable methods of agricultural cultivation and food production has become more critical especially in the developing countries. In order to facilitate this, there are needs to design a precision agriculture system capable of providing farmers with useful data about the conditions of the soil available in their farmlands in a user friendly and easily accessible manner. This work therefore presents a web based automatic soil chemical contents monitoring system. The work combined the use of pH probe, an Arduino sink node and other devices to automate the processing of soil chemical contents data obtained from farmland. Three solutions were used in testing the efficacy of the proposed method and comparing it with the existing method. The result showed that, the proposed design was able to extract the chemical contents of the soil from the farmland and transferred the same to Liquid Crystal Display and a web page.

1. INTRODUCTION

Precision Agriculture (PA) is a farming management concept based on observing, measuring and responding to inter and intra-field variability in crops (Zarco-Tejada et al., 2014; Rasher, 2015). The holy grail of precision agriculture is the ability to define a Decision Support System (DSS) for farm management with the goal of optimizing the returns on inputs while preserving resources (KTNUK, 2015; Whelan

DOI: 10.4018/978-1-5225-9621-9.ch019

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

and McBratney, 2003). PA is technologically feasible as well as being economically and environmentally justifiable. Improving the agricultural process can maximize financial return and increases the stewardship of land, water, and related natural resources (Tayari et al., 2015). There is therefore an optimum need to know the chemical contents of the soil for different crop production (Vellidis et al., 2003). Researches on the effects of soil chemical contents for crop yield on the farms have been extensively studied in the past. With advancements in technology over the past decades, overall plants growth with crop yields have increased significantly while management practices have also changed since those earlier times (Tulberg et al., 2007; Bowman, 2008). These changes have improved the detection of soil contents for today's crops. The new technologies available to producers and researchers with weakness observed in existing knowledge however necessitates new research efforts.

The development of information technology has been having a considerable influence on agriculture. There have emerged a number of new industry-specific technologies and new applications over the past few years, including the ever-widening agricultural application of mobile communications devices and technologies (Szilágyi, 2006). The introduction of Wireless Sensor Network (WSN) technology in agriculture is also evolving rapidly (Ye et al., 2016). While WSNs provide possibilities to sense and gather information of various environmental soil and crop conditions, it remains a challenge for farmers to know real-time data of a farm soil chemical contents as well as incorporating necessary crops to cultivate on such land (Zarco-Tejada et al., 2014).

Arduino microcontroller has proven to be a useful device in precision agriculture. It can be connected with several other devices to measure the activities on the farmland such as irrigation system, soil moisture contents, soil chemical contents, green house monitoring system etc. The results of which can then be viewed on different technology platforms such as, mobile phones, web page, Liquid Crystal Display(LCD), and so on.

There are optimum needs to know the chemical contents of the soil for different crop production. For instance, if the soil is acidic, it may not be the best decision to plant some crop on such soil because such crop may not produce a reasonable yield which may result to loss in the part of farmers. Research on the effects of soil chemical contents for crop yield on the farmland has been studied extensively in the past. With improvements in the technology over the past decades, overall plant growth and crop yields can be increased significantly and management practices can also be changed.

Manipulating the soil contents however is highly dependent on the monitoring and controlling of the chemical contents of the soil (Finžgar et al., 2006). There are several ways by which soil monitoring can be carried out ranging from the traditional methods of measuring soil chemical contents with the use of pH meter to keeping a manual digital record of pH level on a digital display with the aid of pH sensor interface. Measuring and monitoring the soil contents in order to make decisions in research and/or automation is however laborious and error prone (Kumar et al., 2015). Existing works show that measuring of soil chemical contents such as lead, nitrogen, potassium, phosphorous etc. are mostly carry out in the laboratory which are time consuming. In other cases, some farmers do not even test the chemical contents of their soil until they see the output in form of yield from their farm which usually leads to lower yield from their various farm. It is then important that a system capable of monitoring the soil chemical contents with little or no human intervention be provided to help farmers in realizing better output and also in making accurate decisions in research as well as maximization of crop yield. The need to develop an automated system that monitor soil chemical content becomes a necessity.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. RELATED WORKS

Mikó (2009) studied the effect of green manuring on soil and different crops. The work carried out an investigation of the effect of soil penetration resistance, soil humidity content, plant phenology, chemical composition of plants, crop yields, and the effect of nitrogen fertilization on soil and crops. Soil penetration resistance was carried out using penetrometer. It was discovered that the difference between soil penetration resistance of plots covered with green manure plants and the control were proven to be higher in deeper layers than of those close to soil surface. The work also demonstrated the steps required in measuring the chemical contents of the soil.

Zografos (2014) developed a system for precision agriculture which provides farmers with useful information about the soil, the water supply, and the general condition of their fields. The system utilizes sensor boards which consist of a microcontroller connected to one or more sensors along with a ZigBee transceiver, transmitting data which are then retrieved at a gateway. The system act as a monitoring system constantly reporting on the status of farms or livestock and as a recommendation system for prospective farmers. The work showed that, it is possible to monitor a farm remotely without the farmer being present on the field. Rigoberto (2015) also developed a system that allow users to monitor the server room temperature through a website by using any computer or mobile device with internet access. The system was implemented using Arduino Uno, Ethernet shield, thermistor, carbon resistor, web server, and database server. The system helps users keep track of the server room temperature from a remote location. The authors demonstrated the possibility of monitoring the result from arduino remotely on a web page. The work however made use of ethernet shield in order to send the result of the aggregated data to the web which required too many cables.

According to Kumar et al., (2015), the studied proposed an in-situ soil pH sensor with nanoparticles of antimony and zinc which overcame the existing drawbacks and requires no power source for its operation. The proposed device is portable, simple and easy to use in-situ pH meter for direct measurement of soil pH. The work detailed soil pH sensing techniques based on nanotechnology, in which nanoparticles of Zinc Oxide (ZnO) was used. The work proposed an implementation of an efficient and improved in-situ soil pH sensing approach.

Design and implementation of a remote greenhouse temperature monitoring system using wireless sensor networks was carried out by Olaoye (2015). The system used the combination of wireless sensors, Arduino sink node, Zigbee transceivers and Zigbee protocol in implementing the receipt and processing of temperature data obtained from a greenhouse. The author concluded that wireless sensor networks can be used to monitor and present temperature data in greenhouse for automation and research purposes. Zigbee Based Soil Moisture Monitoring System was also considered by Kirandeep et al., (2016). The authors presented a system that can help the farmers to get proper information about the amount of water required for irrigation as well as the temperature and humidity of atmosphere. The system works by sending data to remote location using Zigbee based Wireless sensor network. Soil moisture sensor measures the content of water present in the soil. When soil sensor is embedded into soil, it gives percentage of water present in the soil on LCD and laptop. The data received from the sensors is displayed on integrated development environment serial monitor, which gives the value of soil moisture in percentage, atmospheric temperature in degree Celsius and relative humidity in percentage.

Franz et al. (2016) used Cosmic-Ray neutron probes to monitor landscape scale soil water content in mixed land agricultural systems. The work explored the use of the newly established Cosmic-Ray Neutron Probe and method to monitor landscape average Soil Water Content in a mixed agricultural

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

land. The work claimed that the ability of the Cosmic-Ray neutron probe to provide real-time and accurate landscape Soil Water Content measurements makes it an ideal method for establishing long-term monitoring sites in agricultural ecosystems to aid in agricultural water and nutrient management decisions at the small tract of land scale as well as aiding in management decisions at larger scales. Kim et al. (2016) also followed this approach by considering the possibility of an automated field-deployable Bioaerosol Monitoring System using Carbon Nanotube-based Biosensors.

In another work, Ye et al. (2016) designed a Zigbee based farmland environmental remote monitoring system. The design realized the function of farmland environment remote monitoring system, and then sends the data to the intelligent decision system for statistical analysis. The work is useful to guide agricultural production by helping farmers to monitor the situations of their farm remotely. Experimental results show that, the system realized remote real-time and accurate monitoring of farmland environment data on external devices such as mobile phone, notebook and personal computers. The idea of Ye et al. (2016) is close to the work of Mitralexis and Goumopoulos (2015). The authors designed, implemented and evaluated the performance of an integrated agricultural monitoring and irrigation system using energy-autonomous wireless sensors and actuators. Monitoring and irrigation of the field were carried out through a web application that collects data from a Wireless Sensor Network deployed in a farmland and also displayed relative information in real time. The work only considered the irrigation, and chemical contents of the soil were not considered. The concept employed in this work however was useful in developing our proposed system.

Liao et al. (2015) also designed a Zigbee and General Packet Radio Service (GPRS) based remote farmland monitoring system. Using these two technologies, the system carried out data collection which were illumination, Carbon dioxide, temperature and humidity of soil for transmission. When compared with traditional monitoring scheme, the proposed method provided a strong scalability and flexibility especially in a harsh environment and improved the monitoring mode effectively while decreasing human cost to some extent. Manikandan and Rajaram (2016) in their own work also developed an automatic monitoring system for a Precision Agriculture using Wireless Sensor Networks. The work considered bridging the gap between water usage and water wastage. The work proposed a low cost and efficient wireless sensor network technique to acquire the soil moisture and temperature from various locations of farm and as per the need of crop controller, take the decision either to make irrigation ON or OFF. Wireless Sensor Network was also used by Gayathri et al. (2015) to monitor corn farmland.

In this paper, we take the advantage of depth of literature in precision agriculture to propose an effective system capable of detection soil chemical contents and providing the same to the farmers wherever they are in an easy and efficient manner.

3. METHODOLOGY

The procedures, techniques, tools and documentation aids which were channeled towards the implementation of this work is hereby presented. Arduino UNO, PH meter probe, GPRS Shield, Connecting Wires, Server unit (Apache CentOS) and 9v Battery were interconnected to produce a soil chemical contents monitoring system. Also, fritzing, Arduino Integrated Development Environment, Hypertext Preprocessor, Structure Query Language (MySQL), Hypertext Markup Language (HTML), JavaScript and Cascading Style Sheet were used as part of the software used in achieving the design.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.1. System Architecture

The overview of the system architecture is given in Figure 1. The design consists of pH probe connected with arduino uno board necessary to detect the chemical contents of the soil and transferred the aggregated soil chemical contents to the arduino board. This will be displayed on a Liquid Crystal Display (LCD) and/or a web page. The design can be adapted to more than one farmland. The pH meter and the Arduino sink node were deployed in the farm and form the main components of the monitoring system. The pH measures the pH of the soil and report back to the sink node using pH circuit that was designed for the pH probe. The result was displayed on LCD. The Arduino sink node also aggregates the data on the external memory module and pushes the data to the remote server through the GPRS Shield Module and the Web Service to the remote database. The user or farmer interested in monitoring the chemical contents of a farm uses the web dashboard to view the pH statistics of the farm via a web browser. The web dashboard pulls the data that has been stored via RESTful Application Programmer Interfaces (REST APIs) provided by the web service. The result is then compared to the standard pH value to know the type of elements that is present in the farm, hence predict the type of crop to cultivate on the farm. The components as demonstrated by DFROBOT (2015) were incorporated by connecting the pH electrode to the Bayonet Neill-Concelman (BNC) connector on the pH meter board using the connection lines as shown in Figure 2. The pH meter board was connected to the analog port 0 of the Arduino controller.

The connection of the LCD with the arduino uno interface was achieved through combination of several pins. The physical connection and the schematic diagram are shown in Figure 3 and Figure 4 respectively. The system model was designed using fritzing electronic modeling tool. This is also shown in Figure 5.

3.2. Arduino Sink Node

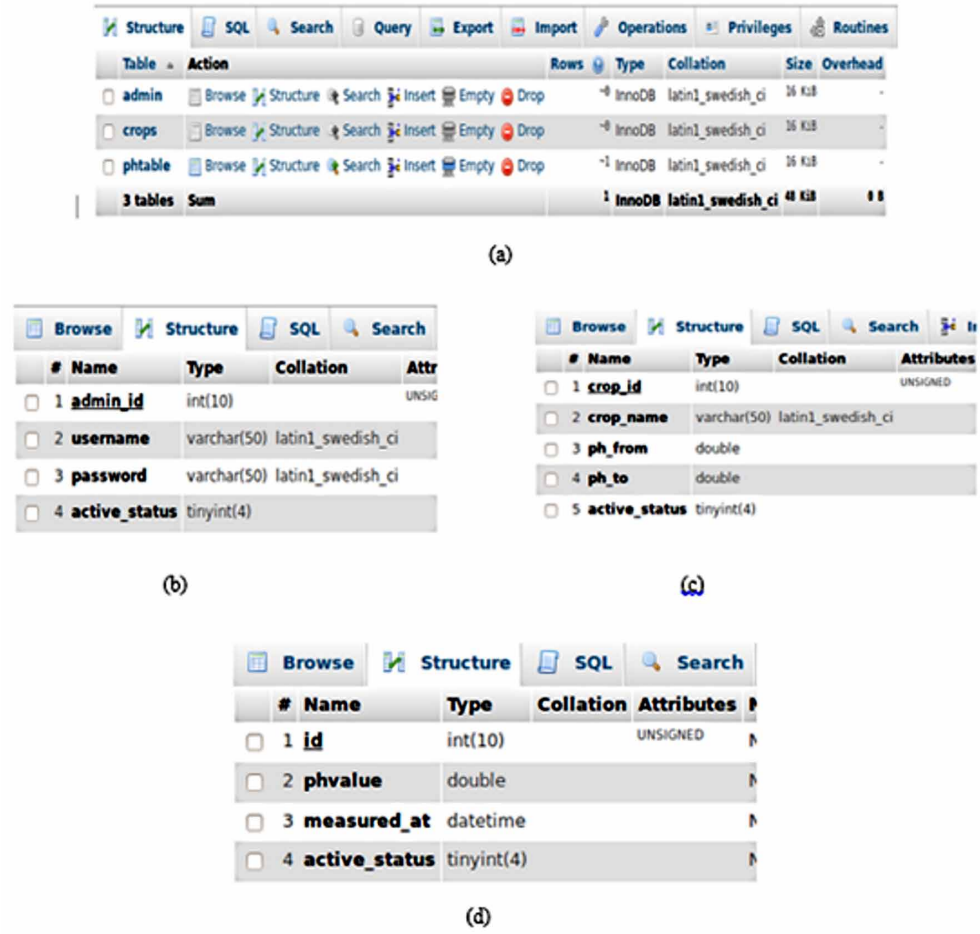
The Arduino board was mounted with pH meter which have been configured using AT commands and acts as the sink node, receiving real-time pH value from the pH meter. The transfer of data was implemented by making Hypertext Transfer Protocol (HTTP) request calls via the GPRS shield Module to the web service hosted on the remote server.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.3. Web Service

Web service is an essential component of the system which serves as an interface between the database and the rest of the system. The main function of the web service is to display the pH value of the soil measured from the base station to the farmer every 48 hours on the web dashboard, the duration can however be changed depending on the farmers' decision on how frequent the web should be updated. The model of the web service was service oriented because it acts as a utility system providing information and serve as means of communication between web dashboard and database. It was implemented using Yii PHP framework, applying the object-oriented programming paradigm to make the web service robust and allow a high level of code reuse for rapid development. The database used in the development of the web service is a MySQL Database. The developed database served as the location where the data from the base station were stored. The database was relational in nature and has three tables which are admin, crops and pH table shown in Figure 6a. The admin table basically stores the username, password, admin id and the status of the recording (active or inactive) as shown in Figure 6b. The crops table basically

Figure 6. Admin, Crop and pH tables respectively



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

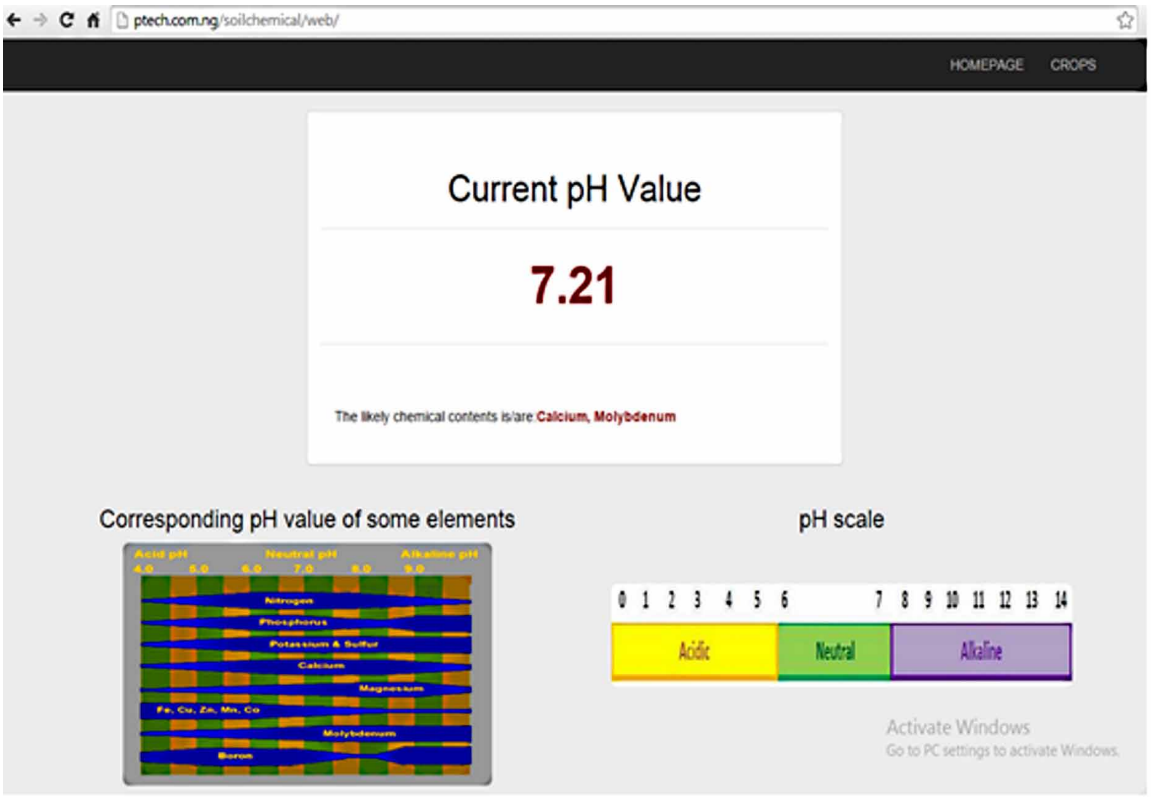
stores the crop id, crop name, previous pH value, updated pH value and the status of the recording (active or inactive) as shown in Figure 6c. The pH table as shown in Figure 6d basically stores the pH identity (pH id), pH value, measured time and the status of the recording (active or inactive).

4. RESULTS AND DISCUSSION

The web dashboard presents the data pushed to the database via the web service. It was implemented using PHP, JavaScript, CSS and HTML5. The aggregated pH data is presented in the web and the value can be interpreted based on the elements that are found on such soil at a particular time as shown in Figure 7. The pH value of 7.21 indicates that the likely possible elements in the soil are Calcium and Molybdenum. Table 1 shows the pH ranges and corresponding possible element present. The web dashboard has homepage and crops page which represent the view of soil pH from the farm and list of crops with their corresponding pH respectively.

Also, admin can update the pH value of different crops on crops page of the website by login with username and password and delete or update the pH value and/or name of a crop. The web dashboard was hosted temporarily at http://ptech.com.ng/soilchemical/web/_during the time of testing.

Figure 7. Web interface of the project



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Ph ranges with their corresponding elements

S/N	pH range	Elements
1	4.00 - 5.00	Iron, Copper
2	5.00 – 6.00	Zinc, Boron, Manganese, Cobalt
3	6.00 – 7.00	Nitrogen, Phosphorus, Potassium, Sulphur
4	7.00 – 8.00	Calcium, Molybdenum
5	8.00 – 9.00	Magnesium

Each of the components of the system and the system, as a whole, were tested to ensure that they functioned properly. This is to ensure that the implementation was done satisfactorily based on the model proposed. The different components were tested based on their nature and structure. The web service and web dashboard were tested properly in order to uncover any bug or loop hole in the design. The implementation was tested in Biochemistry Department laboratory, Obafemi Awolowo University, Ile-Ife in Nigeria. The testing was done around 2pm within a period of three hours. This was due to the preparation of the solution to be used for the testing. Solutions were preferred instead of soil due to regular cleaning of pH probe required each time the probe is inserted to the soil. This however does not change the reliability of the outcome of this research work. The result obtained using laboratory method is shown in Table 2 while the result obtained using the proposed method is shown in Table 3. Three solutions were used in testing the efficiency of the designed system. The solutions were tested for both methods at pH values of 4.00, 7.00 and 9.18 respectively. The result obtained showed remarkable agreement with the existing method.

Table 2. Result from the existing and proposed methods (part 1)

pH Value	A	B	C	Average = (A+B+C)/3
4.00	3.99	4.00	3.99	3.99
7.00	7.00	7.00	7.02	7.01
9.18	9.18	9.17	9.17	9.17

Table 3. Result from the existing and proposed methods (part 2)

pH Value	A	B	C	Average = (A+B+C)/3
4.00	3.95	3.98	3.99	3.97
7.00	7.00	6.99	6.99	7.00
9.18	9.16	9.16	9.17	9.16

Note:
A – First measurement of a solution.
B – Second measurement of a solution.
C – Third measurement of a solution.
Average – Sum of A, B and C divided by three.
Where the values of X and Y obtained are; 3.99, 7.01, 9.17 and 3.97, 7.00, 9.12 respectively.

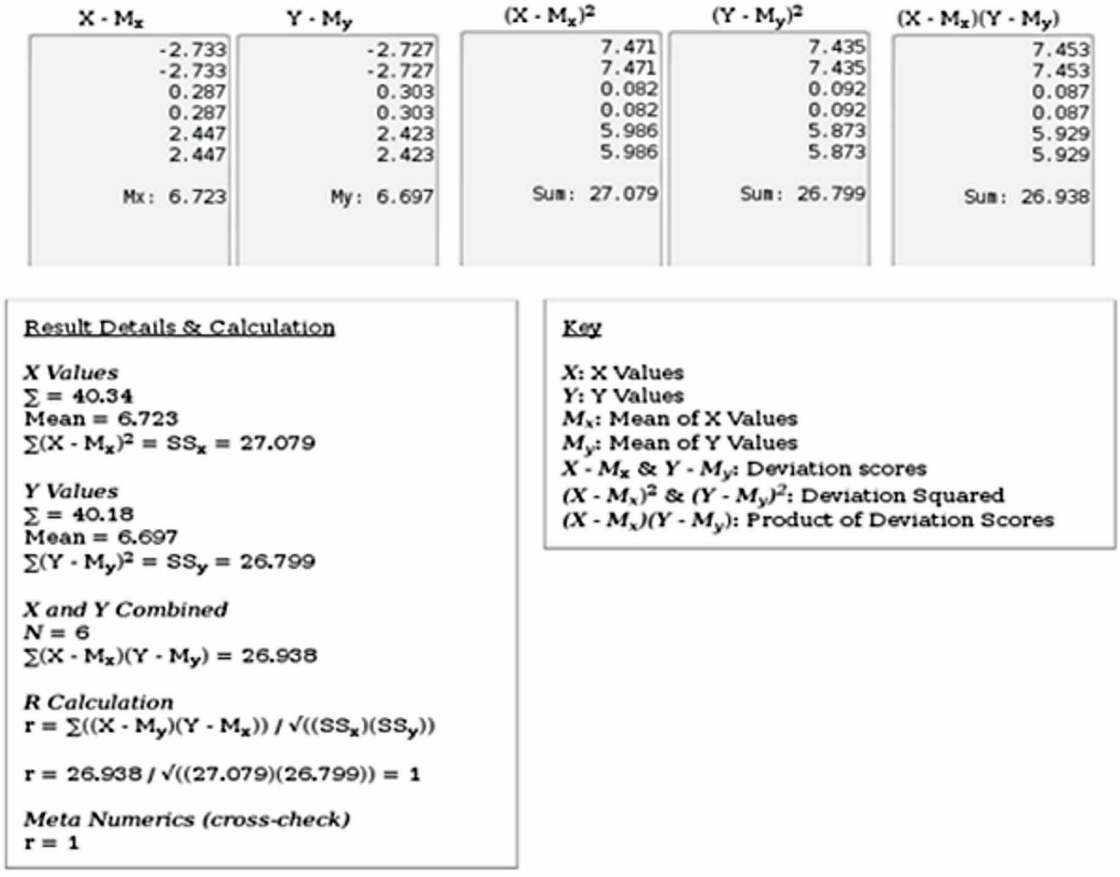
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In order to confirm the accuracy of the proposed method, the efficiency of the design was carried out using Pearson correlation as shown in Figure 8. When r known as correlation coefficient is closer to 1, it indicates a strong positive relationship. A value of 0 indicates that there is no relationship. Values close to -1 signals a strong negative relationship between the two variables. The result showed r to be one (r = 1) signifying the reliability and acceptability of our proposed method. We took X to be the result obtained using the traditional method usually being carried out in the laboratory and Y to be the result obtained using our proposed automated method.

5. CONCLUSION

The project produced a system capable of generating the soil chemical contents. Our proposed method agreed with existing one signifying the reliability of our design. The results showed different pH values for different solutions. The values were automatically displayed on LCD and web page. This will facilitate the decision making on the type of crops to cultivate on any farmland if implemented on large scale. With the value of r (correlation coefficient) equals 1, this is a strong positive correlation, which

Figure 8. Calculation using Pearson correlation coefficient



$X - M_x$	$Y - M_y$	$(X - M_x)^2$	$(Y - M_y)^2$	$(X - M_x)(Y - M_y)$
-2.733	-2.727	7.471	7.435	7.453
-2.733	-2.727	7.471	7.435	7.453
0.287	0.303	0.082	0.092	0.087
0.287	0.303	0.082	0.092	0.087
2.447	2.423	5.986	5.873	5.929
2.447	2.423	5.986	5.873	5.929
Mx: 6.723	My: 6.697	Sum: 27.079	Sum: 26.799	Sum: 26.938

Result Details & Calculation

X Values
$\sum = 40.34$
Mean = 6.723
$\sum(X - M_x)^2 = SS_x = 27.079$

Y Values
$\sum = 40.18$
Mean = 6.697
$\sum(Y - M_y)^2 = SS_y = 26.799$

X and Y Combined
$N = 6$
$\sum(X - M_x)(Y - M_y) = 26.938$

R Calculation
$r = \sum((X - M_y)(Y - M_x)) / \sqrt{((SS_x)(SS_y))}$

$r = 26.938 / \sqrt{((27.079)(26.799))} = 1$

Meta Numerics (cross-check)
r = 1

Key

X: X Values
Y: Y Values
M_x: Mean of X Values
M_y: Mean of Y Values
$X - M_x$ & $Y - M_y$: Deviation scores
$(X - M_x)^2$ & $(Y - M_y)^2$: Deviation Squared
$(X - M_x)(Y - M_y)$: Product of Deviation Scores

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

means that X variable values agree with Y variable values. This means that the result obtained from the automated method proposed agrees the existing traditional method of testing the chemical contents of the soil from the laboratory. The system will be useful as a decision support system thereby complimenting human experts' knowledge of suggesting the contents of the soil. The system can also allow the condition of soil on a farmland to be monitored remotely eliminating the stress of traveling to the farmland most of the time.

5.1. Future Work

This work has been able to use pH meter to obtain the chemical contents of the soil and transferred the aggregated value to the web page. A lot of research are still needed to be done on technological way of getting chemical contents directly from the soil without a need to interpret the pH value before suspecting the possible chemical contents present in a soil. In our future work, we plan to design an arduino based device that can detect some of or all of the soil chemical contents automatically such as Nitrogen, Potassium, Phosphorous etc. instead of using pH meter for approximation. We also intend to propose an automatic soil chemical contents adjustment system that can automatically regulate soil chemical contents so that farmers would not need to apply the deficit soil chemical contents manually.

Chapter 20
The Empirical Study on the Evolutionary Game Based Agricultural Products Supply Chain

Jun Sun
Dalian Polytechnic University, China

Ruben Xing
Montclair State University, USA

ABSTRACT

This research paper is to use a method of Evolutionary Game to investigate the relationship between a large supplier and a franchised supermarket in China. The authors would like to go through their empirical study with their filtered answers from the survey using SPSS software on agricultural supply chain for their quality safety factors. Their research is using factor analysis with five target factors which are: the excess return, cost, the relative size of cooperative enterprises, hitchhiking, and overflows income. Applying these factors to the evolutionary game model, analyze the earning status from the both players under their own policies, then make suggestions or proposals for quality and safety issues of agricultural supply chain management.

1. INTRODUCTION

Regarding the application research of game theory on the food supply chain security, some scholars' studies are focusing on the issues of food supply chain and agricultural supply chain security from the perspective of game theory, while some other scholars are analyzing the relationship between the main body of food supply chain and food enterprises based on evolutionary game theory. Yet, there were no conclusions for the quality safety of agricultural products supply chain, no game analysis on the cooperation between the supplier and the seller. Nor resolved the problems for the quality and safety problems of agricultural supply chain in the presence of node enterprises.

This research intends to investigate the quality-safety problems of agricultural products supply chain from the perspective of evolutionary game theory. Also to establish an evolutionary game model between upstream and downstream stakeholders of agricultural products supply chains, propose possible solutions to the quality, safety of agricultural products supply chains from the perspective of empirical analysis.

2. PROBLEM DESCRIPTION

Given the consistency of the chain of agricultural supply chain, the paper aimed to study one typical agricultural supply chain. Based on the Lotus Town of Dalian Pulandian City which is located in the foothills of White Cloud Hill in the central Pulandian, is the conjunction center with strong radiating outward traffic of North-South Corridor Tang Hing highway and the Central City Eight Midline Line highway. This location is very conducive to guarantee the timely transport of agricultural products, fresh and shelves. Lotus Town has more than 400 vegetable greenhouses covered an area of 800 acres, 3000 acres of high oil soybean, 5,000 acres of peanuts under plastic mulch. There are several famous local products like "Flagpole bottom" cucumber, and mulberry, which are conducive to the development of the local characteristics of agricultural products, also conducive to brand building. It is more conducive to the development of agricultural supply chain in Lotus Town.

3. DATA COLLECTION

This investigation was conducted mainly in the form of issuing questionnaires and field random sampling survey. Our insurance of questionnaires went through with the main respondents. Based on Lianshan Town area, they were selected from the reginal farmers, suppliers, vendors, consumers and regulators as well (see Figure 1). Total 278 of 320 issued questionnaires were recovered, and 261 responses were confirmed the valid ones after effective screening. The recovery rate was 86.875% with the effective rate of 81.56%. There were 96 males and 165 females among the effective respondents. After issuing, recovering the questionnaires, and excluding invalid ones through initial screening, and analyzed by SPSS18.0 data analytics software. Subjects of the investigation are mainly farmers, suppliers, sellers, customers, regulators. The proportion and numbers of the respondents are listed in Table 1.

Table 1. The fieldwork investigation object of the quality-safety of agricultural products supply chain

Respondents	Proportion
Farmer	16.9%
Supplier	19.5%
Sellers	15.7%
Consumer	41.8%
Regulators	6.1%

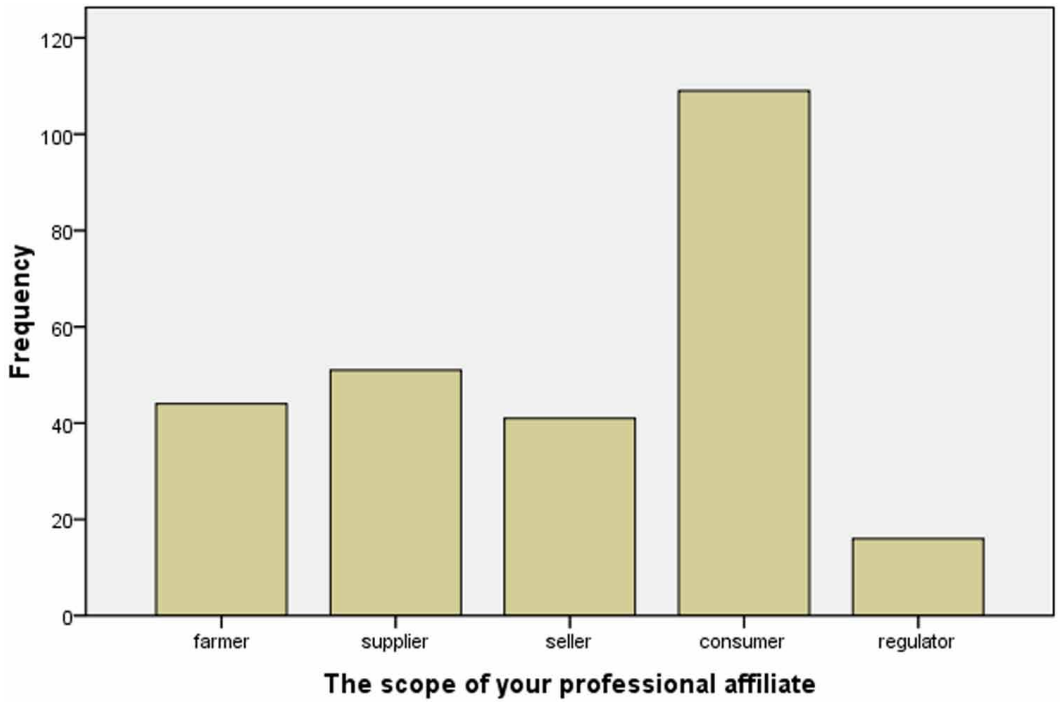
Figure 1. Professional scope of respondent



4. DATA ANALYSIS

In order to investigate whether there is any direct impact that the average monthly income could be any factor to choose large supermarket chains for green agricultural products consumptions, our field survey included a question of respondent's monthly income. In addition, for the same concerns, the respondent's educational background was also included in our questionnaires.

The ranges of respondents' average monthly income are <2,000, 2001-3000, 3001-4000, 4001-5000, and >5001 (the unit is RMB-Yuan) as shown in Table 2.

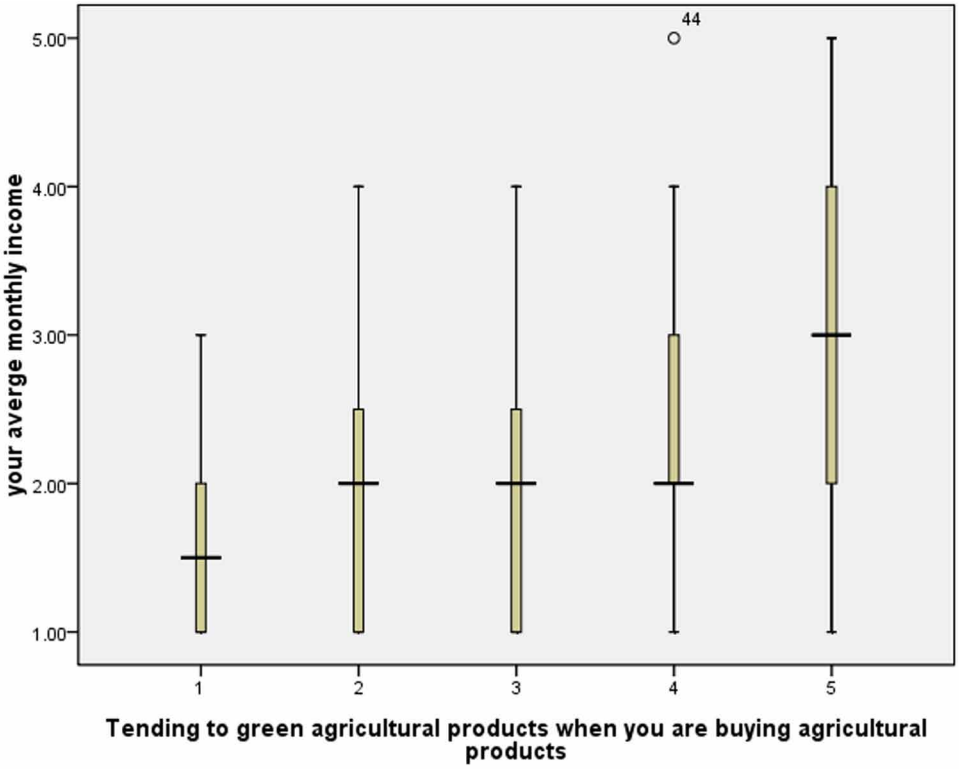
In the consumption of agricultural products, there are 2.3% of respondents strongly disagree to choose green products, 2.7% of them disagree, 9.2% are neutral, 41.8% agree, and very much in favor of 44.1%. As shown in Figure 2, except those whose income are below 2000 yuan, the majority of respondents

Table 2. The respondent's average monthly wage with their quality-safety field of agricultural products supply chain

The average monthly income (yuan)	The number
≤2000	34
2001—3000	89
3001—4000	80
4001—5000	44
≥5001	14

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. The relevance of the average monthly income and tending to green agricultural products



with middle and higher income are in favor of choosing green agricultural products, and factor more on quality-safety concerns.

The education background of respondents are: 12.6% with junior high school or below, 23.8% with high school, vocational school are accounted for 19.9%, and 32.6% with a university degree, while 11.1% with graduate degree. In the purchase of agricultural products, the attitude of the primary consideration for the quality and safety factors is divided into: strongly disagree, disagree, neutral, agree, and strongly agree. The number of people with different attitude is shown in Table 3. Two survey shown in Figure 3 indicates that with the improvement of people's education, people pay more attentions to the green logo and quality of agricultural products.

Table 3. The respondents of the quality-safety of agricultural products supply chain hold the attitude that considering quality-safety priority when buying agricultural products

Attitude	The number
Strongly disagree	4
Disagree	10
Neutral	34
Agree	106
Strongly agree	107

4.1. Reliability and Validity of the Questionnaire

Through the entire process of the survey, whether it was from questionnaire, the process of investigation, or the final recovery and data analysis, each link has made a detailed planning and control, which is the guarantee of good validity. After all the survey data archived, our research used SPSS18.0 to carry on the statistical data analysis to ensure the reliability of data. To verify the validity of the questionnaire, we used the Cronbach's Alpha coefficient analysis method. As shown in Table 4, the Alpha value was 0.897 which indicated that the reliability and validity of the survey questionnaire was good, and it was in line with the research requirements. The analysis of construct validity will be elaborated in the section of factor analysis below.

Table 4. Reliability Statistics

Cronbach's Alpha	N of Items
.897	30

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.2. Factor Analysis of Questionnaire

Based on the specific circumstances, this research utilized factor analysis questionnaire. Firstly, the data adaptability was tested by KMO (Kaister-Meyer-Olkin) and Bartlett's Sphericity test (Bartlett test of Sphericity). As shown in Table 5, the testing result of KMO value was 0.869 which was bigger than 0.5.The observation value of Bartlett Sphericity testing statistic was 1.051E4, its corresponding probability P value was close to 0. When the significance level α value equals to 0.05, considering the observed value of P values is less than the significance level α, the original assumption should be considered false, meaning that there is significant difference between the correlation coefficient matrix and the unit matrix. The $\chi 2$ statistical significance probability value of the Bartlett Sphericity test is 0.000, which is smaller than 0.001, so this group of data is more suitable for factor analysis.

In this paper, several independent factors were extracted from the original variables, and the majority of the original variables are explained by these factors. Five factors were extracted from the initial factors. As the Table 6 shows, the first column is the factor number; the second to the fourth column describe the case where the initial factor solution. It can be seen from the table, the first column factor eigenvalues are 8.053, explaining the original four variables of the total variance 26.843%, the cumulative variance contribution rate was 26.843%. The eigenvalues of the second factors are 4.948, 16.494% of the total variance of four variables, the cumulative variance contribution rate was 43.337%, considering the extraction of all the variables in the initial solution, the total variance of the original variables was explained away. Fifth column to the seventh column describe the situation of factor solution: due to five factors were extracted during the process of the statistical analysis, the five factors explained 79.701% of the original variables of the total variance. On the whole, the original information is lost less, and the absolute value of each variable factor is relatively high, indicating that the original variables in each factor has a more significant correlation, which has reached the purpose of factor analysis. The last three columns describe a case of final factor solution. After rotating the factors, the cumulative variance ratio remained the same, meaning that the degree of co-existing variables were not changed. Since factor rotation reallocated each various factor which explained the variance of the original variables, changed the factor of variance contribution rate, the factors could be explained more easily.

In this paper, five factors that affect the quality and safety of agricultural products supply chain are extracted from the rotated factors load matrix and named as shown in Table 7. Overall, the five factors explained 79.701% of the variance in the data.

1. **Factor 1 (F1):** The excess returns. It consists of total seven factors of Q29, Q30, Q31, Q32, Q33, Q34, Q35. These factors are constituted the various factors that are related to the excess returns, and among which, the Q30, Q29, and Q35 are the most representative and explanatory power of the factor.

3. **Factor 3 (F3):** The relative size of cooperative enterprises. F3 consists of Q23, Q24, Q25, Q26, Q27 total five factors. These five factors are constituted the various factors associated with the relative size of cooperative enterprises. In particular, the Q23 has the strongest representative and explanatory power of this factor.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. **Factor 4 (F4):** The hitchhiking. It consists of Q18, Q19, Q20, Q21, Q22 total five factors. There five factors are constituted the various factors associated with the hitchhiking. Among which, the Q20, Q22, and Q18 have the strongest representative and explanatory power of this factor.
5. **Factor 5 (F5):** The overflow income. F5 consists of two factors of Q15 and Q17. These two are constituted the various factors related to the overflow income, and the Q15 has the strongest representative and explanatory power of the factor.

The five factors referenced herein are related to various dimensions influencing the quality-safety of agricultural supply chain. Along with these selected factors, we analyzed and evaluated our target objects. Thus, the structure of this kind of classifications is more systematic and comprehensive.

5. TEST OF HYPOTHESIS MODEL

In the agricultural supply chain, the supplier's strategic set is (provide agricultural products with safety, provide agricultural products with violations), and the strategic set of large supermarket chain is (assume responsibility, assume with no responsibility). Both sides of the game can conduct random strategic selections independently, and repeat the game model. Here, the strategy of assume responsibility refers to the time when the agricultural safety problems occur, the large supermarket chains alone bear the responsibility for compensations. If both parties are simply considering their own interests, and select the strategy of providing agricultural products with violations, and assuming with no responsibility upon the accident of agricultural products safety, both sides may obtain their general profits which are: $\pi 1$, $\pi 2$. If both players have a high sense of responsibility, they can receive excess returns which are r1e, r2e. Herein, r represents the distribution coefficient, e is the excess return. With a high sense of responsibility on both sides, along with good faith cooperation, the two parties can get overflow income $\beta 1m2$, $\beta 2m1$ where β is coefficient for the overflow with the good faith cooperation. m represents the cooperative enterprise size and strength. When upstream stakeholders provide safe agricultural products, and downstream stakeholders assume their responsibilities, the cost of both parties is $\alpha 1m1$, $\alpha 2m2$, α is the cost factor. Finally, when upstream stakeholders provide safe products while downstream stakeholders won't take responsibilities, or downstream stakeholders assume their responsibilities while upstream stakeholders provide agricultural products with violations, it would be a free-rider problem. The latter will be benefited from the former's hitchhiking income $\lambda\beta 2m1$, $\lambda\beta 1m2$, here λ is the pick-up factor.

Table 8. Game matrix of upstream and downstream stakeholders of agricultural products supply chain downstream stakeholders of agricultural products supply chain

	Bear Responsibility	**Not liable**
Provide agricultural products safety	π_1-$\alpha_1 m_1$+$\beta_1 m_2$+$r_1 e$, π_2-$\alpha_2 m_2$+$\beta_2 m_1$+ $r_2 e$	π_1-$\alpha_1 m_1$, π_2+$\lambda\beta_2 m_1$
Providing agricultural products violation	π_1+$\lambda\beta_1 m_2$, π_2-$\alpha_2 m_2$	π_1, π_2

5.1. Static Game Analyzing

Among the game between the upstream and downstream stakeholders of agricultural products supply chain, when the excess returns is less than the cost of the upstream or downstream stakeholders, the final balancing of the game is (provide agricultural products with violations, assume with no responsibilities). Whereas, when the excess return greater than the cost of the upstream or downstream stakeholders, and when the downstream stakeholders choose to assume responsibilities, the upstream stakeholders will provide agricultural products with safety, while the downstream stakeholders choose not to assume responsibilities, the upstream stakeholders will provide agricultural products with violations. Conversely, when the upstream stakeholders provide agricultural products with safety, the downstream stakeholders will assume responsibilities, while the upstream stakeholders provide agricultural products with violations, the downstream stakeholders would choose not to assume responsibilities (see Table 8). When both sides are in the unknown with other's strategies, to ensure their own interests, they will have two Nash equilibrium.

With the improvement the detection level for the quality-safety of agricultural supply chain, and as well as strengthen of the supervision management of the government, the participants get mutually consistent and reliable information, strengthen their mutual trust, cooperation, to minimize the risk. Both parties eventually achieve the Pareto optimality, namely

$$\left(\pi_1 - \alpha_1 m_1 + \beta_1 m_2 + r_1 e, \pi_2 - \alpha_2 m_2 + \beta_2 m_1 + r_2 e\right).$$

5.2. Evolutionary Game Analyzing

In the games, the ratio of the upstream stakeholders to provide agricultural products with safety is x, the proportion of agricultural products with violations is 1-x, the proportion of the downstream stakeholders to assume responsibilities is y, the ratio of without assuming responsibilities is 1- y.

1. The fitness of the upstream stakeholders providing agricultural product with safety:

$$u_x = y\left(r_1 e + \beta_1 m_2\right) + \left(\pi_1 - \alpha_1 m_1\right)$$

The fitness of the upstream stakeholders providing agricultural products with violations:

$$u_{1-x} = y\lambda\beta_1 m_2 + \pi_1$$

The average fitness of the upstream stakeholders:

$$\overline{u_x} = x\left[y\left(\gamma_1 e + \beta_1 m_2\right) + \left(\pi_1 - \alpha_1 m_1\right)\right] + \left(1 - x\right)\left(y\lambda\beta_1 m_2 + \pi_1\right)$$

The replicator dynamics equation from the upstream stakeholders:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\frac{dx}{dt} = x\left(1-x\right)\left[y\left(\gamma_1 e + \beta_1 m_2 - \lambda\beta_1 m_2\right) - \alpha_1 m_1\right]$$

2. The fitness of the downstream stakeholders to assume responsibilities:

$$u_y = x\left(r_2 e + \beta_2 m_1\right) + \left(\pi_2 - \alpha_2 m_2\right)$$

The fitness of the downstream stakeholders for not to assume responsibilities:

$$u_{1-y} = x\lambda\beta_2 m_1 + \pi_2$$

The average fitness of the downstream stakeholders:

$$\overline{u_y} = y[x(\gamma_2 e + \beta_2 m_1) + (\pi_2 - \alpha_2 m_2)] + (1-y)(x\lambda\beta_2 m_1 + \pi_2)$$

Replicator dynamics equation which is from downstream stakeholders of agricultural products supply chain:

$$\frac{dy}{dt} = y(1-y)[x(\gamma_2 e + \beta_2 m_1 - \lambda\beta_2 m_1) - \alpha_2 m_2]$$

By the replicator dynamic equations we find five stable points, namely (0,0), (0,1), (1,0), (1,1) (p*,q*), $p^* = \frac{\alpha_2 m_2}{r_2 e + \beta_2 m_1 - \lambda\beta_2 m_1}$, $q^* = \frac{\alpha_1 m_1}{\gamma_1 e + \beta_1 m_2 - \lambda\beta_1 m_2}$.

The evolutionary stability can be determined by analyzing the local stability of the Jacobian matrix which was created by the cooperative and competitive systems.

$$J = \begin{pmatrix} \left(1-2x\right)\left[y\left(\gamma_1 e + \beta_1 m_2 - \lambda\beta_1 m_2\right) - \alpha_1 m_1\right] & x(1-x)(\gamma_1 e + \beta_1 m_2 - \lambda\beta_1 m_2) \\ y\left(1-y\right)\left(r_2 e + \beta_2 m_1 - \lambda\beta_2 m_1\right) & \left(1-2y\right)\left[x\left(r_2 e + \beta_2 m_1 - \lambda\beta_2 m_1\right) - \alpha_2 m_2\right] \end{pmatrix}$$

$$\det J = \left(1-2x\right)\left[y\left(\gamma_1 e + \beta_1 m_2 - \lambda\beta_1 m_2\right) - \alpha_1 m_1\right]\left(1-2y\right)\left[x\left(r_2 e + \beta_2 m_1 - \lambda\beta_2 m_1\right) - \alpha_2 m_2\right]$$
$$-x\left(1-x\right)\left(\gamma_1 e + \beta_1 m_2 - \lambda\beta_1 m_2\right) y\left(1-y\right)\left(r_2 e + \beta_2 m_1 - \lambda\beta_2 m_1\right)$$

$$trJ = \left(1-2x\right)\left[y\left(\gamma_1 e + \beta_1 m_2 - \lambda\beta_1 m_2\right) - \alpha_1 m_1\right] + \left(1-2y\right)\left[x\left(r_2 e + \beta_2 m_1 - \lambda\beta_2 m_1\right) - \alpha_2 m_2\right]$$

$$r_1 e + \beta_1 m_2 < \alpha_1 m_1 + \lambda\beta_1 m_2, r_2 e + \beta_2 m_1 < \alpha_2 m_2 + \lambda\beta_2 m_1 \quad (1)$$

Table 9 shows the evolutionarily stable results.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 9. Evolutionary stable results (1)

When the upstream stakeholders' excess return is less than the input costs, the excess return of the downstream stakeholders is greater than input costs, as the evolutionary stable results (0,0).

Figure 5 depicts the phase evolution of the process. The final evolution result will converge to the set of (provide agricultural products with violations, not to assume responsibilities).

$$r_1 e + \beta_1 m_2 > \alpha_1 m_1 + \lambda \beta_1 m_2, r_2 e + \beta_2 m_1 < \alpha_2 m_2 + \lambda \beta_2 m_1 \tag{3}$$

The Table 11 shows the evolutionary stable result

When the upstream stakeholders' excess return is greater than the input costs, the excess return of the downstream stakeholders is smaller than its input costs, as the evolutionary stable results (0,0). Figure 6 depicts the phase evolution of the process. The final evolutionary result will converge to the set of (provide agricultural products with violations, assume with no responsibilities).

$$r_1 e + \beta_1 m_2 > \alpha_1 m_1 + \lambda \beta_1 m_2, r_2 e + \beta_2 m_1 > \alpha_2 m_2 + \lambda \beta_2 m_1 \tag{4}$$

Table 12 shows the evolutionary stable results.

When the upstream stakeholders' excess return is greater than the input costs, the excess return of the downstream stakeholders is also larger than its input costs, which is the evolutionary stable results (0,0), (1,1) from the evolution of the phase diagram. There are still two unstable points (0,1), (1,0) and the saddle point (p *, q *). Figure 7 depicts the process of the view of dynamic evolution from the saddle point and instability point even into the fold between the two game sides which converges on the critical line in different states. The evolution of the game results will change along with the saddle point and converges to a different equilibrium.

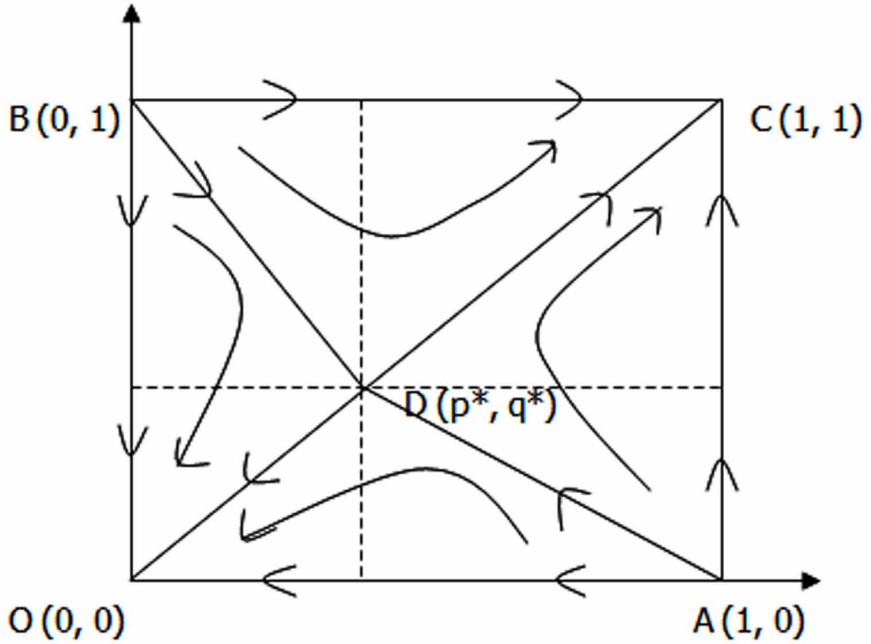
6. CONCLUSION

6.1. Test Results

It can be seen that the relative size of the cost and the excess return of upstream and downstream stakeholders of agricultural products supply chain will directly affect the ultimate evolutionary stable results.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Phase diagram of the evolution (4)



1. **In Case of the Excess Returns Are Less Than the Cost of the Upstream or Downstream Stakeholders:** By means of the evolutionary stable results of (0,0) from the three former evolutionary phase diagrams, whether what the initial state it starts from, the final results will converge to the evolutionary set of (provide agricultural products with violations, assume with no responsibilities).
2. **In Case of the Excess Returns Are Greater Than the Input Costs of Upstream and Downstream Stakeholders:** When the evolutionary stable results set to (0,0), (1,1), it means the upstream and the downstream stakeholders select to provide agricultural products with violations and not to assume responsibilities, or select to provide agricultural products with safety and assume responsibility individually. There are two unstable points (0,1), (1,0) and a saddle point (p *, q *) in the evolutionary phase diagram. The Figure 7 depicts a dynamic evolution with the critical line that was converged by a fold line between the saddle point and unstable point with the two parties during the game process. As seen in the upper right area ADBC, the system converges to the strategy set of (provide agricultural products with safety, assume responsibilities), and in the lower left area AOBD, the system converges to the strategy set of (provide agricultural products with violations, assume with no responsibilities).

In a long evolutionary process, the outcome of the game will be varying along with the saddle point change, and will converge to different equilibriums.

1. The smaller the cost coefficient α, the greater of the top right area is, and the evolutionary game should become more possible to converge to (1,1). When the supply chain of agricultural products is becoming more and more refined, the chain is getting shorter and shorter, the market pays more attentions to standardization, the cost will be reduced accordingly. Meanwhile, the cost will be

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

affected by the changes of cooperative enterprise operations management, the new technologies, the improved policy environment, and other factors. In order to reduce the cost factor for upstream stakeholders of agricultural products supply chain, the large-scale management must be formed, the establishment of supply alliances, the standardized management not only reduces costs but also ensure to offer the quality and safety of agricultural products. For the downstream stakeholders, the government policy support and incentive, such as willingness to assume responsibility of enterprises to implement certain compensations, rewards, and reducing the costs.

2. The degree of synergy between the two sides of the game affects the overflow coefficient β. If the upstream stakeholders provide safe agricultural products, the downstream stakeholders assume responsibilities, both sides of the game launched an effective cooperation, and there is no evasion of responsibility, then one party can get the overflow income from the other side. The larger the overflow coefficient, the bigger the upper right ADBC area of the fold line is, the greater the probability of convergence of the evolutionary game (1,1) is.
3. The higher the excess return, the greater the probability that the result of evolutionary game will converge to (1,1). Because getting excess return by both players is the shift in the relationship, so the game both parties can only be benefited mutually by improving the excess return e.
4. When the corporate strength between both game sides has any gaps, the free-riding behavior may occur. In the case of upstream stakeholders providing agricultural products with violations, the downstream stakeholders are willing to assume responsibilities, when a product safety accident occurs, the government regulators should force suppliers take responsibility to reduce their hitchhiking earnings. Similarly, when the product-safety is provided by the upstream stakeholders, not assuming responsibility from the downstream stakeholders, in order to curb free riding behavior and reducing corresponding free-rider gains, raising the purchase threshold and signing accident-responsibility-sharing agreement should be a necessary action to take.
5. The larger the gaps between the two sides of the game, the smaller the upper right area of ADBC is, and the more likely the game results will converge to the (0,0). Conversely, the smaller the gaps between the two sides, the more probabilities of the game results converge to the (1,1), and more possibilities of providing agricultural products with safety, and assuming greater accountability will be. In order to get a rational situation, the cooperation strength between two sides should be equivalent, then it about to converge to the (1,1), and ultimately to achieve stable results.

6.2. Policy Recommendations

According to the above analysis of the game model, the long-term equilibrium outcome of the game may have two distinct states. The final equilibrium point is determined by the value of each parameters in the payoff matrix and the initial state of the game.

6.2.1. Increase the Excess Return

Because of the higher excess returns, the evolutionary game strategy between the upstream and downstream stakeholders of agricultural products supply chain will converge to (1,1) which is the strategy set of (provide agricultural products with safety, assuming responsibilities). Therefore, raising the excess earnings will improve the quality-safety of agricultural products supply chain.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

6.2.2. Reduce Collaboration Costs and Improve Penalty Costs

Due to the cost factor α is smaller, the evolutionary game strategy between the upstream and downstream stakeholders will converge to (1,1). Therefore, reducing the costs of the upstream and downstream stakeholders should make both sides do not have to worry about their benefits from the impact of high costs. It can also avoid the adverse effects for reducing costs by paying the price of cutting the strategy of quality-safety of agricultural products.

6.2.3. Reduce the Relative Size of Cooperative Enterprises

When a node enterprises on an agricultural supply chain to cooperate, along with the increased size of the game between the two sides, the game results will converge to (0,0), namely the set of (provide agricultural products with violations, assume with no responsibilities). The inconsistency of the relative size can easily lead to the problem of earnings gap. To avoid such problems, happen and get a rational situation, the cooperation strength between two sides should be equivalent, so that to avoid the income gap impacts on the quality and safety of the agricultural products supply chain.

6.2.4. Minimize Free-Riding

When the corporate strength between both game sides has any gaps, the free-riding behavior may occur. When the free-riding factor gets higher and higher, the game results will converge to (0,0). Hitchhiking may easily lead to make noncompliance of agricultural products mixed into and then flow to the consumer market, affecting the quality and safety of agricultural products supply chain

6.2.5. Increase Overflow Income

With the effective cooperation carried by both sides of the game on the agricultural supply chain, one side can obtain spillover income from the other side, and the more spillover income, the more possibly the evolutionary game will converge to (1,1). Increasing overflow income can make both sides of the game to promote cooperation in good faith, and also better able to improve the quality and safety of agricultural supply chain.

Chapter 21
IoT Based Agriculture as a Cloud and Big Data Service: The Beginning of Digital India

Sukhpal Singh Gill
University of Melbourne, Australia

Inderveer Chana
Thapar University, India

Rajkumar Buyya
University of Melbourne, Australia

ABSTRACT

Cloud computing has transpired as a new model for managing and delivering applications as services efficiently. Convergence of cloud computing with technologies such as wireless sensor networking, Internet of Things (IoT) and Big Data analytics offers new applications of cloud services. This paper proposes a cloud-based autonomic information system for delivering Agriculture-as-a-Service (AaaS) through the use of cloud and big data technologies. The proposed system gathers information from various users through preconfigured devices and IoT sensors and processes it in cloud using big data analytics and provides the required information to users automatically. The performance of the proposed system has been evaluated in Cloud environment and experimental results show that the proposed system offers better service and the Quality of Service (QoS) is also better in terms of QoS parameters.

1. INTRODUCTION

Emergence of ICT (Information and Communication Technologies) plays an important role in the agriculture sector by providing services through computer-based agriculture systems (Singh and Chana, 2015). But these agriculture systems are not able to fulfill the needs of today's generation due to processing of large amount of data, lack of important requirements like processing speed, data storage space, reliability, availability, scalability etc. and even resources used in computer-based agriculture systems are not utilized

efficiently. Agriculture-as-a-Service (AaaS) applications exhibit Big data characteristics. For example, the volume of agriculture dataset captured by environments such as Open Government Data Platform India (data.gov.in, 2015), India Agriculture and Climate Data Set (Sanghi et al.), and regional land and climate modelling in China (Shangguan et al., 2012) can be in order of 1000000 records with size of 3.5 GB. The data is coming in large data variety and volume from both users in the form of images like damaged crop images due to weather, insects etc. and devices through Internet of Things (IoT) sensors and satellites (GPS systems) that send weather related images. As a result of regular capturing and collection of datasets, they grow with the velocity of 80.72 KB/minute or more (data.gov.in, 2015). To solve the problem of existing agriculture systems, there is a need to develop a cloud-based service that can easily manage different types of agriculture related-data based on different domains (crop, weather, soil, pest, fertilizer, productivity, irrigation, cattle, and equipment) through these steps: i) gather data from various sensors through preconfigured devices, ii) classify the gathered data (heterogeneous, high volume of big data) into various classes through analysis, iii) store the classified information in cloud repository for future use, and iv) automatic diagnosis of the agriculture status. As large number of users are using agriculture systems operating on large datasets simultaneously, there is a need of highly scalable and elastic distributed computing environment such as cloud computing. In addition, cloud-based autonomic information system should be able to identify the QoS (Quality of Service) requirements of user request and resources should be allocated efficiently to execute the user request based on these requirements.

The main aim of this paper is to design architecture of Agriculture-as-a-Service (AaaS) that manages various types of agriculture-related data based on different domains. This is realized through the following objectives: i) propose an autonomic resource management technique which is used to a) gather the information from various users through preconfigured devices, IoT sensors, GPS (Global Positioning System), etc. b) extract the attributes, c) analyze the information by creating various classes based on the information received, d) store the classified information in cloud repository for future use and e) diagnose the agriculture status automatically and ii) perform resource allocation automatically at infrastructure level after identification of QoS requirements of user request.

The rest of the paper is organized as follows. Section 2 presents related work of existing agricultures systems. Proposed architecture is presented in Section 3. Section 4 presents Autonomic Resource Management. Sections 5 describe the experimental setup and present the results of evaluation. Section 6 presents conclusions and future scope.

2. RELATED WORK

Existing research reported that few agriculture systems have been developed with limited functionality. Related work of existing agriculture systems has been presented in this section.

2.1. Existing Agriculture Systems

Ranya et al. (2013) presented ALSE (Agriculture Land Suitability Evaluator) to study various types of land to find the appropriate land for different types of crops by analyzing geo-environmental factors. ALSE used GIS (Global Information System) capabilities to evaluate land using local environment conditions through digital map and based on this information decisions can be made. Raimo et al. (2010) proposed FMIS (Farm Management Information System) used to find the precision agriculture requirements for

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

information systems through web-based approach. Author identified the management of GIS data is a key requirement of precision agriculture. Sorensen et al. (2010) studied the FMIS to analyze dynamic needs of farmers to improve decision processes and their corresponding functionalities. Further they reported that identification of process used for initial analysis of user needs is mandatory for actual design of FMIS. Zhao (2002) presented an analysis of web-based agricultural information systems and identified various challenges and issues still pending in these systems. Due to lack of automation in existing agriculture system, the system is taking longer time and is difficult to handle dynamic needs of user which leads to customer dissatisfaction. Sorensen et al. (2011) identified various functional requirements of FMIS and information model is presented based on these requirements to refine decision processes. They identified that complexity of FMIS is increasing with increase in functional requirements and found that there is a need of autonomic system to reduce complexity. Yuegao et al. (2004) proposed WASS (Web-based Agricultural Support System) and identified functionalities (information, collaborative work and decision support) and characteristics of WASS. Based on characteristics, authors divided WASS into three subsystems: production, research-education and management.

Reddy at el. (1995) proposed GIS based DSS (Decision Support System) framework in which Spatial DDS has been designed for watershed management and management of crop productivity at regional and farm level. GIS is used to gather and analyze the graphical images for making new rules and decisions for effective management of data. Shitala et al. (2013) presented mobile computing based framework for agriculturists called AgroMobile for cultivation and marketing and analysis of crop images. Further, AgroMobile is used to detect the disease through image processing and also discussed how dynamic needs of user affects the performance of system. Seokkyun et al. (2013) proposed cloud based Disease Forecasting and Livestock Monitoring System (DFLMS) in which sensor networks has been used to gather information and manages virtually. DFLMS provides an effective interface for user but due to temporary storage mechanism used, it is unable to store and retrieve data in databases for future use. The proposed QoS-aware Cloud Based Autonomic Information System (AaaS) has been compared with existing agriculture systems as described in Table 1.

All the above research works have focused on different domains of agriculture with different QoS parameters. None of the existing agriculture systems considers self-management of resources. Due to

Table 1. Comparisons of existing agriculture systems with proposed system (AaaS)

Agriculture System	Mechanism	QoS-aware (Parameter)	Domains	Data Classification	Resource Management	Big Data
ALSE (Elsheikh et al., 2013)	Non-Autonomic	**Yes** (Suitability)	Soil	Yes	No	No
FMIS (Nikkila et al., 2010)	Non-Autonomic	**No**	Pest and Crop	No	No	No
WASS (Hu et al., 2004)	Non-Autonomic	**No**	Productivity	No	No	No
AgroMobile (Prasad et al., 2013)	Non-Autonomic	**Yes** (Data accuracy)	Crop	Yes	No	No
DFLMS (Jeong et al., 2013)	Non-Autonomic	**No**	Crop	No	Yes	No
Proposed System (AaaS)	Autonomic	**Yes** (Cost, Time, Resource Utilization, Latency, Throughput and Attack Detection Rate)	Crop, Weather, Soil, Pest, Fertilizer and Irrigation	Yes	Yes	Yes

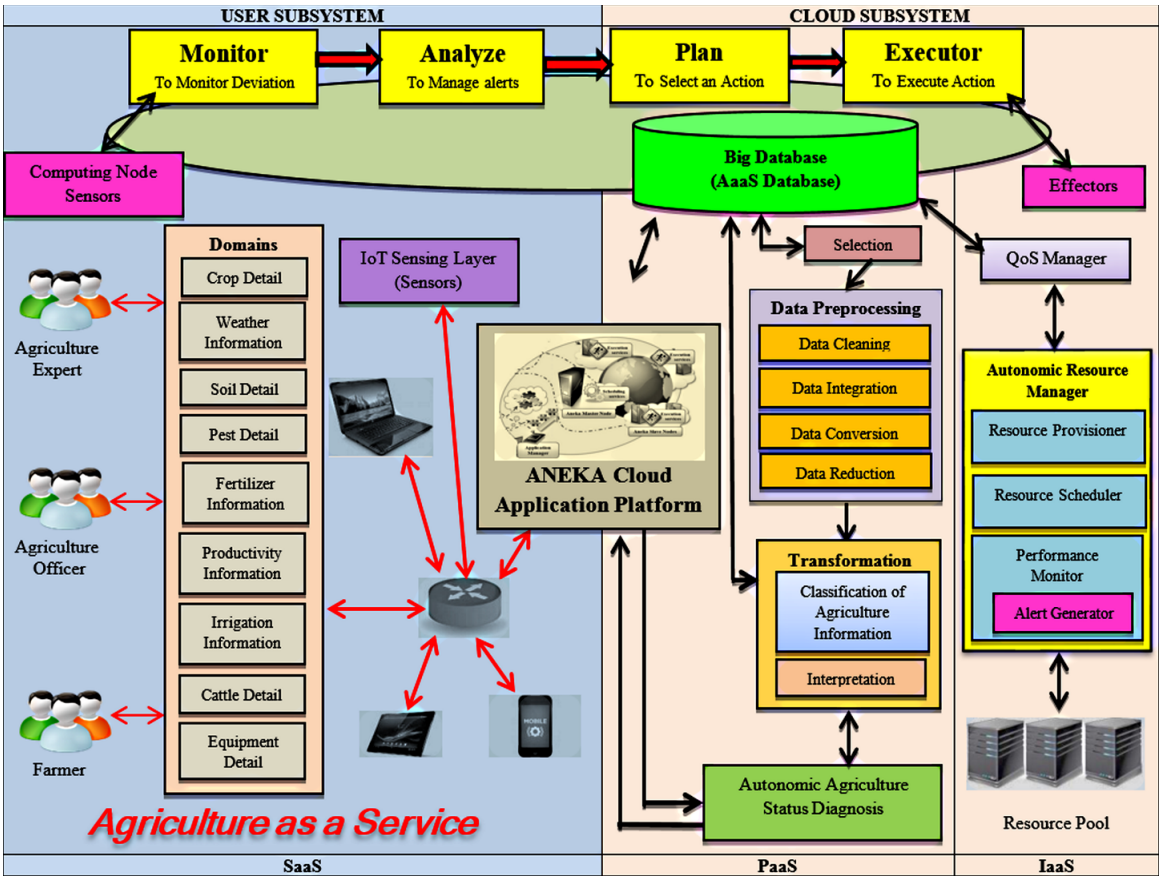
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

lack of automation of resource management, services become inefficient which further leads to customer dissatisfaction. The proposed system is a novel QoS-aware cloud based autonomic information system and considers various domains of agriculture and, allocates and manages the resources automatically which is not considered in other existing agriculture systems.

3. AGRICULTURE-AS-A-SERVICE ARCHITECTURE

The existing agriculture systems are not able to fulfill the needs of today's generation due to lacking in important requirements like processing speed, data storage space, reliability, availability, scalability etc. Even resources used in computer based agriculture systems are not utilized efficiently. To solve the problem of existing agriculture systems, there is a need to develop a cloud-based autonomic information system that delivers Agriculture-as-a-Service. This section presents architecture of cloud-based autonomic information system for agriculture service called *AaaS* that manages various types of agriculture-related data based on different domains. Architecture of AaaS is shown in Figure 1. QoS parameters (execution time and cost) must be identified before the allocation of resources. AaaS is the key mechanism that

Figure 1. Agriculture-as-a-Service architecture



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ensures that the resource manager can serve large amount of requests without violating SLA terms and dynamically manages the resources based on QoS requirements identified by QoS manager. The services of AaaS has been divided into three types: SaaS (Software as a Service), PaaS (Platform as a Service) and IaaS (Infrastructure as a Service). In SaaS, a user interface is designed in which users can interact with system. Aneka is a .NET-based application development PaaS, which is used as a scalable cloud middleware to make interaction between cloud subsystem and user subsystem. In IaaS, an autonomic resource manager manages the resource automatically based on the identified QoS requirements of a particular request. The architecture of AaaS comprises of two subsystems: i) user and ii) cloud.

3.1. User Subsystem

This subsystem provides a user interface, in which different type of users interact with AaaS to provide and get useful information about agriculture based on different domains. Nine types of information of different domains in agriculture has been considered: crop, weather, soil, pest, fertilizer, productivity, irrigation, cattle, and equipment. Users are basically classified in three categories: i) agriculture expert, ii) agriculture officer, and iii) farmer. The agriculture expert shares professional knowledge by answering farmer queries and updates the AaaS database based on the latest research done in the field of agriculture with respect to their domain. Agriculture officers are the government officials that provide the latest information about new agriculture policies, schemes, and rules passed by the government. Farmer is an important entity of AaaS who can take maximum advantage by asking his queries and getting automatic reply after analysis. Users can monitor any data related to their domain and get their response without visiting the agriculture help center. It integrates the different domains of agriculture with AaaS. The queries received from user(s) are forwarded to cloud repository for updates and response sends back to particular user on their preconfigured devices (tablets, mobile phones, laptops etc.) via internet.

3.2. Cloud Subsystem

This subsystem contains the platform in which agriculture service is hosted on a cloud. Details about users and agriculture information are stored in a cloud repository in different classes for different domains with unique identification number. The information is monitored, analyzed, and processed continuously by AaaS. The analysis process consists of various sub processes: selection, data preprocessing, transformation, classification and interpretation as shown in Figure 1. Different classes for every domain and sub classes for further categorization of information have been designed. In storage repository, user data is categorized based on different predefined classes of every domain. This information is further forwarded to agriculture experts and agriculture officers for final validation through preconfigured devices. Further, a number of users can use cloud-based agriculture service so the QoS manager and autonomic resource manager in cloud subsystem have been integrated. QoS manager identifies the QoS requirements based on the number and type of user queries as discussed in previous research work (Jeong et al., 2013; Singh and Chana, 2015; Singh et al., 2015). Based on QoS requirements, autonomic resource manager identifies resource requirements automatically and allocates and executes the resources at infrastructure level. Performance monitor is used to verify the performance of system and also maintain it automatically. If the system will not be able to handle the request automatically then the system generates an alert.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

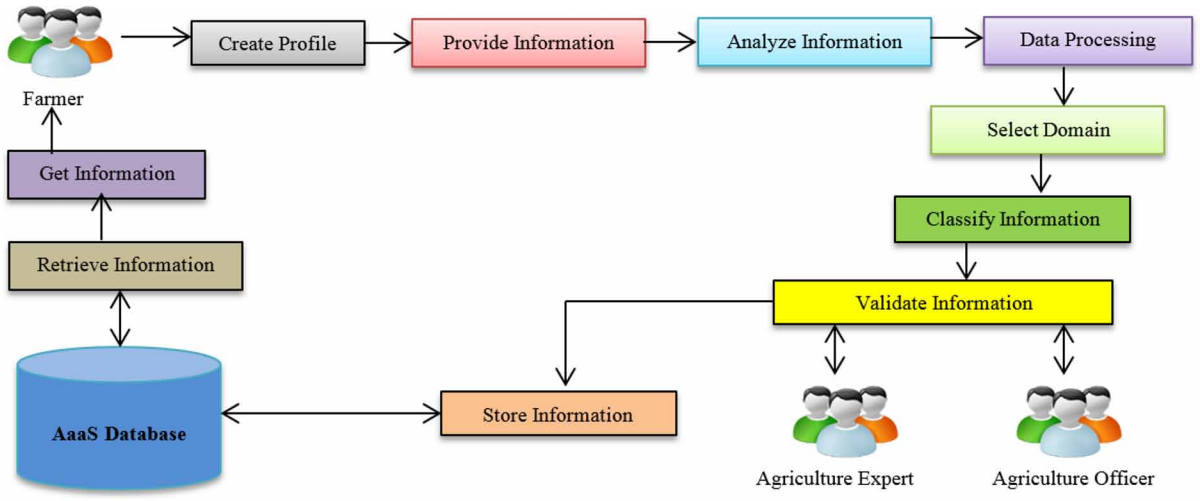
3.2.1. Cloud-Based Agriculture Service

Cloud-based agriculture service provides a user platform through which user can access agriculture service as shown in Figure 2. Firstly, agriculture service allows user to create profile for interaction with AaaS. After profile creation, the user is required to provide his personal details along with the details of information domain. AaaS analyses the information to verify whether the data is complete or not for further processing by performing various checks. Further data is processed and redundancy of data is removed and data is used to select domain to which data belongs. Information is classified properly in order with unique identification number. This information is forwarded to agriculture experts and agriculture officers for final validation through preconfigured devices. After successful validation of information, it is stored in *AaaS* database. If user wants to know the response of their query, then system will automatically diagnose the user query and send the response back to that user.

3.2.2. Detailed Methodology

AaaS allows users to upload the data related to different domains of agriculture through preconfigured devices and classified them based on the domains specified in database. Subtasks of information gathering and provided in AaaS are: i) selection, ii) preprocessing, iii) transformation, iv) classification and v) interpretation. In *selection*, target datasets are created based on the relevant information that will further be considered for analysis in next sub process. In *preprocessing*, different users have different information regarding agriculture. To develop a final training set, there is need of preprocessing steps because data might contain some missing sample or noise components. In AaaS, data preprocessing contains four different sub processes: i) data cleaning, ii) data integration, iii) data conversion and iv) data reduction. Data *transformation* provides an interface between data analysis sub process (classification) and data preprocessing. After data preprocessing, this process converts the labeled data into adequate format suitable for classification. In *classification*, AaaS classify the agriculture information of different users of different domains based on the extracted data. K-NN (k-Nearest Neighbor) classification mechanism

Figure 2. Functional aspects of AaaS



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

has been used in this research work to identify the different class labels of users. K-NN is supervised machine learning technique which is used to classify the unknown data using training data set generated by it. K-NN used to identify the productivity level through Training Instance Dataset (TID). Figure 3 describes the K-NN Algorithm.

In K-NN algorithm, distance is computed from one specific instance to every training instance to classify that unknown instance. Both k-nearest neighbor and *k* minimum distance is determined and output class label is identified among *k* classes. During training phase, K-NN Algorithm utilizes training data. Figure 4 illustrates the classification process used in this research work.

K-NN model is used to identify the productivity level through Training Instance Dataset (TID). Five levels of productivity (A - E) have been fixed as shown in Table 2. The level *'A'* indicates the productivity is very high while level *'E'* indicates the productivity is very low. Based on the given information, TID identifies the class in which given data belongs.

Figure 3. Pseudo code of K-NN algorithm

Algorithm 1: K-NN Algorithm

Table 2. Productivity Levels

Productivity Level	Description
A	Very High Productivity
B	High Productivity
C	Neutral Productivity
D	Low Productivity
E	Very Low Productivity

Test data is an input of this model and it is compared with TID and identifies the class in which data laid using following rule:

Rule: **If** {Crop Name ^ Temperature ^ Soil Texture ^ Season ^ Pesticide ^ Fertilizer} **then** *Productivity*

The final step is to *interpret* the agriculture data submitted by different users of different domains which helps user to understand the classified datasets. AaaS is capable to diagnose the agriculture status based on the information entered by user and send the diagnosed agriculture status to particular user automatically. Six attributes have been considered: Crop Name, Temperature, Soil Texture, Season, Pesticide and Fertilizer and one output: Productivity. Based on these six attributes, AaaS designs rules. Values for six variables are considered as TID. For example, refer to Table 3.

AaaS uses the rule shown in Table 3 to find the productivity level using TID (see Table 4).

Similarly, any type of query related to different domains can be asked by users and AaaS executes the user query and send response back to particular user automatically based on the rules defined in *AaaS* database. Through AaaS, users can easily diagnose the agriculture status automatically.

3.2.3. Infrastructure Management (IaaS)

Efficient management of infrastructure in cloud is mandatory to maintain the performance of the Agri-Info. It comprises of two sub units: QoS Manager and Resource Manager.

Table 3. User wants to retrieve the productivity level using AaaS

User Query						
Crop Name	**Temperature**	**Soil Texture**	**Season**	**Pesticide**	**Fertilizer**	**Productivity**
Soybean	21-27 °C	Slity Loam Clay	Winter	Organochlorine	Urea	?

Table 4. AaaS response utilized to in order to find the productivity level using TID

AaaS Response						
Crop Name	**Temperature**	**Soil Texture**	**Season**	**Pesticide**	**Fertilizer**	**Productivity**
Soybean	21-27 °C	Slity Loam Clay	Winter	Organochlorine	Urea	**C**

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.2.3.1. QoS Manager

User submits a request to Agri-Info to retrieve some specific agriculture related information. Agri-Info identifies the QoS parameters required to process the user request through analysis based on user request. Based on the key QoS requirements of a particular user request, the *QoS Manager* puts the user request into critical and non-critical queues through QoS assessment. For QoS assessment, *QoS Manager* will calculate the execution time of user request and find the approximate user request completion time. If the completion time is lesser than the desired deadline then it will execute immediately with the available resources and release the resource(s) back to resource manager for another execution otherwise calculate extra number of resources required and provide from the reserved stock for current execution.

3.2.3.2. Resource Manager

Further, two resource scheduling policies (Singh and Chana, 2015) are used to schedule the resources for execution of user queries: time based and cost based scheduling policy. *Time based scheduling policy* works as per following: First, the allocation agent begins to compute the Deadline Time of the user request in the given budget. Allocate resources based on time, the user request which has shortest Deadline Time will execute first. If the two requests have same deadline time then that request will execute first that has lesser execution time. The allocation agent then schedules all the requests with smallest execution time request to the resources that provide high QoS. The rules for time based scheduling policy are described in Table 5 along with their conditions.

Cost based scheduling policy works as per following: First, the allocation agent begins to compute the cost of each request then sort, as the priority is given to the request which has maximum budget. If the two requests have same budget then that request will execute first that has lesser execution time. The allocation agent then schedules all the requests with high budget request to the resources that provide high QoS. Finally, all other requests are scheduled on the available resources set. The rules for cost based scheduling policy are described in Table 6 along with their conditions.

4. AUTONOMIC RESOURCE MANAGEMENT

Working of autonomic element of Agri-Info is based on IBM's autonomic model that considers four steps of autonomic system: i) monitor, ii) analyze, iii) plan and iv) execute as shown in Figure 1. The objective of resource provisioning in autonomic resource management is to provision the resources to process user requests. The requests submitted should be executed within their budget and deadline. Requests submitted by user to resource provisioner are stored as bulk of workloads for their execution.

Table 5. Rules of time based resource scheduling

Request Pending	Urgency	Add Resource	Request
Yes	Yes	Reserve	Submit
Yes	No	Available	Submit
No	-	-	Finish

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Rules of cost based resource scheduling

Request Pending	$R_A > 0$	$E_t > W_d$	$B_A > P_r$	Status
Yes	True	True	True	Add Resource
Yes	False	True	True	Add Resource
No	-	-	-	Finish
Yes	True	False	True	Finish
Yes	True	True	False	Finish

R_A = Resource Available, E_t = Estimated Time, P_r = Resource Price, W_d = Desired Deadline and B_A = Available Budget.
Details of both time and cost based scheduling policy is given in previous research work (Singh and Chana, 2015).

All the submitted workloads are analyzed based on their QoS requirements. Based on importance of the attribute, weights for every cloud workload are calculated. After that, workloads are clustered based on k-means based clustering algorithm for better resource provisioning (Singh et al., 2015). If the value of workloads executes within deadline and budget and [Resource Consumption and Requests Missed is lesser than Threshold Value] then it will provision resources otherwise generate alert for analyses the workload again.

After successful provisioning of resources, Resource Scheduler (RS) takes the information from the appropriate workload after analyzing the various workload details which user request demanded (Singh and Chana, 2015). Knowledge Base contains details of all the resources available in resource pool and reserve resource pool. Based on Cloud consumer details, RS assigns resources and executes Cloud workloads. During execution of a particular cloud workload, the Resource Executor (RE) will check the current workload. If the resources are sufficient for execution then it will continue with execution otherwise request for more resources. If the value of Resource Consumption and Requests Missed is lesser than threshold value, then RE will execute workloads otherwise RE will generate alert. After successful execution of Cloud workloads, RE releases the free resources to resource pool and RE is ready for execution of new cloud workloads. During execution of user requests, performance is monitored continuously using sub unit performance monitor to maintain the efficiency of Agri-Info and generates alert in case of performance degradation. Alerts can be generated in two conditions generally: i) if resource consumption is more than threshold values of resource consumption to execute user request (*Action:* Reallocates resources) and ii) if the number of missed requests are greater than the threshold value (*Action*: Predict QoS Requirements Again). Same action is performed twice, if Agri-Info fails to correct it then system will be treated as down. Components of autonomic system are described below:

4.1. Sensors

Sensors get the information about performance of other nodes using in the system and their current state. Firstly, the updated information from processing nodes is transfer to manager node then manager node transfers this information to sensors. Updated information includes information about QoS parameters (execution time, execution cost and resource utilization etc.).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.2. Monitor

Initially, Monitors are used to collect the information from sensors for monitoring continuously performance variations by comparing expected and actual performance, and monitors the value of resource consumption and missed requests. Actual information about performance is observed based QoS parameters and transfers this information to next module for further analysis.

4.3. Analysis and Plan

Analyze and plan module start analyzing the information received from monitoring module and make a plan for adequate actions for corresponding alert. Following formula is used to calculate Resource Consumption (Equation 1):

$$Resource_{Consumption} = \sum_{i=1}^{n} \left(\frac{\text{Actual Resource Usage}}{\text{Predicted Resource Usage}} \right) \tag{1}$$

where $\text{Actual Resource Usage}$ is usage of resource to execute particular number of user requests and $\text{Predicted Resource Usage}$ is resource usage estimated before actual execution and *n* is the number of resources. Assumed: $\left[\text{Predicted Resource Usage} \leq \text{Actual Resource Usage}\right]$. Value of $ResourceConsumption$. is more than 1 generally because $\text{Actual Resource Usage}$ is more than $\text{Predicted Resource Usage}$ but ideally it will be 1 when both are equal. In this research rk, maximum values for $ResourceConsumption$ has been fixed and that is called threshold value. Following formula is used to calculate number of requests missed $\left(Requests_{Missed}\right)$ in a particular period of time (Equation 2):

$$Requests_{Missed} = [Number\ of\ Requests\ Executed\ Successfully - Number\ of\ Requests\ Missed\ Deadline] \tag{2}$$

For successful execution of resources, value of $Requests_{Missed}$ is lesser than threshold value. Algorithm 1 is used to analyses the performance of management of resources.

With the help of (Equation 1) and (Equation 2), resource consumption is calculated and allocates the resources for execution and then compares the resource consumption with threshold value $\left(Th_c\right)$. If resource consumption is less than threshold value and value of $Requests_{Missed}$ is less than threshold value $\left(Th_m\right)$ then execution of resources continues otherwise no resource is allocated and process of reallocation is started using Algorithm 1. After meeting this condition, resources are allocated for further execution and value of resource consumption and $Requests_{Missed}$ are checked periodically. In case of more value than threshold, alert will be generated by performance monitor.

4.4. Executor

Executor implements the plan after analyzing completely. To reduce the execution time and execution cost and improve resource utilization is a main objective of executor. Based on the output given by

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Algorithm 1. Analyzing and Panning Unit (AU)

2. **if** (Required Resources > Provided Resources) **then**
   Allocate new resource from reserve resource pool with minimum $Resource_{consumption}$ and $Requests_{Missed}$ and [$Resource_{consumption} \leq Th_c$ && $Requests_{Missed} \leq Th_m$]
3. **end if**
4. **for all** resources
5. **if** ($Resource_{consumption} \leq Th_c$ && $Requests_{Missed} \leq Th_m$) == '*FALSE'* **then**
6. Restart the resource and start execution
7. **else if**
8. Declared resource as dead node and removed
9. Resource(s) is required to process data without degradation in performance
10. **if** (Availability of Resource(s) == '*TRUE')*
    Allocate new resource from resource pool with minimum $Resource_{consumption}$ and $Requests_{Missed}$ and [$Resource_{consumption} \leq Th_c$ && $Requests_{Missed} \leq Th_m$]
    else
11. Resource(s) is required to process data without degradation in performance
    Add new resource from reserve resource pool with minimum $Resource_{consumption}$ and $Requests_{Missed}$ and [$Resource_{consumption} \leq Th_c$ && $Requests_{Missed} \leq Th_m$]
12. **end if**
13. **end for**

analysis and executor tracks the new user request submission and resource addition, and take the action according to rules described in knowledge base.

4.5. Effector

Effector is used to exchange updated information and it is used to transfer the new policies, rules and alerts to other nodes with updated information.

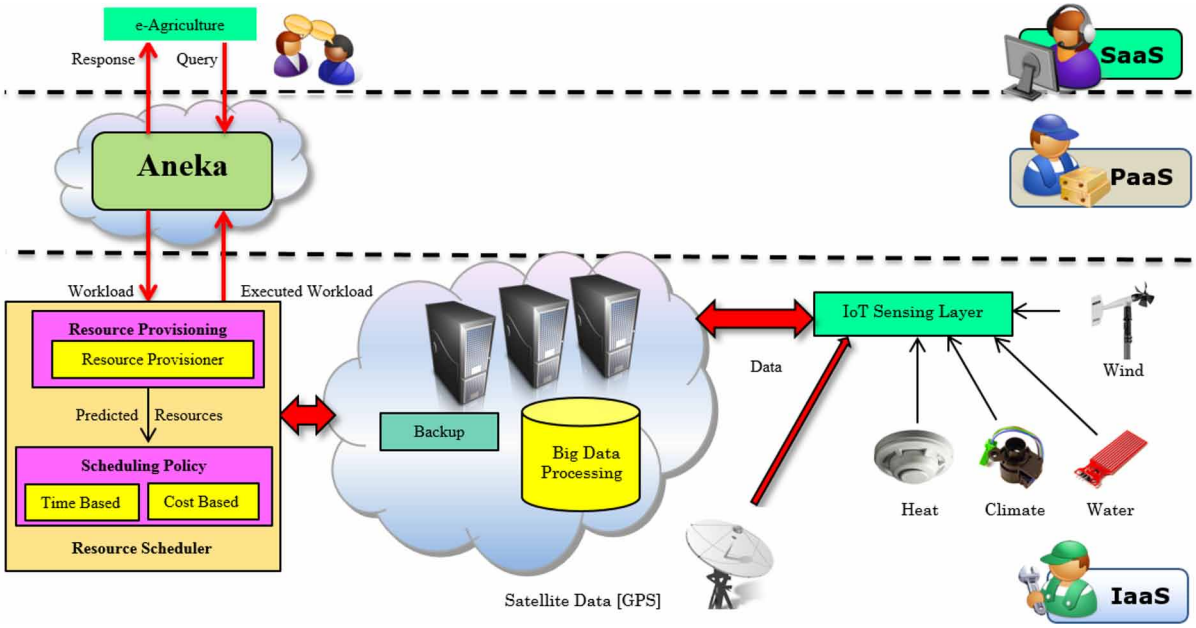
5. PERFORMANCE EVALUATION

The aim of this performance evaluation is to demonstrate that it is feasible to implement and deploy the agriculture as a service on real cloud resources. Tools used for setting up cloud environment for performance analysis are Microsoft Visual Studio 2010 (SaaS), Aneka (PaaS), SQL Server 2008, and Citrix Xen Server (IaaS). Aneka has been installed along with its requirements on all the nodes that provide cloud service. Nodes in this system can be added or removed based on the requirement. AaaS is installed on main server and tested on virtual cloud environment that has been established at *CLOUDS Lab, University of Melbourne, Australia*. Different number of virtual machines have been installed on different servers, and deployed the AaaS to measure the variations. In this experimental setup, three different cloud platforms are used: Software as a Service (SaaS), Platform as a Service (PaaS) and Infrastructure as a Service (IaaS) as shown in Figure 5.

At ***SaaS level***, Microsoft Visual Studio is used to develop e-agriculture web service to provide user interface in which user can access service from any geographical location. At ***PaaS level***, Aneka cloud application platform is used as a scalable cloud middleware to make interaction between IaaS and SaaS, and continually monitor the performance of the system. At ***IaaS level***, three different servers (consist of virtual nodes) have been created through Citrix Xen Server and SQL Server has been used for data storage. Scheduler as shown in Figure 5, runs at IaaS level on Citrix Xen Server. Computing

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Deployment of components at runtime and their interaction



nodes used in this experiment work are further categorized into three categories as shown in Table 7. The execution cost is calculated based on user request and deadline (if deadline is too early (urgent) it will be more costly because there is a need of greater processing speed and free resources to process particular request with urgency). There is individual price is fixed (artificially) for different resources because all the resources are working in coordination manner to fulfill the demand of user (demand of user is changing dynamically).

Experiment setup using 3 servers in which further virtual nodes (12 = 6 (Server 1) +4 (Server 2) +2 (Server 3)) are created. Every virtual node has different number for Execution Components (ECs) to process user request and every EC has their own cost (C$/EC time unit (Sec)). Table 1 shows the characteristics of the resources used and their Execution Component (EC) access cost per time unit in Cloud dollars (C$) and access cost in C$ is manually assigned for experimental purposes. The access cost of an EC in C$/time unit does not necessarily reflect the cost of execution when ECs have different

Table 7. Configuration Details of Cloud Environment

Resource_Id	Configuration	Specifications	Operating System	Number of Virtual Node	Number of ECs	Price (C$/EC Time Unit)
R1	Intel Core 2 Duo - 2.4 GHz	1 GB RAM and 160 GB HDD	Windows	6	18	2
R2	Intel Core i5-2310-2.9GHz	1 GB RAM and 160 GB HDD	Linux	4	12	3
R3	Intel XEON E 52407-2.2 GHz	2 GB RAM and 320 GB HDD	Linux	2	6	4

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

capabilities. The execution agent needs to translate the access cost into the C$ for each resource. Such translation helps in identifying the relative cost of resources for executing user requests on them. Due to limited number of resources, cost increases with increase in user requests. Cost is varying in two different cases: i) relaxed deadline and ii) tight deadline. In both cases, when the deadline is low (e.g. 200 secs), the number of user requests processed increases as the budget value increases. When a higher budget is available, the execution agent uses expensive resources to process more user requests within the deadline. Alternatively, when scheduling with a low budget, the number of user requests processed increases as the deadline is relaxed. Different number of experiments has been performed by comparing AaaS (QoS-aware Autonomic) as discussed in *Section 4* with non-autonomic resource management technique (non-autonomic) in which no autonomic scheduling mechanism is considered while allocating resources to process the user requests.

5.1. Datasets

Datasets used in this research work are downloaded from the Open Government Data Platform India (data.gov.in, 2015), India Agriculture and Climate Data Set (Sanghi et al.), and regional land and climate modelling in China (Sanghi et al.) can be in the order of 1000000 records, with size of 3.5 GB. The data is coming in large data variety and volume from both users in the form of images like damaged crop images due to weather, insects etc. and devices through Internet of Things (IoT) sensors and satellites (GPS systems) that send weather related images. As a result of regular capturing and collection of datasets, they grow with the velocity of 80.72 KB/minute or more (Sanghi et al.). Five different tables used to process the different types of data as described in Table 8 to Table 12.

Table 8. Crop Information

CropId	Crop Name	Crop Type	Soil Texture	Min Land	Growing Period	Seed Type	Price	Quantity
C1	Rice	Kharif	Slity Clay	5 Acre	3 Months	Wet	1200 Rs./Kg	2 Kg/Acre
C2	Maize	Rabi	Slity Loam Clay	4 Acre	4 Months	Dry	1600 Rs./Kg	1 Kg/Acre
C3	Wheat	Zaid	Loam Clay	3 Acre	3 Months	Wet	1000 Rs./Kg	2 Kg/Acre
C4	Sugarcane	Cash	Slity	4 Acre	6 Months	Dry	800 Rs./Kg	6 Kg/Acre

Table 9. Weather information

Crop Name	Temperature	Season	Pressure (CFM)	Wind Speed	Rainfall	Location
Rice	15-18 °C	Winter	0.75 to 1.5	16 Km/h	300–650 mm	Ambala
Maize	17-22 °C	Summer	0.05 to 0.5	12 Km/h	100–150 mm	Amritsar
Wheat	25-30 °C	Rainy	1.5 to 5.2	17.3 Km/h	200–250 mm	Ganga Nagar
Sugarcane	35-40 °C	Summer	1 to 10	8 Km/h	400–600 mm	Pathankot

Table 10. Soil information

Soil Texture	Bulk Density	Inorganic Material	Organic Material	Water	Air	Color	Structure	Infiltration
Slity Clay	2.60 to 2.75 grams per cm^3	Sand and clay	Plant and animal residues	25%	28%	Brown	Plate-like	15 mm/hour
Slity Loam Clay	2.7 to 2.75 grams per cm^3	Sand and Slit	Animal residues	22%	18%	Red	Prism-like	10 mm/hour
Loam Clay	2.60 to 2.75 grams per cm^3	Clay and Slit	Plant residues	37%	21%	Brown	Block like	18 mm/hour
Slity	2.60 to 2.75 grams per cm^3	Sand, Slit and Clay	Plant and animal residues	31%	29%	Black	Sphere like	22 mm/hour

Table 11. Pest information

Crop Type	Crop Disease	Effect	Treatment	Pesticide Name	Solubility in Water	Price	Outcome
Kharif	Bacterial brown spot	Degrade soil fertility	Reduce Irrigation	Carbonate	Yes	Rs. 1500/L	Improve Productivity
Rabi	Zonate eye spot	Degrade productivity	Distribute Soil	Organophosphate	No	Rs. 2200/L	Improve soil fertilization
Zaid	Dwarf bunt	Increase risk of other disease	Spray irrigation	Parathyroid	Yes	Rs. 2300/L	Reduce risk of other diseases
Cash	Ergot	Degrade productivity	Drip Irrigation	Parathyroid	Yes	Rs. 1800/L	Reduce productivity

Table 12. Fertilizer information

Crop Type	Fertilizer Name	Nutrient Composition	Price
Kharif	Urea	Nitrogen in form of urea (amide) (N)	7000 Rs./10 Kg
Rabi	Ammonium-Nitrate	Ammoniacal Nitrogen, Nitrogen Nitrate and Urea Nitrogen	9100 Rs./10 Kg
Zaid	Ammonium-Sulphate	Ammoniacal nitrogen and Sulpher	6200 Rs./10 Kg
Cash	Urea-Ammonium	Ammoniacal nitrogen and Neutral ammonium citrate Soluble phosphate	13200 Rs./10 Kg

5.2. Performance Metrics

The following metrics are used to calculate the execution cost, execution time, resource utilization, latency, detection rate and scalability for processing user requests as taken from previous work (Singh and Chana, 2015; Singh et al., 2015; Singh and Chana, 2016):

Execution Time is a ratio of difference of request finish time $\left(WF_i\right)$ and request start time $\left(WStart_i\right)$ to number of requests. Following formula is used to calculate Execution Time (ET) (Equation 3):

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$ET_i = \sum_{i=1}^{n} \left(\frac{WF_i - WStart_i}{n} \right) \tag{3}$$

where n is the number of requests to be executed.

Execution Cost is defined as the total amount of cost spent per one hour for the execution of request and measured in Cloud Dollars (C$). Following formula is used to calculate execution cost (C) (Equation 4):

$$C = ET_i \times Price \tag{4}$$

Latency is a defined as a difference of time of input cloud workload and time of output produced with respect to that workload. Following formula is used to calculate Latency (Equation 5):

$$Latency_i = \sum_{i=1}^{n} \left(time\ of\ output\ produced\ after\ execution - time\ of\ input\ of\ cloud\ workload \right) \tag{5}$$

where *n* is number of workloads.

Resource Utilization is defined as a ratio of actual time spent by resource to execute workload to total uptime of resource for single resource. Following formula is used to calculate resource utilization (Equation 6):

$$ResourceUtilization_i = \sum_{i=1}^{n} \left(\frac{actual\ time\ spent\ by\ resource\ to\ execute\ workload}{total\ uptime\ of\ resource} \right) \tag{6}$$

where *n* is number of workloads.

Security is measured in terms of detection rate. Experiment has been conducted with different type of attacks (DoS, R2L, U2R and Probing) and different tools used to launch different attacks are metasploit framework for DoS, Hydra for R2L, NetCat for L2R and NMAP for probing. *Detection Rate* is the ratio of total number of true positives to the total number of intrusions (Sorensen et al., 2010):

$$Detection\ Rate = \frac{Total\ Number\ of\ True\ Positives}{Total\ Number\ of\ Intrusions} \tag{7}$$

Scalability is measured in terms of throughput. It is the ratio of total number of workloads to the total amount of time required to execute the workloads. Following formula is used to calculate throughput (Equation 8):

$$Throughput = \frac{\text{Total Number of Workloads} \left(W_n \right)}{Total\ amount\ of\ time\ required\ to\ execute\ the\ workloads \left(W_n \right)} \tag{8}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

5.3. Experimental Results

Experiment has been conducted with 180 user requests for verification of execution cost, execution time, resource utilization, latency, detection rate and scalability. With increasing the number of user requests, the value of latency is increasing. The value of latency in QoS-aware autonomic system is lesser as compared to non-autonomic based resource scheduling at different number of user requests as shown in Figure 6. The maximum value of latency is 193 seconds and minimum value of latency is 59 seconds in QoS-aware autonomic resource management technique. Average latency in QoS-aware autonomic is 15.22% lesser than non-autonomic resource management technique. The value of average cost for both QoS-aware cloud based autonomic resource management technique and non-autonomic resource management is calculated with different number of user requests as shown in Figure 7. Average cost is increasing with increase in number of user requests. At 180 user requests, average cost in QoS-aware autonomic is 25.36% lesser than non-autonomic resource management technique. QoS-aware autonomic performs excellent with different number of user requests. Execution cost in QoS-aware autonomic is 27.65% lesser than non-autonomic resource management technique.

As shown in Figure 8, the execution time is increasing with increase in number of user requests. At 90 user requests, execution time in QoS-aware autonomic resource management technique is 24.66% lesser than non-autonomic resource management technique. After 120 user requests, execution time increases abruptly in non-autonomic resource management technique but QoS-aware autonomic performs better than non-autonomic technique. Average execution time in QoS-aware autonomic is 18.960% lesser than non-autonomic resource management technique. With increasing the number of user requests, the

Figure 6. Effect of change in number of user requests on latency

Figure 7. Effect of change in number of user requests on execution cost

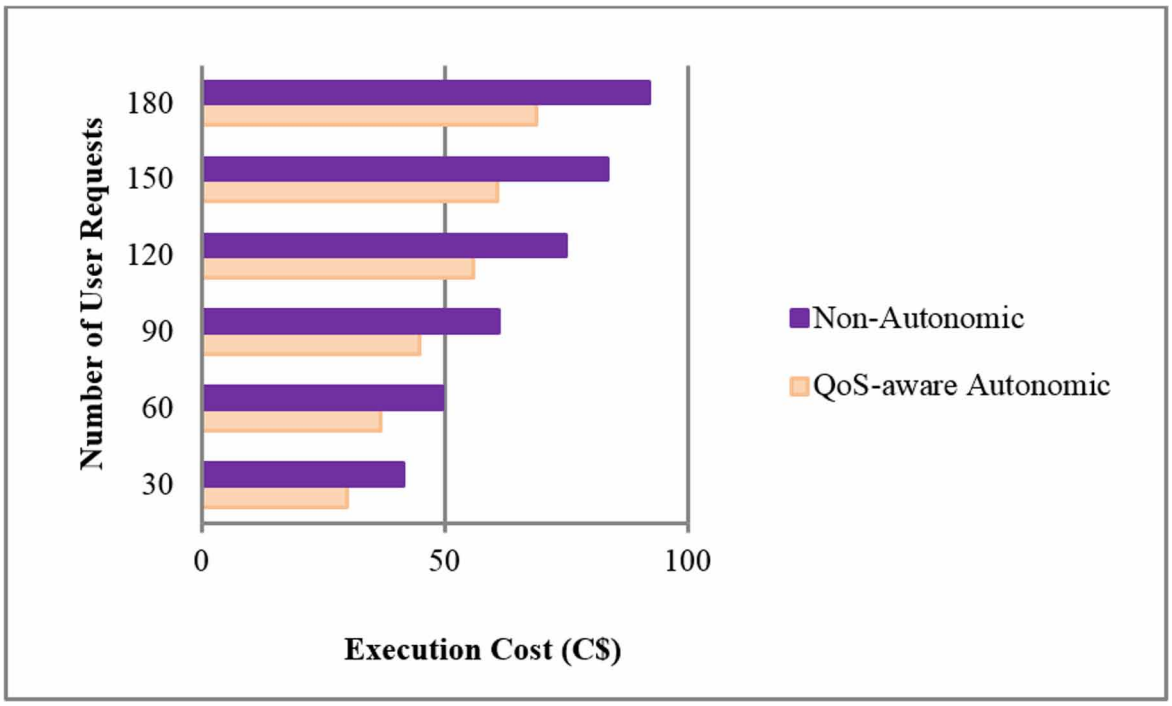

Figure 8. Effect of execution time with change in number of user requests

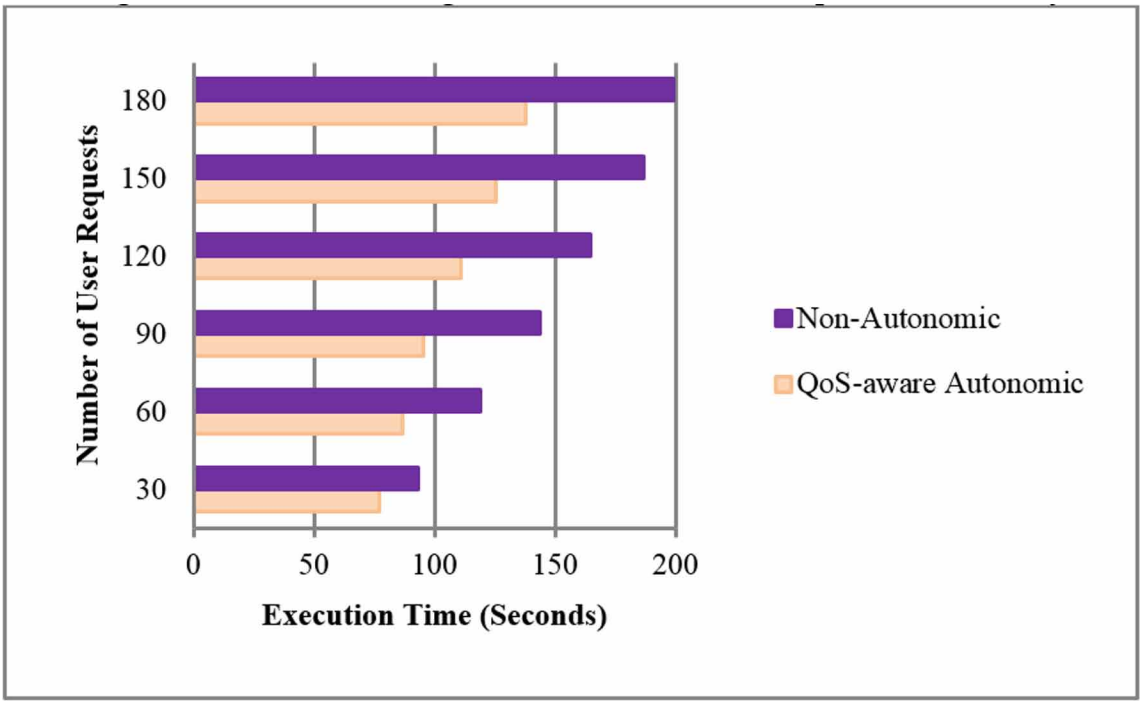

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

percentage of resource utilization is increasing. The percentage of resource utilization in QoS-aware autonomic resource management technique is more as compared to non-autonomic resource management (non-autonomic) at different number of user requests as shown in Figure 9. The maximum percentage of resource utilization is 94.66% at 180 user requests in QoS-aware autonomic but QoS-aware autonomic performs better than non-autonomic technique. Average resource utilization in QoS-aware autonomic is 31.96% more than non-autonomic resource management technique.

Scalability is measured in terms of throughput. Number of software, network and hardware faults (fault percentage) has been injected to verify the throughput of the proposed system with 100 user requests. Figure 10 shows the comparison of throughput of both QoS-aware autonomic resource management approach and non-QoS based resource management technique (non-autonomic) at 100 user requests and it is clearly shown that QoS-aware autonomic performs better than non-autonomic. In this experiment, it has been found the maximum value of throughput at fault percentage 45% i.e. QoS-aware autonomic has 26% more throughput than non-autonomic. Detection rate increases with respect to time and it considers the number of blocked and detected attacks. For new attack or intrusion detection, database is updated with new signatures and new polices and rules are generated to avoid same attack. Experiment has been conducted for known attacks; it is clearly shown in Figure 11 that QoS-aware autonomic performs better than snort anomaly detector (non-autonomic). Further signatures of some known attacks have been removed from database to verify the working of proposed system.

Table 13 describes the comparison of execution time used to process different number of workloads (90 and 180) on cloud environment for proposed system with different number of Virtual Machines (VMs). The number of VMs used to execute the workloads was incremented gradually showing how

Figure 9. Effect of change in number of user requests on resource utilization

Table 13. Total execution time of a bulk of cloud workloads distributed in three servers

Number of Workloads	Virtual Nodes			Total Workers	Execution Time (Seconds)
	R1	R2	R3		
45	1	0	0	1	436.12
45	1	1	0	2	428.69
45	2	1	0	3	418.97
45	2	2	0	4	407.55
45	3	2	0	5	398.17
45	4	2	0	6	380.30
45	4	2	1	7	361.66
45	4	3	1	8	345.18
45	5	3	1	9	331.21
45	5	3	2	10	315.03
45	5	4	2	11	299.97
45	6	4	2	12	276.16
90	1	0	0	1	1803.11
90	1	1	0	2	1771.18
90	2	1	0	3	1759.66
90	2	2	0	4	1736.15
90	3	2	0	5	1691.77
90	4	2	0	6	1668.96
90	4	2	1	7	1636.11
90	4	3	1	8	1625.19
90	5	3	1	9	1578.21
90	5	3	2	10	1551.68
90	5	4	2	11	1529.11
90	6	4	2	12	1503.11

the total execution time was reduced when more VMs were added to the cloud. With one virtual node running on Server R1, execution of 45 workloads finished in 436.12 seconds. With 12 virtual nodes (6 running on R1, 4 running on R2 and 2 running on R3), the application took 276.16 seconds. It is noted that the execution time is reduced with adding additional virtual nodes.

5.4. Statistical Analysis

Statistical significance of the results has been analyzed by Coefficient of Variation $\left(Coff.\ of Var.\right)$, a statistical method. $Coff.\ of Var.$ is statistical measure of the distribution of data about the mean value. $\mathrm{Coff.\ of\ Var.}$ is used to compare to different means and furthermore offer an overall analysis of performance of the technique used for creating the statistics. It states the deviation of the data as a proportion of its average value, and is calculated as follows (Equation 9):

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$Coff.\ of Var.\ = \frac{SD}{\mathrm{M}} \times 100 \tag{9}$$

where SD is a standard deviation and M is mean. $Coff.\ of Var.$ of execution time and have been studied of QoS-aware autonomic resource management technique and non-autonomic resource management technique as shown in Figure 12 and Figure 13. Range of $Coff.\ of Var.$ (0.25% - 1.69%) for execution time and (0.37% - 1.96%) for cost approves the stability of QoS-aware autonomic resource management technique as shown in Figure 12 and Figure 13. Small value of $Coff.\ of Var.$ signifies QoS-aware autonomic resource management technique is more efficient in resource scheduling in the situations where the number of user requests has changed. Value of $Coff.\ of Var.$ decreases as the number of user requests is increasing.

6. CONCLUSION AND FUTURE DIRECTIONS

Cloud-based autonomic information system (AaaS) for agriculture service has been presented, which manages the various types of agriculture-related data based on different domains through different user preconfigured devices. K-NN (*k*-Nearest Neighbor) classification mechanism is used to classify the agriculture data. Further, classified data is interpreted and users can easily diagnose the agriculture status automatically through AaaS. In addition, AaaS uses two resource scheduling polices (time and cost) for efficient resource allocation at infrastructure level after identification of QoS requirements of user request. The performance of proposed system has been evaluated in cloud environment and experimental results show that the proposed system performs better in terms of execution time, cost, resource utilization, latency, scalability and security. In future, the proposed technique can be extended by incorporating other QoS parameters like network bandwidth, availability, customer satisfaction, computing capacity etc. Proposed technique can be extended by developing pluggable scheduler, in which resource scheduling can be changed easily based on the requirements.

Chapter 22
ICTs for Agricultural Development and Food Security in Developing Nations

Bhattacharjee Suchiradipta
Independent Researcher, India

Raj Saravanan
National Institute of Agricultural Extension Management (MANAGE), India

ABSTRACT

Development has many faces and complete wellbeing of human population is the most important one of them which in more than one ways involves agriculture and the farming population. Providing needed information at the right time to the rural population is the first step in their empowerment and ICTs can play an immensely important role in providing that information by increasing the dialogue between development professionals and rural people at every stage of development process. According to recent statistics released by ITU, over the last 15 years, ICTs have grown in unprecedented ways providing huge opportunities for social and economic development and this growth can be an advantage to rural advisory services. Providing correct and personalized information needs expert opinions and so multi-stakeholder engagement makes the process more efficient and ICTs provide a very unique and important platform for such collaboration, thus bringing together different stakeholders for efficient partnership. The various tools and technologies can also be tailored according to the needs of end users. But in spite of the advantages, ICTs can only be universally accepted and used when the challenges of accessibility, acceptability, funding, and sustainability are overcome. There are no formula for sure success with ICTs and situation is the best determinant of the strategy to be used and so, a balanced and strategic use of ICTs depending on the clients' needs can best utilize its potential for agricultural development and food security in developing nations.

INTRODUCTION

Global development has many faces and all of them concern human development – taking people out of poverty, assuring food security for everyone, and ensuring a fairly comfortable life. This is a difficult task considering one in nine people in the world suffer from hunger. The problem becomes complicated with the uneven distribution of the famished population with higher concentration in countries of Sub-Saharan Africa where one in four people suffer from chronic hunger, as well as Southeast Asia which has the largest number of undernourished persons (FAO, 2015). One of the largest missions taken worldwide in recent times to ensure human development was the Millennium Development Goals (MDGs) adopted at the Millennium Summit of 2000 of the United Nations, where the member countries promised global partnership and set time bound quantified targets with a deadline of 2015. These MDGs were formulated with the goal of all round human development by eradicating hunger and poverty, providing universal primary education, promoting gender equality and women empowerment, reducing child mortality, improving maternal health, combating major life threatening diseases across the world, ensuring environmental sustainability, and developing a global partnership for development (Millennium Project, 2006). The MDGs targeted world poverty in its many dimensions and by 2015, though the target of halving extreme poverty has been met, it was far from being well distributed across the continents. While a few Asian countries accounted for most of the decline, the absolute number of poor has risen in Sub Saharan Africa.

Poverty and food insecurity in the world right now is predominantly rural with 78 per cent of the world's extreme poor living in rural areas with the majority dependent on agriculture. In addition, almost 60 per cent of child labour worldwide is found in agriculture. The world has the capacity to produce enough food to feed everyone equally, even with the estimated 60 per cent increase in production to meet the projected demands of 2050, yet still, the rural poor - mostly consisted of subsistence producers, family farmers, and landless labourers – live on less than $1.25 USD per day. After 2015, the development agenda shifted from goals and targets to measurements and means. As a result, discussions on building on innovative ways to address the world's most pressing challenges began and Sustainable Development Goals (SDGs) were implemented. One of the five agents of change identified for transforming development economies is family farmers and small scale producers. Agricultural growth is up to five times more effective than any other sectoral growth in resource poor low income countries in reducing poverty (FAO, 2015) but the problem is more than sustainable agricultural production; it is of connecting the farmers and making them informed, and helping them to organize themselves to get the most out of their investment in their agricultural fields. In so doing, Information and Communication Technologies (ICTs) can be a very important aid to rural advisory services.

INFORMATION EMPOWERMENT

Information is a critical input in agriculture and given at the right time, it can prove to be the most important one (Saravanan and Suchiradipta, 2015b). Providing needed information at the right time to the rural population is the first step in their empowerment and ICTs can play an immensely important role in providing that information by increasing the dialogue between development professionals and rural people at every stage of the development process. Information empowerment of rural people helps them to be active partners in development efforts and not mere beneficiaries. ICTs make the job easier

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

through TV, radio, computer, mobile phones, and recently social media. But in developing countries, information poverty is one of the more significant and insidious obstacles to effective exploitation of information processing and other types of technology (Sadowsky, 1996).

According to recent statistics released by ITU, over the last 15 years, ICTs have grown in unprecedented ways providing huge opportunities for social and economic development. Since 2000, internet penetration has increased 7 fold from 400 million users in 2000 to 2.2 billion users in 2015. Mobile subscriptions are up from 738 million to 7 billion and developing countries provide a wide opportunity for further development with new users and more population to reach (ITU, 2015). Social media, the recent addition to the world of ICTs, is gaining popularity very fast with a global penetration of 29 per cent, a 12 per cent increase from 2014 with a major boost from increased mobile subscriptions. Facebook is the most popular social media platform with about 1.5 billion users worldwide (Kemp, 2015) and the number increasing every day. But conditions in least developed countries (LCDs) are still challenging. Internet penetration is 9.5 per cent for population and 7 per cent for households, mobile broadband subscription is only 12 per cent of the population and fixed broadband subscription negligible at 0.5 per cent. Also, the fact that monthly fixed broadband prices are three times higher and mobile broadband prices are two times higher in developing countries than in developed countries (ITU, 2015) is only adding to the cause with poor households finding it difficult to invest in internet services.

ICTs in Rural Advisory Services (RAS)

With increasing diversities in agriculture, more stakeholders and increasing need to produce more to reach farmers at the right time with correct and needed information is not limited only to the extensionists. Moreover, information being one of the most critical inputs in agriculture, farmers are willing to pay for it, thus making extension a profitable business. But providing correct and personalized information needs and expert opinions on a timely basis is a complex process and so multi-stakeholder engagement makes it more efficient. ICTs provide a very unique and important platform for such collaboration, thus bringing together different stakeholders for efficient partnership.

Philosophy and Principles of ICTs for Agricultural Development (Adopted From Saravanan et al., 2015a)

ICTs are better enablers for information and knowledge access and sharing among agricultural innovation system actors compared to conventional methods. They also complement the conventional extension advisory methods. The guiding principles (World Bank, 2011; Saravanan 2011b; Saravanan, 2013) of ICTs for a more efficient extension and advisory services (EAS) are:

- **Relevant Content:** Contextualized or farmer specific, need based, timely and quality content is the major aim of ICT based EAS.
- **Appropriate ICT:** Among a variety of ICTs, choose the formats, channels, tools, devices and applications that best match the purpose, content and clientele.
- **Integration of Methods, Actors and Services:** Integrating ICTs with other conventional extension methods (like Farmer Field Schools (FFS), Community Knowledge Workers (CKWs), etc), pluralistic actors (public, private, Farmer Based Organisations (FBOs), etc) with their services along the value chain will create synergy in extension and advisory services.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Information PLUS:** To convince the clientele, (i.e. show and tell). ICT based information alone is not enough and needs to be combined with field demonstrations, exposure visits, group discussions etc. Not just advisory information, but a complete resource package across the agricultural value chain[1] needs to be provided.
- **Human Element:** Commitment of the extension stakeholders to use ICTs, development of ICT champions with the legacy of promoting continuous leaders and followers are important.
- **ICTs Complementary to EAS:** ICTs can play only a complementary role in extension. If they are used appropriately, they create synergy and better impact with conventional extension efforts.
- **Institutionalizing ICTs:** Institutional policy and guidelines to use, developing the ICT literacy and competency among the human resource and infrastructure development should be an integral part of the institutional set-up.
- **Reasonably Long Term and Continuous Engagement with ICTs**: To see the better outcome, ICTs need to be integrated with the conventional extension approaches for a reasonably (at least for 5 years) long period.

Broad Areas of ICT Implementation for Agricultural Development (Adopted From Saravanan et al., 2015a)

ICTs based extension advisory methods are implemented along the agriculture value chain activities such as pre-production, production, post-harvest and marketing, financial services (credit, payment, savings, insurance, etc.), climate and other data. Five broad areas[1] of ICTs implementation are:

1. **Offering Localized and Customized Information, Advisory and Other Services:** Farmers call centres (FCCs), mobile apps, radio, TV etc.
2. **Helping to Create, Document, Store, Retrieve, Share and Manage the Information:** Web portals, crop specific portals, knowledge banks, expert systems and agricultural information management systems etc.
3. **Enabling Collaboration, Sharing and Partnerships for Innovation Among Extension Actors:** Social media, Dgroups etc
4. **Enabling Farmers and Others to "Gain a Voice":** Community radio, tele-centres, videos, communities of practice (COPs) etc.
5. **Facilitating Capacity Development of Farmers, Extension Professionals and Other AIS Actors:** E-learning mechanisms (Open Distance Learning (ODL), Learning Object Repositories (LOR), Massive Open Online Courses (MOOCs) and other e-learning mechanisms etc.), training by using ICTs, survey and monitoring tools and applications.

ICTs have been used in various forms depending on the need of the clientele, location specificity, availability and accessibility of technology and so on. Major forms of ICT tools and applications in Rural Advisory Services (RAS) are discussed below:

- **Radio and Television:** Radio and TV are the earliest forms of ICTs used in agricultural extension and advisory services and are the most popular with the rural communities. They have been very helpful in dissemination of information and technologies among the farmers in rural areas but

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

their very nature inhibits interactivity or location specificity which restricts their scope in information dissemination in an era of technology. In recent times though, community radio stations have tackled the problems of location specific information and have made the rural people major stakeholders in information dissemination and discussions about community development.

- **Interactive Multimedia Compact Discs (IMCDs), Decision Support Systems (DSS), and Expert Systems:** Multimedia is a combination of text, graphics, art, sound, animation, and video elements where the viewers can control what elements are delivered and when. This is known as interactive multimedia. IMCDs offer learners complete and individual control over their learning and encourages better understanding between individual learners and the subject matter. Decision support system (DSS) is a computer program application that analyzes data and presents it so that users can make decisions more easily. DSS uses Artificial Intelligence (AI) and expert systems to present data in a format suitable to the users. Expert systems are tools for information generation from given information by simulating human reasoning about a problem domain. The knowledge acquisition process for building an expert system facilitates the integration of knowledge and experiences of different specialties which help generate advice based on its knowledge base and reasoning mechanism from all developed extension documents.
- **Web Portals:** Web portals are digital platforms that provide organized gateways to information or act as aggregators of knowledge from various stakeholders. They are specifically designed single access points to information collected from diverse sources. In agricultural extension and advisory services context, web portals can be of two types – those providing technical and market knowledge to end users at the grassroots level, and those helping with capacity development of extension personnel. Financially and socially, portals can have far reaching impact on users. Illiteracy – both educational and technological – can be a barrier in accessing web portals by grassroots level users but with the help of extensionists, they can be of much help to the rural communities (Saravanan et al., 2015b). A few examples of some successful initiatives to use web portals for agricultural communication are discussed below.

University Web Portal

TNAU Agrictech Portal has been catering to the needs of farmers, extensionists and other stakeholders in agriculture and allied sectors since 2009. It offers a diverse range of information from crop related to weather information, daily market prices, schemes and programs for farmers, daily news, events and publications supported by multimedia, expert systems and many others. The portal can also be accessed in Tamil and English languages and offers a keyword search facility. Farm technology portal (http://agritech.tnau.ac.in) was designed by integrating the allied sectors of agriculture, horticulture, agricultural marketing and agriculture business, agricultural engineering, sericulture, seed sector, forestry, fisheries and animal husbandry. This dynamic portal page holds more than half a million pages in Tamil and English with multiple media content. According to Google Analytics, from April 1st 2015 the daily visitors ranged between 26000-28000, new visitors numbered 1,44,100 at the rate of 57%, the new sessions were 2,33,168 with an average session duration of 4:09 minutes, number of page views were 7,39,706 with a bounce rate of 62%. The average page/session was 3:17 minutes.

The online input information service ensures timely sourcing of critical inputs to farmers in the state. By using the last mile connectivity, Short Message Messages (SMS), more than 10,000 million SMS

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

have been sent to farm beneficiaries in English and Tamil through m- kisan mobile linked interface. The agritech portal is linked to social media networks like blogs, twitter and YouTube, and Facebook messages are updated on agriculture related news on a daily basis both in English and Tamil.

Crop Specific Portal

"Rice Knowledge Management Portal" (www.rkmp.co.in), as the name exemplifies, facilitates efficient management of the enormous knowledge on rice crop on a single click. With more than 16,000 pages of validated and localised content in seven vernacular languages and 18 stakeholder platforms, this is considered as the largest repository of knowledge on any single crop across the globe. Today, a rice farmer from any corner of the country is able to get all the rice related reliable information specific to their region in the language of his choice. The dream of any extension professional to provide the right information at the right time and context in the local languages to the farmers is realized through Rice Knowledge Management Portal - the one stop shop for rice related information.

Web Portal for Agriculture Videos

Access Agriculture (www.accessagriculture.org) is a video based web portal started in 2012 with training videos in agriculture and allied sectors, business skill development and market development. It has something to offer to all agricultural stakeholders. The online videos can also be downloaded and language of the audio can also be requested as per preference of the user. The web portal also has social media presence in Facebook and LinkedIn and has a video social media site called AgTube.

Web Portal by the Extension Organisation

eXtension (www.eXtension.org) is an interactive learning environment delivering the best, and most researched knowledge from the land-grant university minds across America. eXtension connects knowledge consumers with knowledge providers - experts who know their subject matter inside out. eXtension is unlike any other search engine or information-based website. It's a space where university content providers can gather and produce new educational and information resources on wide-ranging topics. Because it is available to students, researchers, clinicians, professors, farmers as well as the general public, at any time from any Internet connection, eXtension helps solve real-life problems in real time.

Web Portal for Integrated Rural Advisory Services

As part of the India Development Gateway initiative of Government of India, Vikaspedia portal (www.vikaspedia.in) is aimed at creating a versatile collective knowledge repository and demand driven information in the development oriented sectors including Agriculture. This multilingual portal is serving as a collaborative content creation, knowledge sharing and utilization platform for the stakeholders in agriculture and allied sectors[14]. Currently, Vikaspedia is one of the largest knowledge portal hosting information/knowledge in 10 Indian languages, offering information on success stories, best practices, government schemes, technologies, market information and related value added services in Agriculture.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Online Learning Platforms:** Learning platforms are interactive online services that provide learners with resources to support and enhance educational delivery and management. They are virtual learning environments that make the process interactive with integrated discussion boards, chat rooms and other such facilities where contents are both expert suggested and user generated. These kinds of learning platforms also serve as online repositories and can be very helpful for all agricultural stakeholders to increase their expertise on practical topics while sharing experiences with their colleagues across the globe and leaning from others' experiences. A good example of online learning platforms is Massive Open Online Courses (MOOCs) that have recently become very popular among all agricultural stakeholders.
- **Mobile Phones:** Mobile phones are devices that can create, store, access and share information anytime, anywhere and teamed up with extension and advisory services can help improve the livelihood of rural people by taking timely information to their fingertips at potentially low cost. They also provide the unique opportunity of instant feedback and one on one interaction with experts. mExtension can facilitate the creation of scalable, replicable and commercially sustainable advisory services for rural clients and women can especially benefit from the services if access to mobile phones can be ensured (Saravanan and Suchiradipta, 2015c).
- **mExtension:** Agricultural extension and advisory services are provided through a number of modes – push and pull SMS, interactive voice response (IVR), mobile apps (mApps), and so on – sometimes individually and sometimes integrated. While SMS and IVR services are accessible from both feature and smart phones, mApps require smart phones. Services can be free or subscription-based. Cost does not seem to affect popularity as shown by services such as IKSL in India, iCow in Kenya, Kilimo Salama in Kenya and Rwanda, and e-Krishok in Bangladesh. Mobile-based advisory services are mostly targeted at farmers and the rural population but collaboration among stakeholders in agricultural innovation systems (AIS) for providing content is not unknown. The advisory services also vary from providing solely agricultural information (e.g. Gobi Sahana Sarana in Sri Lanka) to providing micro insurance to rural people (Kilimo Salama in Kenya and Rwanda), real time market information (e-soko active in 10 African countries), farmer-specific fertiliser recommendations (NMRiceMobile in Bangladesh, China, India, Indonesia, Phillipines and West Africa) or integrating agricultural and weather information along with entertainment to attract large numbers of rural people (Nokia Life Tools) (Saravanan and Suchiradipta, 2015c).
- **Social Media:** Social media are web based tools of electronic communication that allow users to personally and informally interact, create, share, retrieve, and exchange information and ideas in any form (text, pictures, video, etc.) that can be discussed, archived and used by anyone in virtual communities and networks (Saravanan and Suchiradipta, 2015d). While social media has been playing a significant role in personal communication and development communication across the globe, in the agriculture sector its popularity has also been increasing. Increased use of social media in agvocacy (agvocacy is the combination of two words agriculture and advocacy, and means talking for and about agriculture) can increase the dialogue among agricultural stakeholders and make information access much easier for rural smallholders. Also, with proper planning, a social media communication strategy can be scalable across geography (local, regional, national, global), topics of interest (e.g. business, career, agronomic practices, crops, etc.), and type of clients (women, young people, smallholders, etc.) (Saravanan et al., 2015c).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Extension professionals are using social media to form networks and farmers are taking to social media to talk to peers and consumers. All big things in agriculture – new technology or innovations, seminars and meetings, workshops and trainings, reports, publications – get tweeted or hashtagged. Facebook, Twitter, YouTube, and blogs are the major platforms for agricultural information dissemination. The uses of socially integrated messaging apps are also increasing in the rural areas. But still, there is a difference in the intensity of use in developed and developing countries – basically due to economic conditions and infrastructure availability. In spite of the differences, use of social media is picking up in rural areas of developing and least developed countries as well (Suchiradipta and Saravanan, 2016)

GFRAS Global survey on use of social media in agricultural extension and rural advisory services conducted online during 2015 across 62 countries and 229 respondents provided interesting responses. Facebook was found to be the most popular social media platform used by extension professionals. The major activity on social media was searching for news events and sharing information. A major impeding factor for social media use was the lack of authenticity of information shared online. Social construction of information (development and publication of information socially by the users) was considered the most important feature of social media (95.1%). Ninety five percent of the respondents believed social media can play an important role in bridging the gap between stakeholders in Agricultural Information services (AIS). Reaching clients (77.4%) was a major use of social media in AEAS. Training in social media use was uncommon, and 71% of the respondents said they need training on social media use. If and when there was training conducted by the respondents' organizations, it mainly focused on the specifics of different social media platforms and awareness creation on the use of social media in agricultural extension. But on an organizational level, social media is still not given much importance by higher authority and social media policy restricts rather than encourages its use. Also, weak or non-existent connectivity in rural areas, high cost of data charges, illiteracy of the clients and low participation and lack of interest of clients are reported to be major problems. Overall, the survey found that social media is a very useful tool in agricultural extension and rural advisory services. To quote one respondent, "social media is not only a tool for reaching large audiences; it is also an opportunity to develop relationships." (Suchiradipta and Saravanan, 2016)

The use of social media is becoming more and more pronounced in agriculture and a few of the popular social media accounts and handles across various platforms, as in Table 1, will give a better idea into their works.

ICTs have provided many opportunities for collection, processing, storage, retrieval, managing and sharing of information in multiple format for providing a wide range of services (information, awareness, promotional, advisory, knowledge, technology transfer, training, education, and much more) to farmers and other agricultural innovation system (AIS) actors in a timely, comprehensive, cost-effective, and interactive manner (Saravanan et al., 2015a). But one important factor that impacts the success of ICT based projects is the suitability of the technology used. In areas where the majority of the end users are illiterate, TV, radio, voice based mobile advisory services and video- based web portals are more appropriate; community radio and mobile phones are more suitable media to engage women farmers. Young farmers can be most engaged on social media platforms like Facebook, Twitter and Whatsapp, and depending on the electronic device availability with the client, the development organizations need to provide basic infrastructure like internet kiosks to access the information provided. To make ICTs a real success and not a piecemeal approach in RAS, more attention needs to be paid to the 'I' and 'C' of

TNAU Agritech Portal blog (Tamil Nadu Agricultural University) (http://tnauagritechportal.blogspot.in/)	The blogs of TNAU Agritech Portal deals with everything agriculture – from sowing to harvesting, crop protection to crop management, weather, recent happenings in the agriculture industry, schemes and programs for farmers, ICTs, and many more. A total of 940 blog posts have been made since 2012, 541 of which are made in 2015 itself, by 43 members consisting of extensionists, researchers, academicians, and farmers.	Farmers, agripreneurs, extensionists	India
YOUTUBE			
Farming First (https://www.youtube.com/user/FarmingFirst/)	This channel highlights the mission of the agricultural development coalition of the same name, founded in 2009. Made up of 131 organizations worldwide, Farming First prioritizes the protection of natural resources, knowledge sharing, local infrastructure, harvests, market access, and innovative research (www.foodtank.com).	Policy makers, researchers, agricultural enthusiasts and practitioners	Global
CGIAR Research Program on Climate Change, Agriculture and Food Security (CCAFS) (https://www.youtube.com/user/CCAFS)	The videos shared by the channel features stories of smallholder farmers, interviews with leading agricultural experts across the globe, and innovative information on climate-smart agriculture (www.foodtank.com).	Researchers, farmers, policy makers	Global
IFADTV (https://www.youtube.com/user/IFADTV/)	It is a well produced and highly engaging channel from the International Fund for Agricultural Development (IFAD). Videos feature news stories about smallholder farmers in addition to interviews with agriculture experts (www.foodtank.com).	Policy makers, farmers, extensionists	Global
Farmers Weekly Video (https://www.youtube.com/user/FarmersWeeklyVideo/)	It is produced by U.K.-based Farmers Weekly, a multimedia independent information service for farmers and agricultural businesses. Videos contain information on how to make agri-businesses sustainable, advice on farming careers, and information on different crop inputs (www.foodtank.com).	Farmers, extensionists, agribusinesses	U.K.

(Suchiradipta and Saravanan, 2016)

ICTs rather than the 'T' only (Saravanan and Suchiradipta, 2015a). This requires shifting the focus to specific target groups and engaging them fruitfully to ensure successful implementations of ICTs. Youth everywhere can be the most important stakeholder in this process.

Youth and ICTs in Agriculture

ICTs for Youth (ICT4Y) in Agriculture

ICTs and youth can prove to be a great catalyst in agriculture. ICTs are the developmental tool kits to empower the rural youth to fight against the odds of poverty, backwardness and illiteracy and come out victorious in their agricultural fields. It is not a mere technological innovation to come and go but application of ICTs in agriculture is a permanent solution to many of the problems of the sector in developing countries. It will also bridge the gap between the present and past making young people the catalyst for the change among their peers. Moreover, forming an opportunity of employment for the rural youth does not only help them but saves the society from many odds. ICTs empower the rural youth and channel their energy in a desired direction.

Of the other direct impact of ICTs on youth in agriculture are forming virtual peer groups to share their experience. The youths from various parts of the world with the Web 2.0 can gain exposure to what is happening in the agricultural front in other parts of the world and thus gain a better understanding of their own situation. This helps them to take better decisions in their own condition. It also gives them the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

opportunity to give their voice in the policy making process. ICTs increase the productivity and inspire the youth to venture in agripreneurship. ICTs also increase the social status of the farmers and the need for social recognition attracts others to the use of technology in their conditions. It also increases the negotiating power of the farmers and makes them more informed for so as not to be cheated by others.

The role of ICTs, thus, can be felt in every sphere of life of the farm youth. As shown in the Figure 1, it is a lifelong process of learning from their own experiences, from others in the community (both actual and virtual) or from access to the worldwide knowledge repository and also passing that knowledge to those who need it. Not only that, it also helps in their skill formation and proper planning and management of their investments thus ensuring an inclusive individual and community development.

In many countries, mobile phones have reduced the work of farmers allowing they to devote to other works. They do not have to walk long distances in order to transfer money from the bank or get information about market prices. It has also inspired the farm youth to take entrepreneurial steps in innovative ways to make agriculture remunerative and thus reduce the drudgery involved.

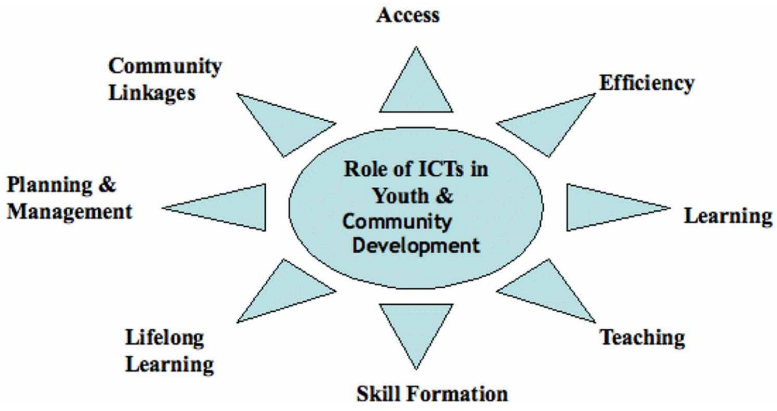
Youth for ICTs (Y4ICT)

All the discussions till now have been on how the ICTs can revolutionize agriculture. But like all other technologies, it needs a carrier to take it forward and implement it. ICTs are powerful only as long as they are used to their fullest potential. The youth who form a major portion of the developing world can get the best out of them because of their natural affinity to technology. It is important for the young people to participate in the ICT initiatives and their implementation, as they know best the needs of their community and themselves. It also adds the bottom-up approach to the project implementation making it more realistic and fruitful. The youth can play a big role in bridging the digital divide that exists in developed and developing countries and also the rural and urban areas. They can not only help themselves but also the other community members to get the best out of their land (Suchiradipta and Saravanan, 2013).

Youth and ICTs: Example of a Fruitful Relationship

In North-East India, Jhum cultivation (Slash and Burn Agriculture) is the most predominant form of agriculture. The prevalence of number of tribal dialects makes communication difficult for change

Figure 1. Potential of ICTs in youth and community development (Haddad, 2007)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

agents. Hence, considering the farming situation and difficulty in communication of appropriate farm information, an e-extension project (e-Arik) was initiated since 2007 in East Siang district of Arunachal Pradesh state. To overcome communication difficulty and also to motivate rural farm youth and others to take up profitable farming activities, four educated tribal farm youth were used as 'farmer facilitators' along with ICTs. They were given advanced farm technological training at the constituent college of the Central Agricultural University (CAU) and KVK. The farm youth helped to create general agricultural and rural development awareness among tribal farmers, facilitated eco-friendly and sustainable farm technology dissemination, developed vocational efficiency among farmers, formed farmer groups for self-help, facilitated use of local resources, helped to make timely decisions by the farmers themselves and suggested alternative ways to solve farming and other rural problems in twelve selected villages. By the efforts of farm youth facilitators by following 'farmer to farmer communication' approach and using ICT tools, 44 percent and 92 percent of farmers adopted the information on climate smart practices on paddy (Oriza sativa) and Khasi Mandarin (Citrus reticulata) crops respectively. After three years of project initiation, 55 percent of farmers developed new Khasi Mandarin orchards in their Jhum field, which means they are permanently moving from age old Slash and Burn agriculture to settled cultivation. Even after the completion of the project, trained farm youth are serving as a link between agricultural development departments and tribal farmers for facilitating advanced farm trainings and advisory services and they become 'local knowledge managers' to foster agricultural development in the remote tribal villages" (Saravanan, 2011a & b).

IMPLEMENTATION OF ICTs IN RAS

Appropriateness of ICTs depends on the situation and their use is most successful as a catalyst of development and to do so a few logical steps need to be followed. While the steps may be indicative of the logical delivery of ICT projects, they are not absolute in any terms, but very much flexible depending on the need of the situation and best judgements of the extension organisation, based on detailed need assessment surveys among clientele and other stakeholders (Saravanan et al., 2015a).

1. **Need Assessment:** EAS is most useful and applicable when information and services provided are localized and need based and so for the ICT projects to be successful, the first and foremost action of a host organization should be need assessment of the target community.
2. **Benchmark Survey:** Standards or points of reference are very important for ICT enabled services to meet their objectives and this makes benchmark surveys a necessity. They are also useful as standards of monitoring and evaluation.
3. **Content Development:** Localized and customised content needs to be developed based on the results of need assessment and benchmark surveys to avoid the problem of blanket recommendation.
4. **ICT Selection, Development and Testing:** Based on localised needs, content, and target groups, the appropriate ICT tool needs to be selected, developed and pilot tested for determination of suitability.
5. **Awareness Programs and Registration:** One major drawback in ICT projects is lack of awareness of target users about its existence or benefits and to solve that, innovative awareness campaigns need to be conducted to make them aware of the projects. In the case of subscription based services, it is more important as the users need to register to receive the benefits.

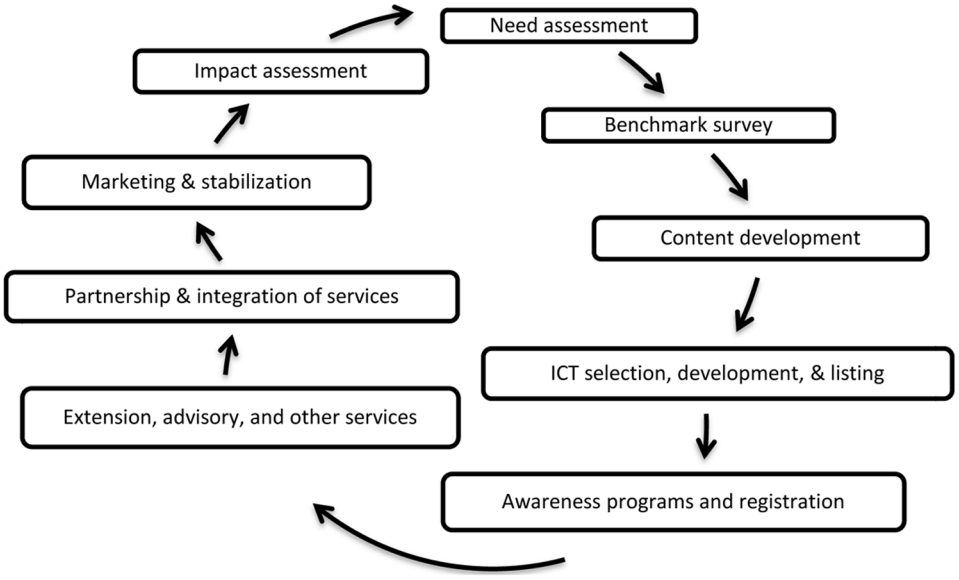
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. **Extension, Advisory and Other Services:** Based on demand and needs of the users, the services are to be provided to the targeted groups.
7. **Partnership and Integration of Services:** Depending on the need of the project and the services provided, collaboration among stakeholders needs to be formed and integration of services are to be determined to provide quality service to the users.
8. **Monitoring and Stabilization:** Continuous monitoring is an important function, especially in the pilot phase, to determine the suitability of the project to target users and accordingly modify the services offered to ultimately scale up the project in a profitable manner.
9. **Impact Assessment:** It remains one of the most important steps in implementation of ICT projects as the impact ultimately decides the degree of success of the projects in bringing the desirable changes in the target group as well as the factors deciding its sustainability for the long run.

SWOC ANALYSIS OF ICTs IN RAS

ICTs no doubt have the immense benefit of reaching the unreached, thus making it one of the most important supplements to RAS. This gives a huge opportunity to reach the BoP farmers and provide them necessary information to commercialize their agricultural practices and become self-sufficient. Then again, ICTs are only useful when the farmers can access the infrastructure, which is oftentimes non-existent in rural parts of the developing world, mostly when they are literate and tech savvy and also can bear the cost of the devices necessary. However, once these challenges of funding of projects, sustainability and acceptance by rural people are overcome, ICTs can become the most important catalyst in development of the rural population in the developing countries. The various strengths, weaknesses, opportunities and challenges of ICTs in RAS are presented in Table 2.

Figure 2. Steps for implementation of ICT enabled RAS (Saravanan et al., 2015a)



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Strengths, weaknesses, opportunities, and challenges of ICTs in RAS

Strengths	Weaknesses	Opportunities	Challenges
Better access to services Cost-effective Timely Any time anywhere Supplements the role of extensionists Better research-extension-client system linkages	Success depends on human commitment Lack of personal touch in RAS Lack of ICT skill and competency Lack of institutional ICT policy in RAS Long-term sustainability	Continuous improvement of ICT infrastructure Penetration of high end mobile phones Reducing cost of ICT infrastructure and services Multiple players in RAS services provision using ICTs	Farmer-specific and relevant content Language barriers Low literacy of rural farmers Imparting skill and competence among RAS stakeholders to use ICTs Duplication and contradictory information flow

(Saravanan et al., 2015a)

Capacities Required for Using ICTs in Agricultural Development

ICT is an umbrella term used for different types of communication technologies that sometimes require completely different kind of skill set to productively develop, implement, and use them for development purposes. Also, depending on the target user, content modification becomes a very important issue. All these require professional capacities in both technology and social sciences. Table 3 below discusses the various capacities needed for successful implementation and ways to develop the major ICT tools predominant in agriculture.

Governance in ICTs for Agricultural Development

In the context of Agricultural Innovation Systems (AIS), to provide a quality extension and advisory services to the users, development and maintenance of the ICT projects needs to be a well thought out and planned measures involving more than one stakeholder working together. And this calls for a well-structured system that involves aptly positioned stakeholders to avoid overlapping roles. Depending on the type of ICT application, the type of governance varies and it is detailed in Table 4.

Table 3. Capacities required in and ways to develop ICT based interventions

ICTs	Capacities Required	Ways to Develop
Social media	Basic knowledge and skill in using internet and social media	Creating interest groups, awareness and training programmes and regular interaction and sharing
Radio, TV, tele-centres	Minimum knowledge of operating the stations and creation of suitable programs for selected medium. RAS professionals should create and deliver appropriate content.	Training in script writing, and content treatment. Need and location specific program creation and inclusion of farmers in the programs
Web portals, expert systems, Mobile apps, MOOCs	Proficiency in IT, expertise in choosing and packaging the content. Knowledge of web content development, content creation, interactive portal management, etc.	Specialized training for developing IT and subject matter experts. Integrating and updating content regularly, interactivity and knowledge base creation

Table 4. Governance of ICT based projects in agriculture

ICTs	Maintenance	Partnership	Stakeholders	Roles
Social media	Individually maintained by extension organizations	Generally does not arise. Groups and communities can be managed in partnership mode.	All agricultural stakeholders can be brought on same platform	Host organization connects to clients and other stakeholder for better coordination and information sharing among the actors in AIS
Radio, TV, tele-centres	Programs recorded by extension organization, TV stations broadcast	PPP model, collaboration among public organizations.	Extension organizations, radio/TV stations or tele-centres, agricultural institutions, farmers	While extension organizations develop content of program, it is recorded by the radio/TV station or tele-centre crew. Agricultural institutions can act as information resource and farmers are the end users
Web portals, expert systems, Mobile apps, MOOCs	Hosted by extension organization, they provide information to farmers	Depending on stakeholders involved, it can be manned from PPP to profit oriented models.	Extension organization, web content developer/ app developer/course content developer, agricultural institutions (optional), and farmers	Development and management is a collaborative task, considering the involvement of many stakeholders. While the developers need to give constant upgrade, enhancements, maintenance and support, the RAS/ subject matter organization deals with content to be fed and expert service if needed to keep the information up-to-date. Farmers and others are end users.

Costs for Using ICTs for Agricultural Development

Cost of using/ developing ICTs ranges from free to a few million USD depending upon the infrastructure and scale of coverage. Capacity development activities also require considerable amount of money (Table 5).

CRITICAL ANALYSIS OF MAJOR ICTs

It is true that ICTs have transformed communication but in terms of its global reach, there are many more landmarks that need to be crossed. With increased access to the internet and increasing number

Table 5. Tentative costs of hosting different ICT based initiatives

ICTs	Items	Indicative Cost Involved
Social media	Internet with ICT device	ICT device cost (mobile phone/ or tablet or laptop or computer) and internet charges.
Radio, TV, tele-centres	ICT infrastructure, training for the facilitators, content creation	Depending on air time, the cost can vary from a few hundred to several thousand USDs. However, most of the state/ NGO owned TV, Radio stations can be used freely by the agricultural advisory institutions for extension and advisory services.
Web portals, expert systems, Mobile apps, MOOCs	Hiring a software specialist, training for maintenance, content collation, multimedia content, hosting etc	• Creating a basic website (USD 300 – USD 2,000), CMS integration (USD 2,000 -10,000), simple semantic portals (with 500 nodes of content USD 10,000 – 25,000) and multi-site semantic portals with multiple portlets (USD 25,000 – 60,000) and maintenance of web portals also requires considerable cost. • Expert systems may cost USD 1,000- 10,000 depending upon the design, software, and size of contents. • mApp development can be free of cost to USD 70,000 depending on its architecture and web interface

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of communication technologies with diversified working principle, a multifaceted situation is gaining traction which requires immediate attention to details for faster and wider acceptance. This specifically brings attention to the need for critically examining the advantages as well as the drawbacks of all these tools and build upon the information to make them an integral part of rural agricultural advisory systems worldwide. Table 6 deals on the same in details.

Problems

Implementers' Perspective

1. **Connectivity and Infrastructure:** Poor connectivity in rural areas, absence of electricity, transportation, markets and other infrastructural inadequacies restrict the implementers in using ICTs for development.
2. **Technical Workforce:** Technical human resource for ICT projects is very important for their smooth functioning. Functions like regular and timely updating of databases, developing location specific information, web integration and arrangement of links in case of web portals, transforming data/information in accessible formats for all type of users need technical workforce, which needs to be specifically trained in the tasks which is another challenge for the implementing agencies (Saravanan and Suchiradipta, 2015a).
3. **Sustainability of Funding:** ICT projects at the initial or pilot phase are more often than not funded by an external agency but after the pilot phase, in most of the cases, funding dries up and so do the projects. Financial sustainability is often addressed too late or never and so, irrespective of the influence of the projects on rural farming, communities have to wrap up, thus disappointing the beneficiaries and making them disinterested in such future attempts.
4. **Effective Participation of Communities:** Lack of proper planning, differences in project objectives and community needs, limited capacity building program of projects, lack of or limited interest of the community in projects due to their temporary nature, uninvolved communities as major stakeholders in projects, etc. (Saravanan, 2012) are some important factors that keep agricultural communities away from the ICT projects.
5. **Lack of Leadership:** To diffuse ICTs and implement them in a large scale in rural areas, effective leadership is needed at both institutional and community level. Opinion leaders in communities often lack interest in them and the younger generation does not have enough followers to effectively diffuse them in the communities, which makes a barrier in increased use of ICTs by rural communities.
6. **Farmers' Access to ICTs:** The rural smallholders often do not have access to any ICTs – personal or otherwise - which makes information delivery through those media or applications redundant.
7. **Institutional Barriers:** Lack of flexibility in content delivery, limited innovation, lack of institutional ownership, limited technical human resource, conflict of interest among project partners, limited research collaboration, red-tapism, and project tourism attitude, etc. (Saravanan, 2012) often take the focus away from the major objective of the projects – development of communities.

Table 6. Critical analysis of major ICTs

	Information and Communication Technologies (ICTs)														
	TV		Radio		Mobile Phones (Basic/ Feature)		Computer/ Laptop/ Smart phones								
							Without Internet			With Internet					
	TV Broadcasting	Video with DVD	Radio Broadcasting	Community Radio	Text	Voice	Expert Systems/ DSS/ IMCDs	Digital Video	Animation	Web Site/ Web Portal/ Knowledge Banks/Online Repositories	Tele/ Video Conference	Mobile Apps	e-Learning Platforms (MOOCs)	Social Media
Target groups	Farmers, agripreneur, input dealers, stakeholder in value chain, extensionist	Farmers, agripreneur, extensionist	Farmers, agripreneur, input dealers, stakeholder in value chain, extensionist	Women farmer, agripreneur, stakeholder in value chain, input dealer	Literate farmers, agripreneur, input dealer, stakeholder in marketing channel, extensionist	Farmers, agripreneur, input dealer, stakeholder in marketing channel, extensionist	Literate farmers, extensionist, agripreneur	Farmers, agripreneur, extensionist	Illiterate farmers, extensionist	Literate farmers, agripreneur, input dealer, stakeholder in marketing channel, extensionist, policy maker	Farmer, extensionist	Mostly literate farmers, entrepreneur, input dealer, stakeholder in marketing channel and value addition, extensionist	Extensionist, researcher, academician, farmer, agripreneur, policy maker	Literate farmers, agripreneur, input dealers, stakeholder in marketing channels, extensionist, research and academic institution, experts, policy maker
Major RAS functions	Awareness, advisory, technology transfer, mass advisory, promotional, documenting and sharing of ITK	Advisory, technology transfer, awareness, documenting and sharing ITK	Awareness, advisory, technology transfer, mass advisory, promotional	Awareness, advisory, technology transfer, knowledge sharing, mass advisory, feedback	Awareness, advisory, market information and linking, credit and banking access, mass advisory, promotional, linking with AIS actors	Advisory, market and information linking, mass advisory, feedback, awareness, promotional, linking with AIS actors	Advisory, knowledge sharing, technology transfer, mass advisory	Knowledge sharing, documenting and sharing ITKs, technology transfer, training, knowledge sharing	Advisory, technology transfer, awareness	Advisory, documenting and sharing ITKs, market information and linking, input linking, M&E, enumeration, survey, linking with AIS actors, feedback	Training, advisory, linking with AIS actors, feedback	Awareness, advisory, knowledge sharing, market information and linking, credit and banking access, input linking, feedback, promotional, technology transfer, M&E	Training, education	Awareness, promotional, advisory, knowledge sharing, documenting and sharing ITKs, technology transfer, market information and linking, mass advisory, linking with AIS actors, feedback
Advantage	-Suitable for all stakeholders -Good medium for demonstrations	-Easy way of demonstration -Portability -Popularity in rural community	-Portability -Low cost -Popularity in rural community	-Tool of social learning -Increased women participation	-Low cost -Location and farmer specificity -Timely information	-Low cost -Portability -Easy feedback -Accessible for illiterates -Increased access to public information	-Easy access to expert advice -Location and farmer specific solution -Instant solutions	-Suitable for demonstrations -Low cost -High popularity -Increased women participation	-Suitable for awareness creation -Innovative and interesting	-Integrated information -Location specificity -Interactive -Open access	-Expert advice -Good scope for training	-Interactive -Updated information -Customization of information based on personal needs	-Integrated information -Location specificity -Interactive -Open access	-Interactivity -User generated content -Easy access in multiple devices -Increases dialogue among development practitioners
Limitation	-One way communication -Location specificity -Relevancy of personal context -Popularity	-Availability of playing device with farmers - Relevancy of personal context	-Location specificity -	-Lack of skill -Lack of funding	-Illiteracy -Network coverage - Relevancy of personal context -Popularity in agricultural use	-Network coverage -Relevancy of personal context - Popularity in agricultural use	-Illiteracy -Access to kiosks -Popularity among rural community -Updated database	-Access to player -Very specific type of information -Relevancy in personal context	-Limited scope -Less popular	-Illiteracy -Needs technical expertise -Possibly outdated content -Limited customization for individuals -Limited access by women farmers	-Limited access Limited scope -Unavailability of infrastructure in rural areas -Rarely used	-Illiteracy -Accessible only in smart phones -Information not personalized	-Illiteracy -Needs technical expertise -Possibly outdated content -Limited customization for individuals -Limited access by women farmers	-Illiteracy -Limited access -Costly data charges -Redundancy of information -Unauthenticated information

(Source: Saravanan et al., 2015a; Saravanan et al, 2015 b; Saravanan et al., 2015c; Saravanan and Suchiradipta, 2015c)

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

End Users' Perspective

1. **Illiteracy:** ICTs, for example mobile phones, social media, web portals, online knowledge repositories, etc. require functional literacy at the least but even that is absent in many rural areas of developing and least developed countries. Furthermore, education illiteracy which is technical illiteracy remains another constraint. And in such cases, the illiterate farmers have very few options in accessing information and so reach is limited.
2. **Infrastructure:** Basic infrastructures in rural areas still have a long way to go. While in some areas telecommunication structures are poor or absent, in many parts of the world, electricity is yet to reach. Added to that is the absence of other infrastructures likes markets, credit facilities, transportation and so on, that limits or discourages the use of ICTs by the rural communities.
3. **Cost of Technology:** Affordability of technology is also a hindrance in its use to many smallholders. While devices like kiosks, computers, video players, etc. can be accessed from telecentres, mobile phones and other such personal devices are often out of reach for many farmers in developing countries. Also, the cost of data and other charges become expensive for many to afford (Suchiradipta, 2012).
4. **Information Explosion:** While a large amount of information is available in the public domain to access by anyone, this information can be confusing to many users. While filtering of important information is done by extensionists to suit the needs of the individual farmer, the farmers may not always be as competent in filtering those which may be more confusing than helpful.
5. **Lack of Awareness and Promotion:** Since ICTs are new introductions in extension services in many rural areas, proper awareness is needed in making the rural communities interested in using them. Also, because of lack of promotion, they often do not participate in the initiatives as active stakeholders.

Evidence of Impact and Potential Scalability of ICTs for Agricultural Development

Impacts of development efforts are generally multifaceted and their impact on social and personal lives of the benefactors is both direct and indirect, making them harder to point out clearly. With a two-sided argument existing around ICTs, mapping out the impact indicators can go a long way in evaluating the impact of the ICT based efforts and clearly state the achievements and limitations. They can also help with the potential scalability of ICT projects across the world, where crossing the hurdle of pilot stage is still a big concern. Table 7 discusses the same in details:

Issues of Sustainability in Using ICTs for Agricultural Development

Major factors that determine the sustainability of ICT use are the ICT tools used, the domain of the service providers (public or private) and the cost incurred in providing the services. Generally, advisory through TV, Radio and community radio, social media are free of cost services. Mobile, web, interactive multimedia CDs, Videos etc. are fee based value added services or free of cost depending upon the host institutions. Governments/ public sector service providers mostly provide free of cost services (Farmers call centres, Front line SMS etc). Private sector actors are generally implementing financially sustain-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Impact indicators and potential scalability of ICT based projects in agriculture

ICTs	Impact Indicators	Potential Scalability
Social media	Large number of YouTube channels hosted by farmers, popularity of the Twitter handle of AgChat, highly active social media pages in extension like GFRAS, AESA and farmers' pages like Mkulima Young provide the evidence of impact. Participation of the members in the continuous engagement and discussions, creation and sharing of contents, increase in the membership subscription and feedback of members can serve as impact indicators for social media.	Facilitation of social media platforms is key for achieving the growth of audience and scalability is continuous with the increase of members' enrolment which requires high level of participation and engagement of stakeholders
Radio, TV, Tele-centres	Significant knowledge enhancement through radio programs has been noticed among farmers is exposed to radio programs[5]. Before-after comparison of knowledge is an important impact indicator of broadcast services indicator.	Increasing number of programs in the prime time can give the agricultural programs larger audience and increased popularity
Web portals/ web sites/ MOOCs	e-Chaupal initiative in India for market price dissemination increased the price of soybean by 1.7 per cent and the result was instantaneous. It increased farmers' share in producers' money and reduced the cost incurred[7]. Access Agriculture, through videos hosted in the web portal, has changed the life of farmers across Asia and Africa, especially of women by taking information to them and organizing and empowering them[8].Time and cost saved, income increased, increased market participation, etc. after use of information provided through web portals, can act as impact indicators for web based information services.	Continuous monitoring and evaluation and based on the findings making necessary changes depending on clients' response is the best way to scale up web portals/expert systems and MOOCs
Mobile based advisory services	Higher market participation by farmers, reduced wastage, increased transaction, and declined search and transportation costs can serve as indicators of effectiveness of mExtension services. Information through mobile phones have strengthened local livelihoods, natural resources, increased awareness and networking opportunities, especially among women. Time saved, cost saved, income increased after use of information provided through mExtension services can act as impact indicators	Financial sustainability of mobile based services is the major issue in their scaling up and profitable business model is a necessity. Also, development beyond thepilot phase is most important for long term sustainability.

able and profitable models (e-Choupal in India, iCow and Kilimo Salama in Kenya, FCC in Uganda, and IKSL in India etc). However, for the profit oriented services, end users' perception of usefulness of information is the ultimate determinant of the success of the business model.

Sustainability of ICT projects beyond pilot phase has been a major drawback in their long term existence and there is more than one factor that influences their sustainability. The business model is very important factor since finances are the major cause of their cessation beyond the pilot stage. Also, profit oriented or financially sustainable services are more user demand oriented as subscription is important for incoming cash flow and with satisfactory service, users are found to be willing to pay for the services as in case of e-Choupal and IKSL in India, iCow and Kilimo Salama in Kenya, FCC in Uganda among many others. The funding agency also decides the business model to some extent, for example, as with government funding, cost-free services are more common whereas with public or private funding, profit motive is also a major factor along with development. The cost of providing the services impacts the business model to some extent.

Another factor that impacts sustainability of ICT projects are demand based information delivery. Agriculture being location specific, crop specific and time specific, blanket recommendations are helpful to none. Customized demand based information and advisory in ICTs are not choices but a necessity for long term sustainability.

Also, with changing dynamics of agriculture and time, farmers are focusing more on commercialization and so are demanding to be highly engaged to advisory service providers as important and active

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

stakeholders of the system rather than mere beneficiaries of top-down development approach. Applications like social media, mApps, mobile and web based advisory services enable high user engagement and help them to customize the information they retrieve, thus making it personalized and applicable. This is an important feature in sustainability of ICT projects for long term.

CONCLUSION AND RECOMMENDATIONS

With increased technological advancement and its increased use in rural areas, farming communities are to gain a lot from the use of ICTs in information access related to their life and livelihood. Information is more important in agriculture and ICTs have the potential to be an aid in taking the much needed information to the farming communities. Inspite of the potentials, problems are many as discussed earlier and to overcome those, some steps become necessary, as discussed below:

1. **Implementation from Where Users Are:** Information provided to smallholders, irrespective of the means of delivery, needs to be location specific and timely. For any ICT based application, that is an opportunity as well as a challenge as the easier means of communication requires it to be updated regularly. And since access is easier compared to other traditional means, to gain and retain the users' faith in the service, the information needs to be location specific, and if possible, personalized.
2. **Youth Involvement:** The youth are the first to adopt any technological innovation in a social system and their involvement in planning and implementation is very important for overall success of the projects (Suchiradipta and Saravanan, 2013). Moreover, they can be leaders in community and family in diffusion of technologies for agricultural information.
3. **Institutionalization of ICTs:** To make ICTs an integral part of extension, the concerned institutes need to make their use an integral part of the work environment and the employees need to be encouraged about their use. Institutions also need ICT policies to encourage their use along with setting standards and boundaries that define the use of ICTs like social media focusing on the objectives and mandates of the institutions.
4. **Providing Basic Infrastructures:** Use of ICTs can only help the rural communities so far without any basic infrastructures like transportation, markets, credit facilities, etc. to translate the information acquired into practical action. Providing these basic facilities in rural areas is as important as the information, maybe more and so, in collaboration with competent authorities, development of infrastructure also needs to be prioritized.
5. **Appropriate Partnerships:** Appropriate partnerships are very important in the implementation of ICT projects for ensuring a smooth flow of resources (especially the funds to purchase and maintain ICTs), participation of local communities and institutions, regular updating of recent information in timely manner, effective management of stakeholders, and avoiding conflict for smooth functioning.
6. **Partnership with Local Institutions:** ICT applications are best applicable to smallholders when specific to their situations and to develop data and information that is timely and location specific, forging partnership with local research stations, universities, and other local institutions is desirable. Moreover, this makes getting up-to-date data easier and link-ups fruitful (Saravanan and Suchiradipta, 2015a).

Chapter 23
Exploring Alternative Distribution Channels of Agricultural Products

Kallirroi Nikolaou
Aristotle University of Thessaloniki, Greece

Efthimia Tsakiridou
Aristotle University of Thessaloniki, Greece

Foivos Anastasiadis
Aristotle University of Thessaloniki, Greece

Konstadinos Mattas
Aristotle University of Thessaloniki, Greece

ABSTRACT

Fresh fruits and vegetables constitute the basis of many people's daily nutrition habits and different distribution systems have been developed to cover daily supply needs. Important components of alternative distribution channels among others are high quality, high standards and consumer-producer trust. Although numerous studies have been conducted on alternative types of distribution channels, there is a lack of research on consumer behaviour towards these ways of distribution. The aim of this article is to identify consumer attitudes and preferences towards alternative agricultural distribution channels regarding fresh fruits and vegetables. In addition, this article contributes to the understanding of consumer behaviour, by pointing out the factors that affect the final purchase of agricultural products.

INTRODUCTION

Globalization and recent economic trends have created highly complex supply chains and as a result their design, organization, interactions, competencies, capabilities and management have become key issues (Ashby et al., 2012). A close study of past research has shown only some traces of a structured approach to supply chains including their weak aspects and the risks involved (Svensson, 2000, Sheffi, 2001,

DOI: 10.4018/978-1-5225-9621-9.ch023

Zsidisin et al., 2000, Guertler and Spinler, 2015, Dekker et al., 2013, Cantor et al., 2014, Heckmann et al., 2015). In order to have an integrated supply chain, a totally new approach needs to be implemented, whose development involves other related disciplines, such as market research and operational strategic management, incorporating empirical research theories and methodologies (Cheng and Grimm, 2006, Wisner, 2003). The aim of any commercial operation, including the agrifood sector, is obviously competitive advantage, which can be created by synchronizing supply chain strategy with competitive policy (Porter, 1985). This can be accomplished by establishing a wide spectrum of alternative and opportunity networks, such as distribution channels, that form a coordinated, integrated whole (Achrol, 1997, Tsang, 2000).

Important components of alternative distribution channels among others, are high quality, high standards and consumer-producer trust (Whatmore, 2003). A customer-centered approach (Spiller, 2008) and a short distribution channel direct product provision from producer to consumer, are fundamental to optimal distribution. It was found that short supply chains incorporate farmers' markets, street stalls and street markets, direct farm sales and more recently the Internet. A key priority of agriculture and rural development is to strengthen both the means of distribution and the processes and functions of the short supply chain (Burt and Wolfley, 2009, Mauleón, 2003, Falguera et al., 2012). A competitive perishable food industry, can not only provide healthy and safe food to consumers but also may constitute a factor in stabilizing the economy by generating jobs, for instance, even during the global economic crisis (Mattas and Tsakiridou (2010).

Although numerous studies have been conducted on alternative types of distribution channels, there is no specific research in the field on consumer behaviour towards the use of alternative distribution channels of agricultural product in Greece.

LITERATURE REVIEW

To begin with, the salient characteristics of innovativeness which reinvigorate supply chain management have appeared in conceptual and empirical studies (Chapman et al., 2003, Roy et al., 2004, Soosay et al., 2008, Panayides and Venus Lun, 2009), while Yu et al., (2014) stress that integrated green supply chain management has a positive result on operational performance. In their explanation on the historic evolution of Decision Theory in management, French et al.(2009) state that for an up-to-date, successful decision-making process, the characteristic of sustainability is needed.

There are many researches that focus on the estimation that there is a lack of structured approach regarding supply chains that also include the weak aspects and the risks involved (Sheffi, 2001, Svensson, 2000, Guertler and Spinler, 2015, Dekker et al., 2013, Cantor et al., 2014, Heckmann et al., 2015). Ashby et al (2012) find that the design, organization, interactions, competencies, capabilities and management of complex supply chains have become key issues. Xue et al., (2014) investigate that alternative channel structures are affected by supply chain, and consumer behavior is affected by alternative channel structures. A key priority of agriculture and rural development is to strengthen both the means of distribution and the various processes and functions of the short supply chain (Burt and Wolfley, 2009, Mauleón, 2003, Falguera et al., 2012). Mattas and Tsakiridou (2010) focus on a competitive perishable food industry during the global economic crisis, besides providing healthy and safe food for consumers, may become a factor of stabilizing the economy. Generally, there is growing interest in alternative food systems within the context of environmental and social sustainability (Cleveland et al., 2014).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

As concerns the Local food networks focus on sustainable food production, distribution and consumption through collaboration to establish local, self-reliant economies (Katchova and Woods, 2013). As concerns the Fair trade, is associated with people's rights to an acceptable standard of living, quality of life, equal participation opportunities, and ecological sustainability (Micheletti and Stolle, 2012).

By adopting green marketing, firms can emphasize their social responsibility and promote their businesses as friends of the environment (Almossawi, 2014). The promotion of green purchasing behaviour to young people is a growing tendency (Almossawi, 2014). Furthermore, consumer perception, organic product characteristics, such as product labelling, product innovations and the range of products on the market, is increasing (Schleenbecker and Hamm, 2013).

The new construct of Consumer Sustainability Consciousness enables an understanding of sustainable consumption products and consumer behaviours through an integrated Triple Bottom Line (TBL) perspective (Carvalho. et al., 2015). There are specific models of personalities of on-line consumes based on emotions, attitudes and perception that affect purchasing behaviour (Schröder et al., 2015). Consumer purchasing behaviour of minimally processed fresh fruit and vegetables has implications for marketing strategies (Stancu et al., 2016). Rödiger and Hamm, (2015) find that price affects consumer behaviour in their willingness-to-pay for organic food has mixed and contradictory results. The use of EU quality labels on food products is slowly but steadily affecting consumer purchasing decisions (Grunert and Aachmann, 2016). Suprem et al, 2013, find that the application of technology systems is an emerging area and plays an important role in the agrifood sector.

As results based on previous researches about the characteristics and criteria of alternative agricultural distribution channels, it becomes obvious that there is a great interest for further studies regarding the attitude and behaviour of consumers towards these alternative channels of distribution. The objective of this research is to investigate consumer attitudes and preferences towards alternative distribution channels regarding agricultural products and especially, fresh fruits and vegetables. Thus this study contributes to the understanding consumer behaviour, highlighting the factors that affect the final purchase of agricultural products. This objective includes the main research on how willing consumers are to trust alternative ways of distribution.

The research hypothesis constitutes a possible answer to a research question and it is determined after a review of a relevant literature, which leads the researcher to expect a specific relationship between variables (Syed, 2009). Based on the research objective, the following hypotheses are defined and examined:

H1: There is a relationship between the use of alternative distribution channels for purchasing agrifood products and consumer's socio-economic characteristics or consumer behaviour is affected by alternative channel structures (reveals from 2 and 3 section of questionnaire).

H2: A key priority of agriculture and rural development is to strengthen both the means of distribution and the various processes and functions of the alternative distribution channels (reveals from 2 and 3 section of questionnaire).

H3: There is growing interest in alternative food systems within the context of environmental and social sustainability (reveals from the first section of questionnaire).

H4: The new construct of Consumer Sustainability Consciousness enables an understanding of sustainable consumption products and consumer behaviors through an integrated Triple Bottom Line (TBL) perspective (take into account the sustainability issue, the Social- environmental-economic perspective and reveals from 2 and 3 section of questionnaire).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

H5: Consumer purchasing behaviour is influenced by inter-personal suggestion (reveals from the first section of questionnaire).

H6: The application of technology systems is an emerging area and plays an important role in the agri-food sector (reveals from the first section of questionnaire).

H7: Consumer purchasing behaviour of minimally processed fresh fruit and vegetables has implications for marketing strategies (this reveals from the results from all the research and it is affairs of the study contribution).

METHODOLOGY

The research took place in Thessaloniki during January to March 2016 using a random sampling approach and collecting 420 valid questionnaires. Descriptive statistics, cross-tabulation and Qualitative-Research (Q-R) hybrid methodology were applied in order to measure consumer behaviour towards alternative distribution channels of agricultural products.

The present study illustrates that consumers are interested in alternative distribution channels and the supply of fresh fruits and vegetables. The results of the survey may offer constructive conclusions for policy makers, entrepreneurs, consumers and the academic sector. In particular, the present study concluded, that consumers trust alternative distribution channels for purchases of fresh fruit and vegetables, since they believe that these channels increase employability. The study concludes that there is space for further development and promotion of alternative distribution channels in the agricultural and food sector.

In accordance with relative literature in the same cases due to investigate consumer behaviour use this methodology model (Kim and Lee, 2015). Especially, Q methodology has been applied to explore subjective perspectives in many research cases (Zanoli et al., 2015, Chapman et al., 2015, Kraak et al., 2014). For the analysis through SPSS tool, we could use frequency, cross-tabulation and concerning the core of Q–R hybrid methodology, Multivariate Analysis of Variance (MANOVA) (Chen et al., 2015). Especially, Q methodology includes a qualitative research and R methodology based on empirical approach, although this study will design a Q tool as a Q–R method that forms a link between qualitative and quantitative research.

More specific, the aim of this study is to discover and interpret a systematic classification of customer types based on the subjectivity of Q theory in a qualitative approach. Following, the theoretical and conceptual interpretations are verified and generalized in sequence by combining the Q and R empirical methods. The results of this research can be applied in the investigation on consumer behavior towards alternative distribution channels of agricultural products (Kim and Lee, 2015). With this method we could explore local resident's experiences and perceptions, could examine 42 statements concerning attitudes towards alternative distribution channels of agricultural product and mainly fresh fruits and vegetables.

The Q method is a qualitative research approach based on process theory that examines human (consumers') behavioral and motivational traits in the field of market research. It is a model based on subjectivity research that investigates human characteristics, such as feelings and emotions, preferences and choices, tastes and ideals. The individual 'subjective' experience each consumer has with the real- world functions within an "internal frame of reference", forming the 'schemata' that appears in questionnaires with words and phrases such as 'me', 'to me' 'in my opinion', 'in my view', etc. (Kim and Lee, 2015).

Q method is a new scientific approach in consumer behavior research that enables the formulation of hypotheses by focusing on discovery rather than preconceived concepts (Kim et al., 1993, Kim and

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

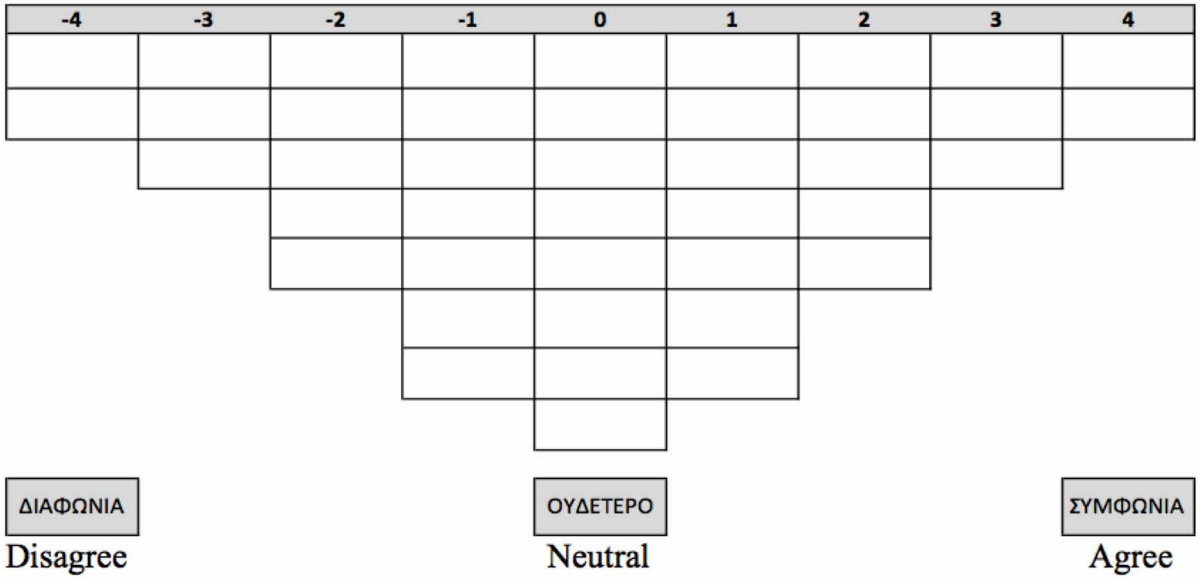
Lee, 2015). In comparison to the R method, which is a simpler type of quantitative study, the Q method is far more complex. Variables in Q concern a person, not items as in R. The R method requires a relatively large sample size so as to estimate the population characteristics, whereas Q sampling is a much more intricate process. It involves the careful attention of the researcher in order to obtain every case of subjectivity that is expressed. Q method, which involves the study of human beings, compares the intra-individual differences of one stimulus rather than inter-individual ones (Kim and Lee, 2015).

Q-Methodology

In order for methodology Q to be conducted, 42 statements based on recent bibliography were created, and they were printed in 42 numbered cards. Then, the participants were asked to read the statements in the cards and then divide them in 3 categories. In the first category, they put the statements they disagree with, in the second those statements which they had a neutral attitude towards and in the third category belonged the statements they agree with. Then, the participants were asked to categorize these 42 cards in the survey's questionnaire, as it is shown in picture 1. Initially, two statements that the participants disagreed with were listed in position -4 (absolutely disagree), then three statements were listed in column -3 (strongly disagree), five statements were listed in column -2 (disagree), and seven statements in column -1 (moderately disagree). The same charting of statements was conducted for the statements, which the participants agreed with or they felt neutral about (Figure 1).

In a few words, the participants were asked to list 42 statements in a questionnaire of 42 cells, where 17 statements were distributed in the 17 cells that expressed absolute disagreement till partial disagreement, 17 statements in the cells that expressed agreement, partially or absolutely, and eight statements in the column intended for neutral attitude, the process of filling out the questionnaire was approximately 60 minutes.

Figure 1. The Q deck of Q methodology in which participants were asked to fill in 42 statements in 42 cells



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In total, 80 questionnaires were filled out by consumers which know about alternative distribution channels and the fruit and vegetables that are being distributed through them. Every completed questionnaire of qualitative survey represents the subjective opinions of every participant regarding alternative distribution channels, agricultural fruit and vegetables, agricultural products, supply chains and the effect of capital controls on the raw fruit and vegetable market.

After the questionnaires had been filled out, the data were inserted in the PQMETHOD program, via which Factor analysis was conducted. Each factor represents the opinions of the participants. From the analysis above two factors have derived. In particular, in the first factor the statements which participants agreed with the most are presented in Table 1, while the statements which participants disagreed with the most are presented in Table 2.

Results

In Table 1, it is evident that social media, act as a means of advertising which affect consumer attitude towards fruit and vegetable. It is also evident that how much customers trust the producers is very important. Plus, capital controls affect which alternative distribution system of raw fruit and vegetable consumers are going to choose. Then, in factor number, the interest of consumers in the further development of alternative distribution channels is evident, while they believe that farmers should be educated on new technologies, which will enforce the alternative distribution channels of agricultural products.

From the statements that express disagreement, in factor 1, we can conclude that customer-centred approach in not an important factor in today's market, while environmental conscience is absent from the

Table 1. Factor 1 – Statements, which customers mostly agreed with

Statement	Rank
Social media affect the purchase of raw fruit and vegetable via alternative channels distribution.	+4
Trust towards raw fruit and vegetable producer is of crucial importance for choosing the alternative distribution channel	+4
Capital controls affect consumers' preference, when they choose alternative distribution channels.	+3
I am interested in up-dating and modernizing of alternative distribution systems	+3
I believe that farmers should receive proper training on new technologies, so that distribution channels will be enhanced and developed.	+3

Table 2. Factor 1 – Statements that participants mostly disagree with

Statement	Rank
Promoting a "green" purchasing behaviour of young people is a growing trend.	**-4**
There is a luck of structured approach regarding supply chains, which include their weaknesses and risks.	**-4**
Designing, organising, interactions, and possibilities as well as management of complicated supply chains have become important issues.	**-3**
In today's market customer centred approach is important.	**-3**
Alternative distribution channels are affected by the supply feature in the chain and consumer behaviour is affected by the alternative structures in the channel.	**-3**

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

purchasing behaviour of young consumers. Furthermore, one can observe that customers disagree with poorly structured supply chains, with the effect of supply chains on alternative distribution systems and on consumers' attitude. Lastly, it derives that the design, structure and perspectives, as well as management of complicated supply chains are not important issues to the participants.

In Tables 3 and 4 the statements of the second factor are presented (Factor2) which represent the strong agreement and strong disagreement of the participants. In particular, in Table 3 gender appears to affect very much the purchase of products, especially via internet, and it is also observed that customers become more and more familiar with the alternative distribution channels. Furthermore, the use of alternative distribution channels could possibly affect and change consumers' way of living, while suggestions from one person to another on a personal level seem to affect purchasing behaviour. Therefore it is believed that the use of technology systems will greatly affect the agricultural and food sector.

In Table 4, it is evident that statements which cause disagreement in Factor 1, are also included in Factor 2, in a different ranking position nonetheless. Results regarding "disagreement statements" enforce the consumers' beliefs regarding "green" purchasing attitude of young people, supply chains, and the necessity of adopting a customer oriented approach in today's market.

Eleven statements derived from this survey which cause either agreement or disagreement in both factors, and they are presented in Table 5. It is believed that these statements represent the positive (or negative) attitude of consumers towards the sectors of alternative distribution channels and agricultural products.

In particular, on a statistical level smaller than 0.01 (p-value<0.01), participants agree that the new models of alternative distribution channels contribute to the decrease of unemployment and poverty. Furthermore, social media, as a means of promoting fruit and vegetable, affect consumer purchase at-

Table 3. Factor 2 – Statements consumers strongly agree with

Statement	Rank
I believe that gender strongly affects online products purchase.	*+4*
My way of living has changed dramatically since I started buying products via alternative distribution channels.	*+4*
The use of Technological systems play an important role in agricultural and food sector.	*+3*
Purchasing behaviour is affected by suggestions on a personal level.	*+3*
The more I use an alternative distribution system, the more familiar I feel towards it.	*+3*

Table 4. Factor 2 – Statements participants mostly disagreed with

Statement	Rank
Promoting a "green" purchasing behaviour of young people is a growing trend.	-4
There is lack of structured approach regarding supply chains, which include their weaknesses and risks.	-4
In today's market customer centred approach is important.	-3
Designing, organising, interactions, and possibilities as well as management of complicated supply chains have become important issues.	-3
Alternative distribution channels are affected by the supply feature in the chain and consumer behaviour is affected by the alternative structures in the channel.	-3

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

titude. Therefore, tradesmen of fruit and vegetable can use social media to advertise their products, in order to affect and attract consumers.

Furthermore, it is evident that the use of alternative distribution channels makes the purchase of agricultural products easier in comparison to the conventional distribution methods. The above statement sets the prerequisites for promoting alternative distribution channels by entrepreneurs and policy makers, since the development of these channels will create new jobs and customers will be more pleased by the whole purchase experience. In order to promote alternative distribution channels, motives should be in order to attract farmers to get educated on new technologies, so that alternative channels will be promoted. Furthermore, the excellent designing and structure of the channels should be a priority, since these two elements set the base for their sustainability. Consequently, the people already involved in the channels and people who wish to get involved should examine the organizing and designing, so they will create the bases for the channels' sustainability.

Furthermore, farmers and traders of fruit and vegetables can provide solutions regarding the post-crop value of the products, since this is an important factor which affects customers even when they purchase in conventional markets. Lastly, it is important that there is the belief that globalization and complexity of the supply chains haven't affected alternative distribution channels, and this proves that they are powerful alternatives for fruit and vegetable as well as agricultural products distribution.

In Table 6, the statements which are differentiated regarding agreement and disagreement between the two factors are presented. These statements create the prerequisites for further inquiry, in order to answer why consumers have an opposing attitude towards alternative distribution systems of raw fruit and vegetable.

Table 5. Statement with unanimity in both factors

Unanimous Statements	F1	F2	p-value
New models of alternative distribution channels of agricultural products, contribute to the decrease of unemployment and poverty.	2	1	<0.01
Social media affect the purchase of raw fruit and vegetable via alternative channels distribution.	4	1	<0.01
Trust towards raw fruit and vegetable producer is of crucial importance for choosing the alternative distribution channel	4	1	<0.01
I believe that farmers should get educated on new technologies, so that alternative distribution channels are enhanced.	3	1	<0.01
Proper designing and structure of the channels should be a priority, since these two elements are the base for their sustainability.	1	2	<0.01
By using an alternative distribution channel, I realise that the purchasing process is easier in comparison to conventional channels.	1	2	<0.01
A key priority of agriculture and rural development is to reinforce the means of delivery and operating procedures of alternative distribution channels.	-2	-2	<0.01
The recent economic developments and globalization have created very complex supply chains.	-2	-2	<0.01
Alternative distribution channels are affected by the supply chain, and consumer behaviour is influenced by alternative channel structures.	-3	-3	<0.01
The designing, organization, interactions, the possibilities and the management of complex supply chains have become key issues.	-3	-3	<0.01
Although the nature of fresh fruits and vegetables are "sensitive" in the sense that they can easily be damaged and lose their nutrients, I prefer to purchase them from alternative distribution channels.	-1	-1	<0.05

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Distinctive statements between two factors

Distinctive factors	F1	F2	p-value
I believe that the encouragement and the trend for consumers to purchase products environmentally friendly encourage consumers to adopt "green" purchasing behaviour.	2	-2	<0.01
Connecting local food systems with educational programmes for children and adults and professionals, the purchasing behaviour of consumers and their mentality can change, creating a higher demand for local products.	1	-1	<0.01
Consumers' interest in organic products is increasing while offer is changing as well.	1	-2	<0.01
By adopting a "green" marketing policy businesses can be socially responsible and promote themselves as environmentally friendly.	1	-1	<0.01
Consumers' purchase behaviours is affected by interpersonal suggestions.	-1	3	<0.01
The price defines the behaviour of consumers towards buying organic products.	-1	1	<0.01
Consumers' purchase behaviour regarding fruit and vegetable consumption have consequences on marketing strategies.	-1	1	<0.01
I believe that apart from financial and commercial benefits, local distribution networks provide more social cohesion for the population.	1	-1	<0.01

In particular, it can be investigated why consumers of factor 1 agree that encouraging consumers to buy environmentally friendly agricultural products, encourages the spreading of "green" purchasing behaviour, while consumers of factor 2 disagree. Furthermore in factor 1 it is observed that educational programmes for children, adults and professionals that focus on local food distribution systems can affect consumers' behaviour towards local products.

Consumers of factor 2, seem to agree with the above situation, creating this way the prerequisites for their investigation, so that the necessary data will be found and policy makers and entrepreneurs can use them in order motivate consumers towards local products and the corresponding distribution channels.

In the organic product sector, consumers of factor 1 seem to agree with the statement that the increase in offer of differentiated organic products will positively affect customers' buying interest. This belief provides the necessary information which helps entrepreneurs and farmers of organic products to attract more customers and increase their income. However, consumers of factor 2 seem to disagree with this statement, creating this way the motive for further investigation of the causes and characteristics, so that the differentiated organic product market and their advertising is conducted via targeted criteria.

Conclusions

It derives from this study, that consumers are highly interested in alternative distribution channels and raw fruit and vegetable supply. This behaviour creates the necessary conditions so motives for the development of alternative distribution systems are created. The results of this study can contribute useful information to the policy makers, to entrepreneurs, consumers and academics. In particular, through this study is concluded that alternative distribution channels, which consumers trust for their fruit and vegetable and agricultural product purchase, contribute to the increase of employment and the reduction of poverty. Therefore, there is the need for developing and further promoting alternative distribution channels.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, due to capital controls, the massive development of the internet and its use by consumers, it is believed that creating incentives and educating farmers on new technologies can positively affect the purchase behaviour of consumers. Since new technologies are expected to play an important role in agricultural and food sector, the policies that will encourage farmers and everybody that is involved in distribution channels to get educated on these technologies and adapt them, are believed to encourage development and expansion of local economy, by promoting local products. However, for this purpose to be achieve, it is important that there is an excellent designing and organisation of the alternative distribution systems, so there is a solid foundation for their sustainability.

Furthermore, the use of social media in order to promote agricultural products and in particular raw fruit and vegetable is a method for attracting consumers and for increasing the purchase of raw fruit and vegetable. Therefore, the necessary foundations are created for further investigation of the consumers' characteristics, who are affected by the advertising of fruit and vegetables and the factors that positively affect purchasing behaviour, so that promoting fruit and vegetables can be enhanced. Consequently, it is important that the social space is created, where local products and distribution channels are advertised. This social space will be an opportunity for proper up-dating of customers regarding the above sectors, so that customers will trust them more and develop a trend towards them.

Lastly, after the end of this study the necessary foundation for further investigation of the factors, that customers disagree with, regarding alternative distribution channels, raw fruit and vegetable purchase and the use of technology, which will enhance their development.

RESULTS OF DESCRIPTIVE RESEARCH

Consumers' Profile

Out of the 420 consumers that participated in the survey in the region Thessaloniki, 49% were male and 51% male. 4.8% of the participants were 18 to 25 years old, 11% were 26-35 years old, 43.3% were 36-45, 23.8% were 46-55 years old, 8.3% were 55-56 and 8.8% were above 66 years old. As far as education is concerned 4.3% of the participants had a Masters or PhD degree. 51% have completed their undergraduate studies in Universities, 42.4% are Private College graduates and graduates from technological faculties, while are Lyceum (high school) graduates, Gymnasium graduates and are primary school graduates represent 2.4% of the total number of consumers. Furthermore 40.7% of the consumer sample is married while 57.6% is single. Lastly, the income of the 3.1% of consumers was less than 750€, 37.9% earns 751 to 1000€, 6.4% earns 1001- 1500€, 19.3% earns 1501-2000€, 16.7% earns 2001-2500€, while 13.3% earns 2501-3000€, 1% earns 3001- 3500€, and 2.4% earns more than 3501€ (Table 7).

Purchasing Behaviour

In Figure 2, the use of alternative distribution channels by consumers is presented. Particularly 15% of consumers buy their agricultural products directly from producers on a daily basis, 34.8% more than once a week, 26.4% once a week, 17.6 once a month and 6.2% never buy directly from producer. 43.3% of consumers buy their vegetables from the local grocery's store once a week, 12.4% more than once a

	401 – 600€	27	6.4
	601 – 800€	81	19.3
	801 – 1.000€	70	16.7
	1.001 – 1.500€	56	13.3
	1.501 – 2.000€	4	1.0
	> 2.001€	10	2.4

week, 1.2% on a daily basis, 38.3% every month and 4.8% never buy vegetables from these shops. 61.9% of consumers choose local specialized stores once a week, 23.8% more than once a week, 1.2 on a daily basis, 9% once a month and 4% never uses specialized stores. Furthermore 80.2% of consumers buy their agricultural products once a week at a supermarket, while 13.8% once a month and 6% never buy their products at a super market. Open-air flea markets are used by 55.2% of consumers on a weekly basis, 37.6% once a month. While 7.1% never buys agricultural products at an open-air market. E-commerce is used by 54.8% on a weekly basis. While 34.8% uses e-commerce every month and 10.5% never uses e-commerce. From the above data it is evident that the majority of consumers uses alternative distribution channels for the purchase of agricultural products.

In Figure 3 it is evident that 83.8% of consumers use e-commerce for the purchase of raw fruit and vegetables, 72.4% buy straight from the producer, and 32.4% prefer Fair trade products.

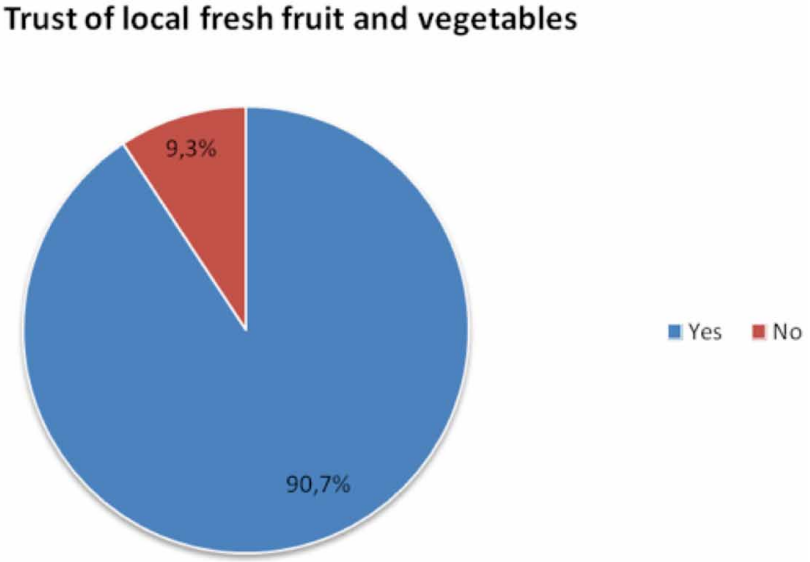

Figure 5. Consumers' opinion on the prices of products that are distributed via alternative distribution channels

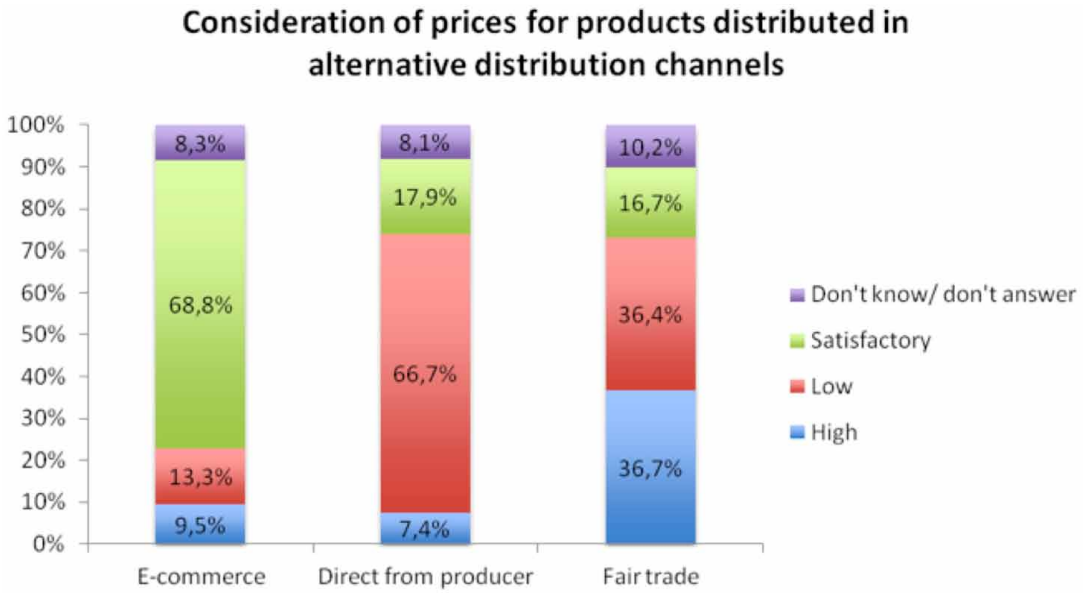

low and 17.9% that prices are satisfactory and 7.4% stated prices are high. As far as fair trade is concerned, 36.7% of consumers believe that the prices of agricultural products are high, 36.4% think they are low, and 16.7% believe that the prices of agricultural products are satisfactory.

Table 8 shows the statements on the purchasing behaviour of consumers towards alternative distribution channels. Specifically, 90.7% of consumers said that the use of alternative distribution channels

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 8. Statements regarding the purchasing behaviour of consumers towards alternative distribution channels

Statement 1: Easy access to food purchase
Statement 2: The price of raw fruit and vegetables are lower
Statement 3: Limited variety of raw fruit and vegetable
Statement 4: Customer service is direct
Statement 5: Customers can directly check the origin of raw fruit and vegetable
Statement 6: Fresh fruit and seasonal vegetables are available
Statement 7: Raw fruit and vegetables are available on a daily basis
Statement 8: A healthier diet is promoted
Statement 9: Participation in protecting the environment
Statement 10: The alternative distribution channels support sustainability and sustainable development
Statement 11: Alternative distribution channels appeared in Greece due to the economic crisis
Statement 12: Capital controls affect the choice of the alternative distribution channel

is distinguished for the easy process of purchasing products. 46.7% believe that the prices of fruit and vegetables are lower in alternative distribution channels. 23.1% of consumers say that alternative distribution channels offer a limited variety of fresh fruit and vegetables. Furthermore, 39.3% of consumers say that the service is direct and 39.5% believe that it is possible for them to check the origin of fresh fruit and vegetables. Moreover, 73.3% of consumers said that the alternative distribution channels provide fresh fruit and seasonal vegetables. 79.7% of consumers agree that fresh fruit and vegetables are available on a daily basis in alternative distribution channels and 79.8% of consumers believe that their nutrition is improved. 79.2% of consumers said that by purchasing via alternative distribution channels they participate in environmental protection and that these channels ensure sustainability and sustainable development (78.1%). 71.4% of consumers believe that alternative distribution channels appeared in Greece due to the economic crisis. Lastly, 74.3% of consumers agree that Capital controls affect the choice of the alternative distribution channel.

Figure 6 shows the factors why customers choose alternative distribution channels. Specifically, consumers said they choose alternative distribution channels because they believe that the products are safer (81.4%), healthier (78.8%), have high quality (77.9%) and high nutritional value (77.4%). In addition, 72.3% of these consumers stated that the products- in the alternative distribution channels of their choice- are suitable for the nutrition of their children and 74% said that they have better prices in comparison to conventional means of distribution of agricultural products. 55.5% of consumers agree that they choose alternative distribution channels because environmental consciousness plays an important role in their lives and 65.7% of consumers choose alternative distribution channels, because they meet their standards and values.

Fair Trade

In Figure 7, it is shown that 32% (n = 136) of the sample consumers use Fair trade. They products that they choose are cereal, chocolate and coffee.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Factors that affect consumers when the choosing an alternative distribution channel

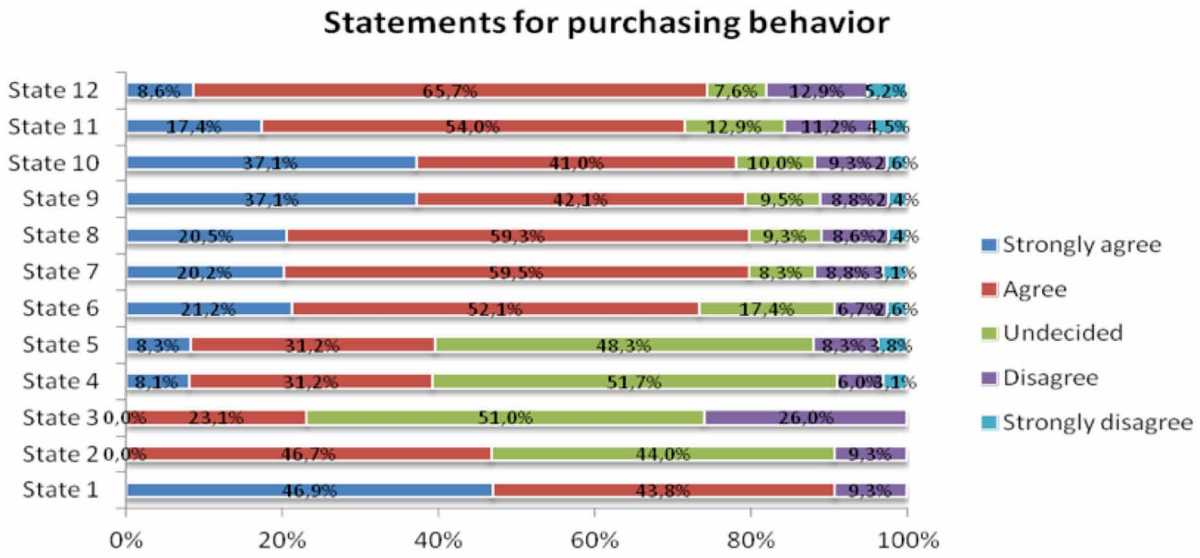

Figure 7. Distribution of consumers who choose Fair Trade

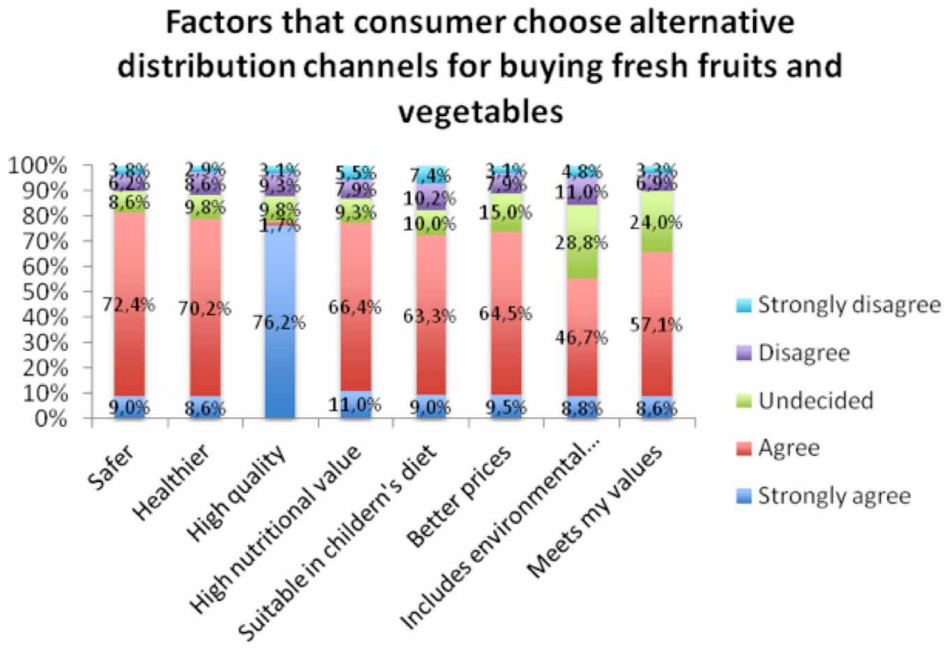
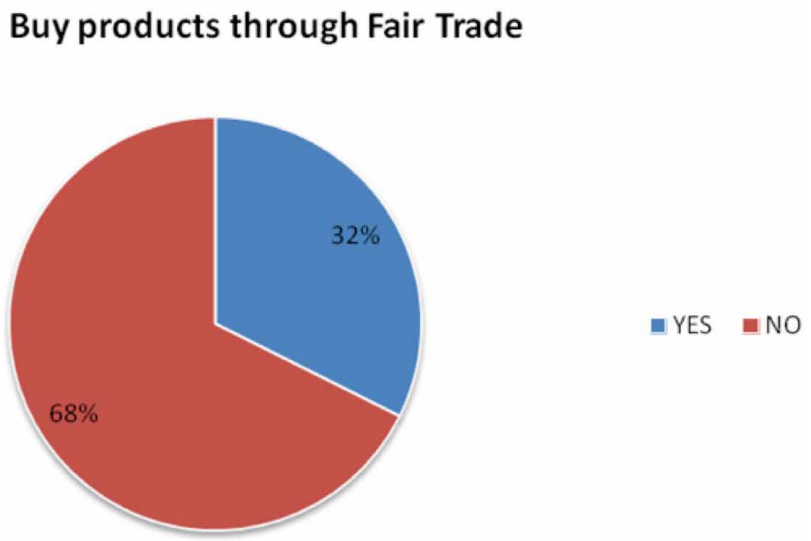


In Figure 8, the tendency of consumers towards Fair trade is presented. Consumers mainly buy cereal, chocolate and coffee.

The most important factors for choosing Fair trade products are social contribution and the improvement of the quality of life in the lands, where these products are produced.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Products that consumers buy through Fair Trade



Consumer Behaviour Towards Fresh Fruit and Vegetable

In Figure 9, the most important factors that affect consumers when buying fresh fruit and vegetables are presented. The most important factors are improvement of their health (89.3%), price, habit, quality (88.6%), land of origin (88.1%), appearance (88.6%), technology (88.1%) and authenticity (87.6%).

In Figure 10 we learn how people get informed about the alternative distribution channels. Particularly, consumers are affected mostly by commercials (50.2%), by social media (53.8%) TV (51.2%), family (49.8%) and friends (49.8%).

As we can see in Figure 11, last week, 9% of consumers spent less than 20€, 55% spend 21 to 40€, 31% spend 41 to 60€, while 4% spends 61 to 90€ and 1% more than 90€.

When consumers were asked to compare the amount of money they spent on fresh fruit and vegetables before and after the implementation of capital controls, 93% of consumers answered that they do not spend the same amount of money. Therefore, capital controls have affected consumer behaviour regarding the purchase of fruit and vegetables (Figure 12).

In Figure 13 we can see that the majority of consumers (85%) believes that the prices of fruit and vegetables, since the implementation of capital controls, are high. Only a mere 6% of the total number of consumers believes that prices are low and no one believes that they are the same and only 5% think prices are satisfactory.

In Figure 14, it is shown that 82.6% of consumers believe that bank controls have enhanced the internet as a fundamental channel for transactions by individual consumers.

In Figure 15, it is evident that there is an increase of transactions by credit card, before as well as after the implementation of capital controls. Particularly, before the implementation of capital controls in Greece, 35% of consumers paid by credit card 1-3 times a month and 45.7% 3-4 times a week, 13.3% less frequently than that, 6% never used a credit card and no one used credit cards for their transactions.

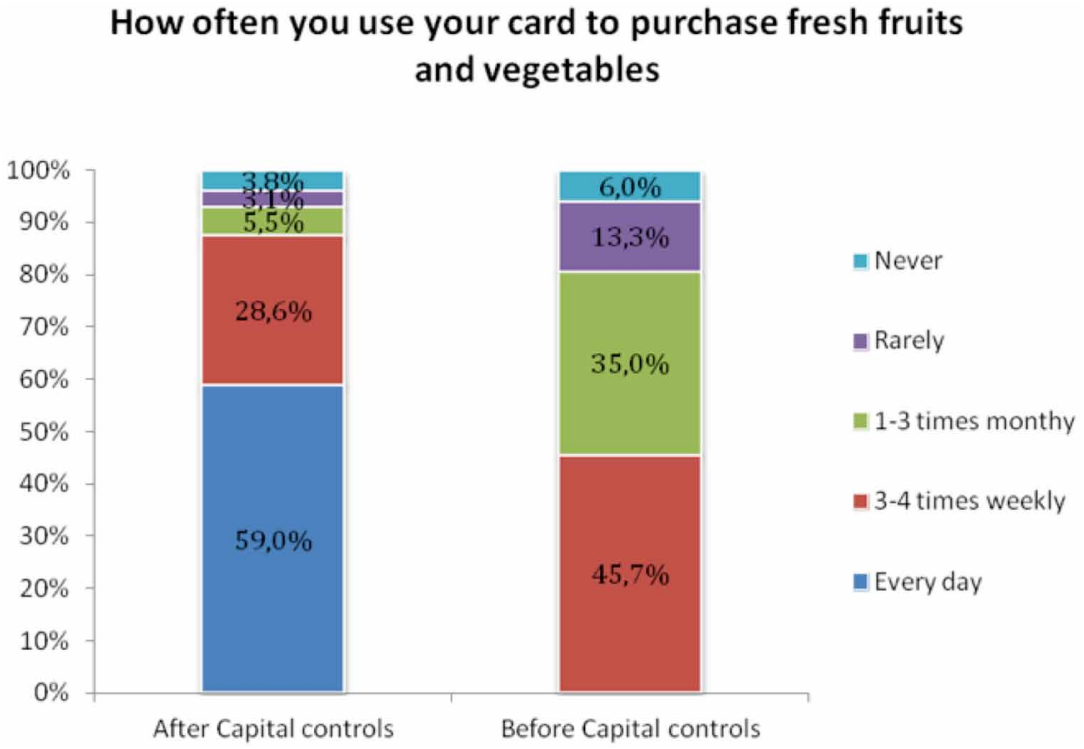
Figure 15. Use of credit cards for the purchase of fresh fruit and vegetables before and after the implementation of capital controls in Greece



After the implementation of capital controls, 59% of consumers use credit cards on a daily basis, 28.6% 1-3 times per week, and 5.5% 1-3 times a month, 3.1% uses credits cards less frequently and 3.8% never use a credit card for their transactions.

Quantitative Analysis Hypotheses Testing

For the Testing of quantitative analysis hypotheses, the methodology of one-way Manova and Q methodology were used. Paricularly, hypotheses 1,3,4 and 6 are tested via Manova Methodology, while hypotheses 2,5 and 7 are checked via Q methodology. So, in the present chapter the results of the quantitative testing (Manova) are presented.

For the investigation of the first case the variables "purchase of fresh fruit and vegetables direct from the producer," "purchase of fresh fruit and vegetables from e-commerce" and "use of alternative distribution channel: Fair Trade" were selected as dependent variables. In the part of the independent variables consumers' age and monthly family income were selected.

Hypothesis 1: There is a relationship between the use of alternative distribution channels for the purchase of agricultural and socio-economic characteristics of consumers.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 9 shows the results of Manova for the first case. In particular, the purchase of fresh fruit and vegetables through e-commerce is significantly associated with age, since F-value=2.561, p<0.05. So, the use of e-commerce for the purchase of fruit and vegetable differs among consumers of different age. The purchase of fresh fruit and vegetables through e-commerce is significantly associated with income, since F-value = 3.727, p < 0.01.

Moreover, the use of alternative channel: "Directly from the producer", on an one-variable level is correlated with monthly income (p<0.05), but there was no correlation with age. So, the use of the channel "directly from producer" for the purchase of fruit and vegetable differs regarding only monthly family income.

The use of fair trade for the purchase of agricultural products is related with consumers' age (F-value = 2.704, p < 0.020) and the monthly family income (F-value=4.332, p<0.01). So, consumers who use Fairtrade for the purchase of agricultural products differ significantly regarding income and age.

In order to assess the third case the selected dependent variables were "purchase of fresh fruit and vegetables from e-commerce", "purchase of fresh fruit and vegetables direct from the producer" and "use of alternative distribution channel: Fair Trade." The independent variable is the statement "Alternative channels of agricultural products ensure sustainability and sustainable growth and development" and the factor "The channels includes in the distribution a type of environmental consciousness" for the use of alternative distribution channels by consumers.

Hypothesis 3: There is growing interest in the use of alternative distribution channels regarding the environment, sustainability and sustainable development.

Table 10 shows the results of Manova methodology for the testing of the third hypothesis. It seems that the use of the fair-trade channel by consumers is correlated with the statement that: "Alternative distribution channels ensure sustainability and sustainable development. Moreover, sustainability and sustainable development it seems that affect consumers who buy directly from producers, since there is a correlation (F-value = 2.224) on a significance level of p=0.066.

Table 9. Results of Manova for the first hypothesis – correlation between the use of alternative distribution channels and socio-economic characteristics of consumers

Independent variables	Dependent Variables	Mean Square	F	Sig.
Age	Which alternative agricultural channel do you use - Fair trade	0.439	2.704	0.020
	Where do you buy fresh fruit and vegetables – Directly from Producer	1.286	1.079	0.371
	Where do you buy fresh fruit and vegetables – e-commerce	1.979	2.561	0.027
Monthly Family Income	Which alternative agricultural channel do you use - Fair trade	0.703	4.332	0.000
	Where do you buy fresh fruit and vegetables – Directly from Producer	5.181	4.347	0.000
	Where do you buy fresh fruit and vegetables – e-commerce	2.88	3.727	0.001
Age x Monthly Family Income	Which alternative agricultural channel do you use - Fair trade	0.398	2.451	0.001
	Where do you buy fresh fruit and vegetables – Directly from Producer	1.043	0.875	0.619
	Where do you buy fresh fruit and vegetables – e-commerce	0.838	1.085	0.363

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 10. Model Manova results for the third hypothesis - correlation between the use of alternative distribution channels and variables relating to the environment, sustainability and sustainable development

Independent variables	Dependent Variables	Mean Square	F	Sig.
Sustainability and sustainable development	Where do you buy fresh fruit and vegetables – Directly from Producer	2.629	2.224	0.066
	Where do you buy fresh fruit and vegetables – e-commerce	0.851	1.036	0.388
	Which alternative agricultural channel do you use - Fair trade	0.520	3.469	0.008
Environmental awareness	Where do you buy fresh fruit and vegetables – Directly from Producer	0.995	0.841	0.499
	Where do you buy fresh fruit and vegetables – e-commerce	0.948	1.154	0.331
	Which alternative agricultural channel do you use - Fair trade	0.303	2.021	0.091
Sustainability and sustainable development x Environmental awareness	Where do you buy fresh fruit and vegetables – Directly from Producer	1.943	1.644	0.071
	Where do you buy fresh fruit and vegetables – e-commerce	0.900	1.095	0.361
	Which alternative agricultural channel do you use - Fair trade	0.506	3.381	0.000

Regarding environmental consciousness, there is a correlation with the use of Fair trade channel on a significance level $p = 0.091$. Moreover, the use of fair trade and purchases directly from producers are correlated with the multivariable "Sustainability and sustainable development X environmental consciousness" on a significance level of $p = 0.00$ and $p = 0.071$ accordingly.

However, there was no correlation between "environmental consciousness and sustainable development" and the use of e-commerce by consumers for the purchase of fresh fruit and vegetables. This outcome highlights the need of informing consumers though the internet about the benefits of e-commerce, sustainability and sustainable development.

In order to test hypothesis 4, we investigated the relationship between the dependent variables of Triple bottom line (environment, economy, social responsibility) with the use of alternative distribution channels. Particularly in the economic field, the dependent variable is the statement "The price of fruit and vegetables is lower", for the environment the dependent variable is the factor in the choice of alternative distribution channels "During the distribution they include an environmental distribution" and regarding social responsibility the dependent co-variable is "use of alternative distribution channel: Fair Trade", as consumers use it primarily because it enhances the living standards in the area that produces the products. The independent variables are "purchase fresh fruit and vegetables via e-commerce" and "directly from the producer."

Hypothesis 4: Triple bottom line

Table 11 shows the results of the correlations of the Manova model on the fourth hypothesis. Particularly regarding the sector of economy, there seems to be a correlation between the consumers who purchase agricultural products straight from producers (F-value = 5.826, $p<0.01$) and via e-commerce (F-value = 40.188, $p < 0.01$). As far as environmental consciousness is concerned, there is a correlation with the purchase behaviours and tendencies of consumers who buy agricultural products through e-commerce (F-value = 6.303, $p < 0.05$) and directly from producer (F-value = 7.594, $p < 0.01$). Lastly, regarding

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 11. Results of Manova model for the fourth hypothesis - correlation between the use of alternative distribution channels and variables relating to the environment, economy and social responsibility (Triple bottom line)

Independent Variables	Dependent Variables	Mean Square	F	Sig.
Environmental awareness	Where do you buy fresh fruit and vegetables – Directly from Producer	8.971	7.594	0.006
	Where do you buy fresh fruit and vegetables – e-commerce	4.880	6.303	0.012
Prices of fresh fruit and vegetables are lower	Where do you buy fresh fruit and vegetables – Directly from Producer	6.882	5.826	0.003
	Where do you buy fresh fruit and vegetables – e-commerce	31.116	40.188	0.000
Purchase of Agricultural goods via Fair Trade	Where do you buy fresh fruit and vegetables – Directly from Producer	0.360	0.305	0.581
	Where do you buy fresh fruit and vegetables – e-commerce	13.730	17.734	0.000

social responsibility, as we can see in table 4.4, there is a correlation with the consumers who prefer e-commerce for their purchases (F-value = 17.734, $p < 0.01$). From the above data we conclude that economy, environmental consciousness and social responsibility (triple bottom line) plays an important role in the choice of alternative distribution channels by Consumers.

In order to test hypothesis 6, part of the dependent variables included "purchase of fresh fruit and vegetables directly from the producer," "purchase of fresh fruit and vegetables from e-commerce" and "use of alternative distribution channel: Fair Trade". Regarding the independent variables the selected variables were "important factor when buying fresh fruit and vegetables: "Technology" and "information regarding fresh fruit and vegetables through social networks".

Hypothesis 6: The application of technology systems is an emerging field and plays an important role in the food processing sector.

Table 12 reveals that the relationship between alternative distribution channels of agricultural products (agricultural sector) and Technology systems. Specifically, on an one-variable level, the use of

Table 12. Manova model results for the sixth hypothesis - correlation between the use of alternative distribution channels and variables regarding technology

Independent Variables	Dependent Variables	Mean Square	F	Sig.
Important factor when buying fresh fruit and vegetables: Technology	Where do you buy fresh fruit and vegetables – Directly from Producer	2.002	1.688	0.152
	Where do you buy fresh fruit and vegetables – e-commerce	4.692	5.479	0.000
	Which alternative agricultural channel do you use - Fair trade	1.284	12.74	0.000
Information source: Social networks	Where do you buy fresh fruit and vegetables – Directly from Producer	1.800	1.518	0.209
	Where do you buy fresh fruit and vegetables – e-commerce	0.660	0.771	0.511
	Which alternative agricultural channel do you use - Fair trade	0.406	4.027	0.008
Technology x Social networks	Where do you buy fresh fruit and vegetables – Directly from Producer	2.427	2.046	0.033
	Where do you buy fresh fruit and vegetables – e-commerce	2.083	2.432	0.011
	Which alternative agricultural channel do you use - Fair trade	0.437	4.342	0.000

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Fair Trade relates to the technology factor (F-value=5.479, p<0.01) but not with the social networks (p-value> 0.05. Therefore, technology in relation to sources of information correlates with the agricultural purchases through e-commerce. Similarly, regarding purchases directly from producer there is a statistically significant correlation with the technology factor and the information through social media.

The "Fair Trade" channel is correlated on one-variable and a multivariable level with the factor "information through social media".

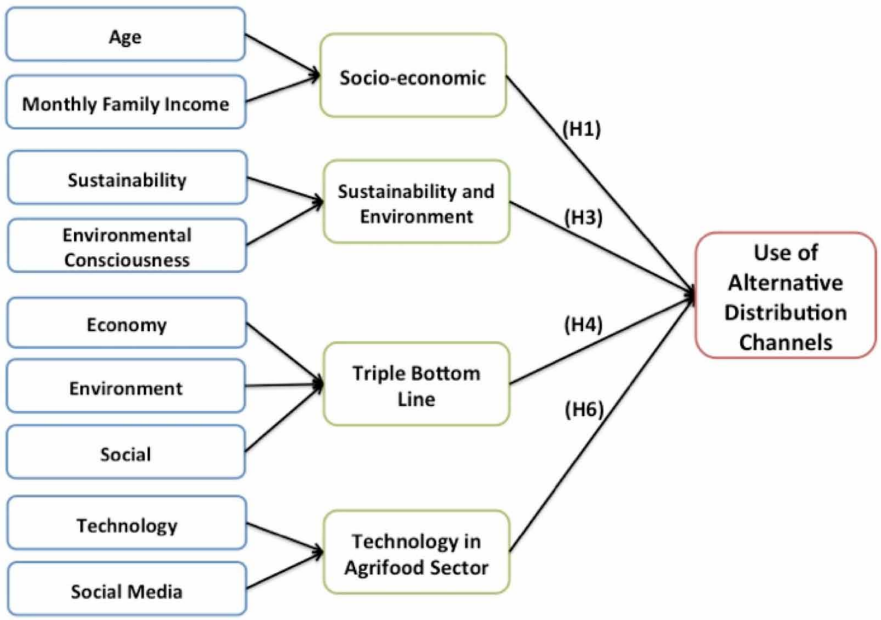
Summary

In the research, which was conducted in Greece, the hypotheses H1, H4 and H6 have been confirmed, while H3 was not confirmed, since the dependent variables are not correlated with the use of e-commerce for the purchases of fruit and vegetables. However, the variable "sustainability and sustainable development is correlated with the distribution channel: "directly from producer" and with the use of fair trade, while the variable "environmental consciousness" is correlated with the use of fair trade (Figure 16).

CONCLUSION

The present study illustrates that consumers are currently showing a considerable amount of interest in alternative distribution channels and the supply of fresh fruits and vegetables. This attitude, on the behalf of consumers, creates the necessary conditions, in order to provide the necessary incentives for the development and enhancing of alternative distribution channels. The results of the survey may offer constructive conclusions for policy makers, entrepreneurs, consumers and the academic sector. In par-

Figure 16. Hypothesis testing



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ticular, the present study concluded, that the fact that consumers trust alternative distribution channels that consumers for purchases of fresh fruit and vegetables, enhances the increase of employability and promotes the reduction of poverty. The need for the further development and promotion of alternative distribution channels, with the aim of creating new jobs, stimulating the local economy and local agricultural producers, has already emerged.

In addition -due to the imposition of controls on capital transactions, the development of the Internet and its use by consumers- it is estimated that the creation of incentives and further training for farmers on new technologies can provide a positive impact on consumer behaviour towards the purchase of agricultural products. Due to the fact that new technologies are expected to play an important role in the food processing sector, policies that will provide opportunities for training and will encourage farmers and others in the agri-food sector to adopt these policies, are expected play an important role in the development local economy, through the promotion of local products. However, a functional design and organization of alternative distribution channels is more than necessary, in order to create the basis of their sustainability. The spreading of this idea from mouth to mouth is a crucial factor, since consumers are affected by family or friends for the use of alternative distribution channels. Therefore, the implementation of the right policies, by those involved is going to have a positive effect on the use of alternative channels distribution.

Furthermore, the use of social networks as a means for the promotion of agricultural products and certain fresh fruit and vegetables, is a method to attract consumers and increase fresh fruit and vegetables market. Thus, the necessary basis for further investigation of the characteristics of consumers (who use and are affected by the promotion of fresh fruit and vegetables) and the factors (that positively influence consumer behaviour) should be created, so their effective use and the targeted promotion of agricultural products can be achieved. Subsequently, it is important to create a social space, where local agricultural products and distribution channels can be advertised and promoted. In such places, consumers will have the opportunity to get informed about the above sectors, so they can trust these alternative channels even more and use them more frequently.

The implementation of policies that will connect supply chains with the alternative distribution channels, in order to reduce operating costs and increase revenue, will play an important role. Consumers' opinion that this is not a priority for agriculture, creates the conditions to expand the use of supply chains in alternative distribution channels by farmers. This expansion will benefit consumers because prices will be reduced. It will also benefit producers because their revenues will be increased and the state will also be positively affected by the increase of tax income.

Therefore, from the above data, it becomes clear that the implementation of policies that will enhance the use of new technology (Technology), promotion of alternative distribution channels (Marketing) and training of professionals involved with the alternative distribution channels (Training) will enhance the development of local products and the local economy. We should also take into account the socioeconomic characteristics of consumers. The education level, gender, family income and employment are the main factors why the use of new technology, promotion and the training of professionals will enhance the expansion of alternative distribution channels and the local economy.

The policies for promoting new technologies, marketing and training of those involved in alternative distribution channels, while taking into account the socioeconomic characteristics of consumers. The objective of these guidelines- if the socioeconomic characteristics of consumers are taken into account- is: the increase of sales of local products and the development of the local economy. Similarly,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

entrepreneurs and agricultural producers who distribute their products through alternative distribution channels, are expected to benefit from increased sales and revenues.

Finally, the data of this research will enhance further investigation, by the academic sector, regarding the policies which are mentioned above. Providing incentives for the use of distribution channels, implementing new technological tools and training of farmers will play an important role in the development of the local economy.

Chapter 24
Mobile Networks and Indian Agricultural Sector

Lokesh Jain
UIET, Panjab University, India

Harish Kumar
UIET, Panjab University, India

ABSTRACT

Information dissemination in agricultural sector for its growth using information and communication technology (ICT) as a tool is need of the hour. This can be achieved using information systems. ICT benefits are helpful in exchange and dissemination of information among farming stakeholders. By using the latest tool of mobile technology, farmers can get the current information related to their farming jobs around the clock and at any location, as the mobile network have touched every part/location of the India. Using the features of the mobile-phones like GPS etc. one can get the localized information. Only need is to structure the abundant information available across the various organizations. So, a mobile based agricultural information system framework 'mAgIDS' has been proposed employing the hybrid mobile application architecture approach. Client-server architecture using the location Application Programming Interface (API) has been proposed. Inference mechanism of the system has implemented on the basis of improved fuzzy rule promotion technique.

INTRODUCTION

Agriculture and its related functions are indisputably the largest source of livelihood to large number of Indian rural population. Agriculture sector accounts for approximately 14% of India's Gross Domestic Product (GDP) and 11% of its export. 68.8% of Indian population lives in rural areas. Income of 31.55% of this rural population depends upon agriculture and its related activities. Also, agricultural produce is a source of raw material for a large number of industries. Average rate of agricultural growth in India was 2.38% during 10th five year plan (2002-07) that rose to 3.6% per annum during 11th five year plan (2007-12). In 2012-13, the first revised estimate of agricultural growth has been declared at 1.42% per annum. In advance estimates for India-Macro Economic survey for 2013-14 (Annonymous, 2014), 4.64%

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

of agricultural growth has been expected to be contributed in Indian GDP. It is important to increase growth of agriculture production (Government of India, 2013) using technology to achieve targeted 8% GDP contribution during 12th five year plan (2012-17) and to meet escalating demands for food due to high population growth, increase in per capita income *etc*. To improve the quality and quantity of agricultural produce, a tremendous amount of efforts are being put by various organizations like Indian Council of Agricultural Research (ICAR), Central and State Agricultural Universities (SAUs) and their Regional Research Stations (RRSs), Krishi Vigyan Kendras (KVKs) along with other public and private organizations. It is very important for these organizations to disseminate appropriate, precise and latest information to farmers for timely action to improve the agricultural output. There is a greater need to lay emphasis on the dissemination of scientific information from laboratory and test fields to its actual stakeholders using latest technological tools. These institutions work dedicatedly for the welfare of agricultural community but their initiatives have been usually criticized for their limited coverage, sustainability and its effect on agricultural community. Therefore, it is required that agricultural inputs should be timely disseminated to its appropriate quarters using latest information technological tools provided relevant quarters are ready to adopt these tools required for information transfer. Improvement of agricultural and rural development is being focused through emerging field of E-Agriculture using improved information and communication processes. Print and electronic media such as news-papers, pamphlets, libraries, televisions and information centers (like Kissan Call Centers *etc.*) are playing very important role in providing information to the farmers. These information centers are basically providing information to farmers using the available resources to them. Improved data management for better decision-making can be achieved by the utilization of information with appropriate information and communication technology (ICT). Enhanced focus on research planning, monitoring and evaluation lead to better research and hence it can provide more benefits to farmers. For providing online information to distantly located stakeholders ICT can be used in breaking the blockades of these remote places, which is the major concern for information dissemination.

Information Systems

An Information system (IS) uses Information Technology (IT) to sustain various operations and management of people's activities. (Silver, Markus, & Beath, 1995) discusses two views on IS namely IS-centered view comprising of hardware, software, procedures, data and people, and managerial view that incorporates people, business processes *etc.* ISs are specifically designed to enable individuals to execute these tasks for which the individual understanding is not so proficient, such as, handling bulk amount of information, performing scientific calculations, and controlling many parallel processes. Thus, such systems are very helpful for providing the best and up to date information to associated stakeholders. IS acts as an interface between individuals, algorithmic processes, data and technology (Information System, 2011). It also refers to the manner in which individuals interact with technological tools in support of assembly of allied, planned actions or tasks that can fabricate a particular service or product or serve a specific goal for stakeholders. It can be envisioned as flowchart of a sequence of events to achieve a certain product or service. The activities of an IS are committed to process information by means of capturing, communicating, keeping, recovering, handling and exhibiting the information. As such, IS inter-relates with data and activity systems. These are a type of communication systems in which data is represented and processed to generate information which is useful to the end users. Human decision-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

making and action is supported by considering it as a semi-formal language. ISs are seen as having the ICT component to help in controlling the performance of business processes. When an individual realizes and appraises the processed information then it becomes knowledge (Kürşat DEMİRYÜREK, 2010). These are social systems whose performance is inclined to the aims, principles and philosophies of people, as well as the performance of the technology (Angell & Smithson, n.d.).

Information and Communication Technology

World Bank report (World Bank, 2011) mentions that private and public sector are involved in research to find efficient answers to address short and long term concerns and challenges in agriculture that includes means and methods for responding to the information needs of the farmers. ICT based solutions have incredible potential to improve agriculture in emerging countries like India. The costly, bulky and energy-consuming equipment which were once available to the very few to store and analyze agricultural and scientific data, are now easily available with the farming community. With the booming wireless, Internet and mobile communication industries and reducing cost of electronic gadgets, ICT has become a part of daily routine of poor smallholder farmers. Its ability to bring recharged momentum to agriculture appears more convincing in view of increasing investments in agricultural research, strong attention in the development & spread of ICT by the private and public sector and the expansion of organizations committed to the agricultural development programmes. As described in (Vu, 2011), emerging nations need a more strategic focus on promotion of ICT penetration as a vital source of development, this includes the up-gradation of the ICT infrastructure and reduction of costs of its use and focus to increase the vital effects of its penetration. This can be helpful in improvement of the availability of information and technology, nurturing the novelty and exchange, and augmenting the excellence of decision making.

Emergence of digital convergence, explosive growth of wireless communications and increasing penetration of broadband technologies all over the world have made the adoption of ICT necessary to explode socio-economic development (Armenta, Serrano, Cabrera, & Conte, 2012). Availability and utilization of Telecom Infrastructure is invariably linked to the living standards and economic development in emerging countries (Garbacz & Jr, 2007). Pricing for telecom services like mobile phones and value added services have emerged as a vital factor that drives the quick adoption of mobile phones in emerging nations like India, Sri Lanka, China *etc.* Information about the affordability of ICT services (i.e. fixed line phones, mobile phones and fixed and mobile broadband Internet subscriptions) as adjudged against average gross national income per capita is expressed in terms of ICT Price Basket has been devised by International Telecommunication Union (ITU) (International Telecommunication Union (ITU), 2011a). Recent statistics indicate that cost for Internet access and mobile phones have decreased considerably throughout the world. Specifically, the cost of ICT has significantly decreased in Asian countries in previous decade. Thus, access to ICT services has become quite reasonable in these nations. This situation has unlocked the gate for a range of mobile-based services and applications that can be implemented in the region.

Creation, assessment and manipulation of information have been enabled by ICT as a combination of IT and communication technology (Information and communication technology, 2011). It can play a considerable task in conserving the attributes of information as it comprises computer, communication and information. These are concerned for handling, trading and supervising data, information and knowledge. Benefits of ICT include:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Preservation of properties of information during its processing, exchange and management;
- Capability to record text, diagrams, multimedia, procedure descriptions *etc.*, in digitized formats;
- Production of duplicates of requisite information at lower cost;
- Transfer knowledge and information instantaneously all over the world through networks;
- Processing of large information rapidly using predefined algorithms;
- Achieving greater interactivity in connecting, appraising, creating and sharing useful knowledge and information.

The encouraging effect of ICT is quite evident in service oriented sector, where the productivity has gone high. Business process outsourcing, financial sectors *etc.* are taking full benefit of the ICT revolution.

Agricultural Information Needs and ICT

The application of ICT in agriculture is important. E-Agriculture (Information and communication technology, 2011) is an emerging area that focuses on the escalation of rural and agricultural development through superior information and communication processes. It involves the conceptualization, strategy, expansion, appraisal and use of innovative ways to ICT in the rural area, with a major attention on agriculture. Various E-Agriculture initiatives include information dissemination system (IDS), weather projection, seed sowing using sensor, irrigation monitoring *etc.* It is expected that scope of E-Agriculture will further evolve, as the understanding in the agricultural area improves.

Information requirements of farmers have also increased as the agricultural sector has been affected by latest global technological advancements. The international market requirements and ecological issues along with the national food security must be addressed by the agricultural development. Indian agriculture being a part of the global agricultural system has to keep momentum with continuous and immensely changing technologies and have to develop new products and product varieties, expanding and harnessing ICT for development of ISs, new market tactics, new services and so on (P. Singh, 2004).

In past, pamphlets, posters, radio, television *etc.* were used for the dissemination of information to the farmers. Huge amount of time was wasted in reaching the information to the appropriate quarters. The need for providing the accurate agriculture related information to the concerned at appropriate time leads to application of ICT in agriculture.

Concepts of virtual community or e-community, E-publications of agricultural literature, various information networks, institutional repositories, social networks sites and information kiosks *etc.* are being employed for dissemination of agricultural information. Various ICT initiatives/tools like multimedia, web and mobile applications are being deployed for the dissemination of information among various stakeholders.

Need for Mobile Communication in Agriculture

Advancement and accessibility of ICT has been the ultimate communication revolution during the last few years. The decreasing cost of hardware, expansion of communication set-up and its availability at district and block level has opened up vast potential for agro-worker to reach the rural community in a more dedicated, accurate and specific manner. Understanding of hardware, software, ICT indicators and home/global networks can be a value addition to the knowledge base of extension functionaries. One such tool is mobile phone network. It is simple, economical and convenient to use. Illiterate people

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

are also easily adopting the usage of the smart mobile phones as compared to the laptops/computers. Access to mobile networks is now available even in the remote regions. It is possible for everyone and everything to be connected and this connectivity has a huge impact on society. For community development, it is pronounced as the most transformative tool (Kirk et al., 2011). This connectivity not only offers people the ability to stay in touch with friends and family but it also provides access to finance, improved healthcare solution, supply chain efficiencies and increasingly automated mobility. ICT services are commercially successful and therefore, it is believed that these are more sustainable in long term and provide more benefits to society.

Countries like India have a rising mobile market, deep diffusion of mobiles and elementary ICT infrastructure. Mobile phone subscription has increased tremendously over the years and during 2005-10, there was 50.7% per annum rise in mobile phone subscription (UNESCAP, n.d.). In a report (International Telecommunication Union (ITU), 2011b), the number of mobiles subscription per 100 inhabitants was 61.4, where households having a computer were 6.1. Mobile phones is a reasonable tool for communication and learning than personal computers (The Economist, 2011). Mobile communication has become an important tool for voice and data transfer. Telecom Regulatory Authority of India (TRAI) has released data showing that there are 893.31 million mobile subscribers in India as on 31st January, 2014. About 40.75% of these subscribers belong to rural areas with a rural tele-density of 42.43 as against urban tele-density of 139.42 (TRAI, 2014). The mobile subscription base has been projected about 900 million in 2015-16 as compared to 90 million in 2005-06 (S. K. Singh, 2008). The base is already touching this projection in the year 2013-14. Mobile devices are now becoming the most suitable means to disseminate agriculture related information to farmers in rural areas with 1.21% monthly growth of rural mobile subscription. These devices have lot of benefits over computers/laptops such as low cost, easy interface and convenient usage by farmers and higher penetration in the emerging nations (Gichamba & Lukandu, 2012). Growth in the mobile subscriber base will have vital impact for the prospective plans of mobile service and infrastructure providers, handset manufactures and vendors. This projected growth may be due to Internet and customized applications for individual use on their mobile handset. Agriculture sector can also harness the advantage of this growth.

Mobile networks access is broadly available at district and block level as well as in remote areas. This has opened up wide opportunities for agricultural scientists and extension workers to work with agricultural community in more focused and personalized manner.

Information Dissemination Systems

Various initiatives have been taken by different organizations to cater to the needs of the agricultural stakeholders. These include development of Information dissemination systems like Experts System (ES) and Decision Support System (DSS) *etc.* Most of these have been focused for the use by the extension specialist and computer literate farmers. These systems have static database of information and knowledge, which is constantly being used to deliver the results. Agriculture is a complex process which has unpredictable and uncertain solutions. To get the inference for such solutions soft computing techniques are used. These techniques deal with inaccuracy, vagueness, fractional truth, and approximation to achieve practical, robust and low cost solution. As such it forms the basis of a considerable amount of machine learning techniques. Usage of these techniques in agricultural systems has given tremendous scope to provide the precise output.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Mobile Based Systems for Localization

Localized information needs of the farmers are very vital. Certain agricultural activities are prominent in some regions and may be irrelevant to the other nearby regions. Information processing and dissemination to the farmers on the basis of their geographical area is very crucial. Information provided in the native language is a boon for the farmers. This can generate interest among the farmers for information. Mobile systems /handsets with some additional features may help in getting the localized information. So, there is a need for the development of mobile based information dissemination systems for transferring the localized multi-lingual information from the knowledge repositories so that the information may be available round the clock.

Possible Gaps in Information Dissemination

Various ESs, DSSs for agricultural activities have been developed but most of these are standalone or web based systems or relevant to market related agricultural activities like commodity exchanges, web based information repositories *etc.*, These are confined to the knowledge base of domain expert and knowledge engineer.

Following are the possible Gaps for information dissemination in agricultural based activities:

Lack of Exploiting Soft Computing Techniques in Agriculture Decision Making and Information Dissemination

Agriculture itself is a vast field having complex activities in its domain. Understanding these complicated activities along with the techniques of soft computing, which are approximation to the accuracy of the decision and information dissemination, is a cumbersome job for an agricultural researcher. This area has been focused in this study.

Lack of Mobile Network Usage for Agricultural Information Dissemination

Various experts', decision support and fuzzy logic based systems for agricultural activities and processes have been developed. But most of these are standalone or web based system or they are related to agricultural marketing activities like commodity exchanges, AGMARKNET (www.agmarknet.nic.in), e-Choupal *etc.* IT knowledge is the basic requirement for a farmer to use these kinds of systems. It is felt that the mass understandable and economical technology needs to be exploited for dissemination of agricultural related information. The mobile phone network is one such popular technology that can be exploited easily for such information dissemination. Mobile phone networks are available in almost all the geographical areas of India and used by majority of farmers (Jain, Kumar, & Singla, 2011).

Localization of the Desired Agricultural Activity

Web based systems are not able to guess the exact location of the agricultural activity under review. Therefore it is required to use the telecommunication infrastructure to accurately define the location of agricultural activity under consideration. By getting this accurate information, the soft computing based information systems can give localized information for better decision making. It is possible to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

exploit the power of mobile technology to transfer this knowledge to the concerned at any location on 24x7x365 basis. The knowledge can be made available in the native language of the farmers. In this study, localization of desired agricultural activity has been achieved using the features of mobile phone like Global positioning System (GPS) for location detection, multilingual for local language of the farmers.

Information Dissemination in Agricultural Sector

Agricultural and its allied activities are the sources of income for most of the Indian rural population. Therefore it is very important to enhance their agricultural productivity, which is a complex and cumbersome activity. It requires a lot of practice and latest information about the latest tools, implements, procedures and knowledge about the various activities involved in practicing agriculture. Various methods have been used to transfer these latest information to the farmers that include, pamphlets, farmer fests, multimedia involving television and radio talks, public and private organizations (like ICAR's and SAU's research station, KVK's, ITC, TATA Consultancy Services), Internet based web and mobile applications etc.

ICAR is premier organization committed to developing and governing agriculture under Ministry of Agriculture, Government of India. It has a number of specialized research institutes for different crops, animals, soils, regions *etc.* Under its leadership, the agricultural education, research and extension programmes are also governed which involves the state agricultural and veterinary universities and other organizations. These institutes are committed to the transfer of knowledge and information available to them through research and other means to the farmers through different types of extension initiatives.

Role of ICT in Agriculture

The potential of ICT to contribute towards agriculture and rural development of a nation has been well recognized e.g. Establishment of Rural ICT centers in Iran has played an efficient role in rural development through improving e-governance in these areas (Alibaygi, Karamidehkordi, & Karamidehkordi, 2011). In order to make the most of this potential, nations have two issues: firstly, empowerment of small farmers with ICT services and assets, which can improve their productivity, incomes as well as which can secure their food security and livings, and secondly harnessing ICT commendably to compete in swiftly changing and complex global markets. These issues can be addressed by execution of a complex set of strategy, innovation, investment, and capacity-building processes *etc.*, in consultation with concerned stakeholders. This can inspire the growth of localized applicable, cheap, and viable ICT setup and facilities for the rural economy (World Bank, 2011).

The association of the usage and adoption of ICT by farmers practicing conventional extension systems as well as policy suggestions for bridging the evolving digital gap within the agricultural community have been described in (Anastasios, Koutsouris, & Konstadinos, 2010).

Nokia life tool is an example of agriculture based information systems on mobiles, which is a payment based information service intended for developing markets. It provides a vast variety of information service. It covers education, entertainment, healthcare and agriculture ("Nokia Life Tools - Wikipedia, the free encyclopedia," n.d.). mKrishi, an initiative of TATA Innovation Lab, is the one of the good mobile application involved in disseminating the agriculture related information to the farmers at the nominal cost. It associates farmers with a system that assists them to make sound decisions about agriculture which can drive higher profits and preserve the environment. With the help of Integrated Voice Response (IVR) technologies the software can also transport voice messages between farmer and the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

expert. aAQUA which stands for almost All Questions Answered, is an online question & answer and community discussion forum for generating and providing information significant to farmers (Ramamritham, 2004), (Ramamritham, Bahuman, Duttagupta, Bahuman, & Balasundaram, 2005). It allows members using a web browser on a computer to create, view and manage content in local languages. A large number of farmers have reported fairly affirmative changes in quality of yield, crop diversification due to Agropedia and aAQUA (Yadav, 2011) thus improving their income. Agropedia is a good resource of the agricultural information ("Agropedia," n.d.).

Use of Multimedia in Agriculture

Green revolution in India is possible because of the transfer of technology from the research fields to the farm field. In earlier years, the print media played vital role in transforming the agricultural productivity from extremely low to reasonably good point. Information dissemination using the CDs and DVDs have further strengthened agricultural output.

Multimedia, which includes all the customary forms of communication like – audio, video, photographs, graphics, animation and text, is an admirable tool for extension and communication. Each learning task is most effectively taught through the optimum usage of relevant media. Multimedia describes fusion of text, records, visuals, animation, optical storage, image processing and sound. Using the multimedia data types such as video, graphics, images or animation, any participant can introduce illustrative material to facilitate better communication. Incredible images and animations, audio, audio-visual clips and raw textual information can inform, educate, persuade and entertain the users. This can help in electrifying the public's mind. Thus, the process of transfer of technology, from the laboratories and research field, among the stakeholders must be strengthened and must reach the farmers at the earliest (Philip, Vennila, & Gomathy, n.d.).

Multimedia as transfer of technology can function in the field of agricultural extension. It can be used to illustrate the issues in an interactive, interesting and effective format. Photographs, pictures *etc.* of symptoms of diseases, insect pest damage and of insects can be made available using multimedia for their effective monitoring and management. Solutions of the problems can also be depicted using figures, photographs or pictures. Using a chat room, crop pest specialists can be consulted to know how to identify accurately and control the pests. Quality of extension material and process can be supplemented time to time by multimedia and virtual reality.

Now a day, work is being done to attain the second green revolution. This can be achieved by harnessing the power of ICT. Usage of various tools of ICT can be very helpful to agricultural community. The Digital Green (Gandhi, Veeraraghavan, Toyama, & Ramprasad, 2007) system propagates targeted agro-info to small and marginal land holders in India through digitized video. Concept of participatory learning is implemented in the system. Database of videos, which is generated by farmers and experts, is included in it. These videos are distributed to the farmers through a repository. Farmers are motivated and trained by these recorded experience. Development of Internet and online agricultural repositories has further added to enhance the agricultural output. The strengthening and broadening field of Internet over the mobile phones in developing nations can provide an exclusive interface for adoption of agricultural technologies using ICT.

Government policies and announcements can be made available to farmers and extension workers from time to time with the use of multimedia. The information on weather parameters, cropping systems availability of high yielding varieties, other related information on varieties, irrigation, fertilizer manage-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ment, Integrated Pest management (IPM) *etc.* can be made available to farmers using multimedia and convince them easily. Multimedia offers immense potential today as well as for the future and it will help extension worker and scientist to integrate modelling, visualization and decision making processes associated with farming systems. This will definitely accelerate development in the field of agricultural extension and ultimately farmers of the country will be able to harvest the benefits at the desired level.

Web and Mobile Applications

ICT enables users to build, retrieve and handle the information. It is combination of IT and communications technology (Information and communication technology, 2011). In modern arena, it lays emphasis on the role of integrated communications and amalgamation of tele-communications, smart information managing arrangements and multimedia arrangements. Being an arrangement of three major technologies: Computer, Communication and Information Management, it is playing a vital role in preserving the characteristics of information. These tools are smeared for handling, trading and managing data, information and knowledge. With the help of various ICT tools, it is possible to produce exact copies of such information at considerably lesser cost, rapid transfer of information and knowledge globally through communication networks, develop standardized algorithms to synthesis quickly the vast quantities of information, achieve greater interactivity in producing, transferring, appraising, and sharing beneficial knowhow and information.

Mobile and Internet based communication are precise, fast and economical mode to transfer the information from research farms and laboratories for disseminating agriculture related information to farmers. It has also reached almost all the districts and administrative blocks of India (Chauhan, 2010). Farmers are eager and become concerned to get rapid, true and reliable information in globally changing agricultural scenario. Transfer of requisite and latest agricultural information to the farmers in scattered locations at diverse geographical situation in India is a very tough job. Still it can be said that development of technology and its dissemination to the farmers is a continuous process (Mehta, 2003). This has been tried to be accomplished by the various web portals (Raj, 2013).

Portable Chemical Analysis (PCA) using a mobile phone has been presented in (García et al., 2011). Built-in camera is used for clicking the image of a single-use colorimetric chemical sensor. A software application processes this image to obtain its characteristic H (hue) value related to analytic concentration. Using mobile phone the water and sand samples have been analysed using the reflectance measurement (Iqbal & Bjorklund, 2011). The screen of phone work as a light source and the detection is done by front view camera. PCA for the taxonomy of several compounds and their concentrations in water has been done using the reflected intensities of red, green, white and blue colours. For Arsenic detection in groundwater, discoloration caused, because of its presence in groundwater, was analysed with the help of model coloured sand samples. In (Sumriddetchkajorn, Chaitavon, & Intaravanne, 2013), it has been experimentally demonstrated that for analysis of chlorine concentration in water can be estimated with the help of embedded digital camera in a mobile device, which can be used to function as a colorimeter. The feasibility of using mobile phones cameras for DNA detection has been investigated in (Lee, Chou, Yeh, Chen, & Chen, 2011).

In (Confalonieri et al., 2013), a smartphone application has been discussed and it implements (App-L & App-G) methods for Leaf Area Index (LAI) estimation. LAI is an important parameter in environmental and agronomic studies. It can estimates the amount of radiation captured by the canopy and describes crop water requirements. It can be judged with the help of the developed application. This application

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

is based on the usage of the sensors present in the most of the smart-phone and their processing powers. Gap fraction estimation at 57.5° (to obtain values that are almost free of leaf inclination) for luminance estimated above and below the canopy has been used in the first method (App-L). The gap fraction has been estimated via automatic processing of pictures obtained below the canopy using the second method (App-G). The data has been collected in scatter-seeded paddy farm-field in northern Italy. The performances of two methods implemented in application were assessed using this data. The results were matched with those of the LAI-2000 and AccuPAR ceptometer, by determining the methods' accuracy and linearity. The performances of App-G were similar to those shown by these instruments, whereas App-L attained the best true value, although it has resulted in lower precision, necessitating a great number of replications to provide trustworthy estimations. It has been shown that the proposed application can be considered as a substitute to commercially available instruments and useful in perspectives characterized by cost-effective resources or when the maximum portability is necessary.

A quick and mobile nitrogen management risk assessment tool, Nitrogen Index application for android smart-phones, has been developed that can be carried to the field and elsewhere (Delgado, Kowalski, & Tebbe, 2013). A desktop version of the Nitrogen Index, which can be used on desktop and laptop computer, has also been developed. Users can email the results from their Nitrogen Index application developed for smartphones/tablets in the field to their computer back at the office (or a farmer's or consultant's computer) using their portable device's Internet service. This portable technology can enable the use of small devices such as smart-phones to conduct an assessment on site and visit with a farmer at any given field site where a wireless connection is available. The Nitrogen Index is a quick tool, and its assessments of nitrogen loss risk are correlated with observed values. Nitrogen Index application is first of its kind in the world and it is assumed as the beginning of more advances to come in the field of portable agricultural technology. New advances in software (e.g., applications) and technology are bringing us to a new frontier of technology transfer, and portable technologies (e.g., smartphones, tablets) are making possible the development of '*smart* agriculture'.

Agricultural Information in Farmer's View

Mobile phone subscription is increasing day by day in rural areas of India. Farmers require the timely and precise information. To study the requirements of the farmer for information dissemination a survey had been conducted on a sample of farmers in Punjab, India(Jain, Kumar, & Singla, 2014). This survey included the usage of internet on mobile, computer for agricultural information needs. The information from the survey was compiled and it is found that 63% know Internet usage and only 38% of farmers surf the Internet to get agriculture-related information. Approximately 99% of farmers use mobile phones efficiently having multimedia features, etc., 95% of farmers opted for getting the information using SMS services etc.

Presentation of Agricultural Information

A lot of agricultural information is available and it is needed to be presented to the user so that he can best make the use of it to increase agricultural; productivity. Various information systems, expert systems, decision support systems have been developed in this direction.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Among ICTs for agriculture, Kissan Call Centre, an initiative of Government of India, e-Sagu (www.esagu.in), e-Arik (www.earik.in), India development gateway (www.indg.in) and e-aAqua (www.*aaqua.org*) are prominent examples (Saravanan, 2008), (Saravanan, 2010).

AgrIDS (Reddy & Ankaiah, n.d.) is a framework for an IT-based agricultural information dissemination system integrating IT and agriculture. The system have been developed using web technology and it aims to provide fresh and expert agricultural advice to needy farmers quickly and personalized manner for crop productivity improvement. It also aims to increase the cost-effectiveness of farmer by escalating the efficiency of agricultural inputs and decreasing the production cost. Some of the agricultural information systems have been provided in Table 1. Using Internet and communication networks, AgIS should capture various parameters like precise location, quality of soil, soil health, rainfall, agro-climatic conditions *etc.* of farm location to suggest best practices. Soft-computing techniques can process this set of parameters concurrently to deliver timely, precise and appropriate inferences. Various parameters like localized information along with generic information from the farmer are required to reach at a decision.

Farmers may not be comfortable or be trained to enter localized information into the computing systems. Automation can help to capture certain parameters. For example, longitude and latitude of the mobile device can be obtained using the communication networks automatically and this can be passed to the AgIS server, which in turn, can obtain the various other parameters like the type of soil, ground water level, weather conditions, prominent diseases *etc.* of the location. Soft-computing techniques, implemented at server level, process the generic and local information collected automatically using the AgIS. Processed information in the form of resultant expert like inference of agriculture practice can be delivered to the farmers in their native language, which can be helpful to them in decision making. It can enable them to improve their agricultural productivity and livelihood. However, there is need to involve agriculture experts, software developers and computer scientists to develop such a system in the local

language of farmers. In some cases, language experts are also required to translate scientific knowledge into the local language. All the diverse partners need to understand the practices of other professions, so that this kind of system should be in place.

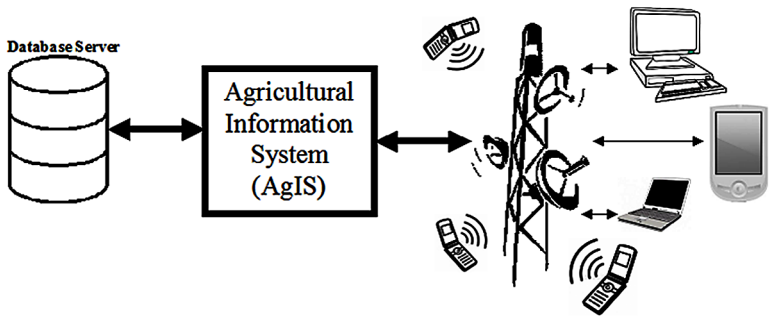
The task of creating IS based on mobile application supporting native language of farmers to cater to the complex spectrum of Indian agriculture is a giant task. Complicated information may be compiled in a structured and user friendly AgIS available round the clock. Low cost mobile phone technology and its availability with most of the farmers can provide localized information to them. Content of AgIS in local languages can engender interest in farmers and others at grassroots level. Majority of farmers are not aware of such systems. Awareness can be generated by extension specialists at ADO, BDO, SAUs, and KVKs *etc.* Use of soft computing techniques to process information required in conjunction with mobile networks and technologies, for dissemination of complex agricultural information, is one of the ways in the future to deliver expert advice to farmers.

Mobile Based Agricultural Information System Framework

Creation of databases and applications to cater to the complex spectrum of Indian agricultural scenario is a challenging opportunity. Dissemination of agricfultural information to the farmers freely in their local language is a giant task which can be achieved using the knowledgebase of existing set-up of SAUs, agricultural research institutions, state agricultural departments *etc.* Skilled manpower available in these organizations can be useful in developing mobile applications. A structured AgIS can be formulated using this information stored in the database which can be made available round the clock freely using the electronic devices like mobile-phones, laptops, desktops *etc.* as shown in Figure 1. In the present conditions, penetration of Internet is increasing but the farming community is not well conversant with the use of Internet and computer. The commonly available mobile handset e.g. smart-phones are capable of installing these mobile based information systems for providing the localized information. Various backend techniques to process the information may be deployed for developing AgIs.

Harnessing the power of mobile based communication technology can provide the localized information which is very crucial at one location but may be irrelevant at another location. The Application Programme Interface (API), which is available in the mobile phone, can tell us the precise location and it may be used for fetching the various other parameters at that location such as soil type, soil fertility, agro-climatic conditions, ground level of water using the hybrid mobile application *etc.*

Figure 1. Basic architecture for flow of agricultural information from/to AgIS



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

The following section discusses and proposes architecture to develop a mobile based dynamic and hybrid system, named as '*Mobile based Agricultural Information Dissemination System* (*mAgIDS)*' for various agricultural processes and activities based on the location of the mobile device being used and to propose the possible solutions as provided by the experts of agricultural process in the preferred language of the farmer.

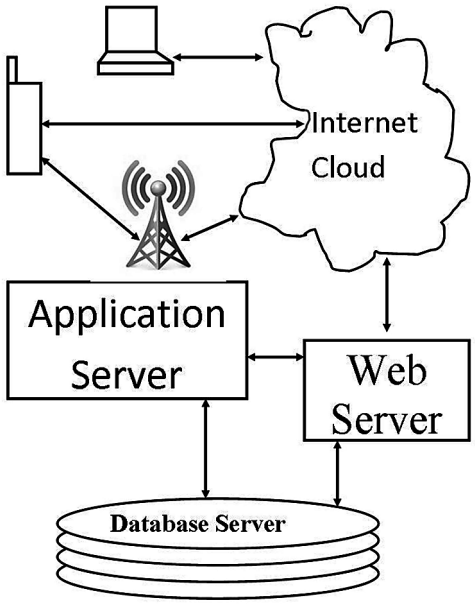
Hybrid Mobile Application Architecture

Hybrid applications are those which install on the competing device but interact with the webserver for various data processes and requirements. The proposed architecture of the hybrid application is based on client-server methodology as shown in Figure 2. The application installed on an electronic device, for example, a mobile phone, is available to the web server through the Internet Cloud using either of the means like mobile operator provided Internet, Wi-Fi, hotspot *etc.* Web server interacts with database and application server for various internal processes and activities.

Database Server

The database server stores location maps, various agricultural activities and processes, their symptoms in the form of rule base, their weights as provided by agricultural experts to a symptom of an activity, user information and storage of final results of a selected location unit.

Figure 2. Hybrid mobile application architecture



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

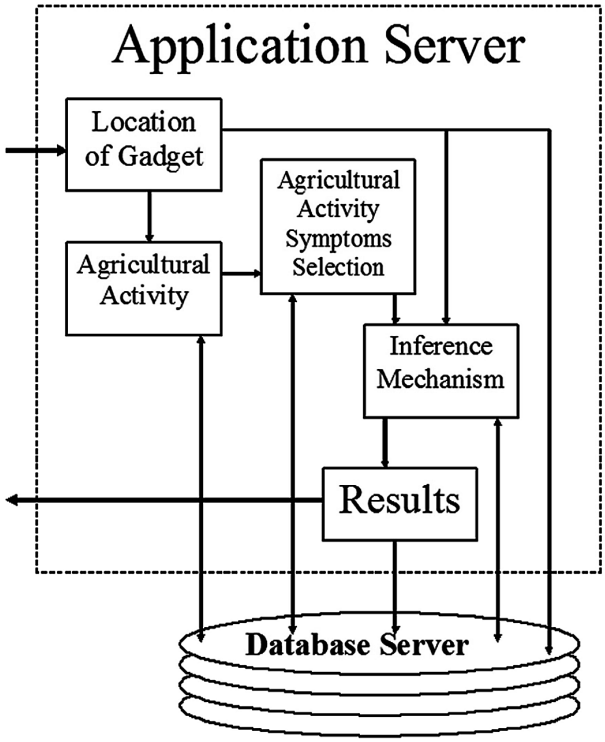
Application Server

Application server interacts with both web and database server for different activities. The web server sends a request to the application server with location parameters of the mobile device which in turns finds the exact smallest location unit name from the database using the predefined instructions employing the location API (Jain, Kumar, & Singla, 2013). Then the web server sends other parameters related with agricultural activity under consideration to the application server for selecting symptoms of agricultural activity, which interacts with the database containing set of various activities, symptoms and rule-base of agricultural processes (Figure 3).

Localization of Information

Technological advances are opening up huge opportunities. With new technologies, unmatched developments, and booming economies, the face of the world of telecommunication and IT is changing rapidly. Integrating the locale into this change and adopting the technologies for maximizing the impact in rural areas is a challenging task (Nanda & Arunachalam, 2010). Mainly mobile technologies have created new channels to communicate with others through a well-located manner. The penetration of mobile applications in the rural market is increasing day-by-day due to reducing cost of smart phones, PDA, tablets *etc.* The mobile application developer can use the manufacture provided API of these phones/technologies to develop various applications for providing localized services to the farmers. For getting the location information at the micro-macro level (administrative block level), two techniques have been employed:

Figure 3. Application server architecture



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Selection based techniques,
- Automatic location information.

There are 29 states and 7 union territories in India with overall 640 districts and 6451 administrative blocks (Census of India, 2011). Thus, the whole nation is divided into smaller units called administrative blocks. These blocks have diverse information related to geography, geology, administration, ecology *etc.* Thus localized information can be obtained if stored in the digital format. In the selection based techniques, a database is populated with the information of the state, district and blocks of the country, for example, in MNREGA (Mahatma Gandhi National Rural Employment Guarantee Act) database, desired information can be obtained by selecting the state, district and administrative blocks under observation.

In automatic location information technique, Global Positioning System (GPS) of a mobile device can pass information related to longitude and latitude to the server. Location API on server can process this information to get the geographical data of administrative blocks in which this device is located. Then based on this, geographic agricultural data can be extracted and disseminated to this device. The server Location API can access the Geographical Information System (GIS) maps, which is imported in the database server supporting spatial information. This information is used further for processing of the other parameters. Both techniques have been described in Figure 4.

Figure 5 describes the way an electronic device, whether GPS enabled or not, accesses the Location API and uses the other APIs to process the location information. This information is used in the ISs for

Figure 4. Flow chart for implementation of location based search

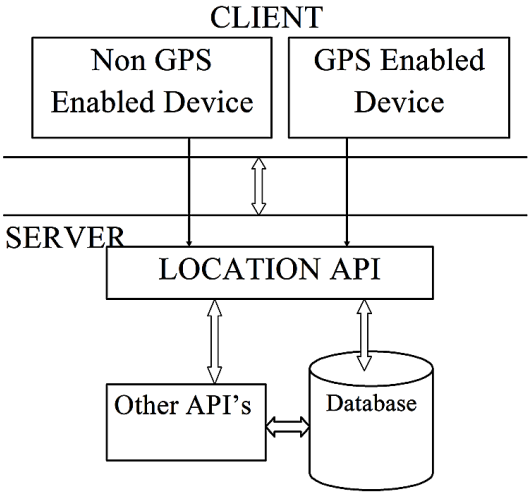
Figure 5. Client-server architecture using the location API



getting localized knowledge. Storing the information about the local spoken language can further localize it. Based on this input, data can be disseminated in the localized format.

Inference Mechanism for an AgIS

Various techniques of Soft computing like fuzzy logic, artificial neural networks, Genetic algorithm, support vector machines, Bayesians approaches etc. are being used for making the inferences. These techniques give precise result which can be used for delivering the precise agricultural information.

Mobile Based AgIS (mAgIDS)

Various initiatives have been taken to disseminate the agricultural information to farmers. An initiative name 'mAgIDS' has been taken to provide the agricultural information precisely and round the clock. This Android-based mobile phone application 'mAgIDS', using the improved dynamic fuzzy rule promotion (Jain, Kumar, Singla, Singh, & Singh, 2014) based technique to infer the advice to farmers, has been developed.

A dynamic fuzzy rule promotion approach (Kolhe, Kamal, Saini, & Gupta, 2011) for the promotion of confidence factor of a rule for every successful session for diagnosis of activity by using the specific rules have already been proposed in the literature. This technique has the limitation that error in the initial estimation of weights reduces linearly after every session the rule is being used. An improved approach has been proposed using square root of sum of squares of frequencies, which are spread around mean true value to reduce error around mean value. The improved approach decreases error in uncertainty of estimation of weight for rules after every successful session. This approach has been used in the 'mAgIDS' application.

The application uses Global Positioning System (GPS) for localized inference, and local language selected by the user. The required information is collected and transferred to the application server over

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the mobile networks. This information is processed incorporating the improved dynamic rule promotion technique. Application has been tested on the dataset of various symptoms (rules) for disease diagnosis (activity) of paddy crop. Chi-Square ($\chi 2$) test has been used to match the result of the mAgIDS system with the expert's inferences. It has been found that the results of the system and experts match with accuracy of 95.84% at 5% level of significance. Twenty two scientists working at various locations within Punjab state in India were contacted for validation of the system with fifteen relevant parameters. It has been found that the proposed system is statistically valid. The real time application of this system is in process and implementation of the system can provide immense and timely help to the farmers for taking appropriate decisions for their crop production.

CONCLUSION

Generic Information and knowledge furnished to farmers may not be relevant to them at their respective geographical locations. Dissemination of local level information through mobile networks can help them to improve their productivity and hence socioeconomic aspects. The experts can get the information about the location unit where a particular agricultural activity is more prevalent and it can help them to research that location unit. The information being requested can be processed for use in further sessions to get improvement in decision level and this can make the decisions dynamic based on previous experiences. Information dissemination in local language is one of the main requirements for proper transfer of agricultural information to the user and has to be explored.

Chapter 25
Sustainability Assessment in a Geographical Region and of the Activities Performed

Berrin Kurşun
Marmara University, Turkey

Bhavik R. Bakshi
The Ohio State University, USA

ABSTRACT

The applicability of emergy analysis (EA), a nature oriented thermodynamic analysis technique, as a regional sustainability assessment tool is explored in the context of an Indian village (Rampura). EA provides information about how much environmental support is required, system renewability, system efficiency, load of system to environment and dependency of system on external resources (self-sufficiency). The results of Rampura analysis reveal that sustainability is achieved neither at village level nor at subsystem levels. The chapter shows that the effective use of the renewable local resources can reduce the dependence on external resources and increase self-sufficiency and sustainability

INTRODUCTION

Sustainability is a complex concept since social, economic, technical and complex dynamic factors are decisive in a simultaneously interacting manner (Bakshi, Ziv, & Lepech, 2015). Hence, considering only one dimension of events does not create success in assessing a multi-dimensional phenomenon like sustainability. In today's world where many of thresholds of Earth's carrying capacity in life support mechanisms have been crossed (Steffen *et al.*, 2015), analyzing the interaction of natural and anthropogenic systems is crucial in order to cease the further deterioration and start the restoration of natural capital (Mellino *et al.*, 2015). In that regard, emergy analysis (EA) can be an effective tool to evaluate the interaction between natural and anthropogenic systems because of the insights it can provide.

EA is a nature oriented, thermodynamic analysis technique. Odum (1996) expresses emergy as "the total amount of available energy of one kind that is directly or indirectly required to make a given product or to support a given flow." EA quantifies total available energy (emergy) input flows to a system and classifies these flows as renewable, non-renewable and purchased. Classification of emergy input flows enables calculation of emergy metrics providing information about how much environmental support is required for the area or process in question, system renewability, system efficiency, load of system to environment and dependency of system on external resources. Detailed information about emergy analysis and its application are given in *Emergy Analysis Technique* section which follows *Background*.

The aim of this chapter is to validate the applicability of EA as a regional sustainability assessment tool and to evaluate sustainability of human activities and their interaction with nature. With this purpose, The Ohio State University research team chose Rampura Village in Jhansi district of Uttar Pradesh, India as the project site. Rampura village is chosen as the project site because of successful implementation of capacity building applications as well as availability of wide range of data which improves analysis quality. Moreover, Bundelkhand is a semiarid region suffering from lack of water and vulnerable to climate change. The area went through a 4-year-long drought, which caused greater suffering for the village residents who are already bearing some effects of climate change problems (Development Alternatives, 2011). Hence, the area needs a quick shift towards sustainability and assessment of the activities performed. Here, the research team worked in collaboration with a non-governmental organization (NGO), Development Alternatives, uniting NGO's field experience with their holistic analysis experience. Development Alternatives works in the area of sustainable development, and capacity building of rural people to improve their income generation capabilities (DevAlt, 2013). Its technology disseminating branch TARA (Technology and Action for Rural Advancement) has been working in the Bundelkhand region (region including Rampura village) of Central India for over 10 years (TARA, 2013). More detailed information about Rampura, Development Alternatives and emergy analysis study carried out can be found in *Rampura Village Case Study* section.

BACKGROUND

Prior to performing a regional sustainability assessment study, one should define what sustainability or sustainable development means. One definition for sustainable development given by World Commission on Environment and Development (WCED) in 1987 is "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987). This definition is vague in terms of foreseeing what the needs of future generations will be and how the current needs will be met without compromising an unknown future (Marshall & Toffel, 2005). The vagueness in this definition of sustainability is also due to lack of unanimity in defining what is regarded as sustainable. To Costanza and Patten (1995), sustainability is not a "definition", but a "prediction" problem. One can only determine a system as sustainable after seeing the results for certain. In that regard, to better objectify the sustainability concept, the "time and space scales" should be specified regarding what is considered as sustainable and unsustainable (Costanza & Patten, 1995). In nature, systems are interconnected within a hierarchical order through energy and material exchanges (Odum, 1996).

Entities which are higher in the hierarchy encompass broader time and space scales. For instance, ecosystems have longer lifetimes than the species they contain or species survive longer than an individual of the species. Hence, each entity has an expected life span increasing as the entity ascends higher in the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

hierarchy. Based on this fact, Costanza and Patten define a sustainable system as "one attains its full expected lifespan within the nested hierarchy of systems within which it is embedded" (Costanza & Patten, 1995). Hence, actions which cause a system survive shorter than its expected life span diminishes that system`s sustainability. Pollutants shortening human life or excessive nitrogen and phosphorous flows released into water resources causing algal blooms affect the functionality of these systems negatively, thus reducing their sustainability (Costanza & Patten, 1995; Marshall & Toffel, 2005). To achieve or improve sustainability, actions supporting and enhancing the harmony of a system with its life support mechanisms should be adopted (Costanza & Patten, 1995). Resources utilized in a system should not be consumed faster than their renewal rate. Pollutant and toxic material emission rates should not be greater than their assimilation rate in an ecosystem (Marshall & Toffel, 2005).

Past development pathways, the developed countries pursued (generally fossil energy and external input (mostly non-renewable) dependent) induce many of the environmental problems humanity fight against today (Steffen, Persson, & Deutsch, 2011). Energy generation, transportation and agriculture are the main human activities affecting Earth and its support mechanisms (Steffen *et al*., 2011; Rockstrom et al., 2009) because the rate of resource utilization and waste creation by these processes exceed the resource formation and waste elimination rates of Earth's life support system (Steffen *et al.*, 2015). For the last 10,000 years (Holocene), Earth has had a considerably benign climate which enabled the development of human civilization (agriculture, towns and cities) (Griggs *et al*., 2013). And, this support system can continue to function in this human-friendly way only below certain thresholds above which catastrophic results may arise for humanity (Steffen *et al.*, 2015).

In that regard, there are increasing efforts toward a paradigm shift in how humanity needs to function while sustaining Earth`s life support system. This came with the recognition of fundamental importance of natural capital in supporting humanity (Griggs *et al.*, 2013). The earlier three pillars (economic, social and environmental) of sustainable development are integrated within a hierarchical model taking Earth`s support function as a basis on which society and economy thrive (Griggs *et al*., 2013; Rokstrom *et al.*, 2009). However, most of earlier engineering efforts to achieve or improve sustainability generally focused on increasing resource or energy use efficiency (Bakshi, 2011). However, this reductionist approach does not lead to sustainability. Thus, sustainability assessment of a system should be performed within a systems thinking paradigm.

Likewise, classical economics considers only human labor and money as limiting factors for a production activity and perceives nature as a free resource that supplies raw materials and eliminates waste (Mellino, Bounocore, & Ulgiati, 2015). However, the role of ecosystem services in supporting the systems analyzed should be accounted for (Ulgiati *et al*., 2010). And, ecosystem services should be perceived as the third limiting factor for production activities. All systems need external energy or material inputs to sustain themselves. What matters in terms of sustainability is how renewable these inputs are and if their utilization rate is within the carrying capacity of the surroundings. If resource use is within the carrying capacity of the relevant surroundings, then the system is likely to become sustainable (Bakshi, 2011), since such a system would satisfy a necessary but not sufficient condition for sustainability (Bakshi *et al.*, 2015). Therefore, reducing reliance on nonrenewable sources is a common goal of many efforts toward sustainable development. If developing countries follow the same paths that the developed countries did for their development, it is highly unlikely that a sustainable future awaits humanity given the huge populations of these countries (China, India) and possible impacts of such a development path.

In the literature, there are numerous applications of emergy analysis that evaluate human created systems and their interactions with their surroundings. For instance, Coscime *et al.* evaluated natural

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

capital of many nations and how the characteristics of the natural capital translate into their economic systems (Coscime *et al.*, 2014). They classified nations based on their findings. *A striking outcome of the study is the superiority of ecosystems in creating useful outputs over economic activities*. Emergy analysis can also be utilized for regional planning purposes and recommendations for decision makers. Vega-Azamar *et al.* analyze island of Montreal and quantify resource consumption, waste generation and their relation with population density. This analysis points out importance of recovery of degraded areas to improve sustainability of the region (Vega-Azamar *et al.*, 2013). A similar assessment for Canada and its provinces has been done for emergy mapping and regional evaluation (Hossaini & Hewage, 2013). Geographical information systems (GIS) can be aided to quantify different emergy flows to and from regional boundaries considered (Mellino *et al.*, 2015; Mellino *et al.*, 2014). Furthermore, emergy analysis can be utilized to evaluate self-sufficiency and dependence of a region on external inputs (Zhang, Yang, & Chen, 2007). Several agricultural systems, economic patterns and relative sustainability of these actions can also be assessed by means of emergy analysis (Jiang *et al.*, 2009; Lin, Huang, & Budd, 2013; Nakajima & Ortega, 2014).

Several other methods are available to assess regional sustainability such as human and environmental risk assessment, ecological footprint, material and energy flow analysis, ecological network analysis etc. A detailed discussion of these techniques, their pros and cons can be found in Loiseau *et al.* (2012). Comparison and discussion of these methods are beyond the scope of the present chapter. However, utilizing emergy analysis in evaluation of sustainability in a region enables quantification of environmental work invested in activities taking place, interaction and dependence of these activities to each other as we show in emergy analysis case study of Rampura and its subsectors. Utilizing solar emergy as a common denominator to represent emergy of all inputs enables accounting for quality differences among the resources (Odum, 1996 and Ulgiati *et al*., 2010). Energy sources like tidal energy or crustal heat not having a solar origin are transformed solar equivalents by certain conversion factors. Emergy accounts for all the environmental work spent back in time for formation of natural resources, creating an "energy memory". In short, emergy represents the environmental support invested by nature for the activities taking place in a region (Odum, 1996).

In the rest of this chapter, emergy analysis fundamentals and framework are introduced followed by a section about Rampura village emergy analysis case study to express the applicability of emergy analysis as a regional sustainability assessment tool. Chapter ends with a section that discusses future research areas and a conclusion section expressing the inferences and recommendations based on the case study results.

EMERGY ANALYSIS TECHNIQUE

Fundamentals of Emergy Analysis

Emergy is defined as the total amount of available energy of one kind that is directly or indirectly required to make a given product or to support a given flow" (Odum, 96). Hence, emergy types such as coal emergy, oil emergy or solar emergy can be employed (Ulgiati *et al.*, 2010). Solar equivalent joule (sej) is generally chosen to be the emergy unit because of sun being the motor that drives all transformations in nature and human activities. Odum (1996) suggests that solar energy is transferred among living things (producers, primary consumers, predators) or in formation of energy sources. All natural or human

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

dominated systems forms a network of energy transformations by concentrating and increasing the quality of lower quality energy into higher quality energy and waste heat (Hau & Bakshi, 2004a; 2004b). Solar energy is converted by green plants into chemical energy via photosynthesis or electricity is produced in coal power plants in a way to use a dilute energy form and create higher quality one. Hence, biological and economic systems sustain themselves and support each other by creating an "energy hierarchy" (Brown & Ulgiati, 2004; Hau & Bakshi, 2004b).

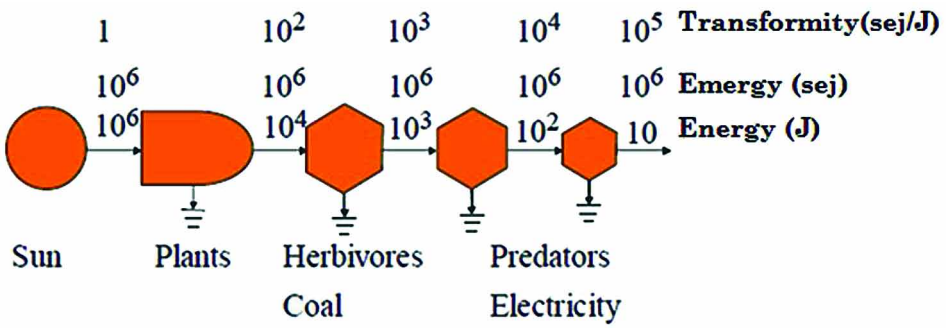
Solar energy that is needed to produce one gram, one joule or one dollar of a resource or product is called transformity or specific emergy (Brown & Ulgiati, 2004). Hence, transformity can be in units of sej/J, sej/g or sej/$. It is accepted as an indicator of energy quality since in energy transformations, energy is concentrated and its quality is increased. As a result, transfromity of a resource becomes higher as it ascends higher in the energy hierarchy (Hau & Bakshi, 2004a; 2004b). In other words, it takes more solar equivalent joules of energy or environmental work to make a higher quality product. Figure 1 elaborates these energy transformations within ecosystems and economy related systems as explained above.

To calculate emergy of an input to a system, transformity of the input is multiplied by its quantity (energetic or material quantity). Then, total emergy input to the system can be calculated simply by adding emergy of all input flows (Odum, 1996; Pizzigallo, Granai, & Borsa, 2008). Emergy classifies input flows as locally available renewable (R) and non-renewable (N) inputs and external purchased (F) inputs. By this way, emergy indicators are calculated as indicators of environmental performance for the system or region evaluated. The calculated ratios are indicators of system renewability, system efficiency, load of system to environment and dependency of system on external resources (or self-sufficiency) (Odum, 1996 and Ulgiati et al, 2010). In the following subsection, emergy analysis procedure will be introduced followed by a subsection regarding emergy algebra.

Emergy Analysis Procedure

Emergy analysis procedure includes energy systems diagram drawing, emergy evaluation table construction and calculation of emergy ratios. In energy systems diagramming, emergy flows entering and leaving the defined system boundary and emergy flows among system components are defined. In construction of emergy table, all input quantities, related transformity values and calculated emergy values for each input are listed. Emergy tables can be used to graph the emergy flows calculated for each input to show

Figure 1. Hierarchical transformation of sun energy in nature
Adapted from Odum, 1996 and Hau & Bakshi, 2004b.



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

the distribution of the emergy input flows to the system assessed. Based on different classification of emergy inputs (local renewable (R), non-renewable (N) and external purchased (F)), emergy ratios are calculated at the last stage (Odum, 1996; Brown, Rugei, & Ulgiati, 2012).

Energy Systems Diagrams

In energy systems diagramming, a pictorial model of the system to be studied is formed. Here, the purpose is to understand and determine the external energy and material flows, to identify material and energy exchanges and interactions among system components and to identify the patters of interaction between the system analyzed and its surroundings (Brown, 2004; Odum, 1996).

Figure 2 presents fundamental symbols used to draw energy systems diagrams. Of these symbols, circles represent either natural forcing functions such as sun, rain and rain or purchased forcing functions such as diesel and gasoline. Arrows represent material or energy flows among system components and flows from or to the analysis boundary. Green plants or algae are represented by producer symbol. For example, producer symbol is used to represent agriculture in emergy analysis of Rampura village. Storage represents any entity that accumulates within the analysis boundary and has a potential of creating flows. Topsoil and underground water are the storages for Rampura energy systems diagrams. Consumer symbol hexagon is used to represent livestock and domestic sector in Rampura. Interaction symbol is utilized to identify interactions and transformations among system components (Odum, 1996; Brown, 2004).

Emergy Evaluation Table

Emergy evaluation table is constructed based on the energy systems diagram drawn for the considered system. This table forms the inventory data for emergy analysis and the following emergy ratios calculation. All inputs, outputs, their quantities for a specific time interval, transformity values for each input and calculated emergy values are all listed in the table (Odum, 1996). Table 1 presents a generic emergy evaluation table. Addition of all emergy inputs gives total emergy input to the system. Division of dedicated emergy yield by the quantity of the system outputs gives the transformity value of outputs (Odum, 1996).

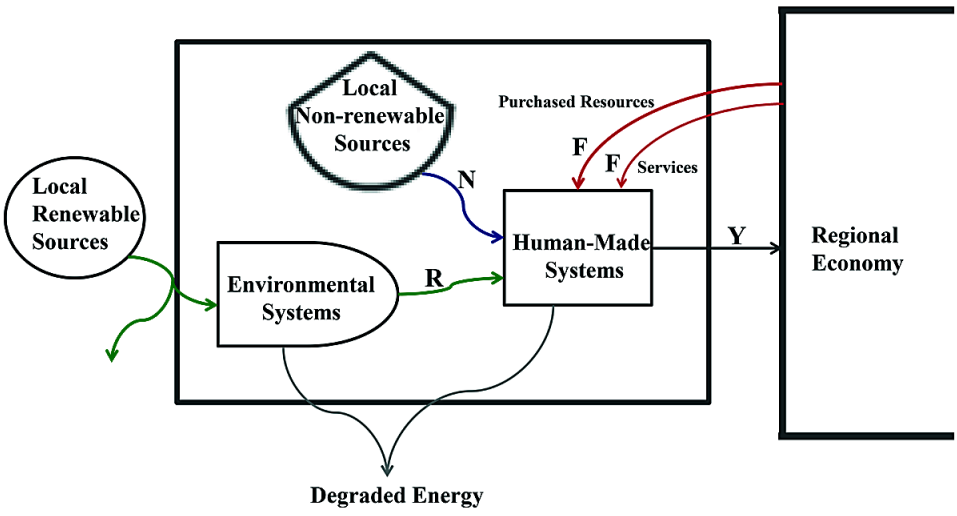
1	First item	xxxx	J/year	Xxxx	Em_1
2	Second item	xxxx	g/year	Xxxx	Em_2
…	…	…	…	…	…
n..	nth item	xxxx	J/year	Xxxx	Em_n
O	Output	xxxx	J/year or g/year	Xxxx	$\sum_{1}^{n} Emi$

Calculation of Emergy Ratios

Emergy inputs which are free and provided by nature locally are classified as renewable. Examples of renewable emergy inputs are solar radiation, wind and rain. Amounts of these renewable inputs are flow-limited and their amount cannot be increased or decreased by human intervention. Non-renewable inputs are also local resources but not necessarily free. Examples of non-renewable emergy inputs can be topsoil, ground water or minerals such as quartz. For these inputs to be non-renewable, their regeneration rate by nature should be slower than their withdrawal rate else they are classified as renewable. And, purchased or feedback emergy flows are external inputs which are neither free nor locally (within the analysis boundary) available (Ulgiati & Brown, 1998).

Emergy can connect natural systems to human created economic systems. Figure 3 summarizes classification of emergy inputs and how this translates into the interaction of natural systems with economic systems. Classification of emergy inputs enables calculation of emergy ratios. By this way, inferences about environmental performance of a human created system can be made (Ulgiati *et al.*, 2010).

Figure 3. Classification of emergy flows to a system which is the basis for calculation of emergy ratios



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Of the emergy indicators yield (Y) or total emergy input quantifies the environmental work or available energy (including the ones accumulated back in time) invested by nature to the system analyzed. The quantity of yield equals the sum of all emergy inputs to the system. Renewability (Re) represents the ratio of renewable emergy inputs in the yield. Renewable emergy is provided by natural Earth processes and is related to the carrying capacity of the surroundings within which the analyzed system exists in. For that reason, high renewability is and indicator of long term sustainability for a system (Odum, 1996). As a result, the higher the Re of a system, the more sustainable it can be. Emergy yield ratio (EYR) is an indicator of a system's ability to contribute to the economy by exploiting local resources (Ulgiati *et al.*, 2010). EYR is the ratio of yield (Y) to purchased emergy (F). In essence, it is reciprocal of economic efficiency and represents the reciprocal fraction of external (purchased) emergy within the yield. Hence, a process with higher EYR is preferred over the one with a lower EYR. Environmental loading ratio (ELR) is an indicator of stress exerted on the surroundings by the studied system due the activities performed. ELR represents the non-renewable portion of emergy input and equals the ratio of non-renewable and purchased emergy inputs to renewable inputs. A high ELR translates into a stress beyond the carrying capacity of surroundings (Odum, 1996; Paoli, Vassallo, & Fabiano, 2008; Pizzigallo *et al.*, 2008 and Ulgiati *et al.*, 2010). Hence, a system with a lower ELR is preferred over the one with a higher ELR. Ratio of ELR to EYR results in a new ratio called environmental sustainability index (ESI) which is an indicator of a high output with low environmental loading. Environmental investment ratio (EIR) expresses the ratio between local versus imported resources and is the ratio of purchased inputs (F) to renewable (R) and non-renewable (N) local inputs. Due to high dependence on external resources, a high EIR value usually indicates a fragile system (Odum, 1996, Paoli *et al.*, 2008, Ulgiati *et al*., 2010). Calculation of emergy ratios based on the classification of emergy inputs is presented mathematically in equations 1-6.

$$\text{Emergy Yield } (Y) = R + N + F \tag{1}$$

$$\text{Renewabiliy} = \frac{R}{Y} \tag{2}$$

$$\text{Emergy Yield Ratio } (EYR) = \frac{Y}{F} \tag{3}$$

$$\text{Environmental Loading Ratio } (ELR) = \frac{(N+F)}{R} \tag{4}$$

$$\text{Environmental Sustainability Index} = \frac{EYR}{ELR} \tag{5}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\text{Environmental Investment Ratio} = \frac{F}{(R+N)} \tag{6}$$

Emergy Algebra

Co-Products and Splits

"Emergy algebra" is a set of rules governing the allocation of total emergy yield to multiple outputs of a system (Brown & Herendeen, 1996). In general, allocation is avoided in emergy analysis and emergy yield is allocated to each of the co-products. Allocation in splits is performed based on the available energy contents of the splits (Hau & Bakshi, 2004a). Hence, it is necessary to define what co-products and splits are to allocate total emergy yield correctly in related analyzes.

Co-products can be defined as products that can only be produced jointly and have different properties and purposes of use (Bastionani *et al.*, 2009). Animal draft, milk and cow dung which are the outputs of husbandry sector in Rampura can be classified as co-products because these outputs cannot be produced separately and they have different functionality (purposes of use).On the other hand, splits are products of similar characteristics with similar functionality and they can be produced separately (Odum, 1996 and Bastionani *et al.*, 2009). For instance, outputs of an agricultural activity can be classified as splits since different crops can be grown independently from each other and they have similar functionality (food). Emergy yield is allocated according to the available energy content in splits.

The co-products of earth processes such as rain, wind, earth cycle are assigned all emergy yield available to earth in a year. And their transformity equals the ratio of this total emergy to their available energy content (Odum, 2000). To calculate available energy contents of some co-products of earth processes, the fundamental equations utilized are given in equations 7-9.

$$\text{Available Energy of Sun in a Year} = \text{Land Area} \times \text{Solar Irradiation} \times (1 - \text{Albedo}) \tag{7}$$

Here, albedo is the fraction of sun energy reflected back by the analyzed land area.

$$\text{Available Energy of Rain} = \text{Land Area} \times \text{Precipitation} \times \text{Density of Water} \times \text{Gibb's Free Energy of Water} \tag{8}$$

$$\text{Available Energy of Top Soil Loss} = \text{Land Area} \times \text{Energy Content of Organic Matter} \times \text{Organic Matter Percentage} \tag{9}$$

Additionally, wind energy in Rampura is 491 J/m^2 and earth cycle available energy is 1.00x 10^6 J/m^2 (DevAlt, 2011; Odum, 1996).

Rules of Emergy Algebra

Emergy algebra includes three basic rules. First rule governs the allocation of emergy yield for co-products. It is stated as follows: "All source emergy is assigned to the process outputs." This means that allocation

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

is avoided for co-products of a system (Brown & Herendeen, 1996). The second rule is about allocation of emergy yield in splits. It states that "When a pathway (co-product) splits, emergy is assigned into each leg based on its percentage of the total energy flow on the pathway." This means that allocation of emergy yield is based on the available energy content ratio of each split (Brown & Herendeen, 1996).

Figure 4 elaborates partitioning of total emergy yield among co-products and splits according to the rules of emergy algebra. Here a total emergy yield of 5000 sej is assigned to each of the co-products in a. Then, in b, 5000 sej is assigned to two co-products first. Afterwards, 5000 sej is allocated between the two splits of first co-product in a way that is directly proportional to their available energy content.

The third rule of emergy algebra is to prevent double counting and states that "Emergy cannot be counted twice within a system. Co-products, when they are reunited, cannot be added to equal to a sum greater than the source emergy from which they are derived." (Brown & Herendeen, 1996; Bastionani *et al.*, 2009). Hence emergy of splits are additive whereas emergy of co-products are not. In case of co-products the emergy of co-product with maximum magnitude is chosen to avoid double counting (Odum, 2000).

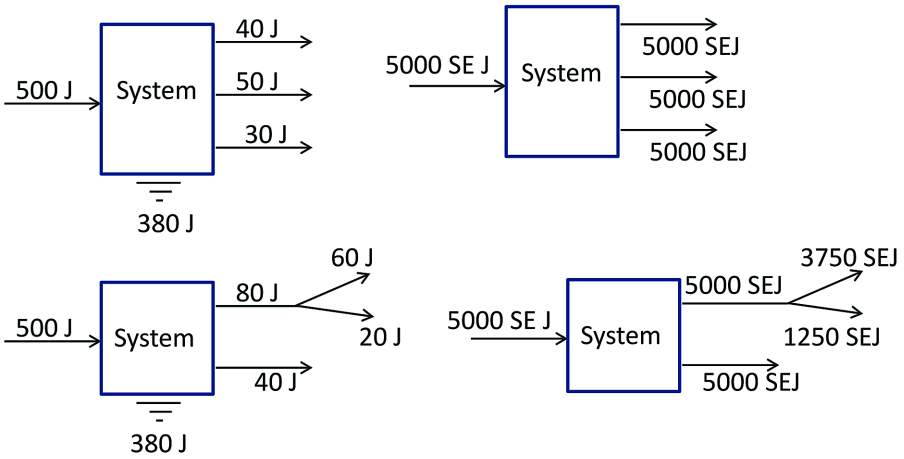
RAMPURA VILLAGE CASE STUDY

Rampura Village, Development Alternatives, and Project Preparation Process

Project Site

This case study is realized in a village named Rampura founded in Jhansi district of Uttar Pradesh, India. The reason of choosing Rampura village as project site is the successful implementation of capacity building applications as well as availability of wide range of data which improves analysis quality. Bundelkhand which also includes Rampura village is a semiarid region suffering from lack of water and prone to climate change. The area went through a 4-year-long draught making village suffer from the existing climate change problems more severely (Development Alternatives, 2011).

Figure 4. Partitioning of total emergy yield among co-products and splits



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

In Rampura village, there are 436 individuals of which 179 are males, 149 are females and the rest is children. The literacy in the village is 70% (DevAlt, 2013). Of the 69 households in the village, 44 are connected to the 8.7 kWp multi-crystalline silicon solar grid implemented by Development Alternatives (project partner) in collaboration with Scatec Solar (Scatec Solar, 2013). The houses which are connected to the solar grid utilize solar electricity for lighting and those which are not connected utilize kerosene for the same purpose. Cooking needs are supplied from wood, agricultural residues and cow dung cake. Table 2 summarizes the amount of each energy source utilized in the village annually. Of the 133.6 hectares total village area, 89 hectares are cultivable land and 68 hectares of cultivable land is irrigated. In the village there is no dedicated grazing land or reserve forest. According to the season, non-irrigated land is utilized as grazing land.

The main income generating activities in the village are agriculture and animal husbandry. The main crops grown are wheat, pulses, groundnut, mustard and different vegetables. The annual amounts of each product grown are given in table 3[1]. There are 117 buffalos, 45 bullocks, 55 cows, 36 calves and 155 goats in the village totally. Bullocks and sometimes buffalos are utilized as draft animals. Cows, goats and buffalos produce milk. While goats open graze and are not fed fodder, other animals are fed fodder consisting mainly of wheat straw. Vegetables and milk are the items for liquid cash flow within the year.

Table 2. Annual energy use in Rampura Village

Energy Use in Rampura	Amount/Year
Electricity (kWh)	6935
Kerosene (liter)	1278
Wood (kg)	355875
Agricultural Residues (kg)	100375
Dung Cake (kg)	189800

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Project Partner

The project partner for Rampura Case study is Development Alternatives (DA), a local non- governmental organization (NGO). Development Alternatives works in the area of sustainable development, and capacity building of rural people to improve their income generation capabilities (DevAlt, 2013). Its technology disseminating branch TARA (Technology and Action for Rural Advancement) has been working in the Bundelkhand region of Central India for over 10 years (TARA, 2013). In Rampura study, the role of DA is to participate in preparation of village surveys to have household level data and provide cumulative village level data.

DA has a campus (Orchha) in Tikamgarh district of Madhya Pradesh where they empower local communities by increasing their capabilities in value creation activities. For instance, local women produce paper souvenirs from waste fabric or peanuts grown in the region are peeled off and packed to be sold at a higher price in the market. People are trained by DA for these activities first and machinery needed is rented also by DA to the locals. The Pahuj campus of DA in Uttar Pradesh offers agricultural and societal networking solutions for sustainable development. Agrarian communities are trained for effective water use and innovative agricultural practices. Trainings on roof-top rain water, underground water harvesting, seed germination in trays to obtain seedlings and to increase yield takes place on this campus. Shri Ram Raja Gaushala is a cowshed founded near Orchha campus of DA. Here, biogas electricity generated from cow dung is utilized for value creation activities and cowshed is mainly operated by local women with minor support from DA (DevAlt, 2011).

Preparation Process

The first step of preparation was to prepare a survey to be applied to the villagers in Rampura. Questions related to social status, amount of land area owned, types of crops they grow, irrigation, pesticide and fertilizer usage, number and types of livestock owned, what fraction of the crops and animal products they sell at the market, how they transport their products to the market and means of transportation were asked in the survey. Following survey preparation, these questions are asked to households from different economic status. Surveys provided the household level data. Additional data such as irrigation patterns for different crops, crop to residue information, available local resource information were provided by DA. Raw data obtained from surveys and DA were then processed to define village system and subsystems and form the energy systems diagrams.

Characteristics of Village System and Energy Systems Diagramming

In Rampura village, there are three subsystems interacting, systems that exchange materials and energy among themselves. These subsystems are animal husbandry, agriculture sectors and human ecosystem or domestic sector. Human ecosystem provides the labor needed in husbandry for the animals to be fed, barns to be cleaned etc. In agriculture, labor is needed to manage animals or tractors for fields to be ploughed, to apply fertilizers and pesticides and to harvest the crops. Husbandry sector provides the animal draft for the fields to be ploughed and manure as fertilizer. Milk produced by cows, buffalos and goats is an important nutrition source for the people in the village. Furthermore, cow dung dried under the sun is an important energy source for cooking activities. Around 40% of the agricultural residues are fed to cows as fodder and around 34 % of agricultural residues are used for cooking purposes by people

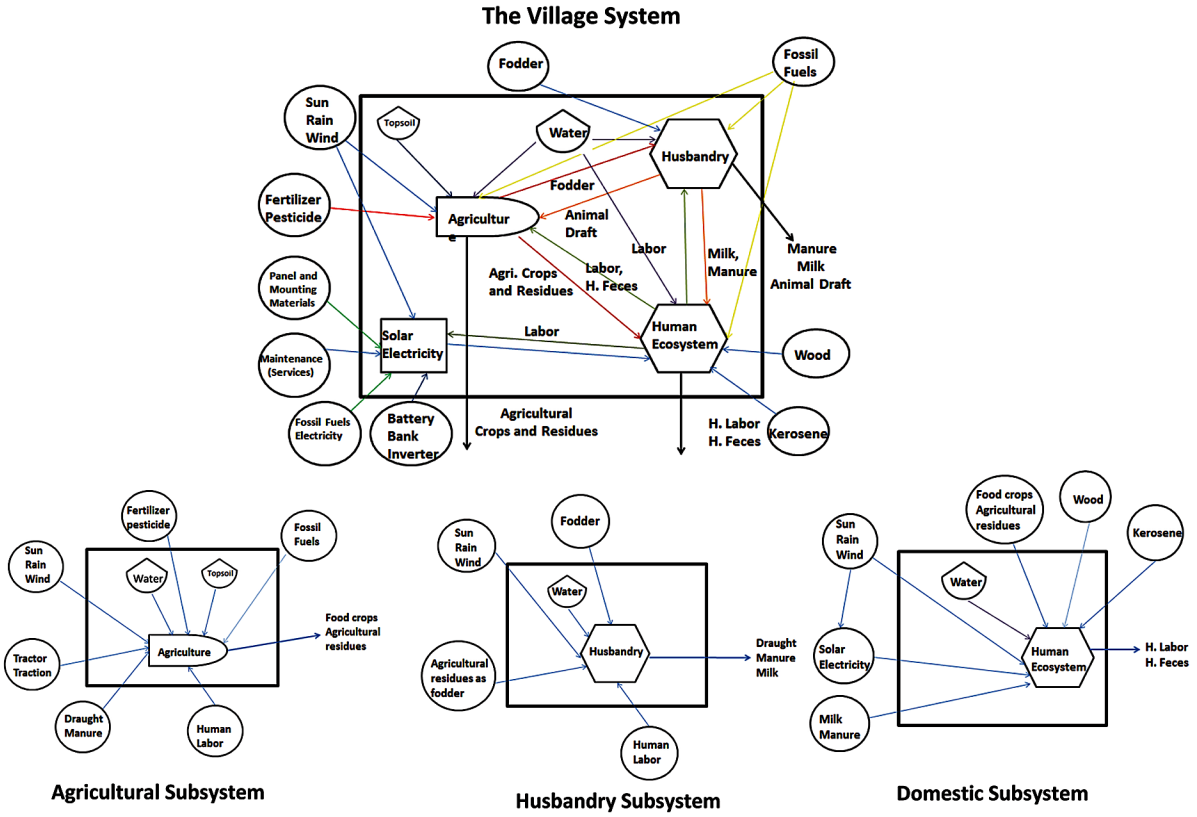
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the village. Since emergy analysis is an input-output analysis method, only external inputs to the village and outputs from the village are taken into account for village level emergy analysis (Odum, 1996; Ulgiati & Brown, 1998). Interactions among three subsystems within the village boundary have not been considered at this level. However, the interactions among subsystems determine the need for external inputs. If agricultural residues were not used as fodder, more fodder would be purchased from the market for animals; or if cow dung was not used for cooking, another energy source would be needed. Figure 5 presents village level and subsystem level energy systems diagrams drawn for the systems analyzed. Given the influence of internal interactions (among subsystems) within the village on overall village system, the three subsystems are also analyzed separately to understand their relative sustainability and their individual effects on the overall village system.

Classification of Emergy Inputs and Emergy Evaluation Tables

At the village level, inputs provided locally and freely by nature such as sun, rain and wind are classified as renewable. The external inputs, fossil fuels, fertilizer, pesticide, inputs related to the solar panel in the village, purchased fodder for animals, kerosene used for lighting, which are neither free nor locally available, are the purchased external inputs contributing to the overall village system. Wood, ground water and soil erosion (topsoil loss), which are utilized faster than their renewal rate by nature, are the local non-renewable emergy inputs contributing to this system.

Figure 5. Energy systems diagram for Rampura village and village subsystems



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Of the three interacting subsystems of Rampura, husbandry sector provides animal draft, manure and milk outputs. Agricultural crops and residues are the outputs from agriculture. Human ecosystem outputs are human labor and feces. There is an important point to be emphasized for the village level analysis. The output quantities stated are the net amounts coming out of the village analysis boundary. For example, the value given for agricultural residues is equal to total residues minus the residues utilized in domestic and husbandry sectors.

Table 4 presents the emergy evaluation for village level emergy analysis of Rampura. In the last column of this table, references for transformity values utilized are given. As can be seen from the table, the largest emergy input to the village is fodder input for animals followed by ground water. There is an upper and lower limit for total yield calculated originating from topsoil loss and tractor traction. Topsoil loss for this area is taken as 5-10 tonnes/ha/year (Yedla & Peddi, 2003) and there is a range for diesel use per season utilized by farmers of Rampura to plough their fields and transport their crops to the market.

Table 4. Emergy evaluation table for village level emergy analysis of Rampura

Inputs	Amount	Unit	Transformity (Sej/Unit)	Emergy (Sej/ Year)	Reference
Sun(land)(100% R)	1.86E+15	J	1	1.86E+15	Odum,2000

Manure		1.34E+09		7.08E+12	

The first subsystem analyzed is the husbandry sector. In this subsystem sun, rain and wind are the locally available renewable emergy inputs. Groundwater is the local non-renewable input since underground water level in Rampura has been declining. Human labor is categorized as 20 % renewable and 80 % purchased of which calculation is presented in human ecosystem emergy analysis. Likewise, agricultural residues are 20 % renewable and 80% purchased inputs of which calculation is presented in agricultural sector emergy analysis. As in case of village level emergy analysis, fodder purchased and gasoline used for the transportation of milk to market are classified as purchased inputs contributing to husbandry sector.

Animal draft, manure and milk are the products (outputs) obtained from the husbandry sector. These outputs are co-products which cannot be produced independently. For that reason, the total emergy yield is assigned to all products without allocation according to the emergy algebra rules (Odum, 1996 and Bastianoni *et al.*, 2009). And, product transformities are calculated by division of total emergy yield by product's available energy (exergy) or product's mass. Emergy evaluation table for husbandry sector that is presented in Table 5 shows the emergy flows calculated for all these inputs. References from which

transformity values for each input obtained are listed in the last column of the table. Fodder is the largest emergy input to the husbandry sector followed by agricultural residues used as fodder.

The second subsystem, agricultural sector, provides food, agricultural residue to be used as fuel for cooking to the people of Rampura and provides around 10% of the fodder that animals consume. Some of the agricultural products are consumed by villagers and the remaining are sold at the market in Jhansi. At this subsystem, ground water and topsoil are non-renewable inputs to agriculture since they are utilized faster than they are replenished by nature. Sun, wind and rain are renewable inputs. Fertilizer, pesticide, fossil fuel (diesel) used for irrigation and tractor traction (diesel) are imported purchased inputs contributing to the subsystem. As in husbandry sector, human labor is 20% renewable and 80 % purchased. Animal draft from husbandry sector is 10 % renewable and 90 % purchased. For emergy analysis, emergy flow related to each input is calculated.

Table 6 is the emergy evaluation table for agricultural sector of Rampura. Human labor and animal draft are the largest emergy inputs to the agricultural system. Groundwater and rain are also important emergy inputs. In Rampura, agriculture is not highly mechanized as can be inferred from the contribution of tractor traction to the total emergy yield. Outputs of agricultural sector (food crops and agricultural residues) are classified as splits since they can be produced independently and serve to meet similar purposes (Bastionani et al., 2009). According to the emergy algebra rules, the total emergy of a system is allocated among splits according to their available energy (exergy) content. Based on the ranges for tractor traction diesel use and topsoil loss, there is an upper and lower range for total emergy yield calculated. Consequently, upper and lower transformity values for outputs are calculated.

The last subsystem, domestic sector, provides the human labor required in husbandry and agricultural sectors. Human feces can also be a source of organic fertilizer despite not being utilized in the village currently. Food crops and agricultural residues are 20% renewable, 80 % purchased emergy inputs to domestic sector classified according to the analysis results of agricultural sector. Milk and manure are 10% renewable, 90% purchased inputs classified similarly according to the analysis results of husbandry sector. Wood and groundwater are non-renewable local inputs which are utilized faster than their replenishment rate by nature. Sun, rain and wind are local renewable inputs. Lastly, kerosene and inputs for solar electricity are purchased emergy inputs contributing to domestic sector.

As in the other subsystems of Rampura village, emergy flow belonging to each emergy input is calculated. Table 7 is the emergy evaluation table for domestic sector presenting the values for each emergy flow related to each input and the references for related transformity values. Here, emergy flow

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Emergy evaluation table for domestic sector in Rampura

Milk(10%R,90%F)	6.20E+07	g	1.40E+10	8.74E+17	Self-Calculation
			Total	**1.71E+18**	
Outputs					
Human Labor	1.25E+12	J	1.37E+06	1.71E+18	
Human Feces	3.13E+11	J	5.46E+06	1.71E+18	

belonging to each emergy input is calculated. Cow dung and milk are two co-products of husbandry sector contributing to domestic sector. According to the emergy algebra rules, emergy flows for co-products cannot be added but the emergy flow having the maximum value is picked (Odum, 1996; Basianoni *et al*., 2009). For that reason, emergy flow of milk is accounted for in emergy evaluation. On the other hand, food crops and agricultural residues are the products of agricultural sector. However, their emergy flows can be added up since they are splits not co-products (Bastianoni *et al*., 2009). The largest emergy input to domestic sector is milk, almost containing 50% of total emergy inputs followed by wood and agricultural residues utilized for cooking purposes. Rain and food crops are other significant emergy inputs to domestic sector.

Emergy Indicators

After quantification emergy flows at the village and subsystem levels; renewable, non-renewable and purchased emergy flows are calculated for each system. Then, emergy ratios (renewability, EYR, ESI, ELR and EIR) for each system are calculated to evaluate individual and relative sustainability of these systems.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Fodder is the main driver affecting emergy ratios in all systems directly or indirectly. In overall village system and husbandry sector, fodder constitutes 70% and 75% of all emergy inputs as a direct input. Although fodder is not a direct input to the agricultural system, renewability of fodder affects the renewability of animal draft. When fodder is 20% renewable, animal draft becomes 25% renewable. When fodder is 40% renewable, animal draft becomes 40% renewable. Fodder is not a direct input to domestic sector, however renewability of fodder affects the renewability of milk directly and the renewability of the agricultural residues indirectly. When fodder is 20% renewable, milk becomes 25% renewable and agricultural residues become 26% renewable. When fodder is 40% renewable, milk is 40 % renewable and agricultural residues are 30% renewable. Characteristically, fodder purchased from the market in Rampura is mainly wheat straw which is also an agricultural residue. As it can also be seen from agricultural sector emergy analysis, there are renewable (rain, sun, wind) or partially renewable (human labor, animal draft) inputs for production of agricultural outputs. For that reason, fodder cannot be classified as 100% purchased despite being an imported input. A sensitivity analysis is performed to detect the effects of changes in renewability of fodder on the overall village system and subsystem emergy ratios considering fodder as 100% F, 20% Re-80 % F and 40 % Re-60 % F.

Figure 6 shows the renewability, EYR and ESI values for the village and subsystems analyzed. For these indicators, the higher the value of the indicator the better sustainability becomes. Bar graphs show the case where fodder is 20 % Re-80 % F. Top of error bars represent the values of emergy ratios for the case where fodder is 40 % Re-60 % F whereas the bottom of bar graphs represents the case that fodder is 100 % F. Figure 7 shows ELR and EIR values for the village and subsystems. For these indicators, the lower the value of indicator the better sustainability becomes. In figure 7, bar graphs also show the case where fodder is 20 % Re-80 % F. However, top of error bars represents the values of emergy ratios for the case where fodder is 100 % F whereas the bottom of bar graphs represents the case that fodder is 40 % Re-60 % F.

Based on these considerations, the village has low renewability (0.05), an EYR a little higher than 1 due to the dominance of purchased inputs (mainly fodder) contributing to the system at the base case (fodder 100% F). Similarly, village system has high environmental loading ratio (ELR) and environmental investment ratio (EIR) again due to the high fraction of purchased external inputs in the total emergy yield. Environmental sustainability index (ESI) which is the ratio of EYR to ELR is much lower than 1 because of low EYR and high ELR values at the base case (fodder 100 % F). As renewable fraction of fodder emergy increases, system renewability (0.2) and EYR increases significantly. Accordingly, ELR and EIR ratios decrease. With increasing EYR and declining ELR, ESI increases considerably. From these results it can be concluded that fodder purchase should be limited and fodder should be grown in more renewable ways in the village as a local resource to improve the overall sustainability.

In husbandry sector, renewability and EYR of the husbandry subsystem also increase as the renewable fraction of fodder increases. In other words, as the fraction of purchased input flows decrease Re and EYR increase. Despite being lower than village level, husbandry sector has also high ELR value decreasing with increasing fodder renewability. Husbandry EIR is higher than village level EIR mainly due to the higher fraction of purchased fodder and lower fraction of local non-renewable inputs in the total emergy yield. As ELR, EIR also reduces with increasing fodder renewability. ESI increases due to increasing EYR and decreasing ELR values. These results also support the conclusion that fodder should be grown in more renewable ways in the village as a local resource.

At the base case (fodder 100 % F), agriculture in Rampura is more renewable than the village and the husbandry sector. This situation is due to higher portion of renewable emergy flows contributing

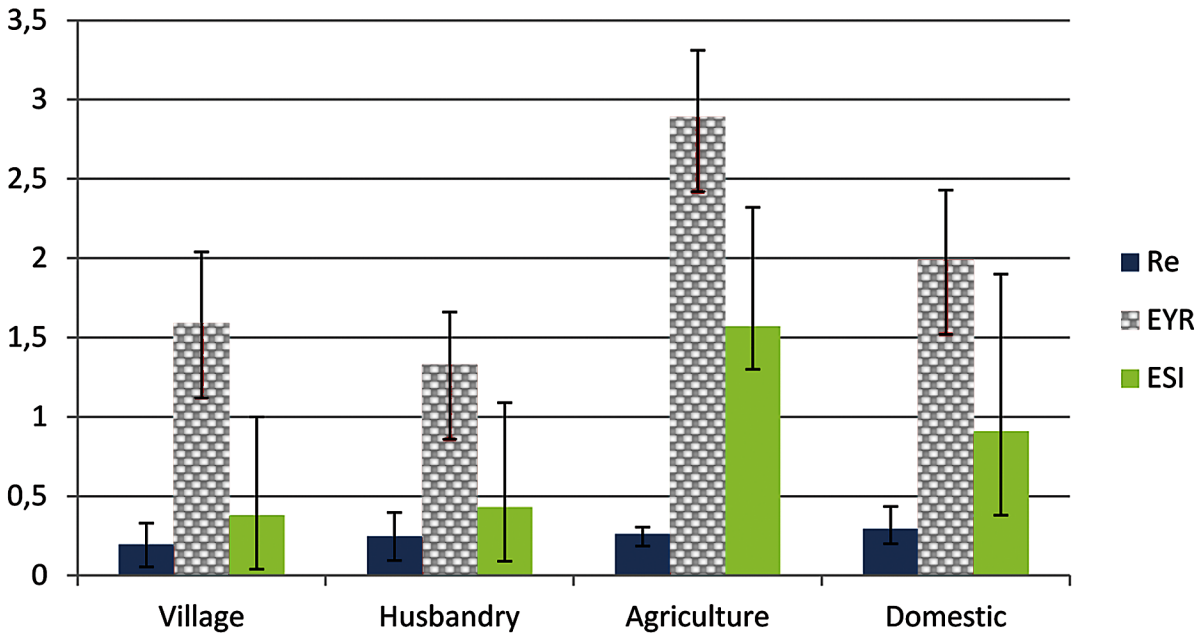
EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

to the agricultural system. Based on the same reason, agricultural system has higher EYR and lower ELR than the other two systems. Furthermore, agricultural system EIR is lower than husbandry and village level EIR values. Consequently, the agricultural sector is more sustainable (higher ESI) than the husbandry sector and the overall village system when fodder is considered 100 % F. As in husbandry sector, increase in renewability of fodder increases agricultural system renewability and EYR. System ELR and EIR reduces. As a consequence of increased EYR and reduced ELR, system ESI increases indicating an improvement in overall system sustainability for agriculture. Furthermore, decreasing fertilizer and pesticide and fossil fuel usage can improve agricultural sector self-sufficiency consequently sustainability further.

Domestic sector obtains inputs from both husbandry and agricultural sectors. Many of the emergy indicators have values between husbandry and agricultural sectors at the base case. As in husbandry and agricultural sectors, increase in renewability of fodder increases domestic sector renewability and EYR. System ELR and EIR reduces as a result of reduced fraction of purchased and increased fraction of renewable emergy inputs. As a consequence of increased EYR and reduced ELR, system ESI increases indicating an improvement in domestic sector sustainability. Due to dual dependence of domestic sector, interventions increasing sustainability of husbandry and agricultural sectors can also improve domestic sector sustainability.

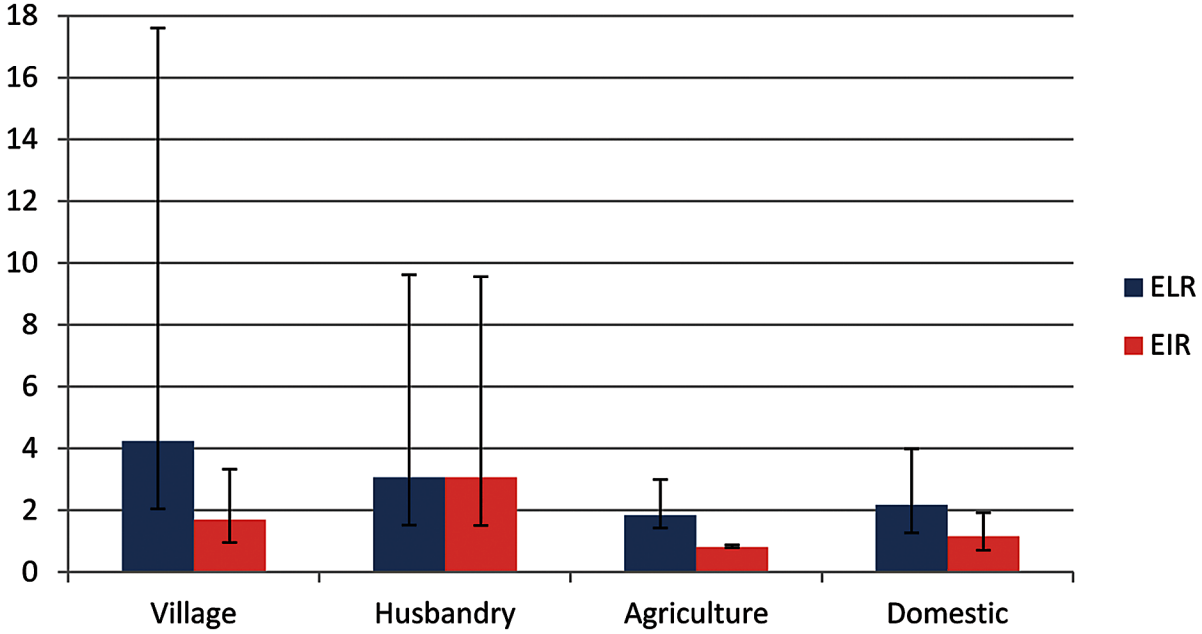
A sustainability assessment study is performed on three Chinese villages by Yong, Andreas and Guojie (2009). This study also yields similar results (low renewability, EYR and high ELR) for the analyzed Chinese villages as found for Rampura village indicating high reliance on non-renewable external inputs. Even at village level, sustainability is not achieved in these developing countries. However, if the renew-

Figure 6. Renewability, EYR, and ESI results for the overall village system and the three subsystems analyzed



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. ELR and EIR results for the overall village system and the three subsystems analyzed



able local resources are utilized effectively within the carrying capacity of these regions, dependence on external resources can be reduced also increasing the self-sufficiency and sustainability. Ways of improving sustainability by relying on local resources and less consumptive life styles are well presented in a study by Levine, Hughes, Mather and Yanarella (2008). In their study, Levine *et al.* (2008) interpret how life styles in traditional Chinese villages can be adapted to modern life and they point out how this low consumptive, high productive life style can lead to development of sustainable towns.

FUTURE RESEARCH DIRECTIONS

Emergy analysis is a nature oriented or donor-side thermodynamic analysis technique. It can evaluate natural capital which includes sources whose role is not captured in market prices. Like other methods for analyzing large systems, emergy analysis also faces problems of reproducibility. To improve emergy analysis in terms of accuracy and reproducibility of results, there are attempts to integrate emergy analysis within life cycle assessment (LCA) framework and harmonize their calculation techniques (Marvuglia *et al.*, 2013; Rugani & Benetto, 2012). In our opinion, standardization of emergy analysis through a robust framework construction will be the trend for methodological research related to emergy in the future. Additionally, emergy analysis does not evaluate carrying capacity of a region despite evaluating natural value of resources. Developing analysis techniques which can account for the carrying capacity of a region and integrating them with emergy are important steps to be taken in the future.

CONCLUSION

Today, Earth is in a transitional state in which the resources that can be provided by the planet become the limiting factor for human activities rather than money or work force. This can transform planetary support mechanisms irreversibly and reduce their ability to support human activities. In that regard, analyzing the interaction of natural and anthropogenic systems is crucial in order to cease further deterioration and start restoration of natural capital. In analyzing the interaction between natural and human-dominated systems, emergy analysis can be an effective tool. While emergy can be used to evaluate many forms of human-nature interactions, utilizing emergy analysis in evaluation of sustainability of a region enables quantification of environmental work invested in activities taking place in the area and also the interaction and dependence of these activities to each other. In this work, Rampura Village case study is presented to demonstrate applicability of emergy analysis in regional sustainability assessment.

At the overall village level, emergy analysis results show that the village is not self-sufficient and is highly dependent on non-renewable external material and energy inputs. Of the three subsystems interacting in Rampura, husbandry sector has the lowest renewability, EYR, ESI and the highest ELR, EIR values while agricultural sector has highest renewability, EYR, ESI and lowest ELR and EIR. This reveals that the husbandry sector is the subsystem that contributes most to the detected unsustainability in Rampura.

When the subsystem level emergy results are examined in detail, it is seen that the largest emergy input is purchased fodder for feeding animals in husbandry sector followed by agricultural residues of crops grown in the village and fed as fodder to animals. In emergy analysis of agricultural sector, renewability of agricultural residues is found to be around 20%. If renewability of fodder is considered as 20%, renewability of animal power and husbandry products becomes 25%. 75 % of emergy inputs to the sector come from purchased external and non-renewable inputs. Even when fodder is considered as 20% renewable, husbandry sector has high ELR (3.06) and low EYR (1.33) and ESI (0.43) values. If fodder were considered 100% purchased, these indicators would be worse.

In agricultural sector, human labor and animal draft are the largest emergy inputs; renewability of animal draft input depends on fodder renewability. As a result, agricultural products and residues have a renewability of 26% when fodder is accounted as 20% renewable. Agricultural system has better emergy indicators (higher %Re, EYR, and ESI, lower ELR) than the husbandry sector due to higher share of renewable inputs. However, agricultural system in Rampura is also not a self-sufficient system which is dependent on non- renewable external inputs such as fertilizer, pesticide and fossil fuels.

Domestic sector in Rampura benefits both from agricultural and husbandry sectors by providing human labor in exchange. Agricultural sector provides food and energy resources (agricultural residues) to this subsystem and husbandry sector provides cow dung and milk. Renewability of fodder indirectly affects the renewability of products of the domestic sector. When fodder is considered as 20% renewable, the renewability of human labor in Rampura becomes 30%. Domestic sector has more favorable emergy indicators than the husbandry sector, however, this subsystem is also not self-sufficient or sustainable.

Overall, these results indicate that Rampura village is not a self-sufficient, sustainable system. To improve the sustainability in Rampura, dependency on purchased inputs fodder, fertilizer and diesel and non-renewable cooking fuel wood should be reduced. But, mainly fodder should be grown in more renewable ways in the village as a local resource. This assessment also demonstrates the applicability of emergy analysis as a successful regional sustainability assessment tool.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, study results about the state of sustainability in Rampura are compatible with the results found for Chinese villages. Even at village level, sustainability is not achieved in these developing countries. However, if the renewable local resources are utilized effectively within the carrying capacity of these regions, dependence on external resources can be reduced also increasing the self-sufficiency and sustainability. Designing sustainable human systems necessitates consideration of social, economic and environmental aspects simultaneously. Besides, these systems must be in harmony with biosphere they exist in (Griggs *et al.*, 2013; Martin *et al.*, 2010). Hence, conscious consumption patterns relying on renewable resources within the carrying capacity of the planet can lead to the achievement of global sustainability (Kurşun *et al.*, 2015).

Chapter 26
Environmental Audit in Integrated Audit System

ABSTRACT

The niche of a narrow literature in the field inspires the core objective of this chapter which is to develop a coherent and eco-efficient outline for environmental audit in an integrated audit management system. The research paradigm is based on the stakeholder theory refined with Hart's vision of the entity based on natural resources in order to recognize the natural environment as the main stakeholder of any entity. The revision of the literature enables ascertaining the determining factors for an environmental audit integrated in the audit management system. The result is built on the management component of the continuous improvement and creates knowledge for a way of action to implement an environmental management system and environmental auditing and implicitly, to react to social corporate responsibility. Future researches regard the increase the auditor's role in integrating various areas of the sustainability reports.

INTRODUCTION

Placed in the context of stakeholder theory, the main objective of this chapter is to develop a coherent and eco-efficient framework for environmental audit in an integrated audit management system. The starting point is the normative-managerial approach of the theory, offered and argued by Donaldson and Preston (1995). The normative approach involves using of accepted concepts and theories in the

field, to substantiate the structures, attitudes and management practices designed to equally consider and meet the interests of all stakeholder groups. Gomes and Gomes (2007) believe that stakeholder theory is opposable to the understanding of the influences that an entity has and perceives, as a member of the community and environment in which it operates. In this context, the authors consider stakeholder theory to be the theoretical alternative to the junction between the resource dependence theory and the institutional theory, with the entity's social and cultural compliance under the environmental pressures as a central point (Scott, 1998). The foundation of resource dependence theory is the existence of relationships between the entity and the specialized environment in which it operates (Orrù, Biggart, & Hamilton, 1991). Like Jacobs (1997), Phillips and Reichart (2000) or Haigh and Griffiths (2009), this discourse recognizes the natural environment as the main stakeholder of any entity. The environment influences the entity performance and is directly affected by the entity activities. From this perspective, the vision of the entity based on natural resources developed by Hart (1995) is the theoretical paradigm complementary to stakeholder theory, which offers the same challenge for environmental audit as part of an integrated audit management system.

The sovereign opinion on the entity activities is assumed by the auditing process used to improve its functionality in a large variety of fields (Jasch, 2000) and to transfer information between non competing entities (Ammenberg & Sundin, 2005). The audit process is influenced by the attitudes and beliefs of each individual/group, which are parts of the ethical environment organization (Meyers, 2004; Martinov-Bennie & Pflugrath, 2009), and it is a tool of management control (Verschoor & Reijnders, 2001, cited in Mironeasa & Codina, 2013). Improving functionality in miscellaneous turfs, audits generate benefits in a variety of the environmental aspects dimensions. First, audits should decrease costs, especially, the costs of compliance with any effluent limit imposed by the relevant environmental protection agency. For instance, audits should offer information relating to the most cost-effectively set up to better control the pollution. Second, audits should increase the social responsibility promoting a "green" image. Third, audits may generate other regulatory and non-regulatory benefits; for instance, if the regulator body knows the audit engagements then, these engagements may generate goodwill that might increase the awareness of the authorities on the future potential issues (Earnhart & Leonard, 2013).

The current chapter aims to contribute to the literature from the perspective of the effects and actions need to adapt to the climate change, as a substantiation to assess the current level of environmental management and to identify environmental and social elements that are relevant for entities to include in their corporative management. Achieving the objective, has determined, in the first section of the research work, the description of the scientific context by developing the concept of adaptation to global climate change and multiple perspectives identified in approaching the concept, both in the literature and international regulators. Next section discusses the environmental audits in the context of an integrated audit system as the European Union Eco-Management and Audit Scheme (EMAS), which requires assessing the current degree of environmental management implementation. The following section completes this picture with a managerial approach on environmental audit to create a coherent framework for an eco-efficient corporative management. Finally, there are presented the future research directions and conclusions of the debate conducted along the chapter.

DETERMINANTS AND THEORETICAL GROUNDWORK

The context of sustainable development is strongly influenced by current global climate changes. The extent and intensity of environmental impacts caused international, national, regional, local, and individual positions and actions (in terms of individuals and economic entities). In a broader sense, climate change is understood as any form of climate deviation that has no physical cause and is not statistical in nature. The causes of this complex phenomenon are *natural* (changes in solar activity, long-term alterations of the Earth's orbit, internal natural processes of the climate system) and *anthropological* (the increase in carbon dioxide and other greenhouse gases atmospheric concentration). In a narrow sense, climate change indicates significant alterations of climatological elements during a given period, entailing economic, social and environmental consequences. Climate change is an environmental problem leading to risks in the development process (European Commission [EC], 2009). Food crisis, water shortage, spread of diseases in new areas, damage caused by floods, the labor migration forced by the desertification of farmlands and the rising sea and ocean levels are only few effects of climate change that all countries must recognize.

The perspective of the planetary history explains and refines the understanding of the problem. Effects such as global warming have been offset by stimulating the development of new species that have found favorable conditions for life and multiplied explosively in the absence of competition, recreating an atmosphere with less carbon. Therefore, the answer is primarily provided by nature instead of technology or policy, and has as a result the disappearance of some species and the emergence of others. This is already perceived as a risk: dozens of species disappear each day, and biotechnologies based on cultures of microorganisms having a versatile enough behavior to meet technological needs/purposes are able, at least in theory, to generate global epidemics, leaving the nature as the sole regulating factor of the climate change. Nowadays, the danger of climate change must be approached not only from an ecological, but as well as from social and economic perspectives.

Adaptation to Climate Change: Concepts and Perspectives

In the Fifth Assessment Report (AR5) released by the Intergovernmental Panel on Climate Change [IPCC], (2014), strategies to reduce the risks of climate change impacts over different periods are mitigation and adaptation. If mitigation addresses the latter decades of the 21st century and beyond, adaptation ensures the ways to deal with current risks inferring to the emerging ones. The two fundamental choices in response to risks caused by anthropogenic climate change were earlier discussed in Füssel and Klein (2005). In *Table 1* the authors of this chapter present an adapted view of the two strategies addressing climate change.

Currently, adaptation to climate change has become a pervasive topic in public debates on environmental policies. Detailed and regionalized cost estimates, as a basis for cost-benefit analyses, are rare (Osberghaus & Reif, 2010). Accounting, as a communication and managerial tool, is expected to provide a comprehensive account of resource consumption and its effects; audit has to provide an independent opinion on those aspects. However, in terms of *natural* resources and regeneration of natural resources, the following question arises: Can one speak-on the correct application of the comprehensiveness principle? Gray and Bebbington (2000) raise the problem of a fundamental conflict between the main objective of a business (profit) and environmental protection, especially from the perspective of sustainable

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Mitigation vs. adaptation to climate change

	Mitigation of climate change	Adaptation to climate change
Benefited systems	All systems	Selected systems
Scale of effect	Global	Local to regional
Life time	Centuries	Years to centuries
Lead time Decades	Decades	Immediate to decades
Effectiveness	Certain	Generally less certain
Ancillary benefits	Sometimes	Mostly
Polluter pays	Typically yes	Not necessarily
Payer benefits	Only little	Almost fully
Monitoring	Relatively easy	More difficult
Responsibility	Unidentified	Specialized organizations (e.g., IPCC) and entities
Research	Exact sciences	Post-normal sciences

development goals. In addition, Ngwakwe (2012) highlights, the lack of a current accounting alternative to communicate corporate sustainability information.

Adapting to climate change is an intensely debated issue in the literature. This assessment is based on the conceptual approach provided in *Table 2*.

Academia was the first in addressing this issue and leading the way towards institutional efforts and specialized regulations. *Table 3* presents the concept of adaptation to climate change, as defined by specialized organizations.

The negative impact of climate change, including climate variability and extreme weather events on natural and anthropic systems determines the degree of system vulnerability. Watson et al., (1996) believe that vulnerability depends not only on the system sensitivity, but also on its adaptive capacity when confronted with new climate conditions. The instruments, resources and institutional structures needed to effectively implement the measures for adaptation constitute the *adaptive capacity*, which is enhanced by an adaptive management system oriented towards the sustainable performance: economic, social and environmental performance. A successful adaptation depends on technological advancements, institutional commitments, financing availability, and the willingness to communicate (Watson et al., 1996). The disastrous effects, the greater risks and the difficulties in coping with climate change impacts convince Wise, Fazey, Stafford Smith, Park, Eakin, Archer Van Garderen and Campbell (2014, p. 332) to assert the *adaptation science,* designed to be more effective and influential for decision-making process and for managing the existing complex socio-ecological systems.

Stakeholders and Externalities and Environmental Audit

Stakeholders can be defined as "any group or individual who can affect or is affected by the achievement of the firm's objectives" (Freeman, 1984, p. 46). In support of this concept, Freeman (1984) refines the idea that entities produce externalities that affect several internal or external sectors of an organization.

Externalities often motivate stakeholders to increase their influence over the organizations, in order to reduce the negative impacts in favor of positive ones. The stakeholder theory, initially formulated by

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Adaptation to climate change – conceptual approach

Source	Concepts
Burton, 1992, cited in Smit, Burton, Klein and Street, (1999, p. 203)	*Societal adaptation to climate* is "the process through which people reduce the adverse effects of climate on their health and well-being, and take advantage of the opportunities that their climatic environment provides".
Smit, 1993, cited in Smit et al., 1999, p. 203	*Adaptation* involves "adjustments to enhance the viability of social and economic activities and reduce their vulnerability climate, including its current variability and extreme events as well as longer term climate change".
Stakhiv, 1993 cited in Smit et al., 1999, p. 203	*Adaptation* means "any adjustment, whether passive, reactive or anticipatory, that is proposed as a means for ameliorating the anticipated adverse consequences associated with climate change".
Smith, Ragland, & Pitts, 1996 cited in Smit et al., 1999, p. 203	*Adaptation to climate change* includes all adjustments in behaviour or economic structure that reduce the vulnerability of society to changes in the climate system.
Watson, Zinyowera, & Moss, 1996 cited in Smit et al., 1999, p. 203	*Adaptability* refers to "the degree to which adjustments are possible in practices, processes, or structures of systems to projected or actual changes of climate".
Tol, Fankhauser, and Smith, 1998	Adaptation is considered in a balanced context, seen as a change not static but a dynamic response to continuous climate change. This will in turn help to determine the optimal control level of greenhouse gas emissions, and optimal government policies to adapt to climate change.
Smit, Burton, Klein and Wandel 2000	Adaptation to climate stimuli includes the ability to adapt through feedback to extreme events, to yearly climate variability and long-term changes in the mean conditions, both individually and in interdependence.
Füssel and Klein, 2005	Adaptation primarily aims at moderating the adverse effects of unavoided climate change through a wide range of actions that are targeted at the vulnerable system. (It may also include taking action to seize new opportunities brought about by climate change.)
Blanco, Alberti, Forsyth, Krizek, Rodriguez, Talen and Ellis., 2009	Adapting to climate change is somewhat similar to mitigating natural hazards, through climate change results in spatially dispersed and systemic impacts, while natural hazards are generally localized, episodic events.
Hallegatte, Lecocq and de Perthuis, 2011	Adaptation to climate change is defined as the set of organization, localization and technical changes that societies will have to implement to limit the negative effects of climate change and to maximize the beneficial ones.

Table 3. Adaptation to climate change – regulatory approach

Source	Concepts
IPCC, 2001	Adaptation refers to actions that people take in response to or in anticipation of projected or actual changes in climate, either to reduce the adverse impacts or to take advantage of opportunities offered by such changes.
EC, 2007	Adaptation aims at reducing the risk and damage from current and future harmful impacts cost-effectively or exploiting potential benefits.
IPCC, 2007	Adaptation means the adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities.

Freeman (1984), represents a corporate management and business ethics tool that allows the harmonization of an entity's interests with those of its stakeholders. Generally, there are two groups of stakeholders affecting organizations: internal and external stakeholders. The pragmatic approaches of stakeholder theory analyze what are the groups of individuals that management pays attention to (Mitchell, Agle, & Wood, 1997). According to the stakeholder theory, stakeholders are receivers and senders in rela-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion with an entity's actions, requiring a legitimate confidence in the organization. In relation with the environment, legitimacy takes the form of environmental audit, for the moment, a voluntary area for most entities. The environmental standards ISO 14000 stipulates environmental audit principles and standards for auditing environmental management systems. Compared with the entities that do not resort to environmental audit, the environmental audited organizations are associated with various degrees of stakeholders' influence perception. The environmental audit provides an entity with a better investment protection due to the auditing process that imposes compliance with procedures and systems able to support sustainable activities from the environmental management perspective (de Moor & de Beelde, 2005). Environmental audit identifies environmental problems before these escalate, diminishing the negative environmental impact, risks and remediation costs for improving external image of the entity. Therefore, organizations who use environmental audit communicate complete and reliable information to stakeholders, regarding their environmental concerns.

Internal stakeholders include management and non-management employees (Waddock & Graves, 1997) and they have a direct economic role within the organization, being typically located inside the organization (Freeman, 1984). Internal stakeholders are relevant for environmental audit because employees are the initiators of proactive activities within the entity (Daily & Huang, 2001; Hanna Newman, & Johnson, 2000; Ramus & Steger, 2000). Such initiatives are deeply rooted in the employees' specialized knowledge, organizational abilities and the way they connect with the natural environment. In this context, environmental audit used by organizations is definitely associated with the acknowledged influence of internal stakeholders.

External stakeholders have a more limited influence and control over the entity's resources (Mitchell et al., 1997; Sharma & Henriques, 2005). Nevertheless, there are certain situations where external stakeholders have the ability to regulate the entity's operation and organization (Fineman & Clarke, 1996; Freeman, 1984). Their influence and authority vary, depending on their affiliation to different interest groups:

- Stakeholders having regulatory powers (for example, syndicates or trade unions that can initiate public campaigns and protests that increase internal pressure on entities to improve sustainable performances) influence entities to apply the current environmental regulations, or threat to take legal action pursuing their own agenda (Henriques & Sadorsky, 1996). Environmental audit used by organizations is associated with the perception of the influence exercised by rules-promoting stakeholders;
- Social stakeholders are represented by interest groups in the area of environmental, community and professional organizations. They all have the capacity to influence the public opinion in favor or against an entity, influencing indirectly organizational behavior. Social stakeholders grant an entity's "social certificate" (Gunninghamn & Thornton, 2004), and can be decisive factors in its decision to resort to environmental audit;
- Stakeholders being directly or indirectly involved in satisfying customer demands (suppliers, transporters, retailers, clients themselves) ensure a positive qualitative impact on the environment by reducing the possibilities to use products that are presented as environmental-friendly, but do not meet such requirements (Green, Morton, & New, 2000).

Exploring a broader area of decision-making situations in public and private organizations in developed countries involves special attention to the information needs of stakeholders, including consumers

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Bebbington, Brown, & Frame, 2007). Stakeholder engagement to sustainable development issues is crucial to the legitimacy and quality of decisions. In order to accept the complexity of value judgments in decision-making and accountability processes, stakeholders need new experiences to interact with traditional ones in their cooperation to generate knowledge on sustainability. Ideological pluralism and value diversity are also essential to conceptualization of the sustainability and implementation of the Post-normal Sustainable Technologies (PNSTs). The value-based nature of the issues involved is expressed in a way that seeks multidimensional support offered by accounting and auditing procedures.

To conclude, one has to state that the influence exercised by internal or external stakeholders' is correlated with their interests and power over the environmental audit types. Environmental audit provides stakeholders with assurance that the audited entity complies with sustainability objectives, by minimizing negative external effects and optimizing positive effects on the natural environment (Darnall, Seol, & Sarkis, 2009).

ENVIRONMENTAL AUDIT FROM INTEGRATED AUDIT PERSPECTIVE

Globally, the concerns about sustainable development have resulted in the last decade as an exponentially increased confidence in the companies' systems for auditing environmental impact and environmental performance, creating the competitive advantage in strategic positioning. Sustainable actions involving entities give high importance to the economic, social and environmental factors in providing benefits and information to stakeholders and reflect sustainable performance. The management of sustainable performance requires a sound management framework, which links environmental and social management to the business and competitive strategy management. Furthermore, it is necessary to integrate environmental and social information with business information, reporting and auditing in order to provide a comprehensive image about the entity (Caraiani, Lungu, Dascălu, Cimpoeru, & Dinu, 2012).

An institution acknowledgement that guarantees the trusted environment responsibility effectively performed is recognized as environmental auditing. Environmental audit should diminish irregularity of information and drives to dutifully environmental responsibilities performance. This target is achieved through auditors' independent examination and evaluation of the performing status of the entrusted environment responsibility (Stafford, 2005, cited in Huang, 2011).

Issues and Controversies in Relation to the Integrated Environmental Audit

The main topic of this chapter is the audit. In order to avoid misconstructions some essential concepts are defined in *Table 4*, from the perspective of the international standards. The worldwide major designer of voluntary International Standards is the International Organization for Standardization [ISO]. For business environment, ISO International Standards are strategic gears that reduce costs by diminishing waste and errors, increase productivity, provide access to new markets, offer the same opportunities for developing countries and empower free and fair global trade. Nevertheless, literature on the integration auditing subsystems is much meager.

Bernardo, Casadesus, Stanislav Karapetrovic and Heras (2010) itemize the existence of some guidance on integrated auditing that are stated in different documents on management systems integration, such as the related ISO handbook (ISO, 2008), as well as national standards, for instance the Australian/New Zealand AS/NZS 4581: 1999 (SAI Global, 1999), the Danish DS 8001: 2005 (Dansk Standard,

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Concepts about audit as of ISO standpoint

Concepts	Definitions	ISO Source
Audit	A systematic, independent and documented process for obtaining audit evidence and evaluating it objectively to determine the extent to which audit criteria are fulfilled	**ISO 19011:2002 ISO 9000:2005**
Internal (first party) Audit	Audit is conducted by, or on behalf of, the organization itself for management review and other internal purposes, and may form the basis for an organization's declaration of conformity	
External Audit	Audit is conducted parties outside of the entity: • Second-party audit is conducted by parties having an interest in the organization, such as customers, or by other persons on their behalf; • Third-party audit is conducted by external, independent auditing organizations, such as those providing certification/registration of conformity.	
Combined Audit	Simultaneous audits of quality and environmental management systems, which are separate systems, conducted by separate audit teams, under separate management.	**ISO 19011:2002**
Joint Audit	Audit conduct by two or more auditing organizations cooperate to audit a single auditee	
Integrated Audit System	Full audit integration necessitates the establishment of a single audit system across all functions and hence a complete amalgamation of all cross-functional goals, processes and resources.	Karapetrovic and Willborn, 1998; Karapetrovic, 2002, 2003. **No ISO source**

2005), the Spanish UNE 66177: 2005 (AENOR, 2005), and the British PAS 99: 2006 (British Standards Institution, 2006).

Integrated audit system needs the involving of all the components amid cross-functional audits, like quality, environmental and safety management system audits. However, practically, the integration of quality, environmental, safety and other kinds of management systems audits can be reduced to involve the sharing of a selected number of the aforementioned components among cross-functional audits (Karapetrovic, Casadesus, & Heras, 2006).

Literature on the integration auditing subsystems is much meager and unfortunately, empirical researches on the integration of audits or integration of management systems are few. In order to be concise the authors of this chapter have summarized some of empirical investigation and their main topics in the *Table 5*.

The worldwide major designer of voluntary International Standards is the International Organization for Standardization [ISO]. For business environment, ISO International Standards are strategic gears that reduce costs by diminishing waste and errors, increase productivity, provide access to new markets, offer the same opportunities for developing countries and empower free and fair global trade. ISO 14001:2004 stretches the recommendations for environmental management systems and recalls its global relevance for entities asking to trigger in an environmentally sustainable manner. According to the ISO statistics the state of ISO 14001 certifications and their trend in 2011-2012 period are presented in *Table 6*. The greatest reported number of certifications is in China followed by Japan and Italy, whilst regarding the growth in number of certificates the top three are China, Spain and Italy.

These statistics reveals that organizations worldwide have aligned their management systems with ISO 14001, to accomplish external environmental audit as a condition of the activity's certification.

Table 5. Empirical studies on integration of auditing subsystems

Empirical studies	Main topic/findings
Karapetrovic et al., 2006; Salomone, 2008; Kraus and Grosskopf, 2008; Bernardo et al., 2010	The integration of management system audits
Baldi, 1999; Douglas and Glen 2000; Beckmerhagen, Berg, Karapetrovic and Willborn, 2003; Bamber, Sharp and Castka, 2004; Rajendran and Devadasan, 2005; Bernardo et al., 2010	The integration of internal auditing subsystems or external function-specific audits, like the ones performed against a Quality or an Environmental Management system.
Zeng, Tam, Tam and Deng, 2005; Zeng, Shi and Lou, 2007; Zutshi and Sohal, 2005; Asif, Fisscher, Joost de Bruijn and Pagell, 2010; Bernardo et al., 2010; Khanna, Laroiya and Sharma, 2010; López-Fresno, 2010.	The integration of management systems
Baldi, 1999	Classification of integrated audits: • *fully integrated audit* when a multidisciplinary audit team conducts the audit at a certain moment; • *simultaneous audit* involve auditing distinctly but at the same time the elements of the management system; • *overlapping audits* cover distinct aspects of the integrated management system, but may join in terms of preparation and areas audited; • *sequential audits* entail auditing one management system first, followed by the next one at another point in time.
Berbardo et al., 2010	Levels of integration: • *Not Integrated*, indicating different audit teams; different times when audits are conducted; audits of independent management system; as well as different plans and reports, • *Partially Integrated*, meaning single audit teams and/or simultaneous audits, but only for the selected standardized management systems or against certain management system standards; audits of interrelated management systems; as well as single audit plans, but different audit reports • *Fully Integrated* referring to a single audit teams and/or simultaneous audits for all management systems or standards, audits of integrated management systems, and single audit plans and reports.

Table 6. ISO 14001:2004 certificates

	Certificates in 2012	Certificates in 2011	Dynamics	Dynamics in %
Number of certificates	285 844	261 957	+23 887	109%
Number of countries	167	158	+9	106%

Source: adaptation from ISO, 2012

Extending these requirements, many entities have implemented internal environmental audit and currently use both auditing systems (Darnall et al., 2009).

The European model for promoting corporate social and environmental responsibility is known as Eco-Management and Audit Scheme (EMAS), being voluntarily accepted and experienced in line with stakeholders' expectations and interests. Voluntary adoption of EMAS involves recognition and complying with all the provisions, as the guarantee of reliable and accurate approach to environmental management. EMAS is a European regulation with specific requirements, compulsory external audit, and publication of the audit report.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

This subsection evaluate the current knowledge in the field of environmental audit, aiming integration of the environmental issues within the accounting profession, and it proposes an action plan for the implementation of Environmental Management System (EMS) and consequently of environmental audits, towards corporate social responsibility. The environmental audit is a voluntary activity, standardized by independent professional bodies with no regulatory power. This standpoint allows identifying the central features of the topic: (1) establishing the need for regulation in the field of environmental audit; (2) reviewing of the specialized literature; and (3) the development of a framework for environmental audit missions in the context of integrated management systems audits.

Concept and Necessity: Consideration for Environmental Audit

In the '70s, in the United States were first attempts to audit the environment, as support, supplier and beneficiary of the industrial business entities. Environmental audit has developed based on remediation and penalties cost-cutting reasons, recognized in industrial accidents having human and environmental impact, and on the requirement to manage the environmental impact and performance.

Environmental audit has been promoted by multinational companies which have applied specific procedures both at the corporate and the horizontal level of the subsidiaries in other countries, facing different rules depending on the policies implemented by the states where have been created operational and functional structures. With the development of the audit procedures and the emergence of the obvious environmental and socio-economic crisis, the vertically scope enlarged, by requesting "green" certificates for all business partners involved in the provision of goods and services of multinational companies. Worldwide, environmental auditing has become an important tool for creating competitive advantages to the interested entities that are revealed by identifying potential markets, internal and external stakeholders benefit sustainable earnings, financial savings, and improved public image of the entity.

The audit is performed in the context of a philosophy of auditing, in compliance with ethical rules and using the construction, acceptance and implementation of specific procedures to provide, to the stakeholders, a competent opinion on the audited subject. Reasons of accountability, of individuals or communities, society have an increasingly evident tendency to evaluate the various practices of audit (Power, 1997). From the natural environment perspective, the audit has been developed as a means of guaranteeing entity's compliance with environmental standards in terms of assessment and information, and creation competitive advantage in the current global environmental crisis.

Various practices, procedures, objectives and targets have been applied since the first environmental audits performed at national, European and international level. These are now found under the concept of environmental auditing, an independent concept, and part of the most new approach to audit, an integrated audit system. The Confederation of British Industry [CBI] presented a representative definition in 1990: environmental audit is the systematic examination of the relationship between the processes, procedures and activities of the entity with the environment. In a broad approach, this relationship includes the emissions, the legal restrictions on land and water use, the effects on neighboring community, the conservation and protection of natural landscapes, complying with the principles of ecology, public perception of the entity in the local context etc. Formally, a management tool that provides systematic documentation and evaluation of how the entity, equipment and technologies, involved in its activity, protect the natural environment is identified with the concept of environmental audit (International Chamber of Commerce [ICC], 1991). Complementing this concept, the European Communities Council [ECC], (1993) defines the environmental audit as a management tool consisting of systemic, documented, periodic and objective

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

evaluation of the entity's performance, of the management system and the processes designed to protect the environment. The aim is to control the practices having an environmental impact and to assess their conformity with the entity's policies of the entity.

Types of partial environmental audits carried out by the international practice have been shared by the academic environment (Thompson & Thervie, 1991; Welford & Gouldson, 1993) and by professional organisms in the field (Environmental Resources Management [ERM], 1996). These are:

- *Compliance Audit*, the most common type of audit consisting of checks against environmental legislation and company policy;
- *Issues Audit* is described as an evaluation of how a company's activities relate to an environmental issue or (e.g. global pollution, energy use) or an evaluation of a specific issue (e.g. buildings, supplies);
- *Health and Safety Audit*, an assessment of risks and contingency planning (sometimes merged with environmental auditing because of the interconnected impacts of industrial processes and hazards);
- *Site Audit,* an audit of a particular site to examine actual or potential environmental problems;
- *Corporate Audit,* an audit of the whole company and its polices, structures, procedures and practices;
- *Due Diligence Audit*, an assessment of potential environmental and financial risks and liabilities carried out before a company merger or site acquisition or divestiture (e.g. contaminated land remediation costs);
- *Activity or Operational Audit*, an assessment of activities that may cross company departments or units (e.g. energy or waste management) and
- *Product or Life Cycle Audit*, an analysis of environmental impacts of a product throughout all stages of its design, production, use and disposal, including its reuse and recycling (cradle to grave).

The principle of audit integration address all forms of audit described in the literature to apply the environmental perspective. *External environmental audit* aims to evaluate environmental conditions at local, regional, and national level and express the opinions in a report on the environment status. *Internal environmental audit* focuses mainly on two directions:

- The impact assessment of the entity's policies, through a systematic study of the activities, objectives, services, practices affecting the environment; and
- The audit management system, through a review of procedures and structures that drives the environmental policy by entity.

In the last twenty years, the companies' management has reacted to the stakeholders' influence, demonstrating environmental responsibility. Some of them began to publish environmental information using corporate reporting, either as a part of their annual report, or as standalone voluntary environmental reports. Financial reporting requirements allow full recognition and disclosure of current and/or potential environmental issues. In countries concerned about current environmental issues, corporate reports including the environmental component have been originally adopted by public companies, and then by the private entities wishing to release consistent environmental reporting, the requirement for

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

acceptance and participation in a sustainable business (Darnall, Gallagher, & Andrews 2001). Moreover, environmental reporting has become a characteristic of any activity (Gray & Bebbington, 2001). Some entities have advanced the integration of environmental information in decision-making processes through voluntary certification under the requirements of ISO 14001, but also, by implementing comprehensive environmental management systems. As part of this complex integration operation, the entities are using environmental audit (Darnall et al., 2009).

Alternatives and Perspectives of Environmental Audit Approach

In the current regulatory global context, the environmental audit is a voluntarily activity. Entities carrying out an environmental audit face the management of the pros and cons identified in connection with performing of this audit. Arguments *in favor* of environmental audit emerge from sustainable development and the position of the entity into the relevant market. One category of arguments refers to the early detection of environmental problems over which the entity can act before they become significant (Stanwick & Stanwick, 2001) by avoiding major damage, risks and costs of environmental remediation, with substantial improvement of the public image of the entity. The second category of arguments refers to the protection of entity's investments through the procedures and systems created in the audit process in order to improve continuously the environmental performance (de Moor & de Beelde, 2005; O'Dwyer, 2001; Pfaff & Sanchirico, 2000). The third one that refers to the investments of entities' own resources in environmental friendly technologies are significant and must be managed responsibly to achieve sustainable governance (Portney & Stavins, 2000). Arguments *against* environmental audit arise when nonconformities or flagrant violations of environmental regulations are identified. In such cases, the entity is legally obliged to report discrepancies to the rules, leading to sanctions, financial penalties or even their closing (Watson & Emery, 2004). However, implementation of the environmental audit involves a series of training costs, motivating the management to conduct an internal audit, or to budget substantial fees for an external audit.

The research field of environmental auditing is relatively narrow. Research to date refers to the general concept of audit rather than its environmental side. The authors of the researches addressing this subject perceive environmental audit as a standardized category of environmental management practice (Hillary, 1998; Tilt, 2001; Khanna & Anton, 2002), without discussing the factors associated with using of different types of environmental audits (Darnall et al., 2009). Specialized environmental audit engages the collection, the confrontation, the analysis, the interpretation and the presentation of information necessary for: (1) assessing performance in the context of the requirements and objectives for a particular aspect; (2) complying with the environmental legislation and the entity's policy; (3) measuring performance in accordance to the requirements of environmental management standards.

To this end, the environmental audit is organized in terms of well-identified circumstances, adapted to the entity size, to the appropriate activities and the corporate culture. The auditing purpose and its techniques may differ, but generally, available steps and activities may be identified, as presented in *Table* 7.

Under the impact of global and, consequently, the environmental crisis, there is a growing requirement to present audit reports. Thus, the first request was expressed by the ECC in 1990 and this was supported by the EMAS, requiring participants to publish the environmental reports, adopted by the ECC in 1993. Given the pros and cons of environmental audits and environmental management systems, standardized and convergent to the sustainable development principles, four alternatives for environmental audits have been outlined in the literature. These are provided in *Table 8*.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. The general framework of an environmental audit mission

Steps	Activities
Audit preparation	• Full commitment to the management entity; • Setting the objectives, general goals and environmental priorities to be audited; • Choosing a team to ensure objectivity and professional competence of the mission.
Audit mission	• Audits on the spot, with the correct and systematic protocols and priorities; • Verification of the documents, registers, accounts etc.; • Examination of applied policies; • Discussions, interviews, questionnaires; • Inspections.
Post-auditing	• Evaluation of findings and results; • Reporting the recommendations; • Preparation of action plan; • Tracking implementation of mitigation or enhancement measures.

Table 8. Alternatives for organizing environmental audit

Alternatives	Characteristics	Limits	References
No environmental audit organized	The entity may adopt positive measures relating to the environment	Does not systematically check and periodically evaluate the environmental impact	Darnall et al., 2009
Organizes internal environmental audit	Determines the compliance with regulations and make recommendations for reducing negative environmental impact; Examines the provisions for uncertain events and validates the quality of environmental accounting	Only satisfies internal stakeholders, either managers or employees; Does not meet the requirements for implementing EMAS (mandates for the external environmental audit)	Dittenhofer, 1995; Power, 1997
Organizes external environmental audit	Determines compliance with environmental regulations; Examines the impact of environmental issues on the financial statements; Expresses an opinion on overall performance; Is objective and independent, as executed by an person outside the entity; Provides assurance on the legality of the activity, by presenting an environmental statement that meets the requirements of external stakeholders	Incurs high fees as provided for the independent external auditors' team Does not refer to the negative aspects of environmental impacts, existing in the deepest structures of the entity	Dittenhofer, 1995; Power, 1997; Solomon, 2000; Karapetrovic and Willborn, 2001; Kollman and Prakash, 2001
Organizes internal and external environmental audit	The most effective alternative; Combines the thorough knowledge coming from the entity's experiences ⇒ maximizes the external auditors beneficial environmental effects and increases the external credibility; Serves the interest of all stakeholders (internal and external)	It is the most costly alternative of organizing environmental audits, but also the most efficient in terms of benefits and credibility	Stanwick and Stanwick, 2001; Watson and Emery, 2004

From a cultural and traditional perspective, the auditors and the accountants are dissociated from the environmental aspects and environment conservation. They are increasingly involved in the environmental issues, as information and reports providers and as guarantors of the accuracy of the financial and accounting outputs used into decision process. The influence of accountants and auditors comes from their access to financial and performance information, their studies, reports and communications for decision-making process. They also encourage transparency, the right decision on purchasing and resource consumption and the recognition of environmental impact without breaching existing account-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing standards and regulations. International Organization of Superior Audit Institutions [INTOSAI], through its Working Group on issues of environmental audit [WGEA] identified three perspectives of the audit focused on environmental issues: financial statement audit, compliance audit and performance audit (INTOSAI WGEA, 2000).

Financial statement audit focuses on relevant issues related to the environment, the impact on their specific components, such as: measures to prevent, stop or remedy environmental damage; conservation of renewable and non-renewable resources; consequences of violating environmental laws and obligations imposed by governments (ecological charges, liability for damages caused by previous owners etc.). *Compliance audit* relating to the environment is able to provide guarantees that the audited activities are consistent with environmental laws, standards, and policies. *Environmental performance audits* include certifications regarding: the eco-performance indicators, correctly retrieved in the entity's overall performance and environmental programs conducted economically, efficiently and effectively.

Discussions on Environmental Audit Managerial Approach

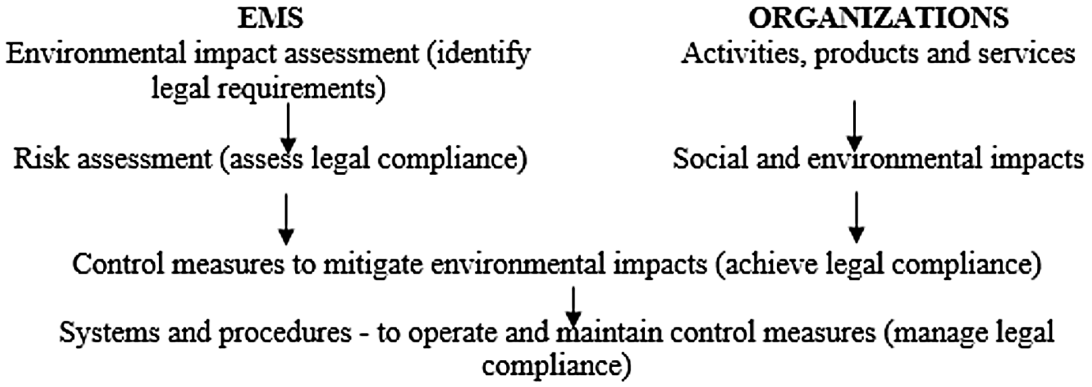
An EMS is "that part of an organization's management system used to develop and implement its environmental policy and manage its environmental aspects" (ISO 14001, 2004). Figure 1 shows a schematic of the key elements of an EMS. The EMS process can be expressed in terms of environmental management techniques set out below.

The normative view offers opportunities for the debate, design, and implementation of an environmental management system, in the context of area-specific and voluntary regulations. The choices depend on the degree of responsibility, culture and respect for the environment. Table 9 provides a synthetic view of the main normative options in the field of environmental management systems.

The voluntary adoption of EMAS involves the recognition of and the compliance with the entire set of provisions, as a sole guarantee of a reliable and rigorous approach of the environmental management. The main characteristics of EMAS are summarized below:

- is an European regulation with precise requirements;
- involves the binding obligation of an external audit;

Figure 1. Key elements of an EMS



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 9. EMS – Normative choices

	Description	Applicability	Standard/ Regulation
In-house EMS	Many companies choose to design and implement an EMS to their own specification. An in-house EMS may be as effective as any other, but the main drawback for regulators is that it is more difficult to assess the effectiveness of such an EMS in the absence of a standard approach, including assessment criteria.	International	**-**
EMS: Requirements with Guidance for Use	The standard specifies the different elements of an EMS and how they relate to one another based on a methodology known as plan-do-check-act. The overall aim of the standard is to support environmental protection and prevention of pollution in balance with socio-economic needs. In common with all management systems, the standard provides a means for continual improvement of performance. Conformity against the requirements of ISO 14001:2004 can be demonstrated through self-declaration, accredited certification or by other independent means. Organization are also required "to establish, implement and maintain a procedure(s) to identify and have access to applicable legal requirements and other requirements to which the organization subscribes related to its environmental aspects" and "to determine how these requirements apply to its environmental aspects". This requirement is intended to promote knowledge and understand legal responsibilities. This standard does not require an organization to establish libraries of legal or other documents that will rarely be referenced or used, but to develop information that will help the organization to know what is legally required and how it relates to their organization.	International	**ISO 14001/ 2004**
EMS: Guide to the phased Implementation of an EMS including the use of Environmental Performance Evaluation	The standard: • provides guidance to organizations on environmental management and the use of environmental performance indicators; • describes a six-phase, incremental approach to implementing an EMS using environmental performance evaluation; • is suitable for any organization, particularly small and medium-sized enterprises, to implement an EMS – for example to ISO 14001 standard; • may be used to demonstrate improved environmental performance to customers and stakeholders.	British entities	**British Standard (BS) 8555/ 2003**
Eco-Management and Audit Scheme (EMAS)	It is a registration scheme, not simply a standard. It is a voluntary initiative designed to improve organizations' environmental performance. Its EMS specification is the same as that of ISO 14001:2004 but it places additional emphasis on legal compliance and environmental performance.	European	**European Council, Directive 1836/1993**

- requires the mandatory disclosure of the audit report and the disclosure of results arising from the implementation of measures resulting from the audit, to inform stakeholders;
- operates under the specific requirement of compliance with legal provisions;
- the focus is the continuous improvement of environmental performance/impact.

The main EMAS objective is the continuous improvement of environmental performance through the implementation of adequate measurement, evaluation and reporting tools. The main results consist of the continuous improvement of environmental issues management, as well as providing reliable information in the field. This voluntary environmental management tool is operational since 1995. The development of EMAS has undergone three major qualitative stages:

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- EMAS I – 1993-1995 – EMAS is adopted by the European Council and opens for participation by industrial companies;
- EMAS II – 2001 Regulation *No. 761/2001*adopted by the European Council open to all economic sectors including public and private services;
- EMAS III – 2009 – 2010 New Regulation *No. 1221/2009* adopted by the Council and entered into force on 11 January 2010. This new regulation aims voluntary participation in EMAS of all entities inside and outside the European Community. EMAS III has bought some new elements regarding (1) the improvement of the applicability and credibility of the scheme and (2) consolidation EMAS' visibility and outreach.

  The application of environmental auditing activities is performed by the entities that use the audit function at the highest-level performance. Having the desire to assume the continuous improvement process, entities that rely on quality audit have the guarantee that a proficient assessment is done consistently. When product defects or activity deficiencies are reported appropriate corrective measures are taken (Corbett, Montes-Sancho, & Kirsch 2005). They also use long-term planning and monitoring progress to achieve the expected results. Similarly, entities that use environmental audit seek to assure themselves that the environmental impact is continuously measured, the environmental objectives are met and the improvement actions are taken when problems occur (Darnall et al., 2009).

Management proceeds through two major components: maintenance and continuous improvement of the activity. The current global circumstances impose the complying with the principles of sustainable development, which means treatment with responsibility and competence in the environmental matters. In Europe, concerns about the natural environment are very serious and they are supported by a General Directorate for Environment (DGEnvironment) of EC, to promote, implement and certify the EMAS. In a quantitative evaluation released by the EC, dominated by numbers and unilateral elliptic reasoning with qualitative connotations, EU countries have implemented EMAS in 2.956 organizations with 9.836 sites certificated in 2015. The top three EU countries who had implemented EMAS starts with Italy, 1.047 organizations, España, with 906 organizations and Deutschland with 330 organizations. According to the same source, 18% are large organizations, 30% medium, 32% small and the rest micro entities (EC-EMAS, 2015).

This chapter viewpoint might be resume as a need for a mindful environmental management, both at micro and macroeconomic levels, in order to friendly cohabit with natural environment, in a sustainable development principles context-dependent. It is the example of the EMS that allows entities to target, to achieve and demonstrate continuous improvement in their environmental performance (Caraiani, Lungu, & Dascălu, 2007). EMS is part of an integrated environmental management, characterized by a series of phases that include environmental audits, which are standardized at international, national and European level. These phases are:

- Adopting an environmental policy to confirm and promote the continuous improvement of environmental performance;
- Acceptance of systematic checks to identify significant environmental issues and their effects;
- Development of environmental programs with clear and precise objectives, goals and actions;
- Adoption of an EMS to implement actions necessary to achieve the objectives;

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Organizing standard environmental audits to measure the performance and the environmental impact;
- Preparing an environmental statement on eco-performance;
- Obtaining independent certification of the environmental report, based on the external audit.

Standing on the management component of continuous improvement the authors of this chapter bring into discussion the Deming's diagram, commonly known as the *PDCA* cycle for *Plan – Do – Check – Act*:

- *Plan*: design or revise business process components to improve results;
- *Do*: implement the plan and measure its performance;
- *Check*: assess the measurements and report the results to decision makers;
- *Act*: decide on changes needed to improve the process.

In its essence, the PDCA cycle is the feedback loop performed after each closing of the circle, so that managers could identify and improve processes and procedures, which are not sufficiently consistent with objectives (Dascălu, Caraiani & Lungu, 2008). The continuous development model led to the construction of quality management standards (ISO 9000:2000, ISO 9001:2008) and was taken in environmental management standard (ISO 14001, 2004), which is EMAS European correspondent. Although the international standard and European management and audit scheme are convergent, there are aspects of approach and details that distinguish them (Table 10).

To implement an effective EMS, the four phases of the diagram are taken up in a cyclical process, with the activities fulfillment during each phase. In Figure 2 the structure of the PDCA cycle with some appropriate activities are presented. This research assesses the knowledge in the environmental audit, promotes environmental issues within the accounting profession and proposes an action for implementing EMS and environmental auditing implicitly, to respond to social corporate responsibility. The scientific approach has shown that environmental audits are interesting both for the internal stakeholders (shareholders, partners, managers and ordinary employees) and for the external ones (potential investors, suppliers, current and potential customers, etc.) (Dascălu, Caraiani, Guşe, & Lungu, 2009).

This approach was encouraged by the narrow literature comparing the current frameworks of EMS. Converging with this chapter proposal were Testa, Rizzi, Daddi, Gusmerotti, Frey and Iraldo (2014), in their attempt to dispute the effectiveness of improvement environmental performance under an EMS framework, either EMAS, or ISO 14001. They empirically tested the environmental performance and found that, under ISO 14001 entities show improvements of their short-run environmental performance.

Table 10. EMAS vs. ISO 14001

EMAS	ISO 14001
Regulation operable in EU	International Standard
Requires initial analysis of the environmental impact	Does not require original analysis of the environmental impact
Aims to improve performance through best available techniques	EMS continuous improvement reflected in increased eco-performance
Requires public environmental statement, directly targeting the environmental policy and programs	Suggests external communication without formal requirements, but requires access to environmental policy

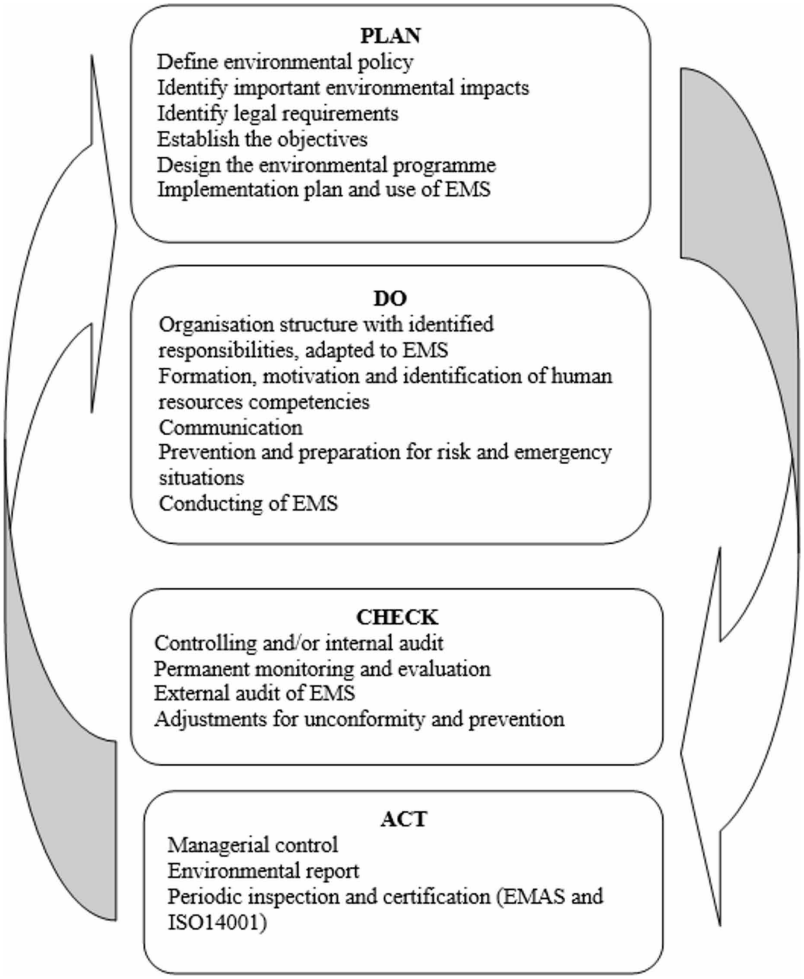
Figure 2. PDCA cycle for Environmental Management System



The EMAS framework much involves the authorities and promotes transparency and collaboration. These values are warranties on long-term, and as such are the improvements in environmental performance.

FUTURE TRENDS

Environmental impact is a major problem for the sustainable development of companies. The economic quantitative statements are based on the erroneous assumption of a steady natural environment. When the environment becomes unstable and resources become exhaustible, more complex situations arise. These complex situations can no longer be assessed by classical mechanisms but through instruments developed by complexity sciences. The sustainability mechanisms are no longer linear but complex and are based on the link method of the information flow and data or material accumulation described in this

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

chapter. This aspect requires a holistic approach on reporting and auditing procedures which should be achieved through integration. In this respect, worldwide accounting and audit professional organizations, for instance Public Company Accounting Oversight Board [PCAOB] and Sustainability Accounting Standards Board [SASB] become more preoccupied about the environmental crisis and sustainability that may be the starting point to transcend the crisis.

Established by US Congress through the Sarbanes-Oxley Act of 2002, the PCAOB oversees the audits of public companies in order to protect investors and the public interest by promoting informative, accurate, and independent audit reports (PCAOB, 2013). PCAOB has been working with the SASB "to come up with standards for the external assurance of sustainability reporting" using the already-established assurance standards of the PCAOB (Bogoslaw, 2013).

The contemporary business-model of Corporate Social Responsibility (CSR) involves sustainable development because of its corporate self-regulation dimension. In order to comprise this component into their reports, companies have to convey sustainability-related information in a comparable manner with financial reporting. A sustainability report is a report published by a company or organization about the economic, environmental and social impacts caused by its everyday activities (Global Reporting Initiative [GRI], 2013), organization's values and governance model. This kind of reporting should highlight the connection between organizational strategy and its commitment to a sustainable global economy.

Regarding the role that audit has to play in the new age of sustainability reporting it is obvious that focusing only on financial data is not enough anymore (Du Toit, 2008). Additionally, due to the audiences of company reports that entail more than simply financial data accounting certainly have to be changed. As Puaschunder (2011) suggests the current requests for changing in accounting have been catalyzed by the recent financial crisis. Whether or not one agrees with such a conclusion, the shift towards non-financial information reporting is clear and evident when considering a recent report found that 95% of the Global 250 issue sustainability reports (Ernst & Young, 2013).

Johnson (2010) suggests an interesting approach to the future of audit. He adapts the "physician paradigm" to the auditing procedures. In his view, the auditing profession employs a holistic approach of disclosure and suggests going beyond financial performance numbers as in medicine the blood test results only are not enough anymore. Then, he proposes consideration of organizational design, environmental issues, implementation procedures and company culture (which in medicine may be referred as behavioral and genetic risk factors). This forward-looking perspective concerned with ongoing health and sustainability (Eccles, Cheng, & Saltzman, 2010) awake the awareness of accounting consultancy companies that must consider the rapid development of sustainability reporting as a signal to train and prepare their current and future employed audit professionals for comprehensive auditing procedures.

Complex approach to global environmental crisis, especially to climate change provides a solution to create projections of reality that can be studied by integrated analysis. It validates the need to create an integrated framework to "reduce complexity" so that it becomes predictable, controllable and responsive to the actions of correcting the destructive effects caused by natural or human forces. Future researches have to generate auditing procedures that should allow integrating a variety of areas relevant to sustainability, including both natural and social sciences and using a system of values that are recognized, identifiable and quantifiable. They should be accessible to decision-makers, combining different effects of options in various areas, and that call for the development of human abilities, which are now limited to monitoring a small number of dimensions of reality (Huppes & Ishikawa, 2009).

CONCLUSION

Improving the performance requires action oriented towards the reduction of complexity and the clarification roles and obligations of each individual in the group. Resources must be targeted where they are actually needed. It is necessary to plan expertise activities for skill development of the employees, the managers and the directors, but also to create opportunities for inclusion of auditors and lawyers specialized in the requirements of social and environmental reporting. All these measures are designed to ensure reduced business risks through a systematic process that prioritizes actions to eliminate discrepancies. The results will be seen in the social and environmental audit reports, in the proposals for corrective actions intended, for example, to reduce accommodation risks arising from the relocation of employees (Caraiani, Guşe, Lungu, & Colceag, 2009).

The content of sustainability reports tend to appear in forms and measuring units that are not easily convertible into monetary terms. In this chapter, the idea of intensifying the pressures to increase corporate responsibility in all its dimensions is supported. The overlap and the convergence of reporting financial and sustainability performance seem more obvious and possible. Full integration in the form of a single report, describing the global performance (traditional financial, but also economic, environmental and social) is already practiced by some leading companies. The improved analytical methods and the increasing demands of interested stakeholders will continue to support the move towards a new generation of reporting performance.

KEY TERMS AND DEFINITIONS

Adaptation to Climate Change: Set of organization, localization and technical changes that societies have to implement to limit the negative effects of climate change and to maximize the beneficial ones.

Climate Change: An environmental problem leading to risks in the development process.

Eco-Management and Audit Scheme: A voluntary initiative designed to continuous improvement of organizations' environmental performance through the implementation of adequate measurement, evaluation and reporting tools.

Environmental Audit: An institution agreement that guarantees the trusted environment responsibility to be fulfilled effectively.

Environmental Management System: Part of an organization's management system used to develop and implement its environmental policy and manage its environmental aspects.

Integrated Audit: Involves of all the components amid cross-functional audits, like quality, environmental and safety management systems audits.

Plan-Do-Check-Act Cycle: The feedback loop performed after each closing of the circle that allows managers and auditors to identify and improve processes and procedures, which are not sufficiently consistent with objectives.

Stakeholder: Any group or individual who can affect or is affected by the achievement of the entity's objectives.

Sustainability Report: A report published by a company or organization about the economic, environmental and social impacts caused by its everyday activities.

Chapter 27
Spatio-Temporal Variability of Seasonal Drought Over the Dobrogea Region

Monica Ionita
Alfred Wegener Institute Helmholtz Centre for Polar and Marine Research, Germany

Silvia Chelcea
National Institute of Hydrology and Water Management, Romania

ABSTRACT

In this study we have examined the spatial and temporal variability of seasonal short-term drought over Dobrogea region over the period 1965 -2005. The dominant mode of spatial variability captures an in-phase relationship of drought conditions over the entire analyzed region, for all the seasons. We show that the Arctic/North Atlantic Oscillation patterns control a significant part of the interannual drought variability over the Dobrogea region in all seasons. Dry (wet) periods in Dobrogea region are associated with geopotential height anomalies at 850mb that project onto the negative (positive) phase of Arctic/North Atlantic Oscillation. Moreover, the SST anomalies from the Atlantic Ocean realm and potential evapotranspiration anomalies over the south eastern part of Romania play also a significant role on the variability of drought conditions over Dobrogea region.

INTRODUCTION

Drought is one of the most complex phenomena which may have a strong impact on agriculture, society, water resources and ecosystems. Drought affects many regions of the world and is the costliest climatic hazard globally (Wilhite, 2000). One of the reasons for this is the usually large spatial extent of droughts and their lengthy duration, sometimes reaching continental scales and lasting for many years. Generally, drought originates from a deficiency of precipitation over an extended period of time, usually a season or more. Investigations of drought are carried out all over the world. However, because of the complexity of this phenomenon, a uniform methodology for implementing drought studies has not been developed, although some indices of drought are widely used (Dai et al., 2004; Wells et al., 2004; Palmer, 1965).

Drought is viewed in different ways by different constituency of water users. Drought definitions are of two types: a) *conceptual* and b) *operational* (Wilhite, 2000). *Conceptual* definitions help to understand the meaning of drought and its effects. For example, drought is a prolonged period of deficient precipitation, which causes extensive damage to crops, resulting in loss of yield. These definitions do not provide quantitative answers to 'when", "how long", "how severe" a drought is and are often used as a startup in scientific papers and reports. *Operational* definitions help to identify the drought's beginning, end and degree of severity. To determine the beginning of drought, operational definitions specify the degree of departure from the precipitation average over some time period. This is usually accomplished by comparing the current situation with the historical average. An operational definition for agriculture may compare daily precipitation to evapotranspiration to determine the rate of soil-moisture depletion and express these relationships in terms of drought effects on plant behavior. These definitions are used to analyze drought frequency, severity and duration for a given historical period. Varied definitions, depending upon the influential factor used, of droughts are seen in the literature which can be grouped as follows: a) Precipitation based drought definitions; b) Evapotranspiration based drought definitions; c) Streamflow based drought definitions; d) Soil moisture based drought definitions; and e) Vegetation based drought definitions ((Ped, 1957; WMO, 1975; Wilthie and Glantz, 1985; Farago et al., 1989; Maracchi, 2000; Dai, 2011b). The groups in a) and b) refer to *meteorological drought* conditions, group c) refers to *hydrological droughts* and those in d) and e) refer to the *agricultural droughts*.

Drought propagation depends strongly on climate (Sheffield and Wood, 2011). At European scale, research on drought variability has been mainly focused on regional scales and/or over regions which are exposed to severe droughts [Iberian Peninsula (Estrela et al., 2000; Vicente-Serrano, 2011); the Mediterranean Region (Livada and Assimakopolous (2007) and south-eastern part of Europe (Koleva and Alexandrov (2008)]. Looking at other European regions, Briffa et al. (2009) showed that high summer temperatures in the western and central part of Europe are responsible for the large extent of summer drought conditions. Trnka et al (2009) emphasized that the drought conditions in the central part of Europe are triggered by different atmospheric circulation patterns and that the drought phenomenon is very pronounced in early vegetation period (April – June). Ionita et al. (2012a) showed that summer drought conditions over Europe are strongly influenced by previous winter SST anomalies and different ocean and atmospheric modes of variability (e.g. Atlantic Multidecadal Oscillation (AMO), Pacific Decadal Oscillation (PDO) and North Atlantic Oscillation (NAO)).

Large areas of Europe have been affected by drought during the 20th century. Severe and prolonged droughts observed mainly in the Mediterranean region have highlighted the vulnerability to this natural hazard and alerted the governments, stake holders, operational agencies to the disastrous effects of droughts on the society and economy and the need for mitigation measures (EEA, 2001). In this context, Romania is very likely to experience a wide range of impacts in response to climate change, mainly due to the temperature increases which in turn can perturb the hydrological cycle. In Romania, drought has a very strong impact on agriculture and affects 7.1 million ha, which represent 48% from the total agricultural land. The south, southeast and eastern parts of our country, where also Dobrogea region is located, are the most affected areas (< 600 m^3 water /hectare –extreme and severe pedological drought). During extremely dry years the average yields of various crops represent only $35\% \div 60\%$ of the potential yields. The climate evolution in Romania indicates a diminution of the annual precipitation especially over the south-eastern part of the country (Busuioc et al., 1995), the most affected area being Dobrogea region.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Dobrogea region is situated in the South-Eastern part of Romania between the lower Danube and Black Sea (Figure 1a). This region is characterized by the existence of two climate units: a) a western unit, where the climate is continental and influenced by the Black Sea (the mean annual temperature is about $11^{\circ}C$ and the precipitation is 400 mm) and b) an eastern unit, where the climate is influenced by the moderate continental belt (Maftei and Barbulescu, 2008). In this context, in this chapter we present the results of the spatio-temporal analysis of drought conditions over Dobrogea region and the influence of the large scale atmospheric circulation and sea surface temperature on the drought variability.

DATA AND METHODS

Data Sets

To calculate the Standardized Precipitation Index (SPI) we used monthly precipitation totals recorded at 47 stations situated in the Dobrogea region (Figure 1b), which cover the period 1965 - 2005. Here we show the results for SPI of one accumulation period of 3 months. The precipitation data are a compilation provided by the National Meteorological Administration (10 stations) and the National Institute of Hydrology and Water Management (36 stations).

To calculate the self-calibrating Palmer drought Index (scPDSI) and the Standardized Evapotranspiration Index for one accumulation period of 12 months (SPEI12), we used monthly mean air temperature and monthly precipitation totals recorded at two stations: Constanta and Sulina. For this two station the mean air temperature and precipitation totals cover the period 1900 – 2004, which allows for a direct comparison of the drought indices over different time spans and to identify the possible changes in different types of drought conditions over these periods. From the long precipitation time series, at Constanta and Sulina stations, we computed also SPI for one accumulation periods of 12 months. The long term data sets for these two stations were extracted from the European Climate Assessment & Dataset project (Tank et al., 2002).

To investigate the link between seasonal modes of SPI3 variability and the Northern Hemisphere atmospheric circulation we used the Geopotential Height at 850mb from the Twentieth Century Reanalysis (V2) data set (NCEPv2, Whitaker et al., 2004; Compo et al., 2006; Compo et al., 2011) on a $2^{\circ} \times 2^{\circ}$ grid, for the period 1965 - 2005. To analyze the relationship of SPI3 with global sea surface temperature we used the Hadley Centre Sea Ice and Sea Surface Temperature data set – HadISST (Rayner et al., 2003). This data set covers the period 1871 – 2012 and has a spatial resolution of 1° x 1°. For the present study we only used data for the period 1965 – 2005. The potential evapotranspiration (PET) data set is extracted from the CRU T.S. 3.20 dataset (Harris et al., 2013), which has a spatial resolution of $0.5^{\circ} \times 0.5^{\circ}$ and covers the period for the period 1900 - 2012. For this study we used just the period 1965 – 2005.

We also made use of the time series of six monthly teleconnection indices: Arctic Oscillation (AO), North Atlantic Oscillation (NAO), East Atlantic pattern (EA), East Atlantic Western Russia pattern (EAWR), Polar-Eurasian pattern (POL) and Scandinavian pattern (SCA). These indices were extracted from the Climate Prediction Center webpage (http://www.cpc.ncep.noaa.gov/data/teledoc/telecontents.shtml). They cover the period 1950 – 2013, but for this study we used just the period 1965 - 2005. From

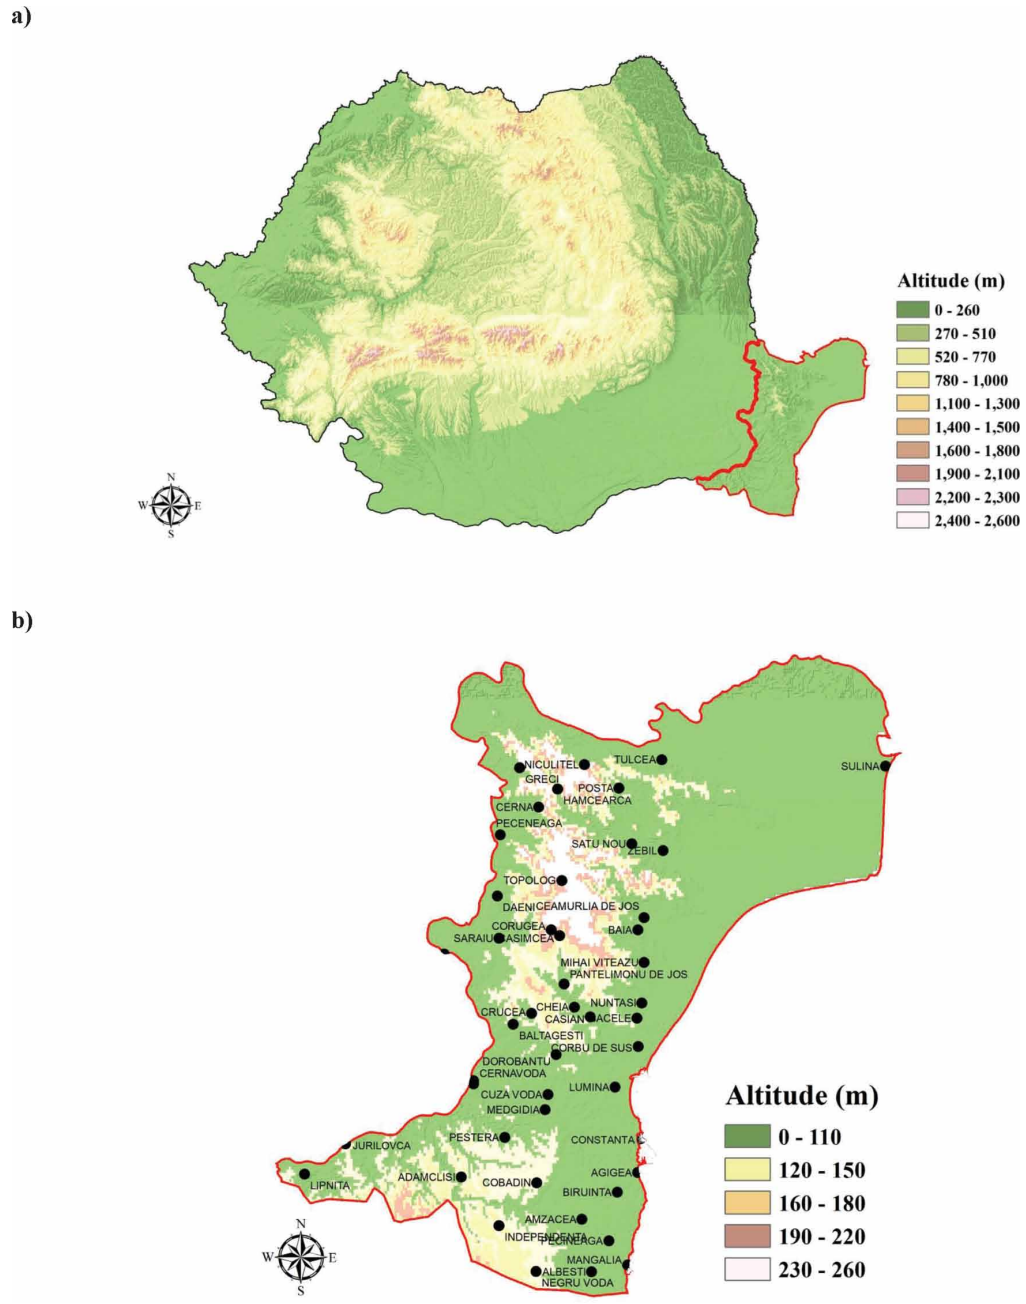
Figure 1. a) The topographical map of Romania and the location of the Dobrogea region (red area); b) The location and names of the hydrological stations used in this study.



the monthly time series the seasonal means were computed by averaging the months December/January/February (DJF), March/April/May (MAM), June/July/August (JJA) and September/October/November (SON). The time series were detrended and normalized by their corresponding standard deviation. A detailed description off all the teleconnection indices used in this chapter is given in the Global teleconnection patterns section.

Methods

Empirical Orthogonal Functions Analysis (EOF)

The patterns of the dominant modes of SPI3 variability are based on Empirical Orthogonal Function (EOF) analysis (e.g. von Storch and Zwiers, 1999). The EOF technique aims at finding a new set of variables that captures most of the observed variance from the data through a linear combination of the original variables. The EOF analysis represents an efficient method to investigate the spatial and temporal variability of time series which cover large areas. This method splits the temporal variance of the data into orthogonal spatial patterns called empirical eigenvectors. In this study the EOF was applied to the detrended and standardized anomalies of seasonal SPI3. By construction, the EOF patterns and the principal components are independent. Two factors inhibit physical interpretation of EOFs: (1) the orthogonality constraint and (2) the derived patterns may be domain dependent. Physical systems are not necessarily orthogonal and if the patterns depend on the region used they may not exist if the domain changes. Still, even with these short comings, classical EOF analysis has proved to be very useful, especially for climate related variables.

Kriging Method

The spatial representation of the EOF results was done with the usage of the Surfer 11 software package. Generally there are two groups of techniques for estimating grid points on a surface from scattered observations. The technique used to represent the spatial structure of the EOFs is called "local fit", and estimates the surface at successive nodes in the grid using only a selection of the near closed data points. In this regard, the kriging method and specifically the ordinary kriging method was used. The basic function of kriging is:

$$V(x) = \sum_{i=1}^{n} w_i * V(x_i) + \left[1 - \sum_{i=1}^{n} w_i\right] * m$$

where $w_i(x)$ - kriging weights, assigned to the sample data $V(x_i)$.Values $m(x)$ and $m(x_i)$ are expected values (means) of $V(x)$, $V(x_i)$. The number of data n used for the estimation and their weights may vary depending on the estimation point x. If kriging is compared with other methods used for the creation of interpolation surfaces (*i.e.* inverse distance weighting, deterministic splines, Thiessen polygons), it looks more flexible as an approach. Depending on the scale of fluctuation, weights of higher or lower influence may be used, whereas *i.e.* in the Thiessen method the same weights are continuously used regardless of whether the equation has smaller or larger scale fluctuations.

Global Teleconnection Patterns

The global atmospheric circulation has a number of preferred patterns of variability, all of which have expressions in surface climate. Monthly mean surface pressure varies markedly about the long-term mean of the sea level pressure (SLP) distribution. This variability occurs in well-defined spatial patterns (Wallace and Gutzler, 1981; Barnston and Livezey, 1987) particularly during the boreal winter over the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Northern Hemisphere (NH). Such variations are commonly referred as "teleconnections" in the literature, since they result in simultaneous variations in weather and climate over widely separated points over the earth. Regional climates in different locations may vary out of phase, owing to the action of such teleconnections, which modulate the location and strength of the storm tracks and poleward fluxes of heat, moisture and momentum (Hurrell et al., 2003; Quadrelli and Wallace, 2004; Trenberth et al., 2005b). Such monthly, seasonal and longer-time scales anomalies have direct impacts on humans, as they are often associated with floods, droughts, heat or cold waves and other factors that can directly affect and disrupt agriculture, water supplies, and can modulate the fresh water quality, energy demands and human health. The strength of teleconnections and the way they influence surface climate varies over long time scale.

One of the most prominent patterns that act over the NH and especially over the North Atlantic region and the surrounding continents is the North Atlantic Oscillation (NAO). The NAO refers to a north-south oscillation in atmospheric mass between the Icelandic Low and the Azores High-pressure centers (Walker and Bliss, 1932). The NAO is the dominant pattern of near-surface atmospheric variability over the North Atlantic, accounting for one third of the total variance in monthly SLP in winter. The positive phase of this pattern is associated with higher than normal surface pressure south of 55° N combined with a broad region of anomalously low pressure throughout the Arctic and subarctic. Consequently, this phase is associated with stronger-than-average winds across the mid-latitudes of the Atlantic onto Europe, with anomalously southerly flow over the eastern United States and anomalously northerly flows across Greenland, the northern part of Canada and the Mediterranean region and enhanced easterly trade winds over the sub-tropical North Atlantic (CPC, 2005). During the negative phase, both the Icelandic low and Azores high-pressure systems are weaker-than-normal, so both middle latitude westerlies and the sub-tropical trade winds are also weak. The negative phase brings higher-than-normal pressure over the polar region and lower-than-normal pressure at about 45° N. The negative phase allows cold air to plunge into the Midwestern United States and Western Europe, and storms bring rain to the Mediterranean.

The Arctic Oscillation (also referred to as the northern annular mode) is closely related to the NAO, with the observed time series correlating at 0.95 for monthly data (Deser, 2000). The AO is the dominant mode of variability on interannual time scales in the Northern Hemisphere and exhibits an annular pattern with decreased SLP over the Arctic basin associated with increase SLP at midlatitudes with centers of action in the North Atlantic and North Pacific. As such, the AO essentially encompasses the NAO variability but emphasizes the zonally symmetric nature of the hemispheric variability. The oscillation exhibits a "negative phase" with relatively high pressure over the polar region and low pressure at midlatitudes (about 45 degrees North), and a "positive phase" in which the pattern is reversed. In the positive phase, higher pressure at midlatitudes drives ocean storms farther north, and changes in the circulation pattern bring wetter weather to Alaska, Scotland and Scandinavia, as well as drier conditions to the western United States and the Mediterranean. Weather patterns in the negative phase are in general "opposite" to those of the positive phase.

The East Atlantic (EA) pattern is the second prominent mode of low-frequency variability over the North Atlantic region and appears as a leading mode in all months. The EA pattern is structurally similar to the NAO, and consists of a north-south dipole of anomaly centers spanning the North Atlantic from east to west. The anomaly centers of the EA pattern are displaced southeastward to the approximate nodal lines of the NAO pattern. For this reason, the EA pattern is often interpreted as a "southward shifted" NAO pattern. However, the lower-latitude centre contains a strong subtropical link in association with

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

modulations in the subtropical ridge intensity and location. This subtropical link makes the EA pattern distinct from its NAO counterpart. The positive phase of the EA pattern is associated with above-average surface temperatures in Europe in all months and with below-average temperatures over the southern U.S. during January-May and in the north-central U.S. during July-October. It is also associated with above-average precipitation over northern Europe and Scandinavia and with below-average precipitation across southern Europe. In the negative phase the weather patterns are in general "opposite" to those of the positive phase.

The East Atlantic/ West Russia (EA/WR) pattern is one of three prominent teleconnection patterns that affects Eurasia throughout year. The East Atlantic/ West Russia pattern consists of four main anomaly centers. The positive phase is associated with positive height anomalies located over Europe and northern China, and negative height anomalies located over the central North Atlantic and north of the Caspian Sea. The surface temperature anomalies associated with the positive phase of the EATL/ WRUS pattern reflect above-average temperatures over eastern Asia, and below-average temperatures over large portions of western Russia and northeastern Africa. The precipitation anomalies reflect generally above-average precipitation in eastern China and below-average precipitation across central Europe (CPC, 2005).

The Scandinavian pattern (SCA) consists of a primary circulation centre over Scandinavia and two weaker centers of opposite sign over Western Europe and eastern Russia/ western Mongolia. The Scandinavian pattern has been previously referred to as the Eurasia-1 pattern by Barnston and Livezey (1987). The positive phase of the Scandinavia pattern is associated with below-average temperatures across central Russia and also over Western Europe. It is also associated with above-average precipitation across central and southern Europe and below-average precipitation across Scandinavia (CPC, 2005).

The Polar/ Eurasia pattern appears in all seasons. The positive phase of this pattern consists of negative height anomalies over the polar region and positive anomalies over northern China and Mongolia. This pattern is associated with fluctuations in the strength of the circumpolar circulation, with the positive phase reflecting an enhanced circumpolar vortex and the negative phase reflecting a weaker than average polar vortex (CPC, 2005). The Polar/Eurasian pattern is associated with above-average temperatures in eastern Siberia and below-average temperatures in eastern China and above-average precipitation in the polar region north of Scandinavia.

Drought Indices Review

To monitor and quantify drought, various indices have been developed, but a unique and universally accepted drought indicator does not exist yet (Heim, 2002; Dai, 2011b). One of the most used drought index is the Palmer Drought Severity Index (PDSI) (Palmer, 1965). The Palmer Drought Index is based on a supply-and-demand model of soil moisture and it enables the measurement of both wetness (positive values) and dryness (negative values). The index has proven to be most effective in determining long-term drought — a matter of several months — and not as good with conditions over a matter of weeks (Alley, 1984; Weber and Nkemdirim, 1998). One of the main disadvantages of PDSI is that it has a fixed temporal scale and does not allow the identification of different types of drought (e.g. agricultural, hydrological or meteorological). This may act as a drawback because drought is considered a multiscalar phenomenon (McKee et al., 1993, Vicente-Serrano et al, 2010). An improvement was made by McKee et al. (1993) with the development of the Standardized Precipitation Index (SPI), which takes into account the multiscalar nature of droughts. But SPI has a major drawback: it is based only on precipitation and does not take into account the effect of evapotranspiration, which has a strong impact on drought

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

conditions. Recently, a new drought indicator, the Standardized Precipitation - Evapotranspiration Index (SPEI) (Vicente – Serrano, 2010) has been developed to quantify the drought condition over a given area. SPEI takes into account both precipitation and evapotranspiration and can be computed on time scales from 1 to 48 months. SPEI combines the sensitivity of PDSI to changes in evaporation demand with the multiscalar nature of SPI. More detailed description of SPEI and the method of computation are given by Vicente-Serrano et al. (2010).

Palmer Drought Severity Index (PDSI) and Self-Calibrating Palmer Drought Severity Index (scPDSI)

The most used drought index is the Palmer Drought Severity Index (PDSI) (Palmer, 1965); an index which is based on a supply-and-demand model of soil moisture and it enables the measurement of both wetness and dryness. The PDSI was developed during the early 1960's by W. C. Palmer as a standard way to quantify the severity of drought conditions. Since then, the PDSI has become one of the most widely used drought assessment tools. This index has proven to be most effective in determining long-term drought - a matter of several months - and not as good with conditions over a matter of weeks (Alley, 1984; Weber and Nkemdirim, 1998).

The index is a sum of the current moisture anomaly and a fraction of the previous index value. The moisture anomaly is defined as:

$$d = P - \hat{P}$$

where *P* is the total monthly precipitation, and $\hat{P}$ is the precipitation value climatologically appropriate for existing conditions' (Palmer, 1965). $\hat{P}$ represents the water balance equation defined as:

$$\hat{P} = \overline{ET} + \overline{R} + \overline{RO} - \overline{L}$$

where *ET* is the evapotranspiration, *R* is the soil water recharge, *RO* is the runoff, and *L* is the water loss from the soil. The over bars signify that these are average values for the given month taken over some calibration period. $\hat{P}$ is a hydrological factor and needs be parameterized locally. The Palmer moisture anomaly index (*Z* index) is then defined as:

$$Z = Kd$$

where *d* represents the deficit or surplus of moisture, adjusted for the seasonal changes in climate, and *PDSI* for month *i* is defined as:

$$PDSI_i = 0.897 PDSI_{i-1} + \frac{1}{3} Z_i$$

K acts as a climate weighting factor and is applied to yield indices with comparable local significance in space and time. PDSI is usually calculated over a monthly period. However, there is nothing to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

prevent calculations across other time periods, e.g. weekly or bi-monthly. The values of 0.897 and 1/3 are empirical constants that Palmer derived using data from two climate divisions. They are known as the Duration Factors, because they determine how long a spell will last.

Values for the duration factors and the climate characteristic can be calculated for each location by examining the historical climate of the location. This will calibrate the behavior of the index based on the climate of the location, giving more consistent results. The duration factors affect the sensitivity of the index to moisture deficits or surpluses by determining how much weight is given to the current moisture anomaly and the previous index value. The duration factors are most important, however, in determining when an established spell ends. If the duration factors do not represent the characteristics of the given climate, an extreme drought may never end, and the PDSI value would get steadily more negative.

Clearly, one location will be more sensitive to a given moisture deficit than another location. Also, one location may be more sensitive to a moisture deficit than to a moisture surplus of the same magnitude. Thus, two sets of duration factors are needed for each location; one will be used during wet spells and the other during dry spells.

Palmer also used an empirical value in the definition of the climate characteristic *K*. Taking into account the classification of PDSI values that Palmer developed, extremely dry *PDSI* values are defined as those at or below -4.00. Similarly, extremely wet PDSI values are at or above 4.00. By intuition, these extreme events should not occur much more often than once in a generation, or twelve months out of every 50 years. This corresponds to a frequency of 2% of extremely dry and extremely wet *PDSI* values. This means that the expected 2nd percentile of the PDSI values is -4.00 and the expected 98th percentile is 4.00. Using these two expected values of the PDSI in a definition of the ratio leads to the following formula for *K*:

$$K = \begin{cases} (-4.00/2^{nd}\ percentile)K^i\ if\ d{<}0 \\ (4.00/98^{th}\ percentile)K^i\ if\ d{\geq}0 \end{cases}$$

This definition of *K* may seem a little confusing because it depends on the PDSI values, which in turn rely on the climate characteristic. The solution to the problem is to calculate the PDSI using as the climate characteristic. Then the *K* can be used as the climate characteristic to recalculate all the PDSI values. This procedure calibrates the PDSI so that 2% of its values fall at or below -4.00 and 2% at or above 4.00. This, in all practicality gives the index upper and lower bounds. These bounds also lend more meaning to the intermediate values of the index.

The self-calibrating Palmer Drought Severity Index (scPDSI) automatically calibrated the behavior of the index at any location by replacing the empirical constants in the index computation with dynamically calculated values. The analysis of the self-calibrating PDSI has shown that it performs much more consistently than the original PDSI (Wells, 2004). The different classes of drought classification based on the values of scPDSI are given in Table 1.

Standardized Precipitation Index

The SPI is a drought index first developed by McKee et al. (1993). The SPI is used for estimating wet or dry condition based on precipitation variable. This wet or dry condition can be monitored by the SPI on a variety of time scales from subseasonal to interannual scales. The SPI is expressed as standard devia-

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

tions that the observed precipitation would deviate from the long-term mean, for a normal distribution and fitted probability distribution for the actual precipitation record. Since precipitation is not normally distributed, a transformation is first applied, followed by fitting to a normal distribution. The SPI calculation is based on the long-term precipitation record for a particular location and long-term period (longer than 30 years is desirable). The calculation method is comprised of a transformation of one frequency distribution (e.g., gamma) to another frequency distribution (normal, or Gaussian). The first step to calculate SPI is to adequately choose a particular probability distribution (e.g., gamma distribution, incomplete beta distribution (McKee et al. (1993, 1995)), and Pearson III distribution (Guttman (1998, 1999)) that reliably fits the long-term precipitation time series and conduct fitting to that distribution. Gamma distribution has been widely used, as the gamma distribution has been understood as the reliable fit to the precipitation distribution. The fitting can be achieved through the maximum likelihood estimation of the gamma distribution parameters. The percentile value from this probability distribution is then transformed to the corresponding value in the new probability distribution. As a result, the probability that the rainfall is less than or equal to any rainfall amount will be the same as the probability that the new variate is less than or equal to the corresponding value of that rainfall amount. The normal distribution is usually used for this another transformation so that the mean and standard deviation of the SPI for a certain station and long-term period is zero and one, respectively (Edwards and McKee 1997). Positive SPI values indicate wet condition greater than median precipitation, whereas negative values the dry condition less than median precipitation.

The monthly precipitation time series are modeled using different statistical distributions. The first is the gamma distribution, whose probability density function is defined as:

$$g(x) = \frac{1}{\beta^{\alpha}\Gamma(\alpha)} x^{\alpha-1} e^{-x/\beta} \qquad for\ x > 0$$

where $\alpha > 0$ is a shape parameter, $\beta > 0$ is a scale parameter, and $x > 0$ is the amount of precipitation. $\Gamma(\alpha)$ is the gamma function, which is defined as:

$$\Gamma(\alpha) = \lim_{n\to\infty} \prod_{v=0}^{n-1} \frac{n\,!\, n^{y-1}}{y+v} \equiv \int_0^{\infty} y^{\alpha-1} e^{-y} dy$$

Fitting the distribution to the data requires α and β to be estimated. Edwards & McKee (1997) suggest estimating these parameters using the approximation of Thom (1958) for maximum likelihood as follows:

$$\hat{\alpha} = \frac{1}{4A}\left(1 + \sqrt{1 + \frac{4A}{3}}\right)$$

$$\hat{\beta} = \frac{\overline{x}}{\hat{\alpha}}$$

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

where, for *n* observations:

$$A = \ln\left(\overline{x}\right) - \frac{\sum \ln(x)}{n}$$

Integrating the probability density function with respect to x and attach α and β parameters yields the cumulative probability distribution function *G(x)*:

$$G(x) = \int_0^x g(x)dx = \frac{1}{\hat{\beta}^{\hat{a}}\Gamma(\hat{\alpha})}\int_0^x x^{\hat{a}}e^{-x/\hat{\beta}}$$

substituting *t* for $\frac{x}{\hat{\beta}}$ yields the incomplete gamma function:

$$G(x) = \frac{1}{\Gamma(\hat{\alpha})}\int_0^x t^{\hat{a}-1}e^{-t}dt$$

The gamma distribution is undefined for $x = 0$ and $q = P(x=0) > 0$, where $P(x=0)$ is the probability of zero (null) precipitation. Thus, the cumulative probability distribution function becomes:

$$H(x) = q + (1-q) * G(x)$$

The cumulative probability distribution function is converged into the standard normal cumulative distribution function so that both of them have the same probability. The different classes of drought classification based on the values of SPI are given in Table 1.

Table 1. Drought classification by scPDSI and SPI values

scPDSI		SPI	
scPDSI values	**Category**	**SPI Values**	**Category**
4 or more	Extremely wet	2.00 or more	Extremely wet
3.00 to 3.99	Very wet	1.50 to 1.99	Severely wet
2.00 to 2.99	Moderately wet	1.00 to 1.49	Moderately wet
1.00 to 1.99	Slightly wet	0 to 0.99	Mildly wet
0.50 to 0.99	Incipient wet spell		
0.49 to -0.49	Near normal		
-0.50 to -0.99	Incipient dry spell		
-1.00 to -1.99	Mild drought	0 to -0.99	Mild drought
-2.00 to -2.99	Moderate drought	-1.00 to -1.49	Moderate drought
-3.00 to -3.99	Severe drought	-1.50 to -1.99	Severe drought
-4 or less	Extreme drought	-2 or less	Extreme drought

Standardized Evapotranspiration Index (SPEI)

SPEI is similar to the Standardized Precipitation Index (SPI) (McKee et al., 1993) but it includes the role of temperature. SPEI is a multi-scalar drought indicator based on monthly precipitation totals (PP) and temperature means. The procedure to calculate the index uses the monthly difference between precipitation (PP) and Potential Evapotranspiration (PET) which represents a simple climatic water balance calculated at different time scales to obtain the SPEI (Vicente-Serano et al., 2010).The SPEI is really simple to calculate, and is based on the original SPI calculation procedure. The SPI is calculated using monthly (or weekly) precipitation as the input data. The SPEI uses the monthly (or weekly) difference between precipitation and PET. This represents a simple climatic water balance which is calculated at different time scales to obtain the SPEI. A number of equations exist to model PET based on available data (e.g. the Thornthwaite equation, the Penman-Monteith equation, the Hargreaves equation, etc), and the SPEI is not linked to any particular one. With a value for PET, the difference between the precipitation (P) and PET for the month *i* is calculated:

$$D_i = P_i - PET_i$$

which provides a simple measure of the water surplus or deficit for the analyzed month. The calculated D_i values are aggregated at different time scales, following the same procedure as for the SPI. In this paper we have used the Thornthwaite equation to compute SPEI for one accumulation period of 12 months.

RESULTS

Precipitation Climatology

The climatological background plays a crucial role in the formation and variability of drought conditions as well as on the hydrological processes. The Dobrogea region is characterized by a temperate-continental climate. The precipitation amounts over the Dobrogea region have a strong seasonal cycle. In winter, the highest precipitation amounts (up to 135 mm/season) are recorded over the extreme northern and southern parts (Figure 2a), while the lowest amounts (around 55 mm/season) are recorded in the north-eastern part of the region. In spring, the spatial structure of the precipitation distribution is different than in winter (Figure 2b). There is a clear dipole like structure in the distribution of precipitation between the western part and the eastern part of the Dobrogea region. The highest precipitation amounts are recorded at the stations situated in the northern part (up to 145 mm/season). As in the case of winter, the lowest precipitation amounts are recorded in the north-eastern part of the region. For the summer season, the precipitation distribution follows the same dipole-like path, like for the spring season, but the highest precipitation amounts are recorded in the western part of the Dobrogea region (Figure 2c). Summer, is the season in which the highest precipitation amounts are recorded, up to 160 mm/season at stations located in the western part of the region. In autumn, the highest precipitation amounts are

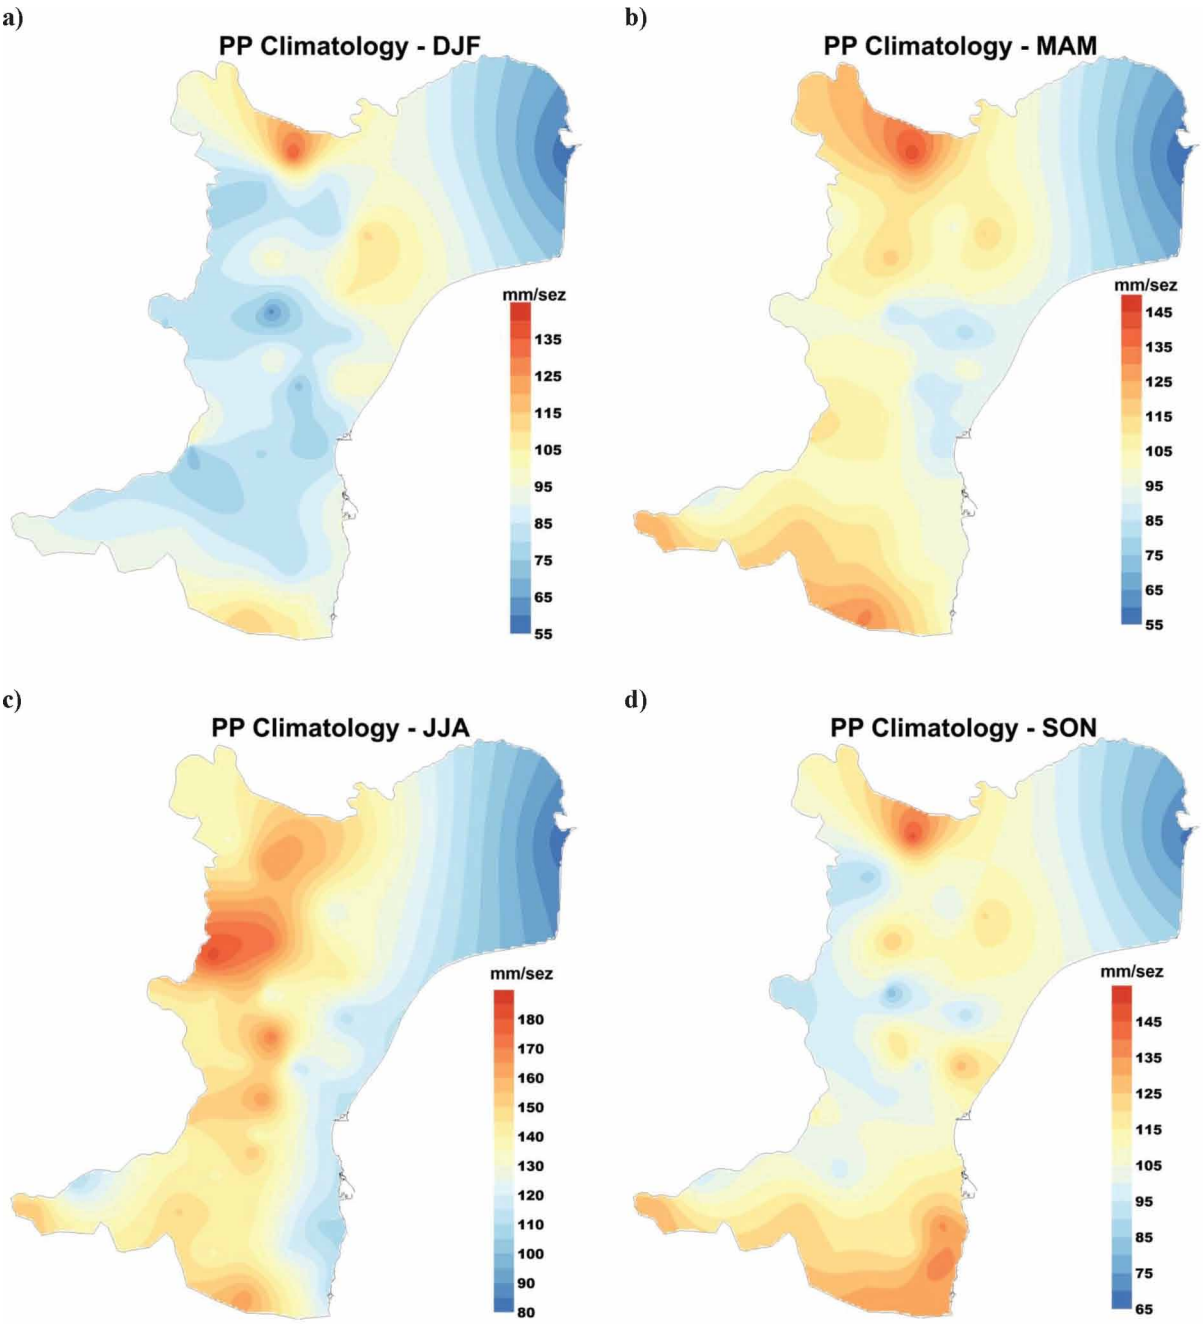
Figure 2. a) The winter precipitation climatology over the Dobrogea region; b) same as a) but for the spring season; c) same as a) but for summer season and d) same as a) but for the autumns season.



recorded in the southern part (up to 125 mm/season) and the northern part (up to 135 mm/season). The lowest precipitation amounts are recorded, like in the case of the other seasons, at the stations situated in the north-eastern part of the region. The north-eastern part of the Dobrogea region is very exposed to low precipitation amounts and more drought events.

Drought Variability and Large Scale Circulation, Teleconnection Patterns, and Atlantic SST

Drought results from a combination of meteorological, physical and human factors. The primary cause of any drought is a deficiency in rainfall and, in particular, the timing, distribution and intensity of this deficiency in relation to existing storage, demand and water use. Temperature and evapotranspiration may act in combination with rainfall to aggravate the severity and duration of the event. The precipitation and temperature variability is driven mainly by the large-scale atmospheric circulation. As a consequence is very important to analyze the variability of drought conditions in relationship with large scale atmospheric circulation.

The first EOFs resulted from the standardized SPI3 seasonal data (anomaly divided by the standard deviation) allows us to recognize the region with similar or different climatology and to filter out some errors in precipitation observations. Moreover, to identify the physical mechanism, if any, responsible for the connection between the seasonal SPI3 variability and atmospheric circulation, the correlation maps between the principal components corresponding to the first seasonal EOFs and the geopotential height at 850mb, the global SST and the potential evapotranspiration are computed. There are relatively few studies that have analyzed the influence of different teleconnection patterns on the variability of climate variables over Romania (Bojariu and Paliu, 2001; Tomozeiu et al., 2002; 2005; Ionita et al., 2013), but none of the aforementioned studies has dealt with the influence of this well known mode of variability on the drought conditions, especially over the south-eastern part of Romania, a region which is prone to extreme droughts.

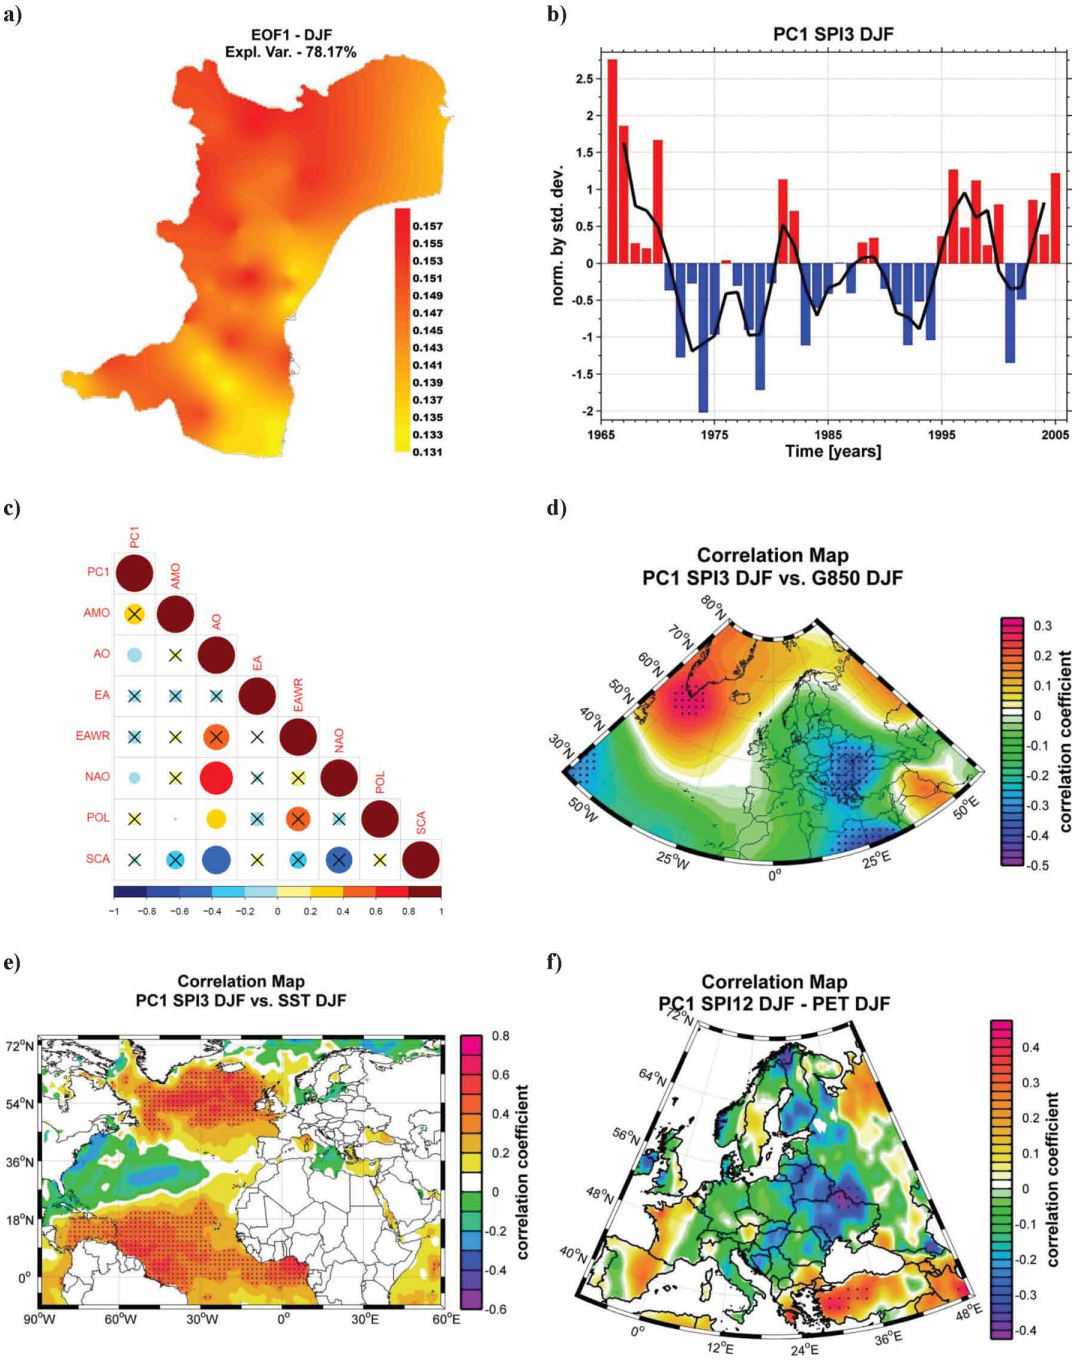
Winter

The first EOF of winter SPI3 is characterized by a monopolar structure, with positive loadings over the whole Dobrogea region. The highest loadings are observed in the central and northern part of the region, while the lowest loadings are observed over the southern part of the region (Figure 3a). The first winter EOF explains around 78.17% of the total variance. The monopolar structure emphasizes the fact that a large amount of the drought variability in the Dobrogea region is influence mainly by the same factors. The corresponding principal component (PC1) presents pronounced interannual and decadal variability (Figure 3b). Periods characterized by prolonged drought conditions have been observed for the years 1970 – 1974; 1976 – 1980; 1983 – 1985; 1990 – 1994 and 2001 – 2002, while periods characterized by wet conditions have been recorded for the years: 1965 – 1969; 1981 – 1982; 1995 – 2000 and 2003 – 2005. An interesting aspect of the dry/wet conditions, during the winter season, is the fact that the dry conditions are always grouped in 4 or 5 consecutive years.

In terms of large scale well-known teleconnection patterns, the PC1 was found to be correlated with the winter AO/NAO. The correlation coefficient between winter PC1 and winter AO/NAO is significant (90% significance level) and shows an out-of-phase relationship between PC and AO/NAO implying that wet (dry) conditions are associated with the negative (positive) phase of AO/NAO (Figure 3c). To emphasize this relationship between winter PC1 and AO/NAO, the correlation map between winter PC1 and the geopotential height at 850mb is shown in Figure 3d. Wet (dry) periods over Dobrogea region are associated with positive (negative) Z850 anomalies over the north Atlantic Ocean and Greenland extending up to the eastern Russia and negative (positive) Z850 anomalies over the central Atlantic Ocean and the eastern part of Europe, with a significant and deep cyclonic (anticyclonic) area over the

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. a) First EOF of winter (December/January/February - DJF) SPI3; b) The corresponding time series (PC1); c) The correlation coefficients of winter PC1 with the winter teleconnection pattern indices; d) The correlation map between winter PC1 and winter geopotential height at 850mb; e) The correlation map between winter PC1 and winter sea surface temperature from the Atlantic Ocean basin; f) The correlation map between winter PC1 and winter potential evapotranspiration. (The dotted areas indicate regions where the correlations are exceeding the 95% significance level). In Figure 3b, positive values indicate wet conditions, while negative values indicate drought conditions.



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Black Sea and eastern part of Romania (Figure 3d). Moreover, wet (dry) periods over the Dobrogea region are strongly correlated with SST anomalies from the Atlantic Ocean basin. Wet (dry) periods are associated negative (positive) anomalies in the central Atlantic Ocean flanked by significant positive (negative) SST anomalies in the tropical Atlantic Ocean and the northern part of the Atlantic Ocean (Figure 3e). A similar pattern was identified in the North Atlantic Ocean by other authors (Hurrel, 1995; Deser and Blackmon, 1993; Dima et al, 2001; Ionita et al., 2012a, 2012b). This pattern has been found to have a quasi-decadal variation of about 12 years.

An important aspect of the drought conditions is related to the influence of the evapotranspiration and the soil moisture. As such, in Figure 3f it is shown the correlation map between winter PC1 and the Potential Evapotranspiration at European scale. As it can be inferred from Figure 3f, there are no significant correlations between winter PC1 and PET field. This is not surprisingly for the winter season, since during the winter months the soils are either frozen or covered by snow, thus reducing or cancelling the influence of the potential evapotranspiration on the drought conditions.

Spring

The first EOF of spring SPI3 is characterized, like in the case of the winter season, by a monopolar structure, with positive loadings over the whole Dobrogea region. The highest loadings are observed in the northern part of the region, while the lowest loadings are observed over the central and north-eastern part (Figure 4a). The first spring EOF explains around 76.13% of the total variance. The corresponding principal component (PC1) is characterized by pronounced interannual variability (Figure 4b), with altering wet and dry periods. Periods characterized by prolonged drought conditions have been observed for the years 1967 – 1968; 1972; 1974 – 1976; 1982 – 1983; 1985 – 1987; 1989 – 1991; 1994, 1998, while periods characterized by wet conditions have been recorded for the years: 1966; 1969 – 1971; 1973; 1977 – 1979; 1981; 1984; 1988; 1992 – 1993; 1995 – 1997; 2001 - 2002 and 2004 – 2005. For the spring season, the dry/wet periods vary on shorter time scales comparing to the winter season and they are more exposed to strong interannual variability.

Spring PC1 was found to be negatively significant (99% significance level) correlated with spring AO/NAO index. This significant correlation can be observed also in the spatial structure of the correlation map between spring PC1 and spring Z850. Wet (dry) periods over Dobrogea region are associated with negative (positive) Z850 anomalies over the central North Atlantic Ocean that extend up to the eastern part of Europe and positive (negative) Z850 anomalies over Greenland and northern part of the Atlantic basin. The spatial structure of the correlation map projects onto the Z850 anomalies associated with the negative phase of AO/NAO (Figure 4d) in agreement with the high value of the correlation coefficient between spring PC1 and spring AO/NAO. Wet (dry) periods over the Dobrogea region are also associated with negative (positive) SST anomalies over the east coast of U.S. flanked by positive (negative) SST anomalies in the tropical Atlantic Ocean and in the northern part of the Atlantic Ocean basin. A similar pattern was found also for the winter months, implying a certain persistence of the SST anomalies form the winter season to the spring one, with the same effect on the drought conditions in the Dobrogea region. Spring PC1 shows negatively significant correlations with spring PET (Figure 4f) over the eastern part of Romania, where Dobrogea region is located. The high correlations over the eastern part of Romania imply that during the spring season the potential evapotranspiration plays an important role for the variability of drought conditions.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Summer

The first summer mode of SPI variability (Figure 5a) has the highest loadings over the northern and central part of the Dobrogea region and explains approximately 62.17% of the total variance. The explained variance of summer EOF1 is much smaller compared to the explained variance explained by winter EOF1. This is not surprisingly, since the summer months are characterized by a more variable atmospheric circulation and convective precipitation, while in winter the atmospheric circulation is less variable and the snow cover can play a significant role on the drought/moisture conditions. The corresponding summer PC1 (Figure 5b) is characterized mainly by interannual and high-frequency variability. The driest summers were recorded for the following years: 1966 – 1968, 1976, 1981 – 1982, 1986, 1990, 1995 – 1996 and 2003 – 2004, respectively. In contrast to this, the wettest summers, in Dobrogea region, were recorded for the following years: 1969 – 1972, 1975, 1977 – 1980, 1983, 1987, 1991, 1997, 1999 and 2004 – 2005.

As in the case of the winter season, there is a weak relationship between summer PC1 and well-known teleconnection patterns (Figure 5c), like summer AO/NAO. Based on the correlation map between summer PC1 and summer Z850 (Figure 5d), wet (dry) summers over the Dobrogea region are associated with a low (high) pressure center located over the eastern part of Europe and centered over Romania and a high (low) pressure center over the northern part of the Scandinavian Peninsula. The low pressure center located over Romania favors the advection of moist and warm air from the Mediterranean area towards the southern part of Romania and triggers enhanced precipitation over this area, where Dobrogea region is also located. Wet (dry) summers, over the analyzed region, are also associated with positive (negative) SST anomalies over the tropical Atlantic Ocean and in the southern part of Greenland (Figure 5e).

As in the case of spring season, the potential evapotranspiration plays an important role on the drought conditions over the Dobrogea region. Wet (dry) summers are strongly related with reduced (enhanced) PET, especially over the eastern part of Romania. The correlations between summer PC1 and summer PET have values up to -0.6 over the Dobrogea region.

Autumn

Autumn EOF1 has a retuned explained variance of 68.73% and as in the case of the other seasons, it has the same sign over the entire Dobrogea region, indicating that a large part of the autumn SPI variability is controlled by the same large-scale factors. The corresponding principal component (PC1) presents interannual variability and very pronounced multidecadal variability (Figure 6b). Periods characterized by prolonged drought conditions have been observed for the years 1969, 1973, 1977 – 1994 and 2001 – 2002, while periods characterized by wet conditions have been recorded for the years: 1965 – 1967; 1971 – 1972, 1995 – 1999 and 2002 – 2005. The most striking feature of the temporal evolution of autumn PC1 is the negative values (dry autumns) that persisted for almost 20 years, between 1975 and 1995, with some small exceptions. Autumn PC1 is significantly correlated (90% significance level) to autumn AO/NAO (Figure 6c) and this is also visible in the correlation map between autumn PC1 and autumn Z850. The spatial structure of the correlation map projects onto the negative phase of the AO/NAO. Wet (dry) autumns are associated with negative (positive) Z850 anomalies over the central North Atlantic Ocean and positive (negative) Z850 anomalies over Greenland extending up to the Scandinavian Peninsula. In terms of SST anomalies, the correlation map between autumn PC1 and autumn SST resembles the structure of the correlation map between winter/spring PC1 and winter/spring

SST. Wet (dry) autumns are associated with significant negative (positive) SST anomalies over the eastern U.S. coast flanked by positive (negative) SST anomalies in the tropical Atlantic Ocean and in the northern part of the Atlantic Ocean. The similarity in the SST anomalies between the autumn, winter and spring seasons shows a kind of persistent feature, implying that a part of the SPI variability is related to similar SST conditions in the Atlantic Ocean basin over different seasons. This persistence can give a hint of potential predictability of SPI variability based on the SST anomalies from the Atlantic Ocean basin. As in the case of spring and summer seasons, the correlation map between autumn PC1 and autumn PET shows the highest negative correlations (~ -0.6) over the southern part of Romania and Bulgaria. Reduced (enhanced) evapotranspiration over the aforementioned regions is associated with wet (dry) conditions over the Dobrogea region.

Drought Indices Comparison

For two stations located in the southern part (Constanta) and eastern part (Sulina) of the Dobrogea region, a long data set, which covers the period 1901 – 2004, for precipitation and temperature, is available. Based on these data sets we have computed the scPDSI, SPI12 and SPEI12 for different time spans: 1900 - 1934, 1935 - 1969 and 1970 - 2004, respectively. The aim of splitting the data sets in different periods was to test if there are significant changes in drought conditions over different periods. The frequency of time in each dry or wet category, expressed as the percentage of months in a given category, is shown in Figure 7 for Constanta and Sulina stations. The percentage of months in a given category is shown for scPDSI, SPI12 and SPEI12, for different periods and different dry/wet categories. We choose SPI and SPEI for an accumulation period of 12 months due to the fact that the highest correlations between scPDSI and SPI and SPEI were for this particular accumulation period.

As can be observed from Figure 7, SPI12 and SPEI12 tend to have almost the same frequencies, for all the analyzed periods, since they are normalized indices, while scPDSI shows lower frequencies for mild-wet category and higher frequencies for dry categories, for both stations and for all the analyzed periods. For Constanta station there is an increase in mild-wet and mild-dry periods for the time frame 1970 – 2004 compared to the time frames 1900 – 1934 and 1935 – 1969, respectively. Moreover, there is a slight decrease in severe and extreme drought for the period 1970 – 2004 (Figure 7d) compared to the other two periods analyzed. The most striking feature of Figure 7 is the disappearance of extreme and severe wet category at Sulina station for the period 1970 – 2004 (Figure 7h). This feature is accompanied, at Sulina station, by a strong increase of moderate, severe and extreme droughts for the same period of time (1970 – 2004) compared to the periods 1900 – 1934 and 1935 – 1969, respectively. While the period 1900 – 1934 was characterized by a high frequency of mild-wetness, at Sulina station, for the periods 1935 -1969 and 1970 - 2004 there is a tendency towards more frequent mild-droughts and a higher frequency towards mild and extreme droughts over the last 35 years of the analyzed period. This tendency towards increased frequency of extreme drought over the last 35 years, at Sulina station, is due to the fact that the amount of precipitation has decreased by an order of $1/3$ compared to the period 1900 – 1934. At Sulina station, the mean annual precipitation for the period 1900 – 1934 is 364.85 mm/year, for the period 1935 – 1969 is 338.20 mm/year, while for the period 1970 – 2004 the annual amount of precipitation is reduced to 250 mm/year. This decreasing trend in the annual precipitation amount at Sulina station is not valid also for Constanta station. For Constanta station, the annual precipitation

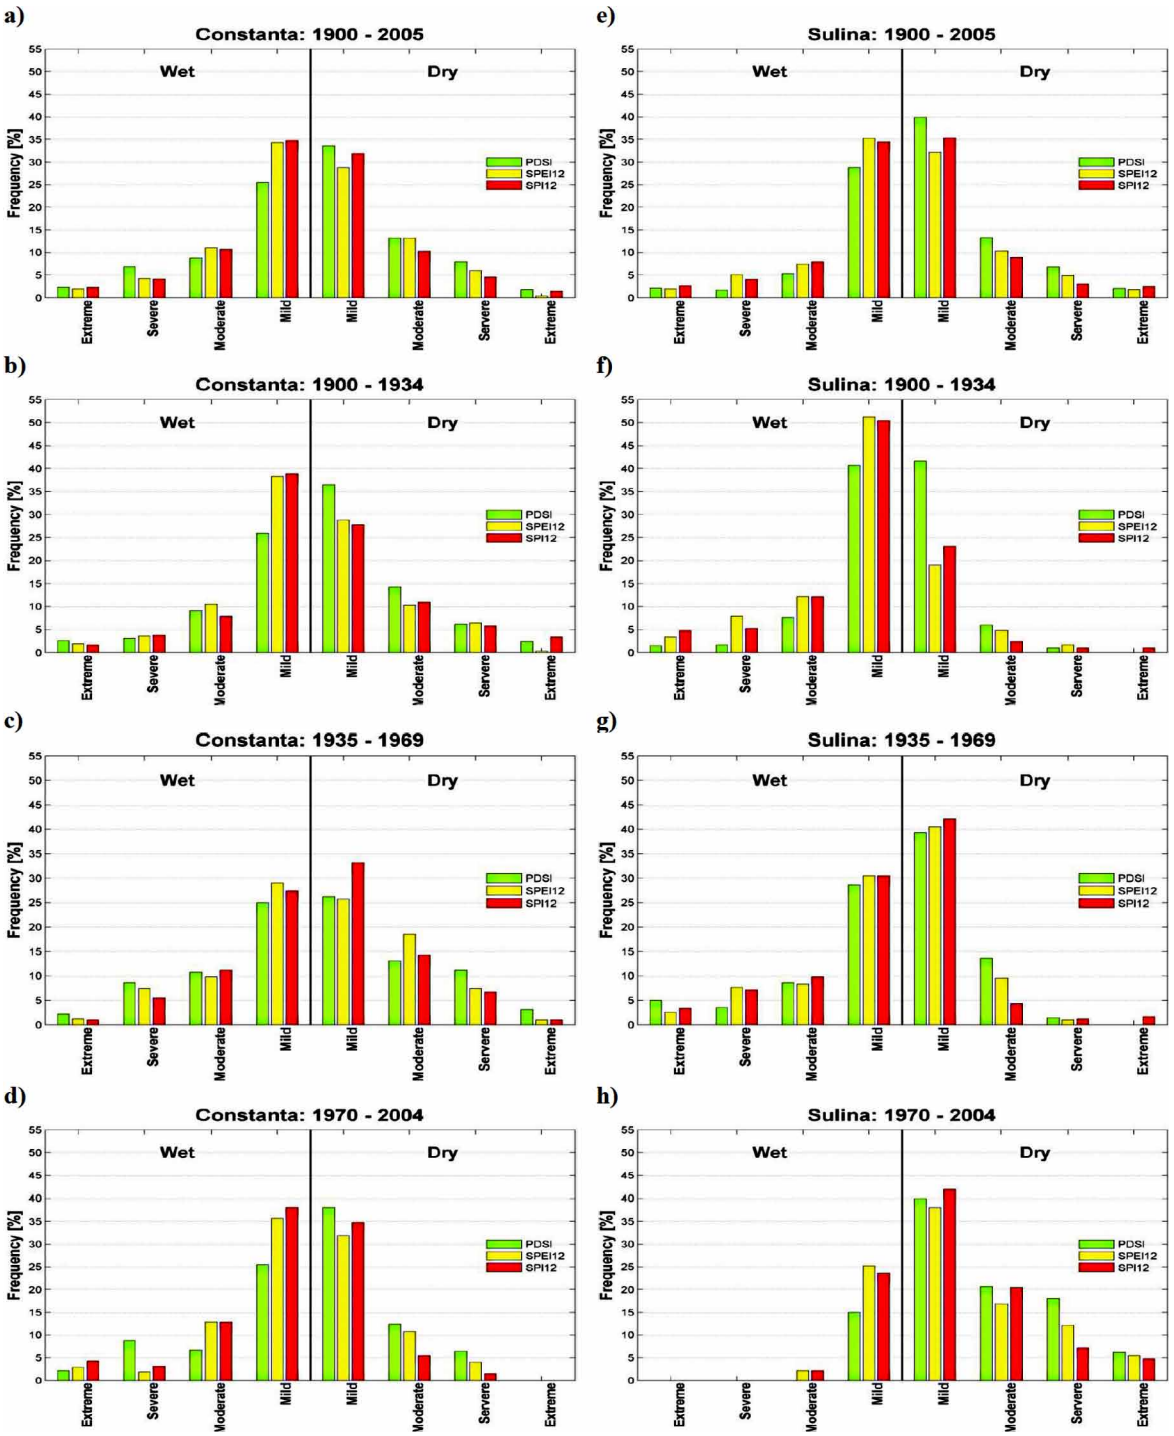
Figure 7. Frequency of time (%) in each dry or wet category of scPDSI, SPEI12 and SPI12 for there different periods at Constanta (left panels) and Sulina (right panels) stations. a) and e) period 1900 – 2005; b) and f) period 1900 – 1934; c) and g) period 1935 – 1969; d) and h) period 1970 – 2000.



EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

amount for the period 1900 – 1934 is 377.41 mm/year, for the period 1935 – 1969 is 380.89 mm/year, while for the period 1970 – 2004 the annual precipitation amount is 409.62 mm/year, which is even higher compared to the other two periods.

CONCLUSION

In this chapter we have investigated the spatio-temporal variability of seasonal drought variability over Dobrogea region and its relationship with large-scale atmospheric circulation and he North Atlantic SST. The leading modes of variability of SPI3 are definitely season – dependent. Although the spatial structure of the leading modes of seasonal variability of SPI3 may show conformity with each other, the temporal evolution (in terms of principal component time series) differs significantly from one season to another. The analysis of seasonal correlation maps between the principal components time series and seasonal Z850, SST and PET pointed out on a specific and significant role of each of these climatic variables on the seasonal short-term drought variability.

The leading EOFs (EOF1) of the seasonal SPI3 have a monopolar structure, suggesting that a large part of the SPI3 variability is driven by the same mechanisms via the large-scale atmospheric circulation. The first principal component for the winter season is characterized by a strong decadal variability, with a period of approximately 12-14 years. The spring and summer PC1 presents strong interannual variability, while autumn PC1 is characterized also by enhanced decadal to multidecadal variability.

On a seasonal timescale, SPI3 variability is connected to well-known climate modes of variability, namely: AO/NAO. Dry (wet) periods in Dobrogea region are associated with geopotential height anomalies at 850mb that project onto the negative (positive) phase of Arctic/North Atlantic Oscillation. Moreover, the SST anomalies from the Atlantic Ocean realm and potential evapotranspiration anomalies over the south eastern part of Romania play also a significant role on the variability of drought conditions over Dobrogea region. Several studies have established that large-scale SST fluctuations can be linked to atmospheric circulation patterns that produce precipitation fluctuations and streamflow variability (Dai et al., 1997; 2000; Rajagopalan et al., 1998, Gamiz-Fortis et al., 2011; Ionita et al., 2008, 2011, 2012, 2015). Here we show that wet (dry) conditions that prevail over the Dobrogea region are associated with a tripole-like SST pattern in the Atlantic basin characterized by negative (positive) SST anomalies over the eastern coast of U.S. flanked by positive (negative) SST anomalies in the tropical Atlantic Ocean and in the northern part of the Atlantic Ocean. The influence of the potential evapotranspiration anomalies on drought variability was found to be strongest during summer, spring and autumn. PET has little or no effect on drought conditions in winter and this can be due to the fact that during the winter months the soils are either frozen or covered by snow, thus reducing or cancelling the influence of the potential evapotranspiration on the drought conditions.

In conclusion, we have shown that the short-term drought variability over the Dobrogea region is strongly related to large-scale atmospheric patterns and North Atlantic Ocean SST. This kind of analysis can be useful to connect drought variability to climate forcings. A next logical step will be to perform the same analysis for mid-term and long-term drought conditions and identify possible resemblances or differences in the large scale atmospheric patterns responsible for the drought variability at different time scales.

KEY TERMS AND DEFINITIONS

Drought: A recurrent feature of the climate which occurs in virtually all climatic zones.

Dry Period: A dry period implies below normal precipitation anomalies or discharge.

Empirical Orthogonal Function Analysis (EOF): Represents an efficient method to investigate the spatial and temporal variability of time series which cover large areas.

Teleconnection Patterns: A recurring and persistent, large-scale pattern of pressure and circulation anomalies that spans vast geographical areas. Teleconnection patterns are also referred to as preferred modes of low-frequency (or long time scale) variability.

The North Atlantic Oscillation (NAO): One of the most prominent teleconnection patterns in all seasons, characterized by a north-south dipole of anomalies, with one center located over Greenland and the other center of opposite sign spanning the central latitudes of the North Atlantic.

The Standardized Precipitation and Evapotranspiration Index (SPEI): A meteorological drought indicator which is based on monthly precipitation totals and temperature means.

The Standardized Precipitation Index (SPI): A meteorological drought indicator which is based just on precipitation data.

Chapter 28
The Role of Mobile Phones Use on Agricultural Output and Household Income in Rural Rwanda

Ildephonse Musafiri
University of Rwanda, Rwanda

ABSTRACT

This paper assesses the role information and communication technology (ICT) on agricultural output and household welfare of smallholder farmers. The data used in this study comes from a household survey carried out in Nyabihu District, one densely populated area of rural Rwanda. The findings suggest substantial impact of cellular phones technology adoption by farm households. Using the propensity score matching technique, the author finds that agricultural output for mobile phone users is at least 38 percent higher than non-users, whereas their income levels are 26 percent higher on average. The provision of network infrastructure and electricity at community level will enhance agricultural and rural development through increased adoptions of telecommunication technology by smallholder farmers.

1. INTRODUCTION

The rationale of this section is to investigate the impact of Information and Communication Technologies (ICTs) on agricultural output and income levels. Today, ICTs are meant to include equipment that facilitates capturing, processing, display, and transmission of information such as computers (and their accessories), telecommunication equipment (and related services), and audio visual equipment and services. In the context of this study, we consider telephony (the use of cellular phones by farm households) as a proxy of ICTs adoptions due to its outstanding role to facilitate improved access to information and communication on one hand, and to play as prerequisite to advanced technologies use such as internet on the other (Torero & von Braun, 2006).

Studies have stressed the leading role of ICTs in economic growth and development at both the micro and macro levels. ICT has become a foundation of every sector of every economy around the world because of its multifaceted role in expanding economic opportunities such as reduction of transaction costs and productivity increase, enhancing a flow of information, increasing choice in market place and widening the geographical scope and others (Kramer, Jenkins, & Katz, 2007). Goyal (2013) proved that ICTs can make difference by closing information gaps, and by empowering smallholders and improve market opportunities of farmers. According to von Braun (2010), ICTs may impact the livelihoods of the poor by increasing their access to markets, improving the quality of public goods and services provision, improving human resources quality, and facilitating effective utilization of social networks.

More specifically, cellular telephone technologies are believed to boost economic growth through job creation, increased agricultural and industrial productivity, and diffusion of innovation among farmers. However, much more skeptical views in respect to benefits of ICTs for the poor have emerged. They postulate that access to (or adoption of) ICTs is itself driven by a number of factors such as education, income, and wealth; consequently, the shortage or lack of the above resources may prevent the poor from ICTs adoptions, widening information gap and increasing income disparities within and between countries (Torero & von Braun, 2006; von Braun, 2010).

Recent statistics show that more than 45 percent of Rwandan households use mobile phone technology in their daily activities (NISR, 2012). The Government of Rwanda believes that ICTs can open doors to more economic opportunities for rural poor; efforts have been put in ICT investments over the past decade. The e-Rwanda Project funded by World Bank and implemented by the Rwanda Information Technology Authority intends to empower rural farmers and enable a full access to information about market prices and successful farming. With a network coverage of about 80 percent of the whole territory, even farmers from very remote areas can use their mobile phone devices to check on agricultural commodity prices and can take better price decisions concerning their produce.

However, though much is said about the role that mobile phones can play in agricultural development in Rwanda, no attempt was made to measure the extent at which this technology has impacted the level of output, fertilizer use, and household income among smallholders. This study contributes to the existing literature by measuring the impact of mobile phone use on agricultural output and household income in small scale farmers in Rwanda. In the following subsections, we consecutively present the ICT strategy in Rwanda, the relevant literature, empirical strategy, data description, results, and subsequent interpretations.

2. RWANDAN ICT STRATEGIES

The institutions and mechanisms to create an enabling environment for ICT development in Rwanda were established in 2000. Today, the most prevalent technologies in Rwanda are internet services, mobile applications, outsourcing, information security, clouds computing, and green ICT that aims at creating awareness on increasing environmental regulation. The National ICT strategies are adopted and implemented in four five-year phases under the "National Information Communication Infrastructure (NICI)" designation and coincide with the main policy document "Vision 2020". The NICI I (or NICI-2005 Plan) was adopted in 2001 and its main focus was to create an enabling environment to the growth of ICT sector in Rwanda through establishment of sound institutional and legal framework. The second

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

phase of ICT strategy (NICI II or NICI-2010) was adopted in 2006 and aimed at providing outstanding infrastructures that will support the future of ICT requirements (Rwanda, 2011).

The current phase of the strategy (NICI III or NICI-2015 plan) was adopted in 2011 and is being implemented with a special emphasis to improve ICT service delivery to the citizens. More specifically, as a pre-final phase of the ICT strategy that will drive the country towards its vision 2020, NICI III targets high skill and knowledge based-ICT, ICT enabled private sector development, E-Government, and cyber security.

In order to accomplish these missions, the government of Rwanda has set a number attainable objectives that include capacity building in ICTs and enabling improved access to education and training, fostering innovation through research and development, developing a private-led competitive ICT sector, create ICT awareness in communities, and increased citizen participation and access to services through ICT-enhanced systems. In addition, through the NICI-2015 plan, the government intends to increase transparency and accountability through ICT, establish a legal environment enabling easy adaptation to emerging technologies, and ensure total protection of Rwanda's ICT infrastructures and systems against cyber-attacks. From these missions and objectives, a number of implementable projects have been designed and some being in their execution phases (Rwanda, 2011).

NICI-2015 is being implemented under a strong multi-stakeholder framework in which the Rwanda Development Board (RDB) is designated as coordinating and implementing agency of all ICT related initiatives. The strategic directions are provided by the National Steering Committee chaired by the Ministry in charge of ICT (MINICT). Through this partnership, Rwanda believes to obtain important and quantifiable measures of ICT contributions to the GDP.

3. RELEVANT LITERATURE

A number of studies have emerged over the last decade on the relevance of mobile phones use on economic welfare in developing countries. Aker (2010) found that the expansion on network coverage accompanied by intensive use of mobile phone use by local traders in Niger have significantly reduced market disparities and improved market performance. It is believed that mobile phone adoption in Sub-Saharan countries have positive impact on agriculture and labor market efficiency even though empirical evidences on this matter are still thin (Aker, 2008; Aker & Mbiti, 2010).

Mittal, Gandhi, and Tripathi (2010) found that farmers use mobile phones as means of communication to check on the availability of inputs and market prices, resulting in higher crop yields because of better adjustment of supply to market demand. Similar effects have been observed on fishermen who registered a decrease in losses due to full market information. Mwakaje (2010) analyses the impact of access to ICT, including radios, telephone, internet and newspapers by rural farmers from Rungwe village in Tanzania and found that farmers who used mobile phones in their activities have sold more quantities and at better prices than others.

However, the same study pointed out that access to ICT facilities is constrained by the lack of money income and electricity. Evidence from Uganda confirmed the mobile network expansion enhanced market participation for producers of perishable products such as banana (Muto & Yamano, 2009). Regarding the determinants of mobile phone adoption, Muto and Yamano (2009) found that the age of the household head, the level of education of both male and female adults, and farm asset values are the most important determinants of mobile phone acquisition in Uganda. Younger household heads are likely to

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

adopt the mobile phone technology, and this also increases by the level of education and household assets. Evidence from Rwanda showed that mobile phone ownership is associated with wealth, education, and gender (Blumenstock & Eagle, 2010).

Okello, Kirui, Njiraini, and Gitonga (2011) analyzed the drivers of ICT use by smallholder farmers in Kenya, and found that mobile phone adoption is driven by farm and farmer characteristics, capital endowment and regional characteristics. Other things being equal, the use of mobile phones is positively correlated to the male headship, household fare, education, income, and assets and negatively correlated with the family size and age of the household head. Kirui, Okello, and Nyikal (2012a) found that the use of mobile phone-based money transfer services in Kenya has impacted agricultural production among smallholder farmers because farmers use the remitted funds to purchase inputs, equipment and to pay hired labor.

Houghton (2009) analyzed the impact of mobile phone use on agricultural productivity in selected developing nations using a two-stage regression model. The micro-data results showed that mobile phone ownership significantly increase agricultural productivity at household level in Swaziland, Cambodia, and Honduras. In their study on mobile phone and economic development in rural Peru, Beuermann, McKelvey, and Vakis (2012) found that the use of mobile phone has significantly contributed to household income consumption, and reduced extreme poverty by five percent in the area during the study period. The use of mobile phone by smallholder farmers in Oyo State in Nigeria (Bolarinwa & Oyeyinka, 2011) have enhanced a full time access to extension services and increased agricultural output more than non-mobile phone users. Chong, Galdo, and Torero (2009) also confirmed that the level of income per capita was higher for households with access to telephone services.

4. EMPIRICAL STRATEGY

Measuring the impacts of ICTs on rural households' welfare can be done through different methodologies. The frequently used techniques are compensating variations, willingness to pay, consumption functions, and matching (von Braun, 2010). To analyze the impact of mobile phone on outcomes such as agricultural output, fertilizer use and household income, we start from a linear function:

$$Y_i=\beta_0+\beta_1 X_i'+\beta_2 M_i+\varepsilon_I \quad (1)$$

where Y_i is agricultural output, X_i is vector of inputs, M_i is a binary variable representing one if the household owned a mobile phone during the past 12 months, and zero otherwise; βi are unknown parameters to be estimated.

Even though mobile ownership from the equation (1) is treated as exogenous, it may also happen that households with higher agricultural output and income are likely to own mobile phone. Then mobile phone ownership is not random and estimation of this equation by simple OLS will yield biased estimates. As pointed out by Owusu, Abdulai, and Abdul-Rahman (2011) the Heckman two-steps procedure has been used in many applications to correct the selectivity bias but it relies on restrictive normality assumptions. The instrumental variable (IV) technique as a second alternative is more demanding when it comes to find a good instrument and reveal itself difficult to apply.

To solve the selectivity bias associated with mobile phone ownership, we employ the propensity score matching (PSM) developed by Rosenbaum and Rubin (1983). Compared to the techniques described

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

above, the PSM requires no assumptions about the functional form in specifying the relationship between outcome and outcome predictors (Ali & Abdulai, 2010; Owusu et al., 2011). As a non-experimental method, the PSM is judged suitable to a non-randomness of mobile phone adoption in our sample (Abebaw & Haile, 2013; Spreeuwenberg et al., 2010) and we will employ statistical matches to address the self-selection problem. The idea behind the PSM is to identify non-adopters of mobile phones who are similar to adopters in their observed characteristics; and the first step is to estimate by Logit model, the propensity score or the predicted probability that a farm household own a mobile phone such that:

$$P(Z_i) = \text{Prob}(M_i=1 \mid Z_i), \tag{2}$$

where M_i=1 if the household own a mobile phone, and M_i=0 otherwise; Z_i is a vector of observed personal, household and farm characteristics susceptible to influence mobile phone adoption. The next step of the PSM consists of selecting the best matching estimator which does not eliminate too many of the original observations in the final matching and try to provide equal covariate means for households in the treatment and control groups (Austin, 2009; Caliendo & Kopeinig, 2008).

Our principal concern is to answer the following question: "What would be the level of agricultural output, and household income in case the households had adopted mobile phone technology?" To answer this question, we will use the predicted propensity score from equation (4.29) to estimate the treatment effects. Following Ali and Abdulai (2010), Abebaw and Haile (2013); Owusu et al. (2011), the average treatment of the treated (ATT), which is in our case the average impact of mobile phone adoption on agricultural output, fertilizer use and income, is given by:

$$\begin{aligned} ATT &= E\left(Y_{1i}^k - Y_{0i}^k M_i = 1\right) = E\left[E\left\{Y_{1i}^k - Y_{0i}^k M_i = 1, P\left(Z_i\right)\right\}\right] \\ &= E\left[E\left\{Y_{1i}^k M_i = 1, P\left(Z_i\right)\right\} - E\left\{Y_{0i}^k M_i = 0, P\left(Z_i\right)\right\}\right] \end{aligned} \tag{3}$$

where Y_1 and Y_0 are the values of treatment variables of mobile phone adopters and non-adopters respectively; *i* stands for household; *k* refers to outcome variables being analyzed such as output, and household income.

The PSM is hereby employed as a probability that a farmer adopts mobile phone technology given pre-adoption socio-economic characteristics. In the absence of experimental data, the PSM technique uses the conditional independence assumption (Burke, Jayne, Freeman, & Kristjanson) to create the conditions of randomized experiment (Ali & Abdulai, 2010). This means that mobile phone technology adoption is random and uncorrelated with the outcome variables if Zi are controlled for (Imbens & Woodridge, 2009).

The literature suggests a number of algorithms the adopters and non-adopters of mobile phone technology with similar propensity score. The most widely used include the nearest neighbor matching which attempts to match close adopters with the closest non-adopter with similar characteristics, caliper matching which uses the nearest neighbor within each maximum propensity score, and the kernel matching method which try to use more non adopters for each adopter in order to reduce variance (Kirui, Okello, & Nyikal, 2012b; Owusu et al., 2011).

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, a hidden bias may arise when the matching estimator is not robust (Rosenbaum, 2002). This problem is solved by controlling a large number of covariates to minimize the omitted variable bias; the sensitivity analysis is conducted to check the robustness of our estimates to hidden bias.

5. DATA DESCRIPTION

The data used in this section are derived from household surveys conducted in 364 households randomly selected from five sectors of the Nyabihu district in 2012. The area was selected as the most densely populated rural district of Rwanda as per the 2012 population census. About 49 percent were using mobile phones at least 12 months before our visit in 2012, and they were principally households with relatively younger heads. Table 1 compares the means of key characteristics of mobile phone adopters and no adopters. Mobile phone adopters work more outside the farm than non-adopters on average, and are relatively richer.

The levels of household asset, income, and output of mobile phone users are significantly higher than those of non-users. In addition, the summary statistics show that mobile phone users are more educated (5.5 years of schooling) than non-users (4.2 years). This may be due to the fact that the manipulation of mobile phone device requires basic knowledge of at least one foreign language (English or French); this limits the less educated people from adopting such technologies in rural area. The latter prefer use public phone services where dealers operate the devices on their behalf. Besides, statistics show that male headed households are more likely to use mobile phone technology in agriculture than female-headed households.

6. EMPIRICAL RESULTS AND DISCUSSION

As mentioned earlier, the point of departure to implement the propensity score technique is to calculate the propensity scores through a Probit or a Logit estimation of the treatment variable on control variables.

Table 1. Descriptive statistics of sample households by mobile phone adoption

Variable	Non adopters (51 percent)	Adopters (49 percent)	t-value for mean difference
Age of the head	46.72	41.73	3.07***
Gender (% male)	75	82	-1.57
Off-farm job (1=yes)	43.5	56.2	-2.42**
Institutional membership (1=yes)	68.8	71.3	-0.52
Farm size in hectares	0.40	0.46	-0.95
Assets in Rwandan francs (current)	193,836	289,610	-2.95***
Education	4.2	5.5	-4.46***
Output value (current Rwf)	125,578	207,916	-2.69***
Household income (expenditure)	289,207	409,808	-4.01***

* p<0.10, ** p<0.05, *** p<0.01

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2 below presents the Logistic results on the determinants of mobile phone adoption at the household level. The age of household head, household assets, and the head level of education are important factors to enhance mobile phone use in the study area. Other things being equal, older household heads will reduce the log odds of adoption of mobile phone use by 0.017.

However, there is a positive correlation between asset value and mobile phone use on one hand, and a significant positive relationship between education level of the head and the probability of mobile phone adoption on the other hand.

Results from matching presented in Table 3 indicate that mobile phone services have a positive and significant impact on agricultural output value and household income (here household expenditure stands as income proxy). Both Kernel-based and radius or caliper matching algorithms indicate that the level of agricultural output value is 38-43 percent higher for mobile phone users than their counterparts, while the level of household income is 26-27 percent higher for mobile phone users. These results are expected since farmers who use mobile phone are likely to have access to information and stay informed on the availability of inputs and markets prices or both inputs and output. They can also get easy access to extension services more than non-users, which enable smoothness in production activities. With full information on prices, farmers know the best options to sell their produce and maximize profits from their agricultural crops; hence, their agricultural income is higher.

Table 2. Logit results of household level determinants of mobile phone adoption

Variable	Coefficients	Robust Standard Errors
Age of the head	-0.017**	0.008**
Gender (1= male)	-0.139	0.313

Pseudo R-squared	0.0613	LR=-215.97

Table 3. Impact of mobile phone use on output and income

Matching algorithm	Outcome indicator	Treated (N=163)	Control (N=169)	ATT T-statistics (.)	Critical value of hidden bias
Kernel-based matching	Output value	201,348	145,919	55,429* (1.66)	1.52-1.53
	Household income	419,680	333,801	85,878***(2.70)	1.16-1.17
Radius matching	Output value	201,348	141,680	60,135* (1.80)	1.41-1.42
	Household income	419,680	329,251	90,429***(2.86)	1.22-2.23

*, **, and *** indicate the statistical significance at 10, 5, and 1 percent, respectively. T-values are indicated between brackets; ATT is the average treatment effect of the treated.

EBSCOhost - printed on 2/14/2023 11:28 AM via . All use subject to https://www.ebsco.com/terms-of-use

We tested the conditional independence assumption (CA) after propensity score matching. Table 3 indicates a substantial reduction bias in propensity score covariates after matching (more than 50 percent in each). Except for the education level of the head, the mean differences on covariates between the mobile phone users (treated) and non-users (control) after matching were not statistically different. Figure 1 shows that the mobile phone users and non-users were within the region of common support, indicating that all treated households (mobile phone users) have got corresponding untreated households (non-mobile phone users) with similar characteristics. The quality of matching is judged good as all individuals could be successfully matched and the bias reduction is far above the threshold of 20 percent (Rosenbaum & Rubin, 1983).

The sensitivity analysis results also presented in the last column of Table 3 indicate that our propensity score matching results on output value are more robust to hidden bias than household income. The critical level of gamma (Γ), at which the causal inference of significant impact of use of mobile phone may be questionable is comprised between 1.52 and 1.53, meaning the significance of average treatment effect for output would be questionable only if the odds of mobile phone adoption for two households with similar characteristics differ by the factor of 53 percent. Likewise, the significance of average treatment effect on household income will be questionable if the odds of mobile phone use between two households with the same vector of characteristics differ by the factor of 23 percent. Across two different matching algorithms, the lowest critical value on output ATT is 1.41 and the highest is 1.53 while for household income ATT, the small critical value is 1.16 and the highest is 1.23.

The results suggest that a large amount of hidden heterogeneity will not alter the inference about the estimated treatment effects on output, while the treatment effects on household income are sensible to large amounts of hidden bias.

However, Ali and Abdulai (2010) pointed out that the main purpose of the propensity score matching is to balance the distribution of relevant variables between the groups (here mobile phone uses and non-users) rather than obtaining a precise prediction of selection into treatment. In this regards, the overall indicators of matching before and after matching presented in table 4 confirmed the results presented above that the large absolute mean reduction was obtained after matching indicating the balancing power of our estimates.

The pseudo R-squared is lower after matching and the likelihood ratio tests before and after matching indicate that the joint significance of regressors is always rejected after matching, while it couldn't be rejected before. We conclude that for the two outcomes of interest (output value and household income), there is no systematic difference in covariate distribution between mobile phone users and non-users after matching.

7. CONCLUSION

The paper investigated the role of ICT as a driver of agricultural output, with a focus on the recently cellular phone adoption by smallholder farmers. Our findings suggest that households using mobile phones in their daily activities have performed better on than farm than non-users. Cellular phone adopters achieved 38 and 26 percent more of agricultural output and household income respectively. However, access to mobile phone is itself driven by education level of the household head and household wealth. Relatively

KBM: Kernel-based matching; RM: Radius matching

richer households are likely to acquire and use mobile phone, other things remaining unchanged. The maximum from ICT will be obtained if not only necessary ICT infrastructure is expanded in rural area, but also if community illiteracy is carefully addressed. More importantly, facilitating access to credit markets will enhance asset acquisition at household level and, hence, provide means to ICT adoptions in rural area.
