Chapter 3

Anterior Horn Cell Disease

Introduction

The hereditary anterior horn cell diseases most often affect children. The major anterior horn cell spectrum that confronts the adult neurologist is that of late onset spinal muscular atrophy, adolescent Kugelberg-Welander disease, and amyotrophic lateral sclerosis and its variant. Storage and degenerative diseases also affect anterior horn cells. The molecular revolution has discovered multiple genes (SMN1, SMN2, NAIP, P44, H4F5, occludin) that affect all components of the motor unit and contribute to the phenotype of anterior horn cell disease. Due to its treatment potential, other exciting aspects of anterior horn cell diseases are the autoimmune causes of motor neuron pathology and axonopathy such as GM1, GALNac-GD1a in autoimmune axonal neuropathy (AMAN) and the range of immune globulin G (IgG) antiganglioside antibodies that may be part of the differential diagnosis of anterior horn cell disease. There are many variants of both ALS and anterior horn cell disease that are associated with hereditary degenerative disease such as Frontotemporal lobe dementia with gene mutation chromosome 9 open reading frame 72 (C9ORF72). It is now important to characterize anterior horn cell entities because of gene therapies and conformity for upcoming clinical trials with small molecules.

Adult Spinal Muscular Atrophies Linked to Chromosome 5q11.12-13.3

Spinal muscular atrophy (SMA) is a heterogeneous genotypic and phenotypic group of lower motor neuron diseases. They show dominant, recessive, or x-linked inheritance patterns. The most common form of SMA is that linked to 5q, a proximal recessive form that is caused by loss or mutation of the survival motor neuron 1 gene (SMN1) with retention of the SMN2 gene. Other types of SMA are caused by mutations in genes that are expressed in both the CNS and other tissues.

Proximal 5q SMA

1. Clinical Subtypes:
 - a. Type O
 - i. Most severe
 - ii. Weakness at birth
 - b. Type 1
 - i. Onset < 6 months
 - ii. Inability to sit
 - iii. Most common
 - c. Type 2

- i. Onset between 6–18 months
 - ii. Achieves sitting, but unable to walk
- d. Type 3
 - i. Onset > 18 months
 - ii. Temporally achieves ambulation
- e. Type 4
 - i. Adult onset
 - ii. Mild proximal weakness

Genetics

1. The loss of mutation of the SMN1 gene with retention of the SMN2 gene causes SMA
2. There is a one nucleotide difference between SMN1 and SMN2 in exon 7 that alters a splice modulator. SMN2 transcripts lack exon 7 which alters oligomerization and results in degradation of the SMN protein
3. Phenotypic severity of SMAs is related to the copy number of SMN2. The greater the copy number of SMN2 the less severe the illness
 - a. Variations in the SMN2 gene itself may increase full-length SMN protein and is seen in milder SMA
 - b. There are modifiers of SMA that are outside of the SMN locus
 - c. Mutations of regulators of SMN2 splicing may underlie differences in phenotypic expression in haploidentical patients

SMN Protein Function

1. Pivotal in the assembly of Sm protein into small nuclear RNA (snRNAs) which is essential to splicing
2. Putative mechanisms of SMN function:
 - a. Splicing
 - b. Axonal function
 - c. Combination of above functions
3. SnRNA most affected by SMN reduction
 - a. Involved in splicing minor introns

Other Functions of SMN

1. Decreased SMN in axons cause decreased B-actin, mRNA transport, and axon defects
2. Interaction with the Golgi adaptor protein COP and Hu D which are present in some RNA granules in axons
3. Possible defects in transport of SM1

The Spinal Muscular Atrophies

SMA (Infantile) Werdnig-Hoffman Disease

General Characteristics

1. Autosomal recessive
2. Homozygous SMN1 deletion
3. Onset less than six months
4. Incidence is between 4–10 per 100,000 live births
5. The most severe form of SMA

Clinical Manifestations

1. Short life expectancy
2. Tongue fasciculations
3. Arthrogryposis
4. Mothers may recognize a decrease of fetal movements in utero
5. Severe proximal predominant or generalized weakness with hypotonia
6. Minimal or spared facial musculature and no oculomotor involvement
7. Fasciculations of the tongue are present
8. Abdominal breathing > poor cry and suck are evident
9. Intercostal > diaphragmatic weakness
10. Pectus excavatum and decreased anterior-posterior chest diameter are present
11. Cognition is normal

Laboratory Evaluation

1. CK is less 5x normal values
2. EMG:
 - a. Low amplitude compound muscle action potentials
 - b. Fibrillation potentials and positive sharp waves
 - c. Reduced number of motor unit potentials of increased amplitude and duration
 - d. Normal sensory nerve action potentials (SNAP) amplitude

Neuropathology

1. Muscle biopsy
 - a. Rounded atrophic fibers of both fiber types
 - b. Some hypertrophic type 1 fibers; rare type grouping
2. SMN1 deletion with L3SMN2 copies

SMA Type II*General Characteristics*

1. Autosomal recessive homozygous

Clinical Manifestations

1. Onset between 6–18 months
2. Can sit independently but are never able to stand
3. Generalized proximally predominant weakness
4. Tongue fasciculations
5. Postural hand tremor
6. Areflexia
7. Kyphoscoliosis
8. Approximately 2/3 of patients survive until age 25

Neuropathology

1. Muscle biopsy similar to SMA I or may demonstrate hypertrophic type 2 fibers and type grouping
2. Denervation and reinnervation

SMA III (Juvenile Form, Kugelberg-Welander Disease)*General Characteristics*

1. Genetics:
 - a. AR homozygous

Clinical Manifestations

1. Onset after 18 months
2. Patients stand and walk
3. Proximal weakness, areflexia, tongue fasciculations and hand tremor
4. A large percentage of patients are walking at age 60 (if the onset > 3 years) and may have a normal life expectancy
5. Limb fasciculations

Neuropathology

1. Muscle biopsy demonstrates type grouping and group atrophy of type 1 and 2 fibers
2. Some fiber splitting, endomysial connective tissue and increased internal nuclei (pseudomyopathic features)

Laboratory Evaluation

1. Mutational analysis
2. Mildly elevated CK
3. SMN1 Deletion with four SMN2 copies
4. Partial denervation and denervation

SMA IV (Adult Onset)*General Characteristics*

1. Genetics:
 - a. 30% AD
 - b. AR may be SMN related
 - c. X-linked form

Clinical Manifestations

1. Onset in the third or fourth decade in the AR form
2. Proximal weakness of the hip flexors and extensors and knee extensors; shoulder abductor and elbow extensor weakness occurs after weakness of the lower extremities
3. Tongue fasciculations, hand tremor, and rarely calf hypertrophy occur
4. Normal life expectancy

Laboratory Evaluation

1. EMG
 - a. Chronic partial denervation and reinnervation
2. Molecular genetics analysis

Neuropathology

1. Muscle biopsy reveals features of chronic denervation

Genetic Correlations in SMA I–III

1. Severity of the phenotype correlates with the number of SMN2 copies:
 - a. SMN2 gene lacks exon 7. Its protein product is unstable and degraded, but its SMN protein is partially effective
 - b. Two copies of SMN2 gene are associated with SMA I
 - c. Three copies SMA II
 - d. Four copies with SMA III
 - e. Homozygous patients for SMN I mutations that have 5 copies of the SMN2 gene may be asymptomatic

X-Linked Bulbospinal Muscular Atrophy (Kennedy's Disease)

General Characteristics

1. Genetics:
 - a. X-linked androgen receptor gene mutation
 - b. Instability of CAG triplet repeats that encode polyglutamine (pol Q) stretches in the gene

Clinical Manifestations

1. Onset in the fourth to the fifth decade
2. Early symptoms include muscle cramping associated with CK (creatinine kinase) elevation; weakness occurs in mid to late adulthood
3. Proximal predominant symmetrical muscle weakness; some patients have an asymmetric onset
4. Approximately 10% of patients have initial swallowing alterations, and a dropped jaw (weakness of muscles innervated by cranial nerve V)
5. Perioral and tongue fasciculations
6. Associated sensory neuropathy
7. Rarely occurs in women who are heterozygous (similar features to young men)
8. Androgen insensitivity that causes:
 - a. Gynecomastia
 - b. Impotence
 - c. Testicular atrophy
 - d. Decreased fertility
 - e. Increased incidence of DM
9. Tremor

Laboratory Evaluation

1. EMG
 - a. Partial denervation and reinnervation
 - b. CMAP are decreased or normal
 - c. Absent or low SNAPs and H reflexes
2. Increased CK

Neuropathology

1. Muscle biopsy
 - a. Neurogenic atrophy of both fiber types, pyknic nuclear clumps (tombstones of neurogenic atrophy); fiber type grouping
2. Some pseudomyopathic features (inflammation around necrotic fibers)
3. Sural nerve biopsy demonstrates loss of myelinated fibers
4. Consequences of androgen receptor poly Q chain elongation
 - a. AR (androgen receptor) nuclear and cytoplasmic aggregates
 - b. AR coactivators are sequestered into the nuclear inclusions that putatively cause translational dysregulation

Juvenile Segmental SMA (Hirayama Disease)

General Characteristics

1. Genetics:
 - a. Sporadic inheritance

Clinical Manifestations

1. Insidious onset in the teens of unilateral or asymmetric atrophy of the hand and forearm of C7, C8, T1 innervated roots
2. Sparing of the brachioradialis
3. Primarily a disease of young males between 15 and 25 years of age
4. Irregular course tremors
5. May be bilateral
6. Progression for 1–3 years and then either an arrest of the disease or a benign course
7. Worsening of symptoms with cold ("cold paresis")
8. Over years, there may be spread to more proximal arm muscles
9. Absent sensory loss, preservation of reflexes with no cranial nerve, pyramidal tract, lower limb, sphincter or cerebellar deficit
10. Hyperhidrosis of the involved limb
11. An Indian variant affecting the lower extremity with primary involvement of the quadriceps has been described

Laboratory Evaluation

1. EMG evaluation
 - a. Segmental motor neuron disease
 - b. Variably reduced median and ulnar CMAP with normal motor and sensory conduction velocities
 - c. Distal latencies and F-wave latencies are normal or variably affected. Sparing of C5, C6 dermatomes

Neuroimaging

1. MRI protocol in neutral position followed by imaging in hyperflexion
 - a. Asymmetrical or symmetrical atrophy of the lower cervical cord, anterior shifting of the posterior dural sac on flexion, and prominences and enhancement of the posterior epidural venous plexus on dynamic flexion
 - b. Loss of the attachment between the posterior dural sac and subjacent lamina in the neutral position

Neuropathology

1. Abnormal cervical dura with few elastic fibers
2. Loss of motor neurons in involve segments from ischemia

Scapuloperoneal Form of SMA (Davydenko Syndrome)

General Characteristics

1. Genetics:
 - a. Autosomal dominant; 1 patient with 17P11.2 deletion
 - b. Scapuloperoneal spinal muscular atrophy and CMT2C are allelic disorders:
 - i. Mutations in the gene encoding the transient receptor potential cation channel, subfamily V, member 4 (TRPV4)

- ii. Both diseases display increased calcium channel activity
- iii. Maps to Chromosome 12q24.1-q24.31

Clinical Manifestations

1. Onset in late childhood
2. Initial manifestations are weakness of shoulder girdle and foot dorsiflexion muscles
3. Weakness may generalized over time
4. High-arched foot deformity
5. Distal large fiber sensory loss

Laboratory Evaluation

1. EMG
 - a. Chronic partial denervation and re-innervation

Neuropathology

1. Muscle biopsy
 - a. Fiber type grouping and atrophy, endomysial fibrosis, variability of fiber size, nuclear bags, and fiber splitting; type 1 and 2 fibers are affected
 - b. No loss of neurons in the brain or spinal cord (one autopsied patient)
 - c. Pathologic features support a diagnosis of spinal neurogenic amyotrophy secondary to a peripheral motor neuropathy

Autosomal Dominant SMA (B1CD2)

General Characteristics

1. Genetics:
 - a. Mutations in B1CD2 (bicaudal D homologue-2 (*Drosophila*)) that map to chromosome 9q22.3
 - b. The gene encodes:
 - i. A Golgi and motor adaptor protein involved in antegrade and retrograde transport, synaptic vesicle and membrane traffic and Golgi structure; dynein-dynactin microtubular transport (links dynein molecular motor with its cargo)

Clinical Manifestations

1. Proximal and distal muscle weakness with atrophy of the lower limbs; muscle cramps
2. Waddling gait
3. Congenital contractures of the ankle and feet (some patients)
4. Benign slowly progressive course
5. Early childhood onset

Laboratory Evaluation

1. EMG
 - a. Motor nerve conduction velocities and amplitude and CMAP are normal; sensory NCVs are also normal

Neuropathology

1. Muscle biopsy demonstrates neurogenic features
2. Golgi fragmentations (electron microscopy)

Autosomal Dominant SMA (DYNC1H1) Mutations

General Characteristics

1. Genetics:
 - a. Chromosome 14q32.31
 - b. Mutations in the tail domain of the heavy chain of cytoplasm dynein (DYNC1H1)
 - i. Disrupts dynein complex assembly and function

Clinical Manifestations

1. Early childhood onset
2. Proximal leg weakness and muscle atrophy
3. Waddling gait
4. Minimal progression of weakness
5. Late in disease hand interosseous muscle atrophy without fasciculations or contracture
6. Hip extension and flexion and muscles of the upper extremity are minimally involved
7. Quadriceps more affected than the hamstrings
8. Excessive lumbar lordosis
9. No sensory loss
10. A different missense mutation causes a CMT phenotype (CMT20)
 - a. Length-dependent weakness
11. Tail domain mutations may also demonstrate learning disabilities
12. A phenotypic spectrum exists for DYNC1H1-related diseases

Laboratory Evaluation

1. EMG (clinically weak muscles)
 - a. Chronic denervation with giant motor unit action potentials (> 10 mV)
 - b. Nerve conduction studies demonstrated small motor response amplitudes in the feet and normal sensory amplitudes

Neuropathology

1. Decreased binding to microtubules in the presence of ATP

Brown-Vialetto-Van Laere Syndrome (Childhood Bulbar SMA)

General Characteristics

1. Genetics:
 - a. Brown-Vialetto-Van Laere (BVVL) syndrome is caused by a homozygous mutation in the C200rf54 gene that maps to chromosome 20p13
 - b. BVVL syndrome and Fazio-Londe disease are now considered the same entity
 - c. BVVLS2 is caused by a mutation Mutations occur in the SLC52A2 gene and maps to chromosome 8q
 - i. Encodes the intestinal (hRFT2) riboflavin transporter is causative in some patients

Clinical Manifestations

1. The onset of the disorder is usually in the second decade, but earlier and later patients have been described

2. The first symptom is usually sensorineural deafness which is progressive and severe
3. The onset of other signs and symptoms in males is five years and females up to 11 years of age
4. Other initial features include:
 - a. Weakness
 - b. Respiratory compromise
 - c. Dysarthria
 - d. Facial, neck and shoulder weakness
 - e. Infections have been associated with disease onset in some patients
 - f. Manifestation may be vocal cord paralysis (Stridor) with early onset patients
5. Lower cranial nerves VII–XII are most commonly affected; less frequent involvement of CN II–VI occurs
6. Lower motor signs are seen in the lower extremities; rare upper motor signs are seen
7. Sensation is rarely affected
8. Rare reported fundoscopic signs that have been reported include:
 - a. Optic atrophy
 - b. Retinitis pigmentosa
 - c. Macular hyperpigmentation
9. Rare signs and symptoms include:
 - a. Autonomic dysfunction
 - b. Seizure
 - c. Cognitive impairment
 - d. Decreased horizontal eye movements
 - e. Tremor
10. Non-neurologic manifestations include:
 - a. Auditory hallucinations
 - b. Abnormal behavior
 - c. Diabetes insipidus
 - d. Delayed puberty and hypogonadism
 - e. Dismorphisms
 - f. Gynecomastia
 - g. Hypertension

Neuropathology

1. Neuronal loss in cranial nerve nuclei III, V, VI as well as VII–XI
2. Loss of anterior horn cells
3. Degeneration of corticospinal and spinocerebellar tracts
4. Loss of neurons in brainstem nuclei

Laboratory Evaluation

1. EMG evaluation
 - a. Chronic or active muscle degeneration
 - b. Visual evoked potential
 - i. Prolonged latencies in approximately 50% of patients
 - c. Auditory sensorineural deafness
2. MRI
 - a. Atrophy of the brainstem and cerebellum in some patients
3. CSF protein may be mildly elevated

Madras Motor Neuron Disease Variant (MMNDV) and Familial MMND

General Characteristics

1. Genetics:
 - a. Reported from Southern India
 - b. No genetic defects have been identified
 - c. Families with autosomal dominant and X-linked inheritance have been described

Clinical Manifestations

1. Onset prior to age 15
2. Slight male predominance
3. Thin habitus
4. Distal limb muscle wasting and weakness
5. Bilateral optic atrophy (some patients)
6. Impaired hearing
7. Dysarthria, hypophonia and tongue atrophy
8. Pyramidal tract dysfunction in some patients

Neuropathology

1. Severe loss of anterior horn cells
2. Sclerosis of the ventrolateral columns
3. Neuronal loss in cranial nerves VII, IX, and XII

Laboratory Evaluation

1. Audiological assessment
2. Screening to rule out SLC52A1, SLC52A2 and SLC52A3 as well as C9orf72 expression
3. EMG
 - a. Neurogenic findings in affected muscles

Differential Diagnosis

1. Amyotrophic lateral sclerosis
2. SCA syndromes
3. Brown-Vialetto-Van Laere (BVVL) syndrome
4. Progressive spinal muscular atrophy
5. Post-polio syndrome

Distal Spinal Muscular Atrophy

Overview

These are a heterogeneous group of progressive hereditary disorders that cause distal symmetric weakness without sensory loss. They are autosomal dominant, recessive and rarely X-linked.

As noted earlier, SMN protein is localized to both the nucleus and cytoplasm and is pivotal in the assembly of small nuclear ribonucleoproteins (snRNPs). These are key components of spliceosomes. There is mounting evidence derived primarily from animal models that snRNP assembly and pre-mRNA splicing are defective in autosomal recessive SMA. Experimented evidence now supports a role for SMN in the maintenance of motor neurons by regulation of cytoplasmic and axonal mRNAs. Defects in these functions may be important in the dying back axonopathies represented by the distal SMAs.

The distal hereditary motor neuropathies are genetically heterogeneous and show a wide spectrum of phenotypic features. Some of the dHMNs genes underlie Charcot-Marie-Tooth (CMT) disease and spinal muscular atrophy SMA. There is overlap between phenotypically distinct forms of dHMN. In general, they show a length-dependent predominant motor neuropathy, but some forms also have minor sensory abnormalities and upper motor neuron features. They may overlap within 1. axonal forms of CMT; 2. juvenile forms of ALS; and 3. hereditary spastic paraplegias. They demonstrate autosomal dominant, recessive and X-linked pattern of inheritance. It is apparent that approximately 80% of patients have undiscovered gene mutations.

Functional patterns caused by these gene mutations can be characterized by:

1. Mutations that cause protein misfolding:
 - a. HSPB1
 - b. BSPB8
 - c. BSCL2
2. Mutations involved in RNA metabolism:
 - a. IGHMBP2
 - b. SETX
 - c. GARS
3. Mutations involved in axonal transport:
 - a. HSPB1
 - b. DYNC1H1
 - c. DCTN1
4. Mutations causing cation-channel dysfunction:
 - a. ATP7A
 - b. TRPV4

Mutations in Genes That Cause AD Distal HMN

1. Glycyl-t RNA synthetase (GARS)
2. Dynactin 1 (DCTN1)
3. Small heat shock 27 kDa protein (HSPB1)
4. Small heat shock 22 kDa protein 8 (HSPB8)
5. Berardinelli-SEIP congenital lipodystrophy (BSCL2)
6. Senataxin (SETX)
7. Mutation in the (VAMP) associated protein B and C genes
 - a. Brazilian families
 - b. AD inherited MND
 - c. Clinically atypical
8. A C-terminal HSPB1-mutation is associated with upper motor neuron signs

Dominant Mutation in FBX038 with Distal Spinal Muscular Atrophy

General Characteristics

1. Genetics:
 - a. Mutation in F-box protein 38
 - b. Encodes a protein coactivator of the transcription factor Kruppel-like factor (KLF7); regulates genes for neuronal axon outgrowth and repair and possibly motor neuron maintenance. Also, may impair the activation of KLF7 target genes

Clinical Manifestations

1. Onset from 13–48 years
2. Weakness beginning in the calves with slowly progressive weakness of both distal and proximal leg and arm muscles
3. Particular upper extremity weakness
 - a. Intrinsic hand muscles (abductor pollicis brevis and first dorsal interosseous muscles)
 - b. Triceps
4. Loss of ankle tendon reflexes
5. Possible sensory loss in some patients (confounding illnesses)

Laboratory Evaluation

1. EMG
 - a. Chronic neurogenic pattern that includes fibrillation and positive sharp waves that support active denervation
 - b. Nerve conduction studies
 - i. Reduced motor-evoked amplitudes in the lower limbs with normal sensory conduction

Neuropathology

1. Muscle biopsy neurogenic changes

DYNC1H1 Mutations in Distal SMA

General Characteristics

1. Genetics:
 - a. Neck and motor domain mutations
 - i. Encodes the heavy chain of cytoplasmic dynein 1
 1. A motor complex important for retrograde axonal transport

Clinical Manifestations

1. Mutations in DYNC1H1 associated with:
 - a. Autosomal dominant CMT type 2
 - b. Distal SMA affecting the legs
 - c. A form of cognitive dysfunction and migrational disorder

Neuropathology

1. These two novel mutations in DYNC1H1 (c.3581A>G and c.9142G>A)
2. Affect Golgi function
3. Associated with cortical malformations
4. A motor for the intracellular retrograde motility of vesicles and organelles along microtubules

Laboratory Evaluation

1. Molecular genetic evaluation
2. EMG
 - a. Neurogenic findings in the lower extremities

Receptor Expression-Enhancing Protein 1 (REEP1) Mutations Associated with Distal Hereditary Motor Neuropathy Type V

General Characteristics

1. Genetics:

- a. Missense mutations in GARS are found in classic dHMN and dHMNV as well as overlapping CMT2D
- b. BSCL2 mutations also seen in dHMNV
 - i. Missense mutations (c.263A>G) and (c.264C>T) that affect glycosylation
 - ii. Associated with:
 - 1. Silver syndrome
 - 2. Spastic paraplegia
- 2. Clinical manifestations of classic dsHMN:
 - a. The motor features include:
 - i. Muscle weakness and wasting primarily of thenar and first dorsal interosseous muscles

Neuropathology

- 1. REEP (receptor expression enhancing protein 1) mutations:
 - a. Underlie SPG 31 (AD form of HSP)
 - b. The mutation identified with distal hereditary motor neuropathy c.304-2A>G lacks exon 5
 - c. Function of REEP protein:
 - i. Stabilize of the membrane curvature in the tubular endoplasmic reticulum (ER)
 - d. REEP1 clinical spectrum correlates closely with BSCL2 missense mutations
 - e. Clinically REEP mutations have a phenotypic spectrum for both upper and lower motor neuron disease

Laboratory Evaluation

- 1. Molecular genetic evaluation
- 2. EMG
 - a. Neurogenic findings in affected muscles

Outline of dSMA (Hereditary Distal Motor Neuropathies)

- 1. dSMA I
 - a. Genetics
 - i. AD
 - b. Clinical features
 - i. Juvenile onset
 - ii. CMT phenotype
- 2. dSMA II
 - a. Genetics
 - i. Chromosome 12q24.3
 - 1. AD
 - 2. Encodes heat shock protein 22
 - 3. Allelic to CMT2F
 - ii. Chromosome 7q11-q21
 - 1. AD
 - 2. Encodes heat shock protein 27
 - b. Clinical features
 - i. Onset 15–25 years of age
 - ii. Rapid progression
 - iii. CMT phenotype
 - 1. CMT phenotype
- 3. dSMA III
 - a. Genetics
 - i. AR
 - b. Clinical features
 - i. Early adult onset
 - ii. Slow progression
- 4. dSMA IV
 - a. Genetics
 - i. AR
 - b. Clinical Manifestations
 - i. Juvenile onset
 - ii. Severe
 - iii. Diaphragmatic paralysis
- 5. dSMA V (see above)
 - a. Genetics
 - i. AD
 - ii. Maps to Chromosome 7p15
 - iii. Encodes glycyl t-RNA synthetase
 - iv. Allelic to CMT2D
 - b. Clinical features
 - i. Onset in hands (APB and first dorsal interosseous muscles)
 - ii. Some patients with spastic paraparesis
 - c. Genetics (alternate form)
 - i. AD; Chromosome 11q12-q14
 - 1. Gene mutated is BSCL2
 - 2. Allelic to Silver syndrome (SPG17) whose clinical features are:
 - a. AD inheritance
 - b. Lower limb spasticity
 - c. Amyotrophy of hand muscles
 - ii. BSCL2 (Seipin)
 - 1. Allelic to Berardinelli-Seip congenital lipodystrophy
 - 2. Clinical features are:
 - a. AR
 - b. Severe generalized lipodystrophy
 - c. Insulin resistance
 - d. Development of diabetes mellitus and dyslipidemia
 - e. Dysmorphic facial features
- 6. dSMA VI
 - a. Genetics
 - 1. AR 11q13-q21
 - a. Encodes immunoglobulin-binding protein 2
 - 2. Clinical features
 - a. Infantile-onset severe diaphragmatic paralysis
- 7. dSMA VII
 - a. Chromosome 2p14 Genetics
 - i. AD
 - ii. Clinical features
 - 1. Adult onset vocal cord paralysis
 - a. No upper motor neuron signs and no sensory loss
 - b. Chromosome 2p13 Genetics
 - i. AD

- ii. DCTN1 (dynactin)
- iii. Clinical features
 - 1. Adult onset associated vocal cord paralysis and facial weakness
- c. X-linked (Xq13.1-q21)
 - i. Brazilian families
- 8. Congenital non-progressive dSMA with arthrogryposis
 - a. Chromosome 12q23 Genetics
 - i. AD
 - b. Clinical manifestations
 - i. Congenital, non-progressive with arthrogryposis
- 9. Jerash Type – Jordanian children
 - a. Chromosome 9p21.1-p12 Genetics
 - i. AR
 - b. Clinical manifestations
 - i. Onset 6–12 years of age
 - ii. Pyramidal tract and sural nerve involvement
- 10. Juvenile onset CMT phenotype
 - a. Chromosome 9q34 Genetics
 - i. AD
 - ii. Allelic to ALSH
 - iii. Encodes senataxin
 - b. Clinical manifestation
 - i. Some upper motor signs and symptoms
 - ii. CMT phenotype
- 11. Austrian Kinship
 - a. Clinical manifestations
 - i. Onset in arms with pyramidal tract involvement
- iii. Facial diplegia
- iv. Contracture
- v. Mental retardation
- d. Congenital myasthenia syndromes
 - i. Fatigable muscle weakness
 - ii. Pattern of weakness is determined by which genes are mutated
 - iii. Ocular, bulbar and limb muscle involvement
- e. Pompe's disease:
 - i. Large fasciculating tongue
 - ii. Cardiomegaly
- f. Congenital myopathy:
 - i. Nemaline
 - 1. Hypotonia
 - 2. Proximal weakness
 - 3. Lax ligaments
 - 4. Areflexia
 - 5. Skeletal deformities
 - ii. Centronuclear (myotubular myopathy):
 - 1. X-linked form
 - 2. Marked weakness
 - 3. External ophthalmoplegia
 - 4. Respiratory failure
- g. Infantile Botulism:
 - i. Symmetric cranial nerve palsies
 - ii. Flaccid paralysis of voluntary muscles
 - iii. Respiratory compromise
- h. Congenital Hypomyelination Neuropathy
 - i. Hypotonia
 - ii. Distal muscle weakness
 - iii. Areflexia
- i. Infantile Mitochondrial Myopathy:
 - i. Multiorgan involvement
 - ii. Encephalopathy
 - iii. Peripheral Neuropathy
 - iv. Lactic acidosis
- j. Neonatal tetanus:
 - i. Severe spasms
 - ii. Lower cranial nerve involvement
 - iii. Spasms in facial muscles

Summary of Manifestations of Distal SMA

1. Weakness of ankle dorsiflexors, evertors and toe extensors
2. Pes cavus
3. Four genotypes of dSMA have concomitant pyramidal features:
 - a. Glycyl-t-RNA synthetase (chromosome 7p15; dSMA5)
 - b. BSCL2 gene (chromosome 11q12-q14); dSMA5
 - c. Senataxin gene
 - d. Jerash kindred
4. There is clinical overlap with phenotypes of hereditary spastic paralysis (HSP), CMT and ALS

Differential Diagnosis of the Spinal Muscular Atrophies

Congenital Presentation

1. The floppy infant
 - a. CNS alterations
 - b. Neuromuscular diseases
 - i. The infants are alert, cognitively intact, but areflexic
 - c. Congenital myotonic dystrophy:
 - i. Hypotonia
 - ii. Respiratory failure

Diagnostic Point

1. Fasciculations of the tongue favor the diagnosis of Werdnig-Hoffman disease
2. Pompe's disease has fasciculations of the tongue with cardiomegaly

Differential Diagnosis of Proximal Symmetric Weakness of Childhood to Early Adulthood Versus SMA (II, III, IV)

1. Limb-girdle muscular dystrophy
2. Congenital myopathy
3. Glycogen or lipid storage myopathy

4. CIDP
5. Emery-Dreifuss muscular dystrophy
6. Mitochondrial disease
7. Myotonic dystrophies

Diagnostic Features for SMA

1. Tongue and limb fasciculation
2. Tremor
3. Other disorders have specific features:
 - a. Mitochondrial disease (short stature, hearing loss, fatigue, short stature)
 - b. Congenital myopathies:
 - i. Thin muscles
 - ii. Dysmorphisms
 - c. Emery-Dreifuss:
 - i. Cardiac abnormalities
 - ii. Contractures
 - d. Specific features of LGMD
 - e. Dystrophinopathy
 - i. Calf hypertrophy
4. Laboratory evaluations:
 - a. DNA mutational analysis for SMA or dystrophinopathy
 - b. EMG and nerve conduction studies for MG and neuropathy (CIDP)
 - c. Assays for botulinum toxin and EMG

Diagnostic Features of Kennedy's Disease

1. Seminal clinical features of Kennedy's disease
 - a. Presents in men in the 3rd–5th decade
 - b. Proximal > distal weakness
 - c. Distal weakness in the upper extremities > lower (wasting of intrinsic hand muscles)
 - d. Neurogenic cramps
 - e. Hand tremor may occur prior to weakness
 - f. Facial fasciculations
 - i. Most prominent around the mouth and chin
 - g. Weakness and atrophy of facial muscles and those of mastication may precede that of other muscles
 - h. Dysarthria and dysphagia after ten years
 - i. Normal sensory exam
 - j. Gynecomastia
 - k. Absent/hypoactive deep tendon reflexes
 - l. Some patients with joint contractures
2. Laboratory evaluation
 - a. Elevated CK
 - b. Denervation on muscle biopsy
 - c. DNA mutational analysis
3. EMG evaluation
 - a. Weak and wasted muscle:
 - i. Normal NCV
 - ii. CMAP is low
 - b. Low amplitude or absent SNAPs

c. Needle EMG

- i. Denervation of extremity muscles; facial and mentalis muscles; grouped repetitive discharges with activation

ALS

1. Progressive bulbar palsy form
 - a. Symptomatic dysphagia early in the disease process
2. Myasthenia gravis:
 - a. Degrees of ophthalmoplegia
 - b. Weakness with exercise
 - c. Retained reflexes
 - d. Minimal, if any wasting
 - e. Laboratory evaluation
 - i. EMG
 - ii. Anti-acetylcholine receptor and muscle-specific kinase antibodies
3. Inclusion body myositis:
 - a. Seminal clinical features
 - i. Older age male
 - ii. Difficulty swallowing and limb weakness
 - iii. Wrist and finger flexion weakness
 - b. Laboratory evaluation:
 - i. Muscle biopsy (inflammatory)
 - ii. EMG
4. Lambert-Eaton syndrome:
 - a. Increased strength with exercise
 - b. Limited cranial nerve involvement (ptosis)
 - c. Loss of reflexes
 - d. Laboratory evaluation
 - i. EMG
 - ii. Antivoltage calcium channel antibodies
5. Oculopharyngeal dystrophy
 - a. Limb weakness
 - b. Mild dysphagia
 - c. Ptosis often presenting signs
 - d. Laboratory diagnosis
 - i. EMG
 - ii. DNA mutational analysis for polyadenylate-binding protein type 1
6. Multifocal motor neuropathy
 - a. Seminal clinical features
 - i. Weakness without atrophy
 - ii. Distribution is in a nerve rather than a segmental distribution; not limited to C7, C8, T1 as in Hirayama
 - b. EMG evaluations
 - i. Demyelinating characteristic in nerve conduction studies
 - c. Laboratory evaluation
 - i. GM1 ganglioside antibodies and GM1/GalNAc-GD1a antibodies
7. ALS (brachial variant)
8. Syringomyelia

- a. Pain and suspended sensory loss (primarily spinothalamic modalities)
 - b. Segmental atrophy
 - c. May have increased reflexes below the syrinx (absent at the segmental level)
 - d. Neuropathic shoulder joint
 - e. MRI:
 - i. Demonstrates the syrinx
 - ii. Some tumors have associated syrinx
9. Cervical cord pathology
- a. Cervical spondylosis and stenosis
 - b. Calcified posterior longitudinal ligament
 - c. Dislocation of C2–C3
 - d. Schwannoma (dumbbell tumor)
 - e. Neuroimaging
 - i. Cervical cord MRI with enhancement
 - f. Laboratory features
 - i. Anti-CM1 and GM1/GaNC1-GD1a antibodies

Differential Diagnosis of the Spinal Muscular Atrophy

1. The fluffy hypotonic infant:
 - a. The majority of hypotonic infants (approximately two-thirds) have a CNS disorder
2. Infant child neuromuscular disorders are characterized by:
 - a. Cognitively intact child
 - b. Diminished or absent deep tendon reflexes
3. The differential diagnosis includes:
 - a. Congenital myasthenic syndrome
 - b. Neonatal myotonic dystrophy
 - c. Pompe's disease
 - d. Nemaline myopathy
 - e. Myotubular myopathy
 - f. Centro nuclear myopathy
 - g. Rod body myopathy
 - h. Central core disease
 - i. Infantile botulism
 - j. Hypomyelinating neuropathy

Differential Point

1. A large fasciculating tongue with concomitant heart disease such as Pompe's disease; a small fasciculating tongue is more for Weinig-Hoffman disease
2. Ptosis, constipation, and loss of head control favor infantile botulism
3. Proximal muscle weakness of childhood in early adulthood
4. Dystrophinopathy
 - a. Large calves (pseudohypertrophy)
 - b. Loss of reflexes
 - c. Cardiac involvement
5. Limb-girdle muscular dystrophies
 - a. Equal occurrence in males and females
 - b. Specific features are defined by the specific mutations

- c. Congenital myopathies
 - i. Thin muscles surprisingly strong for their appearance
 - ii. Dysmorphic features
- d. Glycogen and lipid storage myopathies
- e. CIPD
 - i. Sensory loss (large > small fibers)
 - ii. Loss of reflexes

Differential Diagnosis of Kennedy's Disease

1. Bulbar ALS
2. Inclusion body myositis
 - a. Atrophy and contracture of forearm musculature
 - b. Atrophy of distal 1/3 of the quadriceps muscle
3. Myasthenia gravis
 - a. Ptosis and ophthalmoplegia
 - b. Reflexes are generally retained
 - c. Fatigue with exercise
 - d. Fazio-Londe disease
 - e. Brown-Vialetto-Van-Laere disease
 - i. VIIIth cranial nerve involvement
 - f. Lambert-Eaton syndrome
 - i. Autoimmune symptomatology
 - ii. Increased strength with exercise
 - iii. Loss of reflexes
 - g. Oculopharyngeal dystrophy
 - i. Symmetrical severe ptosis and ophthalmoplegia

Differential Diagnosis of Hirayama Disease

1. Multifocal motor neuropathy
2. ALS (monomelic variant)
3. Syringomyelia
4. Cervical disc disease
5. Congenital cervical malformations
6. Diseases with lax ligaments (affecting the cruciate ligament of the odontoid process)

Differential Diagnosis of Scapulothoracic Syndrome

1. FSH dystrophy
2. Congenital myopathy
3. Charcot-Marie-Tooth

Differential Diagnosis of Distal SMAs

1. Charcot-Marie-Tooth (axonal form)
 - a. The presence of sensory abnormalities is a major differential point
2. Mutations of the kinesin motor protein-1-b (KIF1B) gene, heat shock protein gene 27 (7q11-7q21), and a specific

- mutation of chromosome 7B may be associated with CMT2A, 2F, and 2D or with a distal SMA phenotype
3. Distal myopathies
 - a. Distal SMAs and distal myopathies both are:
 - i. Slowly progressive
 - ii. Symmetric weakness of dorsiflexion
 - iii. Both may be associated with vocal cord paralysis and fast deformities

Differential Diagnosis of Fazio-Londe and Brown-Vialetto-Van Laere Syndrome

1. Infiltrative brainstem astrocytoma or glioma
2. Bulbar ALS

Amyotrophic Lateral Sclerosis

Introduction

Amyotrophic lateral sclerosis is a lethal motor neuron disease with multiple variants that progresses to paralysis of almost all skeletal muscles. Lumbosacral motor neurons appear more susceptible than cervical ones and extra-ocular, and sphincter muscles are resistant. The cellular pathology appears focal at onset and spread by the involvement of contiguous motor neuron populations. Pathology reveals aggregated proteins in motor neurons and oligodendrocytes (approximately 10% of cases are inherited: approximately 24 familial genes and six for sporadic disease). There are approximately five patients per 100,000 individuals/year.

Molecular research in ALS began with discovery of mutations in the superoxide dismutase (SOD1) gene.

SOD1 General Characteristics

1. Ubiquitously expressed protein that catalyzes the detoxification of superoxide
2. >150 mutations of the SOD1 gene associated with ALS most of which are dominant and missense
3. Mutant SOD1 toxicity is mediated by:
 - a. Protein misfolding
 - b. Oligomerization
 - c. Gain of function toxicity
4. Effects of toxicity are:
 - a. Altered mitochondrial metabolism
 - b. Axonal transport failure and degeneration
 - c. Excitotoxicity
 - d. Proteasome disruption
 - e. Endoplasmic reticulum stress
5. Wild-type SOD1 toxicity is being investigated in sporadic ALS (SALS); putative conformational change that propagates similarly to prion disease

TDP-43 General Characteristics

1. TDP-43 gene mutations occur in approximate 4% of familial ALS

2. TDP-43 is a ubiquitously expressed DNA/RNA-binding protein whose function include:
 - a. Gene transcription
 - b. RNA splicing
 - c. RNA shuttling and translation
 - d. MicroRNA biogenesis
3. In disease states: TDP-43 is ubiquitinated, hyperphosphorylated and cleared:
 - a. Forms intranuclear and cytoplasmic inclusions
 - b. Transported from the nucleus to the cytoplasm and axons
4. TDP-43 importance:
 - a. In development
 - b. Maintenance of motor neurons

FUS/TLS (*Fused in Sarcoma/Translated in Liposarcoma*) Gene Mutations

1. Cause approximately 4% of familial ALS
2. ALS-related mutations putatively may alter its intranuclear structure that dysregulates its function and cause intracytosolic aggregation. A mechanism of its pathogenesis in ALS may be the propagation of misfolding of its protein and its interaction with TDP-43 aggregates

C9orf72 Gene

The most common genetic cause of ALS is the hexanucleotide expansion in chromosome 9 open reading frame 72 (C9orf72) gene. It accounts for approximately 50% of familial ALS (FALS) in patients of European descent, 25% of familial Frontal Temporal Lobe Dementia (FTLD) and approximately 5% of sporadic ALS.

The putative mechanisms of C9orf72 mediated ALS are:

1. Haploinsufficiency as there is decreased C9orf72 transcripts in autopsied CNS material of ALS patients
2. Formation of nuclear RNA foci that form G-quadruplex structures and hairpin loops in both DNA and RNA. The G-quadruplex are important for transcription, translation, RNA transport, and telomeric stability. The C9orf72 expansion may sequester the proteins which G-quadruple bind. The repeat may also bind and sequester transcription factors. Another mechanism suggested for the neurotoxicity of the C9orf72 expansion is deregulated protein translation termed repeat-associated non-ATG (RAN) translation which has been identified in spinocerebellar ataxia 8 and myotonic dystrophy 1 (DM1)

Accumulating evidence supports a role for the axons, dendrites, and synapses in the neuropathology of ALS. The earliest changes in ALS occur in these peripheral components of the motor unit. TDP-43 aggregates are seen early within motor axons, and mutant-SOD1 mice develop denervation and terminal axonal degeneration prior to anterior horn cell loss.

Multiple other genes and non-neuronal cells can modulate the ALS phenotype.

The modified El Escorial Criteria is an excellent platform to define the clinical diagnosis of ALS. A clinically

definite diagnosis requires the presence of upper motor neuron (UMN), as well as lower motor neuron (LMN) signs in three body regions. Probable ALS has clinical evidence of UMN and LMN signs in at least two body regions with some UMN signs rostral to the LMN signs. Clinically probable and laboratory-supported ALS patients have clinical signs of UMN and LMN in one region or if clinical UMN signs are present in one region associated with LMN signs defined by EMG criteria in at least two limbs. Clinically possible ALS is the association of UMN and LMN signs that are in only one, two, or more regions or if LMN signs are found above UMN signs, but there is no EMG evidence of spread to LMN disease.

Some clinical difficulties remain with the criteria. Some patients with motor neuron disease (MND) have a restricted syndrome with a divergent natural history from ALS, and approximately 25% of patients with rapidly progressive MND succumb prior to meeting clinical criteria. ALS affects the autonomic system as well as cognitive behavioral networks in some patients. MND may occur with both autoimmune and neurodegenerative diseases.

Epidemiology of ALS

1. Incidence of ALS is 1.8/100,000 individuals
2. Women are affected twice as frequently as men
3. There is evidence that the incidence is equal after menopause
4. Women may have a greater incidence of bulbar signs
5. There are specific geographical areas with a high incidence such as Guam and the Western Pacific as well as the Ryukyu Islands of Japan
6. There are many specific clinical variants both in type of ALS and in patients with SNPs within the genetic forms of the disease
7. Genetic mutations are thought to account for 5–10% of patients. Over 24 genes have been identified for familial ALS and 6 for the sporadic disease

Clinical Manifestations

1. Initial signs and symptoms
 - a. The signs are asymmetric and often monomelic (one extremity)
 - b. Approximately 10% of patients present with bulbar symptomatology
 - c. Decreased head control
 - d. Altered breathing
 - e. Fasciculations (in some patients); fasciculation in weak muscles with atrophy
 - f. Cramping (neurogenic) in an exercised muscle

Lower Motor Neuron Signs

1. Weakness
2. Atrophy
3. Loss of deep tendon reflexes

4. Fasciculation
5. Coordinative difficulty in proportion to weakness

Upper Motor Neuron Disease

1. Difficulty in initiating and maintaining fractionated extremity movements
2. Synkinetic muscle contraction to overcome weakness of prime movers
3. Spasticity
4. Pathologic reflexes (spread from a segmental zone with lower threshold to elicit)
5. Sustained clonus
6. Babinski sign
7. Emotional lability (pseudobulbar palsy) that consists of:
 - a. Pathologic laughter or crying; laughter without mirth; crying without tears
 - b. Increased gag or jaw reflex
 - c. Spasticity
 - d. Hyperreflexia
8. Yawning
9. Increased reflexes in a weak and wasted muscle

Classic ALS

General Characteristics

A patient presents with both UMN and LMN signs and symptoms. Initially, the LMN signs predominate in a limited group of muscles. This is considered LMN-dominant disease (LMN-D).

This pattern in the upper extremity often is initiated by atrophy of intrinsic hand muscles in various patterns:

1. Weakness and atrophy of the first dorsal interosseous muscle
2. Lateral hand split
3. Medial hand, benediction sign

The fourth and fifth fingers are involved first as they are with cervical syringomyelia. In chronic regional pain syndrome (CRPS) these fingers are dystonic. A painless foot drop may be the initial presentation in the lower extremity. Patients may also present with proximal muscle weakness. The differential diagnosis of UMN and LMN signs in one extremity is restricted and is strong for a diagnosis of ALS. Approximately 2/3 of patients with ALS present with limb-onset disease and 1/3 of these present with pure LMN involvement. Approximately 70% of these patients develop the Escorial criteria (with UMN involvement) over a six year period. At autopsy, many patients who demonstrate only LMN features have degeneration of the corticospinal pathways and the ubiquitinated inclusions of MND characteristic of ALS.

A variant of slowly progressive spinal muscle atrophy and ALS is bi-brachial (flail arm syndrome) or causes paraplegia. Over time in both variants, there is a spread of signs to other regions. Five of the autosomal dominant SOD mutations have an LMN dominant phenotype. The A4V SOD1 mutation is the most common of this genetic variant.

The ALS presentation with bulbar signs has the following features:

1. Occurs in approximately 25% of patients
2. Dysarthria is more common than dysphagia
3. Women are more frequently affected than men
4. Associated more frequently with FTLT than limb onset variants
5. May be predominant UMN, LMN or a combination of signs
6. May occur in familial ALS (FALS)
7. A prominent sign of LMN involvement of the cranial nerves is an atrophic fasciculating tongue

Other measures of cranial nerve involvement in ALS are:

1. Neck extension weakness (flexor weakness favors myopathy)
2. Weak tongue protrusion
3. Masseter and pterygoid weakness (dropped jaw is a late feature)
4. Facial weakness
5. Nasal voice (tensor veli palatini weakness)

Ptosis and ophthalmoparesis are extremely rare. With frontal lobe degeneration, patients may present with apraxia of eyelid opening. Synkinesis of jaw movement with side-to-side tongue movement is similar to difficulty with fractionated movement of the fingers in limb dominated ALS.

Primary lateral sclerosis, the exclusive involvement of predominantly UMN, presents in approximately 2–5% of ALS patient.

The primary clinical features of PLS are:

1. Onset at age 50
2. Asymmetry
3. Legs are initially involved in approximately 75% of patients
4. Spasticity is more dysfunctional than weakness
5. In approximately 15% of patients, bulbar signs are initially affected
6. Upper extremities may be initially affected in 10% of patients
7. Detrusor-sphincter dyssynergia occurs due to UMN involvement (extremely rare in classic ALS)
8. A percentage of PLS patients evolve into ALS (usually within four years)
9. Patients may maintain primarily UMN signs for as long as 20 years prior to evident LMN involvement
10. Life expectancy is usually 7–14 years

Less than 1% of ALS patients present with respiratory failure. The symptoms of increased pCO₂ and decreased pO₂ include:

1. Sleep apnea
2. Early morning headache
3. Asterixis
4. Dilated cerebral veins (rare papilledema)
5. Fatigue
6. Orthopnea
7. Cognitive dysfunction

8. Dyspnea on exertion
9. Difficulty weaning from a respirator (in association with another medical condition and similar to myasthenia gravis)
10. Diaphragmatic weakness demonstrated by paradoxical abdominal movements with respiration

Behavioral and Cognitive Alterations in ALS

1. May occur in both sporadic and familial forms of the disease
2. Approximately 10% of ALS patients meet criteria for FTLT
3. Domains affected:
 - a. Executive dysfunction
 - b. Language
 - c. Behavioral

Genetic Mutations Causing FTLT with Associated MND

1. Mutation at 9p13.2-21.3:
 - a. UMN and LMN degeneration
 - b. Behavioral, personality changes
 - c. Language dysfunction
 - d. Pathology:
 - i. Non-tau inclusions in both anterior horn cells and the granular layer of the dentate gyrus
2. Chromosome 17; mutation of the progranulin gene
 - a. Non-tau genetic locus
 - b. Extrapyramidal, behavioral and amyotrophic component
3. Chromosome 3; mutation of the chromatin modifying protein 2B gene
 - a. Usually linked to FTD but patients with bulbar signs and cognitive impairment have been reported

Genetic Forms of ALS

SOD1 Mutation

1. General Characteristics
 - a. Chromosome 21q22.1
 - b. >160 mutations in the gene that associated with ALS
 - c. Catalyzes the detoxification of superoxide dismutase
 - i. Most are dominant missense mutations
 - d. Toxicity is mediated by protein misfolding and oligomerization that leads to:
 - i. Alteration of mitochondrial metabolism
 - ii. Failure of axonal transport
 - iii. Axonal degeneration
 - iv. Excitotoxicity
 - v. Proteasome Disruption
 - vi. Endoplasmic reticulum stress
2. Clinical manifestations:
 - a. LMN predominant – A4V; LS4V; D101N
 - b. UMN predominant – D90A
 - c. Slow progression – G37R; G41D; G93C; L144S; L144F
 - d. Fast progression – A4T; N86S; L106V; V148G

Clinical Manifestations by Mutation

Late onset – G85R; H46R

Early onset – G37R; H46R

Female-predominant – G41D

Bulbar onset – V148I

Low penetrance – D90A; I113T

Posterior column involvement – E100G

Alsin (ALS2)

1. Juvenile AR; chromosome 2q 1SIN
2. Mutation; small deletion; nonsense mutation; missense mutations
 - a. Premature termination of translation; or substitution of an amino acid
3. ALS2 activates Rab5 small GTPase involved in endosome membrane trafficking
4. Clinical manifestations
 - a. AR; ALS2
 - b. Juvenile primary lateral sclerosis
 - c. Infantile-onset ascending hereditary spastic paralysis
 - d. Ascending degeneration of UMN with or without LMN involvement

Senataxin (ALS4)

1. Chromosome 9q34
 - a. Juvenile onset

Senataxin (L389S)

1. Juvenile onset ALS wasting of somatic musculature
2. Involvement of central and peripheral motor neurons
3. Overlap syndrome of ataxia tremor and MND
4. Distal amyotrophic; UMN signs

Dynactin

1. Chromosome 2p13; DCTN1 gene
2. Dynactin is a large multi-protein complex:
 - a. Subunit DCTN1 binds to dynein and microtubules that allow for axonal transport. Putative mechanism in ALS is failed axonal transport due to dysfunction of the dynactin subunit
 - b. Clinical manifestation
 - i. Adult onset LMN signs
 - ii. Some patients with vocal cord paralysis and facial weakness
 - iii. Late-onset Parkinsonism and frontotemporal atrophy
 - iv. Associated with Perry syndrome
 1. AD Parkinsonism
 2. Depression
 3. Weight loss
 4. Central hypoventilation

Vesicular Associated Membrane Protein (VAPB) ALS

1. Chromosome 20q13.33
2. VAPB gene mutations occur in FALS and SALS

3. VAPB is required for intracellular membrane trafficking and dendritic growth; ER morphology
4. P56S and T46I point mutation of hVAPB are causative
5. Form aggregates associated with motor neuron death
6. A recently described mutation V234I-VAPB has similar ALS phenotype without aggregates
7. Clinical manifestations (ALS8)
 - a. Adult onset
 - b. ALS phenotype

Fused in Sarcoma Gene (ALS6)

1. Chromosome 16q12
2. FUS gene
3. In both FALS and SALS; occurs in 5% of FALS
4. An RNA-binding protein (in the nucleus)
5. Major component of ubiquitinated inclusion bodies (autopsy material)
6. FUS mutations have been identified in FTLN with or without motor neuron involvement
7. Interacts with TDP-43
8. Both or either:
 - a. A loss of function (mislocalization from the nucleus to the cytoplasm)
 - b. The gain of function (abnormal accumulation of aggregate-prone protein by the loss of nuclear imports)
9. Clinical manifestations
 - a. Adult onset
 - b. Classic ALS phenotype

TDP-43

1. Chromosome 1P36.22
2. TARBP (TAR DNA-Binding Protein Gene)
 - a. A DNA/RNA-binding protein
 - b. Role in gene transcription; RNA splicing, RNA shuttling/translation and micro-RNA biogenesis
 - c. Possess prion-like domain; insoluble TDP-43 may seed TDP-43 aggregation; may be a mechanism for the propagation of misfolded protein between mutant and wild type TDP-43 proteins
 - d. TDP-43 protein is ubiquitinated, hyperphosphorylated and cleaved to form intranuclear and cytoplasm aggregates; mutant TDP-43 may increase cleavage and is more resistant to degradation than the wild type protein
 - e. Clinical manifestations:
 - i. Adult onset
 - ii. Classic ALS phenotype

Optineurin Gene

1. Chromosome 10
2. Optineurin gene encodes:
 - a. Cytosolic protein
 - b. A negative regulator of the NF-KB pathway; a role in mitotic progression; membrane trafficking pathways for proteins
 - c. Pathology:

- i. Golgi fragmentation
- ii. Foci formation
- iii. Increased apoptotic activity
- d. Clinical manifestations:
 - i. Open-angle glaucoma
 - ii. ALS; adult onset with classic phenotype in FALS Caucasian patients

ALS 7

- 1. Chromosome 20p tei-p13
- 2. Clinical manifestations:
 - a. Adult onset
 - b. Classic ALS phenotype

ALS-FTD

- 1. Chromosome 9q21
- 2. Clinical manifestations
 - a. Adult onset
 - b. Usually FTD phenotype but ALS occurs

ALS 3

- 1. Chromosome 18q21
- 2. Clinical manifestations
 - a. Adult onset
 - b. Classic ALS phenotype

ALS with PD and Dementia

- 1. Chromosome 17q21 microtubule-associated tau
- 2. High prevalence foci of ALS and Parkinsonism-Dementia complex (PDC)
- 3. Exist in Japanese on the Kii Peninsula, in the Chamorro people of Guam and areas of New Guinea
 - a. Some Kii Peninsula ALS patients have C9orf72 repeat expansions
 - b. Polymorphisms in MAPT which encodes tau increases the risk for ALS-PDC complex
- 4. Clinical manifestations:
 - a. Linear epithelial retinopathy
 - b. Severe dementia
 - c. Akinetic-rigid Parkinsonism

ALS X-Linked

- 1. Chromosome XLD-xpII:
 - a. Adult onset
 - b. Classic ALS phenotype
- 2. Inclusions positive for p62, TDP-43, FUS, and OPTN

ALS 5

- 1. AR; chromosome 15q
- 2. Clinical manifestations:
 - a. Juvenile onset
 - b. UMN
 - c. Pseudobulbar signs
 - d. Minimal spasticity
 - e. Long survival

UBQLN2

- 1. Chromosome-Dominant X-linked
- 2. Encodes ubiquitin-like protein
 - a. Ubiquitin 2
- 3. Regulate the degradation of proteins
- 4. Penetrance is 90% by the age of 70
 - a. earlier onset in males than females
- 5. Clinical manifestations:
 - a. Dementia phenotypically FTD which is progressive
 - b. Classic ALS; dementia preceded motor changes in some patients
 - c. X-linked juvenile and adult-onset ALS and ALS/dementia

Valosin Containing Protein (VCP) Mutations

- 1. Chromosome 9
- 2. Valosin-containing protein (VCP) gene
 - a. A member of the AAA-ATPase superfamily
 - b. Affects:
 - i. Muscle (inclusion body myositis)
 - ii. Bone (Paget's disease of bone)
 - iii. Brain (FTD)
- 3. Clinical manifestations:
 - a. Accounts for small percentage of FALS
 - b. Marked intrafamilial and interfamilial phenotypes that include:
 - i. FTD
 - ii. ALS
 - iii. Parkinsonism
 - iv. Myotonia
 - v. Cataracts
 - vi. Anal incompetence
- 4. Putative mechanisms of mutations:
 - a. Altered protein degradation
 - b. Autophagy pathway dysfunction
 - c. Apoptosis
 - d. Mitochondrial dysfunction

Angiotensin

- 1. Chromosome 14
- 2. Angiotensin is the product of the hypoxia responsive gene
 - a. Mutation causes the loss of RNAase and antigenic function
 - b. An important neurodevelopmental protein, mutation way impair neurite outgrowth
 - c. Functionally similar to vascular endothelial growth factor
- 3. Clinical manifestations:
 - a. ALS
 - b. Possible association with PID

Profilin 1

- 1. Chromosome 17
- 2. Profilin 1 gene
 - a. Involved in actin filament formation

- b. Most PFN1 alleles are in FALS the exception being E117G (but also found in control populations)
- 3. Clinical manifestations:
 - a. Primarily limb onset ALS

FIG4 (phosphatidylinositol 3,5-bisphosphate 5-phosphatase)

- 1. Chromosome 6q21
- 2. FIG4
 - a. A lipid phosphatase that regulates PI (3,5) P2, a signaling lipid on the cytosolic surface of membranes of the late endosome compartment
 - i. PI (3,5) P2 mediate retrograde trafficking of endosome vesicles to the trans-Golgi network
- 3. Clinical manifestations:
 - a. Cause CMT4J (involvement of both sensory and motor neurons)
 - b. ALS and PLS patients have been described; 1–2% of ALS patients

Neuropathy Target Esterase (NTE)

- 1. Chromosome 19p13; AR
- 2. Neuropathy Target Gene Esterase (NTE)
- 3. Neuropathy target esterase:
 - a. A neuronal membrane protein
 - b. Hydrolyzes intrinsic membrane lipids
 - c. Cell signaling pathway that controls interactions between neurons and accessory glial cells in the developing nervous system
- 4. Clinical manifestations:
 - a. Consanguineous kindred
 - b. Occurrence of MND in organophosphate compound-induced delayed neuropathy
 - c. Evaluated kindred:
 - i. Ashkenazi, Jewish ethnicity
 - ii. Progressive spastic paraplegia and distal muscle wasting
 - iii. Phenotypically resemblance to patients with Troyer's syndrome (SPG20/spartin) gene mutation and delayed organophosphate neuropathy
- 5. Mechanism in MND
 - a. Role for NTE in maintaining axonal integrity of the corticospinal tract and peripheral motor axons

D-Amino Acid Oxidase (DAO)

- 1. Chromosome 12
- 2. D-amino acid oxidase gene
 - a. Aberrant excitability of motor neurons has been implicated in pathogenesis of ALS
 - b. D-serine, an endogenous coagonist of N-methyl-D-aspartate receptors, is increased in both FALS and SALS
 - c. Mutation in D-amino acid oxidase (DAO) gene:
 - i. Encodes a D-serine degrading enzyme
 - ii. Associated with putative loss of DAO activity in one family with classic ALS
- 3. Clinical manifestation:
 - a. Classic ALS phenotype (R199W-DAO)

TATA-Binding Protein-Associated Factor 15

- 1. Chromosome 17q12
- 2. TATA-binding protein-associated factor 15
 - a. A FET protein (along with Ewing's sarcoma and FUS)
 - b. Physiologic role in RNA transcription, processing, transport, micro-RNA processing, and DNA repair
 - c. Primarily localized in the nucleus but shuttle back and forth to the cytoplasm
 - d. Putative pathogenic defect in transporting mediated nuclear import
- 3. Clinical Manifestations
 - a. Classic phenotypic ALS

Paraoxonase

- 1. Chromosome 7q21.3
- 2. Paraoxonase 1–3 gene cluster
 - a. Single nucleotide polymorphism (SNPs) of the paraoxonase gene family (PON, PON2, PON3)
 - i. Associated with the risk of developing sporadic ALS in Caucasians
- 3. A component of the antioxidant defense system
- 4. Environmental factors that may increase the risk of ALS include:
 - a. Insecticides
 - b. Pesticides
 - c. Arylesterase
 - d. Oxidants in cigarette smoke
 - e. Increased incidence in Gulf War Veterans
- 5. PON1 enzyme is a major protective mechanism to hydrolyze exogenous toxic compounds in the serum. PON2 and 3 protect against lipid peroxidation
- 6. Clinical manifestations
 - a. Association between PON gene cluster polymorphisms an increased risk of SALS

Multisystem Proteinopathy (HNRNPA2B1 and HNRNPA1)

- 1. Heterogeneous nuclear ribonucleoproteins B1 and A1
- 2. Nomenclature (multisystem proteinopathy)
 - a. MSP1 (VCP)
 - b. MSP2 (HNRNPA2B1)
 - c. MSP3 (HNRNPA1)
- 3. Genetic defects in MSP are associated with:
 - a. RNA processing
 - b. Protein Homeostasis
- 4. HNRNPA1-mutation on chromosome 12q
- 5. HNRNPA2B1 mutation on chromosome 7p
- 6. Clinical characteristics:
 - a. Mutations in HNRNPA2B1 and HNRNPA1 are causal in some families with Inclusion Body Myopathy associated with Paget's disease of bone (PDB) and/or Frontotemporal Dementia (IBMPFD)
 - b. Weakness in IBMPFD is caused by myopathy and a neurogenic process
 - c. Deposition of TDP-43, HNRNPA1B1 and HNRNPA1 protein in affected tissues
 - d. Phenotypic ALS

7. Pathogenic mechanism
 - a. Prion-like domains occur in HNRNPA2B1 and HNRNPA1 and are:
 - i. Enriched in proteins that undergo assembly and disassembly into non-membrane-bound organelles (granules)
 - ii. Prion-like domains of these proteins mediate fibrillation, pivotal to recruitment into cytoplasmic granules which may be detrimental to unaffected RNA

ALS/Sigma 1

1. Chromosome 9p
2. Sigma receptor 1 gene
3. Mutations in the gene are associated with:
 - a. Altered location of the receptor
 - b. Loss of function
 - c. Experimental studies demonstrate:
 - i. Abnormal ER morphology
 - ii. Mitochondrial alterations
 - iii. Impaired autophagic degradation
 - iv. Role in lipid raft and intracellular calcium homeostasis
4. Clinical manifestations:
 - a. Juvenile ALS
 - b. FTLN

Ataxin-2

1. Chromosome 12q
2. ATXN2 gene
 - a. Ataxin-2 is a polyglutamine protein
 - b. Ataxin-2 with intermediate length repeats (27–33) increases the risk of ALS
 - c. Ataxin-2 with intermediate length repeat (Q31)
 - i. Modifier of FUS pathology in cellular disease models
 - d. Ataxin-2 colocalizes with FUS in sporadic and FUS-linked familial ALS
 - e. Pathology
 - i. Ataxin-2 Q31 with mutant FUS (in cell lines) is associated with:
 1. Golgi fragmentation
 2. Induces apoptosis
 - f. Clinical manifestations:
 - i. Increased risk of ALS in patients with mutations of Ataxin-2 with intermediate length poly Q expansions

SQSTM1 (Sequestosome 1)

1. Chromosome 5q35
2. SQSTM1 gene:
 - a. Encodes the p62 protein
 - b. p62 protein regulates:
 - i. NF- κ B signaling
 - ii. Autophagy pathways
 - iii. Adaptor protein

- iv. Loads malformed proteins into autophagosome for liposomal degradation; accumulation of NBK/BIK protein may initiate apoptosis
- c. Clinical manifestations:
 - i. FTLN
 - ii. ALS
 - iii. Paget's disease of bone

Genes Associated with Sporadic ALS

1. Approximately 11% of SALS have genetic contributions
2. Chromosome 20; CREST gene
3. SS18L1 (synovial sarcoma translocation gene on chromosome 18-like)
 - a. Encodes a calcium- γ responsive and/or neuronal chromatin remodeling complex subunit
 - b. Amino-altering de novo mutations
4. Chromatin regulation (neuronal chromatin remodeling complex component)
5. Mutations inhibit activity-dependent neurite outgrowth in primary neurons
6. CREST associates with FUS protein
7. Clinical manifestation
 - a. Both bulbar and limb onset ALS phenotype

EPHA4 (Ephrin Type Receptor A4)

1. Chromosome 2
2. EPHA4 (a tyrosine kinase)
 - a. Encodes a receptor in the Ephrin axonal repellent system
3. Motor neurons that are most vulnerable to degeneration in ALS express higher levels of Eph4
 - a. Inhibits reinnervation of axotomy motor neurons (experimental models)
4. In humans
 - a. Mutations are associated with longer survival in ALS patients
 - b. Suggestion that Eph4 genetically modulates the vulnerability of motor neurons after axonal degeneration
5. Clinical manifestation
 - a. Longer survival in ALS patients (modifies in SALS)

UNC13A

1. Chromosome 19p13.3
2. UNC13A gene:
 - a. Variant (rs12608932) located within an intron of UNC13A
 - i. Associated with risk of developing ALS
 - b. The protein encoded is unc-13 homolog A, a presynaptic brain protein
 - i. Mouse homologue of the human protein is involved in neurotransmission and neurite outgrowth
3. Clinical manifestations:
 - a. Increased risk of ALS
 - b. Alteration of survival time (decreased)
 - c. Minor allele (rs12608932) is associated with both increased risk and shorter survival

Chromogranin B (P413L)

1. Chromosome 20
2. CHGB (chromogranin B)
 - a. P413L variant is increased in ALS patient
 - i. Causes defective sorting of CHGB into secretory granules (cell lines)
 - ii. Putative mechanism is the enhancement of accumulation of misfolded SOD1 protein an ER-Golgi system

Clinical Manifestation of Mutations

1. Risk factor for ALS
2. Induces an earlier onset of disease in FALS and SALS by approximately ten years

Kinesin-Associated Protein 3

1. Chromosome 1
2. KIFAP3 gene:
 - a. SNP rs1541160 of potential modifier of ALS phenotype
 - i. Reduced KIFAP3 expression and longer survival
 - b. KIF3A, KIF3B and KIFAP3 form a trimetric, motor complex KIF3 that:
 - i. Mediates binding between motor proteins and their cargoes
 - ii. Binds mutant SOD1 protein that may slow axonal transport
 - iii. Colocalizes with mutant SOD1 (human autopsy material)

Clinical Manifestations

1. Increased survival in patients with the mutation (approximately one year)
2. Increase risk of sporadic ALS

ELP3 (Elongated Acetyltransferase Complex Subunit 3)

1. Chromosome 1
2. ELP3 gene:
 - a. RNA polymerase II component
 - b. Involved in RNA processing and histone acetylation
 - i. ELP3 regulates heat shock protein (HSP) 70 expression by acetylation of H3 and H4
 - c. Axonal biology

Clinical Manifestations

1. Phenotypic ALS
2. Possible protective effect

Pathology of ALS

1. Degeneration and loss of myelination in the corticospinal and corticobulbar pathways
2. Loss of motor neurons at all levels of the spinal cord and many cranial nerve nuclei
3. Notably, spared are:
 - a. III, IV and VIth cranial nerves (rare exceptions)

- b. Onuf's nucleus and the anterior horn of segments 2–4
- c. Ventilator care with prolonged life is starting to reveal rare involvement of these neurons
- d. Minimal to no involvement of the intermediolateral column neurons

Inclusions

1. An extremely active area of research and their specificity and role in pathogenesis is being explored
 - a. Ubiquitin inclusions
 - b. TDP-43 inclusions
 - c. RAN polypeptides that are sequester in insoluble aggregates

Intraneuronal and Intraglial Tau Inclusions (with and without cognitive deficits)

1. Involvement of ascending sensory tracts (primarily the dorsal columns) and descending spinocerebellar tracts in the E100G mutation of SOD1
2. Pathologic changes in ALS occur in various systems that include:
 - a. Extrapyramidal
 - b. Sensory
 - c. Cerebellar
 - d. Optic Autonomic
3. Swelling of the proximal axon may be an early sign; there may be a disproportionate loss of large myelinated fibers in motor nerves
4. Loss of Betz cells in the motor cortex with slight frontal lobe atrophy
5. Loss of fibers in the ventral and lateral funiculi possibly a loss of collaterals of motor neurons
6. In patients with dementia:
 - a. Neuronal loss gliosis and vacuolation in the superior frontal gyri and inferolateral cortex of the temporal lobe
7. Some neurofibrillary degeneration is present but much less than in patients with Guamanian Parkinson-Dementia ALS complex

Neuroimaging

1. Conventional Magnetic Resonance Imaging (FLAIR) or fast spin echo proton density-weighted imaging) demonstrate:
 - a. Hyperintensity of white matter along the corticospinal tracts from the centrum semiovale to the brainstem
 - b. Frontal predominant cortical atrophy
 - c. Hypointensity of MI (rare)
2. Advanced MRI:
 - a. Diffusion-based neuroimaging evaluation of white matter fiber bundles:
 - i. Decreased fractional anisotropy in the intracranial portion of the CST (subcortical white matter, internal capsule, and brainstem)
 - ii. Decreased fractional anisotropy in the corpus callosum

- b. Tractography (DTI reconstruction of three-dimensional geometry of the pyramidal tract)
 - i. Decreases in FA limited to paracentral areas
 - ii. In the corticobulbar tract lower FA occurs in patients with bulbar rather than limb-onset disease
- c. Voxel-based morphometric (VBM)
 - i. Allows automated segmentation and quantification of gray and white matter volumes in ALS which demonstrates:
 - 1. Changes in the basal ganglia
 - 2. Superior and inferior thalamic nuclear changes
 - 3. Lateral and inferior portions of the L hippocampus
 - 4. Medial and superior components of the left caudate
 - 5. Alterations of the front striatal network
 - 6. Patients with c9orf72 with ALS but without dementia
 - a. Demonstrated cortical and subcortical frontotemporal involvement
 - 7. DTI evaluation revealed:
 - a. Sporadic ALS patients have greater white matter involvement in motor and extra motor pathways than SOD1 gene-linked FALS

Spinal Cord Imaging

- 1. New technologies allow DTI and magnetization transfer (MT) imaging of the spinal cord:
 - a. Regional atrophy can be identified
 - b. 3T MRI scanners with 300 mT/m gradients permit evaluation of spinal cord microstructure

Functional MRI

- 1. Evidence for reorganization of cerebral networks
- 2. Possible correlation of rfMRI changes with rate of disease progression

Nuclear Magnetic Resonance Spectroscopy

- 1. Allows for the measurement of the neurochemical profile of specific regions:
 - a. In the motor cortex, a decrease of N-acetyl aspartate (NAA) and/or ratios of NAA to choline-containing compounds (CHO) and creatine (CR) demonstrate loss of neuronal integrity
 - b. NAA has relationship with disability
 - c. Metabolic changes may occur early in the course of the illness
 - d. A small study has demonstrated decreased GABA levels in the cortex

Positron Emission Tomography (PET)

- 1. SPECT studies
 - a. Demonstrate a decrease in cerebral blood flow in:
 - i. Primary motor cortex

- ii. Frontal lobes (particularly in patients with dementia)

2. PET studies:

- a. Demonstrate variable decrease in cerebral metabolism
 - i. In patients with C9orf72 mutations have a more widespread involvement than those non-genetic ALS patients
- b. Less extensive GABA receptor involvement in SOD1-linked familial ALS patients
- c. Nigrostriatal dysfunction has been demonstrated by both SPECT and PET
- d. Abnormalities of microglial activation in the motor cortex and temporal lobes early in the disease process

Differential Diagnosis of Immune-Mediated Motor Neuropathies That May Simulate ALS

Immune-Mediated Lower Motor Neuron Syndromes (Motor Neuropathies)

- 1. Multifocal Motor Neuropathy (MMN)
 - a. MMN is an immune-mediated demyelinating neuropathy
 - b. Clinical manifestations:
 - i. Chronic asymmetric distal limb weakness, atrophy, and fasciculations
 - ii. Distal arms are more frequently involved than the legs
 - iii. Distribution of individual peripheral nerves
 - iv. Minimal or no sensory loss
 - v. 8:1 male to female ratio
 - vi. Most patients begin in the fifth decade (range from childhood to the eighth decade)
 - vii. Initiated with wrist or foot drop which slowly progresses to other muscles; rare cranial nerve involvement
 - viii. Lack of atrophy in weak muscles is a seminal sign
 - ix. Longstanding disease may develop secondary axon loss with denervation atrophy (peripheral nerve distribution; ALS is a myotome distribution)
 - x. Signs and symptoms of sensory loss may develop over the course of the illness

Electrophysiology Evaluation

- 1. Conduction block is the hallmark of the disease but is not mandatory
- 2. EMG features include:
 - a. Prolonged distal latencies
 - b. Temporal dispersion
 - c. Slow conduction velocity with delayed or absent F waves on motor NCS
 - d. Some patients have superimposed features of axonal degeneration
 - e. In general, there is normal sensory nerve conduction velocity across the same segment with conduction block

- f. MMN typically has clinical and EMG abnormalities in more than one nerve
- g. A variant has been described of multifocal acquired motor axonopathy (MAMA)

Laboratory Evaluation

1. CSF is generally normal; high protein suggests MADSAM or CIDP
2. Polyclonal IgM GMI antibodies occur the serum of 40–80% of patients
3. Very high titers of IgM suggest MMN. Low titers occur with GBS and CIDP
4. IgM binding to a disulphate heparin disaccharide (Ns6S) is being evaluated

Neuropathology

1. Sensory nerve biopsies are unrevealing
 - a. One study demonstrated demyelination without inflammation at the site of the motor conduction block

Multifocal Acquired Demyelinating Sensory and Motor (MADSAM) Neuropathy

Clinical Manifestations

1. MADSAM is a chronic sensorimotor mononeuropathy multiplex
 - a. An insidious onset with slow progression
 - b. Initial involvement is in the upper extremities that spreads to distal legs
 - c. Single nerve presentation may progress to symmetrical involvement
 - d. Approximately 50% evolve to a CIDP pattern
 - e. A significant proportion of patients suffers pain and paresthesia
 - f. May involve cranial nerves
 - g. Depressed to absent reflexes with disease progression

Electrophysiology Evaluation

1. Conduction block temporal dispersion, prolonged distal latencies slow conduction velocities
2. Delayed or absent F waves in one or more nerves

Laboratory Evaluation

1. Protein:
 - a. Elevated in >80% of patients
 - b. No anti-GM1 antibodies

Neuropathology

1. Demyelinating features on cutaneous sensory nerve biopsy similar to CIDP

Distal Acquired Demyelinating Symmetric Neuropathy (DADS)

Clinical Manifestations

- a. Distal symmetric demyelinating neuropathy

- b. Primarily sensory signs and symptoms with ataxia and tremor
- c. DADS-M are patients with an IgM Kappa gammopathy
 - i. 90% of patients are men
 - ii. Motor signs are distal with 60% of patients demonstrating dorsi and plantar flexion weakness
 - iii. Most patients have predominant sensory symptoms and signs

Electrophysiology Evaluation

1. Motor NCS demonstrate widespread symmetric slowing of distal sensory and motor nerves
2. Rare conduction block
3. Prolonged distal latencies with a short terminal latency index

Laboratory Evaluation

1. Serum antibodies against myelin-associated glycoprotein (MAG)
2. IgM Kappa monoclonal gammopathy
3. Elevated CSF protein

Neuropathology

1. Widely spaced myelin outer lamellae on electron microscopy
2. Deposits of IgM and complement on sural nerve myelinated fibers
3. Skin biopsies reveal distal > proximal IgM deposits on dermal myelinated fibers
4. Decrease in epidermal nerve fiber density (axonal loss) on skin biopsy

Chronic Inflammatory Sensory Polyradiculopathy (CISP)

Clinical Manifestations

1. Approximately 50% will have gait difficulty (wheelchair bound or walking with a cane)
2. Primarily large fiber sensory deficits with associated slight ataxia

Electrophysiology Evaluation

1. Normal nerve conduction velocities
2. Abnormal somatosensory evoked potentials (SSEP)

Laboratory Evaluation

1. Increased CSF protein

Neuroimaging

1. Lumbar nerve root thickening

Neuropathology

1. Lumbar sensory nerve root biopsy
 - a. Thickened lumbar nerve roots
 - b. Loss of large myelinated fibers, segmental demyelination
 - c. Onion bulb formation
 - d. Endoneurial inflammation

Chronic Ataxic Neuropathy with Ophthalmoparesis, Monoclonal IgM Protein, Cold Agglutinins and Disialosyl Ganglioside Antibodies (CANOMAD)

Clinical Manifestations

1. Heterogeneous modes of presentations
2. Distal weakness
3. Ophthalmoparesis
4. Gait and limb ataxia; leg weakness
5. Cranial nerve V and VII may be involved
6. Slowly progressive course with relapses in motor, sensory, bulbar and ocular modalities

Electrophysiology Evaluation

1. Demyelinating pattern on NCS in most patients

Laboratory Evaluation

1. Elevated CSF protein in >60% of patients
2. M-protein in >90% of patients and approximately 50% demonstrate cold agglutinin
3. BD1b and GQ1b antibodies
4. Small percentage demonstrate white matter hyperintensities on cerebral MRI

Neuropathology

1. Nerve biopsy:
 - a. Both demyelination and axonal features

Differential Diagnosis of Genetic LMN Syndromes

1. SMA Type V
2. Distal spinal muscular atrophies
3. Hereditary spastic paraparesis (uncomplicated and complicated)
 - a. HSP genotypes with a lower motor neuron component include:
 - i. SPG 9
 - ii. SPG 10
 - iii. SPG 14
 - iv. SPG 15
 - v. SPG 17
 - vi. SPG 20
 - vii. SPG 22
 - viii. SPG 26
 - ix. SPG 30
4. Progressive spinal muscle atrophy (PSMA)
 - a. Clinical features:
 - i. Middle-aged patients
 - ii. Slowly progressive asymmetric weakness of upper and lower extremities
 - iii. Fasciculations with muscle wasting
 - iv. No upper motor neuron signs
5. May mimic facioscapulohumeral muscular dystrophy (FSHD)
6. Kennedy's disease (adult):
 - a. Fazio-Londe (childhood)
 - b. Brown-Vialetto-Van Laere (childhood)

Multiple System Disorders with Anterior Horn Cell Involvement

1. Hereditary spastic paraparesis
 - a. Variants 9, 10, 15, 17, 20, 22, 26, 30 have LMN features
2. Adult Tay-Sachs disease
 - a. Mutations of the hexosaminidase (Hex) A gene
 - i. Encodes the alpha-subunit of beta-D-N-acetyl hexosaminidase
 - ii. Juvenile and adult Hex A may have some residual Hex A activity (G269S mutation)
 - iii. Clinical manifestations:
 1. MND
 2. Cerebellar deficits
 3. Psychotic episodes
3. Adult Polyglucosan Body Disease (APBD)
 - a. An AR leukodystrophy:
 - i. Multiple mutations in the GEB1 gene
 1. Encodes glycogen branching enzyme
 - b. Polyglucosan bodies accumulate in both the central and peripheral nervous system
 - c. Clinical manifestations
 - i. Neurogenic bladder
 - ii. Spastic paraplegia with associated vibration loss
 - iii. An ALS presentation with only corticospinal and anterior horn cell signs
 - iv. Normal pressure hydrocephalus presentation without other upper or lower motor signs
 - v. A relapsing variant
 - vi. Axonal neuropathy
 - vii. Cognitive decline with disease progression
 - d. Neuroimaging
 - i. WMHs in the periventricular areas, posterior limb of the internal capsule and external capsule
 - e. EMG evaluation
 - i. Slowing of motor NCVs
 - ii. Low amplitude or absent SNAPs
 - f. Pathology
 - i. Sural nerve biopsy
 1. Intra-axonal polyglucosan body deposition
4. Spinocerebellar Degenerations
 - a. Machado-Joseph disease:
 - i. General Characteristics
 1. AD; ATX3 gene
 - a. Encodes an unstable CAG repeat; associated protein misfolding
 - ii. Clinical manifestations
 1. Varies greatly between and among families
 2. MJD has been divided into
 - a. Type I
 - i. Onset at about age 25
 - ii. Spasticity, rigidity, bradykinesia, and minimal ataxia
 - b. Type II
 - i. Most common form

- ii. Young to mid adult years
- iii. Progressive ataxia and UMN signs
- c. Type III
 - i. Late onset (age 50)
 - ii. Ataxia
 - iii. Amyotrophy from peripheral nerve involvement with fasciculation
- iii. Pathology
 - 1. Degeneration and gliosis of the SN, dentate, pontine, cranial nerve nuclei and anterior horns

Rare Degenerative Disease with a Component of Anterior Horn Cell Involvement

1. Hallervorden-Spatz disease (PANK-2)
2. Guamanian-Parkinsonism-ALS complex
3. Huntington's disease
4. Creutzfeldt-Jakob disease
5. Alzheimer (variant)
6. Hereditary spastic paraparesis

Paraneoplastic Motor Neuron Disease

1. General considerations:
 - a. Occurs with multiple cancers
 - b. Most often with small cell cancer of the lung and breast cancer
2. Rare syndromes in cancer patients
3. Rarely removal of the tumor stabilizes the MND; more often there is no change
4. There is "molecular mimicry" between the nervous system and epitopes on tumor cells
5. The MND may precede discovery of the cancer by 4–10 months
 - a. Tumor removal and immune treatments fail to reverse the neurologic signs and symptoms
6. MND may be associated with encephalomyelitis, dorsal root ganglionitis, and subacute large fiber sensory neuropathy
7. Suggestive of Paraneoplastic MND:
 - a. In patients >70 years of age
 - b. Presence of paraproteinemia
 - c. Pleocytosis greater than high CSF protein levels

Antibodies Associated with MND

1. Anti-Hu in the setting of small cell lung cancer (anti-nuclear neuronal antibody 1 (ANNA1):
 - a. Rapidly progressive in some patients
 - b. Brachial amyotrophic diparesis associated with anti-Hu positive anterior horn cell disease and autonomic dysfunction
2. Anti-MA2Ta antibodies:
 - a. Most often associated with limbic encephalitis in male patients with testicular cancer
 - b. Reported in a female patient with pure progressive spastic paraparesis

3. Breast cancer:
 - a. No specific antigen reported, but with upper motor neuron disease
 - b. Purkinje cell autoantibody type 1 (infiltrating ductal carcinoma)
4. Ri/Nova gene-associated paraneoplastic subacute motor neuropathy
5. Anti-CV2 antibodies
 - a. Associated paraneoplastic syndrome includes:
 - i. Encephalomyelitis
 - ii. Cerebellar degeneration
 - iii. Peripheral neuropathy
 - b. Possible association with ALS

Hodgkin's and Non-Hodgkin's Lymphoma

1. Non-Hodgkin's lymphoma > Hodgkin's:
 - a. Anti-Tn antibodies
 - b. Cerebellar degeneration is greater in HL than NHL
 - c. Motor neuron involvement is greater in NHL than HL

Rare Causes of Motor Neuron Disease

Electrical Energy

General Characteristics

1. Electrical injuries are classified as high voltage (1000 volts and higher) or low voltage (less than 1000 volts)

Neuropathology

1. Three mechanisms of injury are:
 - a. Current flow
 - b. An arc injury (current passes from source to an object)
 - c. Flame injury
2. The final injury is determined by:
 - a. Voltage
 - b. Current (amperage)
 - c. Alternating or direct current
 - d. Duration of contact
 - e. Individual susceptibility
3. Lightning strikes often cause cardiac arrest
4. Neurologic and psychologic symptoms are the most common sequela of electrical and lightning injuries
5. Household electrical currents are usually low voltage of 110 to 200 volts with 60 cycles of alternating current

Clinical Manifestations

1. Causes acute transient weakness and paraplegia which may clear over hours to 5–10 days
2. May cause a delayed upper and LMN syndrome
3. Electrical current often travels down corticospinal and bladder pathways
4. Weakness and atrophy may begin at the site of injury
5. Bulbar signs and UMN weakness and spasticity may develop
6. A common cause of chronic regional pain syndrome (CRPS) with its consequent motor phenomena

Post-Radiation Motor Neuron Syndrome

1. General Considerations:
 - a. Dosages in the cervical spine that cause the syndrome are approximately 3000 cGy (usually for head and neck malignancy)
 - b. Distal spinal cord and cauda equine irradiation for seminoma and lymphoma (>50 reported patients);
 - i. Average irradiation dose was 5,225 cGy
 - ii. Average age 33 years
2. Pathology
 - a. Irradiation causes:
 - i. Microglial activation
 - ii. Decreases neurogenesis
3. Clinical manifestations:
 - a. LMN syndrome and other neurological signs and may occur months to years often treatment
 - b. Atrophy of affected muscles with fasciculations
 - c. No sphincter involvement
 - d. Lower extremities are preferentially involved
 - e. Weakness usually stabilizes but has been described to progress over years
 - f. A similar process occurs in the lower cranial nerves with head and neck X-rt. A long segment of the carotid artery is involved that may cause a delayed stroke
4. EMG evaluation
 - a. Fibrillation potentials occur in affected muscles
 - b. Myokymia discharges
5. Laboratory evaluation
 - a. CSF is usually normal
 - b. Protein may be slightly elevated

Diagnostic Point

1. In a setting of brachial plexus X-rt following breast cancer
 - a. Myokymia and a negative gadolinium-enhanced MRI differentiate X-rt from tumor invasion or sarcoma of the plexus

Hyperparathyroidism

1. General considerations
 - a. Isolated case reports and one series report associated motor neuron signs and symptoms with hyperparathyroidism. Skepticism persists due to the general lack of widespread EMG correlation and failure to halt progression of the signs by removal of the parathyroid glands
2. Clinical manifestations:
 - a. Proximal muscle weakness
 - b. Cramps
 - c. Hyperactive reflexes and spasticity
 - d. Minimal and inconstant sensory loss
 - e. Bladder urgency
3. EMG evaluation
 - a. Neurogenic features in some patients

Hypoglycemia

1. General characteristics

- a. The prevalence of hypoglycemic episodes follows the prevalence of diabetes
- b. Causes of severe hypoglycemia:
 - i. Iatrogenic
 - ii. Infections with sepsis
 - iii. Tumor (insulinoma)
 - iv. Related to autoimmune disease
- c. Autonomic symptoms occur first at blood glucose levels of 60–65 mg/dl
 - i. Neuroglycopenia symptoms at 47–54 mg/dl
 - ii. Cognitive function deteriorates between 20–30 mg/dl
- d. MRI evaluation
 - i. White matter is more sensitive than gray matter to hypoglycemia
 - ii. Diffuse and extensive DWI lesions predict poor prognosis
2. Clinical manifestations
 - a. Wasting of extremities with fasciculation
 - b. CNS manifestations are often seen that include organic brain syndromes. Muscle wasting from anterior horn cell damage occurs

*Drugs Associated with Motor Neuron Disease**Lead*

1. General Considerations:
 - a. 25 mg/dl is the lower range of lead toxicity in adults
 - b. Occupational exposure occurs in the mining and battery manufacturing industries
2. Clinical manifestations:
 - a. Primarily neuropsychological deficits that include:
 - i. Cognitive impairment
 - ii. Decreased learning and memory
 - iii. Decline in executive function
 - iv. Deficits in processing speed and visuospatial skills
 - v. Anxiety and depression
 - b. Occupational exposure may cause progressive cognitive deficits years after exposure
 - c. Lower motor involvement of wrist and fingers extensors
 - d. One report of both upper and LMN involvement
 - e. Anterior horn cell involvement may be activity dependent

Organophosphates

1. General characteristics
 - a. A major global cause of mortality and morbidity in developing countries
 - b. There are three stages to this insecticide poisoning:
 - i. Cholinergic phase
 - ii. Intermediate syndrome
 - iii. Delayed neurotoxicity
2. Clinical manifestations
 - a. Delayed neurotoxicity
 - i. Distal sensorimotor neuropathy

- ii. Pyramidal and dorsal column degeneration in some patients
- iii. Recurrent laryngeal palsy in some patients
- 3. Pathology
 - a. Mechanism
 - i. Depression of neuronal and cholinesterase
 - ii. Subacute levels of organophosphates may interact with a large range of target proteins; neuropathy target esterase (NTE) may be particularly important in this regard

Dapsone and Nitrofurantoin

1. Anterior horn involvement from a dying back mechanism that affects anterior horn cells

Human Immunodeficiency Virus-1 and Human T-Cell Leukemia Virus-1 (HTLV)

1. General characteristics
 - a. A small percentage of patients infected with HIV-1 or HTLV-1 develop ALS-like syndromes
 - b. Most patients with HIV and classic ALS symptoms:
 - i. Develop syndrome at an earlier age than classic ALS
 - ii. May improve with treatment
 - iii. Possible association with HERV (human endogenous retroviral sequence expression)
 1. Recent observation of HERV-K polymerase gene transcripts in HIV post-mortem brain tissue
2. Clinical manifestations
 - a. 32% of patients with LMN form; mixed UMN and LMN form in 57%
 - b. Onset at younger age (primarily in 3–4th decade)
 - c. Can develop at any stage of HIV infection
 - d. CD4 counts of <350 cells/mm³ in 56% of patients
 - e. Prognosis is not related to age at onset or initial CD4 count
 - f. Stavudine has been associated with:
 - i. HIV-associated neuromuscular weakness syndrome (HANWS)
 1. Presents with rapidly progressive limb weakness
 2. Some patients have bulbar and respiratory involvement

Human T-Cell Leukemia Virus-1

1. General characteristics
 - a. Estimates that HTLV-1 infects 15–20 million individuals worldwide in endemic areas
 - b. Associated diseases:
 - i. Adult T-cell leukemia/lymphoma (ALT)
 - ii. HTLV-1 associated myelopathy/tropical spastic paraparesis (HAM/TSP)
2. Clinical manifestations of HAM/TSP:
 - a. Slowly progressive

- b. Most patients wheelchair bound after ten years of infection
- c. UMN and LMN signs and symptoms
- d. Bladder dysfunction
- e. Sensory symptoms
- 3. Pathology
 - a. Most consistent with HAM/TSP rather than ALS

Poliomyelitis and Other Neurotropic Viruses

Poliomyelitis

General Characteristics

1. Resurgence of infection in several war-torn areas with unvaccinated populations (primarily the Middle East and portions of Africa)
2. Several hundred thousands of patients survive with the post-polio syndrome

Clinical Manifestations

1. Initial symptoms for 1–2 days:
 - a. Fever, diarrhea, headache, nausea and vomiting in most patients; the infection stops at this point
 - b. Initial symptoms subside for 3–10 days then recur:
 - i. CNS component is the major illness
 1. Meningoencephalitis with or without paralysis
 - ii. Premonitory symptoms prior to paralysis include:
 1. Myalgias
 2. Coughing
 3. Weakness that peaks within 48 hours
2. Clinical neurologic manifestations:
 - a. Asymmetric weakness (flaccid and areflexic)
 - b. Limbs and trunk are affected in 50% of patients:
 - i. Lumbosacral dermatomes > cervical
 - ii. Proximal > distal musculature
 - c. 10–15% have bulbar involvement; VII, IX and X cranial nerves
 - d. Individual fingers and toes may be affected
 - e. Approximately 30–40% have a combination of bulbar and spinal weakness
 - f. No involvement of III, IV, VI cranial nerves
 - g. Painful affected muscles with no objective sensory loss
 - h. Autonomic involvement in severely affected patients:
 - i. Cardiac arrhythmias
 - ii. Blood pressure variation
 - iii. Hyperhidrosis
 - i. Recovery is proportional to the severity of the initial weakness
 - i. Occurs over weeks to months

Laboratory Evaluation

1. In 10% of patients, the CSF may be initially negative
2. In two weeks following initiation of the illness:
 - a. An initial neutrophil leukocytosis
 - b. Usually at this period between 50–200 lymphocytes/mm³
3. Fourfold increase in serum antibody titers
4. Viral culture from stool or pharynx
5. Mild elevation of serum creatine kinase

Neuropathology

1. The polio virus is a small RNA enterovirus of the Picornavirus family
 - a. Serotype 1 is most often associated with paralysis
 - b. Incubation period is 6–20 days
 - c. Oral route of infection is most common; there is a nasopharyngeal route
 - d. Viral load is amplified in non-neural tissue prior to the paralytic phase
 - e. The majority of patients with the major illness (CNS), a small minority of infected patients, develop aseptic meningitis
 - f. Paralytic polio occurs in approximately 2% of infected patients
 - g. The vaccine caused disease is usually type 2 or 3 serotypes; in the USA only inactivated vaccine have been in use since 2000 and therefore vaccine induced poliomyelitis has been eliminated in the USA
2. Early pathology in the ventral horn:
 - a. Pial inflammation
 - b. Vascular dilation
 - c. Petechial hemorrhages
 - d. Perivascular and parenchymal inflammatory infiltrates
 - e. Some degeneration in dorsal root ganglia and the dorsal columns
 - f. Similar changes occur in the:
 - i. CN motor nuclei (Exception III, IV, VI)
 - ii. Vestibular nuclei
 - iii. Brainstem reticular formation
 - iv. Occasional involvement of the paracentral gyrus; the remainder of the cortex is spared

Laboratory Evaluation

1. Confirms involvement of anterior horn cells, ventral or motor nerve in a polysegmental pattern
2. Normal sensory nerve conduction velocities
3. Reduced amplitudes of compound motor action potentials in involved extremities
4. Conduction velocities are normal unless CMAP is <1 mV at which point they may be slowed proportionately to the degree of axon loss
5. Reduced motor unit recruitment with clinical weakness
6. At approximately three weeks following onset, fibrillation, and positive sharp waves are seen in affected muscles
7. After months, there is an increase in both amplitude and duration of motor unit potentials (reinnervation)

Post-Polio Syndrome**General Characteristics**

1. New late manifestations of polio that occur in patients 15–40 years after the acute paralytic illness; occurs in approximately 25–50% of patients

Clinical Manifestations

1. Fatigue

2. Cold intolerance
3. Sleep disorder
4. Possible depression (situational)
5. Muscular skeletal alterations:
 - a. Muscle pain
 - b. Joint pain
 - c. Spondylosis
 - d. Scoliosis (paraspinal muscle involvement-C type)
6. Neurologic manifestations:
 - a. New weakness
 - b. Muscle atrophy
 - c. Dysplasia and dysphonia
 - d. Rare respiratory insufficiency
 - e. Sleep disordered breathing
 - f. Possible cognitive deficits

Laboratory Evaluation

1. Increased levels of the inflammatory cytokines IL-1 and TNF- α

Electrophysiology Evaluation

1. EMG
 - a. Evidence of chronic denervation and reinnervation. Large motor unit potentials

Neuropathology

1. The recovery of an acutely denervated muscle depends on the reinnervation of the denervated muscle by surviving AHCs (collateral sprouting)
 - a. Death of surviving AHCs due to increased metabolic demand
 - b. Acceleration of the aging process

Non-Polio Neurotrophic Viruses Causing Acute Flaccid Paralysis from Anterior Horn Cell Involvement

1. Coxsackie virus group A type 7
2. Rabies
3. Enterovirus 6, 70, 71
4. West Nile Virus
5. Japanese encephalitis virus
6. ECHO virus 6

Enterovirus**General Characteristics**

1. Genus enterovirus; family Picornavirus
2. Traditional taxonomy
 - a. Echovirus
 - b. Coxsackie virus group A and B
 - c. Polioviruses
 - d. Since 1960 newly identified viruses receive a numeric designation (e.g.: enterovirus 71)
 - e. New taxonomy, based on molecular and biologic characteristics, divides human enterovirus into four categories:
 - f. HEV
 - i. A, B, C, D

3. Many acute flaccid paralysis in America are associated with non-polio enterovirus infection (NPEV)
4. Paralysis has been reported with:
 - a. Coxsackie virus B2–B6
 - b. Enterovirus 71
 - c. Echovirus type 3, 4, 6, 9, 11, 19 and 22

Laboratory Evaluation

1. Enterovirus isolates can be obtained from:
 - a. Feces
 - b. Pharyngeal washings
 - c. CSF
 - d. Spinal cord
 - e. Brain
 - f. Heart
 - g. Blood
 - h. Conjunctivae skin
 - i. Mucous membranes

Clinical Manifestations

1. Approximately 60% have fever at the onset of paralysis
2. Asymmetric weakness in >60% of patients
 - a. Approximately 10% have IIIrd cranial nerve involvement
3. Legs are affected > arms
4. Approximately four days from onset to peak of paralysis; residual paralysis in 25%
5. Most patients are young children

Neuropathology

1. Neurophagia
2. Astrocytosis
3. Mononuclear cell infiltration

Enterovirus 71 (EV71)

General Characteristics

1. Major Cause of Hand, Foot, Mouth Disease (HFMD)
2. Large outbreaks recorded from Southeast Asia
3. Primarily a disease of children, but adults may be infected
4. HFMD primarily caused by:
 - a. Enter viruses of the enterovirus A species:
 - i. Coxsackie virus A2–8, 10, 12, 14, 16
 - ii. Enterovirus (EV) 71, 76, 89–92

Clinical Manifestations of HFMD

1. Primarily a benign self-limiting illness of young children and infants
2. Vesicular lesions of the palms and soles
 - a. All parts of the limbs including the groin and buttocks may be involved; usually, there are oral ulcers
 - b. Acute hemorrhagic conjunctivitis may be seen

Neurologic Manifestations

1. Encephalitis:
 - a. Fever

- b. Headache
- c. Vomiting
- d. Neck stiffness
- e. Altered mental status
- f. Seizures
- g. Myoclonus
- h. ANS dysregulation

2. Poliomyelitis-like syndrome:

- a. Usually occurs in children
- b. Isolation of virus decreases with age

3. Similar manifestations have been recorded for echovirus 6

Laboratory Evaluation

1. CSF demonstrates mild lymphocytic pleocytosis

Neuroimaging

1. MRI:
 - a. Meningeal enhancement
 - b. Ventral horn (spinal cord) T2-weighted signal increase and at times gadolinium enhancement

Neuropathology

1. EVs are non-enveloped viruses that are resistant to environmental conditions and mild disinfectants
2. Transmission is through fecal-oral route although the virus has been cultured from respiratory secretions
3. There is retrograde axonal transport to the CNS; involvement occurs in:
 - a. Medulla, pons, midbrain, and cortex

West Nile Virus

General Characteristics

1. Flavivirus family
2. Mosquito-borne (crows are a common vector and may die)
3. Most patients develop a minor non-specific illness with:
 - a. Fever
 - b. Gastrointestinal dysregulation
 - c. Rash
 - d. Back pain
4. Viral transmission occurs through blood and organ transplantation

Clinical Manifestations

1. Meningitis
 - a. Occurs in less than 10/1 of infected individuals
2. Most frequent in patients older than 50 and is often associated with flaccid paralysis
3. Encephalitis
 - a. Rare seizures
 - b. Dyskinesias
 - c. Parkinsonian features
 - d. No resting tremor
 - e. Postural and action tremor
 - f. Postural instability
4. Acute flaccid paralysis:
 - a. Asymmetric muscle weakness

- b. VIIth nerve may be involved
 - c. Weakness progresses over a 3–8 day period
 - d. No sensory complaints
5. Transverse myelitis and GBS phenotypes have been described

Laboratory Evaluation

1. CSF lymphocytic pleocytosis

Electrophysiology Evaluation

1. EMG evaluation
 - a. During the acute illness (patients with flaccid paralysis)
 - i. Normal sensory nerve action potentials
 - ii. Normal or slightly reduced compound action potential amplitude
 - iii. Normal nerve conduction velocities
 - iv. Widespread fibrillation potentials

Neuroimaging

1. MRI
 - a. May demonstrate increased T2-weighted signals from the ventral horn, thalamus and basal ganglia

Neuropathology

1. Perivascular mononuclear cell infiltration of the brain and ventral horn of the spinal cord

Japanese Encephalitis (JE)

General Characteristics

1. Endemic in parts of Asia
2. Most often a disease of children
3. Similar presentation to enterovirus 30 (E30) infection
4. Adult patients are being reported with JE
5. Mosquito-borne virus of the Flavivirus family

Clinical Manifestations

1. Encephalitis/meningitis
 - a. Headache, vomiting, back pain
 - b. Fever
 - c. Altered level of consciousness (common)
 - d. Seizures (common)
2. Pediatric patients have a higher incidence nuchal rigidity, convulsions, and abnormal behavior than adults
3. Patients reported with asymmetric flaccid paralysis (polio-like syndrome)

Laboratory Evaluation

1. Increased bilirubin and aspartate transaminase
2. CSF
 - a. Lymphocytic pleocytosis with moderately elevated protein

Neuropathology

1. Direct neuronal involvement with widespread inflammatory changes

Rabies

General Characteristics

1. Canine rabies is dramatically decreasing in the USA; individual patients from Mexico, South America, Africa that are infected are seen in the USA
2. The virus is of the genus *Lyssavirus* in the *Rhabdoviridae* family
3. In the USA, the primary vectors are bats, skunks, raccoons and foxes. In Mexico and South America, it is the vampire bat

Clinical Manifestations

1. Early signs and symptoms include fever, headache, and malaise
2. In canine rabies, 20% of patients suffer pain, weakness, and sensory symptoms in the area of the bite; vampire bite victims often are unaware that they have been bitten (distal extremities are bitten while the patient is asleep)
3. Progression of the disease is associated with:
 - a. Insomnia
 - b. Anxiety
 - c. Confusion
 - d. Delirium
 - e. Polio-like flaccid paralysis
4. Symptom duration from onset to death is approximately two weeks (range 6–43 days)
5. Unusual signs include:
 - a. Severe abdominal pain
 - b. Generalized itching
 - c. Gagging sensation
 - d. Staring and unresponsiveness (lasting 10–15 seconds)
6. Classic signs of rabies:
 - a. Hydrophobia
 - b. Hallucinations
 - c. Anxiety, confusion, agitation
 - d. Hyperthermia
 - i. Usually occurs four days post-symptom onset

Neuropathology

1. Ventral roots and motor axons are inflamed, rabies virus RNA is found in AHCs
2. Perivascular cuffing

Laboratory Evaluation

1. Saliva can be tested by virus isolation or RT-PCR
2. Serum and CSF reveal antibodies to the virus

Differential Diagnosis of Poliomyelitis

1. Neurotropic Viruses:
 - a. Viral prodrome
 - b. Aseptic meningitis
 - c. Asymmetric bulbar paralysis
 - d. Differential points:
 - i. HFMD (EV71) – vesicular lesions of the palms and soles; flaccid paralysis

- ii. Heart involvement – Coxsackie A variants
- iii. Japanese encephalitis – altered mental status, seizures, and liver involvement
- 2. Guillain-Barré syndrome:
 - a. More symmetric paralysis, motor > sensory involvement (large fiber modalities)
 - b. Decreased reflexes in muscles prior to weakness
 - c. Facial paralysis
 - d. Greater incidence of ventilator dependence
 - e. Cytoalbuminologic dissociation in CSF
 - f. EMG reveals a demyelinating sensory motor neuropathy
- 3. Transverse myelitis:
 - a. More acute onset of paraparesis > quadriparesis
 - b. Band-like sensation at or above the level of weakness
 - c. Bladder and bowel involvement
 - d. MRI evidence of intraparenchymal spinal cord swelling
- 4. Botulism:
 - a. Infantile botulism occurs between 3–6 months; wound botulism; improperly canned foods
 - b. Cholinergic dysautonomia occurs with:
 - i. Non-reactive large pupils
 - ii. Constipation
 - iii. Urinary retention
 - iv. Dry mouth and eyes
 - c. Weakness is generalized and symmetric
 - d. Cranial nerve abnormalities (IX, X, XII) are prominent with dysarthria, dysphagia, and dysphonia
 - e. Frequent occurrence of diplopia and ophthalmoplegia
 - f. Areflexia
 - g. EMG pattern of dysfunction of neuromuscular transmission
 - i. Incremental increase in amplitude to 5–50 Hz repetitive stimulation (10 seconds)
- 5. Rabies
 - a. Approximately 20% of patients present with paralytic rather than encephalitic form of the illness
 - b. Prodromal symptoms of fever, chills, fatigue, irritability and insomnia
 - c. Pain, weakness, and sensory involvement may begin at the site of injury; bat bites (vampire) may be asymptomatic
 - i. Signs and symptoms may occur 1–3 months after a rabid animal bite
 - d. Anxiety, agitation and hydrophobia less common in the paralytic than encephalic form
 - e. Genitourinary and bulbar symptoms occur

Acute Intermittent Porphyria

- 1. AD with variable penetrance
- 2. Associated with severe abdominal pain and vomiting (soft abdomen)
- 3. Psychosis
- 4. Fasting, alcohol, and specific drugs are triggers

- 5. Primarily a motor predominant proximal symmetric neuropathy that may be asymmetric and accompanied by wasting in affected muscles
- 6. Autonomic neuropathy with severe abdominal pain, cardiac arrhythmia and blood pressure variation
- 7. Retained ankle jerks in an otherwise areflexia patient
- 8. Cranial nerves, including III, IV, and VI may be involved

Spinal Epidural Abscess

- 1. Occurs in a setting of:
 - a. Post-spinal surgery
 - b. Preceding discitis
 - c. SBE
 - d. Intravenous drug use (usual involvement is in the thoracic spine)
- 2. Fever, severe at level back pain and acute flaccid para- or quadriparesis (spinal shock)
- 3. Sensory level (often higher 1–2 segments in the back than the abdomen; pattern of intercostals nerve innervations)

Hypokalemia

- 1. Symmetric generalized weakness
- 2. Potassium < 2 meq/L; surprisingly little EKG change
- 3. No myotatic reflexes; deep tendon areflexia; no cranial nerve involvement (extremity rare)
- 4. Weakness is generally proximally predominant
- 5. Neck flexors and extensors may be involved
- 6. No sensory loss; muscles may feel tight

Hypophosphatemia

- 1. Occurs in a setting of diabetic ketoacidosis, burn or intravenous hyperalimentation
- 2. The serum level associated with paralysis is usually <1 mg/dl
- 3. Motor predominant neuropathy that may impair ventilation

ALS Phenotypes

- 1. Classic ALS with both UMN and LMN signs and symptoms
- 2. Genetic sporadic ALS (SALS)
- 3. Familial ALS (FALS)
- 4. Brachial amyotrophic diplegia
- 5. ALS with dementia
- 6. Monomelic (one extremity involvement)
- 7. Hemiplegic variant (Mills syndrome)
- 8. Spinal progressive muscular atrophy phenotype
- 9. Primary lateral sclerosis
- 10. Progressive bulbar palsy

Differential Diagnosis of ALS

- 1. Hereditary spastic paraparesis:

- a. Type SPG 9, 10, 14, 15, 17, 20, 22, 26 and 30 have a LMN component
- b. Pes cavus and dorsal column sensory loss are differential features
2. Distal spinal muscular atrophy type V:
 - a. Mutation of BSCL 2 gene
 - b. Pes cavus, distal amyotrophy, similar to CMT with no sensory loss
3. Structural spinal cord lesions:
 - a. AVM
 - b. Cervical spondylosis and spinal stenosis
 - c. Differential point is no bulbar symptomatology:
 - i. Spondylosis disease is most often at areas of neck movement C5-C6 whereas ALS typically affects C8-T1 initially
4. Copper deficiency:
 - a. Usually large fiber sensory loss
 - b. GI disease that may interfere with absorption
 - c. Concomitant use of zinc compounds (dental adherents)
 - d. Anemia (sideroblastic changes and nuclear maturation defects)
5. Myasthenia gravis
 - a. An important consideration of any ALS patient with a bulbar presentation:
 - i. Usual oculomotor deficits with ptosis; extremely rare in ALS
 - ii. The absence of UMN signs other than hyperreflexia in some patients (spreading acetylcholine sensitivity) and no tongue atrophy. Myasthenia gravis patients on anticholinesterase drugs may demonstrate a fasciculating tongue. This may also occur with hyperthyroidism
 - iii. Other disorders that may affect multiple lower cranial nerves are:
 1. Head and neck cancers with meningeal invasion
 2. Inclusion body myositis
 3. Oculopharyngeal dystrophy
 4. Kennedy's disease
 5. Sarcoid and Wegener's granulomatosis
6. Fazio-Londe disease
 - a. Presentation in the first decade of life
 - b. Rarely VIIth nerve and ophthalmoparesis occurs
7. Brown-Vialetto-Van Laere
 - a. Presents in the first or second decade with bulbar weakness
 - b. Sensorineural hearing loss
 - c. May also have retinal pigmentary degeneration, ataxia, seizures, and dysautonomia
8. Predominantly LMN diseases that may simulate PMA
 - a. Multiple motor neuropathy with conduction block (MMN)
 - i. Weakness without atrophy
 - ii. Nerve rather than segmental pattern of weakness
 - iii. GM1 antibodies, conduction block of motor nerves and brachial plexus swelling by MRI (1/3 of patients) are important laboratory features
9. Inclusion body myositis
 - a. The pattern of weakness is wrist and finger extensors and knee extensors. Often atrophy of the distal 1/3 of the quadriceps
10. Hirayama disease:
 - a. May be focal form of benign amyotrophic
 - b. Spread to opposite extremity in 1/3 of patients
 - c. Evidence for abnormal mobility of the cervical spine
 - d. Lower extremity form primarily described from India (Madras disease)
 - e. Dysphagia
11. Kennedy's disease:
 - a. X-linked
 - b. Gynecomastia
12. Primary lateral sclerosis
 - a. Need at least four years from disease onset of purely UMN signs to be PLS
 - i. Features that predict the evolution to ALS with UMN and LMN signs are:
 1. Focal motor weakness
 2. Bulbar onset
 3. Weight loss
 4. Reduced forced vital capacity
13. Paraneoplastic myelopathy
 - a. Rapid evolution of disease
 - b. Associated primarily with lung and breast cancer
14. HIV/HTLV-1
 - a. May produce a slowly progressive spinal cord syndrome
 - b. HTLV-1 has prominent bladder symptomatology that would be very unusual for ALS (Onuf's nucleus is usually spared)
15. X-linked adrenoleukodystrophy
 - a. Affects middle-aged female carrier
 - b. Progressive paraparesis
16. Adult acid maltase deficiency
 - a. May present with slowly progressive spinal muscle atrophy
 - b. Diaphragmatic involvement earlier than seen in ALS and more proximal muscle involvement are against an ALS diagnosis
17. Late-onset Tay-Sachs disease
 - a. Younger onset than classic ALS
 - b. Predominantly male of Ashkenazi Jewish ancestry
 - c. Balance problems and iliopsoas weakness are often early signs
 - d. All patients had cerebellar atrophy on MRI
 - e. A few patients have psychiatric and oculomotor abnormalities
18. Lyme's disease
 - a. Predominant manifestations:
 - i. Polyradiculopathy
 - ii. Rapidly progressive weakness and atrophy
 - iii. Increased reflexes

Benign Fasciculations

1. Fasciculations are benign if they are unaccompanied by weakness, wasting or reflex change
 - a. Benign fasciculations occur in the thenar eminence, eyelids, calves or orbicular muscles in normal people
 - b. They may continue for days
 - c. In general, they are more constant in location, frequent and rhythmic than those that signal denervation
 - d. Normally modeled motor neuron unit size rather than the large units typical of reinnervation (ALS or MND)
 - e. Some patients complain of fatigue and weakness

Pathologic Fasciculations

1. Occur in weak and atrophic muscles. Fasciculations in association with hyperreflexia may signify UMN and LMN degeneration or a compressive myelopathy with concomitant root involvement (cervical and lumbar spondylosis)
2. Hereditary diseases with fasciculation:
 - a. Hereditary forms of SMA and ALS
 - b. Some forms of hereditary spastic paresis with lower motor components (SPG 7, 9, 14, 15, 20, 24, 26)
 - c. Hereditary distal motor neuropathies (hSMA type V)
 - d. Bulbospinal muscular atrophy
 - e. GM2 gangliosidosis
 - f. Triple-A syndrome:
 - i. Mutation in the AAAS gene that encodes ALADIN
 - ii. Achalasia, Alacrima, and Addison's
 - iii. UMN and LMN signs (late onset form)
 - iv. Motor-sensory or autonomic neuropathy
 - v. Optic atrophy
 - vi. Cerebellar ataxia
 - vii. Parkinsonism
 - viii. Dementia

Non-Hereditary Diseases with Fasciculation

1. Fasciculation in peripheral nerve hyperexcitability syndromes include:
 - a. Isaacs' syndrome
 - b. Voltage-gated potassium channelopathy
 - c. Cramp fasciculation syndrome
 - d. Morvan's syndrome
2. Varied causes of fasciculations (neurodegenerative, autoimmune, infective mitochondrial and genetic):
 - a. Familial amyloidosis
 - b. Some spinocerebellar ataxias
 - c. Huntington's disease
 - d. Rett syndrome
 - e. L1-cell adhesion molecule (L1CAM) mutations
 - f. Fabry's disease
 - g. Gerstmann-Sträussler disease
 - h. Some mitochondrial diseases
 - i. Nerve root compression (cervical and lumbar spondylosis)

- j. Rarely in a muscular dystrophy
- k. Post-polio syndrome (formerly affected muscles)

Rare Signs in ALS

1. Extra-oculomotor abnormalities; may have decrease of vertical saccades
2. Sphincter dysfunction (may occur late in the disease in those on ventilators)
3. Sensory loss (often subtle dorsal column involvement)
4. Extrapyrimal signs in approximately 5%; impairment of postural reflexes (major confounder is age and the onset of other neurodegenerative diseases)
5. Autonomic dysregulation involving:
 - a. Blood pressure control
 - b. Heart rate variability
 - c. GI function

Associated Features

1. Sleep apnea (morning headache)
2. Sialorrhea
3. Silent and asymptomatic aspiration
4. Disturbance of sleep architecture
5. Decline of voice power with speech
6. Cachexia greater than expected from decreased nutrition
7. Absence of expected bed sores (possible changes in type III procollagen)
8. Extremely rarely the process appears to stop
 - a. There are plateaus and fluctuations of neurologic disability in some patients

Chapter 4

Spinal Cord

Overview of Spinal Cord Anatomy

The spinal cord is frequently involved in specific patterns due to varying pathologies which are extremely helpful in differential diagnosis. Recent advances in neuroimaging technology allow visualization of specific cord quadrants and Rexed nuclear layers. Due to differential growth of the vertebral column relative to the spinal cord, spinal cord segments do not correspond to vertebral segments. The spinal cord, in general, lies two segments above the vertebral level. Thus, the lumbar segments lie at the T11–T12 vertebral segment. Various congenital anomalies may also change this anatomy such as the tethered cord syndrome in which the spinal cord segments are below their expected vertebral level. The spinal cord and nerve roots move with both extension and flexion. Cervical spinal roots exit above their corresponding vertebrae while thoracic and lumbar roots exit below their corresponding vertebrae. The foramen through which the nerve root exits are canals. Nerve roots are often the subject of facet hypertrophy, synovial cysts, and root entry zone pathology. The dorsal root ganglia are within the foramen exit canals. They also possess a less tight blood-nerve barrier than the brain.

The spinal cord is surrounded by the pia mater, arachnoid and dura mater which is composed of an inner meningeal and an outer endothelial layer. The endothelial layer forms the periosteum of the vertebral canal and the epineurium of the spinal nerves (outermost covering) at the intervertebral foramina. The loose, irregular trabecular arachnoid is continuous with the cranial arachnoid. The pia mater contains large vessels, adheres to the spinal cord, and gives rise to the dentate ligaments that extend to the dura. They extend from the foramen magnum to the first lumbar vertebrae. The filum terminale is a condensation of the pia mater between the conus medullaris (S1–S5 spinal segments) and the second sacral vertebra. The leptomeninges are formed from the pia and arachnoid which surround the spinal nerves as the perineurium. The CSF, arteries and veins are contained in the subarachnoid space (between the arachnoid and pia mater). The epidural space contains a venous internal vertebral plexus (Bateson's plexus) that has no valves and connects with cerebral veins.

Anatomy of the Spinal Gray Matter

Cytoarchitecture of the spinal cord's neurons is organized by Rexed layers that have specific functions. There is great neuroplasticity of the dorsal horn after peripheral nerve and spinal cord injury and chronic pain states. This is manifest as up or down regulation of ion channels, dendritic spine synap-

tic morphologic configurations, growth factor, neurotransmitter, and cytokine concentrations. These anatomical and chemical changes underpin the physiologic behavior of neurons to produce long-term potentiation and depression, spasticity and spinal shock that are evident in specific pathologies.

Rexed Layer Classification

1. Lamina I
 - a. Posterior marginal nucleus
 - b. Pain discriminative A-delta and C-fiber afferent innervation
2. Lamina II (substantia gelatinosa)
 - a. Pain and temperature modalities:
 - i. A-delta 1–4 micron thinly myelinated afferents:
 1. Fast pain (epicritic)
 2. Cold sensation
 - ii. C-fibers:
 1. Slow conducting, burning pain
 2. Multimodal C-fiber input
 3. Heat modality and heat pain
 4. Axons of these neurons are a major component of Lissauer's zone (dorsolateral fasciculus). They synapse two spinal segments above and below their level of entry
3. Lamina III and IV
 - a. Nucleus proprius, dorsalis
 - b. Primarily receives, touch, pressure and mechanical modalities of sensation
 - c. Contribution to the lateral spinothalamic tract
4. Lamina V
 - a. Synapses with rubrospinal and corticospinal tracts
 - b. Lateral portion contains multimodal pain transmission neurons that receive:
 - i. Nociceptive-specific fibers
 - ii. Sympathetic afference
 - iii. Temperative specific fibers
 - iv. Low threshold mechano receptive neurons (LTM)
5. Lamina VI
 - a. Present in cervical and lumbosacral enlargement; absent in fourth thoracic to second lumbar segments
 - b. The lateral component contains wide dynamic range pain transmission neurons
 - c. Contributes to the lateral spinothalamic tract
6. Lamina VII
 - a. Afferents from the corticospinal (CST) and rubrospinal tract
 - b. Clark's column (origin of the dorsal spinocerebellar tract); first thoracic to the second or third lumbar segment
 - c. Intermediolateral column:
 - i. Sympathetic neurons (first thoracic to second or third lumbar segments)
 - ii. S2–S4 is parasympathetic

- d. Intermediomedial column:
 - i. Extends the length of the spinal cord
 - ii. Receives visceral afferents
7. Lamina VIII:
 - a. In the cervical and sacral enlargements
 - b. Contains commissural neurons
 - c. Afferents from:
 - i. Vestibulospinal tract
 - ii. Reticulospinal tract
 - iii. Tectospinal tract
8. Lamina IX
 - a. Contains proximal and distal motor neurons; extrafusal and intrafusal neurons
 - b. Motor neuron afference:
 - i. Excitatory (glutamatergic) from the cortico-, rubro-, reticulospinal pathways; reflex arcs
 - ii. Inhibitory (glycinergic, GABA) input from propriospinal neurons
 - iii. Motor neurons project inhibitory collaterals to Renshaw cells (inhibitory interneurons)
 - c. Somatotopic organization of alpha motor neurons:
 - i. Abductor neurons are anterior
 - ii. Flexor neurons posterior
 - iii. Extensor and adductor neurons are intermediate; some finger motor neurons are dorsolateral. Approximately 5% of descending CST fibers innervate these neurons directly
 - d. Somatotopic pattern for the lower extremity (lumbosacral segments)
 - i. Trunk neurons are medial
 - ii. Foot neurons are lateral
 - iii. Leg and thigh neurons are intermediate
 - iv. Thoracic segments:
 1. Neurons that innervate the abdominal musculature are medial to those that innervate the intercostal muscles
 2. Neurons that innervate back muscular are intermediate
 - v. Cervical segments:
 1. Hand and finger neurons are most lateral forearm
 2. Forearm and shoulder are intermediate
 3. Trunk neurons are most medial
 - vi. Tonic motor neurons:
 1. Have a low depolarization threshold and innervate Type I oxidative muscle fibers:
 - a. That stain with oxidative enzyme stains such as nicotinamide-adenine dinucleotide tetrazolium reductase (NADH-TR); succinic dehydrogenase (SDH) or cytochrome C oxidase (COX)
 - b. Are slow twitch
 - c. Fatigue resistant
 - d. Are inhibited during dynamic movement

Phasic Neurons

1. Higher firing threshold
2. Innervate fast twitch Type II muscles (myofibrillar ATPase stain)
3. Glycolytic muscle fiber metabolic profile
4. Phasic neurons project more recurrent collaterals to Renshaw cells than tonic neurons

Gamma Motor Neurons

1. Are interspersed among motor neurons
2. Discharge shorter intrafusal fibers and depolarizes motor neurons
3. Motor neurons effect movement by coactivation and modulation of the gamma loop

Ascending Spinal Tracts

1. Dorsal columns (posterior funiculus)
 - a. Somatosensory information transmitted primarily to VPL and VPM of the thalamus
 - b. Modalities encoded include:
 - i. Vibration (Pacinian corpuscles)
 - ii. Position sense
 - iii. Higher cortical sensory modalities such as stereognosis and two point discrimination
 - iv. The deepest fibers may have a role in transmitting visceral pain
 - v. The heavily myelinated fibers of the medial components of the dorsal root pass over the dorsal horn to ascend in the dorsal columns. They give rise to collaterals which terminate in Rexed layers III and IV
 - vi. Sacral, lumbar and the lower six thoracic levels lie medially in the posterior funiculus (dorsal columns) and form the fasciculus gracilis. Fibers from the upper six thoracic segments and all cervical levels are lateral and comprise the fasciculus cuneatus. They terminate in the nucleus gracilis and cuneatus of the medulla and then project to the thalamic nucleus VPL

Neospinothalamic Tract (Lateral Fasciculus)

1. Finely myelinated A-delta fibers (1–4 μ) and unmyelinated C-fibers from the lateral bundle of the dorsal root bifurcate into short ascending and descending branches (usually 2 segments) within the zone of Lissauer to terminate in the substantia gelatinosa of the dorsal horn (lamina I and outer Lamina II). They decussate through the ventral white commissure into the ventrolateral quadrant of the spinal cord to form the lateral spinothalamic tract. Neurons of Lamina I and outer lamina II are nociceptive specific
 - a. The A-delta component of the lateral spinothalamic tract encodes cold and sharp, fast pain that signals lo-

calization, intensity and affect. These fibers project to the thalamus (VPL and intralaminar nuclei) and then to the cortex (SI, SII and the insula). Collateral are given off at many levels

- b. The C-fiber component of the lateral dorsal root bundle (unmyelinated fibers) are slowly conducting and signal poorly localized burning pain. There are many subcategories of polymodal C-fibers that signal specific categories of pain. C-fibers also transmit the thermal modality of heat

Also, comprising a major component of the lateral neospinothalamic pathway are axons from wide dynamic (WDN) pain transmission neurons that arise from the deep dorsal horn in the lateral components of laminae V and VI.

These WDN neurons respond to:

1. Low threshold mechanical stimulation (LTM)
2. Thermal stimuli
3. Sympathetic innervation
4. Nociceptive-specific stimuli

They are a component of static and dynamic allodynia and hyperalgesia.

The neospinothalamic tract is topographically organized such that fibers that originate from cervical levels are dorsomedial, and sacral fibers are ventrolateral. Temperature modalities are dorsolateral, and pain fibers are ventromedial (this information is derived from cordotomies performed for intractable pain).

The Dorsal and Ventral Spinocerebellar Tracts

1. These tracts are located most laterally and originate from the neurons of Clark's column
2. They mediate unconscious proprioception from the lower extremities to the intermediate zone of the cerebellum
3. The cuneocerebellar tract from cervical segments mediates similar information from the upper extremities

Tracts in the Ventral Funiculus

1. The ventral spinothalamic tract carries fibers that transmit light touch, sexual sensation, tickle, and itch. Possible role in affective components of pain
2. The spino-olivary tract relays cutaneous modality information from Golgi tendon organs to the dorsal and medial accessory olivary nuclei
 - a. Golgi tendon organ afferents provide an estimate of muscle tendon complex length which is a component for feedback during postural and dynamic movement
3. The spinoreticular tract:
 - a. Component of the ascending reticular activating system (arousal)
 - b. Ascends through the entire spinal cord
 - c. Derived from axons of Lamina V
 - d. A role in head and eye coordination to a visual target

Descending Tracts

The Corticospinal Tract

1. The fibers of the corticospinal pathway are somatotopically organized at all levels (the exception being the medullary pyramids after their decussation)
2. The pathway takes origin from:
 - a. Primary motor cortex (BA4)
 - b. Lateral premotor cortex (BA6)
 - c. Supplementary motor cortex (BA6)
 - d. Parietal lobe (BA3, BA1, BA2)
 - e. Superior parietal lobule (BA5 and BA7)
 - f. Cingulate gyrus (small component)
3. The decussation of the pyramids occurs at C1–C2 (the arm fibers are more anterior and medial). There are approximately one million fibers in each pyramid and 90% decussate. 10% of pyramid fibers are uncrossed and descend and cross at their level of innervation (contralateral cervical and thoracic segments)
4. The primary termination of the CST is lamina IV through VII (interneurons) that then project to neurons in Lamina IX. There are direct connections (approximately 5% of CST fibers) to neurons in IX that control the digits. The termination of the uncrossed descending CST is contralateral Rexed layers VIII. Somatic organization of motor neurons that innervate the extremity are:
 - a. Axial musculature neurons are in the ventromedial portion of area IX
 - b. Limb-girdle innervating neurons are more lateral
 - c. Intrinsic extremity musculature is dorsolateral
 - d. The same topological pattern for propriospinal neurons is seen in Lamina V–VIII. These fibers project several segments from their origin and thus innervate multiple segments of proximal muscles. Propriospinal interneurons that innervate intrinsic hand muscles project minimally from their segment of origin and modulate restricted groups of distal muscle

Rubrospinal Tract

1. Originates from BA4, BA6 of the frontal cortex and BA3, BA1 and BA2 of the parietal lobe
2. Axons primarily from the magnocellular division of the red nucleus decussate and innervate flexor motor neurons

Lateral Reticulospinal Tract

1. Originates in the medullary and pontine reticular formation (ipsilaterally) and descends in the ventrolateral funiculus
2. Relay for signaling of afference to the reticular formation from the cortex, cerebellum, cranial nerves and hypothalamus to the spinal cord

Vestibulospinal Tracts

1. The lateral vestibulospinal tract (origin is Dieter's nucleus) traverses the entire cord

2. Is excitatory and is essential for vestibular nuclei afference
3. The medial, vestibular nucleus is monosynaptically inhibitory and descends to upper cervical segments

The vestibulospinal tract and the medial reticulospinal tract facilitate alpha and gamma motor neurons that project to anti-gravity musculature. The CST, rubrospinal tract, and lateral reticulospinal pathways inhibit antigravity muscles and facilitate their antagonists.

The Medial Longitudinal Fasciculus

1. Is both ascending and descending
2. Originates from vestibular and reticular neurons
3. Decussates posteriorly at the levels of the VIth nerve and ascends to innervate the contralateral IIIrd nerve. Anteriorly at the IIIrd nerve level it receives optic kinetic and adducting (medial rectus) afference
4. Coordinates III, IV, VI nerve conjugate gaze by integrating vestibular, reticular and hemispheric afference

The Fasciculus Proprius (Propriospinal Tract)

1. Comprises a large proportion of spinal cord white matter
2. An intersegmental tract that ascends and descends (crossed and uncrossed)
3. Mediates spinal cord reflexes

Spinal Cord Disease

General Characteristics

1. The spinal cord is involved in specific patterns and at characteristic levels in specific disease pathologies
2. The lamination of both the dorsal column system and spinothalamic tracts is such that sensory signs and symptoms may not reflect the true segmental levels
3. Spinothalamic lamination reveals the most lateral fibers to convey sacral sensation followed (lateral to medial) by leg, trunk, and upper extremity fibers (most medial); it is a crossed pathway (at the level of entry). Thus, a lateral cervical lesion compressing the cord (not unusual for a neurofibroma) may present with sacral and leg sensory loss. Lissauer's tract projects spinothalamic innervations two segments above and below the level of entry. Thus, a T2 lesion may present as if the level were at T4. The sensory loss is always slightly higher posteriorly than anteriorly. The lamination of the corticospinal tract places fibers innervating the legs lateral to those of the arm. Bladder fibers are between the two, but usually, bilateral involvement is required to produce symptoms (most common with compressive cord lesions)
4. For clinical and neuropathological clarity the spinal cord is divided into three spaces:
 - a. Epidural
 - b. Intraparenchymal
 - c. Intradural and extramedullary

5. Pathologies that compress the spinal cord cause ataxia (early often prior to weakness), a sensory level (best sought with pin-prick and cold), bilateral weakness below the level of the lesion and bladder involvement (retention)
6. If epidural processes are acute, such as metastasis or hematoma or fracture, there will be spinal shock. If this supervenes, all sensation, motor function, bowel and bladder control and reflexes will be lost below the level of the lesion
7. Long standing intraparenchymal spinal cord disease (multiple sclerosis) causes spasticity below the level of the lesion with a neurogenic bladder
8. In the case of a syrinx, there is segmental sensory loss with normal sensation above and below the lesion
9. Occasionally reflexes will be increased above the level of the lesion (Schiff-Sherrington reflex) from loss of ascending spinal cord inhibition
10. Cystic intraparenchymal lesions and tumors often cause minimal bladder dysfunction. Intradural, extramedullary lesions are few and comprise meningioma neurofibroma, dropped metastases and enlarged nerves and roots from congenital hereditary motor sensory neuropathies. If a neurofibroma or meningioma occurs in the thoracic or cervical segments, there is often concomitant root and spinal cord compression. In the lumbosacral areas, only roots are involved as the spinal cord ends at T12–L1 (conus medullaris)

Specific Patterns of Spinal Cord Involvement

Transverse Myelitis

1. Most often these are longitudinal rather than transverse lesions that involve two or more segments. The spinal cord is expanded
 - a. If the involvement is more ventral (enhancement of the anterior horn cells) viral infection is suspected (West Nile virus, poliomyelitis, enterovirus 71, Coxsackie A7 and ECHO 6)
 - b. Dorsal column involvement suggests syphilis, Sjögren's syndrome, B12 deficiency, and toxins
 - c. If there is complete spinal cord transection all ascending and descending tracts are disrupted which is unusual. There will be a complete loss of motor, sensory and bowel and bladder function below the level of the lesion. Most often lesions are incomplete

Differential Diagnosis of Acute Transverse Myelitis

1. Demyelinating disease
2. Trauma
3. Metastatic disease (lung, breast)
4. Lymphoma
5. Hematoma (AVM, anticoagulation)
6. Abscess (IV drug abuse)
7. Herniated disc

8. Autoimmune disease (SLE)
9. Paraneoplastic syndrome (anti-Hu)
10. Post-vaccinal (hepatitis B)
11. Longitudinal myelitis (neuromyelitis optica)

Sensory Abnormalities

1. A bandlike or squeezing sensation at the segmental level:
 - a. Cervical levels may be associated with pain radiation into the arms
 - b. With thoracic levels the pain may radiate to the chest or abdomen. May be confused with intercostal nerve neuropathy (diabetes, amyloid, syphilis) or herpes zoster (prior to the rash)
 - c. Lumbar or sacral level involvement may have leg and perineal radiations

Local Vertebral Pain

1. Particularly elicited by mechanical stimuli:
 - a. Abscess and discitis
 - b. Tumor
 - c. Pathologic fracture

Postural Induced Pain

1. Pain worse with recumbence and relieved by standing is common with malignancy. Putative mechanism is venous "engorgement"
2. Sleeping, sitting up is characteristic for spinal cord tumor or arachnoid cyst (fills with CSF and compresses the cord)

Dropped Sensory Level

1. As noted above due to the somatotopic localization of spinothalamic fibers. The lesion may also be in the medulla (PICA infarction) or lateral pons and parietal lobe

Motor Manifestations

1. Acute lesions are associated with spinal shock (flaccid paralysis, areflexia, bowel/bladder dysfunction). The weakness if below T6 may be associated with bradycardia, hypotension, and slight hypothermia. Ejaculation suggests a severe lesion
2. After four to six weeks the patient may suffer hyper-tonic, flexor and extensor spasms, hyper-reflexia, loss of abdominal and cremasteric reflexes and too easily, obtainable Babinski sign (midfoot level that often elicits flexor spasms)
3. High spinal cord lesions cause extension of the hip and knee while lower lesions cause flexion of the hip and knee
4. At the lesion level, there are signs of anterior horn cell damage that include atrophy, fasciculation, and areflexia

Autonomic Alterations

1. As noted during spinal shock there is bowel/bladder paralysis
2. Partial lesions cause urgency and urine retention. Incontinence supervenes late

3. Constipation is the earliest bowel symptom and evolves from atonia to spasticity of sphincter tone. Dyssynergia between L1–S4 intrinsic bladder contractions with the failure of external sphincter opening often occurs with partial lesions
4. Below the level of the lesion there may be anesthesia, trophic changes in skin, muscle and soft tissue and vasomotor instability
5. Sexual function may be spared if the patient can feel pinprick on the testicles. Sexually important afference appear to be ventral in the spinal cord. Sexual feelings may not be normal (painful ejaculation that may trigger a mass reflex (flexor spasm of the legs with bowel/bladder incontinence)

Brown-Séquard Syndrome (Longitudinal Division of the Spinal Cord)

1. The signs include:
 - a. Ipsilateral loss of proprioception and vibration sensibility below the lesion
 - i. Tactile sensation may be only minimally involved. Possibly from loss of function of the dorsal and ventral spinocerebellar tract rather than the dorsal column
 - ii. The cervical spinal thalamic tract (located above the CST) also carries vibration and touch sensibility as does a small portion of the spinothalamic tract
 - b. Disruption of the lateral spinothalamic tract
 - c. Usually two segments below the lesion; slightly higher in the back than anteriorly (distribution of the intercostal nerves)
 - d. Ipsilateral spastic weakness:
 - i. Interruption of the descending CST
 - e. Segmental LMN involvement
 - i. Loss of sensation at the segmental level (dorsal horn and root involvement)

The usual etiologies include trauma (knife or bullet) extramedullary lesions or X-RT therapy in which individual sulcal arteries may be involved by proliferative endarteritis.

Intramedullary Lesions

1. The spinal cord is swollen over several segments. The parenchyma usually accounts for 2/3 of the spinal canal space while the subarachnoid accounts 1/3
2. The most common causes of central cord syndrome are:
 - a. Syringomyelia
 - b. Hydromyelia
 - c. Hematomyelia

Syringomyelia

1. A slowly progressive process
2. Symptoms and signs depend on the level of involvement. Although often central, a syrinx from a congenital cause or those associated with tumors or trauma may expand asymmetrically (dorsal into the posterior columns, ventrally into anterior horn cells)

Cervical Syrinx

1. Loss of pain and temperature sensation in a capelike distribution (interruption of the decussating spinothalamic tract at C4–C6)
 - a. Light touch and proprioception are often intact
2. Segmental neurogenic atrophy and areflexia
3. Horner's syndrome may be seen if the sympathetic corticospinal center of Budge (lateral extension at C8–T1) is involved
4. Kyphoscoliosis occurs if axial muscles are denervated (represented closest to the midline) which causes a C-shaped deformity away from the involved side
 - a. S-shaped scoliosis occurs in congenital scoliosis from muscular compensation
5. Spastic paraparesis may occur from CST compression which is associated with hyperreflexia and Babinski signs
6. Sacral sparing of sensation occurs due to the lateral position of these fibers in the spinothalamic tract
7. Ventrolateral extension may involve the spinothalamic tract producing thermoanesthesia below the spinal level of the lesion
8. Neuropathic joints may be produced by loss of pain in the affected extremity
 - a. The differential diagnosis for this process includes:
 - i. DM
 - ii. Synthroid
 - iii. Syphilis
 - iv. Syringomyelia

The Differential Diagnosis of Central Cord Syndrome*Syringomyelia*

1. Often associated with Chiari type I or II and the Dandy-Walker in malformation
2. Trauma associated (often above the level of the lesions)
3. Associated tumor which includes cystic astrocytoma
 - a. Frequently an enhancing nodule is noted
 - b. Hemangioblastoma and an astrocytoma that may develop in the wall of a syrinx

Acute Cervical Central Cord Injury

1. Usually occurs after severe hyperextension neck injuries
2. The patients are acutely quadriparetic but regain leg movement within minutes to hours
3. Acute urinary retention occurs in approximately 50% of patients
4. Weakness is more pronounced in the arms, usually distal > proximal
5. Patchy sensory loss below the lesion
6. Major pathology is in the central spinal cord, but there may also be a component of brachial plexus injury
7. Usually, there is significant improvement
8. MRI imaging:
 - a. Intramedullary hyperintense signal on T2-weighted sequences
 - b. Spinal cord compression from a narrowed canal

Epidural Compression

1. Epidural spinal cord compression has a wide differential diagnosis
 - a. Destruction of the vertebral body, particularly of the peduncle is most suggestive
 - b. Bone cysts and hemangioma of the vertebral may also be symptomatic
 - c. These processes may involve only one segment. Disc involvement with concomitant enhancement suggests inflection. The anterior and posterior ligaments often enhance with this pathology
 - d. Lymphoma often starts in the epidural fat. Epidural compression occurs with myelofibrosis or any other form of extramedullary hematopoiesis. Epidural fat may be pathogenic in patients on high doses of corticosteroids
 - e. Spinal AVMs are epidural and are most often dorsal in the thoracic segments. A ventral AVM is rare (Foix-Alajouanine syndrome) is ventral and may compress the cord. Another rare ventral lesion is the neurenteric cyst
 - f. Meningitis of all forms may be most intense dorsally and invades the spinal parenchyma through draining versa or nerve exit foramina
 - g. Sarcoid often thickens the dura at cervical and thoracic levels
 - h. Processes with an expanded dura that may compress the spinal cord include:
 - i. Lymphoma
 - ii. Tuberculosis
 - iii. Cryptococcus neoformans
 - iv. Rheumatoid arthritis
 - v. Idiopathic hypertrophic pachymeningitis
 - vi. Carcinomatosis
 - vii. Amyloid

Pachymeningitis (IgG4 related) carcinomatosis of the meninges thickens the dura but rarely causes spinal cord compression. There is often enhancement with gadolinium in cerebellar and cortical sulci. Amyloid may greatly thicken the dura of both the intracranial and spinal compartment and rarely may form a compressive mass lesion.

Clinical Signs and Symptoms of Epidural Compression*Pain*

1. Radicular pain concomitant with epidural compression is lancinating, unilateral and in a dermatomal distribution. It may be exacerbated with any valsalva maneuver. Radicular pain is rare with intramedullary lesions
2. Vertebral pain is often localized to the segmental vertebra and often elicited with mechanical stimuli. It is prominent at night, particularly with malignant involvement
 - a. It is infrequent with either intraparenchymal or intradural and extramedullary pain. Neurogenic pain is not uncommon with spinal lesions that involve the spinothalamic tract

- b. It is frequently associated with dynamic and static mechano-allodynia and cold pain
 - c. It is not well localized from spinal generators and often is burning or is experienced as a deep dysesthesia
3. Motor function
- a. Both upper and lower motor dysfunction may occur with epidural lesions. Spinal shock occurs with acute lesions and increasing spasticity with chronic ones. Upper motor neuron signs occur late with intramedullary lesions

Sensory Signs

1. Compressive lesions frequently cause an ascending sensory loss that may be mistaken for polyneuropathy
 - a. It frequently is active “pins and needles” reflecting myelinated ($A\beta$ or $A\delta$ fiber pathway involvement). Intramedullary lesions more commonly express descending paresthesia or sensory loss
2. A Brown-Séquard pattern is more common with epidural lesions although it has been noted with traumatic, infectious and post-irradiation
3. A dissociated sensory loss pain and temperature more involved than position and vibration are characteristic of intramedullary lesions
 - a. Vibratory loss is often more severe than proprioceptive
 - b. Sacral sparing is a strong feature of intramedullary lesions (the most lateral fibers in the somatotopic organization of the spinothalamic tract are spared)

Sphincter Function

In general, bilateral involvement of the spinal cord is required for significant sphincter involvement. Characteristic of conus medullaris tumors is an early loss of bowel, bladder, and sexual function. Rarely demyelinating disease or a syrinx may cause dissociated sexual function. The ability to obtain an erection, but the inability to ejaculate. Saddle anesthesia also is common with conus medullaris tumors. Cauda equina lesions tend to have an asymmetric dermatomal sensory loss that is painful associated with sphincter involvement.

The advent of neuroimaging with MRI has made the use of spinal myelography rare in evaluating spine pathology. The exception to this rule is complicated cervical spine disease where the relationship of nerve roots to the exit foramen and facet, needs to be determined prior to decompression. The advantage of myelography with following CT is that contrast outlines the nerve roots and CT images bone detail. MRI images soft tissue such as disc, synovium, and ligaments clearly and contrast enhancement suggests pathology. A saw-toothed or paint brush pattern of contrast is characteristic of epidural pathology.

Intradural Extramedullary Spinal Cord Lesions

This space is the least involved with spinal cord pathology, and the differential diagnosis is restricted. The most common tumor in this space is a neurofibroma or Schwannoma. These

form “dumbbell tumors.” The neural exit foramina are expanded, and the tumor compresses the spinal cord. This is seen as a “cap” sign on myelography. Plexiform neurofibromas may involve multiple nerve roots and are characteristic of neurofibromatosis type I (chromosome 17). Other pathologies that occur in the intradural extramedullary space are:

1. Enlarged nerve roots from hereditary sensory motor neuropathies (Dejerine–Sottas neuropathy)
2. Meningiomas are characteristically found in the thoracic cord in women and are extremely rare in this location in men
3. A free fragment of a disc may migrate in this space for several cord segments
4. Arachnoid cysts may fill in a ball valve fashion and compress the spinal cord intermittently
5. Medulloblastoma (origin is often the superior medullary velum of the IVth ventricle), spinal cord metastasis and, leukemia, as well as subdural hematomas, occur in this location

Posterolateral Spinal Cord Involvement

Posterolateral column degeneration was commonly seen in advanced vitamin B12 deficiency. Patients complain of paresthesia in both hands and feet from concomitant large fiber demyelinating neuropathy. Proprioceptive and vibratory loss are most severe in the lower extremities. Patients have bilateral involvement of the corticospinal tracts with weakness, spasticity, Babinski signs and hyperreflexia. Patients frequently have involvement of cranial nerves I and II as well as ataxia from both sensory and cerebellar involvement. It may produce hyperactive reflexes in a wasted extremity (CST and peripheral nerve involvement).

HIV infection and HTLV associated myelopathy (tropical spastic paraparesis) suffer a cervical vascular myelopathy. This presents as a slowly progressive spastic paraparesis with proprioceptive and vibration loss. There is a lymphocytic CSF pleocytosis and a mild protein elevation. Mild cognitive impairment occurs with both, but bladder involvement is particularly prominent with HTLV-1. The CSF may be normal, but there may be increased IgG and antibodies to HTLV-1.

Cervical spinal stenosis with combined cervical spondylosis usually is a predominant C5–C6 and L5–S1 disease. An inverted radial reflex is common, and atrophy is prominent in the affected dermatomes. Two-point discrimination is frequently diminished in C8–T1 dermatomes while vibration sensitivity is maintained. Routine MRI secures the diagnosis. It is almost invariant that cervical and lumbar spondylosis occur concomitantly.

Posterior Column Spinal Cord Involvement

The classic posterior column disease is tabes dorsalis from neurosyphilis. The lesion is at the level of the dorsal roots with secondary degeneration of the posterior columns. Tabes dorsalis usually develops late in the course of infection (10–20 years after stage 1) and causes severe loss of propriocep-

tion, vibration, and mechanical sensibilities. Higher cortical sensory function is lost causing poor tactile localization. Patients have increased low mechanical thresholds, tactile and postural hallucinations and sensory ataxia. A Romberg sign is prominent and is anticipated by the patient's complaints of inability to walk well at night.

A stamping gait is prominent (the patient attempting to generate more tactile information. Patients may fall forward immediately after eye closure ("sink" sign).

A multitude of neurologic signs occur from neurologic involvement at several levels and include:

1. Tabetic crisis:
 - a. Lightning like lancinating pain to the extremities and the abdomen (severe enough to suggest an emergency). Usually, this phenomenon is concomitant with the development of urinary incontinence and absent patellar and ankle reflexes. The affected extremities are hypotonic but have normal strength
2. Similar crises occur in the larynx which causes stridor and in rectal and urinary sphincters (rare)
3. Proprioceptive and painless joints degenerate due to loss of their usual protective reflexes. These denervated joints are called Charcot joints. The most common is the shoulder joint, but any joint can be involved. Any proprioceptive and analgesic joint can be destroyed. The differential diagnosis is diabetes mellitus, amyloid, a syrinx, and neurosyphilis. The deep pain loss can be clinically tested by squeezing the Achilles tendon (Abadie's sign) which is innocuous to the patient
4. Hitzig zones (areas of the body surface innervated from dorsal root cutaneous collaterals) are involved in severely affected patients. Light tactile sensation is often lost in an ovoid pattern on the trunk. The usual areas of involvement are:
 - a. The mid face (probable dorsal root entry zone)
 - b. The thorax and abdomen
 - c. Ulnar side of the anus and perineal distribution in the lower extremities
 - d. Perianal area
5. Tabes dorsalis is almost always seen with an Argyll Robertson pupil. The pupil is:
 - a. Small (miotic)
 - b. Irregular
 - c. Responds to accommodation but not light
 - d. Does not dilate to mydriatics or the ciliospinal reflex (hard pinch of the trapezius muscle)
6. Optic atrophy (aspirin-like disc is common)
7. Retinitis pigmentosa. The pigment migration is adjacent to blood vessels

Sjögren's Syndrome

1. The dorsal columns may be involved specifically with characteristic symptomatology
2. Cranial nerve V may be selectively involved
3. There is a concomitant sicca syndrome (dry mouth and dry eyes)
4. Sensorimotor neuropathy

Spinal Cord Signs

1. Lhermitte's sign
 - a. Neck flexion elicits a lancinating electric shock-like sensation down the back or into the upper extremities
 - i. The usual cause is multiple sclerosis, but it may also be seen with cervical spondylosis or by progressive compressive spinal cord lesions
 - ii. Reduced threshold to fire of A δ and A β myelinated fibers. The spinal cord is pulled upward with neck flexion approximately 1.5 cm
2. Dr. Jerome Posner has pointed out that there may be early truncal and gait ataxia prior to weakness with spinal cord compression from metastatic tumors. This may occur with normal leg proprioception. The dorsal and ventral spinocerebellar tracts may be affected rather than the posterior columns. This is most common with thoracic spine lesions
3. Dorsal column lesions are frequently prominent in demyelinating disease. Some extremely large lesions have been reported that were asymptomatic

Localization of Spinal Cord Lesions at Specific Levels

Foramen Magnum

1. Suboccipital pain in the distribution of C2 may occur early. This radiation in addition to the posterior neck and scalp projects to the supraorbital area. It frequently is associated with neck stiffness. Lhermitte's sign may be prominent
2. Spastic tetraparesis, long tract sensory loss and neurogenic bladder. The pyramids decussate at C1–C2, the arm fibers anterior and medial to the leg fibers which may produce a cruciate hemiparesis (one arm and the contralateral leg)
3. Cranial nerve IX–XII may be involved
4. Downbeat nystagmus (floccular nodular lobe involvement)
5. Papilledema (CSF obstruction ventral and dorsal pathways)
6. Cerebellar ataxia
7. Patients with a usual hemiparesis (usually from compression at medullocervical C1–C2 level) also demonstrate:
 - a. Arm weakness > leg weakness
 - b. Onion skin pattern of facial sensory loss (decussation of the spinotrigeminal tract)
 - c. Respiratory dysfunction
 - d. Bladder dysfunction
 - e. Lower cranial nerve IX–XII involvement
 - f. Paresthesia in the upper extremities

C1–C4 Cervical Segment Lesions

1. Compromise of CN XI with consequent ipsilateral sternocleidomastoid and upper trapezius muscle weakness (slight head turn to the ipsilateral side and drop of the shoulder). The ipsilesional shoulder cannot be elevated normally to the ear

2. Cervical roots C2–C3 form the pre-auricular nerve with radiations both to the posterior occipital areas and the ipsilateral face. Cervical roots C3–C4 form the post-auricular nerve which radiates to the parietal bone and ear. C2 radiates to the brow and pre-auricular area at the angle of the jaw. C3 may radiate to the side of the neck and C4 to the trapezius ridge. The cap of the shoulder is a C5 radiation (also involved from diaphragmatic irritation)
3. C3–C5 innervates the diaphragm. There is poor expansion of the lower rib cage and dyspnea on exertion. High cervical lesions also interrupt descending fibers from respiratory neurons in the medulla and pons
4. Due to somatotopic segregation of both spinothalamic tracts (hands and arms represented medially) a midline C3–C4 lesion may cause a dropped sensory level to the fingertips (C6–T1) or to the thorax (band like sensation)
 - a. There may be associated clumsiness of the hands (cuneocerebellar tract involvement proprioceptive input from the upper extremity to the intermediate cerebellar zone)
 - b. Usually, cervical spondylosis affects C5–C6 muscle groups to a greater degree than the C8–T1 groups (intrinsic hand muscles). The first dorsal interosseous muscle often atrophies very early with limb-onset ALS

C5–C6 Cervical Segmental Localization

The segmental muscle involvement causes weakness and atrophy of the supra and infraspinati, the deltoid, biceps, brachioradialis, medial and lateral pectoralii, latissimus dorsi, triceps, and the extensor carpi radialis muscles.

The inverted brachial reflex is elicited by a tap of the biceps tendon. There are no biceps reflex (flexion), and no brachioradialis induced supination but increased triceps activity (C7) and finger flexion (C8–T1). The reflex, as noted above is most often seen in cervical spine compression from cervical stenosis (degenerative arthritic changes) occurring in the exit foramina (osteophytes) and cord compression at C4 (ligament disc and facet hypertrophy). The spinal cord compression would disinhibit all reflexes below the level of compression (dysfunction of the cortical spinal tract). Due to the osteophytes or other pathologies at the C5–C6 exit foramina, the sensory stimulation cannot enter the cord at this level. Sensory afference to the cord is achieved by the stimulation of the biceps tendon which induced mechanical stimulation at C4 or C8 or T1.

The spinal cord is disinhibited at C7–C8–T1 (from the C4 lesion), and finger flexion is induced as well as increased activity of the triceps muscle. Usually, as noted the cause in severe cervical spondylosis. The neck will be forward flexed, and there will be decreased movement in all planes. There will be atrophy of the deltoid caps. The spondylitic process also occurs at L5–S1, so there may be increased knee jerks (cervical compression) and absent ankle jerks. The patient will be unable to tandem walk. This process is exceedingly common. Other pathologies at this level such as meningioma, AVM, metastatic are rare.

C7 Cervical Segmental Localization

1. Extension of the arm, wrist and fingers are primarily affected. There may be some weakness of finger flexion
2. Sensory loss is most prominent in the third finger: this becomes slightly complicated as loss of sensation to pin-prick of the third digit with decreased sensation of the thumb and index finger is a lateral cord brachial plexus distribution. Loss of pin-prick sensibility of the ulnar side of the third finger in conjunction with decreased sensation of the 4th and 5th digits is a medial cord brachial plexus sensory radiation. C7 alone may cause some medial forearm sensory loss
3. Similar to lesions at C5–C6 a paradoxical triceps reflex may be elicited. A triceps jerk may elicit flexion rather than extension due to its weakness and intact C5–C6 innervated musculature (biceps and brachioradialis). Most lesions here are spondylitic but trauma, and an occasional neurofibroma can selectively involve this root (or spinal nerve)

C8–T1 Localization

1. The major motor deficits occur in intrinsic hand muscles. If there is a compressive lesion at this level, there will be an associated spastic paraparesis. C8 lesions decrease the triceps reflex (C7–C8), and finger flexor reflexes (C8–T1). A T-1 lesion preserves the triceps, but finger flexion reflexes are decreased
2. Sensory loss occurs in the 5th digit and the medial forearm. The ulnar nerve splits the 4th finger and innervates a small triangle of skin above the wrist. Brachial plexus lower trunk lesions extend from the medial forearm to the medial arm. A Horner's syndrome occurs (ciliary center of Budge) on the side of the lesion. Most lesions at this level are from cervical spondylosis or trauma. The deep muscular branch of the ulnar nerve may be involved by chronic pressure (bicycle riders, specific work injuries) with consequent intrinsic hand muscle atrophy. Rarely monomelic ALS or Hirayama's syndrome may simulate this level. Venous congestion or arterial insufficiency from higher lesions may cause glove sensory loss that can extend as high as the elbows

Pathologies of the Thoracic Spinal Cord

Inflammatory lesions at this level are usually demyelinating. Neuromyelitis optica (NMO), an autoimmune disease (antibodies to Aquaporin 4) causes a three segment spinal cord lesion associated with optic neuritis. On the other hand, most MS lesions cause shorter transverse myelitis and often lesions of the posterior columns. Sarcoid may inflame the parenchyma but usually affects the dura at times enough to cause spinal cord compression. Idiopathic hypertrophic pachymeningitis (IgG4), lymphoma, rheumatoid arthritis and tuberculosis can symptomatically compress the spinal cord. Dural AVMs that hemorrhage are usually dorsal at low cervical to high thoracic levels. The hematoma produced may

compress the cord. Subdural hematomas from trauma and from anticoagulation compress the thoracic cord. Thoracic disc disease is rare and usually occurs with severe valsalva maneuvers or trauma but are very dangerous. The spinal canal is very tight at this level (12–24 mm), so minimal protrusion may be symptomatic. In the thoracic cord, sudden compression causes very rapid paraparesis. Diabetes, a syrinx, and amyloid destroy proprioceptive and pain fibers which may cause a thoracic Charcot joint. Extremely rarely ochronosis (homogentisic acidosis) and relapsing polychondritis may affect thoracic discs. Metastatic disease may be causative (usually one level, although prostate, breast and lung cancer may affect multiple levels). Multiple myelomas affect multiple levels; eosinophilic granuloma, giant bone cysts, osteoid osteoma usually occur monostically and compress the spinal cord from a pathological fracture. Osteoporosis with anterior vertebral body fracture are extremely painful and are common in postmenopausal women but rarely compress the cord. Ganglioneuromas, and chordoma (clivus and the sacral cord) and Ewing's sarcoma are rare tumors of the thoracic cord. An astrocytoma may infiltrate over a long distance and destroy anterior horn cells that innervate the paraspinal musculature asymmetrically giving rise to a C-shaped form of scoliosis (away from the side of the lesion). An S-shaped scoliosis is congenital (with compensatory curves) which is often asymptomatic. Diastatomyelia, a fibrous band that splits the spinal cord, and reduplication of the cord (two spinal cords with their own dural coverings) are rare congenital abnormalities. The thoracic cord may be the termination of septic emboli both from IV drug abuse and SBE (T4 is frequently the involved level). A devastating infection of the thoracic spinal cord is herpes type 6, which leads to necrosis with minimal recovery. West Nile fever, enterovirus 71, Echovirus 6 and Coxsackievirus A7 as well as polio all may involve the thoracic cord during a generalized CNS infection. Paraneoplastic disease with anti-Hu, Ma2/Ta, Purkinje cell autoantibody type 1 anti-CV2 and anti-Ri have all been described to affect the entire spinal cord. HTLV-1 may involve the thoracic cord to a greater extent than the cervical cord (tropical spastic paraparesis). Usually, HIV causes a vasculitic cervical myelopathy. The many forms of hereditary spastic paraparesis affect the thoracic spinal cord severely. In uncomplicated variants, only the spinal cord is affected while complicated variants are also associated with optic nerve, cerebellar, cortical and peripheral nerve involvement. Trauma of all kinds affects the thoracic spine. Specific anatomical syndromes such as the Brown-Séquard syndrome have been reported from knife, bullet wounds, X-RT therapy and compressive thoracic spine lesions. Spondylitic changes are rare as there are no motion segments of the thoracic spine.

Clinical Features of Thoracic Spine Lesions

Lesions at this spinal level cause root or intercostal nerve-like pain. It is usually lancinating and slightly higher posteriorly than anteriorly.

If it is a compressive lesion, there will be a sensory level (usually two segments below the involved segment) accompanied by bladder/bowel alteration and paraparesis. Rarely, there is a Brown-Séquard anterior cord or a central cord presentation.

If the lesion is above T5, there is postural hypotension from loss of sympathetic innervations to the abdomen and lower extremities. Autonomic dysreflexia may occur with higher lesions. This is manifested by:

1. Hypertension
2. Cutaneous flushing
3. Severe vascular-type headache
4. Bradycardia

It is usually precipitated by a bladder catheter change, rectal distension and the lack of prophylactic guanethidine use. It has been associated with intracranial hemorrhages.

If the lesion is at T10 a Beevor's sign may be elicited with neck flexion against resistance. The umbilicus rises 0.5–1.0 cm because lower rectus abdominis muscles are weak while T8–T9 muscles are normal. Occasionally the imbalance is reversed with partial lesions, and the umbilicus is displaced downward if a spinal lesion is above T6. Supraspinal lesions above T6 cause loss of abdominal reflexes. For a lesion at or below T10, the upper and middle abdominal reflexes are maintained. All abdominal reflexes are present if the lesion is below T12.

Overview of Pathology of the Lumbar spine

The lumbar spine is most often affected by mechanical problems from degenerative disc disease or the arthritic changes of spondylosis, spinal stenosis, and spondylolisthesis. The aging process is associated with desiccation of discs (hand disc) and remodeling of bone at motion segments. Nerve roots are trapped in their exit canals by osteophytes and the restoration of facet joints in addition to the loss of disc height.

Spinal stenosis occurs with ligament hypertrophy (dentate) and facet tropism (inward rotation) and hypertrophy. It is exacerbated if the patient has congenitally short pedicles and a tight canal. This is a problem in achondroplasia and many other orthopedic syndromes. The stenosis in achondroplasia occurs at the foramen magnum and T12–L1. Severe arthritis and disc degeneration cause spondylolisthesis which is a forward or backward displacement of the vertebral body. The malalignment places the exiting nerve roots under traction at several levels. In general L5–S1, (the major motion segment and the greatest load segment) suffers the most disc disease, while L4–L5 is more frequently the site of spinal stenosis.

Synovial cysts of the facet joint is a rare cause of radiculopathy but is encountered with severe degenerative disease. Facet hypertrophy with associated tropism (rotation of the inferior facet into the foraminal exit canal) is a common cause of radicular pain in older patients.

Spondylolisthesis may be congenital (poor ossification of the pars interarticularis) with consequent vertebral malalignment. It usually occurs at L4–L5 but may occur at any lum-

bar area. There may be either anterolisthesis or retrolisthesis. In the congenital form, there is usually maldevelopment of L4–5 innervated muscles that cause poor development of the gluteus maximus musculature (a pelvic “shelf”).

In adult populations, meningocele and its variations are rare. A tethered cord, in which the filum terminale is short causes the spinal cord to be lower than its usual vertebral level at L2. It is often associated with unilateral pes cavus, a neurogenic bladder, radiculopathy, and hyperreflexia. The lateral recess component of the nerve root exit canal, particularly at L4–L5 and L5–S1, may be congenitally narrowed which causes nerve root compression. Retroperitoneal hemorrhage, usually in patients on anticoagulation, causes severe lumbosacral root pain, hyperactive reflexes and motor weakness in the effected roots.

The retroperitoneal space may contain surprisingly large benign tumors and sarcomas. The lumbar roots at high levels may be damaged directly by neuropractic injury or by retractors during abdominal surgery. Lipoma, glioma of the filum terminale, and chordoma (also occur in the clivus) are particular to the lumbosacral cord. Lymphomas may occur anywhere in the spine. They tend to envelope the nerve roots of the cauda equina at this level. Sarcomatous degeneration of a lipoma cannot be operated as it is interdigitated within the nerve roots. Plexiform neurofibromas (NF1) occur in the lumbosacral cord.

CMV infections in very ill HIV patients, (<50 CD4+ T cells/mm³) are characteristic of the lumbosacral spinal cord. Rarely a syrinx or demyelinating disease may occur in the conus medullaris.

Clinical Features of Lumbosacral Segment Disease

L1 Segmental Level

An L1 segmental lesion weakens all muscles of the lower extremity. In addition, the lower abdominal musculature (internal oblique, transverses and rectus abdominus) are involved. Palpation reveals decreased tone in the lower abdomen and Beever's sign may be positive. There is a sensory loss at the level of the groin anteriorly and slightly above the buttocks posteriorly. Chronic lesions have exaggerated tendon reflexes at the knees (L2–L4) and the ankles (S1–S4).

L2 Symmetric Level

Abdominal musculature is normal, but chronic lesions cause spastic paraparesis. The cremasteric reflex is absent. There may be slight depression of the knee-jerk (L2 involvement with exaggerated ankle jerks (S1–S2)). Sensation is intact in the upper anterior thigh

L3 Segmental Level

There is a weakness of hip flexion (L1–L3; iliopsoas and sartorius) muscle weakness of leg adduction (adductor longus, gracilis and pectineus). Sensation is intact in the upper anterior thigh. The knee reflex is depressed.

L4 Segmental Level

There is a slight weakness of hip flexion, leg adduction, knee flexion and leg extension. The leg can be stabilized which permits standing. The knee jerk may be slightly depressed, and the ankle jerks are hyperactive. There is normal sensation of the thighs and superomedial knees.

L5 Segmental Level

The patient has normal strength of the quadriceps muscles and can extend the leg against resistance. The knee jerks are active and the ankle jerks hyperactive. The patient has sensation medially in the thighs, legs, and soles.

Segmental Lesions of the First and Second Sacral Segments

There is weakness of the gastrocnemius soleus, flexor digitorum longus, flexor hallucis longus and intrinsic foot muscles. Sensory loss is apparent over the sole, heel and lateral side of the foot and ankle. There is also sensory loss in the medial side of the calf, posterior thigh, and the lateral perineum. S2 lesions primarily affect the flexor digitorum, flexor hallucis longus, and intrinsic muscles of the foot. The ankle jerk is depressed. The sensory loss occurs in the dorsal calf, the dorsolateral thigh, and the perineum.

Bladder Physiology

Storage of urine and its periodic elimination is accomplished by two functional units in the lower urinary tract: a reservoir (the urinary bladder) and the bladder neck, urethra, and the urethral sphincter. The coordination of these two units is complex and is mediated by the brain, spinal cord, and peripheral ganglia. The neural circuits that control bladder function have switch-like or phasic patterns.

Storage and voiding are coordinated peripherally by three sets of peripheral nerves that are parasympathetic, sympathetic and somatic. Afferent sensory fibers from the lower urinary tract to the lumbosacral cord are A δ (thinly myelinated 1–4 μ) and unmyelinated C-fibers. A-delta fibers innervate the detrusor smooth muscle layer and respond to stretch which is perceived as fullness. C-fibers innervate muscles adjacent to the urothelium cells.

1. The sympathetic fibers from thoracic level T11 through L2 project to the inferior mesenteric ganglion. The postganglionic fibers from the hypogastric nerve which stimulates urethral smooth muscle utilizing adrenergic receptors. It inhibits the detrusor muscle by activating B3 adrenergic receptors (NE is the ligand)
2. The parasympathetic pelvic nerves take origin from sacral neurons at S2–S4. They synapse in the pelvic ganglia and innervate (stimulate) the detrusor muscle by means of muscarinic (ACh and purinergic (P2X) receptors whose ligand is ATP and reciprocally inhibits urethral smooth muscle by nitric oxide (NO))
3. The somatic pudendal nerve stimulates the somatic striated muscle of the external urethral sphincter. Acetylcholine is the neurotransmitter

4. Glutamate is the neurotransmitter in sensory afferents from the bladder. Substance P and calcitonin gene-related peptides are additional neurotransmitter colocalized with glutamate in C-fibers

The Storage Phase

The bladder has low levels of pressure during filling due to the intrinsic viscoelasticity of the detrusor muscle. The detrusor muscle and the stimulatory parasympathetic system is inactive during filling until a critical threshold for voiding is attained. Supraspinal projections are contributory to this inhibition.

The guarding reflex (initiated by bladder distension) activates stretch mechanoreceptors in the bladder wall which synapse on sacral (S2–S4) ventral horn pudendal neurons. Efferents from the pudendal nerve stimulate the contraction of striated muscle of the external urinary sphincter which maintains continence.

As the bladder fills and distends, the thoracolumbar sympathetic nerves are stimulated which contracts the internal urethral sphincter and inhibit bladder wall contraction. These storage reflexes are maintained in the spinal cord but may be modulated supraspinally. The pontine micturition center (by means of the reticulospinal tract) activates pudendal neurons that increase urethral resistance.

Voiding Phase

Initiation and completion of voiding are dependent on brain input. Bladder efferents in the pelvic nerve synapse in the spinal cord and beyond and from these second order neurons (S2–S4) ascend to the pontine micturition center. Information from the cortex and subcortical nuclei is integrated with bladder derived sensory afference. Descending projections inhibit sympathetic and somatic neurons in the spinal cord and stimulate parasympathetic neurons. The activation of the spino-bulbo-spinal reflex relaxes the external urethral sphincter, the internal urethral sphincter, and contracts the detrusor muscle which increases bladder pressure and initiates voiding.

The role of the uroepithelium is very important in bladder pathologies from spinal cord disease but is beyond the scope of this presentation.

Clinical Localization of the Neurologic Causes of Bladder Dysfunction

1. Neurogenic spastic bladder:
 - a. Occurs with lesions above sacral bladder neurons (S2–S4) and below the pontine micturition center
 - b. Primary pathologies are spinal cord injury and demyelinating disease. Any destructive lesion at this level can be causative
 - c. Associated with quadriplegia or paraplegia
2. Due to loss of supraspinal inhibition, the detrusor muscle is hyperactive and may contract spontaneously or with coughing or changing posture. This causes:
 - a. Urinary frequency and urgency
 - b. Urge incontinence
 - c. Inability to voluntarily initiate micturition

3. The bladder capacity is small, but there is post-micturition residual from inadequate contraction

Clinical Features

1. Intact bulbocavernosus and anal reflexes
2. If the lesion is above T10 (the splanchnic hypogastric nerve) a distended bladder may produce a mass reflex:
 - a. Paroxysmal hypertension
 - b. Headache (vascular type)
 - c. Diaphoresis
 - d. Reflex bradycardia
3. Detrusor-sphincter dyssynergia:
 - a. A simultaneous contraction of the detrusor muscle and the external urethral sphincter during voiding
 - b. Occurs most often with lesions in the thoracic spinal cord but can be caused by any lesion that blocks descending control of voiding mediated by the pontine micturition center
 - c. Dyssynergia causes:
 - i. Obstructed voiding
 - ii. An interrupted urinary stream
 - iii. Increased residual urine
 - iv. High intra-vesicle pressure (the external urinary sphincter is closed during detrusor contracture)
 - v. Detrusor contraction may be poorly sustained

Spinal Cord Injury

1. Spinal shock supervenes with acute spinal cord injury. If severe there is flaccid paralysis, complete sensory loss and a paralyzed bladder below the level of the lesion. The bladder regains reflex detrusor activity usually within six weeks. Dyssynergia is common with recovery. Spinal shock may be prolonged
2. Detrusor areflexia may occur with lesions below T12 (autonomous neurogenic bladder). A lesion at this spinal level compromises the conus medullaris and the cauda equina
 - a. The bladder is insensate, and the detrusor is paralyzed
 - b. Most often there is urinary retention with bladder distension
 - c. Overflow incontinence with marked increase residual urine occurs
 - d. There is saddle anesthesia with the loss of the bulbocavernosus and superficial anal reflexes. The anal sphincter may be concomitantly paralyzed
 - e. Prolonged bladder distension may cause degenerative changes in the detrusor muscle with bladder atonia and a consequent large residual urine

Motor Paralytic Bladder

1. Injury to the pelvic nerve (innervates the detrusor) or its origin in the sacral spinal cord (S2–S4) may occur from:

- a. Spinal stenosis
- b. Lumbosacral meningocele or its repair
- c. Hysterectomy
- d. Abdominis perineal resection
- e. Trauma
- 2. Clinical features include:
 - a. Painful urinary retention
 - b. Inadequate bladder emptying
 - c. Increased residual urine
 - d. Absent bulbocavernosus and superficial anal reflexes
 - e. Intact sacral and bladder sensation

Sensory Paralytic Bladder

1. Loss of the A-delta and C-fiber innervations of the bladder has been described with spinothalamic and dorsal column spinal cord lesions
2. Urinary retention, overflow incontinence, and frequent infections are common
3. Voluntary initiation of micturition is preserved
4. Bulbocavernosus and anal reflexes may be altered
5. The usual pathologies are:
 - a. Tabes dorsalis
 - b. CMV infection in HIV patients
 - c. Syringomyelia
 - d. Diabetes mellitus
 - e. Amyloid

Fecal Incontinence

The anal sphincter complex comprises the internal and external sphincter:

1. The internal sphincter:
 - a. Accounts for 80% of resting sphincter pressure
 - b. Smooth muscular autonomic control
- c. External sphincter:
 - i. Slow twitch type I striated muscles
 - ii. Innervated by the pudendal nerves (neurons in the ventral horns of S2–S4) and the puborectalis muscle (innervated by the pelvic branches of S3 and S4)
 - iii. The external sphincter and the puborectalis muscle are the voluntary sphincter muscles. A spinal reflex causes contraction of the external sphincter with valsalva maneuvers
 - iv. Mechano stretch receptors in the pelvic floor detect stool in the rectum and are necessary for continence. The usual causes of rectal insensitivity are:
 1. Diabetes mellitus
 2. Autonomic neuropathy
 3. Pudendal neuropathy (trauma and abdominal surgical procedures)
 - v. Rectal insensitivity causes overflow incontinence
 - vi. Fecal incontinence in the elderly is most often due to constipation
2. Clinical manifestations depend on the specific etiology as fecal incontinence can be caused by dysfunction of sen-

sory and motor roots (S3–S4), compression or intrinsic or peripheral neuropathies:

- a. Reduced sphincter tone
- b. Loss of perianal sensation and the anal skin reflex
- c. Laxity of the anal sphincter from deafferentation
- d. Lesions above the conus may cause urgent defecation
- e. Spinal cord pathology often causes both urinary and fecal incontinence

Anatomy of Male Sexual Function

Many aspects of peripheral nerve and central nervous system anatomy that control erectile and ejaculation function have not been elucidated. The genitals are innervated by:

1. The sacral parasympathetic (pelvic nerves)
2. The thoracolumbar sympathetic chain at T4–L2 which protects the inferior hypogastric plexus and whose postsynaptic axons become the hypogastric nerve
3. The pudendal nerve which carries somatic sensation

The sacral parasympathetic system derived from neurons at S2–S4 whose preganglionic axons are in the pelvic nerve synapses in the pelvic plexus. Postsynaptic fibers are carried in the cavernous nerves that mediate dilatation of the corpora cavernosa by the release of nitric oxide. There is some evidence for a sympathetic component from T12 in the process. Descending pathways for erection mechanisms are in the lateral columns of the spinal cord. A spinal cord lesion above T12 impairs the psychogenic component of an erection while a complete lesion of the conus medullaris or cauda equina abolishes a reflex erection. There is some evidence that a psychogenic erection can occur from intact sympathetic innervations.

Neurons in the medial preoptic anterior hypothalamus project to the spinal cord in the median forebrain bundle (traversing the midbrain tegmentum and lateral pons) are particularly important in the erectile process. Ejaculation is proposed to occur from innervation at T12–L1. Reflex ejaculation is possible if afferent innervations (S2–S3) and efferent pathways from (T10–L2) are intact.

Conus Medullaris Syndrome

Varied pathology affects the conus medullaris. In general, there is weakness of the muscles of the pelvic floor (coccygeus, ileococcygeus and pubococcygeus) associated with bowel, bladder, and sexual dysfunction:

1. The patient has an anesthetic bladder, cannot initiate micturition and has a large volume of residual urine
2. Most often the patient is constipated
3. The patient cannot achieve an erection or ejaculate. There may be dissociated sexual function (ability to achieve an erection but inability to ejaculate). Saddle anesthesia is present
4. Pain is rare and a late complication that involves thighs, buttocks, and perineum. There is no extremity weakness or reflex change. The cauda equina and epiconus may be involved

Differential Diagnosis of Conus Medullaris Lesions

1. Demyelinating disease
2. Myxopapillary ependymoma
 - a. Most commonly occur in the conus medullaris-filum terminale
 - i. Conus medullaris syndrome occurs early with asymmetric lower extremity reflex loss
 - ii. The majority of the tumors arise in the spine, and approximately 20% occur from extramedullary sites
3. Cavernous malformation:
 - a. Approximately 1.7% intraspinal cavernous malformations arise in the conus medullaris
 - b. Most patients have a slowly progressive course but a significant proportion of patients have an acute onset with step-wise progression
 - c. Annual rate of hemorrhage is 2%
4. Sacrococcygeal development abnormalities:
 - a. Most often diagnosed in childhood
 - b. Associated with spina bifida occulta
 - c. Developmental abnormalities and tumors:
 - i. Myelomeningocele
 - ii. Meningocele
 - iii. Lipomyelomeningocele and lipoma
 - iv. Dermoid cyst
 - v. Hamartoma
 - vi. Short filum
 - vii. Hind gut cysts
 - viii. Teratoma
 - ix. Ependymomas (may be completely subcutaneous)
 - x. Neuroblastoma
 - xi. Rhabdomyosarcoma
 - d. Conus medullaris syndrome following radionuclide cisternography
 - e. Dural arteriovenous fistula

Tethered Cord Syndrome (TCS)

Tethered cord syndrome is a stretch-induced functional disorder of the spinal cord. Symptoms of a congenital tethered cord are most common in childhood, but symptoms may manifest in adulthood. Patients have an elongated spinal cord and a thick filum terminal. Three categories of TCS have been proposed:

1. A lumbosacral cord under traction from an anchored inelastic filum
2. Caudal and sacral myelomeningocele
3. Two groups of patients:
 - a. Paraplegia myelo- and lipomyelomeningocele with no functional lumbosacral neurons
 - b. Asymptomatic patient with an elongated cord and thick filum

The disease is progressive. Many adult patients suffer back and leg pain as well as bowel and bladder dysfunction. A great number of patients suffer components of spinal dysraphism in conjuncture with their tethered cord. These include:

- a. Spina bifida occulta
- b. Myelomeningocele
- c. Lipoma
- d. Lipomyelomeningocele
- e. Dermoid sinus
- f. Diastematomyelia

Clinical Manifestations

1. Backache
2. Pes cavus
3. Atrophy of the calf or thigh muscles
4. Equine VAS
5. Scoliosis
6. Bowel and bladder alterations
7. Hyperactive reflexes:
8. Cutaneous manifestations of dysraphism:
 - a. Midline hypertrichosis
 - b. Dermal sinus tract (usually a dimple in the midline spine)
 - c. Midline nevus
 - d. Subcutaneous sacral lipoma

Cauda Equina Syndrome

The usual cause is lumbar and sacral root compression below L3.

Clinical Manifestations

1. Asymmetric radicular pain in a lumbosacral root distribution
2. Bowel, bladder, and sexual dysfunction
3. Saddle anesthesia that involves the anal, perianal and genitalia
4. Flaccid, atonic, areflexic paralysis in the distribution of the involved roots
5. Characteristic L5–S1 sensory loss in the legs

Differential Diagnosis

1. Herniated disc
2. Ependymoma
3. Myxopapillary ependymoma
4. Schwannoma
5. Meningioma
6. Lymphoma
7. Metastasis

Differential Points Between Conus Medullaris Versus Cauda Equina Lesions*Conus Medullaris*

1. Early bowel, bladder and sexual dysfunction
2. Symmetric sensory loss
3. Late pain

Cauda Equina

1. Early pain
2. Asymmetric sensory loss
3. Late sphincter involvement

Epiconus Lesions (Spinal Cord Segments L4–S1)

Anatomically this area is spinal segment T10–L1. Lesions involve bladder, bowel, and sexual function as well as pain and leg weakness. A Babinski sign is present.

Trauma, congenital defects, spinal stenosis (achondroplasia) trauma, demyelinating disease and tumors (myxopapillary ependymomas, chordoma, metastasis hemangioblastoma occur at this level.

Trauma

The thoracic and lumbar junction (thoracolumbar junction) are particularly vulnerable to fracture and dislocation. High thoracic level (T1–T10) are stabilized by the rib cage and the intercostal muscle.

The lumbar vertebrae (L3–L5) are more stable because they are larger stronger and have muscular support. For these regions, the majority of thoracic and lumbar spine injuries occur at the T11–L2 level. In general, the conus medullaris terminates in the lower third of the L1 vertebra, but can vary between the lower third of T11 to the upper third of L3. Fracture at the thoracolumbar junction may damage the spinal cord, conus medullaris or the cauda equina.

Lesions of the epiconus affect the lumbar cord and the roots that supply the lower legs and feet but spare sacral roots. Trauma is rarely pure, and epiconus lesions may have conus medullaris and cauda equina components.

Neuropathy from Vertebral Fractures of the Thoracolumbar Junction Classification

1. Upper lumbar cord
2. Epiconus and lumbar roots
3. Conus medullaris and/or cauda equina

Approximately 50% of thoracolumbar junction fracture suffer epiconus lesions and present with flaccid legs and a spastic neurogenic bladder.

Congenital Spinal Defects**Overview**

In general, most of the congenital defects that affect the spinal cord involve failure of fusion of dorsal midline structures of the neural tube which occurs during gastrulation (weeks 2–3), primary and secondary neurulation (weeks 5–6). Spinal dysraphisms are characterized as open or closed:

1. Open dysraphism:
 - a. Exposure of abnormal nervous tissue through a skin defect
 - b. Include myelomeningocele myelocele and meningocele
2. Closed spinal dysraphism:
 - a. Associated with low back subcutaneous masses that include lipomyelocele, lipomyelomeningocele, meningocele, and myelocystocele

- b. Closed spinal dysraphism without a mass include:
 - i. Tight filum terminale
 - ii. Filum and intradural lipomas
 - iii. Persistent terminal ventricle
 - iv. Dermal sinus
 - v. Complex dystrophic states
 1. Defects of midline notochord integration (primarily diastematomyelia)
 2. Defects of segmental notochordal formation:
 - a. Caudal agenesis
 - b. Spinal segmental dysgenesis
- c. Abnormalities of closure of the vertebral arches:
 - i. Spina bifida occulta
 - ii. Meningocele (primarily lumbosacral)
 - iii. Meningomyelocele

Spina Bifida Occulta

1. The spinal cord remains in the canal; no external sac
2. Cutaneous signs of the defect may include a subcutaneous lipoma, dimple or area of hypertrichosis

Meningocele

1. Protrusion of the dura and arachnoid between the non-fused vertebral laminae
2. Cystic swelling in the lumbosacral area
3. The spinal cord remains in the canal

Meningomyelocele

1. More frequent than meningocele
2. The cauda equina more frequently than the cord is extruded and is attached to the cystic mass
3. Clinical features:
 - a. Primarily sacral involvement that affects sphincters
 - b. Lower lumbar and sacral involvement. The buttocks and lower leg (L4–S1) roots are more involved than the hip flexors (L1–L3) and the quadriceps
 - c. Upper lumbar involvement; the feet and legs are less involved, ankle jerks may be present as well as a Babinski response
 - d. An associated anomaly is a Chiari malformation with hydrocephalus

Congenital Defects That May Produce Symptoms in Adult Life

1. Sinus tracts (recurrent meningitis)
2. Lumbosacral lipomas with tethered cord
3. Diastematomyelia
4. Cysts
5. Tumors with spina bifida
6. Chiari malformation and syringomyelia

Sinus Tracts

1. May be associated with a dimple (usually off the midline) or by an area of hypertrichosis (midline)

2. The tract may connect to a myelocele which may be associated with a dermoid cyst or a fibrolipoma in the middle of the tract
3. Cloacal defects (no abdominal wall and no separation between bladder and rectum) occur with anterior meningoceles
4. Sinus tracts are associated with recurrent meningitis

Congenital Cysts and Lipomas

1. Associated with tethered cord

Diastematomyelia

1. A fibrous band or bony specula from the body of a thoracic or upper lumbar vertebra
2. Divides the spinal cord into halves for a variable distance
3. May be associated with a reduplicated spinal cord each with its own dura and spinal roots (diphomyelia)
4. Clinical manifestations:
 - a. Pain
 - b. Bladder (neurogenic)
 - c. Sensory loss
 - d. Weakness of leg muscles

Occult Dysraphism

1. Occurs in the lumbosacral segments
2. Due to abnormalities of the cell mass, that is caudal to the posterior neuropore
3. Associated with:
 - a. Meningocele
 - b. Lipomas
 - c. Sacrococcygeal teratomas

Caudal Regression Syndrome

1. A genesis of the sacrum (may also involve the lower lumbar vertebrae)
2. Clinical manifestations:
 - a. Flaccid paralysis of the legs
 - b. Arthrogrypotic contractures of the legs and feet
 - c. Urinary incontinence
 - d. Normal mentation
 - e. No hydrocephalus

Congenital Anomalies of the Cranial Cervical Junction

1. Congenital fusion of the atlas and foramen magnum:
 - a. If the anteroposterior diameter of the canal is <19 mm there is spinal cord compression at this level
 - b. Associated with fusion of the second and third cervical vertebrae
 - c. Associations of atlanto-occipital fusion:
 - i. Basilar invagination
 - ii. Atlantoaxial instability
 - iii. Vertebral fusion

- iv. The odontoid process may prolapse into the foramen magnum due to the decrease in vertical height of the atlas
- d. Unilateral hypertrophy of the lateral mass of the atlas:
 - i. Associated with atlanto-occipital fusion and an invaginated lateral mass of the atlas and odontoid process that protrudes into the foramen magnum
 - ii. Severe myelopathy caused by compression
- e. Congenital Atlas Hypoplasia:
 - i. Anomalies of the posterior arch of the atlas range from partial clefts to total agenesis
 - ii. May be associated with cervical canal stenosis at C1–C3

Congenital Abnormalities of the Odontoid Process

1. Complete separation of the odontoid process from the axis:
 - a. The atlas is displaced anteriorly in relation to the axial (atlantoaxial dislocation):
 - i. Acute or chronic spinal cord compression
 - ii. Sore neck with limitation of movement in all planes

Os Odontoideum

1. Os odontoideum is an independent piece of bone varying in size. It has a smooth circumferential cortical margin that is separated from a shortened odontoid peg evidence suggests it is traumatic rather than congenital
2. May be asymptomatic or a cause of myelopathy

Morquio Syndrome

1. AR; Mucopolysaccharidoses
 - a. Deficiency of N-acetylgalactosamine-6-sulfatase type IVA and type IVB (deficiency of B-galactosidase)
 - b. Defective degradation of keratan sulfate
2. Skeletal abnormalities:
 - a. Hypoplasia of the odontoid process
 - b. Short neck, pectus carinatum, thoracic kyphoscoliosis and dwarfism
3. Associated anomalies:
 - a. Joint laxity
 - b. Dental abnormalities
 - c. Deafness
 - d. Cardiac defects
 - e. Respiratory dysfunction
4. Neurologic manifestations:
 - a. Atlantoaxial subluxation
 - b. Spinal cord compression

Achondroplasia

1. Most common form of congenital short-limbed dwarfism
2. Genetics:
 - a. AD; 80% are spontaneous mutations
 - b. Mutation G380R mutation in fibroblast growth factor receptor 3 (FGFR3)

- c. Failure of conversion of fetal cartilage to bone in the growth plate. There is increased periosteal bone formation which thickens the vertebral bodies, neural arches, laminae and pedicles (shortened)
- d. Neurologic manifestations:
 - i. Craniocervical stenosis
 - ii. Tight foramen magnum; short clivus
 - iii. Medullary and upper spinal cord compression
 - iv. Lax ligaments
 - v. Hydrocephalus (in patients with stenotic foramen magnum)
 - vi. Children:
 - 1. Central apnea
 - 2. Leg spasticity
- 3. MRI evaluation
 - a. Some achondroplasia patients have a hyperintense T2-weighted signal in the cervical medulla without concomitant focal spinal cord compression. This occurs just below the craniocervical junction between C1–C2 in the gray matter

Platybasia and Basilar Impression

- 1. Platybasia is a flattening of the base of the skull measured by the angle made by the clivus and the plane of the anterior fossa. This angle should not be greater than 135 degrees
- 2. Basilar Impression or Invagination
 - a. An upward displacement of the occipital condyles above the plane of the foramen magnum
- 3. Clinical features of platybasia and basilar impression
 - a. Short neck with restriction of movement in all planes
 - b. Platybasia without basilar impression is asymptomatic
 - c. Basilar impression with indentations of the anterior medulla is associated with:
 - i. Brainstem dysfunction
 - ii. Lower cranial neuropathies
 - iii. Neurogenic dysphagia
 - iv. Hoarseness (involvement of the levator palatini and vocal cords)
 - v. Sleep apnea
 - vi. Intermittent or spastic quadriparesis
 - vii. Tussive headache (C2)
 - viii. Gait disturbance
 - ix. Syncope (with valsalva maneuvers)

Klippel-Feil Syndrome (KFS)

General Characteristics

- 1. A congenital cervical vertebral fusion due to a failure of segmentation
- 2. Associated with basicranial malformations, atlas assimilation and dens malformations
- 3. Classification of subtypes:
 - a. Type I
 - i. Single congenitally fused cervical segment
 - b. Type II

- i. Multiple non-contiguous congenitally fused segments
- c. Type III
 - i. Multiple contiguous congenitally fused segments
- d. Radiographically:
 - i. 25% are Type I
 - ii. 50% are Type II
 - iii. 25% are Type III
- 4. Neurologic manifestations:
 - a. Axial neck symptoms are associated with type I patients
 - b. Type II and III have radicular and myelopathic symptoms and signs
 - c. Mirror hand movements

Hereditary Spastic Paraplegias

Almost all of the congenital cervical spinal cord abnormalities are associated with syringomyelia.

Syringomyelia

General Characteristics

- 1. A chronic progressive degenerative or congenital disorder of the spinal cord
- 2. Cavitation of the central spinal cord although it may be asymmetrical
- 3. The cervical cord is the most common spinal segment involved, but there may be extension to the medullar and pons (syringobulbia) or into thoracic and lumbar spinal cord segments
- 4. There often are associated developmental abnormalities that include:
 - a. Thoracic scoliosis
 - b. Klippel-Feil malformation
 - c. Platybasia
 - d. Basilar invagination
 - e. Chiari I malformation

Acquired Causes of Syringomyelia

- 1. Trauma
- 2. Tumors that include:
 - a. Astrocytoma
 - b. Hemangioblastoma
 - c. Ependymoma
- 3. Hemorrhagic cord necrosis
- 4. Phase contrast MRI techniques provide excellent cerebrospinal fluid imaging that demonstrates:
 - a. Decreased absorption mechanisms of extracellular fluid
 - b. Blockage and alterations of CSF dynamics at the foramen magnum have been postulated as etiologic

Modified Barnett Classification of Syringomyelia

- 1. Type I
 - a. Obstruction at the foramen magnum and dilatation of the central canal

- i. Associated with Chiari I malformations
 - ii. Associated with other high cervical bony malformations
- 2. Type II
 - a. Syringomyelia without obstructions of the foramen magnum (congenital)
- 3. Type III
 - a. Syringomyelia with other diseases of the spinal cord (acquired)
- 4. Type IV
 - a. Pure hydromyelia (developmental dilations of the central canal with or without hydrocephalus)

Clinical Manifestations

1. Dependent on the four types particularly those with associated developmental abnormalities
2. Type I developmental or congenital type:
 - a. Onset is usually between 20–24 years of age
 - b. Insidious onset with an irregularly progressive course
 - c. Valsalva maneuvers or trauma may initiate or exacerbate signs

Neurologic Signs

1. Amyotrophy of muscles innervated by specifically innervated anterior horn cells affected by the lesion
2. Loss of pain and temperature sensation at the segmental level; normal sensation above and below the lesion (suspended sensory loss)
 - a. Disruption of the crossing fibers of the spinothalamic tract in the ventral white commissure (“cape” sensory loss)
3. Light touch, vibration, position sensibility is intact. Occasionally the syrinx is asymmetric, and the cavity expands laterally or dorsally, and other modalities may be involved
4. Claw hand in late stages (cervical syrinx) both thenar and hypothenar eminences are involved; frequently the 4th and 5th fingers are involved first; the “benediction” sign
5. Horner’s syndrome (C8–T1 involvement); destruction of the ciliary center of Budge (loss of intermediolateral column at C8–T1)
6. Bowel, bladder and impotence involvement is late
7. Loss of segmental reflexes at the involved level; hyperactive reflexes below the level
8. Babinski sign is present with corticospinal tract involvement
9. Pain may be severe early in the course of the illness; deep ache or burning quality (neuropathic central pain)
10. Associated syringobulbia may occur (rostral extension of the syrinx; this often is at the level of descending tract of the Vth cranial nerves)
11. Severe thoracic scoliosis (paraspinal muscle involvement)
12. Rarely there is extension into the centrum semiovale (syringoencephaly)

13. Charcot joints occur (shoulder, thoracic spine or hip); lack of pain (no protective reflexes). Joint destruction occurs from repeated small traumas or loss of trophic support
14. Autonomic dysregulation of the affected segment; subcutaneous neurogenic edema
15. Very commonly associated with the Chiari I malformation
16. Painless injuries; particularly burns of the hands
17. Approximately 25% of cervical syrinxes are associated with cervico-occipital malformations

Clinical Features of an Associated Chiari I Malformation

1. Nystagmus; may be down-beat in primary gaze; rotary if vestibular nuclei involved (concomitant syringobulbia)
2. Head and neck pain; lancinating C2 pain with Valsalva maneuvers particularly cough
3. Corticospinal and sensory loss in the lower extremities
4. Hydrocephalus
5. Craniocervical malformations
6. Hydrocephalus

Association of Syringomyelia with an Intramedullary Tumor

1. Clinical manifestations:
 - a. A large dissociated sensory loss
 - b. There are characteristic retinal and cerebellar hemangioblastoma if associated with Von Hippel-Lindau disease

Post-Traumatic Syrinx Clinical Manifestations

1. Delayed (at times years) spread of sensory or motor loss characteristically above the originally involved segments
2. Also associated with arachnoiditis and cord atrophy

Congenital Bony Defects That Compromise the Spinal Cord or Root Exit Foramina

Developmental Spinal Stenosis

1. General considerations
 - a. Measurements:
 - i. Cervical cord C2–C7 (24–26 mm)
 - ii. Thoracic cord (>14 mm)
 - iii. Lumbar cord L1–L5 (>24–26 mm)
2. Block vertebrae (all achondroplasia patients)
3. Short pedicles
4. Trefoil configurations of the canal (lumbosacral levels)
5. Lateral recess stenosis (primarily at the L5–S1 level)

Ossification and Ligament Abnormalities of the Axis, Atlas and Odontoid Process

1. There are five ossification centers in the axis and atlas that may have developmental abnormalities:
 - a. The body and tip of the axis

- b. The lateral mass of C1 and the central part of the axis
- c. A fracture through the most rostral ossification center of the odontoid separates the tip from the body and is frequently asymptomatic
- d. The odontoid process has three major ligaments that anchor it to the skull:
 - i. Posterior cruciate (most important)
 - ii. Two lateral ligaments
 - iii. In an adult during flexion, the atlas should not move more than 3 mm from the axis. In children, the separation may be up to 5 mm
 - iv. The tip of the odontoid process should not extend rostrally more than 3 mm above a line from the hard palate to the inner table of the skull at the foramen magnum (Chamberlain's line). Bull's and the digastric line are other measurements of this parameter that are rarely used. If the odontoid rises above this line, it invaginates (compresses) the ventral medulla
 - v. A tip of the odontoid process fracture is usually asymptomatic and can occur with violent neck flexion
 - vi. The base of the odontoid process may fail to ossify with concomitant basilar invagination
 - vii. Gorlin syndrome:
 - 1. Short atlas
 - 2. Concomitant odontoid malformations

Differential Diagnosis of Congenital Spine Defects

The general physical examination is most helpful with this differential diagnosis. A patient with a short neck with decreased movement to all planes suggests basilar impression or platybasia. Acquired causes are associated with Paget's disease, osteogenesis imperfect (blue sclera), rheumatoid arthritis (ulnar hand deviation) and rarely rickets (except in parts of Africa).

Intermittent lower cranial nerve involvement, particularly hoarseness is common from intermittent brainstem vascular insufficiency with head movement as platybasia with basilar impression causes vertebral artery occlusion. In a patient with increased reflexes induced by neck flexion, there may be excess mobility of the spine at C1–C2 atlantocervical dislocation; this is often accompanied by paresthesia of the hands. In adults, transverse cruciate destruction and laxity are most often encountered in severe rheumatoid arthritis (pannus). It may occur with congenital collagen gene defects, mucopolysaccharidoses (Morquio's type IV; absent odontoid), trisomy 21 and trauma. A short neck with low hairline and limitation of movement is common with osseous cervical congenital malformations.

Chiari I malformation have a shallow posterior fossa and are often associated with a cervical syrinx. Hoarseness and ataxia point to this diagnosis as does a C2 headache induced by a severe cough. A cervical syrinx may present with unilat-

eral hand wasting, a "cape" sensory loss and painless burns on the hands and arms.

An acquired thoracic spine scoliosis or kyphoscoliosis point to diastematomyelia, a reduplication of the spinal cord, diplomyelia or an extensive syrinx. If the scoliosis is C-shaped, there is asymmetric paraspinal muscle involvement. An S-shaped configuration is congenital with muscle compensation. An astrocytoma may also grow asymmetrically; motor neuron disease and primary muscle disease may affect paraspinal musculature asymmetrically. Severe scoliosis and kyphosis also occur with Emery-Dreifuss muscular dystrophy, fiber type disproportion, and limb-girdle muscular dystrophy type II B (LGMD11B). A syrinx may be asymmetric and extend from the cervical to the sacral cord producing a C-shaped scoliosis. Painless burns on the hands and arms, a suspended sensory loss, segmental atrophy and a "Chariot" joint identify this diagnosis.

A tethered cord may be announced in young women during delivery. The dorsal lithotomy position during a difficult birth may cause paralysis of the legs. It is usually associated with unilateral weakness and wasting of the lower extremity associated with pes cavus, bladder dysfunction, and hyperreflexia.

Tufts of hair, strawberry hemangiomas, a skin dimple, and a sacral mass often have underlying spinal and vertebral body defects. These include spina bifida occulta, A-V malformation, hemangioblastomas, and myelomeningoceles. A tuft of hair off the midline may be the marker of a neurenteric cyst or sinus tract that connects with a myelocele.

A short neck and abnormally raised and malformed shoulder and scapula is the Klippel-Feil syndrome with Sprengel's deformity.

Trauma to the Vertebral Column with Spinal Cord Injury

Overview

In civilian practice, the most common causes of vertebral trauma and spinal cord injury are:

1. Motor vehicle accidents
2. Falls
3. Gunshot and stab wounds
4. Diving accidents
5. Crushing industrial accidents
6. Birth injury

The annual incidence of spinal cord injury in the USA is five patients per 100,000 people. Males predominate at approximately 4:1. Approximately 5,000 patients per year die from their spinal injuries. There is frequently a concomitant head injury.

Vertebral Column Injuries

1. Classification
 - a. Fracture-dislocation

- b. Pure fractures
- c. Pure dislocations
- 2. The spinal cord is injured by direct compression from bony fragments or by buckling of intraspinal ligaments. Fracture dislocations of the vertebral column are most frequent and result from force applied at a distance
- 3. All three types of vertebral column injury are caused by a vertical compression with antero or retroflexion (hyperextension)
- 4. The most important parameters in the mechanics of vertebral column and spinal cord injury are:
 - a. Structure of the bones and ligaments at the site of injury
 - b. Intensity direction and point of impact of the force
- 5. Head injuries often cause concomitant cervical spine injury, may fracture the atlas and odontoid process

Acute Cervical Flexion Injury

- 1. The cervical vertebrae are jammed together at the level of the injury
- 2. The anterior inferior edge of the superior vertebra is driven into the next lower level vertebra fracturing it
- 3. The posterior portion of the fractured vertebral body is displaced backward which compresses the spinal cord
- 4. The interspinous and posterior longitudinal ligaments are torn
- 5. Less severe anterior flexion causes dislocation of adjacent vertebrae without spinal cord injury
- 6. Exacerbation of this injury occurs in association with severe cervical spondylosis, a congenital narrow canal, and ankylosing spondylitis
- 7. Extrusion of discs material has occurred with holding in patient's neck in flexion

Hypertension Injuries of the Cervical Spine

- 1. Vertical compression with the head in extension
- 2. Force is primarily on the laminae and pedicles of the mid-cervical vertebrae (C4–C6). The fractures may be unilateral or bilateral, and the anterior ligament is buckled or ruptured
- 3. The displacement compresses the cord between the laminae of the lower vertebrae and the body of the superior one
- 4. Inward buckling of the ligamentum flavum may compress the cord without misalignment of vertebrae, or they have realigned spontaneously

Severe Compression Injuries

- 1. Affects the thoracolumbar area (ski injuries and falls)
- 2. Burst vertebral bodies (a central area of compression with fracture lined radiating outwardly)
- 3. Bone splinter and disc material may extrude into the spinal cord
- 4. Anterior vertebral body wedge fracture. Common in elderly osteoporotic women from minimal trauma (opening a window). Usually only local pain with no neurologic deficit (exacerbated with breathing)

Rotational Injury

- 1. Unilateral pars interarticularis fracture or facet injury
- 2. Rotary facet dislocation. Very difficult to appreciate radiologically. Suspected from increased intraspinal distance at that level and persistent focal spine pain (rupture of an interspinous ligament) and torticollis to the ipsilesional side

Specific Vertebral Fracture and Dislocations

- 1. Rotary force to the head
- 2. Displacement of the occipital condyle in relation to lateral masses of C1
- 3. Atlantoaxial dislocation:
 - a. Flexion forces
 - b. Dislocation of C1–C2
 - c. Myelopathy
- 4. Jefferson fracture of C1:
 - a. Axial downward force on vertex of the head
 - b. Bilateral anterior and posterior arch fracture at C1
 - c. Disruption of transverse ligament
 - d. Often asymptomatic
- 5. Odontoid (dens) fracture:
 - a. Hyperflexion
 - b. C2:
 - i. Type I – tip of the dens
 - ii. Type 2 – base of the dens
 - iii. Type 3 – body of C2
 - c. Asymptomatic to severe myelopathy
 - d. Type 2 has poor healing
- 6. Hangman's fracture:
 - a. Hyperextension with axial loading
 - b. Fracture through the pedicles at C2
 - c. Often asymptomatic
- 7. Subaxial fracture dislocation:
 - a. Severe flexion
 - b. Dislocation (perched or jumped facets)
 - c. Occurs from C3–T1
 - d. Tetra- and quadriplegia
 - e. Vertebral artery dissection
- 8. Burst fracture:
 - a. Usually thoracolumbar level
 - b. Axial loading
 - c. Fracture through the vertebral body
 - d. Root compression from retropulsion of a bone fragment
- 9. Chance fracture:
 - a. Thoracolumbar level
 - b. Axial loading
 - c. Fracture through the vertebral body with facet and posterior element fracture
 - d. May be asymptomatic
- 10. Wedge fracture:
 - a. Hyperflexion
 - b. No loss of height and no subluxation

- c. Local pain; constant movement with breathing makes it difficult to heal
- d. No neurologic deficit

Fatal cervical spine fractures are due to fracture-dislocations at C1–C3 that include atlanto-occipital and atlantoaxis dislocations. Death is usually from respiratory failure.

Clinical Manifestations of Spinal Cord Injury

1. Diaphragmatic paralysis occurs with lesions of C1–C3 cervical segments
2. Quadriplegia usually occurs from a fracture dislocation of the fourth to fifth cervical vertebrae
3. If there is sparing of abduction and flexion of the arms with paralysis of the legs the lesion is at the fifth to sixth cervical vertebrae
4. Fracture at the sixth to seventh cervical levels paralyzes the hands and legs
5. Lesions below the first lumbar vertebra (the spinal cord usually terminates at the rostral edge of the L1 vertebra) cause cauda equina injury
6. Lesions of the lower cervical cord may spare sensation to the nipple line due to the infraclavicular nerves whose origin is the cervical plexus (C3–C4)
7. The somatotopic organization of the spinothalamic tract is lateral to medial. Ascending sacral and leg fibers ascend laterally so that a lateral cervical cord lesion will cause a contralateral sacral and foot loss of sensation to pin-prick and temperature (spinothalamic fibers cross at their level of entry)

Patterns of Spinal Cord Injury

1. Spinal cord concussion
2. Spinal shock
3. Complete cord transection
4. Incomplete transection:
 - a. Brown-Séquard
 - b. Central cord syndrome
 - c. Anterior cord syndrome
 - d. Associated injuries:
 - i. Vertebral artery dissection or occlusion (traverse the transcervical canals)
 - ii. Cauda injury
 - iii. Conus medullaris injury
 - iv. Mixed epiconus cones and cauda equina lesions

Spinal Cord Concussion

1. A transient loss of motor or sensory function of the spinal cord that recovers within a short time (minutes to hours). Deficits may last for days. Transient syndrome includes:
 - a. Brachial weakness (may include an element of neuropractic brachial plexus injury)
 - b. Quadriplegia and rarely hemiparesis
 - c. Isolated sensory symptoms such as “burning hands”
 - d. Hand and arm motor and sensory deficits suggest a central cord injury

Pathology

1. Destruction of gray and white matter with hemorrhage (traumatic necrosis). The changes are maximal at the site of injury but may extend in an ovoid shape 1 or 2 segments rostrally and caudally
2. Healing produces a glial scar or cavitation with hemosiderin
3. Traumatic syringomyelia may occur after a delay of months or years. It usually enlarges rostrally but may be restricted to the central cord. A central cord predominant lesion may produce segmental weakness and sensory loss in the arms with minimal long tract involvement

Radiation Spinal Cord Injury

1. In general, it follows treatment for malignancies of the neck (lymphoma) or mediastinum
2. A transitory syndrome of paresthesia of the arms may occur at 3–6 months associated with Lhermitte’s sign. There are no associated motor or sensory signs and the process resolves
3. Delayed progressive myelopathy:
 - a. May be exacerbated by hyperthermia
 - b. A delayed onset of usually 12–15 months following therapy
 - c. Insidious onset with paresthesia and dysesthesias of the feet and hands (accompanying Lhermitte’s sign with cervical X-RT)
 - d. Often a stuttering course with corticospinal and spinothalamic tract involvement
 - e. An early Brown-Séquard pattern (infarction from proliferative endarteritis) that evolves into a transverse myelitis
 - f. An anterior horn cell amyotrophy of muscles innervated by irradiated segments
 - g. The CSF demonstrate a slight increase of protein but is otherwise normal

Pathology

1. Coagulating necrosis of the irradiated segment with rostral and caudal extension for a few spinal cord segments
2. Secondary demyelination of ascending and descending tracts
3. Necrosis of arterioles
4. Delayed signs and symptoms from peripheral and cranial nerve or plexus involvement may occur 10–15 years after X-RT treatment

Neuroimaging

1. MRI may reveal early cord swelling in irradiated spinal segments. There may be heterogeneous contrast enhancement
2. There is a high T2-weighted signal from fatty infiltration of the irradiated bone marrow which identifies the level of cord involvement
3. The rostral-caudal length of the lesion is longer than that seen with demyelinating disease, tumor or vascular malformation

Electrical Causes of Spinal Cord Injury

Electrical Injury

General Characteristics

1. Approximately 1000 deaths occur annually in the USA from inadvertent electric current contact
2. The quantity of current, not the voltage determines damage to the peripheral and CNS. Modifying factors are the duration of contact and skin resistance
3. There are both immediate and delayed neurologic signs and symptoms. The delay is usually one week, but may be as long as six weeks
4. Immediate effects are from heating the cord

Clinical Manifestations

1. Spinal trophic paralysis:
 - a. Occurs weeks to years after an electric shock
 - b. Most commonly the current has passed through the cervical cord (arm to arm) or from an arm to the leg
 - c. If the head is a contact point, the patient may be rendered unconsciousness and then experience deafness, tinnitus or headaches. There may be transient pain in the involved extremity
 - d. There is early mild weakness which progresses after a latent period of weeks to months and evolves into segmental muscular atrophy. There is often mild leg spasticity
 - e. An occasional patient may suffer a cortical or brainstem syndrome

Pathology

1. Demyelination of long tracts with relating gray matter sparing from high current
2. The gray matter is affected in spinal atrophic paralysis

Lightning Injury

1. Death is from ventricular fibrillation or severe hyperthermia of the brain
2. Initial loss of consciousness; 30% fatality rate
3. Rare agitated or confusional state can last for 1–2 weeks
4. Sensorimotor dysfunction of limbs; may progress to an anterior horn cell variant
5. Chronic regional pain syndrome may evolve from affected limbs that demonstrate early autonomic dysregulation (cold extremities with livedo-reticularis and cyanosis)

Spinal Cord Vascular Disease

General Characteristics

1. Spinal cord strokes account for less than 1% of all strokes and about 5–8% of acute myelopathies
2. Infarction occurs from:
 - a. Aortic disease (clamped aorta)
 - b. Dural fistula
 - c. Bleeding (coagulopathy; anticoagulation)
 - d. Arteriovenous malformations

Vascular Anatomy of the Spinal Cord

The major blood supply of the spinal cord is derived from a series of segmental branches from the aorta and branches of the subclavian and internal iliac arteries.

Segmental Artery from the Aorta

1. Divides into an anterior and posterior ramus
2. A spinal arteriole from the posterior ramus passes through the vertebral foramen to supply the dorsal root ganglia and roots by anterior and posterior radicular branches
3. Anterior radicular arteries supply much of the blood to the spinal cord. Its branches irrigate the vertebral bodies and ligaments
4. Venous drainage is to the posterior veins that form the spinal venous plexus

Anterior Spinal Artery

1. The anterior medullary arteries arise from the distal vertebral artery to form the anterior spinal artery. The artery usually extends the full length of the cord from the spinomedullary junction at the foramen magnum to the filum terminale in the anterior sulcus
2. The anterior spinal artery is also formed by approximately ten unpaired segmental arteries that originate from the distal vertebral arteries and the aorta and its branches
3. Radicular medullary arteries from the anterior spinal artery are divided into three groups:
 - a. Upper cervicothoracic branches from the anterior spinal artery and branches of the thyrocervical trunk and costovertebral arteries
 - b. Middle thoracic branches derived primarily from a T7 radicular artery
 - c. Thoracolumbar artery whose origin is from T10–L1 (the great radicular artery of Adamkiewicz) which supplies the lower 2/3 of the spinal cord
 - d. The posterior medullary arteries form the paired posterior spinal arteries on the dorsal spinal cord surface. The dorsal spinal arteries are also fed by posterior radicular arteries that enter with nerve roots at every spinal level
 - e. Additional segmental arteries from the vertebral, aorta and iliac arteries supply paraspinal structures
4. The most lateral white matter of the ventral 2/3 of the spinal cord is supplied by a pial radial network from the anterior spinal artery
5. Posterior spinal artery penetrating branches supply:
 - a. The posterior columns
 - b. Uppermost Rexed layers of the dorsal horn (I–IV)
 - c. Circumflex anastomotic vessels (the anastomosing plexus of small arteries between the anterior and posterior vessels) supply the superficial white matter

Venous Drainage of the Spinal Cord

1. Radial veins drain the inner cord to form a coronal plexus

2. Deep parenchymal veins drain into central sulcal veins
3. Parenchymal veins drain both sides of the cord
4. Sulcal veins anastomose intrasegmentally
5. Anterior median spinal vein:
 - a. Drains the sulcal vein
 - b. There may be two veins instead of one
6. Extramedullary venous channels:
 - a. Common on the dorsum of the spinal cord
 - b. Eight to twelve anterior radicular veins arise:
 - i. Drain the anterolateral anastomosis from the coronal venous plexus
7. The junction of the anterior radicular vein and the coronal venous plexus is at the nerve roots prior to their exit through the dura
8. The lumbar enlargement is drained by the reticularis magna vein
9. Posterior radicular veins are most prominent in the cervical cord
10. Spinal cord venous blood drains into:
 - a. Epidural and paravertebral plexi (a valveless system)
 - b. Extends from the occipital bone to the sacrum (Bateson's plexus)
 - c. Valsalva maneuvers increase the pressure in the system and are a route for pelvic cancers to metastasize to the posterior fossa (rarely the cerebral hemisphere)
- b. Infarction of the artery is caused by:
 - i. Atherosclerosis of extra vertebral collateral arteries
 - ii. Aortic pathology:
 1. Severe atherosclerosis
 2. Dissecting aneurysm
 3. Intraoperative surgical procedures (segmental artery occlusion)
 4. Cardiac and aortic surgery with cross-clamping for >30 minutes
 5. Aortic arteriography
2. Polyarteritis:
 - a. Occlusion of a spinal medullary artery
 - b. Systemic cholesterol emboli
3. Origin from atherosclerotic aorta:
 - a. Following surgical procedure
 - b. Angioplasty
 - c. Cardiopulmonary resuscitation
 - d. Delayed onset in some instances
4. Extracranial vertebral artery dissection:
 - a. Causes cervical cord infarction:
 - i. Anterior spinal artery territory
 - ii. Central cord ischemia
 - b. Clinical manifestation:
 - i. Vertigo
 - ii. Asymmetric brachial diplegia
 - iii. Suspended sensory loss
 - iv. Radicular and neck pain
5. Other aortic pathologies:
 - a. Cord ischemia:
 - i. Dissection
 - ii. Traumatic rupture
 - iii. Thromboembolic occlusion
 - iv. Ulcerative aortic plaque disease
 1. Obstruction of the orifices of radicular arteries
6. Aortic Dissection:
 - a. Dissection of the arch:
 - i. Associated with sudden pain in the face
 - ii. Contralateral, hemiparesis
 - iii. Brachial artery ischemia (sensorimotor neuropathy)
 - b. Dissection below the subclavian artery:
 - i. Severe interscapular and chest pain
 - ii. Ischemia of arms or legs
 - iii. Hypotension if above T6
 - iv. Paralysis of the sphincters and both legs; sensory loss below the dissection
 - v. Myoclonus and leg spasms
 - vi. Aortic aneurysm surgery:
 1. Paraplegia occurs in approximately 5% of patients with thoracoabdominal aneurysm surgery; rarely after infrarenal procedures
 - a. Delayed occurrence
7. Rare complication of vertebral arteriography:
 - a. High cervical infarction

Spinal Watersheds

1. The longitudinal watershed of the spinal cord is between T2–T4
2. The spinal cord is perfused at a much lower pressure 60–70 mmHg than the brain
3. Infarction of the spinal cord is frequently overshadowed by cerebral signs and symptoms
4. Internal watershed zones in the spinal cord are the:
 - a. Corticospinal tract
 - b. Rexed layers V–VI
5. Selective segmental gray matter necrosis does occur due to thoracic watershed infarction:
 - a. Cross-clamping of the aorta >30 minutes
 - b. Intraoperative surgical occlusion of the segmental spinal arteries at their origin
 - c. Spinal cord infarction after surgical procedures may be delayed for up to three weeks. There may be widespread embolization in this circumstance
6. Systemic hypotension
7. Cardiac arrest
8. Anoxia
9. Aortic dissection
10. Vertebral artery occlusion
11. Carbon monoxide poisoning

Causes of Spinal Cord Ischemia

1. Usually involves the anterior spinal artery distribution:
 - a. Atherosclerosis and thrombotic occlusion of the anterior spinal artery are rare

- b. Immediate sensorimotor paralysis
- c. Painful segmental spasm
- d. Spinal myoclonus and rigidity
- e. Putative vasoconstriction from older contrast agents
8. Progressive ischemic necrosis from arteriovenous malformation
9. Cocaine abuse:
 - a. Infarction may be preceded by spinal transient ischemic attacks
 - b. Signs and symptoms may be immediate or develop over several hours
 - c. Radicular pain may occur
 - d. Paralysis is usually bilateral
 - e. Those with transverse myelopathy:
 - i. Flaccid and areflexic paralysis
 - ii. Spasticity supervenes after weeks
 - iii. Some return of bladder control
10. Heroin Injection:
 - a. Signs occur after the patient regains consciousness
 - b. May be associated with acute pulmonary edema
 - c. Myelopathy occurs after a period of abstinence
 - d. Possible autoimmune reaction to adulterants or vasospasm
11. Embolism
 - a. Common causes of spinal cord embolism with infarction are:
 - i. Bacterial endocarditis
 - ii. Atrial myxoma
 - iii. Non-bacterial thrombotic emboli (most often in cancer patients)
12. Fibrocartilaginous emboli:
 - a. Arises from disc herniations
 - b. Young women > men
 - c. Primarily affects the cervical cord
 - d. Precipitants include minor trauma, sudden neck motion lifting, and prolonged spinal flexion
 - e. Clinical manifestations:
 - i. Pain in the neck or upper back: Radicular pain
 - ii. Rapidly progressive often asymmetric spinal cord syndrome
 - iii. MRI usually fails to demonstrate the herniated disc
13. Angiography
 - a. Catheterization for dural AVM
14. Fat emboli:
 - a. Broken bones (long bones in young patients)
 - b. Hip replacement in older patients
 - c. Diabetic ketoacidosis
15. Tumor cells
16. Nitrogen bubbles (Caisson's disease)
17. Air bubbles:
 - a. Diving accidents
 - b. Cardiac surgery
 - c. Surgical procedure in sitting position (ENT and neurosurgery)
18. Therapeutic renal artery embolization
19. Spinal cord infection and inflammation that cause infarction
 - a. Most common organisms are:
 - i. Tuberculosis
 - ii. Syphilis
 - iii. Cryptococcosis
 - iv. Coccidioidomycosis
 - v. Lyme's disease
 - b. Inflammation of the meninges spreads to the spinal arteries which may cause acute infarction
 - c. *Schistosoma mansoni*
 - i. Parasites invade cord blood vessels primarily in the conus medullaris and cauda equina
20. Chronic adhesive arachnoiditis
 - a. Scarring and obliteration of spinal penetrating arteries primarily affecting the central cord
21. Surfer's myelopathy
 - a. Novice surfers that are prostate for a long time
 - b. Standing with vigorous movements
 - c. Approximately one hour from surfing:
 - i. Severe upper lumbar or thoracic pain followed by paraparesis or paraplegia with urinary retention
 - d. MRI suggestive of ventral spinal cord ischemia

Arterial Spinal Cord Infarction Syndromes

Anterior Spinal Artery Ischemia

1. At the origin of the anterior spinal artery from the vertebral artery:
 - a. Usually severe atherosclerosis of the vertebral arteries
 - b. Medial medullary syndrome:
 - i. Ipsilateral XII nerve palsy
 - ii. Contralateral proprioceptive and vibratory deficit
 - iii. Contralateral weakness of the arm and leg (above the decussation of the pyramidal tract at C2)
 - iv. Crural plegia (arm ipsilateral and leg contralateral)
2. Low anterior spinal artery infarction:
 - a. Involvement of the ventral 2/3 of the spinal cord
 - b. Weakness of the extremities below the lesion
 - c. Loss of temperature and pain below the lesion
 - d. Bladder retention in approximately 50% of patients
 - e. Intact dorsal column sensory function

Differential Diagnosis of Anterior Spinal Artery Syndrome

1. Atherosclerosis of the artery (rare) or its feeding vessel (vertebral arteries)
2. Vertebral artery dissection
3. Aortic dissection
4. Surgical procedures of the aorta
5. Arteriography of the aorta

6. Hypotension (cross-clamped aorta >30 minutes)
7. Emboli:
 - a. Atrial myxoma
 - b. Arrhythmia
 - c. Fibrocartilage embolus
 - d. Air embolus
 - e. Nitrogen embolus
 - f. Cholesterol emboli
8. Infections:
 - a. Syphilis
 - b. Cryptococcus
 - c. Tuberculosis
 - d. Fungi
 - e. Schistosoma
9. Arachnoiditis
10. Idiopathic pachymeningitis (IgG4)
11. Cardiopulmonary and aortic surgical procedures
12. Vasculitis:
 - a. Polyarteritis nodosa
 - b. Sarcoid
 - c. Takayasu's disease
13. Systemic hypotension
14. Cocaine abuse
15. Intravenous heroin abuse

Ischemia of the Lower Thoracic Cord and the Lumbar Enlargement by Involvement of the Artery of Adamkiewicz

1. Renal arteriogram
2. Surgical procedures (cross clamping the aorta)
3. Aortic dissection
4. Atherosclerosis
5. Emboli

Posterior Spinal Artery Ischemia

General Characteristics

1. Extremely rare
2. Atherosclerosis or occlusion of the vertebral arteries
3. Cocaine abuse (vasoconstriction)
4. Trauma
5. Surgery

Clinical Manifestations

1. Severe sensory ataxia (may be acute with arm levitation)
2. Loss of posterior and vibration sensibility

Neuroimaging of Spinal Cord Infarction

1. MRIs obtained in the first hours or even days from the infarction may be normal
2. T2-weighted sequences reveal edema over several segments
3. Slight enhancement with gadolinium
4. Chronic lesions demonstrate an atrophic cord

Venous Infarction of the Spinal Cord

General Characteristics

1. Venous infarction without hemorrhage is hard to distinguish from arterial patterns of infarction
2. Differential diagnosis of venous infarction of the spinal cord:
 - a. Extension of thrombophlebitis of pelvic veins
 - b. Associated with chronic obstructive pulmonary disease
 - c. Polycythemia vera
 - d. Thrombophlebitis of the lower extremities:
 - i. Propagates into the cord via the paravertebral venous plexus
 - e. Subacute necrotizing myelitis:
 - i. Associated with spinal cord thrombophlebitis
 - ii. No systemic foci
 - iii. Associated with chronic obstructive pulmonary disease
 - f. Associated with epidural abscess
 - g. Endoscopic sclerotherapy (esophageal varices)
 - h. Coagulopathy
 - i. Cancer (breast and pancreas)
 - j. Subacute necrotizing myelopathy (paraneoplastic)
 - k. Birth control pills
 - l. Pregnancy
 - m. Disseminated intravascular coagulation

Hemorrhagic Disease of the Spinal Cord

Malformations and of the Spinal Cord and Dura Fistulas

General Characteristics

1. These lesions cause both ischemia and hemorrhage
2. Distinguishing features are:
 - a. Size of the nidus between an artery and vein
 - b. Size and location of feeding and draining vessels
 - c. Newer classification:
 - i. Medullary arteriovenous malformations that involve surrounding structure to a limited extent
 - ii. Intradural perimedullary fistulas (pial and subpial surface of the cord)
 - iii. Dural fistulas

Dural Arteriovenous Fistula

General Characteristics

1. Primarily located in the low thoracic cord and conus medullaris
2. Limited venous drainage system
3. A proportion of dural arteriovenous fistulas is in a dural root sleeve which drains into the perimedullary coronal venous plexus
4. Men > women

Clinical Manifestations

1. Slowly progressive “signs” but may have intermittent exacerbations precipitated by valsalva maneuvers or postural changes
2. Gait imbalance
3. Paresthesia
4. Slowly progressive asymmetric leg weakness
5. Some low back and sciatic pain
6. Urinary involvement
7. Claudication syndrome

Neuropathology

1. Rare bleeding
2. Venous congestion and edema

Neuroimaging

1. MRI reveals swelling of one or more adjacent spinal segments
2. Usually, there is no SAH; those that do bleed are primarily cervical and located near the cervicomedullary junction
3. Thoracic, lumbar and sacral fistulas rarely cause epidural hemorrhage

Intramedullary AVM*General Characteristics*

1. Located on the dorsal surface of the lower spinal cord
2. May occur at any location and at any age but is most often seen in middle-aged or elderly females

Clinical Manifestations

1. Acute lancinating pain often in a sciatic nerve distribution may be the presenting feature; the pain appears in clusters and may be worse in recumbency over weeks
2. Weakness and paresthesias are usually present in the same distribution as weakness
3. An apoplectic or slowly progressive weakness may be its course
4. Gait alteration is frequently by six months

Neuropathology

1. Dorsal surface of the spinal cord demonstrates enlarged veins that may involve roots and penetrate the spinal cord
2. Intramedullary ischemic changes
3. Thrombosis of venous vessels
4. CSF demonstrates elevated protein

Neuroimaging

1. MRI reveals serpiginous flow voids on the dorsal spinal cord
2. Hematomyelia and subarachnoid hemorrhage are rare

Intradural Perimedullary AVMs*General Characteristics*

1. Least frequent malformation
2. Possibly related to Foix-Alajouanine malformation
3. Involves the lower thoracic, upper lumbar or the cervical enlargement

Clinical Manifestations

1. Young patients and men and women are equally affected
2. Evolution may be slowly progressive (spinal cord compression), or it may present apoplectically
3. Mechanism for apoplectic onset:
 - a. Thrombosis of a vessel
 - b. Hemorrhage from a draining vein
4. Compressive myelopathy
5. Sudden onset consistent with transverse myelopathy

*Neuroimaging of Spinal Malformations***Dural Fistulas**

1. Enlargement of the spinal cord at the lesion level
2. T2-weighted MRI signal of the swollen cord over several segments
3. Draining vessels are infrequently imaged
4. Rare gadolinium enhancement
5. Arteriography which demonstrates the fistula in the dura; early draining vein
6. Rarely a fistula or high flow AVM may be in an organ outside of the spinal cord and cause pathology by increasing venous pressure

Rare Vascular Spinal Cord Malformations**Klippel-Trenaunay-Weber Syndrome (KTWS)***General Characteristics*

1. Associated with a cutaneous vascular nevus that overlies the AVM or is in the limb supplied by the affected segment

Clinical Manifestations

1. If the segmental malformation is at cervical levels:
 - a. Upper extremity is enlarged
 - b. Telangiectasia and tortuous veins are prominent
2. Segmental and tract lesions occur from infarction and hemorrhage

Aneurysm of a Spinal Artery with Coarctation of the Aorta and Telangiectasia of the Spinal Cord*General Characteristics*

1. May be associated with Osler-Weber-Rendu (hereditary hemorrhagic type)

Clinical Manifestations

1. Acute spinal cord hemorrhage
2. Acute hemorrhagic lesions with myelopathy

Foix-Alajouanine Syndrome*General Characteristics*

1. Congestive myelopathy due to spinal arteriovenous fistulas described by Foix-Alajouanine in 1926 (named it a necrotizing myelopathy)
2. Increased intramedullary venous pressure that causes an increased arteriovenous pressure gradient and concomitant decrease of cord perfusion

Clinical Manifestations

- a. Lower part of the cord is affected
- b. Gait difficulty
- c. Dysesthesia and non-dermatomal sensory loss
- d. Wasting and weakness of the lower extremities
- e. Sphincter involvement

Cavernous Hemangioma of the Spinal Cord (Cavernoma)*General Characteristics*

1. Benign vascular lesions that are common in the skin, liver and soft tissue
2. Arise from abnormal development of periradicular vessels
3. Most common in the cerebral hemispheres, but can be found anywhere in the neuraxis
4. Incidence is not known:
 - a. Possibly 1% of spinal masses
5. Men > women
6. Lower thoracic and lumbar cavernous hemangiomas are most frequent
7. May be associated with arteriovenous fistula of the lung

Clinical Manifestations

1. Onset with pain, weakness, and sensory symptoms
2. Later bowel and bladder dysfunction
3. Cervical lesions produce earlier symptoms
4. Severe weakness in 20% of patients by six months after presentation
5. Pain may be local or radicular
6. A combination of upper and lower motor weakness

Associations with Onset of Signs and Symptoms

1. Exercise
2. Pregnancy
3. Menstruation
4. May bleed during sleep
5. In 50% of patients, the onset of the first symptoms to diagnosis is three years

Neuropathology

1. Large dilated hyaline vascular channels which are in diffuse patterns. They are associated with thrombosis, perivascular hemosiderin (old bleeds with macrophage ingested hemosiderin) and calcification
2. Histologically the irregular vascular spaces are lined by a single layer of endothelium
3. A capillary hemangioma is a plexus of small capillary-sized vessels
4. The large sinusoid-like vascular channels have few or no intervening neurons or glial cells. They are separated by thin fibrous adventitial tissue

Neuroimaging

1. MRI reveals a heterogeneous well-circumscribed lesion or lesions

2. T2-weighted sequences may reveal a high-intensity signal (more recent bleed) or the lesion may have T1-weighted decreased signal. There is a hemosiderin ring. The lesions may show a homogeneously enhanced lesion on T1 and hypointense on T2-weighted sequences

Epidural Cavernous Hemangioma**Pure Spinal Epidural Cavernous Hemangiomas (PSECH)***General Characteristics*

1. Most spinal cavernous hemangiomas are vertebral in origin with or without epidural extension; pure epidural cavernous hemangiomas not originating from a vertebra are extremely rare
2. Reported incidence of spinal cavernous hemangiomas is 22 cases/million/year
3. 70% of pure spinal epidural cavernous hemangioma (PSECH) are women
4. Average age at diagnosis is 40 years
5. Most commonly located in the thoracic spine, posterolaterally and may extend into the neural foramina (19%)

Clinical Manifestations

1. Slowly progressive paraparesis (71%)
2. Radiculopathy (10%)
3. Rare acute paraparesis from possible intralesional thrombosis or hemorrhage and compression from an epidural hematoma

Neuropathology

1. PSECHs are dynamic lesions due to:
 - a. Intralesional hemorrhage
 - b. Thrombosis
 - c. Cyst formation
 - d. Involution
2. Hemorrhages are less common than what occurs with intra-axial cavernous hemangiomas

Neuroimaging

1. MRI:
 - a. High T2 signal intensity
 - i. Homogeneous, strong contrast enhancement
 - ii. Rarely there is heterogeneous signal intensity after recurrent bleeding
 - iii. No low signal hemosiderin rim whose putative mechanism is the easier removal of blood products because they are outside of the blood-spinal cord barrier

Differential Diagnosis of PSECH

1. Meningioma
2. Lymphoma
3. Metastasis
4. Schwannoma
5. Neuroma

Cobb's Syndrome*General Characteristics*

1. A vascular malformation that is metameric
2. Involves both the spinal and dermatomal segment

Clinical Manifestations

1. Segmental cutaneous angiomatous skin lesions
2. Often at a thoracic level
3. Spastic paraparesis

Bannayan-Zonana Syndrome*General Characteristics*

1. Autosomal dominant; A few sporadic patients

Clinical Manifestations

1. Macrocephaly
2. Multiple lipomas
3. Hemangiomas
4. Spastic paraparesis
5. Intracranial lesions
6. Male > female

Coarctation of the Aorta*General Characteristics*

1. Decreased circulation to the lower spinal cord
2. Weakness of the legs, sensory loss, and sphincter alternations

Subarachnoid Hemorrhage in the Spinal Cord*General Characteristics*

1. Spinal SAH < 1% of all SAH
2. Most common cause is bleeding from a spinal vascular malformation

Clinical Manifestations

1. Acute onset
2. Severe back pain at the level of the hemorrhage
3. Pain quickly becomes diffuse with signs of meningeal irritation
4. Radiculopathy at the site of the lesion
5. If blood diffuses above the foramen magnum:
 - a. Headaches
 - b. Cranial neuropathy (rare)
 - c. Depressed level of consciousness (rare)
6. Over time, there are decreased ankle jerks with increased knee and upper extremity reflexes
7. Increased intracranial pressure with papilledema (rare)
8. CSF evaluation:
 - a. RBC (1,000,000/mm³)
 - b. Within days there may be hypoglycorrachia (severely depressed glucose level < 20 mg%)
 - c. Xanthochromia

Hematomyelia*General Characteristics*

1. Most bleeding is caused by vascular malformations
2. The differential diagnosis of hematomyelia is:
 - a. Vascular malformation:
 - i. Intradural, perimedullary and subpial AVM
 - ii. Intramedullary AVM
 - iii. Dorsal arteriovenous fistula
 - iv. Trauma:
 1. Direct injury to the spine (penetrating and non-penetrating)
 2. Hyperextension and flexion of the cervical spine
 - v. Hemorrhage into a tumor
 - vi. Hemorrhage into a syrinx
 - vii. Coagulopathy
 - viii. Anticoagulation
 - ix. Venous infarction

Clinical Manifestations

1. Presents as spinal shock associated with severe back pain
2. Autonomic instability (postural hypotension if the lesion is above T6)
3. Gray matter is more affected than white matter
4. Spasticity develops below the level of the lesion
5. Atrophy and fasciculation of affected segments occur with time
6. Babinski sign is prominent
7. Sensory level:
 - a. Two segments lower than the lesion (if thoracic)
 - b. Higher posteriorly than anteriorly (follows pattern of intercostal nerves)
 - c. Dropped sensory level to T4–T6 following cervical lesions due to lamination of the spinal thalamic tract
 - d. Rare suspended sensory loss (destruction of the segmental dorsal horn at the level of injury with preserved long tract sensory function)
 - e. Mass reflex after stimulation late in the course of the illness

Disabled Cardiovascular Control After Spinal Cord Lesions*General Characteristics*

1. Lesions of the spinal cord damage autonomic pathways that alter cardiovascular homeostasis
2. The higher the level of the lesion and its severity increases cardiovascular dysfunction
3. Abnormalities of blood pressure control increase the patient's risk of heart disease and stroke

Acute Phase Following Spinal Cord Lesions

1. Bradyarrhythmia
2. Hypotension

3. Enhanced vasovagal reflexes
4. Supraventricular and ventricular ectopy
5. Vasodilation and venous stasis
6. Hypothermia and hyperthermia
7. Neurogenic shock

Chronic Phase of Spinal Cord Lesions

1. Orthostatic hypotension (lesions at or above T6)
2. Impaired cardiovascular reflexes
3. Autonomic dysreflexia:
 - a. Lesions above T6
 - b. Sudden uncontrolled sympathetic response (a stimulus below the level of the injury; urinary catheter replacement; treatment for fecal impaction)
 - c. Abrupt rise in blood pressure that may cause ICH
 - d. Erythema of the upper chest wall
 - e. Severe pounding headache
4. Urinary autonomic dysfunction that includes hyperreflexia or areflexia of the detrusor and/or the external bladder sphincter
5. Reduced sensation of cardiac pain
6. Loss of reflex cardiac acceleration
7. Quadriplegic cardiac atrophy:
 - a. Loss of ventricular mass
 - b. Pseudo-myocardial infarction
8. Spinal cord lesions lead to:
 - a. Atherosclerotic disease from:
 - i. Obesity
 - ii. Lipid disorders
 - b. Metabolic syndrome
 - c. Diabetes
 - d. Predisposed to thrombotic emboli due to venous stasis and hypercoagulability
 - e. Cardiovascular dysfunction during sexual activity and exercise

Epidural Hematoma

General Characteristics

1. Epidural hemorrhage occurs with greater frequency than subdural hemorrhage
2. Peak occurrences are during childhood and the fifth to sixth decade
3. Cervical lesions are more common in childhood; thoracic and lumbar lesions in adults
4. Spontaneous epidural hematomas occur in approximately 40% of patients:
 - a. Pathogenesis of spontaneous bleeding is thought to be venous:
 - i. Valveless epidural venous plexus is subject to pressure from the abdominal and thoracic cavities
 - ii. Hematomas are usually located posteriorly, which is consistent with the anatomical location of the venous plexus. Ventral hematomas are rare (less than 5%)

Clinical Manifestations

1. Sudden onset of back pain at the segmental area of the bleeding
2. Signs of nerve root or spinal cord compression
3. Thunderclap headache has been described when the bleeding is in the cervical spinal cord
4. Horner's syndrome occurs in approximately 10% of cervical lesions
5. May have a pain free interval that can last for days, following which there are signs of a progressive myelopathy

Neuropathology

1. Associated with anticoagulation, spinal anesthetic procedures, trauma, chronic renal failure and hepatitis C

Neuroimaging

1. MRI:
 - a. Oval lesions
 - b. Shifts in the spinal cord in the canal
2. Hyperintense T2-weighted sequences in the parenchyma are associated with poor recovery

Spinal Subdural Hematoma

General Characteristics

1. Comprise approximately 6% of all spinal hematomas
2. Rarely occurs in association with a cranial subdural hematoma
 - a. Concomitant cranial and spinal SDH, the spinal SDH is located below the thoracic levels
 - b. May develop in patients with intracranial hypotension from ventriculoperitoneal shunt placement

Clinical Manifestations

1. Similar to epidural signs and symptoms

Subarachnoid Hematoma

General Characteristics

1. Usual age is between 55 and 70 years old

Clinical Manifestations

1. Meningitic
2. Alteration of consciousness
3. Epileptic seizures

Neuroimaging of Epidural Hematoma

1. T1-weighted sequence:
 - a. Signal intensity of the epidural hematoma is primarily isointense to the spinal cord
 - b. T2-weighted sequences of epidural hemorrhages:
 - i. Heterogeneous hyperintensity as compared to the spinal cord
 - ii. Focal hypointensity (acute blood; deoxyhemoglobin)
2. Direct continuity with adjacent osseous structure

3. Spontaneous spinal epidural hematomas may be located ventrally to the cord:
 - a. Premembranous hematoma
 - b. Posterior longitudinal ligament hematoma

Neuroimaging of Spinal Subdural Hematoma

1. Subdural collection of blood with smooth borders

Laboratory Evaluation of Spinal Subdural Hematoma

1. CSF:
 - a. Motor oil color
 - b. Methemoglobin
 - c. Some RBCs

Differential Diagnosis of Spinal Hematomas

1. Epidural anesthetic procedures
2. Anticoagulation
3. Trauma
4. Vascular malformations
5. Lumbar puncture
6. Neoplasm
7. Thrombocytopenia
8. Following heparinization after lumbar surgery

Differential Diagnosis of Specific Spinal Cord Malformations

1. AVM:
 - a. Dural arteriovenous fistula
 - b. Intraparenchymal
 - c. Intradural perimedullary and subpial
2. Hemangioblastoma
3. Cavernous hemangioma
4. Bannayan-Zonana syndrome
5. Klippel-Trenaunay-Weber syndrome
6. Foix-Alajouanine syndrome
7. Occult vascular malformation of the spinal cord

Hemangioblastoma

General Characteristics

1. May arise in isolation
2. A major manifestation of Von Hippel-Lindau disease (VHL)
 - a. Prevalence of 1/36,000 in the population

Von Hippel-Lindau Syndrome (VHL)

General Characteristics

1. Autosomal dominant; chromosome 3p25-3p26 mutation in gene; deletions or mutations
2. Associated central nervous system hemangioblastomas:
 - a. Cerebellum
 - b. Retinal
3. Associated systemic manifestations:
 - a. Renal cysts
 - b. Renal carcinoma
 - c. Pheochromocytoma (specific alleles of VHL)
 - d. Increased levels of vascular endothelial growth factor

Clinical Manifestations

1. 80% are in the cerebellum
2. 20% in the spinal cord
3. 55% of patients with hemangioblastoma have VHL disease:
 - a. 60% are symptomatic when less than 30 years of age
4. Spinal hemangioblastoma:
 - a. Relationship to VHL is greater when in an infratentorial location
5. VHL patients are younger than sporadic patients
6. VHL patients develop endolymphatic sac tumors:
 - a. Tinnitus and deafness
7. Spinal hemangioblastoma:
 - a. Are often associated with cerebellar hemangioblastoma
 - b. May be multiple
 - c. May be extramedullary in a spinal root location
 - d. Renal cell carcinoma may metastasize to the hemangioblastoma

Neuropathology

1. Associated tumors:
 - a. Renal cell carcinoma
 - b. Pheochromocytoma
 - c. Paragangliomas
 - d. Endolymphatic sac tumors
 - e. Pancreatic neuroendocrine tumors (PNET)
 - f. Papillary cystadenomas of the epididymis
 - g. Adrenal papillary tumors (mesonephric origin)
2. Germline mutation of tumor suppressor gene on short arm of chromosome 3:
 - a. 30% of these patients have large deletions of VHL
 - b. May involve other genes
3. The VHL tumors arise from embryologic hemangioblasts that form endothelial cells and blood cells
4. Distribution of hemangioblastomas in a series of 225 patients:
 - a. Supratentorial (1%)
 - b. Cerebellum (45%)
 - c. Brainstem (7%)
 - d. Spinal cord (36%)
 - e. Cauda equina (11%)
 - f. Nerve roots (3%)
5. Hemangioblastoma growth:
 - a. Increased tumor burden:
 - i. Partial deletions in VHL gene
 - ii. Male sex
 - b. Three new tumors/year associated with:
 - i. Younger age
 - ii. More initial tumors
 - c. Growth:
 - i. No growth in 51%
 - ii. 49% grew in solitary pattern
 - iii. Linear growth in 6%
 - iv. Exponential pattern in 22%
 - d. Faster growth associated with:

- i. Male sex
- ii. Symptomatic tumors
- iii. Tumors associated with cysts

Angiographically Occult Vascular Malformations of the Spinal Cord (AOVMS)

General Characteristics

1. May occur with a dural arteriovenous fistula between a radicular feeding artery and the venous system at the dural sleeve of the nerve root
2. Spinal cord cavernous malformations are the most common lesion

Clinical Manifestations

1. Sensory and motor loss below the level of the lesion
2. Clinical cause:
 - a. Neurologic decline due to repeated episodes of relapse and remission
 - b. Linear neurologic functional decline
3. Cavernous hemangiomas are often intramedullary and may not have characteristic radiographic signs

Neuroimaging

1. Flat panel catheter angiotomography (IFCA) during spinal digital subtraction angiography if standard angiography fails to detect a clinically suspected malformation
2. Surgical microscope-integrated intraoperative near-infrared indocyanine green angiography:
 - a. Rapidly identifies a draining vein as it enters the spinal canal if catheter-based digital subtraction angiography fails

Differential Diagnosis of Angiographically Occult Vascular Malformation of the Spinal Cord

1. Primary hemorrhagic tumors of the spinal cord:
 - a. Ependymoma
 - b. Astrocytoma
 - c. Medulloblastoma
2. Hemorrhagic transverse myelitis:
 - a. Lung metastasis (small cell)
3. Paraneoplastic spinal cord hemorrhagic necrosis:
 - a. Small cell lung cancer
 - b. Anti-Hu antibody syndrome
 - i. Often occurs at the thoracic level
4. Bleeding diathesis:
 - a. Coagulopathy
 - b. Anticoagulation (Coumadin/heparin; status of Xa and direct thrombin inhibitors in this regard has not been established)
 - c. Platelet disorders
 - d. Leukemia/lymphoma
 - e. Hemorrhagic leukoencephalitis
 - f. Spinal SDH
 - g. Parenchymous bleed (trauma)

5. Systemic conditions affecting the spinal cord:
 - a. Whipple's disease
 - b. Gluten-sensitive enteropathy
 - c. Kohlmeier-Degos disease
 - d. Sjögren's disease
 - e. B12 deficiency
 - i. Acute following nitrous oxide anesthesia (cobalamin deficiency)
 - ii. High serum B12 level noted with leukemia and lymphoma
 - f. Vitamin E deficiency
 - i. Dietary
 - ii. Alpha-tocopherol transporter defect
 - g. Copper deficiency
 - i. Genetic
 - ii. Zinc excess (paste in dental adherents)
 - h. Pure spinal angitis
6. Werner's syndrome
 - a. General characteristics:
 - i. AR; WRN gene is located on chromosome 8
 - ii. Encodes a helicase and an exonuclease
 - b. Accelerated aging
 - c. Childhood age of onset
 - d. Clinical manifestations:
 - i. Balding
 - ii. Atherosclerosis of all circulations
 - iii. Premature graying
 - iv. Osteosclerosis
 - v. Diabetes mellitus
 - vi. Juvenile cataracts
 - vii. Hypogonadism
 - viii. Rare spastic paraparesis
 1. Many patients have increased reflexes

Spinal Pseudoathetosis

General Characteristics

1. Occurs after protracted severe loss of proprioception
2. Secondary to:
 - a. Lesions of the dorsal columns or their nuclei
 - b. Lesions of the dorsal root ganglia (DRG)
 - c. Lesions of the dorsal root entry zone

Clinical Manifestations

1. Lateral and up drift of the upper extremities with polymyoclonus
2. Rare flinging of the arms and legs
 - a. Acute lesions that can occur with cocaine abuse
3. Severe proprioceptive loss is partially compensated by the excess movement
4. Pain may precede the pseudoathetosis

Differential Diagnosis of Spinal Pseudoathetosis

1. Spinal trauma (dorsal column destruction)
2. Tabes dorsalis

3. Cocaine abuse:
 - a. Acute signs (putative mechanism in vasospasm of the posterior spinal arteries)
4. Demyelinating disease
5. Syringomyelia
6. Sjögren's disease
7. Friedreich's ataxia
8. SLE
9. Migrated disc
10. Cervical spondylosis
11. B12 deficiency
12. Vascular lesion with hemipseudoathetosis

Spinal Cord Veno-Occlusion

Venous Spinal Cord Infarction

General Characteristics

1. Associated with:
 - a. Vascular malformations
 - b. Hematoma
 - c. Epidural abscess
2. Hemorrhagic venous occlusive disease:
 - a. Back pain at the level of involvement
 - b. Progression is subacute (days to weeks)
 - c. Multiple spinal segments are involved
3. Non-hemorrhagic venous occlusive disease
 - a. Course is over weeks
 - b. Less pain
 - c. Fewer spinal segments are involved
4. Embolic venous infarction:
 - a. Fibrocartilaginous
 - b. Sudden onset
 - c. Pain at the level of involvement (often cervical)
 - d. Asymmetric deficit
5. Venous infarction associated with vascular malformations:
 - a. Subacute neurologic syndrome
 - b. Foix-Alajouanine syndrome
 - i. Congestive myelopathy
 - ii. Stepwise dysfunction due to thrombosis of supplying vessels
 - iii. Intramedullary hypertension due to spinal dural arterial fistula
6. Sclerotherapy:
 - a. Direct penetration of epidural veins
 - b. Occlusion of the anterior spinal artery
 - c. Cirrhosis (acquired or congenital) is often the systemic defect:
 - i. Related AV shunts
 - ii. Inadvertent arterial access following esophageal vein injection
 - iii. Putative mechanism is congestion of the abdominal epidural venous plexus

Varices Increases Thoracoabdominal Pressure – Neuroimaging

1. Small intramedullary high signal intensity is known as “snake-eye appearance”
 - a. Small cystic necrosis of the central gray matter of the ventrolateral posterior columns
 - b. Neuronal loss in the flattened anterior horn
 - c. Described in patients with compressive myelopathy from cervical spondylosis or ossification of the posterior longitudinal ligament

Hereditary Spastic Paraplegia

Overview

There are more than 50 genetic causes of hereditary spastic paraplegia. It is a clinical diagnostic classification for neurologic syndromes the major feature of which is bilateral lower extremity weakness and spasticity and for which a gene has been identified. There is great variation in severity and often associated neurologic and systemic features. There is a wide clinical spectrum between and within genetic types of HSP that include the age of symptom onset and degree of progression.

In general, HSP is classified as “uncomplicated,” which is characterized by lower extremity spasticity, weakness, and slight dorsal column dysfunction.

Complicated forms are associated with:

1. Dementia
2. Ataxia
3. Cognitive impairment
4. Neuropathy, amyotrophy
5. Visual loss
6. Ichthyosis
7. Many genetic forms are associated with both “uncomplicated” and “complicated” syndromes. Genotype-phenotype correlation has not been well defined in many genetic types of HSP which is another cause of clinical variability. The identical gene mutation in a family can cause both “complicated” and “uncomplicated” form of the disease

Clinical Manifestations

1. General features that apply to core elements in HSP. “Complicated” patients have major other system involvement:
 - a. Most patients present with lower extremity weakness and spasticity which impairs gait
 - b. Urinary urgency is an early or even presenting symptom
2. General recognized syndromes:
 - a. Uncomplicated HSP (limited to lower extremity weakness, spasticity, minimal dorsal column involvement and gait alteration)
 - b. Spastic paraplegia with:

- i. Motor neuropathy and/or distal wasting
- ii. Cognitive impairment
- iii. Ataxia
- iv. Neuroimaging abnormalities (thin corpus callosum)
- v. Neurologic and systemic abnormalities
- c. Age of symptom onset
 - i. Variable within a genetic type
- d. Progression may be static, progressive or after a variable period may stabilize:
 - i. Early onset form (SPG3A and SPG4) has a relative non-progressive course
 - ii. More rapid progression during adolescence and decreased progression after 5–10 years of disease are common patterns
- e. HSP gene mutations may be associated with syndromes that are not phenotypically HSP
 - i. SPG3/Atlastin mutation may be associated with a hereditary sensory neuropathy 1 (HSN1)
 - ii. BSL2/seipin mutations when heterozygous cause:
 - 1. AD, HSP (SPG17)
 - 2. Charcot-Marie-Tooth type 2
 - 3. Distal hereditary neuropathy type V
 - 4. Homozygous mutations cause:
 - a. Congenital generalized lipodystrophy type 2
 - iii. SPG11/spastin mutations
 - 1. May present as levodopa responsive juvenile parkinsonism
 - iv. SPG20/spartin (Troyer syndrome)
 - 1. Also a biomarker for colorectal cancer

Neurologic Examination

1. “Uncomplicated” HSP:
 - a. Muscle weakness greater in the iliopsoas, hamstring, and tibialis anterior muscles
 - b. Spasticity is most prominent in the hamstrings, quadriceps, adductor and gastrocnemius soleus muscles
 - c. Easily obtainable (1/2 lateral foot stimulated) Babinski response associated, with hyperactive KJs, AJs and crossed adductor and puboadductor reflexes
 - d. Mild vibration loss in distal lower extremities
 - e. Hyper-reflexia without weakness or spasticity occurs in the upper extremities
 - f. Usual but not invariant pes cavus deformity
2. “Complicated” HSP:
 - a. Core features of weakness, spasticity, hyper-reflexia, subtle vibration loss
 - b. Associated neurologic and systemic features that include:
 - i. Dementia
 - ii. Cognitive impairment
 - iii. Optic atrophy
 - iv. Retinitis pigmentosa
 - v. Extrapyrarnidal features

- vi. Peripheral neuropathy
- vii. Ataxia
- viii. Distal wasting (amyotrophy)
- ix. Cataracts

Genetic Classification

There are dominant, recessive X-linked and mitochondrial forms of HSP that have been designated by the order of their discovery. There are also other inherited disorders with a similar phenotype of lower extremity weakness spasticity and hyperreflexia. SPG7 paraplegia may manifest both as an autosomal dominant or recessive disorder. Genetic penetrance in autosomal dominant HSP is age dependent. There are rare reports of genetic anticipation in SPG3A and SPG4 apparently without trinucleotide repeat expansions.

Putative Molecular Mechanisms

An analysis of the function of HSP encoded proteins surmised by their dysfunction in patients with specific mutations, have given insights into the molecular mechanisms that may be operative in these diseases. The deficits incurred include:

1. Alterations in axonal transport (SPG30/KIFA; SPG10/KIFA; SPG4/spastin)
2. Endoplasmic reticulum alterations (SPG12/reticular; SPG3AA/atlastin, SPG4/spastin and SPG31/Reep)
3. Mitochondrial dysfunction (SPG13/chaperonin 60/heat shock protein 60, SPG7/paraplegia and mitochondrial ATP6)
4. Primary myelin alterations (SPG21 proteolipid protein, SPG42/connexin 47)
5. Protein conformation defects initiating the ER-stress response (SPG16/NIPA1, SPG8 SPG7/BSCL2/Seipin)
6. Neurodevelopment dysfunction of the corticospinal tract (SPG1/L1 cell adhesion molecule, SPG22)
7. Vesicle formation and membrane trafficking (SPG47, K1AA, SPG48, SPG50, SPG51, SPG52, SPG53)
8. Disturbances of lipid metabolism:
 - a. A subset of HSP patients have defects in phospholipid, sphingolipid, and fatty acid metabolism. A major area of present interest is the degree of “cell” autonomous alterations (due to intrinsic abnormalities only in the neurons that are degenerating) versus “non-cell autonomous” (degeneration depends on interaction with other cells). It is clear from the genetic deficits and their functional analysis that corticospinal tract axons are selectively vulnerable in these diseases

Genetic Forms of SPG

1. SPG3A:
 - a. Genetics:
 - i. Chromosome 4q4
 - ii. Protein encoded
 1. Atlastin
 - b. Clinical manifestations:

- i. Uncomplicated
 - ii. Onset primarily childhood; may be in adolescence or adulthood
2. SPG4:
 - a. Genetics:
 - i. Chromosome 2p22; AD
 - ii. Protein encoded
 1. Spastin
 - b. Clinical manifestations:
 - i. Uncomplicated
 - ii. Onset all age groups
 - iii. Most common cause of AD forms
 - iv. Some patients have late cognitive impairment
3. SPG6:
 - a. Genetics:
 - i. Chromosome 15q11.1
 - ii. Protein encoded
 1. NIPA1 (not impaired in Prader-Willi and Angelman syndrome)
 - b. Clinical manifestations:
 - i. Uncomplicated
 - ii. Onset late adolescence and early adulthood
 - iii. Rarely associated with epilepsy or peripheral neuropathy
4. SPG8:
 - a. Genetics:
 - i. Chromosome 8q23-q24
 - ii. Protein encoded
 1. Strumpellin
 - b. Clinical manifestations:
 - i. Uncomplicated
5. SPG9:
 - a. Genetics:
 - i. Chromosome 10q23-q24.2
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Cataracts, gastroesophageal reflex, motor neuropathy
6. SPG10:
 - a. Genetics:
 - i. Chromosome 12q13
 - ii. Protein encoded:
 1. KIF5A kinesin heavy chain
 - b. Clinical manifestations:
 - i. Uncomplicated
 1. Distal muscle atrophy
7. SPG12:
 - a. Genetics:
 - i. Chromosome 19q13
 - ii. Protein encoded
 1. RTN2 protein
 - b. Clinical manifestations
 - i. Urinary symptoms
- ii. Distal sensory impairment
8. SPG13:
 - a. Genetics:
 - i. Chromosome 2q24-34
 - ii. Protein encoded
 1. Chaperonin (heat shock protein 60)
 - b. Clinical manifestations:
 - i. Adolescent and adult onset
 - ii. Uncomplicated
9. SPG19:
 - a. Genetics:
 - i. Chromosome 11q12-q14
 - ii. Protein encoded
 1. BSCL2/seipin
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with amyotrophy of hand muscles (Silver syndrome)
10. SPG19:
 - a. Genetics
 - i. Chromosome 9q33-34
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. Uncomplicated
11. SPG29:
 - a. Genetics:
 - i. Chromosome 1q31, 1-21.1
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Hearing impairment and hiatal hernia
12. SPG31:
 - a. Genetics:
 - i. Chromosome 2q12
 - ii. Protein encoded
 1. Receptor expression enhancing protein (REEP)
 - b. Clinical manifestations:
 - i. Uncomplicated
 - ii. Rarely associated with peripheral neuropathy
13. SPG33:
 - a. Genetics:
 - i. Chromosome 10q24.2
 - ii. Protein encoded
 1. Proteins contain ZFYE zinc fingers
 - b. Clinical manifestations:
 - i. Uncomplicated
14. SPG36:
 - a. Genetics:
 - i. Chromosome 12 q23-24
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestation:
 - i. Onset adolescence to 28 years

- ii. Complicated
 - iii. Associated with sensory motor neuropathy
 - 15. SPG37:
 - a. Genetics:
 - i. Chromosome 8q21, 1-q13.3
 - ii. Protein encoded
 - 1. Not identified
 - b. Clinical manifestations:
 - i. Uncomplicated
 - 16. SPG38:
 - a. Genetics:
 - i. Chromosome 4q16-15
 - ii. Protein encoded
 - 1. Not identified
 - b. Clinical manifestation (1 family)
 - i. Onset 16–21 years
 - ii. Complicated
 - iii. Associated with severe hand atrophy (1 patient)
 - 17. SPG40:
 - a. Genetics:
 - i. Chromosome (locus unknown)
 - ii. Protein encoded
 - 1. Not identified
 - b. Clinical manifestations:
 - i. Onset after 33
 - ii. Uncomplicated
 - 18. SPG41:
 - a. Genetics:
 - i. Chromosome 11q14.1-p11.2
 - ii. Protein encoded
 - 1. Not identified
 - b. Clinical manifestations:
 - i. One Chinese family
 - ii. Adolescent onset
 - iii. Complicated
 - iv. Associated with mild weakness of intrinsic hand muscles
 - 19. SPG42:
 - a. Genetics:
 - i. Chromosome 3q24-q26
 - ii. Protein encoded
 - 1. Acetyl CoA transporter (SLC33A1)
 - b. Clinical manifestations:
 - i. Uncomplicated (one kindred)
 - ii. Onset 4–40 years of age
- Autosomal Recessive HSP*
- 1. SPG5:
 - a. Genetics:
 - i. Chromosome 8p
 - ii. Protein encoded
 - 1. CYP7B1
 - b. Clinical manifestations:
 - i. Complicated with associated with axonal neuropathy
 - c. MRI
 - i. White matter changes, distal or generalized muscle atrophy
2. SPG7:
 - a. Genetics:
 - i. Chromosome 16q
 - ii. Protein encoded
 - iii. Paraplegin
 - b. Clinical manifestation:
 - i. Uncomplicated or complicated
 - ii. If complicated associated with dysarthria, dysphagia, optic atrophy, axonal neuropathy, cerebellar and cerebral atrophy, MRI evaluation suggestive of vascular lesions
3. SPG11:
 - a. Genetics:
 - i. Chromosome 15q
 - ii. Protein encoded
 - iii. Spatacsin (KIAA1840)
 - b. Clinical manifestations:
 - i. Uncomplicated form
 - ii. If complicated associated with thin corpus callosum, cognitive impairment, upper extremity weakness, dysarthria nystagmus
 - iii. Kjellin syndrome:
 - 1. Childhood onset
 - 2. Spastic paraplegia
 - 3. Retinitis pigmentosa
 - 4. Cognitive impairment
 - iv. Some patients have ALS
4. SPG14:
 - a. Genetics:
 - i. Chromosome 3q27-28
 - ii. Protein encoded
 - 1. Not identified
 - b. Clinical manifestations:
 - i. One Italian family
 - ii. Onset approximately 30 years of age
 - iii. Complicated and associated with cognitive deficits, distal motor neuropathy
5. SPG15:
 - a. Genetics:
 - i. Chromosome 14q
 - ii. Protein encoded
 - 1. Spastizin/ZFYVE26
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with:
 - 1. Pigmented maculopathy
 - 2. Distal amyotrophy
 - 3. Dysarthria
 - 4. Cognitive impairment
 - 5. Kjellin syndrome
6. SPG18:
 - a. Genetics:

- i. Chromosome 8p12-p11-21
 - ii. Protein encoded
 1. Endoplasmic reticulum lipid raft associated protein 2 (ERLIN2)
 - b. Clinical manifestations:
 - i. Two families described
 - ii. Complicated
 - iii. Associated with thin corpus callosum, cognitive impairment
 - iv. ERLIN2 mutations associated with juvenile ALS
7. SPG20:
 - a. Genetics:
 - i. Chromosome 13q
 - ii. Protein encoded
 1. Spartan
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with distal muscle wasting (Troyer syndrome)
8. SPG21:
 - a. Genetics:
 - i. Chromosome 15q21-q22
 - ii. Protein encoded
 1. Maspartin
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with:
 1. Dementia
 2. Cerebellar and extrapyramidal signs
 3. Thin corpus callosum
 4. White matter abnormalities on MRI
 5. Mast syndrome
9. SPG23:
 - a. Genetics:
 - i. Chromosome 1q24-q32
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Childhood onset
 - iii. Associated with:
 1. Vitiligo
 2. Premature graying
 3. Dysmorphisms
 4. Lison syndrome
10. SPG24:
 - a. Genetics:
 - i. Chromosome 13q14
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Childhood onset
 - iii. Associated with spastic dysarthria and pseudobulbar signs
11. SPG25:
 - a. Genetics:
 - i. Chromosome 6q 23-q24.1
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. One consanguineous Italian family
 - ii. Adult onset (30–46)
 - iii. Complicated
 - iv. Associated with:
 1. Disc herniation
 2. Peripheral neuropathy
12. SPG26:
 - a. Genetics:
 - i. Chromosome 12p11.1-12q14
 1. Protein encoded
 - a. Not identified
 - b. Clinical manifestations:
 - i. Single Bedouin family
 - ii. Childhood onset
 - iii. Complicated
 - iv. Dysarthria
 - v. Distal amyotrophy in both upper and lower extremities
 - vi. Mild cognitive impairment
13. SPG27:
 - a. Genetics:
 - i. Chromosome 10q22.1-q24.1
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations
 - i. Complicated and uncomplicated forms
 - ii. Uncomplicated form:
 1. Onset age: 25–45
 - iii. Complicated form:
 1. Childhood onset
 2. Associated with:
 - a. Ataxia
 - b. Dysarthria
 - c. Cognitive impairment
 - d. Sensorimotor neuropathy
 - e. Short stature
 - f. Facial dysmorphisms
14. SPG28:
 - a. Genetics:
 - i. Chromosome 14q21.3-q22.3
 - ii. Protein encoded
 1. DDHD
 - b. Clinical manifestations:
 - i. Uncomplicated form with onset in infancy, childhood or adolescence
 - ii. Complicated form associated with axonal neuropathy, distal sensory loss, cerebellar eye movement disorder
15. SPG29:

- a. Genetics:
 - i. Chromosome 14q
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. Childhood onset
 - ii. Uncomplicated
16. SPG30:
- a. Genetics:
 - i. Chromosome 2q37.3
 - ii. Protein encoded
 1. RIFA
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with:
 1. Distal wasting
 2. Defective
 3. Smooth pursuit
 4. Cerebellar signs
 5. Peripheral neuropathy
17. SPG32:
- a. Genetics:
 - i. Chromosome 14q:2-q21
 - ii. Protein encoded
 - iii. Not identified
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with:
 1. Cognitive dysfunction
 2. Brainstem defects
 3. Asymptomatic cerebellar atrophy
18. SPG35:
- a. Genetics:
 - i. Chromosome 16q21-q23
 - ii. Protein encoded:
 1. Fatty acid 2-hydroxylase (FA2H)
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Childhood onset
 - iii. Associated with:
 1. Extrapyrarnidal signs
 2. Dysarthria
 3. Dementia
 4. Seizures
 - iv. White matter alterations and brain iron accumulation
19. SPG39:
- a. Genetics:
 - i. Chromosome 9q13
 - ii. Protein encoded
 1. Neuropathy target extremities (NTE)
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Wasting of distal upper and lower extremities
20. SPG43:
- a. Genetics:
 - i. Chromosome 19q13.11-q12
 - ii. Protein encoded
 1. C 6, 12, or 19
 - b. Clinical manifestations:
 - i. One family from Mali (sisters)
 - ii. Complicated
 - iii. Associated with intrinsic hand muscles atrophy in 1 sister
21. SPG44:
- a. Genetics:
 - i. Chromosome 1a41
 - ii. Protein encoded
 1. Gap junction protein GJA 12/GJC2 also known as connexin (cxH7)
 - b. Clinical manifestations:
 - i. Merzbacher-like disease
 - ii. GJA/GJC2 mutations
 1. Later onset (first and second decades)
 2. Complicated and associated with dysarthria and upper extremity involvement
 3. MRI and MR spectroscopy compatible with hypomyelination and leukoencephalopathy
22. SPG45:
- a. Genetics:
 - i. Chromosome 10q24.3-q25.1
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. One consanguineous family linked from Turkey
 - ii. Complicated
 - iii. Associated with cognitive impairment contractures. Optic atrophy and one patient with pendular nystagmus
23. SPG46:
- a. Genetics:
 - i. Chromosome 9p21.1-q21.2
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with:
 1. Dementia
 2. Thin corpus callosum
 3. Ataxia
 4. Congenital cataracts
24. SPG47:
- a. Genetics:
 - i. Chromosome 1p 13.2-1p12
 - ii. Protein encoded
 1. AB4B1
 - b. Clinical manifestations:
 - i. Consanguineous Arab family
 - ii. Complicated; childhood onset
 - iii. Associated with:

1. Mental retardation
 2. Seizure
 3. Thin corpus callosum
 4. Periventricular white matter hyperintensities
25. SPG48:
- a. Genetics
 - i. Chromosome 14q 32.31
 - ii. Protein encoded
 1. TECPR2
 - b. Clinical manifestations
 - i. Complicated
 - ii. Jewish Bukharin ethnicity
 - iii. Associated with:
 1. Infantile onset dysmorphisms
 2. Severe gait alterations
 3. Gastroesophageal reflex
 4. Recurrent apneic episodes
 5. 2 patients with thin corpus callosum
 6. Cerebellar atrophy
26. SPG50:
- a. Genetics:
 - i. Chromosome 7q22-1
 - ii. Protein encoded
 1. AD4MI
 - b. Clinical manifestations:
 - i. One consanguineous Moroccan family; infantile onset
 - ii. Complicated
 - iii. Associated with:
 1. Cognitive impairment
 2. Adducted thumbs
 3. Ventriculomegaly
 4. White matter abnormalities
 5. Variable cerebellar atrophy
27. SPG51:
- a. Genetics:
 - i. Chromosome 15q21.2
 - ii. Protein encoded
 1. APE1
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Palestinian-Jordanian family
 - iii. Associated with:
 1. Microcephaly hypotonia
 2. Psychomotor issues
 3. Facial dysmorphisms
 4. Seizures
 - iv. MRI revealed atrophy and diffuse white matter hyperintensities (WMH)
28. SPG52:
- a. Genetics:
 - i. Chromosome 14q12
 - ii. Protein encoded
 1. AP4S1
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Consanguineous Syrian family
 - iii. Associated with:
 1. Neonatal hypotonia
 2. Cognitive impairment
 3. Microcephaly
 4. Short stature
 5. Facial dysmorphism
29. SPG53:
- a. Genetics:
 - i. Chromosome 8q22
 - ii. Protein encoded
 1. USP37A
 - b. Clinical manifestations:
 - i. Complicated (2 Arab families)
 - ii. Associated with:
 1. Upper and lower extremity spasticity
 2. Kyphosis and pectus carinatum
 3. Cognitive impairment
 4. Hypertrichosis
 5. Decreased vibration sensibility
30. SPG54:
- a. Genetics
 - i. Chromosome 8p11.23
 - ii. Protein encoded
 1. C120RI65
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with:
 1. Psychomotor delay
 2. Cognitive deficits
 3. Foot contracture
 4. Dysarthria
 5. Dysphagia
 6. Strabismus
 7. Optic hypoplasia
 - iii. MRI
 1. Thin corpus callosum
 2. Periventricular WMH
31. SPG55:
- a. Genetics:
 - i. Chromosome (note identified)
 - ii. Protein encoded
 1. C120RF65
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Japanese consanguineous family (2 brothers reported)
 - iii. Associated with central scotoma and optic atrophy, decreased upper extremity strength and motor sensory neuropathy
32. SPG56:
- a. Genetics:
 - i. Chromosome 4q25
 - ii. Protein encoded

1. CYP201
- b. Clinical manifestations:
 - i. Complicated (early childhood onset)
 - ii. Associated with upper extremity dystonia, cognitive deficits, and axonal neuropathy
 - iii. MRI evaluation:
 1. Thin corpus callosum
 2. Basal ganglia calcification
 3. WMH
33. Cerebral Palsy, Spastic Quadriplegic 1 (CPSQ1)
 - a. Genetics:
 - i. Chromosome 2q31.1
 - ii. Protein encoded
 1. Glutamate Decarboxylase 1 (GAD1)
 - b. Clinical manifestations:
 - i. Consanguineous Pakistani family
 - ii. Spastic cerebral palsy
 - iii. Moderate to severe cognitive impairment
34. Spastic Paraplegia Associated with Optic Atrophy (SPOAN)
 - a. Genetics:
 - i. Chromosome 11q23
 - ii. Protein encoded
 1. Not identified
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with optic atrophy
35. Chaperonin containing t-complex polypeptide 1, subunit 5 (CCT5)
 - a. Genetics:
 - i. Protein encoded
 1. Epsilon subunit of the cytosolic chaperonin containing +-complex peptide 1 (CCT5)
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with sensory neuropathy
36. Sjögren-Larsson syndrome
 - a. AR
 - b. Clinical manifestations:
 - i. Short stature
 - ii. Seizures
 - iii. Retinal degeneration
 - iv. Ichthyosis
37. Hematologic abnormalities with spastic paraparesis
 - a. AD (autosomal dominant)
 - b. May-Hegglin anomaly
 - i. Cytoplasmic inclusions in leukocytes
 - ii. Giant platelets
 - iii. Thrombocytopenia
38. Evan's syndrome
 - a. Spastic paraparesis
 - b. Coombs-positive hemolytic anemia
 - c. Immune thrombocytopenia
 - d. AR

X-Linked HSP

1. SPG1:
 - a. Genetics:
 - i. Chromosome Xq28
 - ii. Protein encoded
 1. L1 cell adhesion molecule (LICAM)
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with:
 1. Mental retardation
 2. Aphasia
 3. Adducted thumbs
 - c. MRI
 1. Hydrocephalus
2. SPG2:
 - a. Genetics:
 - i. Xq28
 - ii. Protein encoded
 1. Proteolipid protein
 - b. Clinical manifestations:
 - i. Complicated
 - ii. Associated with peripheral neuropathy
 - c. MRI
 - i. White matter abnormalities
3. SPG16:
 - a. Genetics:
 - i. Chromosome Xq11.2-q23
 - ii. Protein encoded – Not identified
 - b. Clinical manifestations:
 - i. Uncomplicated and complicated
 - ii. Complicated form associated with:
 1. Aphasia
 2. Nystagmus
 3. Decreased visual acuity
 4. Dysfunction of bowel and bladder
 5. Mental retardation
4. SPG22:
 - a. Genetics:
 - i. Chromosome Xq21
 - ii. Protein encoded
 1. Monocarboxylate transporter 8 (MCT8)
 - b. Clinical manifestations:
 - i. Complicated (Allan-Herndon-Dudley syndrome)
 - ii. Congenital onset
 - iii. Associated with:
 1. Dysarthria
 2. Mental retardation
 3. Ataxia
 4. Facial dimorphisms
5. SPG34
 - a. Genetics:
 - i. X-chromosome mutation
 1. Protein encoded: not identified
 - b. Clinical manifestations:
 - i. Uncomplicated

6. Mitochondrial (Maternal) Inheritances

- a. Genetics:
 - i. Mitochondrial ATP 6 gene
- b. Clinical manifestations:
 - i. Complicated; adult onset
- c. Associated with:
 - i. Axonal neuropathy
 - ii. Dementia (late)
 - iii. Cardiomyopathy

Differential Diagnostic Signs in Complicated HSP

1. Peripheral Neuropathy
 - a. SPG Types: SPG2, 5, 6, 7, 10, 25, 27, 30, 31, 55, 56, SPOAN CCT5, mitochondrial ATP 6 gene
2. Distal amyotrophy
 - a. SPG Types: SPG3A, 4, 5, 10, 14, 15, 17, 20, 26, 30, 38, 39, 41, 43, 55
3. Mental retardation
 - a. SPG Types: 1, 11, 14, 16, 18, 20, 22, 26, 27, 32, 44, 45, 47, 49, 50, 51, 52, 53, 54, 56, GSD1 mutation
4. Dementia
 - a. SPG Types: SPG4, 15, 21, 35, 46 and ATP 6 gene mutation
5. Vision impairment
 - a. SPG Types: SPG15, 16, 45, 54, 55, and SPOAN
6. Deafness
 - a. SPG Types: SPG29
7. Skeletal abnormalities or dysmorphic features
 - a. SPG Types: SPG25, 49, 50, 51, 52, 53
8. Extrapyramidal movement disorders
 - a. SPG Types: SPG21, 35, 56
9. Epilepsy
 - a. SPG Types: SPG6, 35, 42, and 51
10. Dysarthria
 - a. SPG Types: SPG7, 15, 22, 24, 27, 35, 43, 44, 54
11. Ataxia
 - a. SPG Types: SPG7, 21, 22, 27, 30, 32, 46, and 49
12. Spastic Paraparesis and MRI abnormalities
 - a. SPG Types: SPG1, 2, 5, 7, 11, 15, 18, 21, 32, 35, 44, 46, 47, 49, 50, 54, and 56
13. Spastic paraplegia and skin abnormalities
 - a. Types: Sjögren-Larsson syndrome
14. Childhood onset with skin pigment abnormality
 - a. AR
15. Endocrine abnormality
16. Kallmann syndrome
 - a. Spastic paraplegia
 - b. Hypogonadotropic hypogonadism and anosmia

Neuropathology of the Hereditary Spinal Paraplegias (HSP)

1. Axon degeneration involving the corticospinal tracts and to a lesser degree the posterior columns:
 - a. Most severe at the distal end of the long tracts
 - b. Long tracts CST degeneration may extend rostrally to the pons, cerebral peduncle and internal capsule

2. Neuronal loss and gliosis in upper and lower motor neural pathways
3. Particular vulnerability of the longest fiber tracts in the CNS and spinal cord
4. Predominant distributions of axon degeneration are the distal ends of cortical spinal tracts and the fasciculus gracilis fibers
5. Lower motor neuron involvement is demonstrated by distal wasting and amyotrophy in many genetic forms of HSP
 - a. It is particularly severe in SPG11 (similar to juvenile ALS)
 - b. It is also predominant in SPG17 (Silver syndrome) and SPG20 (Troyer syndrome)
 - c. Hyaline inclusions, mitochondrial alterations, and abnormalities in cytoskeletal protein have been noted in AD SPG4
6. Myelin abnormalities in HSP are noted in SPG2 proteolipid protein and SPG42. The mutated genes in these forms of HSP are in oligodendroglia. Abnormal myelin as demonstrated by MRI is seen in many forms of HSP
7. Neurons in other systems, cerebellar, basal ganglia, cranial nerves are also frequently involved
8. Developmental factors as clinically demonstrated by a small spinal cord diameter, white matter hyperintensities and thin corpus callosum are seen in many forms of complicated HSP

Differential Diagnosis of Hereditary Forms of Spastic Paraplegia***Machado-Joseph Disease (Spinocerebellar Ataxia Type 3)****General Characteristics*

1. The most common spinocerebellar ataxia worldwide
2. Clinical heterogeneity among different families and within families
3. Chromosome 14; ATXN3 gene
 - a. Unstable CAG repeat expansion in the coding region of the MJD1 gene (now termed ATXN3)

Clinical Manifestations

1. Core clinical feature is a progressive ataxia. Ataxia never occurs in isolation. Clinical features demonstrate deficits in the brainstem, oculomotor system, extrapyramidal and pyramidal tracts, lower motor neurons and peripheral nerves
2. Presents in young adults and middle-age patients. Prominent early features are gait ataxia, vestibular and speech problem
3. Clinical categories:
 - a. Type 1 disease:
 - i. Age of onset young adult
 - ii. Spasticity, rigidity, bradykinesia, and minimal ataxia

- b. Type II disease:
 - i. Onset in young to mid-adult years; the most common form
 - ii. Progressive ataxia and upper motor neuron signs
- c. Type III disease:
 - i. Late-onset form (mean age at onset approximately 50 years)
 - ii. Ataxia and peripheral nerve involvement with amyotrophy
- d. Type IV disease
- 4. Parkinsonism is prominent
- 5. Bradykinesia, rigidity, and dystonia

Neuropathology

- 1. Neurodegeneration of the basal ganglia, various brainstem nuclei, and the cerebellum
- 2. Disease protein in MJD accumulates within inclusions (ubiquitin-positive intranuclear spheres)

X-Linked Adrenoleukodystrophy

General Characteristics

- 1. X-chromosome mutation
- 2. ABCD1 gene mutations
 - a. Encodes the membrane protein ALDD which is involved in the transmembrane transport of very long chain fatty acids (VLCFA > L22)

Clinical Manifestations

- 1. Involves a clinical spectrum that ranges from isolated adrenocortical insufficiency and slowly progressive myelopathy to severe cerebral demyelination
- 2. Phenotype in male X-linked ALD patients
 - a. Addison only
 - b. Cerebral myeloneuropathy
 - i. Effects almost all patients who reach adulthood:
 - 1. Gradually progressive spastic paraparesis
 - 2. Sensory ataxia with vibratory loss
 - 3. Sphincter disturbance (bladder > fecal)
 - 4. Pain in the legs
 - 5. Impotence

Neuropathology

- 1. Non-inflammatory distal axonopathy that involves the long tracts of the spinal cord and to some extent the peripheral nerves

Neuroimaging

- 1. MRI
 - a. High signal intensities of the pyramidal tract at all levels on FLAIR and T2 sequences

Women with X-Linked ALD (Carriers)

Clinical Manifestations

- 1. Many patients develop AMN signs
- 2. Onset occurs in the 4th and 5th decade
- 3. Sensory ataxia, fecal incontinence, and leg pain may be prominent

Laboratory Evaluation

- 1. Plasma concentrations of very long chain fatty acids are increased in 99% of males and greater than 85% of female carriers

Krabbe's Disease (Globoid Cell Leukodystrophy)

General Characteristics

- 1. Chromosome 14q31
- 2. The deficient lysosomal enzymes are galactocerebrosidase
 - a. Degrades galactocerebroside to ceramide and galactose

Clinical Manifestations

- 1. Approximately 15 variants of globoid leukodystrophy have been reported several with long survival
- 2. Adult Variants
 - a. Progressive quadriparesis
 - b. Mild pseudobulbar signs
 - c. Progressive memory loss
 - d. Dystonic arm posturing and preserved sphincter control
 - e. CSF can be normal although it is usually elevated
- 3. Variant reported by Kolodny:
 - a. 15 patients with onset between 4–73 years
 - b. Pes cava
 - c. Optic pallor
 - d. Progressive spastic quadriparesis
 - e. Demyelinating sensorimotor neuropathy

Neuropathology

- 1. Infantile forms:
 - a. Accumulations of galactocerebroside and a metabolite psychosine destroy oligodendrocytes
 - b. Atrophy of parieto-occipital lobes and periventricular white matter

Neuroimaging

- 1. Symmetrical non-enhancing areas of increased signal in the basal ganglia and internal capsule
- 2. Enlargement of prechiasmatic optic nerves
- 3. Adults demonstrate parieto-occipital atrophy

Laboratory Evaluation

- 1. CSF has protein between 70–450 mg/dl. Adult patients may have normal protein
- 2. Adult patients retain more of the functioning enzyme

Werner's Syndrome

General Characteristics

- 1. Mutations of WRN gene
 - a. AR that maps to chromosome 8p12
- 2. Encodes helicase and exonuclease

Clinical Manifestations

- 1. Severe atherosclerosis

2. Premature aging
3. Premature balding
4. Osteoporosis
5. Hypogonadism
6. Juvenile cataracts
7. DM
8. Peripheral neuropathy
9. Increased reflexes in some patients

Neuropathology

1. Generalized severe atherosclerotic changes in large vessels; often calcification
2. WMH (small vessel disease)

Neuroimaging

1. Topographic strokes in large vessels
2. Generalized WMH

Metachromatic Leukodystrophy

General Characteristics

1. AR; maps to chromosome 22q13.33
2. Deficiency in arylsulfatase A
 - a. Impaired degradation of sulfate

Clinical Manifestations

1. Adult MLD presentation
 - a. Behavioral abnormalities
 - b. Spastic paraparesis
 - c. Late in the disease
 - i. Optic atrophy
 - ii. Intention tremor
 - iii. Brainstem signs

Neuroimaging

1. Severe periventricular white matter involvement
2. Frontal lobe atrophy and white matter involvement

Laboratory Evaluation

1. Elevated protein (75 to 250 mg/dl)
2. Sulfatide in the urine
3. Absence of arylsulfatase in white blood cells
4. Pseudodeficiency of the enzyme
 - a. PD allelic variants
 - b. 10% of enzyme activity is present
 - c. No clinical manifestation

Adult-Onset Leukoencephalopathy with Neuroaxonal Spheroids and Pigmented Glia (ALSP)

General Characteristics

1. Mutation in colony-stimulating factor 1 receptor (SF-1R) gene

Clinical Manifestations

1. Adult onset (3rd–4th decades)
2. Progressive spastic paraparesis
3. Dementia

Neuropathology

1. Neuroaxonal spheroids and pigmented glia

Neuroimaging

1. Frontal lobe involvement with white matter hyperintensities
2. Multiple diffuse white matter involvement without enhancement
3. Corpus callosum involvement

Laboratory Evaluation

- a. Normal CSF

Hyperlysinemia

General Characteristics

1. Chromosome 7q31.3 mutation; AR
2. Gene defect in AASS (alphaaminodic semialdehyde synthase)
3. Defect is in the major catabolic pathway for L-Lysine; the pathway leads to the production of acetyl-CoA

Clinical Manifestations

1. Intellectual impairment
2. Epilepsy
3. Progressive spastic paraparesis
4. The relationship of hyperlysinemia to phenotype has been questioned. Clinical symptoms may require the loss of PTPRZ1 (protein tyrosine phosphatase Receptor-Type IZ Polypeptide1)

Neuroimaging

1. MRI is normal

Laboratory Evaluation

1. Elevated plasma lysine levels ($>600 \mu\text{mol/L}$)

Adult Onset Alexander's Disease

General Characteristics

1. Mutation is in the glial fibrillary acidic protein gene that maps to chromosome 17
 - a. An alternatively spliced GFAP isoform (GFAP-epsilon) may be modulatory

Clinical Manifestations

1. Onset 3rd to 5th decade
2. Spastic paraparesis
3. Brainstem signs including palatal myoclonus and nystagmus
4. Cerebellar intention tremor and ataxia
5. Hyperreflexia
6. Urinary incontinence

Neuropathology

1. Destructive changes in cerebral white matter with frontal lobe predominance

2. Eosinophilic hyaline bodies below the pia and within blood vessels are noted in the cortex, brainstem and spinal cord (Rosenthal fibers)

Neuroimaging

1. White matter hyperintensities throughout the frontal lobe, cerebrum, and middle cerebellar peduncles
2. Atrophy of the medulla that extends caudally to the cervical spinal cord

Metabolic Disorders Affecting the Spinal Cord

Homocarnosine (gamma-amino-butyryl-histidine)

General Characteristics

1. A histidine-containing dipeptide abundant in the CNS and muscle
2. Quenchers of reactive cytotoxic carbonyl species; detoxify 4-hydroxy-trans-2,3-no neural HNE
3. AR; maps to chromosome 18

Clinical Manifestations

1. Spastic paraparesis
2. Mental retardation

Laboratory Evaluation

1. Increased homocarnosine in the CSF

Vitamin B12 (Cobalamin) Deficiency

General Characteristics

1. Conditional deficiency:
 - a. Failure to transfer cobalamin across the intestinal mucosa due to the absence of intrinsic factor and hydrochloric acid (both secreted by parietal cells of the gastric mucosa). It is transported to the ileum and absorbed into the portal circulation
2. Malabsorption Disorders leading to Deficient Cobalamin
 - a. Poor nutrition (elderly patients)
 - b. Atrophic gastritis
 - c. Celiac sprue
 - d. Gastric or iliac surgery
 - e. Overgrowth of intestinal bacteria
 - f. Fish tapeworm infestation
 - g. Exposure to nitrous oxide:
 - i. Depression of methionine synthetase (methylcobalamin dependent enzyme)
 - ii. Operating room personnel, dentists, and abusers (whippets)
 - iii. Chronic exposure may produce complete combined degeneration syndrome
 - iv. Approximately six hours of exposure is required for those that are not B12 deficient prior to exposure; symptoms may occur 2 to 6 weeks after exposure

- v. Methylcobalamin is a cofactor for methionine synthetase; deficiency causes failure of conversion of homocysteine to methionine
- vi. Antibodies that destroy gastric parietal cells may accompany autoimmune disorders

Clinical Manifestations

1. Mild general weakness
2. Active paresthesia of the hands more than feet; constant and progressive
3. Unsteady gait with leg weakness
4. Late manifestations are an ataxic spastic paraplegia

Neurological Signs

1. Loss of vibration sensibility is the most consistent sign (legs > hands) and may occur on the trunk
2. Reflexes are usually increased but rarely the neuropathy may predominant, and they are lost
3. Rare Lhermitte's sign
4. Cognitive impairment
5. Optic, neuropathy

Neuropathology

1. White matter degeneration of the spinal cord with some brain involvement. Swelling of the myelin sheaths with intramyelinic vacuoles and separation of myelin lamellae
2. Late stage – gliosis
3. Rare spongy degeneration in the optic nerves and chiasm
4. Methylcobalamin is a critical cofactor in the conversion of homocysteine to methionine that leads to a failure of DNA synthesis
5. B12 is essential for methylamine-CoA mutase reactions. It is necessary for myelin synthesis. Lack of B12 causes a decrease of the conversion of methylmalonyl-CoA to succinyl-CoA. An accumulation of methylmalonyl-CoA causes a decrease in normal myelin synthesis and the incorporation of abnormal fatty acids into neuronal lipids

Neuroimaging

1. The most consistent MRI pathology finding in B12 deficiency is a symmetrically increased signal of the posterior and lateral columns. Primarily evident in the cervical and thoracic spinal cord
2. In acute patients, the spinal cord may appear to be swollen
3. DWI sequences reveal restriction of water diffusion congruent with intramyelinic edema
4. Rare enhancement of lesions with gadolinium
5. FLAIR and T2-weighted sequences demonstrate high-intensity signal in periventricular white matter

Copper Deficiency

General Characteristics

1. Usually caused by the failure of absorption after bowel surgery or gastric bypass. Excess zinc absorption from dental fixatives can also be causative
2. Associated anemia with ringed sideroblasts, leucopenia, and vacuolated bone marrow myeloid precursor cells

Clinical Manifestations

1. Women > men
2. Presenting complaint is often imbalance
3. Posterior column signs
4. Gait ataxia
5. Spasticity with Babinski sign
6. Reduced ankle reflexes

Neuropathology

1. Antioxidant SOD1 and subunit 2 of cytochrome oxidase may be decreased in blood cells and muscles (5 patients studied)
2. In muscle, deficits of ferritin (iron storage) was detected in the face of normal serum levels
3. Heme proteins including cytochrome C and myoglobin are depressed
4. Muscle expression of the copper transporter CTR1 is up-regulated along with the copper chaperone CCS while the antioxidant protein 1 is decreased

Neuroimaging

1. MRI
 - a. Increased signal intensity in the posterior and lateral columns of the spinal cord similar to that of B12 deficiency

Hyperparathyroidism*General Characteristics*

1. Approximately 100,000 cases of primary hyperparathyroidism occur/year in the USA
2. A multisystem disorder with skeletal, renal, neuropsychological, cardiovascular and rheumatological signs and symptoms
3. Most patients are asymptomatic
4. Changes in calcium homeostasis and the development of bone cysts contribute to neurological spinal cord symptomatology
5. Neurological manifestations occur with primary and secondary hyperparathyroidism (hemodialysis and renal failure)

Clinical Manifestations

1. Dialysis patients may develop brown bone cysts and collapsed vertebrae with spinal cord compression
2. Tetraparesis and severe muscle atrophy may occur
3. Proximal muscle weakness and fatigue
4. Fibrillating tongue, urinary frequency, and generalized hyperreflexia had been described
5. Neurocognitive alterations

Neuroimaging

1. MRI
 - a. Erosion of the radial side of the index fingers and the acromial head of the clavicle

Laboratory Evaluation

1. Elevated serum calcium, PTH and alkaline phosphatase

Neuropathology

1. Severe disruption of bone metabolism

Hyperthyroidism*General Characteristics*

1. Thyroid disease may present first with neurologic signs and symptoms
2. May present concurrently with other neurologic disorders that are most often autoimmune

Clinical Manifestations

1. Amyotrophic lateral sclerosis presentation
2. Presenting as pyramidal tract disease
3. A constellation of nystagmus, spasticity and Babinski signs
4. Associated neurologic complications:
 - a. Encephalopathy
 - b. Hypokalemic periodic paralysis
 - c. Myopathy
 - d. Ophthalmopathy
 - e. Cognitive dysfunction

Portocaval Shunt*General Characteristics*

1. Portosystemic encephalopathy
 - a. Complications of portal hypertension
 - i. Caused by ammonia that is usually removed by the liver
 - ii. Surgical portosystemic anastomosis (PSA) the collateral vessels bypass the liver

Clinical Manifestations

1. Portosystemic encephalopathy (PSE)
2. Portosystemic myelopathy:
 - a. Paresis primarily of the lower extremities
 - b. Spasticity and Babinski signs, no sensory loss or sphincter involvement
 - c. Intervals between surgical shunt and neurological signs
 - i. Total portocaval shunts (median of 16 months)
 - ii. Partial non portocaval shunts (median 60 months)
 - d. Portosystemic encephalopathy develops prior to the myelopathy in most patients
 - e. Myelopathy occurs with splenorenal shunts
 - f. Relationship with type II Alzheimer astrocytes

Neuropathology

1. Loss of anterior horn cells
2. Localized degeneration of the lateral columns

Neuroimaging

1. MRI may be normal in the spinal cord
2. Associated increased T2-weighted signal in the caudate and putamen

Laboratory Evaluation

1. High serum and CSF ammonia concentrations

Hepatic Encephalopathy*General Characteristics*

1. Hepatic encephalopathy may complicate all forms of liver disease and is not related to jaundice or ascites
2. Encephalopathy may be worsened by dietary protein or gastrointestinal hemorrhage. Other precipitating factors are:
 - a. Hypoxia
 - b. Hypokalemia
 - c. Metabolic alkalosis
 - d. Diuresis
 - e. Hypnotic sedatives
 - f. Valproic acid

Clinical Manifestations

1. Mental slowing and confusion that may progress to stupor or coma
2. Asterixis
3. Rare patients exhibit fluctuating rigidity of the trunk and limbs, asymmetry of reflexes and cortical reflexes (suck and grasp)
4. Spinal signs and symptoms (spastic paraplegia) similar to portocaval shunting are common
 - a. These may occur without jaundice and ascites (portal-systemic encephalopathy)
5. Those patients who have suffered multiple episodes of hepatic coma may develop acquired hepatolenticular degeneration (AHLT)
 - a. Clinical features include:
 - i. Dementia
 - ii. Falling backwards
 - iii. Dysarthria
 - iv. Tremor
 - v. Ataxia of gait
 - vi. Choreaathetosis
 - vii. Spastic paraplegia

Clinical Stages of Hepatic Encephalopathy

1. Acute I:
 - a. Personality change (confusion to active psychosis)
 - b. Acute increased intracranial pressures
 - c. Reye's syndrome (increased ICP, vomiting, low glucose, decortication)
2. Subacute stage II:
 - a. Brainstem involvement
 - b. Reversible decerebration
 - c. Spasticity of all extremities
 - d. Pupils <1 mm but reactive to light
 - e. Babinski signs are present
3. Stage III:
 - a. Coma
 - b. Feterhepation
 - c. Failure of Doll's eyes and ice-water colonic

Neuropathology

1. Increased numbers and sizes of protoplasmic astrocytes in the deep layers of the cortex, substantia nigra, dentate and pontine nuclei. These are Alzheimer type II astrocytes
2. Increase in both mitochondria and enzymes that metabolize ammonia
3. Cerebral edema occurs in rapidly evolving patients

Neuroimaging

1. Increased signal intensity of T1-weighted sequences in the globus pallidus from possible manganese deposition in chronic patients
2. Acute hepatic encephalopathy
3. Diffuse cortical edema demonstrated on T2-weighted and FLAIR sequences
4. Diffuse weighted images (DWI) high signal intensity with low signal intensity on apparent diffusion coefficient (ADC) maps
5. High signal intensity alone in the hemispheric white matter in or around the corticospinal tract on FLAIR T2-weighted images

Laboratory Evaluation

1. Increased blood ammonia levels
2. EEG
 - a. Classic triphasic waves

Selected Toxins That Affect the Spinal Cord**Lathyrism***General Characteristics*

1. Due to the consumption of Lathyrus sativus (vetch pea, or grass pea)
2. Common in parts of India and Africa particularly during periods of famine when wheat and other grains are not available

Clinical Manifestations

1. Gradual leg weakness accompanied by cramps, active paresthesias, and urgency of micturition, impotence and sphincter spasms
2. Upper extremity demonstrates coarse tremors and involuntary movements
3. Affects primarily young men; may have a sudden onset

Neuropathology

1. B-ODAP (B-N-oxalyl-dlB-diamino propionic acid) in grass pea is thought to be etiologic
2. A diet of grass pea is deficient in essential sulfur amino acids methionine and cysteine that are important in maintenance of redox homeostasis
3. Loss of ascending and descending spinal cord tracts that include the corticospinal and direct spinocerebellar tracts; loss of posterior column and lateral spinothalamic tract myelination

4. Loss of Betz cells in the cortex but anterior horn cells appear unaffected
5. Gliosis and thickened blood vessels in the degenerated tracts

Konzo

General Characteristics

1. Caused by consumption of improperly processed cassava (*Manihot esculenta*) roots
2. Primarily in remote rural areas of southern Africa and Ethiopia
3. Cyanogenic glycosides are etiologic
4. The disease occurs during famines and droughts as the plant is drought resistant and becomes the major part of the diet
5. May occur suddenly in young mothers after childbirth

Clinical Manifestations

1. Similar to lathyrism
2. Abrupt onset of a non-progressive symmetric spastic para/tetraparesis
3. Clinical signs and symptoms may be precipitated by manual labor or a long walk
4. Paresthesia of the legs, cramping, and pain in the back can precede and accompany the paraparesis. It frequently abates in weeks
5. Upper limb involvement varies from loss of fine movement to spastic quadriparesis
6. Some patients suffer:
 - a. Optic atrophy
 - b. Rotary nystagmus
 - c. Pseudobulbar dysarthria
 - d. Signs of upper motor neuron damage (increased reflexes and Babinski sign) can occur in the absence of paraparesis
 - e. Second attacks occur in approximately 10% of patients
 - f. Contracture occurs in severe patients

Neuropathology

1. Hydrogen cyanide is liberated from cyanogenic glycosides (cyanogenesis)
2. Cyanide is:
 - a. Mitochondrial oxidative phosphorylation blockers
 - b. Derived from the conversion of linamarin
 - c. Possible role for glutathione deficiency

Ethylene Oxide

General Characteristics

1. Ethylene oxide (ETO) is a reactive species and a potent biocide
2. Used widely in the sterilization of hospital equipment. It is in sterilization packs for the operating room
3. Approximately 75,000 health care workers have potential exposure

4. May cause chromosome aberrations
5. Exposure has been associated with leukemia
6. The byproduct ethylene chlorohydrin (EC) may be the toxic agent

Clinical Manifestations

1. Neuropathy
2. Mild cognitive impairment
3. Generalized spasticity
4. Shunt malfunction in children (possible autoimmune reaction)

Neuropathology

1. Sural nerve biopsy
 - a. Axonal damage

Neuroimaging

1. MRI
 - a. Some patients with cerebral atrophy by MRI

Subacute Myelo-Optic Neuropathy

General Characteristics

1. Likely due to the iron chelator
2. Most patients between 1957–1970 in Japan had taken chelator for a prolonged period of time

Clinical Manifestations

1. Optic neuropathy
2. Proprioceptive and vibratory loss
3. Depression
4. Spasticity and gait ataxia
5. Dysesthesia of the lower extremities

Neuropathology

1. Axonal degenerations and gliosis in the cervical spinal cord (fasciculus gracilis)

Neuroimaging

1. MRI
 - a. T2-weighted hyperintensities in the cervical spinal cord
 - b. Volume loss in the dorsal columns
 - c. FLAIR and tractography are normal

Autoimmune Causes of Spinal Cord Dysfunction

Overview

Almost all autoimmune diseases may involve the spinal cord some time in their course. This involvement is frequently overshadowed by cerebral and cerebellar signs and symptoms. Spinal cord involvement in the various forms of MS may be the most prominent etiology of autoimmune disease of the spinal cord. The neuromyelitis-optica spectrum disorder (NMOSD) specifically affects the spinal cord over

many segments with concurrent optic nerve involvement. The spinal cord is less often the predominant pathology in acute disseminated encephalomyelitis in which multiple lesions develop simultaneously. A significant proportion of these patients evolves into a form of multiple sclerosis. Acute hemorrhagic encephalomyelitis has the propensity to involve the left side of the neuraxis and is explosive in onset. Systemic lupus erythematosus may present with transverse myelitis or affect the spinal cord sometime during its evolution. Sjögren's syndrome may preferentially affect the posterior columns, but also causes transverse myelitis. All autoimmune diseases may affect the spinal cord. Sarcoid involves the dura but has an inflammatory component that involves the parenchyma and blood vessels. Graft-versus-host disease most often causes peripheral neuropathy, but may involve the CNS including the spinal cord. Chronic demyelinating inflammatory polyneuropathy overlaps rarely with CNS involvement. Transverse myelitis is the usual spinal cord pathology.

Autoimmune Demyelinating Diseases with Prominent Spinal Cord Involvement

1. Multiple sclerosis
2. Neuromyelitis optica
3. Acute disseminated encephalomyelitis
4. Acute hemorrhagic encephalitis
5. Systemic lupus erythematosus
6. Sjögren's disease
7. Sarcoid
8. Idiopathic hypertrophic pachymeningitis (IgG)
9. Graft-versus-host disease

Multiple Sclerosis

General Characteristics

1. Peak age is approximately 30 years and risk is high in the fourth decade. The risk is low in the sixth decade
2. Spinal cord abnormalities determine a great deal of the clinical disability in MS. The cross-sectional area of the upper cervical spinal cord is a significant spinal cord parameter in determining the expanded disability score
3. Spinal cord gray matter abnormalities are associated with secondary progression and physical disability
4. Some evidence that HLA-DRB1 alleles may have a role in determining the severity and extent of spinal cord involvement

Clinical Manifestations

1. Paresthesias of the palms rather than the fingers (the latter is more characteristic of nerve or brachial plexus sensory loss)
2. Sensory level often to all modalities at the T4 (variants occur with cape like or abdominal presentations)
3. Gait instability and ataxia

4. Spasticity of the lower extremities with easily electable Babinski response, hyperactive reflexes and clonus
5. Loss of superficial abdominal reflexes
6. In almost invariant bladder dysfunction:
 - a. Neurogenic
 - b. Dyssynergia between detrusor contraction and sphincter opening
7. Bowel involvement is usually constipation
8. Focal amyotrophy in the upper extremities may occur
9. Associated neurologic signs:
 - a. Intranuclear ophthalmoplegia
 - b. Afferent papillary defect
 - c. Bilateral cerebellar ataxia
 - d. Bilateral cortical spinal tract dysfunction
 - e. Cognitive decline

Neuropathology

1. Lesions vary in the spinal cord from less than a millimeter to several centimeters. Lesions are sharply demarcated
2. Rarely does a lesion extend past the root entry zone
3. Myelin sheath destroyed early with relative axonal sparing
4. Some anterior horn cell involvement
5. Inflammatory changes predominate early; signs of defective remyelination and gliosis are later manifestations

Neuroimaging

1. MRI:
 - a. Focal cord lesions are evident in > 82% of patients; numbers of plaques are maximal in the cervical cord and increase with disease duration
 - b. Focal lesions are usually round or oval; 35% of patients may have subpial wedge-shaped lesions. Diffuse cord involvement may occur in 10% of patients

Laboratory

1. Approximately 30% of patients with acute onset or during an exacerbation have CSF:
 - a. Mononuclear pleocytosis (<50 cells/mm³)
 - b. IgG and oligoclonal bands are positive in a majority of patients

Neuromyelitis Optica Spectrum Disorder (NMOSD) or Devic's Disease

General Characteristics

1. Prevalence is approximately 0.3–4.4 per 100,000 of the population. It accounts for approximately 1–2% of demyelinating disease in Caucasians, but approximately 20–45% of Asian patients
2. It appears to be more prevalent in black patients in the USA
3. Women are preferentially affected 10:1 over men
4. The age of onset varies with approximately 1% of patients being children or elderly. The median age of onset is 40 years

5. Several HLA variants and polymorphisms have been identified
6. Associated autoimmune diseases occur in 10–40% of patients and include:
 - a. SLE
 - b. MG
 - c. Sjögren's syndrome
 - d. Celiac disease

Clinical Manifestations

1. Approximately 50% of NMO patients present with isolated optic neuritis (ON) of which 20% are bilateral (extremely rare in MS)
2. Profound loss of visual acuity is common (VA 20/200) which differs from MS. Severe visual acuity loss occurs in 80% of NMO patients and 36% of MS during an acute attack
3. NMO optic neuritis is distinguished from MS ON by MRI imaging and functional studies:
 - a. NMO lesions are more extensive and more likely to involve the chiasm
 - b. Due to involvement of the optic chiasm, patients may develop a bitemporal or homonymous visual field deficit
 - c. Optical coherence tomography (OCT) demonstrates a severe peripapillary retinal nerve fiber layer (RNFL) loss in NMO > than that seen with MS

Current Criteria for NMO

1. ON and transverse myelitis
2. Two of three supportive findings
 - a. Contiguous spinal cord 3 vertebral levels
 - b. Brain MRI is not diagnostic of MS
 - c. Aquaporin-IgG 4 seropositivity
3. Seropositive patients with isolated ON or TM have NMO spectrum disorders. This designation carries a high risk of evolution to NMO

Neuropathology

1. A complement-mediated humoral immune reaction against Aquaporin4-expressing astrocytes
2. The target antigen of NMO-IgG is astrocytic foot processes AQP4 (is the most abundant water channel protein in the CNS). The foot processes are expressed primarily at the blood-brain barrier, subpial and subependymal areas
3. Perivascular deposition of immunoglobulins with complement activation occurs within axons

Neuroimaging

1. MRI:
 - a. Longitudinal 3 segment spinal cord involvement with swelling and gadolinium enhancement
 - b. Long optic nerve lesions that may extend into the chiasm and optic tracts

Laboratory Evaluation

1. Immunofluorescence assays for AQP4-IgG have a sensitivity of 2.3–77% and approximately 100% specificity
2. Autoantibodies to myelin oligodendrocyte glycoprotein may be seen in some pediatric patients with aquaporin 4 antibodies
3. GFAP may be elevated in the CSF during acute exacerbations

Acute Disseminated Encephalomyelitis (ADEM)

General Characteristics

1. An acute encephalitic, myelitic or encephalomyelitic process that is most common after an infection in children
2. Usually follows a febrile illness by 2 weeks in children. These are usually uncomplicated respiratory illnesses. The documented viral illnesses that appear to be associated with ADEM are:
 - a. CMV
 - b. HIV
 - c. Epstein-Barr
 - d. Mycoplasma
3. It has also followed vaccination

Clinical Manifestations

1. The encephalitic form is more common in children than adults
2. Abrupt onset as the infection is resolving or after a short latent period
3. Children may have seizures and headache accompanied by ataxia, choreoathetosis, and myoclonus. Rarely decerebration and coma occur
4. New lesions may continue to form after the initial onset (rare)
5. The myelitic form:
 - a. Acute transverse myelitis:
 - i. Partial or complete paraplegia
 - ii. Bowel and bladder involvement
 - iii. A form that simulates anterior spinal artery infarction with primarily ventral cord involvement
 - iv. Sacral variant with severe back pain
 - v. In younger patients, the neurological deficits may be accompanied by slight fever
 - vi. Recovery in adults is the usual

Postvaccinal ADEM

General Characteristics

1. Post-rabies vaccination with older vaccine preparations may cause severe encephalomyelitis similar to that which occurs after measles infection
 - a. The illness may be initiated (after rabies vaccine with neural tissue) into an MS clinical picture
 - b. The process evolves over 2–4 weeks
2. Rarely presents with peripheral nerves and roots involved as with Guillain-Barré syndrome

Neuropathology

1. An acute inflammatory and demyelinating disease
2. Numerous areas of demyelination are seen throughout the hemispheres and spinal cord of approximately the same age. However, there are some evolving and new lesions after the initial event
3. Lesions vary from 1 mm to several millimeters that surround small and medium-sized veins
4. Axons and nerve cells are minimally involved
5. Perivascular lymphocytic and mononuclear cell reaction is frequent
6. Multifocal meningeal infiltration is characteristic

Neuroimaging

1. Multiple T2-weighted high signal intensity plaques throughout the neuraxis of approximately the same age. Many enhance with gadolinium, the lesions have blurred margins
2. Serial MRIs have shown the evolution of new lesions over time in some patients. Lesions may be confluent
3. ADEM patients with corpus callosum lesions:
 - a. Lesions may occur in the corpus callosum (primarily the splenium)
 - b. Usually in the setting of all lesions occurring simultaneously (they all enhance or are non-enhanced)

Laboratory Evaluation

1. CSF
 - a. Lymphocytic pleocytosis; slight protein elevation

**Acute Necrotizing Hemorrhagic Encephalomyelitis
(Weston-Hurst Disease)**
General Characteristics

1. Affects children and young adults
2. Probably the most severe form of ADEM (a variant)
3. Often follows a viral infection of undetermined cause

Clinical Manifestations

1. Abrupt onset accompanied by a headache, stiff neck, fever, and confusion
2. Evolves rapidly to seizures, hemiplegia or quadriplegia, bulbar signs, and coma

Neuropathology

1. The white matter of the hemispheres is severely involved. Severe changes are noted in the brainstem, cerebellum, and spinal cord
2. Widespread neurosis of small blood vessels and the brain tissue around the blood vessels
3. The intense inflammatory cellular reaction, small hemorrhages and an inflammatory meningeal reaction
4. Fibrin is deposited in the vessel wall
5. Fibrin exudation in the spinal cord of a patient with fatal encephalomyelitis has been described

Neuroimaging

1. Bilateral asymmetric extensive hypointensities with mass effect and microhemorrhages in the frontal and mesiotemporal lobes
2. Massive edema on T2-weighted and FLAIR sequences
3. Cortical ribbon may be spared
4. Gray and white matter microhemorrhages are noted

Laboratory Evaluation

1. CSF:
 - a. Acutely there is increased intracranial pressure
 - b. Variable cell counts from a few lymphocytes to a polymorphonuclear count of up to 3,000 cells/mm³; may have RBC's
 - c. Protein is increased
 - d. Glucose is normal

**Differential Diagnosis of Acute Hemorrhagic
Leukoencephalitis**

1. Brain abscess
2. Subdural empyema
3. Focal embolic encephalomalacia
4. Type 1 herpes simplex encephalitis

Graft-Versus-Host Disease*General Characteristics*

1. Neurologic complications after allogeneic hematopoietic stem cell transplantation are common and often severe
2. The incidence of neurologic complications may be related to the degree of human leukocyte antigen (HLA) disparity and the underlying disease
3. Intense immunosuppression regimes (use of fludarabine, busulfan, melphalan, cyclophosphamide or low dose body irradiation in the setting of allogeneic hematopoietic stem cell transplantation)
4. Graft-versus-host prophylaxis consists of cyclosporine A combined with methotrexate

Clinical Manifestations

1. Non-focal encephalopathy
2. Meningoencephalitis
3. Stroke
4. Intracranial hemorrhage
5. Mononeuritis and polyneuropathy
6. Sepsis-related encephalopathy in mechanically ventilated patients

Neuropathology

1. Mechanisms of disease:
 - a. Macrophage induced development of Th17 cells
 - b. Release of S100 proteins that amplify inflammation
 - c. Donor macrophages may be pivotal by secreting CSF1 and CSF-1R in the skin and lung
 - d. No human T-cells

Neuroimaging

1. No MRI CNS studies have been reported

Laboratory Evaluation

1. There is no standardized non-invasive diagnostic method to evaluate graft-versus-host disease
2. Immunologic assay monitors intracellular adenosine triphosphate (ATP) levels in stimulated T-cells

Spinal Cord Involvement in SLE*General Characteristics*

1. CNS is affected in approximately 75% of patients
2. Often neurologic features of SLE develop in the late stage of the illness. They may occur early and be the presenting feature
3. Some neurological features may be secondary to HCVD and Libman-Sacks endocarditis. TTP may complicate the terminal phase of the disease

Clinical Manifestations

1. Psychosis
2. Proximal Myopathy
3. Seizures
4. Choreoathetosis
5. Conducting vessel strokes
6. Features of antiphospholipid antibody syndrome

Clinical Manifestations of Spinal Cord Involvements

1. Patients with extensive longitudinal involvement (4 segments):
 - a. 77% are females with mean age of 29 years
 - b. 23% of patients may be the presenting manifestation
 - c. Sensory > motor > sphincter disturbance
 - d. Cervical to mid-lower thoracic levels are involved
2. Signs and symptoms of acute transverse myelitis

Neuropathology

1. White matter changes in the cerebral hemispheres
2. Longitudinal involvement of the spinal cord of several segments (similar to AQP-4 of Devic's disease)
3. Widespread microinfarcts in the cerebral cortex and brainstem
4. Destructive and proliferative changes in arterioles and capillaries
5. No cellular vascular infiltrate; immune complexes are attached to the endothelium
6. Hypertensive changes and those from emboli of Libman-Sacks endocarditis

Neuroimaging

1. Increased T2-weighted signal intensity in the involved segments (cervical to mid thoracic) that are affected longitudinally
2. Cord swelling and contrast enhancement
3. Rarely transverse myelitis with similar imaging features

Laboratory Evaluation

1. Antibody to double-stranded DNA (anti-dsDNA) is sensitive
2. Coexistent lupus anticoagulant and anticardiolipin antibodies

Wegener's Granulomatosis*General Characteristics*

1. A subacutely evolving vasculitis with necrotizing granulomas of the upper and lower respiratory tract
2. The orbits, heart, skin, and joints may be concomitantly involved along with the nervous system
3. Necrotizing glomerulonephritis follows sinus disease. Overtime, neurologic manifestations occur in 1% to 50% of patients
4. Orbits are involved in 20% of patients and may simulate orbital pseudotumor, cellulitis or lymphoma

Clinical Manifestations

1. Polyneuropathy or mononeuritis multiplex
2. Multiple cranial neuropathies from direct extension of the nasal and sinus granulomas into the upper cranial nerves
3. Episodic hemicrania with periorbital ecchymosis; lower cranial nerve involvement from pharyngeal lesions
4. Rare Neurologic Complications
 - a. Seizures
 - b. Celebritis
 - c. Temporal Arteritis
 - d. Horner's syndrome
 - e. Papilledema
 - f. Ischemic stroke
 - g. Meningitis
5. Spinal Cord involvement with paraparesis:
 - a. Compression from dural thickening (granulomas)
 - b. The spread of inflammation to adjacent areas of the spinal cord

Neuropathology

1. Vasculitis of small arteries and veins
2. Fibrinoid necrosis of vessel walls with infiltrates of neutrophils and histiocytes

Neuroimaging

1. Epidural granulomatous masses that compress the cord (biopsy positive necrotizing granuloma)
2. Minimally hyperintensive epidural lesions on T1-weighted sequences and hypointense on T2-weighted images; minimal contrast enhancement peripherally
3. Intraparenchymal contrast enhancement at the lesion level

Laboratory Evaluation

1. Elevated sedimentation rate, rheumatoid and antiglobulin antibody levels
2. Elevated C-ANCA titers (antineutrophil cytoplasmic antibodies); increased titers of antimyeloperoxidase (MPO)
3. CSF:
 - a. Increase of IgA, IgM and IgG (one patient)

Sjögren's Syndrome*General Characteristics*

1. May occur at any stage of the illness; during the development of the full sicca complex or just with involvement of the minor salivary glands
2. The neurologic symptomatology may precede the other manifestations of the disease
3. Women > men

Clinical Manifestations

1. Posterior root ganglionopathy
2. Sensory peripheral neuropathy
3. Myelopathy
4. Optic neuritis

Neuropathology

1. Lymphocytic infiltration of the exocrine glands, particularly the parotid and lacrimal glands
2. May have associated arthritis, lymphoma, vasculitis, IgM paraproteinemia and renal tubular defects

Neuroimaging

1. Multiple foci of high signal intensity on T2-weighted sequence
2. Transverse myelitis
3. Longitudinal long segment involvement
4. Posterior column involvement

Laboratory Evaluation

1. Positive anti-Ro (SSA) and anti-La (SSB) antibodies
2. Monoclonal IgM immunoglobulins
3. Lip biopsy

Neuro-Sarcoid*General Characteristics*

1. Most involved organs are the mediastinal and peripheral lymph nodes, lungs, liver, skin, phalangeal bones, parotid glands
2. CNS and PNS involvement occurs in approximately 5–50% of patients

Clinical Manifestations

1. Cranial neuropathy (VII); optic neuropathy and retinal vasculopathy; cranial nerve V
2. Mononeuropathy and mononeuropathy multiplex; sensory predominant peripheral neuropathy; lumbar or brachial plexopathy; cauda equina and polyradiculopathy
3. Brain lesions:
 - a. Nodular masses (simulating MS)
 - b. Perivascular infiltration
 - c. Posterior pituitary and perichiasmatic involvement
 - d. Dural involvement of the brain and spinal cord
4. Spinal cord:
 - a. Granulomatous meningomyelitis
 - b. Pachymeningitis

Neuropathology

1. Granular infiltration of the meninges and parenchyma
2. The lesion consists of a focal collection of epithelial cells surrounded by a rim of lymphocytes; giant cells may be seen, but no caseation

Neuroimaging

1. MRI
 - a. Dural involvement
 - b. Nodular masses on T2-weighted or FLAIR sequences that are multifocal
 - c. Thickened spinal dura (Pachymeningitis)
 - d. Posterior hypothalamus and pituitary involvement
 - e. Lesions may enhance with gadolinium and be longitudinally extensive
 - f. Swollen cord at the level of involvement

Laboratory Evaluation

1. Mild anemia, hypercalcemia, slightly elevated sed rate, slight hyperkalemia
2. Angiotensin-converting enzyme (ACE) may be increased in the serum (approximately 2/3 of patients with lung involvement) and the CSF in many with neurologic involvement
3. CSF evaluation:
 - a. Lymphocytic pleocytosis
 - b. Glucose of 30–40 mg/dl
 - c. Protein slight to moderate elevation

Differential Diagnosis of Sarcoid Myelitis

1. Demyelinating disease
2. SLE
3. Wegener's disease
4. Lymphomatoid granulomatosis (if there is lung involvement)
5. Cryptococcus and other deep fungi
6. Syphilis
7. Whipple's disease (large joint arthritis, GI involvement)

Infections of the Spinal Cord**Epidural Abscess***General Characteristics*

1. Staphylococcus aureus is the organism most frequently. The other organisms are:
 - a. Streptococci
 - b. Gram negative bacilli
 - c. Anaerobic organisms
2. Injuries, skin and wound infection or bacteremia are the primary causes
 - a. Bacteremia may seed the epidural space directly or cause vertebral body osteomyelitis with consequent spread to the epidural space
 - b. Following spinal procedures

Bacterial Infection

General Characteristics

1. The most often cause is an infected disc:
 - a. Epidural anesthesia and lumbar puncture give direct access to the epidural space. Prolonged epidural anesthesia for severe pain problems may be associated with catheter infection. This may be exacerbated by steroid epidural infection (may cause cauda equina epidural abscess)

Clinical Manifestations

1. Early there may be low-grade fever and local intense back pain which progresses to:
 - a. Severe radicular pain within a day or two
 - b. Rapidly progressive paraparesis with a sensory level and bowel and bladder dysfunction
 - c. Spine percussion at the infectious site is extremely painful
 - d. Subdural abscess is indistinguishable clinically

Neuropathology

1. Abscess formation with cord compression
2. Following spinal cord decompression, there may be signs of a slowly progressive myelopathy. This is caused by a fibrous and granulomatous reaction at the operative site
 - a. Fever, leukocytosis, elevated sedimentation rate and C-reactive protein suggest continued infection
3. Long standing infection or inadequate therapy may cause adhesive meningomyelitis
4. Venous ischemia of the cord

Neuroimaging

1. Increased signal from the disc space on T2-weighted sequences is often the first manifestation of discitis
2. Enhancement of the posterior and anterior longitudinal ligament, para-spinal muscles and the rim of the abscess itself
3. CT myelography that demonstrates a blurred margin and greater vertical extent in post-surgical incomplete abscess drainage

Laboratory Evaluation

1. CSF:
 - a. Neutrophilic pleocytosis usually less than 100/mm³ and lymphocytosis
 - b. Protein is between 100 mg–400 mg/dl
 - c. Normal glucose
2. Peripheral elevation of the sed rate, C-reactive protein, and leukocytosis

Spinal Cord Abscess

General Characteristics

1. Systemic bacterial infection septicemia, endocarditis, and bed sores are common causes of infection. In this instance,

(bed sores) there may be a subcutaneous fistula that allows bacteria to access the cord through an intervertebral foramen

2. Dorsal fistulous tract

Clinical Manifestations

1. Severe mechanically sensitive back pain at the infected level
2. Radicular pain
3. Paraparesis, sensory level, sphincter dysfunction

Neuropathology

1. Acute bacterial infection

Neuroimaging

1. T2-weighted sequences that demonstrate an edematous swollen cord at, above and below the infected segments

Laboratory Evaluation

1. Similar to those of epidural abscess

Vertebral Body Osteomyelitis

General Characteristics

1. Hematogenous spread of infection or following neurosurgical spine procedures:
 - a. Stabilization instrumentation
 - b. Catheter use
2. Post-surgical procedure organisms:
 - a. Coagulase-negative staphylococci
 - b. Propionibacterium
3. Organisms from bacteremia:
 - a. Low virulence
 - b. May be due to multiple organisms
 - c. May have delayed symptoms and signs (gram negative organisms) up to one month to six weeks following the procedure
 - d. Staphylococcus
4. Bacteremia source:
 - a. Immunocompromised patient (Brucella)
 - b. Uncontrolled diabetes
 - c. Intravenous drug use
 - i. Often at T4–6 a watershed spinal level
 - d. Renal dialysis
 - e. Endocarditis
5. Approximately 20% have associated epidural abscess and in 50% of patients, the source cannot be identified

Clinical Manifestations

1. Fever may not be present
2. Severe local mechanosensitive back pain (pounding on the back), especially if there is associated discitis

Neuropathology

1. In general cancerous involvement does not cross the disc space. Disc involvement most often is an infection
2. Inflammatory exudates and bone infection demonstrated by biopsy

Laboratory Evaluation

1. Elevated peripheral white count, sed rate, and C-reactive protein

Neuroimaging

1. MRI:
 - a. High T2-weighted signal in the vertebral body
 - b. Associated ligament involvement and discitis

Tuberculosis Spinal Osteomyelitis (Pott Disease)*General Characteristics*

1. Tuberculous osteomyelitis of the spine with kyphosis:
 - a. Still prevalent in endemic parts of developing countries
 - b. Children and young adults are most often affected
 - c. Reactivation of tuberculosis from hematogenesis spread

Clinical Manifestations

1. Angulated kyphotic deformity; with additional rotary instability causes a Gibbus Deformity
2. Active manifestations of tuberculosis are often concurrent
3. Compressive myelopathy occurs from:
 - a. The deformity (infrequently)
 - b. Tuberculous abscess
 - c. In USA lumbar > thoracic > cervical segments affected. In Asia, cervical segments are most involved

Neuropathology

1. Infectious endarteritis causes bone necrosis with collapse of a thoracic or lumbar vertebrae
2. Pus or caseous granulation tissue from the infected vertebra compresses the spinal cord
3. Tuberculous meningitis may cause a pial arteritis and consequent spinal cord infarction
4. Tuberculomas are exceedingly rare

Neuroimaging

1. MRI:
 - a. Endplate disruption
 - b. Paravertebral soft tissue (cold abscess)
 - c. High signal intensity of the intervertebral disc
 - d. High sensitivity but low specificity is bone marrow edema

Laboratory Evaluation

1. Organisms may be identified directly in the CSF
2. PCR is positive in the CSF or from bone biopsy

Enterovirus Group A and B*General Characteristics*

1. Selective attack on neurons of the spinal cord and brainstem
2. Non-polio enteroviruses are associated with acute flaccid paralysis in polio endemic areas of Africa and East Asia

3. Enteroviruses are members of the genus enterovirus family Picornaviridae
4. Spread by the fecal-oral route
5. Enterovirus A is divided into two groups:
 - a. Hand, foot and mouth disease group (herpangina; self-limited)
 - b. A group with severe autonomic dysregulation
6. HEV-B species are predominant in many areas

Clinical Manifestations

1. Brainstem encephalitis is characterized by three stages with HEV-71:
 - a. Uncomplicated
 - b. Autonomic nervous system dysregulation
 - i. Pulmonary edema
 - ii. Nucleus tractus solitarius and medullary involvement
 - c. Acute flaccid paralysis

Neuropathology

1. Immunopathogenesis plays a major role in the illness. Regulatory T-cells control the expansion of effector T-cells and modulate inflammation
2. Destruction of vasomotor and respiratory centers in the medial, ventral and caudal medulla (similar to polio)
3. Destruction of anterior horn cells
4. Release of proinflammatory cytokines (hypercytokinemia)
5. Inflammatory cells, necrosis, was found in clusters in the spinal cord. Inflammatory cells were CD 68 positive and CD 15 negative

Neuroimaging

1. Enterovirus 71-related acute flaccid paralysis in patients with hand-foot-mouth disease:
 - a. Anterior horn regions and ventral roots of the cervical spinal cord and below the T9 level are often affected
 - b. High signal in T2-weighted images and low signal T1-weighted sequences in all patients with acute flaccid paralysis. Mild enhancement of anterior horn areas and ventral roots
 - c. Involvement of the central midbrain, posterior portion of the medulla and pons, and bilateral dentate nuclei

Laboratory Evaluation

1. CSF:
 - a. Lymphocytic pleocytosis
 - b. Slight protein elevation

Coxsackie A and B*General Characteristics*

1. Immunosuppressive drugs that target the humoral immune response (rituximab for B-cell lymphoma) may lead to reactivation and increased replication of persistent HEV in the CNS

Clinical Manifestations

1. A cause of hand-foot-mouth disease without neurologic complications
2. Acute disseminating myelitis and transverse myelitis
3. Purpuric and petechial rashes may occur

Neuropathology

1. Anterior horn cell inflammation and neuronal necrosis in those patients with flaccid paralysis

Laboratory Evaluation

1. CSF:
 - a. Lymphocytic pleocytosis
 - b. Mild protein elevation

Poliomyelitis*General Characteristics*

1. Occurs in developing countries and those endemic areas without vaccination programs
2. Polio is an RNA virus of the picornavirus family. Humans are the only known hosts
3. Fecal, oral route of entry; the virus replicates in the pharynx and intestinal tract
4. Only 1–5% of infected patients have nervous system complication

Clinical Manifestations

1. Asymptomatic
 - a. Pharyngitis or gastroenteritis which occurs during viremia
2. Non-paralytic poliomyelitis:
 - a. Fatigue, headache or fever (100–104 degrees)
 - b. Stiff and aching muscles
 - c. Sore throat
 - d. Symptoms may subside which is then followed by recurrence in 3–4 days with an increase of initial symptomatology
 - e. Aseptic meningitis or evolves into the paralytic phase
3. Paralytic phase:
 - a. Weakness occurs with fever
 - b. Muscle weakness may develop over 48 hours or 7–8 days
 - c. Fasciculations are seen in stricken muscles
 - d. Reduced or loss reflexes occur with flaccid paralysis
 - e. Paresthesias without sensory signs are seen in the paralyzed limbs
 - f. Bladder dysfunction may occur early
 - g. Atrophy of affected muscles starts at three weeks and is maximum at 3–4 months
 - h. Involvement of the nucleus ambiguus and n. tractus solitarius respiratory and autonomic control

Neuropathology

1. Lesions in the precentral gyrus, brainstem, and spinal cord. The anterior horn cells and those of the intermediolateral column are severely affected

2. Neuronophagia, leukocyte inflammatory reaction, and perivascular monocyte accumulation occurs
3. Central chromatolysis of motor neurons
4. Mild inflammatory changes in the meninges and dorsal root ganglion

Neuroimaging

1. T2-weighted signal hyperintensities in the ventral spinal cord

Laboratory Evaluation

1. Difficult to isolate the virus from the CSF during the infection (in counter distinction to Coxsackie and echoviruses)
2. CSF findings of aseptic meningitis usually 50–150 lymphocyte/mm³

Differential Diagnosis of Non-Poliovirus Infection with Phenotypic Poliomyelitis

1. RNA viruses:
 - a. Echoviruses
 - b. Coxsackie enteroviruses (A9 and B5)
 - c. Enterovirus 70 (associated conjunctivitis)
 - d. Enterovirus 71 (brainstem and spinal cord)

Herpes Zoster*General Characteristics*

1. An exclusive human neurotropic alpha-herpes virus
2. Primary infection causes chicken pox
3. Latent infection in dorsal root, autonomic and cranial ganglia
4. Reactivation with a decline in cell-mediated immunity in elderly and immune compromised patients

Clinical Manifestations

1. Herpes Zoster
2. Post-herpetic neuralgia
3. Vasculopathy (MCA infarction with V1 root infection)
4. Retinal necrosis
5. Cerebellitis
6. Zoster sine herpete (pain radiculopathy without rash)
7. Herpes Zoster ophthalmicus:
 - a. Skin lesions extend to medial side of the nose (Hutchinson's sign)
 - b. Optic nerve involvement
 - c. Ophthalmoplegia (III and VI, rarely IV)
8. Zoster oticus:
 - a. Rash in the external auditory canal and VIIIth nerve palsy (Ramsay Hunt syndrome); tinnitus with VIIIth cranial nerve involvement

Varicella Zoster Virus Myelopathy*General Characteristics*

1. Cervical or lumbar distribution causes anterior horn cell involvement in the arm and leg

2. Rarely thoracic zoster causes abdominal anterior horn cell necrosis (consequent abdominal herniations)
3. Two major variants:
 - a. "Post-infectious-myelitis"
 - i. Self-limiting monophasic spastic paraparesis
 - ii. Minimal sensory loss and sphincter disturbance
 - iii. Occurs in immune competent patient days to weeks after acute varicella or zoster infection
 - b. Insidious progressive myelitis
 - i. Immunocompromised patients
 - ii. AIDS is the most common medical problem associated with VZV myelitis
 - iii. May have recurrent form

Neuropathology

1. In immune compromised patients:
 - a. Invasion of VZV into the spinal cord parenchyma and adjacent nerve roots
 - b. VZV myelitis may develop with rash
 - c. VZV spinal cord infarction

Neuroimaging

1. AIDS associated VZV myelitis
 - a. Longitudinal serpiginous enhancing lesions

Laboratory Evaluation

1. CSF in immune competent patients:
 - a. Mild mononuclear pleocytosis with normal or slightly elevated protein
- b. CSF in immune compromised VZV patients:
 - i. Mild predominately mononuclear pleocytosis
 - ii. VZV DNA (PCR) or anti-VZV IgG or both in the CSF

HIV

General Characteristics

1. The frequency of spinal cord involvement in AIDS is approximately 20%. Often overshadowed by neuropathy or opportunistic infection

Clinical Manifestations

1. Asymmetric leg or arm weakness, sensory and sphincter disturbance that may develop over weeks
2. Sensory ataxia

Neuropathology

1. White matter of the spinal cord is vacuolated (ballooning of myelin sheaths of long tracts)
2. Some involvement of axons
3. The most severe changes are seen in the posterior and lateral tracts at thoracic levels
4. Rarely similar changes in the brain
5. Lipid-laden macrophages are noted
6. Pathology resembles that which occurs in B12 deficiency

Neuroimaging

1. Transverse myelitis with gadolinium enhancement
2. Long segment involvement with bilateral T2 signal weighted hyperintensity in the thoracic cord without enhancement and with posterior column predominance

Laboratory Evaluation

1. Low lymphocyte count
2. Slight protein elevation
3. Occasional bizarre giant cells

Tropical Spastic Paraparesis (Human T-Cell Lymphotropic Virus Type I) HTLV-1

General Characteristics

1. Primarily found in the Caribbean islands, southern Japan, South America and Africa
2. Transmission occurs from:
 - a. Transfer of infected lymphocytes (CD4+)
 - i. Perinatal
 - ii. Breast feeding
 - iii. Blood transfusions
 - iv. Sexual contact
 - v. Intravenous drugs
3. Both HTLV-1 and HTLV-2 utilize GLUT-1 and NRP1 cellular receptors to gain entry
4. HTLV-1
 - a. Conclusively associated with leukemia/lymphoma (approximately 5% of infected individuals)
 - b. Approximately 5% of infected individuals develop HTLV-associated myelopathy/tropical spastic paraparesis (HAM/TSP)
5. HTLV-2
 - a. Is associated with elevated lymphocytic and platelet counts
 - b. An increase in cancer mortality
 - c. Rarely associated with a myelopathy
 - d. Approximately 10–20 million people are infected worldwide

Clinical Manifestations

1. Primarily occurs in adults
2. Insidious onset with gait alteration and bladder dysfunction as the presenting signs
3. Spasticity and hyper-reflexia of the lower extremities
4. Lower extremity muscle weakness
5. 50% of patients have back pain
6. No cranial nerve involvement
7. Progressive course without remission
8. Associated medical complications
 - a. Uveitis
 - b. Myositis
 - c. Infective dermatitis
9. Coinfected patients (with HIV)
 - a. Present at an earlier age
 - b. <40 years of age
 - c. Present to hospital sooner

Neuroimaging

1. Long segment involvement with bilateral T2 signal weighted hyperintensity in the thoracic cord without enhancement and with posterior column predominance
2. White matter hyperintensities are seen in the brain on T2-weighted sequences
3. Mild atrophy of the thoracic spinal cord

Laboratory Evaluation

1. Low lymphocyte count
2. Slight protein elevation
3. Occasional bizarre giant cells
4. High levels of antibody titers against HTLV-1 antigens in the blood and CSF
5. High HTLV-1 proviral load is found in the blood
6. Moderate increase of CSF protein is seen in the CSF accompanied by intrathecal production of specific HTLV-1 antibody

Neuropathology

1. Chronic inflammation with perivascular lymphocytic cuffing
2. Some parenchymal lymphocytic infiltration
 - a. CD4(+) lymphocytes in early disease
 - b. CD8(+) in later stages
3. Pyramidal tract destruction with both demyelination and axonal loss primarily in the lower thoracic spinal cord
4. Focal spongiform demyelination, destruction of gray matter
5. The posterior columns may be prominently involved

Rabies*General Characteristics*

1. Rare now in the USA; bats, raccoons, skunks, foxes and dogs are the reservoir
2. India has high prevalence and small pockets of disease occur in developing countries
3. Approximately 20–30,000 people receive rabies vaccine/year
4. Inoculation is primarily by the bite of a rabid animal

Clinical Manifestations

1. Incubation period is usually between 20–60 days; face and neck bites may have a very short incubation period (14 days)
2. Tingling and numbness at the site of the bite (which may occur after healing of the wound)
3. 2–4 day prodromal period that includes:
 - a. Fever, headache malaise
 - b. Apprehension
 - c. Dysarthria and dysphagia
 - d. Behavioral alterations
 - e. Severe spasms of muscles of deglutition when attempting to swallow water

- f. Facial numbness and spasms
 - g. Diplopia
4. A spinal form may occur without behavioral alterations or concomitantly
 - a. May follow bat bites
 5. Coma follows the encephalitic phase which evolves to death in 4–10 days

Neuropathology

1. Negri bodies
 - a. Predominately in pyramidal cells of the hippocampus and cerebellar Purkinje cells:
 - i. May be seen in nerve cells of the brain and spinal cord
 - ii. Perivascular cuffing with lymphocytes and monocytes
 - iii. Intense brainstem inflammatory response
 - iv. Focal microglial nodules

Neuroimaging

1. MRI:
 - a. Predilection for midline gray matter
 - b. T2 and Flair sequences involve the dorsal brain stem, thalamus and basal ganglia
 - c. Involvement of central gray matter of the spinal cord
 - d. Involvement of the hippocampus and subcortical white matter occurs

Laboratory Evaluation

1. RT-PCR (100% sensitivity)
2. The direct immunofluorescence test detects rabies viral antigen in 83.3% of rabies positive patients

Epstein-Barr Virus*General Characteristics*

1. Epstein-Barr virus (EBV) is a member of the herpes virus family
2. EBV is a herpes virus that is detectable in >90% of the general population
3. Maybe associated with infectious mononucleosis
4. AIDS patients have 10–20 times as many circulating EBV-infected B-cells than control patients

Clinical Manifestations

1. Meningitis
2. Encephalitis
3. Cranial nerve involvement
4. Peripheral neuropathy
5. Radiculitis
 - a. Myelitis with EBV is rare: May present as Brown-Séquard syndrome
 - b. Transverse myelitis

Neuropathology

1. Neuronal loss in anterior horn cells
2. Lymphocytic perivascular cuffing

3. Inflammatory changes
4. Involvement of white matter long tracts
5. Infiltration of cytotoxic CD8+lymphocyte
6. Deposition of antibody-antigen complexes

Neuroimaging

1. Cervical and thoracic segmental involvement with expansion of the cord; mild gadolinium enhancement

Laboratory Evaluation

1. Lymphocytic pleocytosis
2. Moderately elevated protein
3. Diagnosis by PCR of DNA in the CSF

Cytomegalovirus (CMV)

General Characteristics

1. CMV is a member of the ubiquitous Herpes Virus family
2. Primary infection is usually asymptomatic or mononucleosis-like
3. Reactivation of the virus may have severe consequences in immunosuppressed patients; transplant and AIDS patients

Clinical Manifestations

1. Pneumonitis
2. Hepatitis
3. Uveitis
4. Retinitis
5. Hepatosplenomegaly
6. Colitis
7. Graft rejection
8. Neurologic manifestations:
 - a. Encephalitis
 - b. Myeloradiculitis
 - c. Myelitis
 - d. Conus medullaris and cauda equina involvement in immunosuppressed patients is common
 - e. Brown-Séquard syndrome

Neuropathology

1. Direct cytolysis of neurons
2. Vascular thrombosis
3. Uveitis retinitis, corneal endotheliitis and papillitis

Neuroimaging

1. MRI
 - a. Swelling and gadolinium enhancement of the conus characteristic medullary and the cauda equina

Laboratory Evaluation

1. Anti-CMV IgM antibodies primarily
2. Seroconversion of IgG antibody titer during the illness

Herpes Simplex

General Characteristics

1. A cause of lymphoproliferative disease in immunocompromised patients

2. Herpes virus type 1 (HSV-D and VZV are the most frequent cause of sporadic encephalo/myelitis)

Clinical Manifestations

1. Encephalitis
2. Myelitis
3. Retinitis

Neuropathology

1. Bilateral and asymmetric necrosis of the temporal lobes
2. Leptomeningeal infiltration by lymphocytes, plasma cells
3. Perivascular cuffing and neuronophagia

Neuroimaging

1. MRI: Transverse myelitis

Laboratory Evaluation

1. CD19 and CD20 B-cells in those that have undergone organ transplantation
2. Viral DNA detected in the CSF by PCR

Herpes Virus Type II

Clinical Manifestations

1. Myelitis
2. Encephalitis with posterior uveitis
3. Meningitis and vasculopathy

Differential Diagnosis of Herpes Virus Infections with Transverse Myelitis

1. VSV 1 (Herpes virus)
2. VZV
3. Beta and gamma herpes virus
4. Epstein-Barr virus
5. HHV6 – 8 viruses
6. Hepatic viruses
7. SV 70

Japanese Encephalitis

General Characteristics

1. Endemic virus in Southeast Asia
2. A single-stranded RNA virus belonging to the Flaviviridae family
3. Arthropod-borne

Clinical Manifestations

1. Severe encephalitis
2. Acute flaccid paralysis (spinal cord syndromes)

Neuropathology

1. Perivascular infiltrate is mononuclear
2. Foci of rarefaction and necrosis
3. Gray matter is affected in the thalamus, substantia nigra, cerebral cortex, and hippocampus
4. Spinal cord anterior horn cell involvement

Neuroimaging

1. MRI: Ventral cord hyperintensity on T2-weighted sequences

Laboratory Evaluation

1. Rapid microneutralization test (MNT); neutralizing human antibodies
2. Seroconversion of IgM and IgG by ELISA

West Nile*General Characteristics*

1. Almost all states in the USA have reported patients
2. Migrating birds apparently spread the virus, crows are important reservoir in the eastern USA
3. Virus of the family Flaviviridae
4. Incidence is highest in the Midwest from mid-July to early September; mosquito bite transmission

Clinical Manifestations

1. Meningitis
2. Encephalitis
3. Acute flaccid paralysis
 - a. Approximately 2/3 of patients that have developed paralysis have permanent weakness of the affected extremities

Neuropathology

1. Microglial nodules and perivascular chronic inflammation
2. Neuronal loss with necrosis or neuronophagia

Differential Diagnosis of Arbovirus-Flavivirus with Transverse Myelitis

1. Eastern, Western and Venezuelan equine encephalitis
 - a. The spinal cord is generally spared. If involved the upper cervical cord is affected
2. St. Louis Encephalitis:
 - a. The pathology is usually in the cortex, basal ganglia and cerebral white matter
 - b. Cerebellar infiltration and inflammation is more severe in St. Louis than Western Equine encephalitis
3. Japanese Viral Encephalitis
4. West Nile Fever
5. Tick Born Viruses:
 - a. Ixodes ricinus is the vector
 - b. Reindeer are a reservoir (Scandinavia)
 - c. Clinical manifestations:
 - i. Primarily viral encephalitis
 - ii. Spinal cord may be involved

Myelitis from Bacteria, Fungal and Parasitic Diseases***Mycoplasma Pneumonia****General Characteristics*

1. Children are primarily affected with atypical pneumonia

2. CNS involvement occurs in approximately 2–5% of patients
3. Associated autoimmune disorders include:
 - a. Hemolytic anemia
 - b. Arthritis
 - c. Carditis

Clinical Manifestations

1. Usually, the onset of neurological manifestations is one week after the respiratory illness and includes:
 - a. Meningitis
 - b. Meningoencephalitis
 - c. Encephalitis
 - d. Polyradiculitis
 - e. Cerebral infarction (vasculopathy)
 - f. Cerebellar ataxia
 - g. Cranial neuropathy
 - h. Transverse myelitis

Neuropathology

1. There is direct CNS invasion and an autoimmune component
2. Demyelination
3. Perivenous inflammation
4. Possible arterial vasculopathy

Neuroimaging

1. MRI: Transverse myelitis

Laboratory Evaluation

1. RT-PCR in CSF

Lyme's Disease*General Characteristics*

1. Spirochete of the disease is *Borrelia Burgdorferi*; there are differences between the European and American diseases
2. Tick bite relapsing fever is also caused by *Borrelia*
3. Vascular damage occurs in many organs
4. Early meningeal invasion that is asymptomatic
5. Less acute than leptospirosis and less chronic than syphilis
6. Involves the skin, joints, heart as well as the CNS and PNS
7. Infections are acquired from May to July

Clinical Manifestations

1. Erythema chronicum migrans occurs in 60–80% of patients
2. Transverse myelitis accounts for 4–5% of neuroborreliosis patients
 - a. Acute catastrophic onset with back pain possibly has a poorer prognosis
3. Subacute progressive onset over several days to up to four weeks possibly better prognosis
4. Other neurologic manifestations include:
 - a. Aseptic meningitis

- b. Fluctuating meningoencephalitis
- c. Uni- or bilateral facial palsy
- d. Cardiac manifestations may occur concomitantly:
 - i. Myocarditis
 - ii. Pericarditis
 - iii. Atrioventricular block
- e. Rare neurologic features:
 - i. Seizures
 - ii. Chorea
 - iii. Cognitive decline
 - iv. Cerebellar ataxia
 - v. Myelitic syndrome with quadriparesis
 - vi. Optic nerve and VIth nerve palsy with meningitis
- f. Bannworth syndrome:
 - i. Cranial VII
 - ii. Meningoradiculitis
 - iii. More common in Europe

Neuropathology

1. Perivascular lymphocytic inflammation in the meninges
2. Subcortical and periventricular demyelination
3. Peripheral nerves show lymphocytic infiltration without vasculitis

Laboratory Evaluation

1. CSF lymphocytosis during meningitis with cells varying from 50–3000/mm³
2. Protein varies from 75–400 mg/dl
3. Glucose is normal
4. ELISA demonstrates + IgG; after several weeks patients have + IgM antibody response:
 - a. Western blot of CSF
 - b. PCR-RT

Neuroimaging

1. MRI:
 - a. Cerebral; multifocal and periventricular lesion on T2-weighted sequences
 - b. Spinal involvement:
 - i. Edematous cord
 - ii. Enhancement with gadolinium which may remain in patients with poor outcome

Mechanisms of Spinal Cord Injury from Parasites and Fungi Include

1. Epidural granuloma
2. Local meningitis
3. Meningomyelitis
4. Abscess

Sarcoid

General Characteristics

1. Spinal cord involvement usually occurs during the progression of systemic disease (lung, heart or kidney)

Clinical Manifestations

1. Remission and relapses
2. Paraparesis with bladder dysfunction

Neuropathology

1. Intramedullary granulomatous masses that may occur at multiple levels
2. Dural involvement

Neuroimaging

1. MRI:
 - a. Pituitary and posterior hypothalamic involvement
 - b. Focal T2-weighted gadolinium-enhancing brain lesions
 - c. Dural enhancement and thickening
 - d. Lesions in the spinal cord may enhance; may be longitudinally extensive

Laboratory Evaluation

1. CSF:
 - a. Lymphocytic pleocytosis
 - b. Moderately elevated protein
 - c. Glucose may be slightly depressed (3040 mg/dl)
2. Positive angiotensin converting enzyme

Differential Diagnosis of Granulomatous Spinal Cord Disease

Eosinophilic Granulomatosis with Polyangiitis (Churg-Strauss)

General Characteristics

1. Systemic small vessel vasculitis with asthma and eosinophilia
2. Mean age at diagnosis is approximately 50 years
3. Associated medical problems:
 - a. Ear, nose and throat involvement
 - b. Skin lesions
 - c. Lung infiltrates
 - d. Cardiomyopathy
 - e. Renal involvement

Clinical Manifestations

1. Mononeuritis multiplex
2. Ischemic optic neuropathy
3. Dural granulomas (spinal cord)

Neuropathology

1. Tissue eosinophilia
2. Necrotizing vasculitis
3. Eosinophilic granulomatous
4. Dural and spinal cord masses
5. Bright yellow mass
 - a. Lipid-laden macrophages combined with chronic and acute inflammatory cells
6. Fibrosis and giant cells

Neuroimaging

1. MRI:
 - a. Primary involvement is gall bladder, kidney
 - b. Paranasal sinus involvement
 - c. Intraparenchymal spinal cord lesions
 - d. Eosinophilia > 10% of a differential white blood cell count

Burcellosis*General Characteristics*

1. A zoonotic granulomatous disease
2. Endemic in Middle Eastern and Mediterranean countries
3. Contracted by consumption of unpasteurized milk or its products

Clinical Manifestations

1. The most frequent systemic symptoms are fever, myalgia, malaise, arthralgia, weight loss and night sweats. Lymphadenitis may be prominent
2. Neurologic complications occur in less than 5% of patients
3. Neurobrucellosis includes:
 - a. Chronic encephalitis
 - b. Meningitis
 - c. Radiculoneuritis (often at L5–S1)
 - d. Myelitis; extradural spinal mass
 - e. Behavioral alterations
 - f. Diabetes insipidus
 - g. TIA and stroke (rare)
 - h. Optic neuritis and papilledema have been reported in children
 - i. Pseudotumor cerebri
 - j. Cranial nerve VIII involvement
 - k. Guillain-Barré syndrome
 - l. Cerebral vein thrombosis

Neuropathology

1. Leptomeningeal involvement
2. Vascular inflammation with invasion of plasma cells, lymphocytes, and macrophages
3. Inflammation of the perineurium of nerve roots
4. Edema of the cortex; perivascular mononuclear cell infiltration

Neuroimaging

1. MRI:
 - a. T2-weighted hyperintensities of an infected disc and adjacent vertebral bone
 - b. Cold abscess
 - c. PET/CT detects spread of infection better than MRI

Laboratory Evaluation

1. CSF
 - a. Moderate leukocytosis
 - b. Increased protein
 - c. Slight hypoglycorrhachia
 - d. Increased lactate
2. Positive serologic titers

Meningomyelitis Caused by Fungi, Rare Organisms, and Major Parasites**Actinomycosis***General Characteristics*

1. Anaerobic gram-positive bacteria:
 - a. Colonizes the mouth, digestive and genital tracts
 - b. Cervicofacial infection following a dental focus; pelvic infection with intrauterine devices; pulmonary foci in smokers
 - c. Filamentous gram-positive bacilli
 - d. Spreads contiguously and progressively which mimics a malignancy

Clinical Manifestations

1. Brain abscess
2. Meningoencephalitis
3. Epidural abscess
 - a. Spreads to the spinal cord through vertebral foramen
4. Subdural empyema
5. CNS involvement from:
 - a. Hematogenous spread from the lung
 - b. Contiguously from cervicofacial focus

Neuropathology

1. Mandible is the most affected site which may spread to the CNS by direct extension
2. Multilocular abscesses with central necrotic inflammatory exudates
3. Colonies of branching organisms that form “sulfur granules” that are surrounded by granulation tissue
4. Giant cells are occasionally seen
5. Spinal epidural abscess
6. Actinomycetoma

Neuroimaging

1. Brain abscess
2. Epidural spinal abscesses
3. Cavernous sinus thrombosis
4. Actinomycotic cerebral abscesses are usually single
 - a. Predilection for temporal and frontal lobe
5. Restricted diffusion by DWI
 - a. Pus has a low apparent diffusion coefficient
6. MRI spectroscopic features
 - a. Elevated peaks for:
 - i. Amino acids
 - ii. Lactate
 - iii. Alanine
 - iv. Acetate
 - v. Pyruvate and succinate
 - b. Absent signals for:
 - i. N-acetyl aspartate (NAA)
 - ii. Creatine
 - iii. Choline
7. Osteolysis of affected bone

Laboratory Evaluation

1. Gram-positive branching hyphae
2. Culture
3. Actinomycotic granules have a positive reaction to periodic acids

Blastomycosis*General Characteristics*

1. Endemic to Mississippi and Ohio River Basins and upper Midwest and S.E. USA
2. Men have greater incidence than women
3. Airborne conidia are inhaled from the soil
4. Lung, skin, osseous, genitourinary and CNS infections occur
5. Blastomyces dermatitidis is the causal agent of blastomycosis that can become systemic

Clinical Manifestations

1. CNS infection occurs in 5–10% of disseminated disease and causes:
 - a. Diabetes insipidus
 - b. Pituitary involvement in conjunction with meningitis
 - c. Gains access to the lungs and spreads to the brain through the blood stream
 - d. Meningitis
 - e. Single or multiple abscesses
 - f. Pachymeningitis
 - i. Spinal cord and brain compressions
 - g. Osteomyelitis of bone with contiguous spread from the skull or a vertebra
 - h. Iritis and uveitis

Neuropathology

1. Abscess center contains caseous material, neutrophils, and lymphocytes
 - a. Surrounded by epithelial and giant cells
2. Fungus on H&E demonstrates a central basophilic body surrounded by a clear space

Neuroimaging

1. MRI: Typical brain abscess

Laboratory Evaluation

1. An assay for the detection of antigen is available
2. CSF
 - a. May demonstrate very high protein up to 1000 mg/dl

Coccidioidomycosis*General Characteristics*

1. Endemic mycosis caused by the fungal pathogen coccidioides immitis
 - a. Fungi is the soil of deserts in the western hemisphere
 - b. Infection is from airborne spores (arthroconidia)

Clinical Manifestations

1. Both pathogenic and the cause of opportunistic infections
2. Initially, a mild febrile illness occurs
3. Neurological involvement:
 - a. Occurs in 1/3 of patients
 - b. Meningitis (basal)
 - c. Secondary hydrocephalus
 - d. Osteomyelitis of vertebrae with extension to the spinal cord

Neuropathology

1. Granulomas with small abscesses and caseous necrosis within the brain and spinal cord
2. Disseminated CNS disease in AIDS patients

Neuroimaging

1. MRI:
 - a. Infection of bones and joints
 - b. Typical brain granulomatous lesions
 - c. Osteomyelitis of the patella and sacrum

Laboratory Evaluation

1. Complement fixation (IgG) titers
2. Grocott's methenamine silver staining demonstrates spherule

Cryptococcus*General Characteristics*

1. Cryptococcus neoformans:
 - a. Found in the soil and droppings of some birds
 - b. Southern USA; worldwide distribution
2. Greater than 85% of infections associated with immunocompromised patients

Clinical Manifestations

1. Meningitis; often localized at the base of the cerebellar hemispheres
2. Spinal arachnoiditis
3. Lumbosacral polyradiculopathy

Neuropathology

1. Brain changes are close to areas of meningeal involvement
2. Meningitic exudates have a minimal inflammatory cellular reaction
3. Meninges may demonstrate tubercles of 2–3 mm in diameter
4. Recent foci and in AIDS patients:
 - a. Organisms that produce a "gelatinous" pseudocystic dilatation of the Virchow-Robin spaces
 - b. Intramedullary granulomas

Neuroimaging

1. MRI:
 - a. Associated topographic strokes of the hemisphere
 - b. Thin-walled cysts (dilatation of the Virchow-Robin spaces) in the basal ganglia

Laboratory Evaluation

1. CSF:
 - a. Lymphocytic pleocytosis
 - b. Moderate elevation of protein 80–120 mg/dl
 - c. PCR-based diagnosis

Aspergillosis*General Characteristics*

1. Aspergillosis fumigates primarily infects the external ear, lungs or paranasal sinuses
2. Disseminated form occurs in patients with cancer, collagen vascular disease or immunosuppression (renal or liver transplants)
3. Spreads to the CNS directly from the paranasal sinuses, orbit or hematogenously from the lung or GI tract

Clinical Manifestations

1. Abscess or granuloma in the brain that may be single or multiple
2. Usual infection is in the cerebral hemispheres
3. Epi- and subdural locations in the thoracic cord
4. Sino-orbital infection
 - a. Focal bony erosion
 - b. Grows through blood vessel walls

Neuropathology

1. Branching septate hyphae
2. The degree of inflammatory reaction depends on the immune status of the patient
3. Granulomas occur in the course of a chronic infection
 - a. Aggregates of plasma cells, epithelioid cells, and collagen are seen in areas of necrosis
 - b. Multinucleated giant cells may be seen

Neuroimaging

1. Typical brain abscess found in immunocompetent patients; multiple abscesses in immunocompromised patients
2. Predilection for the sphenoid bone
3. Sino-orbital bone destruction
4. MRI demonstrates focal enhancement

Laboratory Evaluation

1. Culture (Broncho alveolar lavage)
2. Typical branching septate hyphae
3. Elevated (1-3)-B-D-glucan and Galactomannan
4. RT-PCR

Schistosomiasis*General Characteristics*

1. One of the world's most widespread parasitic diseases
2. Affects >200 million patients worldwide
3. Endemic areas for *Schistosoma mansoni* are South America, the Middle East, and sub-Saharan Africa
4. Humans are the definitive host

- a. Fresh water snail (*Biomphalaria*) is an intermediate host:
 - i. Cercaria, a larval form released from snails, penetrates the skin and enters the blood and lymphatic system
5. May infect the spinal cord through Batson's plexus

Clinical Manifestations

1. Acute infection causes:
 - a. Fever
 - b. Headache
 - c. Myalgia
 - d. Diarrhea
 - e. Abdominal pain
2. Spinal schistosomiasis:
 - a. Radicular pain
 - b. Myelopathy with flaccid paraplegia, dysesthesia or incontinence of bowel and bladder
 - c. Acute inflammatory myeloradiculopathy is the most common neurologic complication of *S. mansoni* infection; cord syndrome; transverse myelitis
 - d. Onset of myelopathy may be delayed for months or years

Neuropathology

1. Affects the conus medullaris and cauda equina
2. Granulomas are deposited on spinal roots
3. Deposition of eggs in the spinal cord (inflammation):
 - a. Cerebral hemorrhage is rare

Laboratory Evaluation

- a. Enzyme-linked immune-absorbent assay is sensitive for diagnosis; detects elevated titers of antibody against the schistosoma
- b. CSF:
 - i. Mononuclear and lymphocytic pleocytosis
 - ii. Increased protein
 - iii. Usually normal glucose
 - iv. Eosinophilia
 - v. Oligoclonal IgG bands

Differential Diagnosis of Granulomas in the Spinal Epidural Space

1. Actinomycosis
2. Blastomycosis
3. Coccidioidomycosis
4. Aspergillus
5. Cryptococcus (rare)
6. Echinococcosis (rare)

Syphilis**General Characteristics**

1. Recent shift in presentation from parenchymal involvement to chronic meningovascular disease

2. The number of reported cases has increased both in immunocompetent and in AIDS patients
3. The CNS is usually infected 3–15 months after the initial chancre
4. The initial CNS infection is meningitis which occurs in approximately 25% of patients and is most often asymptomatic or if symptomatic may cause:
 - a. Cranial nerve palsies
 - b. Seizures
 - c. Stroke
 - d. Increased intracranial pressure
5. Early clinical features:
 - a. Aseptic meningitis
 - b. After 1–2 years meningovascular syphilis
 - c. Tertiary syphilis may develop after several years which includes:
 - i. General paresis
 - ii. Tabes dorsalis
 - iii. Optic atrophy
 - iv. Subacute myelitis
 - d. All clinical syndromes derive from meningitis; there are overlapping syndromes

Clinical Manifestations

1. Spinal syphilis:
 - a. Tabes dorsalis:
 - i. Occurs approximately 15 to 20 years after the primary infection
 - ii. Lightning pains (dorsal roots) are involved
 - iii. Ataxia (dorsal column)
 - iv. Urinary incontinence (overflow)
 - v. Impaired vibration and position sense of the lower extremities is associated with a positive Romberg sign and absent knee and ankle reflexes. Argyll Robertson pupil is present in most patients
 - vi. Optic atrophy and ptosis
 - vii. Constipation and megacolon (rare)
 - viii. Charcot joints and tropic ulcers of the feet may be prominent
 - ix. Visual crisis causes severe spasm and pain of the affected organs
2. Syphilitic meningomyelitis:
 - a. Bilateral corticospinal involvement
 - b. Anterior spinal artery syndrome
3. Gummas are extremely rare except in AIDS patients
4. Hypertrophic pachymeningitis (rare)
 - a. Radicular pain
 - b. Amyotrophy of the hands
 - c. Long tract involvement of the legs
 - d. May be prominent at cervical levels

Neuropathology

1. Thinning of the affected nerve roots
2. Degeneration of the posterior columns and atrophy of the spinal cord

3. Inflammation of the posterior roots
4. In meningomyelitis
 - a. Subpial loss of myelinated fibers and gliosis
 - b. Fibrosing meningitis

Neuroimaging

1. Long segment T2-weighted sequence changes of the parenchyma
2. Contrast enhancement
3. Dorsal column involvement
4. Gummas in AIDS patients
5. Frontal lobe atrophy

Laboratory Evaluation

1. Positive VDRL (regain test) serum
2. Positive FTA/ABS in the serum
3. CSF:
 - a. Lymphocytic pleocytosis
 - b. Increased protein
 - c. Normal glucose
 - d. Increased IgG and oligoclonal bands
 - e. Dependent on the stage and type of:
 - i. RPR (rapid plasma reagin) tests may be negative in late syphilis
 - ii. FTA/ABS is directed against treponema antibodies and is needed for evaluation of possible false positive results or those with seronegative results

Autoimmune Spinal Cord Inflammation

Multiple Sclerosis

General Characteristics

1. Most often the brain and optic nerves are concomitantly affected
2. May be exacerbated by infection and heat (Uhthoff's phenomena)

Clinical Manifestations

1. Transverse myelitis:
 - a. Usually painless
 - b. No fever
 - c. Rapid onset over hours to a day
 - d. Level is often at T4–T6 but can be on the abdomen, or both arms may be affected
2. Inflammatory pseudotumor of the cord:
 - a. Similar to an intramedullary tumor (glioma)
 - i. Cervical and thoracic levels most often affected
3. Focal amyotrophy

Neuropathology

1. Inflammatory demyelination
2. Lymphocytic aggregation around venules
3. Loss of axons and anterior horn cells occurs to varying degrees

Neuroimaging

1. Focal intramedullary lesion:
 - a. MRI reveals edema and space occupying characteristics
 - b. "Open loop sign" the area of edema and T2-weighted sequence hyperintensity does not completely surround the lesion
2. Transverse myelitis
3. Cervical spinal cord maps of fractional anisotropy (FA) mean diffusivity, radial diffusivity (RD) reveal:
 - a. Lower FA
 - b. Higher radial diffusivity
4. Spinal cord gray matter radial diffusivity is associated with EDSS (loss of anterior horn cells)

Laboratory Evaluation

1. Lymphocytic pleocytosis
2. Slight protein elevation
3. Presence of oligoclonal bands
4. Increased IgG
5. Normal glucose

Neuromyelitis Optica (Devic's Disease)*General Characteristics*

1. An immune-mediated disorder that is relapsing and remitting
2. A hallmark autoantibody against aquaporin-4 water channel is characteristically found
 - a. A monophasic course associated with antibodies to myelin oligodendrocytes (MOG) may occur most often in children
3. Associated with organ specific and non-organ specific autoimmune disorders that include:
 - a. Myasthenia gravis
 - b. Antiphospholipid antibody syndrome
 - c. Sjögren's syndrome
 - d. SLE
 - e. Pernicious anemia
 - f. Paraneoplastic disorders
4. It is a spectrum disorder:
 - a. Optic nerves or spinal cord can be primarily involved

Clinical Manifestations

1. May have an explosive onset
2. Usually, the disease progresses in a stepwise fashion for months or years
3. Varying degrees of paraplegia, quadriplegia, sensory loss (often with spinal level), sphincter and sexual dysfunction
4. Optic neuritis may be bilateral concomitantly which is unusual for MS. The degree of visual loss and the extent of the optic nerve lesion as well as chiasmatic involvement distinguish the process from MS

Neuropathology

1. Antibodies are directed against aquaporin-4 receptors on astrocytic foot processes. They are IgG in type

2. The process affects capillaries of the brain stem and cerebellum as well as the optic nerves and chiasm as well as the spinal cord
3. Both gray and white matter of the spinal cord are involved
4. Necrotizing myelitis:
 - a. Inflammation and demyelination
 - b. Older lesions are cavitated
5. Complement-dependent cytotoxicity with granulocyte and macrophage infiltration

Neuroimaging

1. MRI:
 - a. Demonstrates a greater than 3 segment longitudinal involvement of the spinal cord
 - b. Double inversion recovery sequence (3D) is sensitive for spinal cord involvement
 - c. Fractional anisotropy is decreased in neuromyelitis optica (NMO) compared to MS in the spinal cord; axial diffusivity is higher in NMO than MS asymmetrically in anterior columns in normal appearing white matter

Laboratory Evaluation

1. CSF-restricted oligoclonal IgG bands are largely absent
2. Intrathecal IgG (rarely IgM synthesis is low and usually restricted to relapses)
3. Pleocytosis occurs in approximately 50% of patients and may include neutrophils, eosinophils, activated lymphocytes and plasma cells
4. Band T-cell subsets are involved in the modulations of inflammation within the CNS and systemically

Post-Infectious and Post-Vaccinal Myelitis*General Characteristics*

1. There is a temporal relationship following a viral infection or vaccination
2. Delayed development of neurologic signs and symptoms
3. Monophasic course
4. The most common organisms are the DNA viruses:
 - a. Epstein-Barr
 - b. CMV
5. Rarer infections:
 - a. Hepatitis B
 - b. Varicella
 - c. Enterovirus
 - d. Rhinoviruses
6. Mycoplasma
 - a. Bacterial trigger
7. Campylobacter jejune does not cause myelitis
8. At times, no antecedent infection can be documented

Clinical Manifestations

1. Progression of signs and symptoms is subacute
2. There is weakness and paresthesia of the lower extremities; this may also involve the upper extremities

3. Ascending sensory signs and symptoms
4. Sphincter alterations occur
5. Backache is frequently felt
6. May develop a sensory level
7. Babinski sign is a differential point that distinguishes the process from Guillain-Barré syndrome
8. Some patients demonstrate meningeal signs and symptoms
9. Typically there is asymmetric spinothalamic and corticospinal tract involvement
10. Latency from infection or vaccination to signs and symptoms is approximately two weeks

Clinical Variants

1. Relapsing myelitis that may be triggered by an infection
2. A pure paresthetic form with posterior column signs
3. Paraparesis and a truncal sensory level; no alteration of deep sensation
4. Dissociated sensory topography:
 - a. Leg or groin sensory loss that can be unilateral or bilateral
5. Saddle anesthesia and sphincter alteration
6. Brown-Séquard syndrome

The Recent Clinical Spectrum of Post-Vaccination

Inflammatory Demyelinating Syndromes

1. Between 1979–2013 there were 71 documented patients
2. The most common vaccinations:
 - a. Influenza
 - b. Human papillomavirus (HPV)
 - c. Hepatitis A or B
 - d. Rabies
 - e. Measles
 - f. Rubella
 - g. Yellow fever
 - h. Anthrax
 - i. Meningococcus
 - j. Tetanus
3. CNS signs and symptoms:
 - a. Usually occurred within two weeks following immunization
 - b. A few patients had a delayed presentation from three weeks to five months (approximately 1/3 of reported patients)
4. Clinical manifestations:
 - a. Optic neuritis occurred in greater than 75% of patients (following influenza and HPV vaccination)
 - b. Topography in a significant number of patients was optic neuritis and myelitis (with or without CNS manifestations of ADEM); similar to NMO spectrum disorder
5. Neuropathology:
 - a. Subpial or perivenular zones of demyelination
 - b. Perivascular and meningeal infiltration of lymphocytes and mononuclear cells
 - c. Pleomorphic histiocytes and microglia are seen

6. Neuroimaging (post-vaccination for H1N1)
 - a. High T2-weighted signal intensity in the cerebellum, sulcal hyperintensities in the frontal and parietal lobes
 - b. Spinal cord may demonstrate:
 - i. Slight enhancement and T2-weighted MRI sequence abnormalities over 2 to 3 spinal segments
 - ii. Swollen cord occurs in the affected segments
7. Laboratory evaluation:
 - a. CSF:
 - i. Lymphocytic pleocytosis (10–50/mm³)
 - ii. Slightly increased protein (no oligoclonal bands)

Myelitis with Connective Tissue Disorders

General Characteristics

1. Myelitis has been described in over 22 connective diseases. The most important and prevalent are SLE and Sjögren's
2. Autoimmune illnesses with primarily transverse myelitis include:
 - a. Myasthenia gravis
 - b. Celiac disease
 - c. Ulcerative colitis
 - d. Sclerosing cholangitis
 - e. SLE
 - f. Sjögren's syndrome
 - g. Thrombotic thrombocytopenic purpura
 - h. B12 deficiency
 - i. Pemphigus
 - j. Narcolepsy
 - k. CIDP
 - l. Autoimmune encephalitis
 - m. Paraneoplastic syndromes
 - n. Insulin dependent diabetes
 - o. Scleroderma
 - p. Mixed collagen vascular disease
 - q. Autoimmune thyroid disease
 - r. Dermatitis herpetiformis
 - s. Psoriasis
 - t. Alopecia areata
 - u. Polymyositis
 - v. Rheumatoid arthritis
 - w. Ankylosing spondylitis
 - x. Sarcoid

Clinical Manifestations

1. Rapidly progressive paraparesis and rarely quadriparesis
2. Usual level at T4–T6 (sensory)
3. Bowel, bladder, and sexual dysfunction

Neuropathology

1. Usually the inflammatory demyelination of transverse myelitis

Neuroimaging

1. MRI:

- b. T2-weighted sequence hyperintensity in less than three spinal cord segments; some entities demonstrate longitudinal involvement
- c. Affected cord segments are edematous, swollen and demonstrate gadolinium enhancement

Laboratory Evaluation

- 1. Systemic biomarkers are dependent on the disease process
- 2. Often there is inflammatory CSF with leukocytosis, moderately high protein and usually normal glucose (may be slightly depressed in some instances)

Systemic Lupus Erythematosus (SLE)

General Characteristics

- 1. Some SLE patients with transverse myelitis have circulating antiphospholipid antibody
- 2. Cardiovascular disease is the leading cause of SLE morbidity and mortality
- 3. Antiphospholipid antibodies are common in SLE:
 - a. Approximately 10% of SLE patients develop antiphospholipid syndrome
 - b. Lupus anticoagulant is associated with thrombotic events

Clinical Manifestations

- 1. SLE has two distinct clinical patterns:
 - a. Gray matter myelitis:
 - i. Prodrome of fever and urinary retention at presentation
- 2. Rapid deterioration (within six hours)
- 3. Paraplegia
- 4. No improvement
- 5. Gray matter disease occurred in the context of active systemic disease
- 6. Patients had more disability and responded poorly to treatment
- 7. White matter myelitis:
 - a. At the time of presentation, patients demonstrate spasticity and hyperreflexia
 - b. Less severe signs
 - c. Slower progression than gray matter disease
 - d. Absent prodromal features
 - e. Clinically similar or related to NMO spectrum disorder
 - f. Polyphasic course
 - g. SLE activity may be absent

Neuropathology

- 1. Widespread vasculopathy of small vessels:
 - a. Variable inflammation and myelitis
 - b. Vacuolar myelopathy

Neuroimaging

- 1. White matter myelopathy

- a. Longitudinal pattern of inflammation, spinal cord swelling and gadolinium enhancement
- 2. Gray matter myelopathy:
 - a. Greater swelling and enhancement with gadolinium on MRI
 - b. Longitudinal patterns of inflammation involving at least three segments occurs in greater than 95% of patients; a similar pattern occurs in >75% of patients with the white matter variant

Laboratory Evaluation

- 1. CSF of gray matter variant:
 - a. Striking inflammatory markers
 - b. Neutrophilic pleocytosis
 - c. Increased protein
 - d. Low CSF glucose
- 2. White matter myelitis:
 - a. NMO IgG autoantibody may be present
 - b. Associated with anti-RO antibodies antiphospholipid antibodies and lupus anticoagulant

Sjögren's Syndrome

General Characteristics

- 1. Chronic inflammation of exocrine glands (lacrimal and salivary glands) leading to sicca complex
- 2. Approximately 1/3 of patients present with extra-glandular neurological, pulmonary or gastrointestinal signs and symptoms
- 3. Neurological symptoms occur in approximately 20% of patients

Clinical Manifestations

- 1. Sensory ganglionopathy
- 2. Polyradiculopathy
- 3. Mononeuritis multiplex
- 4. Autonomic neuropathy
- 5. Cranial neuropathies (primarily II and V)
- 6. Transverse myelitis:
 - a. May occur independently
 - b. Associated with neuromyelitis optica
 - c. An association of anti-RO antibodies and recurrent transverse myelitis

Neuropathology

- 1. Direct invasion of the CNS by lymphocytes
- 2. Vascular injury due to anti-neuronal and anti-SSA antibodies
- 3. Ischemia from small vessel vasculitis

Neuroimaging

- 1. T2-weighted sequence hyperintensities diffusely in the cerebral hemispheres
- 2. Transverse myelitis
- 3. Long segment spinal cord inflammation

Laboratory Evaluation

1. +SSA/SSB antibodies in the serum
2. Lip biopsy

Differential Diagnosis of Spinal Cord Autoimmune Diseases Associated with Longitudinal Myelitis

1. SLE (white myelitis and gray variants)
2. Sjögren's syndrome (sicca complex)
3. Rheumatoid arthritis (small muscle involvement of the hands, C1–C2 spondylolisthesis with spinal cord compression)
4. Mixed connective tissue disease (elements of polymyositis, scleroderma, and SLE)
5. Regional enteritis (usually associated with stroke or cerebral sinus thrombosis due to loss of clotting inhibitors through the gut creating a prothrombotic state)

Stiff Person Syndrome*General Characteristics*

1. Antibodies to glutamic acid decarboxylase (GAD) are present in some patients
2. GABA-R associated (receptor), and gephyrin (intracellular proteins) antigens are also seen in some patients, but may not be pathogenic
3. Glycine- α 1-receptor antibodies have also been reported in a few patients with stiff person syndrome and may be pathogenic

Clinical Manifestations

1. Persistent and intense spasm of proximal and paraspinal musculature (often most severe in the quadriceps)
2. Insidious onset of spasms in middle-aged men and women which are intermittent early and then evolve to occur continuously
3. Spasms are painful
4. Severe patients have involvement of respiration, deglutition, and facial musculature
5. Eyes muscles are rarely involved
6. Noise or mechanical stimuli initiate spasms of all involved musculature
7. Axial spasms cause hyperlordosis
8. Involved muscles become hypertrophic
9. Tendon reflexes are depressed
10. "Stiff" limb syndrome is a variant:
 - a. Clinical features occur in one limb
 - b. Associated with GAD antibodies
 - c. May spread to both legs
11. Hyperekplexia occurs
12. Autonomic signs and symptoms

Neuropathology

1. Associated medical conditions:
 - a. Insulin dependent diabetes
 - b. Thyroiditis

- c. Pernicious anemia
- d. Vitiligo
- e. Celiac disease
2. Suggested central origin:
 - a. Disappearance during sleep
 - b. Absence with anesthesia
 - c. Proximal nerve block abolishes spasms
3. In stiff man syndrome associated with breast cancer:
 - a. Autoantibodies to amphiphysin and gephyrin (proteins associated with synaptic GABA receptors) are detected
 - b. GAD antibodies are detected in approximately 2/3 of patients
 - c. GLYR (glycine receptor) antibodies may be associated with GAD antibody expression

Neuropathology

1. Some autopsied patients showed to have no inflammation and minimal neuronal loss in the spinal cord
2. Positive spinal cord autopsies demonstrate:
 - a. Loss and degeneration of nerve cells with astrocytosis in medial motor nuclei of the anterior horn cells:
 - b. Lymphocytic perivascular infiltration of the brainstem, basal ganglia and spinal cord
 - c. Antibodies may be directed against conformational forms of GAD expressed in GABA-ergic neurons that cause:
 - i. Blockade of GABA synthesis
 - ii. Decreased function of the inhibitory motor network

Laboratory Evaluation

1. High titers of anti-GAD antibodies in the serum and CSF
 - a. Anti-GAD antibodies are seen in 1% of the normal population and 5% of patients with other neurologic disease
 - b. Anti-GAD antibodies occur in insulin dependent diabetes but at much lower titers
 - c. In Stiff Person syndrome (SPS):
 - i. Antibodies are too linear and denatured epitopes in the NH₂ terminal region of the GAD antigen
2. Anti-amphiphysin antibodies are not present in SPS without cancer

Neuroimaging

1. PET evidence of central GABA-ergic changes in stiff person syndrome

Progressive Encephalomyelitis with Rigidity and Myoclonus (PERM)*General Characteristics*

1. PERM is similar to stiff person syndrome
2. More severe, progressive and may be fatal

Clinical Manifestations

1. Additional features to those that are seen with SPS include:

- a. Eye movement abnormalities
- b. Speech and swallowing dysfunction
- c. Respiratory failure
- d. Seizures
- e. Auditory and vestibular dysfunction

Neuropathology

1. Inflammatory exudates are primarily perivascular and consist of both B-cells (CD20x) and T-cells (CD3)
2. Microglial nodules occur in the hippocampal formation and Purkinje cell layer of the cerebellum
3. Gray matter is more involved than white matter; relative sparing of the neocortex; no demyelination
4. Gray matter of the neocortex may be involved in those patients with cognitive impairment

Neuroimaging

1. MRI of the spine may be negative
2. MRI demonstrates (in some patients) T2-weighted sequence hyperintensities throughout the cervical cord and lower brainstem

Laboratory Evaluation

1. Glycine receptor alpha 1 antibodies in the serum and CSF
2. CSF may demonstrate:
 - a. Lymphocytic pleocytosis
 - b. Mildly elevated protein
 - c. Normal glucose
3. Anti-GAD and NMDA antibodies have been recorded in the syndrome

Propriospinal Myoclonus

General Characteristics

1. Propriospinal myoclonus definition:
 - a. Repetitive flexion or extension myoclonus of the torso that is initiated by stretching or movement
 - b. The exact generator is unknown
2. Irregular and segmental myoclonic jerks can occur with:
 - a. Zoster myelitis
 - b. Hyperosmotic states
 - c. Post-infectious transverse myelitis
 - d. Epidural cord compression
 - e. Multiple sclerosis
 - f. Cardiac pacemaker

Clinical Manifestations

1. Usually, the upper abdomen and lower thoracic muscles are involved
2. May be a sensory predominant illness
3. Positional exacerbation (usually supine)
4. A form very similar to SPS has been described

Neuropathology

1. Autopsy material in the form resembling SPS demonstrates:

- a. Primary involvement of the cervical cord
- b. Loss of interneurons with minimal involvement of motor neurons of the anterior horn
- c. Gliosis and microglial activation and proliferation
- d. Lymphocytic cuffing of small blood vessels
- e. Minimal meningeal inflammation

Neuroimaging

1. PET demonstration of GABA-ergic dysfunction (primarily in SPS)
2. T2 sequence hyperintensity of the spinal cord (all segments)

Laboratory Evaluation

1. Mild lymphocytic pleocytosis and protein elevation
2. Ulcerative colitis (most often associated with cerebrovascular accidents, cerebral sinus thrombosis, eye and joint involvement)
3. Relapsing polychondritis (most often associated with disc disease, optic neuritis, collapse of the trachea and larynx)
4. Any of the autoimmune diseases that have been associated with transverse myelitis

Differential Diagnosis of Arteritis Syndrome

1. Simulating autoimmune transverse myelitis:
 - a. Syphilitic proliferative endarteritis
 - b. Occlusion of the vertebral or anterior spinal arteries
 - c. Meningoencephalitis
 - d. In association with HIV (all stages occur simultaneously; "telescoped")
 - e. Pachymeningitis cervicitis
2. Antiphospholipid syndrome:
 - a. Primary
 - b. In association with SLE
3. Takayasu's disease:
 - a. Vertebral and anterior spinal artery occlusions
 - b. Anterior > medullary posterior spinal artery occlusions
4. Isolated angiitis of the spinal cord
 - a. No associated features or laboratory evidence of systemic arteritis
5. Giant cell arteritis:
 - a. Rarely can affect all arteries of the internal carotid system
 - b. A component of the aortic arch syndrome (both carotids and vertebral arteries may be slowly occluded)
6. Kohlmeier-Degos disease:
 - a. Characteristic atrophic skin lesions
 - b. Severe retinal artery spasm
 - c. Rare spinal cord infarction

Paraneoplastic Myelitis

General Characteristics

1. In general, these are subacute necrotic myelopathies

2. Various neurologic syndromes have been described with antibodies in association with specific malignancies that target intracellular antigens. These include:
 - a. Hu
 - b. Yo
 - c. Ri
 - d. Tr
 - e. CV2/CRMP5
3. Neuronal damage with intracellular antigen-antibody interaction is NK-cell mediated inflammatory response
4. Antibodies to cell surface antigens from malignancies:
 - a. Attack neuronal integral membrane proteins
 - b. Modulate the number or function of the specific target protein
 - c. Are probably pathogenic
5. The most common CNS cell surface directed antibodies associated with malignancies are:
 - a. NMDAR
 - b. LGH
 - c. CASPR2
 - d. GLYR
 - e. GABAB
 - f. AQP4
 - g. MOG

Clinical Manifestations

1. Slowly progressive and usually painless
2. Motor dysfunction prior to sensory loss
3. Sphincter alterations

Neuropathology

1. Necrotic lesions
2. Both gray and white matter are affected (white > gray)
3. Minimal mononuclear cuffing of blood vessels which are otherwise normal
4. Some autopsy material demonstrates that the posterior and lateral columns are primarily affected

Neuroimaging

1. T2-weighted sequence hyperintensity that may encompass as long segment
2. Slight gadolinium enhancement
3. Rarely the MRI of the spinal cord is negative

Laboratory Evaluation

1. CSF:
 - a. Slight mononuclear cell pleocytosis and elevation of protein
2. Cell surface antigens are identified with specific syndromes:
 - a. Stiff person syndrome with antiglycine receptor antibodies:
 - i. 5% of SPS is associated with malignancy
 - ii. May have seronegative SPS with malignancy
 - iii. Malignancies are described with SPS and include:
 1. Breast cancer
 2. Lung
 3. Thymoma
 4. Hodgkin's

3. Multiple malignancies have been described in association with subacute myelopathy without the detection of antibodies:
 - a. Hypereosinophilia
 - i. >1,500 eosinophils/mm³
 - b. Associated with:
 - i. Leukemia
 - ii. Stomach carcinoid
 - iii. Colon cancer

Vitamin Deficiencies with Spinal Cord Involvement

B12 Deficiency

General Characteristics

1. Vitamin B12 deficiency is more widespread than generally recognized. It is seen in older patients, pregnant women, vegans and in patients with renal and intestinal disease
 - a. Nitrous oxide depresses methionine synthase, a methylcobalamin-dependent enzyme:
 - i. Exposure to nitrous oxide in:
 1. Anesthesia personnel
 2. Dentists
 3. Drug abusers
 4. Elderly patients that are marginally B12 deficient that get nitrous oxide anesthesia
 - ii. Cause both the anemia and full combined spinal cord degeneration
 1. Usually, they have low levels of B12 but have methylmalonic acid levels

Clinical Manifestations

1. Weakness and extremity paresthesia which occur first in the hands
2. Unsteadiness of gait
3. Weakness and stiffness of the legs that evolves into an ataxic paraplegia
4. Severe loss of vibration sensibility (legs > hands); position is similarly involved
5. Increased reflexes, spasticity, and Babinski signs supervene
6. In general, the process is symmetrical and distal, sensory signs and symptoms precede motor involvement
7. Exclusionary signs for B12 deficiency include:
 - a. Motor signs prior to sensory
 - i. Asymmetry of signs and symptoms
 - ii. Truncal or facial involvement
 - b. Other associated neurological signs and symptoms:
 - i. Behavioral alterations

- ii. Optic neuropathy:
 - 1. Optic atrophy
 - 2. Centrocecal scotoma
- iii. Urinary sphincter and sexual dysfunction
- iv. Cerebellar ataxia

Neuropathology

1. A diffuse degeneration of white matter (demyelination) of the spinal cord and brain
2. Swelling of myelin sheaths by intramyelinic vacuoles with separation of myelin lamellae
3. Vacuolated myelopathy
4. Some axonal destruction
5. Late gliosis of affected areas
6. The process begins in the cervical and upper thoracic segments of the cord and then spreads
7. The optic nerves, chiasms, and central white matter are also affected
8. Posterior and lateral columns of the cord are particularly involved
9. Demyelinating peripheral neuropathy

Neuroimaging

1. MRI T2-weighted sequences demonstrate high-intensity signals in the posterior column and corticospinal tracts
2. May involve long cord segments
3. In acute and severely involved patients the spinal cord is swollen
4. Involvement of anterior columns has been reported
5. Restricted water diffusion in both posterior and lateral columns has been demonstrated on apparent diffusion coefficient maps (ADC maps)
6. Some enhancement with gadolinium due to spinal blood barrier disruption
7. Differential diagnosis of posterior and lateral column involvement on MRI:
 - a. Copper deficiency myelopathy
 - b. Infectious and post-infectious myelopathy
 - c. Multiple sclerosis
 - i. Brain involvement on MRI
 - 1. FLAIR and T2-weighted images
 - ii. High intensity signals in the periventricular white matter

Laboratory Evaluation

1. CSF:
 - a. Usually normal
 - b. Moderate increase in protein
2. Hypersegmented polymorphonucleocytes, macrocytic anemia, and decreased platelets
3. Radio isotope dilution assay for a serum cobalamin level:
 - a. Levels below 100 pg/ml are usually associated with neurologic symptoms
 - b. In 5–10% of patients, a level of 200–300 pg/ml may be pathogenic

4. Increased serum concentrations of methyl malonic acid (normal 73–271 mmol/L) and homocysteine are seen
5. Increased antibodies to intrinsic factor and parietal cells may be detected
6. EMG:
 - a. Slowing of distal sensory conduction
 - b. Some denervation
7. Somatosensory evoked potentials show slowing of central conduction

Vitamin E Deficiency

General Characteristics

1. Genetic form:
 - a. AR; mutations in the TTPA gene that maps to Chromosome 8q12.3
 - b. Encodes for alpha-TTP, a cytosolic liver protein
 - c. Pivotal for intracellular transport of alpha-tocopherol
2. Defect in intestinal absorption
3. Occurs with abetalipoproteinemia
4. Fat malabsorption
5. Cholesteric liver disease
6. Post-gastrectomy

Clinical Manifestations

1. Retinitis pigmentosa
2. Anemia
3. Proximal Myopathy
4. Deafness (rare)
5. Cerebellar and sensory ataxia
6. Cardiomyopathy (rare)
7. Resembles Friedreich's ataxia
8. Ataxia

Neuropathology

1. Degenerations of Clark's and the posterior columns of the spinal cord

Neuroimaging

1. T2-weighted MRI sequence hyperintensities of the posterior columns
2. Cerebellar atrophy

Laboratory Evaluation

1. Low vitamin E levels
 - a. Lipid soluble antioxidant

Spinal Cord Tumors

Overview

General Characteristics

1. Spinal-cord neoplasms may be divided anatomically:
 - a. Intramedullary

- i. Arise from the spinal cord parenchyma
 - 1. Primary
 - 2. Metastatic
- b. Extradural
 - i. Vertebral body origin
 - ii. From tissues or metastases in the epidural space
- 2. In hospitalized patients:
 - a. 5% of tumors are intramedullary
 - b. 40% are intradural and extradural
 - c. Approximately 35% are extradural

Epidural Tumors

General Characteristics

1. The overwhelming majority of tumors that are epidural are metastatic. Multiple myeloma and chordoma are the primary tumors (of the bone) that invade this space
2. Epidural spinal cord compression occurs in approximately 5% of cancer patients
3. 50% of all epidural metastatic lesions are from the lung or breast. Others include:
 - a. Prostate
 - b. Melanoma
 - c. Lymphoma
 - d. GI tract
4. Approximately 70% involve the thoracic cord. 10% the cervical cord and 20% the lumbosacral cord. Lung and breast metastasize to the thoracic spine; colon, prostate, and ovarian tumors to the lumbosacral spine and melanoma to the unusual areas of the spine (in addition to the heart surface, digits and intestinal wall). Metastases may go to any structure
5. Tumors reach the epidural space by:
 - a. Hematogenous spread
 - b. Through Batson's paravertebral plexus (prostate, ovarian, colon)
 - c. Through nerve root exit foramina

Clinical Manifestations

1. Symptoms are primarily related to cord compression:
 - a. Asymmetric spastic weakness
 - b. Sensory level on the trunk (diminished pain and temperature sensibility); posterior column deficits below the lesion (loss of vibration and proprioception)
 - c. Obstipation and ataxia often occur before weakness
 - d. Spastic bladder
 - e. The onset is usually gradual, and progression may be prolonged
 - f. Thoracic lesions often cause asymmetric weakness of the legs
 - g. Foramen magnum compressive lesions cause:
 - i. Pain and stiff neck
 - ii. Atrophy of the hands and posterior neck muscles
 - iii. Paralysis that may be cruciate (arm ipsilateral and leg contralateral) or progressive ipsilateral arm then

the ipsilateral leg, contralateral leg and finally contralateral arm. This depends on the differential involvement of pyramidal fibers at C1–C2. Intracranial spread causes lower cranial nerve and cerebellar dysfunction

- h. Lower thoracic and first lumbar lesions cause:
 - i. Cauda equina and spinal cord symptoms
 - ii. Babinski sign is present
- i. Cauda equina lesions:
 - i. Root pain (often in sciatic distribution (L4–S1))
 - ii. Asymmetric leg weakness
 - iii. Low back pain
 - iv. Involvement of sphincters
- j. Conus medullaris lesions:
 - i. Involve the lower sacral segments of the spinal cord
 - ii. Bowel and bladder sphincter dysfunction are early
 - iii. Back pain
 - iv. Hyperesthesia of sacral nerve roots (may have saddle anesthesia)
 - v. Sensory changes may precede motor involvement
 - vi. Impotence
 - vii. Loss of bulbocavernosus reflex and anal sphincter tone and reflexes
- k. Pain:
 - i. May be unremitting; mechanically sensitive and made worse with recumbency (as opposed to disc pain)
 - ii. Persists with bed rest (putatively related to venous congestion)
- l. Tumors of the thoracic and lumbar cord:
 - i. Induce a very high spinal cord protein
 - ii. Cause hydrocephalus

Laboratory Evaluation

1. CSF:
 - a. Malignant cell determination is directly related to the volume of fluid removed and studied (particularly with carcinomatosis)
 - b. Glucose 30–40 mg% (carcinomatosis)
 - c. Protein of 80–150 mg%
 - d. If the protein is 800 mg to 1000 mg/%, there is a spinal block (Freund's reaction)

Neuroimaging

1. Plain films (metastatic disease):
 - a. Pedicle involvement
 - b. Erosion of the end plates
 - c. Central vertebral body lesions
 - d. In general, bone involvement is cancer; disc involvement is infection
- e. MRI evaluation of metastatic disease of the vertebrae:
 - i. Multiple areas of T1-weighted sequences of low-density areas in the vertebrae
 - ii. Pathologic fractures

- iii. Osteoblastic bone changes:
 1. Rarely myeloma
 2. Prostate cancer
 3. Hodgkin's (marble vertebrae); extremely dense
 4. Rarely breast cancer
- iv. Cancer does not invade the disc space
- v. Increased density of the dura or enhancement in the CSF space between cerebellar folia suggests associated carcinomatosis of the meninges

Primary Tumors of the Vertebral Column with Secondary Epidural Compression

Multiple Myeloma

General Characteristics

- a. The skull and vertebral bodies are primarily involved
- b. Cranial lesions are primarily in the vault
- c. Predilection for the bones of the thoracic cage
- d. Plasma cell tumors, both plasmacytoma and plasmamyeloma, may be associated with HIV infection

Clinical Manifestations

- 1. Vertebral compression fractures with cord compression occur in 10% of patients
- 2. Rare necrotizing myelopathy

Neuropathology

- 1. Multiple myeloma is a tumor of monoclonal plasma cells
- 2. Expands primarily in the bone marrow
- 3. Produces a monoclonal antibody

Neuroimaging

- 1. MRI is standard for the evaluation of bone marrow infiltration
- 2. PET coupled with CT (PET/CT) demonstrates the extent of lesions throughout the body and is the best tool to distinguish active from the inactive disease

Laboratory Evaluation

- 1. 10% or more clonal plasma cells are demonstrated on bone marrow biopsy
- 2. Biopsy proven plasmacytoma plus evidence of associated end-organ damage
- 3. In the absence of end-organ damage, 60% or more of clonal, plasma cells in the marrow is diagnostic

Plasmacytoma

General Characteristics

- 1. May affect the CNS, the nasopharynx, upper respiratory tract, lymph nodes, gastrointestinal tract, testicles and soft tissue
- 2. Plasmacytomas are malignant proliferations of plasma cells that can occur with different plasma cell dyscrasia

Clinical Manifestations

- 1. May occur as solitary intracerebral lesions
- 2. Intraparenchymal spinal cord mass
- 3. The most common spinal cord lesion is involvement of the vertebral bodies with extradural compression

Neuropathology

- 1. Plasmacytomas may be associated with localized amyloid deposits
- 2. A mass of monoclonal neoplastic plasma cells
- 3. Associated histologically with follicle formation and fibrosis

Neuroimaging

- 1. MRI: Bulky soft tissue mass and isointense signal on T2-weighted images due to high cellularity

Laboratory Evaluation

- 1. Production of monoclonal immunoglobulins

Chordoma

General Characteristics

- 1. Constitute 2–4% of primary bone neoplasms
- 2. Intracranial chordomas are present at a younger age than those in the spine
- 3. Vertebral tumors occur between 40 to 50 years of age
- 4. Tumors occur where vestiges of the notochord remain. These encompass the sacrococcygeal, spheno-occipital and bones merge
- 5. Vertebral chordomas:
 - a. Noted anywhere along the spinal canal lumbar > cervical > thoracic spine
 - b. Rare reports of intradural extraosseous chordomas that are usually ventral
- 6. Slow aggressive local growth with a low and late tendency to metastasize
 - a. Approximately 40–60% metastasize over the course of the illness

Clinical Manifestations

- 1. Sacrococcygeal chordoma:
 - a. Pain
 - b. Sphincter incontinence
 - c. Mass over the coccyx
 - d. Radicular sciatic pain
- 2. Vertebral chordomas
 - a. Spinal cord compression with lower extremity weakness, pain (radicular) and bowel and bladder sphincter disturbance

Neuropathology

- 1. Hallmark is physaliphorous cells (bubble cytoplasm); other cells have a solid, eosinophilic cytoplasm
- 2. A lobular pattern from fibrous septae that extends through the tumor

3. MicroRNA-608 and 34a
 - a. Regulate chordoma malignancy in targeting EGFR, Bcl-XL and MET genes

Neuroimaging

1. Vertebrae are irregular (some remodeling)
2. MRI:
 - a. Hypo- or isointense on T1-weighted images; the lesions on T2-weighted sequences are hyperintense
 - b. May calcify and hemorrhage
 - c. Vertebral chordomas tend to extend posteriorly and compress the cord

Laboratory Evaluation

1. Biopsy of the tumor
2. PDGFR-B may be elaborated by the tumor
3. Chordomas usually stain positive for cytokeratin and epithelial membrane antigen

Intradural Extramedullary Tumors

Overview

Intradural extramedullary tumors are primarily neurofibromas and meningiomas. They comprise approximately 50% of all intraspinal tumors. Neurofibromas are primarily in the thoracic and lumbar segments of the spine while meningiomas occur over all segments. The differential diagnosis of extramedullary tumors include:

1. Neurofibroma
2. Sarcoma
3. Vascular tumors
4. Chordomas
5. Epidermoid
6. Teratomas
7. Dropped metastases from medulloblastoma and pinealoma
8. Meningioma
 - a. Extremely rare in the thoracic cord of men

Neurofibroma

General Characteristics

1. Spinal neurofibromatosis is a form of neurofibromatosis type I
2. It affects all spinal roots and may involve all major peripheral nerve branches with or without other systemic manifestations of NF1
3. Genetics:
 - a. NF1:
 - i. AD; associated with germline mutations in chromosome 17q 11.2 of the NF1 gene
 - ii. Encodes neurofibromin:
 1. Involved in the regulation of several cellular signaling pathways (RAS/MAPK)

2. RAS/mitogen-activated protein kinase (MAPK) pathway is pivotal in embryonic and postnatal development
3. NF2 genetics:
 - a. AD; chromosome 22
 - b. Encodes merlin
 - i. Merlin inhibits signaling by integrin and tyrosine receptor kinases (RTKs)

Clinical Manifestations

1. Diagnostic criteria include:
 - a. NF1:
 - i. Six or more café-au-lait spots; greater than two neurofibromas of any type
 - ii. Plexiform neurofibroma
 - iii. Freckling in the axillary or inguinal region
 - iv. Optic glioma
 - v. Sphenoid dysplasia, absence or thinning of long bone cortices with or without pseudoarthrosis
 - vi. First degree relative with NF1
 - b. Neurologic Manifestations of NF1:
 - i. Gliomas and astrocytomas (often midline)
 - ii. Low-grade optic nerve glioma
 - iii. Neurofibroma and plexiform neurofibroma involve peripheral nerves and nerve sheaths
 - iv. Plexiform neurofibromas:
 1. Cause radicular signs and symptoms
 2. Are more frequent in the lumbosacral plexus
 3. Neurofibrosarcoma may develop de novo or from sarcomatous degeneration of a pre-existing plexiform neuroma
 4. Oval shaped tumors that may extend into the spinal canal and compress the spinal cord

Neuropathology

1. The nerve tumors are a combination of fibroblasts and Schwann cells. The predominance of cell types determines whether the tumor is a neurofibroma or schwannoma
2. Both have palisading of nuclei and Verocay bodies
3. Rarely differentiated nerve cells are seen along spinal roots or sympathetic chains which form a ganglioneuroma
4. Malignant degeneration of the tumors occurs in 2–5% of cases:
 - a. Peripherally they are sarcomas
 - b. Centrally they are astrocytomas or glioblastomas

Neuroimaging

1. NF1:
 - a. Midline astrocytomas and gliomas
 - b. Unidentified bright objects (UBO's)
 - i. Non-tumor white matter lesions in the basal ganglia and posterior fossa
 - ii. Diminish with age
 - c. Hydrocephalus
 - d. Dural sac anomalies that may lead to meningoceles

- e. Neurofibroma and plexiform neurofibromas identified by MRI
- f. Osseous lesions include:
 - i. Thoracic scoliosis
 - ii. Posterior scalloping of vertebrae
 - iii. Absence of the sphenoid bone
 - iv. Bowing of the tibia that may cause pseudoarthrosis
 - v. Ribbon ribs
- g. Vasculopathy
- h. Heterogeneity of schwannoma is more than with neurofibroma on T2-weighted MRI sequences enhancement is often a sign of cystic degeneration

Laboratory Evaluation

1. MRI and CT (osseous abnormalities on CT and UBO's of basal ganglia, thalamus, hypothalamus, brainstem and cerebellum)
2. Slit-lamp examination of the irides
3. Visual and auditory evoked potentials (NF1 and NF2)
4. Severe hypertension (urine screen for epinephrine metabolite) to rule out pheochromocytoma

Meningiomas

General Characteristics

1. Genetics:
 - a. The most frequent genetic defects associated with meningiomas are truncating mutations in the neurofibromatosis 2 gene (merlin; chromosome 22q) that occur primarily in fibroblastic and transitional forms
2. Somatic deletions also occur in chromosome 1p, 6q, 9p, 10q, 14q and 18q
3. Epidermal growth factor receptor, P53 and VEGF are expressed by meningiomas
4. VEGF expression may be important in the vascularization of these tumors
5. Some meningiomas contain estrogen and progesterone receptors that may be associated with:
 - a. Increased incidence in women
 - b. Enlargement during pregnancy
 - c. Association with breast cancer (breast cancer metastases to meningiomas)
6. Germline SMARCE1 mutations predispose to both spinal and cranial clear cell meningiomas

Clinical Manifestations

1. Greater than 90% of spinal meningiomas are intradural
2. Rare in the thoracic cord of men
3. Peak incidences are between 40–70 years of age
4. Approximately 80% of spinal meningiomas are in women, and 80% of these are in the thoracic cord
5. Meningiomas (spinal) in men are in the cervical spine and may have an intradural extramedullary configuration
6. Pain in the back (usually central but may have a radicular component) followed by slowly progressive paraparesis

(rarely quadriplegia) sensory loss below the lesions and a neurogenic bladder are common signs and symptoms

7. Recurrence rate after surgery at ten years is less than 0.5%

Neuropathology

1. Origin of the tumor is controversial:
 - a. Arachnoid cap cell (meningothelial cells)
 - b. Dural fibroblasts
 - c. Rarely arise from arachnoidal cells within the choroid plexus that forms an intraventricular meningioma
2. Specific types:
 - a. Meningothelial
 - b. Fibrous (fibroblastic)
 - c. Transitional
 - d. Psammomatous
 - e. Angiomatous
 - f. Clear cell
 - g. Microcystic

Neuroimaging

1. Tendency to calcify and demonstrate extensive vascularity
2. Tumor blush on angiography
3. Homogeneous contrast enhancement on MRI
4. MR spectroscopy of atypical/anaplastic types:
 - a. Restricted diffusion
 - b. Higher Cho/Cr ratio
5. Isointense to spinal cord on T1-weighted and T2-weighted sequences

Laboratory Evaluation

1. Meningothelial cells (MFCo) are the cellular components of the meninges:
 - a. Forms the interface between neuronal tissue and the CSF
 - b. Also a component of the immune response:
 - i. Release proinflammatory cytokines during pathologic stress

Intramedullary Tumors of the Spinal Cord

General Characteristics

1. Ependymoma comprise approximately 60% of primary spinal cord neoplasms. Astrocytomas make up approximately 25%, and oligodendrogliomas are rare
2. The remaining 15% are non-gliomatous and include:
 - a. Lipomas
 - b. Epidermoids
 - c. Dermoids
 - d. Chordomas
 - e. Schwannomas
 - f. Hemangioblastomas
 - g. Hemangiomas
 - h. Meningiomas (rare)
3. There is an association of both gliomatous and non-gliomatous spinal cord tumors with syringomyelia
4. Intramedullary metastasis occurs and is primarily from bronchogenic carcinoma of the lung

Clinical Manifestations

1. Motor, sensory and sphincteric signs and symptoms are dependent on compression and destruction of specific tracts
2. Pain is common in almost all intramedullary tumors and is most common with tumors of the filum terminale
3. Ependymomas and astrocytomas often cause:
 - a. Asymmetric spastic paraparesis
 - b. Sensory level on the trunk primarily to pain and temperature
 - c. Sphincteric disturbance primarily of the bladder
 - d. If the central gray matter is involved, the patient may present with a syringomyelic pattern which exhibits:
 - i. Segmental or dissociated sensory loss; pain and temperature > vibration and position sense
 - ii. Amyotrophy of the involved segments
 - iii. Incontinence
 - iv. Late corticospinal tract involvement
 - v. Sacral sparing of sensation (sacral root representation lateral in the spinothalamic tract)
 - vi. Dissociation of pain and temperature from tactile modalities over several contiguous segments on the trunk
 - vii. Extramedullary tumors rarely give a similar clinical picture

Neuropathology

1. Dependent on the specific etiology

Neuroimaging

1. Enlargement of the involved spinal cord segment
2. Low signal on T1-weighted sequences with blurred tumor cord boundaries; high signal intensity on T2-weighted sequences
3. Peritumoral cysts are common with ependymomas and astrocytomas
4. Most tumors enhance although some astrocytomas do not
5. Ependymomas tend to be central in the cord while astrocytomas may be eccentric
6. Hemangioblastoma is associated with cord swelling and homogeneous contrast enhancement

Laboratory Evaluation

1. Froin's reaction in the CSF:
 - a. The CSF is blocked by swelling of the intramedullary tumor
 - b. The CSF under the blocks:
 - i. Xanthochromic
 - ii. Has an extremely high protein (500 to 1000 mg%)
 - iii. Clotting of the protein may occur

Spinal Ependymoma*General Characteristics*

1. Develop most often in children, adolescents, and young adults

2. Spinal cord ependymomas occur in an older age group (mean age of 40 years)
3. The frequency is equal between males and females
4. Ependymomas are the most common neuroepithelial tumor:
 - a. Most frequent sites are cervical and cervicothoracic segments, the lumbosacral area and the cauda equina
 - b. Ependymomas of the conus medullaris, cauda equina, and filum terminale are considered a separate entity
 - c. Ependymomas may be seen in extraneural areas that include soft tissue, ovary, and mediastinum. Mechanisms include:
 - i. Metastases
 - ii. Direct extension from a primary tumor
 - iii. Primary presacral, pelvic, thoracic or abdominal tumors
 - iv. Primary neoplasm of the sacrococcygeal region

Clinical Manifestations

1. Syringomyelic syndrome
2. Compressive and radicular syndromes
3. Cauda equina syndrome:
 - a. Back pain with L4–S3 root pain
 - b. Asymmetric motor and radicular sensory loss
 - c. Areflexia
 - d. Sphincter disturbances
4. Conus medullaris syndrome:
 - a. Early sphincter disturbance that is severe
 - b. Impotence
 - c. Minimal motor dysfunction
 - d. Symmetric sacral root sensory loss
 - e. Loss of anal and bulbocavernosus reflexes
5. Tumors of the thoracolumbar cord may be associated with hydrocephalus
6. Sensory symptoms may precede motor and reflex changes
7. Pseudotumor cerebri presentation has been reported (possibly due to the usually high protein that blocks CSF reabsorption by the Pacchionian granulations)

Neuropathology

1. The tumors arise from the ependymal lining of the central canal
2. Rosettes are seen in differentiated tumors
3. Perivascular pseudorosettes are not as diagnostic
4. Neoplastic ependymal cells may form tubules and canals or line irregular or slit-like cavities
5. The tumor demonstrates a glial fibrillary background
6. Histological variants include:
 - a. Papillary
 - b. Cellular
 - c. Clear cell

Neuroimaging

1. Spinal cord swelling
2. Contrast enhancement on MRI (homogenous)
3. Tumor is located in the center of the cord

4. Intracranial metastases are the most common site for myxopapillary ependymoma; metastases may be delayed

Laboratory Evaluation

1. Loss of DNA from 22q (NF2 gene)

Spinal Astrocytoma

General Characteristics

1. Peak incidence is in the 3rd to 5th decade
2. 30 years of age for high-grade astrocytomas and 40 years for lower grades. Approximately 75% are low grade
3. Malignant forms are more common in adults than children
4. Approximately 70% are thoracic

Clinical Manifestations

1. Localized back pain:
 - a. May be increased with recumbency; patients may sleep sitting up (tumor blocks venous drainage)
 - b. Malignant astrocytomas may have leptomeningeal spread
 - c. Asymmetric progressive weakness
 - d. Paresthesias > pain
2. C-scoliosis (asymmetric growth which destroys ipsilateral paraspinal muscles)
3. Relentlessly progressive course

Neuropathology

1. Consistent tendency for diffuse infiltration
2. No mitotic activity (low-grade tumors)
3. Occasional cysts (intratumoral)
4. Variants are determined by size, prominence and disposition of cell processes. The major types include:
 - i. Fibrillary
 - ii. Gemistocytic
 - iii. Protoplasmic

Neuroimaging

1. Enhancement patterns on MRI:
 - a. Focal nodular enhancement
 - b. Patchy enhancement
 - c. Inhomogeneous diffuse enhancement
 - d. 20–30% do not enhance
2. Diffuse cord swelling
3. Eccentric growth

Laboratory Evaluation

1. Anaplastic astrocytomas undergo p53 mutations
2. Duplication of 3pter and deletion of 21qter
3. Loss of 17p DNA

Pilocytic Astrocytoma

General Characteristics

1. May occur solo laterally and at different sites in the CNS (usually in association with NF1)

2. 75% manifest in patients < 20 years of age (8–13 years is peak incidence)
3. Spinal cord involvement manifests at a later age than optic nerve/chiasm or cerebellar disease
4. There is no progression to a malignant astrocytoma

Clinical Manifestations

1. Depends on the level of spinal cord involvement
2. Usually severe visual loss with the optic nerve and chiasmal variant

Neuropathology

1. Astrocytes with thin processes that are packed with intermediate filaments
2. Tumor tissue forms a radially oriented mass around blood vessels
3. Rosenthal fibers are present and are a morphological hallmark of the disease

Neuroimaging

1. MRI:
 - a. Lesions are hypo- or isointense on T1-weighted images and hyperintense on T2-weighted images
 - b. Fusiform enlargement of the optic nerve
 - c. Spinal cord lesions appear as a fusiform enlargement over several segments usually within the central cord
2. PET scans show increased glucose utilization

Laboratory Evaluation

1. Pilocytic astrocytomas are driven by the mitogen-activated protein kinase/extracellular signal-regulated kinase pathway
2. Tandem duplication of 7q34 encodes BRAF which produces KIAA1549-BRAF novel oncogenic fusions

Hemangioblastoma

General Characteristics

1. Spinal cord hemangioblastomas in Von Hippel-Lindau disease (VHL) are often multiple
2. Develop most commonly in the posterior fossa; approximately 3% are in the spinal cord
 - a. A rare site is dorsally at the cervicomedullary junction

Clinical Manifestations

1. May occur sporadically as well as with VHL syndrome
2. Usually, there are subtle long tract motor and sensory signs
3. Hemorrhage may cause hematomyelia with quadraparesis
4. An intrasyrinx hemorrhage with hemangioblastoma has been reported in one patient
5. May occur on nerve roots; bleeding causes cord compression

Neuropathology

1. Hemangioblastomas are well circumscribed but unencapsulated

2. They are cystic
3. The solid part of the tumor is composed of blood vessels lined by a single layer of endothelium
4. Stromal cells contain lipid droplets

Neuroimaging

1. In sporadic patients:
 - a. Cyst with a mural nodule
 - b. Some are purely solid
 - c. MRI:
 - i. Spinal cord swelling
 - ii. Homogeneous enhancement

Laboratory Evaluation

1. VHL gene on chromosome 3p25-26

Intramedullary Metastasis

General Characteristics

1. Accounts for approximately 5% of spinal tumors in cancer patients
2. Lung > breast > lymphoma > colorectal > head and neck > renal
3. Most are hematogenous; rarely growth is into the center of the cord from the meninges
4. Approximately 50% of spinal metastases are associated with brain metastasis
5. The conus medullaris is the most common site
6. Approximately 10% are multi-level
7. Occur in up to 8% of patients with non-Hodgkin's lymphoma; 70% of patients with leukemia
8. Risk factors for leptomeningeal spread of non-Hodgkin's lymphoma are:
 - a. Bone marrow and testicular involvement
 - b. Extranodal spread
 - c. Epidural metastasis
 - d. Lymphoblastic histology
9. General rule:
 - a. Primary lymphomas are parenchymal with leptomeningeal spread
 - b. Systemic lymphoma are meningeal with secondary parenchymal spread
10. Most common solid tumors causing infiltration of the arachnoid and pia mater with subsequent intramedullary invasion are:
 - a. Lung
 - b. Breast
 - c. Melanoma
 - d. Gastrointestinal tumors

Clinical Manifestations

1. Rapid progression of clinical signs
2. Weakness, ataxia, sensory level on the trunk (spinothalamic modalities)
3. Sphincter disturbance
4. Syringomyelic presentation (dissociated sensory loss)
5. Weakness is asymmetrical

Neuroimaging

1. MRI:
 - a. Intramedullary swelling of the affected segment
 - b. High-intensity signal on T2-weighted images
 - c. Contrast enhancement

Neuropathology

1. Dependent on tumor type

Laboratory Evaluation

1. Biopsy of systemic tumor
2. Cytology of CSF cells
3. CSF of associated carcinomatosis:
 - a. Flow cytometry
 - b. Histology of tumor cells
4. Protein 80–150 mg%
5. Glucose 30–40 mg%

Differential Diagnosis of Intramedullary Metastasis

1. Meningeal carcinomatosis
2. Paraneoplastic necrotizing myelopathy
3. Radiation myelopathy
4. Inflammatory demyelinating disease
5. Syringa

Differential Diagnosis of Extremely Rare Tumors of the Spinal Cord

1. Oligodendroglioma
 - a. Less than 3% of intracranial neoplasms
 - b. The majority of tumors in adults occur in adults between the 4th and 5th decade
 - c. Extremely rare in the spinal cord
2. Medulloblastoma
 - a. Approximately 20–25% occur after age 20; male > female, 1.6:1
 - b. Origin is most frequently the roof of the IVth ventricle (superior medullary velum)
 - c. Metastasize to the spinal cord via CSF pathways
3. Intravascular Malignant Lymphomatosis
 - a. A rare form of malignant lymphoma
 - b. Selective growth of lymphoma cells within the lumina of vessels without the involvement of adjacent parenchymal tissue
 - c. Predominantly B-cell lineage
 - d. A disease of middle age and elderly patients (61 years median age)
 - e. 34% of patients have myelopathy
 - f. Occludes and infarcts spinal vessels
4. Ganglioma
 - a. Most tumors develop in the temporal lobe
 - b. 20–50% arise in the spinal cord
 - i. Any site may be the origin including the conus medullaris
 - ii. Usual sites:

1. Cervicothoracic > thoracolumbar > multiple spinal cord segments
- c. May be associated with migration defects
5. Gangliocytoma:
 - a. Site of origin is the cerebrum and cervicothoracic spinal cord
 - b. Clinically symptomatic by age 30
 - c. Slowly evolving long tract signs
 - d. Increased number of abnormal neurons
6. Central neurocytoma:
 - a. A rare neuronal tumor; extraventricular neurocytomas putatively originate from bipotent progenitor cells, i.e., the potential for neuronal and glial differentiation
 - b. Large well-circumscribed lesions usually in the cerebral hemispheres (frontal and parietal lobes) but also occur in the spinal cord
 - c. There may be craniospinal dissemination
 - d. Tumors occur in the cervical spinal cord
7. Central Neuroblastoma
 - a. Ganglion cell differentiation occurs in 50% of patients
 - b. Age of onset is approximately 13 years (has been described into the 8th decade)
 - c. Rarely involves the spinal cord and cauda equina
8. Intramedullary Meningioma of the Spinal Cord
 - a. Differential diagnosis:
 - i. Atypical ependymoma
 - ii. Astrocytoma
9. Intradural extramedullary hemangiopericytoma
 - a. May arise from spinal pial capillaries
 - b. Radiographically mimics nerve sheath tumors
10. Diastematomyelia with embryogenic spinal cord
 - a. Diastematomyelia:
 - i. An occult spinal dysraphism characterized by clefting of the spinal cord by a fibrous band
 - ii. Associated with:
 1. Vertebral bony abnormalities
 2. Cutaneous lesions
 3. Myelomeningocele
 4. Hydrocephalus
 5. Hydromyelia
 6. Chiari malformation
 7. Kippel-Feil syndrome
 - iii. Association with dysembryogenic spinal cord tumors in adults is rare (approximately 20 reported patients)

Rare Benign Intramedullary Spinal Tumors

General Characteristics

1. These tumors comprise less than 1% of primary spinal tumors
2. They are usually found in the lumbar area associated with skeletal and skin stigmata which include:

- a. Spinal bifida
- b. Posterior dermal sinuses (primarily in children)
- c. Dimple in or off the midline
- d. Hypertrichosis (hair is thick)
- e. Cutaneous angioma
- f. Pigmented skin
3. Intraparenchymal associations:
 - a. Diastematomyelia
 - b. Syringomyelia
 - c. Tethered cord
 - d. Dermal sinus tract
 - e. Spinal dysraphism
4. Major tumors are:
 - a. Lipoma
 - b. Epidermoid
 - c. Dermoid
 - d. Teratoma

Clinical Manifestations

1. Due to the underlying associated features
2. Lipomas may degenerate into sarcoma and infiltrate the cauda equina

Neuropathology

1. Dependent on tumor type

Neuroimaging

1. Lipomas are high signal intensity on T1-weighted sequences and low signal intensity on T2-weighted images
2. Dermoids have mixed signal intensities
3. Epidermoids are bright on T1-weighted images

Laboratory Evaluation

1. Dependent on specific etiology

Differential Diagnosis of Benign Spinal Cord Tumors

Lipoma

General Characteristics

1. Non-dysraphic spinal intramedullary lipomas are extremely rare in adults
2. The majority of patients are children
3. Primarily occur in the dorsal cervical segments
4. Intramedullary lipomas are not associated with spina bifida or cutaneous stigmata

Clinical Manifestations

1. They may present in the 3rd and 4th decade
2. Non-specific dysesthesia
3. Dissociated sensory loss
4. Long tract motor signs occur later in the disease course
5. Not associated with spina bifida or cutaneous stigmata
6. Clinical features associated with extradural sites are:
 - a. Radicular pain and motor loss

- b. Congenital extradural lumbosacral lipomas present with tethered cord symptomatology
 - i. Conus medullaris is the primary site of involvement
- c. Tethered cord intradural lipoma:
 - i. Cervical to lumbar cord in location
 - ii. Dysesthesia pain (non-radicular)
 - iii. Mixed nerve root symptomatology

Neuropathology

1. Lipomas consist of normal mature fat
2. Greater than 50% have tissues that are derived from ectoderm, mesoderm or endoderm

Neuroimaging

1. No bone destruction
2. Lesions are hyperintense on T1-weighted sequences and less intense on T2-weighted images
3. The classic location of spinal lipomas is extradural; they may be intramedullary or a combination of both sites

Laboratory Evaluation

1. Normal CSF unless there is CSF blockage and a Froin's reaction

Dermoid Cyst

General Characteristics

1. Intramedullary dermoid cysts are rare tumors
2. Most are associated with spinal dysraphism and/or sinus tract
3. Intraspinal cysts are most often located in the lumbar and thoracic spinal segments
4. Most common sites of dermoid cysts:
 - a. Scalp; angle of the eye and the retromastoid region
 - b. Intradiploic skull bones
 - c. Suprasellar region or the posterior fossa
 - d. Intraspinal
5. Slow-growing benign lesion; rare malignant transformation to squamous cell cancer

Clinical Manifestations

1. If associated with a dural sinus tract (connects the skin through the dura) recurrent meningitis may occur:
 - a. Organisms reflect skin flora
2. There may be an associated midline skin dimple:
 - a. Below the inguinal crease they end blindly and do not extend intraspinally
 - b. Dimples above the inguinal fold may connect intradurally
 - c. Dermal sinuses are often associated with spinal cord tethering
3. Pes cavus is associated
4. Asymmetry of motor and sensory loss
5. Bladder dysfunction
6. Those that arise in the filum terminale cause symptoms primarily from the concomitant tethered cord

Neuropathology

1. Well demarcated, smooth, round or oval masses
2. Contain thick, cheesy yellowish material from secreted material of the sebaceous glands and desquamated epithelium; hair may be encountered
3. Connection of the dermoid cysts with dermal sinuses occur in the occipital and lumbar regions (route of recurrent bacterial infection)
4. Cholesterol crystals

Neuroimaging

1. MRI:
 - a. Hypointense on T1-weighted sequences; hyperintense on T2-weighted image
 - b. Rarely signals may be heterogeneous and demonstrate high T1-weighted signal intensity with peripheral rim enhancement
- c. DWI:
 - i. Restricted diffusion
 - ii. Arachnoid cysts which may appear similar on conventional MRI have no restricted diffusion

Laboratory Evaluation

1. Rupture into the CSF pathways may cause a severe meningeal reaction with foreign body giant cells

Epidermoid

General Characteristics

1. There is a low incidence of both epidermoid and dermoid cysts in the cervical spinal segments; related to the embryological process of neural tube closure
2. Usual sites of epidermoids:
 - a. Cerebellopontine angle
 - b. Parasellar
 - c. In the bone diploe of the skull
 - d. Rarely; the IVth ventricle, brain stem and the corpus callosum
3. Extremely rare in the spinal cord:
 - a. May extend into the cervical cord from the cerebellopontine angle

Clinical Manifestations

1. Sites:
 - a. Intramedullary
 - b. Intradural
2. Intradural extramedullary type:
 - a. May have bone or skin malformation that include:
 - i. Spina bifida
 - ii. Dermal sinus
 - b. Acquired from LP:
 - i. Epidermal cells are pushed in by the needle
 - c. Varied motor and sensory signs depending on the level of involvement
 - d. Congenital central site may have dissociated sensory loss; lumbar pain
 - e. Sphincter alterations
 - f. Thoracic epidermoid may cause paraplegia

Neuropathology

1. Well demarcated encapsulated mass of varying size
2. Lining of the cyst is composed of stratified squamous epithelium
3. Presence of keratin
4. Desquamation of keratin forms concentric lamellae which fill the interior of the cysts

Neuroimaging

1. Heterogeneity of signal in T1-weighted and T2-weighted sequences
2. Lack of contrast enhancement
3. Re-tethering of the cord after repair of lipomyelomeningocele

Laboratory Evaluation

1. Rupture of the cyst onto the dura or into CSF pathways causes a severe chemical meningitis

Teratoma**General Characteristics**

1. Teratomas are rare germ cell neoplasms composed of mixed parenchymal cells from one or more of the three germ cell layers (ectoderm, endoderm or mesoderm)
 - a. They are classified as immature or mature depending on the degree of maturation of their cellular components
2. They arise from pluripotent cells which can form skin, muscle bone, cartilage, fat, teeth and hair
3. Primary site of origin is the sacrococcygeal area:
 - a. May also occur in midline or paraxial locations
4. May affect any age group but are primarily seen in childhood
5. CNS teratomas are 0.1% of CNS tumors

Clinical Manifestations

1. Extradural teratomas:
 - a. Cord compression
 - b. May extend through the intervertebral foramina
 - c. Back pain
 - d. Radicular symptomatology
 - e. Cauda equina syndrome
2. Intradural extramedullary tumors:
 - a. Insidious onset
 - b. Localized or radicular pain
 - c. Deterioration of gait
 - d. Weakness
 - e. Paresthesias
 - f. Sphincter alteration
 - g. Scoliosis
3. Intramedullary tumor:
 - a. Weakness
 - b. Paresthesias
 - c. Spasticity
 - d. Autonomic dysfunction
 - e. Radiculopathy is rare

Neuropathology

1. Immature teratomas are the most common:
 - a. Contain cellular populations of an embryonic nature
 - b. Primitive neuroepithelial lineages
 - c. Immature cell lineages of one or more the primitive germ layers
2. Malignant teratomas are derived from the yolk sac or endodermal sinus

Neuroimaging

1. Associated:
 - a. Dystrophic states
 - b. Diastematomyelia
 - c. Lipomyelomeningocele
2. CT evaluation:
 - a. Vertebral body erosion
 - b. Displaced pedicles
 - c. Thinned laminae
 - d. Calcification
 - e. Diastematomyelia
3. MRI:
 - a. T2-weighted sequences
 - i. Inhomogeneous mass
 - ii. High signal intensity

Laboratory Evaluation

1. Alpha-fetoprotein is elevated in malignant teratomas
2. Chemical meningitis if contents are spilled into CSF pathways or on the dura with CSF:
 - a. Leukocytosis
 - b. Sterile on culture
 - c. Elevated protein

Metastatic Spinal Cord Tumors**Overview**

Spinal cord metastasis is the most common spinal tumor and can be divided into extramedullary and intramedullary types. Extradural metastases from carcinoma, lymphoma and myeloma are most common. They occur from the extension of a vertebral metastasis, are hematogenously deposited or invade through the intervertebral foramina. Intradural extramedullary metastasis arises primarily from carcinomatosis of the meninges, lymphomatosis or melanoma of the meninges. Characteristic of bony metastasis are:

1. Pedicle and posterior element involvement
2. Mid vertebral body destruction
3. Does not involve the disc space
4. Pathologic fracture

Clinical features of extradural metastasis are primarily compressive. Boring, mechanically sensitive back pain often prominent at night. Ataxia may occur prior to weakness which is usually overshadowed by the weakness. There is

early bladder involvement although obstipation may be noted prior to bladder symptoms. There is a dropped sensory level, particularly when the cervical spine is affected.

Parenchyma metastasis usually demonstrates asymmetric motor weakness and sensory loss (dissociative if central and spinothalamic fibers are involved), less bowel and bladder involvement and sacral sparing.

Specific Tumor Metastatic Patterns

1. Lung:
 - a. Multiple metabolic sites
 - b. Most common in men
 - c. Associated with hemorrhagic intramedullary necrosis
 - d. Direct extension from a sulcal apex lung tumor (Pancoast tumor)
 - e. Almost always concomitant cerebral metastasis
2. GI tract:
 - a. May destroy the sacrum
 - b. If associated with mucinous "signet cell type"
 - i. High incidence of non-bacterial thrombotic emboli (NBTE)
 - c. Often a concomitant dense cerebral lesion
3. Prostate:
 - a. Local lumbosacral nerve root and bone invasion
 - b. Spinal cord and radicular components (T10–L1–L3) roots are involved rather than L5–S1 roots which are involved in mechanical pathologies (spondylosis, disc and spondylolisthesis)
 - c. Slowly progressive
 - d. Petrous apex and posterior fossa involvement occurs by way of Batson's plexus
4. Renal cell:
 - a. Radicular component
 - b. Hemorrhagic cerebral metastasis that is often single
5. Leukemia:
 - a. Involvement of nerve roots and spinal cord compression
 - b. "Marble" vertebrae (dense on spine film; marrow change on MRI)
 - c. Approximately 70% have leptomeningeal spread
6. Lymphoma:
 - a. May infiltrate vertebral body (dense vertebrae)
 - b. Envelops the lumbosacral dura and cauda equina
 - c. Cord compression and nerve root involvement
 - d. Leptomeningeal spread
7. Drop metastasis:
 - a. Medulloblastoma
 - b. Ependymoma

Differential Diagnosis of Intrinsic Vertebral Body Bone Disease (with Spinal Cord Compression)

1. Paget's disease
2. Fibrous dysplasia
3. Brown bone cyst

4. Articular bone cyst
5. Osteosarcoma
6. Ewing's sarcoma
7. Chondrosarcoma
8. Osteosclerotic myeloma (POEM syndrome)
9. Multiple myeloma
10. Osteoid osteoma
11. Hemangioma of bone
12. Eosinophilic granuloma
13. Osteochondroma
14. Osteoporosis
15. Hyperparathyroidism
16. Ankylosing spondylitis
17. Vitamin deficiency (usually Vitamin D)
18. Osteomalacic syndromes
19. Prolonged IV heparin ("fish-mouth" vertebrae)
20. Chordoma

Paget's Disease

General Characteristics

1. Increased bone resorption followed by increased bone formation
2. Convex masses of partially calcified osteoid tissue project from the vertebral bodies to paravertebral regions
3. Weakened vertebrae may suddenly collapse:
 - a. Lumbar > thoracic levels
 - b. With spinal cord compression 3–5 vertebrae are involved

Clinical Manifestations

1. Usually a slow progression of disease over 6–12 months
2. Sensory loss and weakness occurs early; then spasticity and bowel and bladder involvement
3. Lumbar involvement may be of single vertebrae
4. Cervical involvement is rare
5. Sarcomatous transformation:
 - a. Occurs in skull or spine
 - b. Affects less than 1% of patients
 - c. Malignant degeneration of a vertebrae is rare
6. Associated features:
 - a. Benign giant cell tumor
 - b. Atlantoaxial fracture dislocation
 - c. Epidural calcification
 - d. Extramedullary hematopoiesis

Osteosarcoma

General Characteristics

1. Young patients
2. Long bones are the preferred sites; distal femur most commonly affected

Clinical Manifestations

1. Rare in vertebral bodies (15%)

Osteochondrosarcoma*General Characteristics*

1. Young patients

Clinical Manifestations

1. Painful
2. Rapid progression
3. Brainstem compression
4. Cervical vertebrae are affected
5. Petroclival suture

Neuroimaging

1. Cauliflower appearance (plain x-ray)

Multiple Myeloma*General Characteristics*

1. Multiple vertebrae are involved
2. Severe anemia

Clinical Manifestations

1. Multiple levels are involved
2. Osteoblastic bone lesions
3. Moth-eaten low density lesions on T1-weighted images

Osteoblastic Monostatic Myelomas*General Characteristics*

1. One vertebral body involved
2. May be any bone in the body or any vertebral level

Clinical Manifestations

1. Motor-sensory neuropathy
2. POEMS syndrome:
 - a. Polyneuropathy
 - b. Organomegaly
 - c. Endocrinopathy
 - d. Skin lesions

Eosinophilic Granuloma*General Characteristics*

1. Young patient (10–20 years of age)
2. Involvement of proximal humerus, skull and thoracic spine

Clinical Manifestations

1. Sudden vertebral collapse with spinal cord compression

Neuroimaging

1. Clean punched out oval lesions

Osteochondroma*General Characteristics*

1. Long bones are involved
2. Most often asymptomatic

Clinical Manifestations

1. Associated with syndromes that may affect the spinal cord
2. Bannayan-Zonana syndrome (AVM of the cord)
3. Gardner's syndrome

Giant Articular Bone Cyst*General Characteristics*

1. Often asymptomatic
2. Occur in thoracic vertebrae

Clinical Manifestations

1. Collapse of vertebrae with radicular symptoms
2. Rarely spinal cord compression

Hemangioma of Bone*General Characteristics*

1. Often multiple; uncommon in thoracic vertebral bodies
2. Extremely vascular tumors

Clinical Manifestations

1. Compresses the spinal cord by vertebral fracture and consequent hematoma
2. May become symptomatic with minor trauma

Neuroimaging

1. Reticulated pattern on CT
2. High intensity signal on T2-weighted sequences

Osteoid Osteoma*General Characteristics*

1. Most common in long bones; wrist is frequently involved

Clinical Manifestations

1. Locally painful
2. Affects the posterior vertebral body elements (pedicle and facets similar to metastatic disease)
3. Pain responds better to aspirin than narcotics
4. Frequent muscular atrophy that overlies the lesion:
 - a. Imaging evaluation:
 - i. Affects posterior elements of the vertebral body

Hyperparathyroidism*General Characteristics*

1. Prominent in renal failure (secondary forms)

Clinical Manifestations

1. Muscle symptoms-pain, aches and proximal weakness
2. Bone vertebral collapse
3. Diffuse involvement and weakening of the vertebral column

Ankylosing Spondylitis*General Characteristics*

1. Asymmetrical large joint arthritis

2. Plantar fasciitis
3. Sacroiliitis (often the first joint affected)

Clinical Manifestations

1. Worse in the morning
2. Anterior uveitis (associated)
3. Severe restriction of spinal movement
4. Falls (primarily neck extension) associated with quadriga- and paraparesis

Neuroimaging

1. Bamboo spine (posterior and anterior ligament calcification)
2. Dural ectasia
3. Cysts of lumbosacral nerve roots

Forester's Disease (Diffuse Idiopathic Hyperostosis)

General Characteristics

1. Bridging osteophytes between vertebrae
2. Osteoporotic vertebral bodies

Clinical Manifestations

1. Restriction of spinal movement
2. Spinal cord and root compression

Osteoporosis

General Characteristics

1. Decrease of the mineralized bone matrix without abnormality of bone cell populations or mineral metabolism
2. Vertebral compression fracture (anterior wedge) with minimal trauma
3. Fractures of proximal femur and distal radius

Clinical Manifestations

1. Vertebral compression fracture:
 - a. Local pain for 2–3 months
 - b. Thoracic spine anterior wedging causes dorsal kyphosis
 - c. Lumbar pain is induced from compensatory lumbar hyperlordosis
 - d. Neurologic deficits are rare (need to rule out underlying metastasis if present)
 - e. Back pain without radiographic evidence of fractures are possibly microfracture

Vitamin D Deficiency

General Characteristics

1. Occurs in a setting (in developed countries) of:
 - a. Kidney failure
 - b. Dilantin use
 - c. Dietary causes

Clinical Manifestations

1. Severe bone pain affecting the pelvic girdle

2. Associated proximal muscle weakness of the pelvic girdle > shoulder girdle

IV Heparin Therapy

General Characteristics

1. Thoracic vertebral deformity (fish mouth)

Clinical Manifestations

1. Local pain
2. Heparin use for longer than two weeks
3. Rare vertebral body collapse

Scoliosis

General Characteristics

1. Adult scoliosis:
 - a. A spinal deformity with a Cobb's angle on frontal plane equal or greater than 10° in an adult patient whose skeletal maturity is complete
2. Possibly effecting 1.4–12% of patients worldwide
3. Some neurologic deficit is related to herniated disc fragments
4. Treatment is required for less than 10% of those with curves greater than 10 degrees
5. Complication rate from surgery is high and approximate 25% of patients require a second operation
 - a. Especially for those patients undergoing posterior fusion with instrumentation

Clinical Manifestations

1. Pain (sciatic at the bottom of the curve)
2. Sagittal imbalance
3. Claudication upon standing or walking
4. Irritation of individual roots
5. Causa equina syndrome
6. Spasticity with paraparesis
7. Bladder tends to be spared

Neuropathology

1. Secondary degenerative scoliosis:
 - a. Trauma
 - b. Vertebral fracture
 - c. Osteoporosis
 - d. Metabolic bone disease
 - e. Iatrogenic causes
2. Due to asymmetric loading which causes segmental instability from:
 - a. Intervertebral disc and/or facet joint degeneration
 - b. Osteophyte formation at the facet joint (spondyloarthritis)
 - c. Eburnation at the endplate (spondylosis)
 - d. Hypertrophy and calcification of the ligamentous flavum
 - e. May cause spinal stenosis and facet hypertrophy
 - f. The curvature apex demonstrates synovitis and arthritis

Neuroimaging

1. Bone edema lies in the middle and inner part of the affected vertebrae (the scoliotic spine is C-shaped)
 - a. Due to trabecular microfractures
 - b. Bone remodeling due to excess loading of this component of the vertebrae

Thoracic Spine Kyphoscoliosis*General Characteristics*

1. In the past tuberculosis and poliomyelitis were major causes
2. Associated anomalies:
 - a. Hemivertebrae
 - b. Absence of ribs
 - c. Diastematomyelia
 - d. Myelomeningocele
 - e. Klippel-Feil deformity
 - f. Sprengel's deformity (occurs with Klippel-Feil)
 - g. Arnold-Chiari malformation
3. Kyphoscoliosis occurs in patients with hydrocephalus that is unrelated to congenital spine defects

Clinical Manifestations

1. Similar to those of scoliosis
2. Complications following surgery:
 - a. Halo-femoral or halo-pelvic traction
 - i. Cranial nerve palsies involving VI, IX, X, XI (cervical kyphoscoliosis)
3. Brachial plexus traction injury
4. Horner's syndrome
5. Myelopathy with motor and sensory deficits
6. Instrumentation:
 - a. Paraplegia
 - b. Anterior spinal cord syndromes
 - c. Urinary dysfunction

Neuropathology

1. Acquired kyphoscoliosis of the thoracic spine is from:
 - a. Infection of the vertebral body, lamina or pedicles
 - b. After laminectomy for tumor
 - c. Syringomyelia

Neuroimaging

1. Similar to that of scoliosis

Laboratory Evaluation

1. Awareness and follow-up of complications following surgery (principally that with instrumentation):
 - a. Pedicle screw impinging on a nerve root
 - b. Infection (sed rate and CRP are elevated)
 - c. Lack of fusion with hyperinstability and spondylolisthesis

Extramedullary Hematopoiesis*General Characteristics*

1. Ectopic extramedullary hematopoiesis is the formation of blood cells outside of the bone marrow

2. Associated with:
 - a. Thalassemia
 - b. Polycythemia Vera
 - c. Myelofibrosis
 - d. Hemolytic anemia
 - e. Hemoglobinopathies

3. Can involve the liver, spleen thorax and lymph nodes
4. Involves paraspinal tissues with extension and involvement of the spinal canal

Clinical Manifestations

1. Compressive signs and symptoms:
 - a. Paraparesis, sensory impairment and sphincter dysfunction
 - b. Paraplegia and quadriplegia

Neuropathology

1. Compensatory mechanisms to sustain erythropoiesis
2. Hematopoietic precursor cells in the local extradural space which proliferate with the stress of chronic anemia
3. Spread of activated precursor cells into the epidural space from a paravertebral mass

Neuroimaging

1. The signal characteristics of the lesion on MRI depend on the presence of blood products (iron in ferrous/ferric states)
2. The signal intensity on T1 and T2 changes depending on the presence of deoxyhemoglobin, methemoglobin, hemosiderin or a combination of these elements
3. MRI
 - a. Isointense lobulated mass on both T1-weighted and T2-weighted sequences

Laboratory Evaluation

1. Investigation of the cause for the usual chronic anemia

Epidural Lipomatosis*General Characteristics*

1. Spinal epidural lipomatosis is an abnormal accumulation of unencapsulated epidural fat
2. It can be divided into idiopathic and secondary and genetic forms
3. It can be a component of mutations in the phosphatidylinositol/AKT/mTOR pathway that includes:
 - a. Fibroadipose overgrowth
 - b. Hemihyperplasia-multiple lipomatosis (HHML)
 - c. Congenital lipomatous overgrowth
 - d. These fat overgrowth syndromes overlap with:
 - i. Vascular malformations
 - ii. Epidermal nevi
 - iii. Scoliosis/skeletal and spinal (CLOVES) syndrome
 - iv. Macrodactyly
 - v. Megalencephaly syndrome

- vi. All of the above syndromes have adipose dysregulation
- 4. Secondary forms include:
 - a. Prolonged administration of steroids
 - b. Endocrinopathies
 - c. Cushing's syndrome
 - d. Obesity

Clinical Manifestations

1. Occurs primarily epidurally in the thoracic and lumbar cord
2. Back pain
3. Radicular and slowly compressive myelopathy
4. Male predominance
5. Cauda equina syndrome

Neuropathology

1. Accumulation of normal unencapsulated epidural fat
2. Spontaneous regression has been reported

Neuroimaging

1. Epidural mass lesion of thoracic and lumbar spine
2. High-intensity signal on T1-weighted sequences; much-diminished signal on T2-weighted sequences

Laboratory Evaluation

1. Medical evaluation for underlying endocrinopathy
2. Awareness of the PIK3CA overgrowth spectrum

Differential Diagnosis of Intrinsic Disc Disease with Spinal Cord Involvement

1. Extruded disc fragment (though the posterior longitudinal ligament)
2. Free fragment disc (may migrate)
3. Relapsing polychondritis (autoimmune disc destruction)
4. Ochronosis (homogentisic aciduria)
5. Collagen gene defects (COL A 1–5)
6. Ehlers-Danlos (type IV) syndrome
7. Marfan's syndrome
8. Tuberculosis
9. SBE (staph aureus; acute post-operative infection)
10. Charcot joint (disc destruction):
 - a. Syphilis
 - b. Diabetes mellitus
 - c. Amyloid
 - d. Syringomyelia
11. Gram-negative infections (usually occurs late following surgery)
12. Trauma (exacerbates the existing disc dysfunction; does not cause degenerative disc disease)
13. Fungal infection:
 - a. Nocardia
 - b. Cryptococcus
 - c. Blastomycosis
 - d. Coccidioidomycosis (from contiguous sacroiliac infection)

Disc Disease

General Characteristics

1. Central disc protrusion may compress the spinal cord acutely or chronically at cervical, thoracic and lumbar levels
2. Most dangerous area is the thoracic cord due to the small diameter of the spinal canal at this level
3. A disc fragment may erode through the posterior longitudinal ligament and compress the cord; it may migrate rostrally and caudally
4. Radicular symptoms are most often noted ipsilaterally; rarely contralaterally from loss of bilateral foraminal integrity; this may occur with or without cord compression
5. Initial thoracic disc protrusion signs and symptoms:
 - a. Patients legs collapse during heavy lifting
 - b. Severe thoracic radicular pain
6. Central cervical disc rupture is most common at C5–6 and C6–C7 (greatest flexion and extension movement segments)

Clinical Manifestations

1. Incomplete spinal cord injury
2. Brown-Séquard syndrome
3. Anterior spinal artery syndrome
4. May cause pseudo-peripheral sensory loss (cervical disc protrusion usually) in the lower extremities due to spinal cord sensory laminations (ascending leg numbness)
5. Conus medullaris and cauda equina syndromes

Relapsing Polychondritis

General Characteristics

1. Autoimmune disease of cartilage
2. Associated cartilage involvement of the trachea, pinna, and nose
3. Cause of relapsing meningitis

Clinical Manifestations

1. May affect a disc at any level
2. Rare cord compression

Ochronosis

General Characteristics

1. Defect of homogentisic acid metabolism
 - a. AR; Chromosome 18
 - b. Deficiency of Homogentisate 1,2-dioxygenase (HGD) activity that results in the accumulation of homogentisic acid (HGA)
 - c. Oxidation products polymerize and deposit as a melanin-like pigment primarily in cartilage and connective tissue

Clinical Manifestations

1. A progressive disease

2. Darkening of the urine at birth
3. Ochronosis (dark pigmentation of connective tissue) at around 30 years of age (ear and eye)
4. Severe ochronotic arthropathy at approximately 50 years of age
5. Cardiovascular and renal complications
6. Weight bearing joints and the thoracolumbar spine are most often affected
7. Calcification of thoracic disc ("rugger Jersey")
8. Rare neurologic signs

Charcot Joints and Disc – Destruction of the Thoracic Spine

General Characteristics

1. Also known as spinal neuropathic or neurogenic arthropathy
2. Affects the intervertebral disc and the adjacent vertebral bodies
3. Loss of pain and proprioceptive input to the joint
4. Occurs with:
 - a. Spinal cord injury
 - b. Diabetes mellitus
 - c. Amyloidosis
 - d. Syphilis
 - e. Thoracic or cervical syrinx

Clinical Manifestations

1. Proprioceptive pain and temperature loss at affected levels
2. Back pain
3. Progressive thoracic scoliosis
4. Cord compression with quadriparesis or paraparesis, radicular pain, and segmental sensory loss
5. Collagen defects all may have disc capsule defects with extrusion of the nucleus pulposus:
 - a. Marfan's disease
 - b. COL A 1–5 gene defects
 - c. Ehlers-Danlos (type IV)
 - d. Osteogenesis imperfect

Infections of the Disc Space

Overview

General Characteristics

1. Exquisite pain with movement or vibrating the patients' bed
2. Frequent radicular pain
3. High sedimentation rate
4. Local pain at the level of involvement
5. Involvement of the pre- and postvertebral fascia is common; may extend over several segments
6. Usually, only one disc level is involved; arteries that supply the disc are end arteries
7. Paravertebral muscle involvement:
 - a. Common in the iliopsoas (cold abscess) at L1–L3 levels in American patients with tuberculosis

- b. Asian patients with tuberculosis tend to have cervical involvement
8. SBE with septic emboli:
 - a. Tend to deposit at T4 level (watershed)
9. Post-surgical procedures

Clinical Characteristics of Specific Infections of the Disc Space

1. *Staphylococcus aureus*:
 - a. Common with IV drug abuse and in HIV-infected patients and with acute surgical procedures
 - b. Rapid spinal cord symptomatology
 - c. Can occur at any spinal level but most often at thoracic levels (T4–T6)
 - d. Concomitant with SBE
2. Gram-negative infections:
 - a. Post disc surgery
 - b. *Pseudomonas*, *E coli*, *enterococcus* are the most common organisms
 - c. Signs and symptoms may have a delayed onset; 2–3 weeks after a surgical procedure; rarely 6–8 weeks after surgery
3. *Nocardia*:
 - a. Noted in patients with lung abscess
 - b. May have cervical spinal cord predilection
 - c. Associated with immunosuppressed patients
4. *Cryptococcus*:
 - a. Low cervical and thoracic disc spaces are most commonly involved
 - b. Lung is the origin of the infection
 - c. HIV and immunocompromised patients
 - d. Associated meningitis and cranial nerve II involvement
5. *Coccidioidomycosis*
 - a. The lumbosacral disc spaces are infected from contiguous sacral osteomyelitis:
 - i. Associated arteritis (cerebral)
 - ii. S.W. USA (San Joaquin Valley fever)
6. *Actinomyces*:
 - a. Thoracic and low cervical discs are involved
 - b. Contiguous from a lung infection
 - c. Draining soft tissue sinuses with sulfur granules

Spondylitic Myelopathy

General Characteristics

1. Spondylitic myelopathy is a combination of degenerative disc disease (a biochemical change in the nucleus pulposus; "hard disc") and osteophytic remodeling of bone
2. Hypertrophy of the ligamentum flavum
3. Facet joint arthropathy
4. A progressive slowly developing process
5. The most common cause of compressive myelopathy; may be more severe in patients with a congenital spinal stenosis

Clinical Manifestations

1. The disease process is most severe at the motion segments of the spinal cord (C5–C6 and L5 S1)

2. The patients demonstrate a stiff forward flexed neck with the limitation of movement to all planes. This is invariant in cervical myelopathy. Lumbar spondylosis is frequently associated with positive straight leg raising test but not to the same degree as patients with spinal stenosis (often concomitant processes)
3. Pain is a deep ache noted in the C5–C6 distribution of the upper arms and shoulders. Rare for radiations into the fingers unless an osteophyte compromises a foraminal exit canal. In the lower extremity the pain is often midline. If there is concomitant radicular pain, it is in the L4–S1 dermatomal distributions. S1 frequently radiates into the groin and L5 to the top of the thigh. As a good general, rule-high lumbar root and spinal cord involvement is a medical problem while L5–S1 root disease is mechanical
4. Paresthesias and numbness of the hands (all fingers concomitantly)
5. Asymmetric weakness and atrophy of C5–C6 muscle groups, particular the supraspinatus and deltoids. In the lower extremity the medial gastrocnemius, anterior tibialis, and extensor digitorum brevis are involved. The gluteus maximus is often atrophic. Fasciculation may be seen in affected weak and atrophic muscles
6. There is often an inverted radial reflex due to a combination of cord compression above or at C4 combined with osteophytic occlusion of the C5–C6 intravertebral exit foramina. Ankle jerks are frequently depressed while knee jerks are exaggerated (cord compression at cervical levels combined with L5–S1 radiculopathy)
7. Poor tandem gait (compression of the dorsal and ventral spinocerebellar pathways in the lateral spinal cord). The proprioceptive fibers for the upper extremities traverse the cuneocerebellar tract C1–C4 which is much less involved
8. Babinski sign and clonus are prominent with cervical cord compression. Easily elicitable (1/2 of the outer aspect of the foot). Spasticity of the lower extremities is common
9. Lhermitte's sign (paresthesias of the upper extremities or upper spinal column with neck flexion)
10. A Romberg sign and posterior column dysfunction may be predominant in a subset of patients
11. Mirror hand movements have been reported in severe cervical myelopathy
12. Quadriparesis or paraparesis may occur with moderate flexion or extension of the neck
4. Demyelination or focal necrosis at attachment points of the dentate ligament
5. Loss of myelin occurs in the posterior and lateral columns
6. Loss of anterior horn cell neurons occurs at affected levels
7. Spondylitic symptomatic canals are usually 7–12 mm in the AP diameter (normal is 17–18 mm). There is a great deal of movement of the cervical cord with flexion and extension of the neck that may cause trauma in the setting of stenosis
8. Both arterial compromise and progressive venous outflow obstruction may also play a role in cord pathology

Neuroimaging

1. MRI:
 - a. Demonstrates cord compression. It is not nearly as accurate in estimating bony changes. It demonstrates high-intensity signal within the cord on T1-weighted sequences which portends myelomalacia
 - b. In complicated patients with a combination of root involvement and spinal cord compression, a CT-myelogram is warranted. The contrast outlines the nerve roots while the CT is excellent for detailing the bone compression on the root. The technique also gives an excellent appraisal of facet anatomy and the lateral recesses of root exit canals. Tropism of a degenerative facet (rotation into the foraminal exit canal causing stenosis) is often not appreciated

Laboratory Evaluation

1. There are no laboratory signs of systemic disease
2. EMG:
 - a. Determines the most involved radicular segments
 - b. Nerve conduction velocities help to rule out concomitant peripheral neuropathy as a cause of sensory loss and gait ataxia

Lumbar Stenosis (LSS)

General Characteristics

1. Classified as primary due to a congenital abnormality or a disorder of postnatal development
2. Secondary due to degenerative changes, local infection, trauma or surgery
3. By far the most common cause is a slowly degenerative process of the lower lumbar segments
4. Degenerative lumbar stenosis involves:
 - a. The central canal
 - b. Lateral recess
 - c. Foraminal exit canals

Clinical Manifestations

1. Degenerative lumbar stenosis is uncommon in patients less than 50 years
2. Radicular symptoms are usually referable to L4–S1 roots
3. Back pain with buttock and sciatic radiations that is elicited by sitting, standing and walking. Usually relieved by rest

Neuropathology

1. A spondylitic bar occurs from degenerative changes of the annulus fibrosis. There is frequent disc bulging at several levels
2. The dura is often thickened and adherent to the posterior longitudinal ligament
3. Bone remodeling causes osteophytes in the intervertebral canals that compress the dural sleeves of the nerve roots

4. Neurogenic cramps in the gastrocnemius are frequent. This is usually a dull pain whereas that from vascular claudication tends to be burning
5. Neurogenic claudication:
 - a. A gradual onset of numbness or weakness of the legs that is associated with asymmetric L4–S1 root involvement
 - b. Patient obtains relief with rest and in severe disease utilizes flexion of the hips and knees for pain relief
 - c. The asymmetric leg numbness ascends when the patient walks
 - d. Bladder and sexual function are relatively spared
 - e. Degenerative spondylolisthesis is a frequent concomitant, the symptoms of which include:
 - i. Severe pain with flexion or extension of the spine and with severe loading of the spine at L5. This is usually from sitting for periods of greater than 30 minutes
 - ii. Radiation of pain is usually to the lateral thigh (L5) with radiations into the groin (S1) and top of the thigh (dural projection of L5)
 - iii. A slippage of L5 (forward) over S1 (spondyloptosis)
 1. Protrusion of the lower abdomen
 2. Radicular symptoms at L4–S1
 3. Rarely bladder involvement

Clinical Signs of Lumbar Spinal Stenosis

1. Forward flexed posture
2. Paraspinal muscle spasm
3. Very positive straight leg raising test
4. Preserved muscle strength and bulk
5. Hyperactive reflexes in both upper and lower extremities (due to concomitant cervical stenosis or compressive myelopathy)
6. Concomitant spondylolisthesis:
 - a. Pelvic shelf atrophy of the gluteus maximus, medius and minimus
 - b. Severe pain on extension > flexion of the axial spine
 - c. Radicular signs with mild atrophy of L4–S1 roots
 - d. Rare continuous moving toe syndrome (sinuous toe movements). Continuous moving fingers has been described from cervical stenosis and myelopathy
 - e. Rare to have degenerative lumbar arthropathy without a similar process occurring in the cervical spine

Neuropathology

1. Claudication of the cauda equina is caused by compression of the nerve roots by:
 - a. Hypertrophied facet joints
 - b. Thickened posterior longitudinal, dentate and ligamentum flavum ligaments
 - c. Loss of vertebral height from disc desiccation and bulging of the annulus fibrosis

- d. Osteophytic overgrowth both posteriorly from the vertebral body and in the foraminal exit foramina
2. There may also be a vascular compromise of the arterial supply from branches of the great radicular artery of Adamkiewicz or the vasa vasorum
3. Inflammatory cytokine elevation IL-1B but not of IL-6 or tumor necrosis factor-alpha have been demonstrated in cartilage and synovial membranes of zygapophyseal joints

Neuroimaging

1. Asymptomatic patients may have radiologic features of lumbar spinal stenosis
2. Verbiest suggested that an AP diameter of 10–12 mm was relative stenosis whereas absolute stenosis is present if the diameter is less than 10 mm
3. A trefoil shape of the canal and ligament, facet, hypertrophy, osteophytes from the vertebral body and hard disc bulges all contribute to spinal stenosis
4. Shortened pedicles and a shallow tight canal are components of congenital stenosis

Laboratory Evaluation

1. EMG evaluation:
 - a. Determines the specific root involvement
 - b. Nerve conduction velocities define concomitant neuropathies that need medical evaluation (diabetes mellitus, B12 deficiency, Vitamin E deficiency (rare))

Spinal Cord Compression from Pathology of Ligaments, Arachnoid Cysts, and Pial Processes

Differential Diagnosis

1. Posterior longitudinal ligament calcification
2. Ankylosing spondylitis
3. Acromegaly
4. Mucopolysaccharidosis (Schie's disease)
5. Syphilitic cervical pachymeningitis
6. Familial amyloid polyneuropathy (type-1 with meningeal involvement)
7. Sarcoid infiltration
8. Lipomatous dural thickening
9. Tuberculous meningitis
10. Rheumatoid dural proliferation
11. Ligamentous laxity syndromes
 - a. Mongolism (C1–C2 subluxation)
 - b. Ehlers-Danlos type IV
 - c. Marfan's disease
 - d. Rheumatoid arthritis (pannus formation destruction and erosion of the atlantoaxial ligaments at C1–C2)
12. Spinal arachnoid cysts
13. Hirayama's disease

Ankylosing Spondylitis

General Characteristics

1. Inflammation occurs at the ligamentous insertion into bone with calcification

2. The sacroiliac joint and the lumbar spine are often most severely affected, but all levels are involved; the entire spine becomes fused and rigid
3. Primarily affects young men
4. HLA-B24 is elevated
 - a. Non-major histocompatibility gene complex susceptibility loci include ERAP and IL23R are associated
5. Absence of rheumatoid factor

Clinical Manifestations

1. Modified New York criteria:
 - a. Limited motion of the lumbar spine
 - b. Persistent lower back pain
 - c. Decreased chest expansion
 - d. Radiologic evidence of stenosis
2. Neurological manifestations:
 - a. Spinal stenosis
 - b. Cauda equina syndrome
 - c. Dilatation of the caudal dural sac (possible defect in CSF reabsorption)
 - d. Arachnoidal diverticula on posterior root sleeves
 - e. Thoracic and cervical myelopathy
 - f. Fracture of the vertebral column with minimal trauma; consequent spinal cord compression

Rheumatoid Arthritis of the Spine

1. Ligamentous degeneration of the atlantoaxial junction is affected
2. Pannus formation at this level (C1–C2)
3. Intermittent or permanent quadriparesis
 - a. Sudden death may occur with minimal trauma

Ossification of the Posterior Longitudinal Ligament

General Characteristics

1. Occurs primarily in the cervical spine in Japanese patients
2. Males > females; in patients greater than 40 years of age
3. May extend for only two segments or over the entire spine

Clinical Manifestations

1. Myelopathy > radiculopathy; both may occur concomitantly
2. Posterior cervical pain may be an isolated complaint
3. Usually a slowly progressive myelopathy
4. Trauma may precipitate acute cord compression
5. Most frequently involved segments are C7, C8, T1
6. Partial Brown-Séquard syndrome rarely occurs

Neuroimaging

1. MRI and CT evaluation:
 - a. Cancellous bone formation may occur along a segment of the posterior longitudinal ligament

Hirayama Disease

General Characteristics

1. Muscles innervated by C7, C8 T1 are primarily affected
2. Disease primarily of young men

Clinical Manifestations

1. Asymmetric involvement of the lower cervical roots
2. No fasciculation
3. No sensory changes
4. Painless process

Neuroimaging

1. CT/MRI demonstrate:
 - a. Atrophy and signal changes (MRI) in the ventral cord
2. Buckling of the dorsal dural sac with intermittent anterior displacement and ligamentous compression of involved segments with neck flexion

Paget's Disease of Bone

General Characteristics

1. Enlargement of the vertebral bodies, pedicles, and lamina

Clinical Manifestations

1. Spinal cord compression
2. Elevated alkaline phosphatase
3. Areas of bone growth and lysis

Acromegaly

General Characteristics

1. Major complications include:
 - a. Hypertension
 - b. Hyperglycemia
 - c. Diabetes mellitus
 - d. Cardiomyopathy
 - e. Sleep apnea

Clinical Manifestations

1. Carpal and tarsal tunnel syndromes are often presenting complaint
2. Spinal cord compression with myelopathy (all levels)
3. Elevated growth hormone and insulin-like growth factor 1 levels (IGF-1)

Mucopolysaccharidosis Type IV (MPS IV, also Known as Morquio Syndrome)

General Characteristics

1. AR; deficiency of the enzyme N-acetylgalactosamine-6-sulfatase (GALNS)
 - a. Catalyzes a step in the catabolism of glycosaminoglycan keratan sulfate and chondroitin 6-sulfate
 - b. Accumulation of the KS and C6S in the bone and cornea

Clinical Manifestations

1. Variable age of onset and rate of progression
2. Short stature, pectus carinatum, kyphoscoliosis, genu valgus, cavity of joints and corneal clouding
3. Normal intelligence
4. Congenital absence or hypoplasia of the odontoid bone in conjunction with lax ligaments leads to atlantoaxial subluxation that causes:

- a. Cervical spinal cord compression
- b. Children develop spastic quadriparesis
- c. Delayed walking
- 5. Other mucopolysaccharidoses:
 - a. Severe pachymeningitis of the dura with spinal cord compression

Idiopathic Hypertrophic Pachymeningitis

General Characteristics

- 1. IgG4-related pachymeningitis (IgG4-RHP) is a manifestation of IgG4-related disease
- 2. It is a fibro-inflammatory condition
- 3. Oligoclonal restricted IgG4-positive plasma cells within inflammatory meningeal niches

Neuropathology

- 1. Lymphoplasmacytic infiltration of IgG-4-positive plasma cells, fibrosis, and obliterative fibrosis

Clinical Manifestations

- 1. Cranial nerve palsies
- 2. Compressive myelopathy

Neuroimaging

- 1. MRI:
 - a. Meningeal thickening with gadolinium enhancement

Differential Diagnosis

- 1. Sarcoid
- 2. Lymphoma
- 3. Rheumatoid arthritis
- 4. Syphilis (pachymeningitis cervical)
- 5. Deep fungal meningitis

Ligamentous Laxity Syndrome

General Characteristics

- 1. Atlantoaxial hypermobility
- 2. Odontoid and axis should separate no more than 3 mm on neck flexion in an adult
- 3. The cruciate ligament (behind the odontoid) is the major ligament of the odontoid process; lateral ligaments attach the odontoid to the lateral masses of C1
- 4. Atlantoaxial subluxation > subaxial subluxation

Clinical Manifestations

- 1. Paresthesias of the hands
- 2. Minimal trauma may cause quadriparesis (most common in the spondylolisthesis of rheumatoid arthritis)
- 3. Neck flexion may cause drop attacks with increased reflexes

Arachnoid Cysts

General Characteristics

- 1. Arachnoid cysts occur both intradurally and in the extradural space

- 2. They may occur dorsally and ventrally to the spinal cord
- 3. Etiology is incompletely understood but defined causes include:
 - a. Trauma
 - b. Hemorrhage
 - c. Infection
 - d. In children
 - i. Association with neural defects
 - e. In adults they may be associated with:
 - i. Spinal deformities
- 4. Majority of cases occur in the thoracic and cervical areas

Clinical Manifestations

- 1. Paraparesis (may be intermittent when the cyst fills with CSF)
- 2. Neuropathic pain (radicular)
- 3. Gait ataxia (cervical location)
- 4. Sphincter disturbance

Neuropathology

- 1. Intradural arachnoid cysts are most often dorsal to the spinal cord
- 2. Craniocaudal extension is approximately 3.7 vertebral bodies
- 3. Arachnoid webs occur concomitantly
- 4. Splitting of the arachnoid membrane which is reinforced by a layer of collagen (by EM)
 - a. Normal trabecular arachnoid cells
- 5. Dorsal cysts could arise from diverticula of the septum posticum

Neuroimaging

- 1. MRI:
 - a. High-intensity signal on T2-weighted images
 - b. Occasionally CT myelogram is necessary for long cysts with multiple septae

Laboratory Evaluation

- 1. Evaluation in adult patients for associated congenital defects

Differential Diagnosis

- 1. Intradural:
 - a. Cystic neoplastic lesions
 - b. Acquired arachnoid cysts
 - c. Inflammation following meningitis
 - d. Parasitic lesions

Other Cerebrospinal Fluid Containing Cysts

- 1. Arachnoid diverticulum
- 2. Extradural arachnoid cysts
- 3. Extradural pseudo meningocele

Idiopathic Spinal Cord Herniation

General Characteristics

- 1. Primarily affects the thoracic spinal cord

2. Ventral displacement of the spinal cord through a dural defect
3. Neurologic deficits putatively caused by adhesion and vascular compromise
4. Spontaneous displacement of the spinal cord through an anterior dural defect
5. Theories of pathogenesis include:
 - a. Congenital dural insufficiency
 - b. Trauma
 - c. Pressure erosion of the dura
 - d. Duplication of the ventral dura
 - e. T3–T7 are most frequently affected

Clinical Manifestations

1. Dependent on the site of spinal cord herniation
2. Longstanding prior to diagnosis
3. Affects middle-aged women
4. Progressive partial Brown-Séquard syndrome is most common presentation
5. Paraparesis
6. Sensory disturbances
7. Sphincter dysfunction
8. Chest pain

Neuroimaging

1. MRI:
 - a. Enlargement of the dorsal subarachnoid space
 - b. Ventral displacement and an anterior C- or S-shaped kind of thoracic spinal cord
 - c. The cord is attached to the anterior dural mater with no intervening CSF
 - d. May or may not have cord atrophy; no T2-weighted sequence hyperintensity in the cord
 - e. Nerve roots transverse the dorsal subarachnoid space whereas, with dorsal subarachnoid cysts, the roots are at the periphery of the cyst

Neuropathology

1. Atrophy of the cord in some patients
2. Congenital duplication of dural membranes

Laboratory Evaluation

1. No associated systemic features

Differential Diagnosis (Misdiagnosis)

1. Dorsal arachnoid cyst
2. Thoracic disc herniation
3. Transverse myelitis
4. Arachnoiditis
5. Intradural mass
6. Extradural compressive lesion

Spinal Arachnoiditis

General Characteristics

1. In lumbar arachnoiditis, the arachnoid membrane is thickened or opaque near the cauda equina

2. The term may also apply to thickened arachnoid sheaths around nerve roots
3. In the past, the problem occurred from the use of lipid soluble contrast agents often associated with a mixture of blood
4. Also associated with ruptured discs, operative procedures, and infections. Rarely epidural anesthesia is implicated

Clinical Manifestations

1. Intractable low back pain with radicular signs and symptoms
2. Maybe a delayed onset of signs and symptoms (months to years)
3. Associated progressive syringomyelia or myelomalacia due to spinal cord tethering

Neuropathology

1. The exposed cord and roots are encircled by leptomeningeal fibrous tissue often containing lobulated cysts
2. Spinal cord kinking from focal adhesive arachnoiditis

Neuroimaging

1. MRI:
 - a. Clumping and adhesion of nerve roots on T2-weighted sequences; thickened meninges in the spinal canal
2. Myelographic imaging utilizing true fast imaging with steady-state precession (TrueFISP) sequences

Laboratory Evaluation

1. Signs of aseptic meningitis following a causative procedure (acute CSF sample)

Hypertrophic Nerve Roots

General Characteristics

1. Hereditary sensory neuropathies I, III, and V and chronic inflammatory demyelinating neuropathy are the most common neuropathies to compress the spinal cord

Clinical Manifestations

1. Clinical signs of congenital neuropathy
2. Cauda equina compression
3. Radiculopathy
4. Associated with nerve root cysts
 - a. Rupture of these perineural cysts are associated with low pressure headache
5. Spinal cord compression

Differential Diagnosis of Dural Ectasia

1. Neurofibromatosis type I
2. Marfan's syndrome
3. Ehlers-Danlos type IV
4. Collagen gene defects (I–V)
5. Ankylosing spondylitis
6. Spinal cord dural herniation
7. Meningomyelocele
8. Osteogenesis imperfect

Chapter 5

Radiculopathy

Overview of Pain

Pain problems are a major component of consultative neurology. The perception of pain is complex and is composed of a discriminative component (location, quality, intensity), and an affective component (unpleasantness) and a motivational and emotional component (anxiety, depression, coping maneuvers). Each component has its unique circuitry.

Pain itself may be characterized as:

1. Nociceptive, the physiologic alerting mechanism that guides the organism from further harm
2. Inflammatory pain that ceases when the inciting injury heals
3. Neuropathic pain which is caused by injury to the somatosensory system which often continues after the injury has healed and is destructive to the organism

Specific modalities of pain are expressed in pain state. Hyperalgesia is defined as heightened sensitivity to a painful stimulus. Allodynia is pain that is elicited from a non-painful stimulus. In neuropathic pain conditions mechanical and heat allodynia are cardinal features. Dynamic mechanical allodynia refers to pain elicited by a moving cutaneous stimulus (a wisp of cotton stroked across the skin) whereas static allodynia refers to pain elicited by pressure at ordinarily non-painful thresholds. Mechano-allodynia is carried by A-beta fibers (myelinated 8–12 μ fibers). Thermal hyperalgesia is associated with A-delta fibers that convey cold and polymodal C-fibers that respond to heat, tissue destruction, and chemical stimuli. Mechanical and thermal hyperalgesia (particularly cold) are major modalities of peripheral neuropathic pain that is caused by radiculopathy. Radicular conditions (disc disease, spinal stenosis, trauma to nerves) are primary causes of peripheral neuropathic pain. Pain is a very dynamic and plastic process in that chronic pain afferences actually change the response characteristic of pain transmission neurons (PTNs). In general, they become more responsive. Pain is a very sensitive modality in that only one C-fiber when stimulated during microneurography can convey location quality and intensity of a stimulus. It is now clear that immune mechanisms are important at many levels of pain production and maintenance.

As a general chain of events, a tissue-modifying stimulus triggers the firing of transient receptor potential (TRPV1, TRPV8, and TRPA1) receptors on primary pain afferents. In turn, they initiate action potentials in C-fibers and A-delta fiber nociceptive neurons (cell bodies are in the dorsal root ganglia) that synapse in different components of the dorsal horn. These second order neurons give rise to spinothalamic and other afferents that activate the pain matrix. Specific aspects of inputs into PTNs induce both central and peripheral sensitization of the pain matrix, which modifies anatomic, physiologic, and genetic components of the pain matrix at all levels.

Some Aspects of the Anatomy of Pain

The skin is a complex sensory organ that also serves homeostatic and immunologic barrier functions. It is a neuroimmune cutaneous system that signals the sensory modalities of touch, pressure, temperature, and pain. As noted earlier, these primary modalities are modified in pain states (hyperalgesia, allodynia, and hyperpathia). All chronic pain conditions induce plasticity in pain transmission neurons. It is poorly recognized that there is a descending facilitating and inhibitory pain control system, the diffuse nociceptive inhibitory control system (DNIC) that modifies the transmission and physiology of pain transmission after a painful stimulus. This is a dynamic system at both central and peripheral levels that adjusts its sensitivity (thresholds) by complex mechanisms of central and peripheral sensitization. Sensory transduction occurs following activation of primary intraepidermal nerve terminal C and A-delta nociceptive afferents. Activation of these primary intraepidermal nerve terminal C and A-delta nociceptive afferents is dependent on neuronal and non-neuronal skin cells of the neuroimmune cutaneous system (NICS). The epidermis is primarily composed of keratinocytes, melanocytes, Langerhans and Merkel cells. These cells express sensor proteins and neuropeptides (substance P and calcitonin gene-related peptide) that are pivotal in nociception and neurogenic inflammation (vasodilation, plasma extravasation, and hypersensitivity). Keratinocytes comprise approximately 85% of dermal cells and form a tight junction with primary nociceptive nerve fibers. They express transient receptor potential vanilloid 1 (TRPV1) and transient receptor potential ankyrin (TRPA1) receptors. These channels are members of the transient receptor (TRP) superfamily of nonselective cation channels. TRPV1 channels are noxious heat-gated cation channels that are expressed on nociceptive primary afferents and respond to protons, endogenous lipid ligands that include endocannabinoids, lipoxygenase metabolites, lysophosphatidic and linoleic acid metabolites in the microenvironment following injury. These receptors (TRPV1 and TRPA) that are activated following injury or inflammation depolarize nociceptive primary afferents in the dorsal root ganglia whose central terminals project to the dorsal horn (DH) of the spinal cord. The dorsal root ganglia are composed of large diameter neurons that mediate mechanical modalities, small diameter neurons that mediate pain and temperature, as well as satellite cells that are similar to glial cells in the CNS. There are also blood vessels innervated by unmyelinated autonomic fibers. Following injury, there is upregulation of various receptors on the neuronal elements of the DRG and under specific conditions sprouting of sympathetic fibers from the blood vessels. These fibers may form basket-like terminals around nociceptive and large mechanosensitive neurons. The spinal blood-nerve barrier is not as tight as the blood-brain barrier. This is important in the pathophysiology of neuropathy caused by chemotherapy (direct toxic injury from cisplatin and paclitaxel) as well as from au-

to immune attack from activated lymphocytes and other cellular agents. In the skin, keratinocytes, macrophages, TRPV1-expressing nociceptors release nerve growth factor (NGF), prostaglandins (particularly E2), proinflammatory cytokines (IL-1, IL-6), and transforming growth factor beta 1 (TGFB1) as well as chemokines which sensitize (lower the threshold to fire) primary afferent nociceptors. In many instances, after the nociceptors are exposed to the above noted “inflammatory soup” and they fire spontaneously which is the origin of spontaneous pain in many chronic neuropathic pain syndromes.

Nociceptive afferents are principally unmyelinated ($1\ \mu$) C-fibers and thinly myelinated ($1\text{--}4\ \mu$) A-delta fibers. The A-delta fibers signal location, intensity, cold and the lancinating quality of pain (epicritic qualities or fast pain). C-fibers are slowly conducting, transmit a burning quality of pain, and are poorly localizing (second pain).

A dermatome consists of the primary neurons of the DRG, their peripheral and central afferents that include cutaneous and visceral endings. Each dermatome is segregated as it enters the spinal cord: the medial fibers that are primarily myelinated and are mechanosensitive, and the lateral pain and temperature fibers (segregation of the spinal roots at the dorsal root entry zone (DREZ)). Each dermatome maintains a specific topography throughout its projections in the CNS (brainstem, thalamus, and cortex).

A sclerotome refers to pain projection pathways from bones, ligaments, and fascia that project slightly differently from the dermatomal pattern. After traversing the dorsal root entry zone, C-fibers innervate the specific spinal segment, but also approximately two spinal segments rostrally and caudally by means of Lissauer’s tract. There is thus overlap of sensory pain dermatomal innervations. There is a small contralateral segmental DH innervation through the anterior commissures.

The dorsal horn is cytoarchitecturally organized in Rexed layers (laminae). A-delta fiber afferents synapse in lamina I and the outermost lamina II cells. There are also important synapses from A-delta fibers in lateral lamina V. Large mechanosensitive (heavily myelinated) fibers synapse in layers III and IV. The primary synaptic connections of C-fibers is in the substantia gelatinosa (Rexed layer II). C-fiber collaterals project to the intermediolateral column (ILC) and the motor neurons of Rexed layers IX. Cells in lamina VII (primarily motor interneurons) and lamina VIII (autonomic neurons) also respond to painful stimuli. These neurons receive projections from the DNIC (descending pain-modulating system; principally from the rostral ventral medullary neurons). Rexed layer VII motor interneurons also synapse segmentally with C-fibers. Reflex connections from C-fiber afferents to motor neurons in IX and autonomic neurons of the ILC are activated in pain states. There are sympathetic chemical connections at the site of injury, where released norepinephrine may excite upregulated sympathetic alpha receptors on nociceptive afferents, as well as plastic sympathetic upregulations within the DRG. In addition to the secondary neurons (pain

projecting neurons PTN) of Rexed layers I and II (the primary neurons are in the DRG), the neurons of lateral Rexed layers V and VI are pivotal for many of the secondary modalities of pain sensation seen in neuropathic pain states. Neurons in these layers are widely dynamic in range: they receive low threshold mechanoreceptive input (LTM; A-beta myelinated afferents), sympathetic, temperature (C-fiber; heat; A-delta cold fiber afferents) and nociceptive specific CNS projections. Integration of these afferent inputs determines if these neurons will depolarize.

Ascending Pain Pathways

The secondary axons of Rexed layers I, II (inner/outer layers), lateral V and VI form the major components of the lateral spinothalamic tract. The spinal thalamic tract (STT) decussates in the anterior spinal commissure and ascends contralaterally as the spinothalamic tract that synapses at brainstem and thalamic levels. Pain and temperature fibers decussate approximately at two segmental levels rostral to their level of entry. Therefore, there is a drop of pain and temperature sensations on the trunk of approximately two levels with spinal cord injury (often slightly higher posteriorly). Sacral fibers are outermost in the tract while those carrying cervical and arm pain are most medial. There is also segregation by modality.

The modalities may be segregated superiorly to inferiorly:

1. Temperature
2. Pain
3. Touch
4. Deep pressure

Medially placed anterolateral fascicular fibers comprise the spinoreticular thalamic pathway. It projects to the reticular core of the medulla and midbrain and synapses in the medial (DM) and intralaminar nuclei of the thalamus (centralis medialis, lateralis, and zona reticularis). This paleospinothalamic system synapses with the nucleus gigantocellularis, parabrachial nucleus, midbrain reticular formation, periaqueductal gray (PAG) and hypothalamic nuclei. Other fasciculi of the medial anterolateral pathway synapse with the brainstem reticular core by a series of short interneuronal projections. There is also a direct spinohypothalamic pathway.

The medial fasciculi of the spinothalamic pathway conduct pain from the gastrointestinal tract, periosteum, and peritoneum. There is some evidence that deep visceral pain may also be carried in a deep pathway in the posterior columns. It has been proposed that this primarily medial pathway (slowly conducting with widespread diffuse core and limbic projections) is for the affective components of pain. The direct fast conducting spinothalamic pathway projects to the ventroposterolateral (VPL) and ventroposteromedial (VPM) of the thalamic ventrobasilar complex (VB). This system projects primarily to SI of the primary sensory cortex. This pathway mediates the discriminate aspects of pain (quality, localization, and intensity): it is generally referred to as the lateral pathway.

Visceral pain from the esophagus, stomach, small bowel and proximal colon project via the vagus nerve to the nucleus tractus solitaries (NTS).

The direct spinothalamic tract separates into two major divisions before synapsing in the thalamus (as noted above, it gives off collaterals to many nuclei in the brainstem as it ascends): the lateral division synapses in the VPL and some posterior nuclei, while the medial division synapses in the intralaminar complex and submedial nucleus. As noted above, the spinoreticulorhinal pathway synapse with the parafascicular and centrolateral thalamic nuclei. Thus they overlap medial spinothalamic projections. The laminar fiber projections also overlap with direct spinothalamic projections.

Projections from the dorsal horn are widespread and overlapping. The lateral system, the discriminative pain pathway, is primarily composed of dorsal horn projections to the VB complex (VPM and VPL) of the thalamus and consequently to the primary sensory cortex. The affectual pain circuits comprise components of the reticular formation, the parabrachial nucleus, the amygdala insular cortex, anterior cingulate gyrus, and SII. Both of these circuitries are commonly referred to as the pain matrix that encodes the discriminative and motivational components of the perception of pain.

The primary excitatory neurotransmitter in pain transmission neurons (PTNs) is glutamate. There is a contribution from aspartate and kainate. Na(V)1.7 sodium channels are pivotal for initiation of the action potential while a variety of potassium and HCN (hyperpolarization-activated cyclic nucleotide gated) channels return the membrane to its resting potential. HCN channels are activated with membrane hyperpolarization and conduct an inward excitatory current. Dorsal horn inhibitory interneurons utilize GABA-B and glycine, as their inhibitory neurotransmitters. The potassium chloride co-transporter is essential for inhibition in the DH. It functions under physiologic conditions to decrease intracellular chloride in pain transmission neurons. Thus if it is defective, afferents from inhibitory neurons that release GABA-B onto PTNs would depolarize (excite) PTNs as chloride would follow its electrochemical gradient (leave the cell) and the membrane potential would fall to threshold levels. The NMDA receptor (N-methyl-D-aspartate) is extremely important for plastic changes in the DH which occur in chronic pain states. These are a class of ionotropic glutamate receptors that are essential for the plasticity that occurs in chronic pain states. NMDARs have slow deactivation kinetics, are highly Ca^{2+} permeable, and require partial depolarization to relieve their external Mg^{2+} channel block. C-fibers coexpress substance P and calcitonin G-related peptide in addition to glutamate. Thus, a continual C-fiber input to NMDA receptors depolarizes these receptors due to the release of the neuromodulator SP, which depolarizes the receptor enough to release its Mg^{2+} channel block and allow sodium and calcium influx. Additionally, under conditions of a continuous C-fiber input

lateral synaptic NMDA receptors move to the synapse and acquire more AMPA channels. The increased calcium concentration in the PTN activates calcium calmodulin II which in turn activates mitogen-activated kinase (MAPK) and extracellular regulated kinase (ERK) 1/2 to effect gene expression through cyclic AMP response element (CREB transcription factor). The phosphorylation and dephosphorylation of intracellular enzymatic cascades determine PTN excitability. The induction of new protein synthesis by activation of CaMKII and ultimately the CREB transcription factor is a major cause of neuronal plasticity in chronic pain states.

Radicular trauma from disc and degenerative osteoarthritic conditions, as well as autoimmune disease, are major causes of chronic neuropathic pain. In the area of injury, the microenvironment that includes protons, bradykinin, leukocytes, serotonin, prostaglandin (i.e. an "inflammatory soup") induces peripheral nociceptive afferent terminal sensitization. C-fiber activation (from the inflammatory milieu) induces phosphorylation of ERK in small DRG neurons (PTN). C-fiber stimulation also induces phosphorylation in MAPKs and extracellular signal-regulated kinases (ERKs) in neurons with myelinated fibers. These intracellular enzymatic cascades lower the firing threshold of the C-fiber and A-delta fiber nociceptors. Prolonged nociceptive afferent input from C-fibers (primarily the mechanical insensitive ones) induces central sensitization in the DH and other components of the pain matrix. Central sensitization refers to the increased synaptic efficacy in PTNs (pain transmission neurons at all levels of the pain matrix) that follows intense peripheral noxious stimuli from tissue injury or nerve damage.

Central sensitization is manifested by:

1. Reduction in pain thresholds
2. Enlarged peripheral receptive fields of PTNs
3. Amplification of pain
4. Decreased pain inhibition
5. After sensations (PTN firing is not stimulus bound)

This physiological state is similar in many physiologic parameters to long-term potentiation (LTP) and depression (LTD) that are important for memory and learning.

In parallel with the molecular changes in pain transmission neurons is activation of segmental microglia. Chemokines released from activated neurons (fractalkine) as well as extracellular neuropeptides play pivotal roles in the physiology of PTNs and microglia which express several subtypes of P2XR (purine receptors) which contribute to pain signaling in the spinal cord under pathologic conditions such as neuropathic pain. Activated microglia secrete inflammatory cytokines which both induce and maintain neuropathic pain and contribute to central sensitization.

Nerve roots exit and enter the spinal cord through the neural foramina. These are bony canals of varying length depending on the spinal segment. The contents of the neural foramina (canals) are the spinal nerve roots, recurrent meningeal nerves, and radicular blood vessels. The anatomical boundaries are the pedicles inferiorly and superiorly, anteriorly

the intervertebral disc and vertebral body and posteriorly the facet joint. The superior and inferior facets are lined by synovium. The dorsal root ganglia (DRG) are in the foraminal canals.

The blood supply to a spinal nerve root derives from the corresponding radicular artery. At the root entry zone, blood vessels lie on the surface of rootlets and in inter-radicular spaces. Capillary density is high in the ventral root entry zone. In osteoarthritic degenerative conditions, facet joints are frequently remodeled by hypertrophic bone expansion. Tropism occurs whereby the facet rotates into the foraminal exit canals and the lateral recess. This process impinges on the exiting nerve root at its level. The facet joints are innervated by branches of the posterior primary ramus of the spinal nerve root. The clinical effect of degeneration of the annulus pulposus and the posterior longitudinal ligament are not well categorized. Both structures receive nociceptive innervations. Extruded disc material induces an inflammatory response around the nerve root eliciting the expression of IL-1, IL-6 and tumor necrosis factor- α which directly depolarize nociceptive C-fiber and A-delta afferents. Dorsal root ganglia have a less permeable blood-nerve barrier than the blood-brain barrier. This is important in the context of chemotherapy-induced radiculopathy and autoimmune processes such as Sjögren's syndrome or paraneoplastic processes. The cell bodies for PTNs may thus be directly affected in the course of these disorders.

Radicular pain is caused by depolarization of A-delta and C-fiber nociceptive afferents. A-delta primary nociceptive afferents (1–4 μ) cause lancinating well-localized pain in the expected dermatome. With root irritation, the lancinating pain is frequently followed by a deep aching pain that has a burning quality. This second pain is mediated by 1 μ unmyelinated slowly conducting C-fibers. Sympathetic discharge elicited by somatic sympathetic reflexes may amplify and drive this pain in chronic conditions. The usual radicular pain radiates within its specific dermatomes. However, it may be appreciated in only part of the anatomical confines of the dermatome. Thus, an L5 root injury may be felt just or predominately in the lateral thigh or great toe and not the lower back.

The pain is usually increased by mechanical maneuvers that increase intraspinal pressure or stretch the nerve root. The nervi nervorum that innervate the nerve sheath are sensitized so that a mechanical stimulus rather than a tissue destructive one will depolarize then (basis for the straight leg raising test and other provocative stretch maneuvers).

Dorsal Root Entry Zone

There is segregation of spinal root afferents at the dorsal root entry zone (DREZ). Medial dorsal root fibers carry proprioception, vibration, and light touch. Lateral dorsal root fibers (closest to the area dorsolaterally where discs extrude) carry lancinating pain (A-delta fiber mediated), cold (A-delta fiber), temperature and burning pain (C-fiber). Lesions that affect

the dorsal root entry zone are, in general, painful. Lesions peripheral to the DRG in the neuronal exit canals cause numbness. Lesions of the medial branch of the posterior primary division of the dorsal root are associated with numbness and paresthesias (1½ inches laterally from the spinous process). Meningeal afferents from the dorsal root innervate the dura at each spinal segmental level. These are the recurrent branches of Spurling. The L5 branch is particularly relevant as its referred pain is to the top of the thigh when it is stimulated (often mistaken for L1, L2, L3 root pain).

Ventral Root Lesions

Ventral root lesions cause segmental weakness. If these axons are injured, there will be associated atrophy and fasciculation along with weakness of the innervated muscles. Early with compressive or irritative lesions, reflexes may be enhanced. This has been posited to result from the differential susceptibility of inhibitory afferents in the ventral root. In the lower extremity (if reflexes are increased), the examiner must always be aware of compressive or intrinsic spinal cord lesions that may injure the corticospinal tract and disinhibit neurons below the lesion level.

The Structural Bone and Ligamentous Anatomy of the Spine

The vertebral bodies are connected by intervening discs and partially supported by the anterior and posterior longitudinal ligaments. The posterior elements from the vertebral bodies are composed of the pedicles, laminae, and dorsal spine. The transverse dorsal spinous processes are the origin and insertions of the paraspinal musculature. The ligamentum flavum is on the ventral surface of the laminae, and the posterior longitudinal ligament runs dorsally on the vertebral body. The dentate ligament connects the spinal cord to the dura. The interspinous ligaments connect the spinous processes and facet joints. The facet and sacroiliac joints have a synovial lining. Spine stability depends on the integrity of its skeletal and ligamentous components as well as active muscular support from the paraspinal musculature. The L5 vertebral body is the load segment for the lower spine (subject to the weight of the upper body). The skeletal and ligamentous structures are most vulnerable at movement segments (C5–C6 cervically and L5–S1 in the lumbar spine). If a segment is fused, the next uppermost spinal segment becomes the movement segment. Stress on bone activates osteoblasts and molecular mechanisms that remodel bone. This is evidenced by endplate increased bone density (Modic's sclerosis). Transforming growth factor beta-1, osteoblast and osteoclast activation, as well as complicated bone metabolism, are all important in this process. Voluntary and reflex activity of the paraspinal, sacrospinalis, abdominal, gluteus maximus and hamstring musculature not only support the spinal column but adjust their activity following pathologic processes. These adjustments change gait and posture, which in turn modify load and stress points in the vertebral column.

After the exit of the lumbar spinal roots from the cord, they course downward in the subarachnoid space prior to entering the exit foramina. The area on the inner surface of the pedicle (area prior to their entrance of the foramina) is known as the lateral recess. This area may be compromised by congenitally shortened pedicles (common in achondroplasias and other congenital bony dysostosis) or extruded disc fragments.

Far lateral disc protrusions may just entrap the exiting nerve root affecting one spinal segment. A more medial extrusion may compress the exiting nerve root and the next lower root as it descends prior to its exit. Degenerative changes in the nucleus pulposus (alterations of its glycosaminoglycans) contribute to its water loss and shrinkage with age. This distortion may compromise the exit of nerve roots contralaterally as well as ipsilaterally.

General Features of Radicular Pain

All parts of the body are innervated by a nerve root and a peripheral nerve and have a specific pattern of referred pain. Thus, sensory complaints may be overlapping such that a particular pain distribution may be composed of a root, nerve, or plexus distribution as well as its referred pattern. The sensory patterns may be difficult to discern in the face and extremities. Further complicating sensory patterns are the radiations of sclerotomes and those of the posterior rami of the lower back. Each body part receives some overlapping root rostral and caudal innervations, and there is further overlap in the dorsal horn as noted above from Lissauer's tract.

Face

The V1–V3 divisions of the facial nerve are well demarcated. The C2–C3 roots comprise the pre-auricular nerve that innervates the side of the face overlapping V2 and V3. C2 innervates alone innervates an area just anterior to the ear. C2–C3 comprises the lesser occipital nerve which innervates the back of the head. C3–C4 comprises the post-auricular nerve that innervates the ear and portions of the parietal skull. C3 primarily innervates the neck and C4 the trapezius ridge. C5 innervates the top of the shoulder. C6 innervates the thumb and index finger, C7 primarily the third and 4th finger and C8 the little finger. T1 innervates the lower forearm and T2 the inner humerus. T4 innervates the nipples, T10 the umbilicus and L1 the groin. L2 and L3 innervate the anterior thigh while L5 innervates it laterally. The cap of the knee is L3, the inner knee L4 and the outside of the knee is innervated by L5. A strip of the inner lower leg is innervated by L4. The outside of the lower leg and foot is innervated by S1. L5 innervates the great toe and top of the foot. The bottom of the foot medially is L5 and laterally it is S1. The medial posterior thigh is L3 and more laterally S3. The anus is usually presented as being innervated by S5 roots. Saddle areas are primarily S2–S4. A sclerotome is derived from an enlarged somite. During

development, the somite develops into a variety of different structures. These include disks, cartilage, joint capsules and ligaments which refer pain to the body surface in specific patterns. In general, when a portion of a sclerotome is irritated by a mechanical or chemical stimulus (rupture of a disc, facet and ligament irritation from disc material) pain may be experienced as originating from the dermatome innervated by a nerve although it originated from the facet. Sclerotogenous pain is often reported as a dull ache and is diffuse.

Referred Pain

A primary mechanism of referred pain is somatic and visceral convergence. The skin surface and a specific internal organ are innervated by the same DRG. In the instance of referred pain, the spine may be projected to the visceral or other structure in the territory innervated by lumbar and upper sacral roots. Pelvic and abdominal viscera may refer pain to the spine. Sclerotomal pain radiations from the upper part of the lumbar spine may be referred to the medial flank, groin, hip and anterior thigh. This occurs most often (my experience) from discogenic disease at L5–S1. The literature supports irritation of the superior cluneal nerves (that are derived from the posterior divisions of the first three spinal nerves) which innervate the upper buttocks as a source of referred pain. It has been proposed that pain radiations into the lower buttocks and posterior thigh originate from lower lumbar and upper sacral roots. As a general rule referred pain: 1. has the same intensity as local pain; 2. stretch maneuvers that increase local pain similarly exacerbate referred pain.

Pain referred to the spine from visceral processes may be posturally related but are not influenced by back movement. A common functional relationship of root irritation and visceral activity is micturition and defecation initiated by L5–S1 root irritation.

Local Pain

Local pain in the spine is caused by pathological processes of the facet joint, ligaments, periosteum, capsule of apophyseal joints and the annulus fibrosis. If there is pain from annulus fibrosis stretch or tear is debated. It is innervated by nociceptive fibers and disc contents initiate an immune response that may induce the release of inflammatory cytokine (IL-1, IL-6, and TNF-alpha among others) that theoretically could irritate nociceptive afferents.

Pain from these spinal structures is:

1. Steady and aching
2. Not well circumscribed and may be intermittent and sharp
3. Is appreciated at the site of pathology
4. May be referred in a sclerotomal distribution

Radicular Pain

Radicular pain, in general, is:

1. Intense

2. Lancinating or sharp (A-delta fiber)
3. Confined to a specific dermatome
4. Usually exacerbated by stretching, irritation or compression
5. May be superimposed on the dull ache of referred pain
6. Often radiates from a paracentral spinal area to a component of its root territory
7. Often is increased by valsalva maneuvers

Examination reveals:

1. Paresthesia or sensory loss in components of the involved dermatome
 2. Mechanically evoked pain (pressure) in innervated muscles
 3. Weakness, atrophy, and fasciculation of involved muscles
- In general, referred pain from lumbar bony, articular or ligamentous structures does not project below the knee. It is not associated with clear neurologic deficits.

In general, involvement of upper lumbar roots suggests a medical problem such as metastasis, retroperitoneal bleeding, autoimmune disease, and infection. Lower L4–L5–S1 involvement suggests spondylosis, disc disease, spinal stenosis, spondylolisthesis, facet hypertrophy, and spondylolysis. The history, age, relieving and exacerbation factors, as well as the examination, should determine etiology in the vast majority of patients.

Diagnostic Points of the Low Back Examination

1. Inspection determines:
 - a. Scoliosis, kyphosis and a pelvic tilt (Trendelenburg sign) and gibbus:
 - i. An S-shaped (scoliotic) curve is compensatory
 - ii. C-shaped scoliotic curve suggests asymmetric loss of paraspinal musculature from a spinal tumor
 - iii. A gibbus (severe kyphotic angulation) suggests a fracture
 - b. Atrophy of the gluteus maximus with a dropped gluteal fold (primarily an S1 root). Bilateral gluteal atrophy and weakness suggest spondylolisthesis in young patients
 - c. L5–S1 radiculopathy causes a flexed leg (relieves pressure on the sciatic nerve). If there is posterolateral disc extrusion (impingement on the lateral dorsal root entry zone), the patient may be unable to lie down and straighten the spine
 - d. Severe paraspinal muscle spasm suggests local disease and possible posterior ramus syndrome
2. Gait
 - a. As a general rule patients with radiculopathy do not limp. This is much more common in patients with lower extremity joint degeneration
 - b. An antalgic gait suggests that any weight bearing increases pain
 - c. A forward flexed posture with minimal or no gastrocnemius atrophy suggests spinal stenosis. The patient usually has a shortened swing phase of the gait

- d. Patients that are more comfortable standing than sitting suggest L5–S1 disc disease or spondylolisthesis

3. Positional Testing:

- a. Decreased forward flexion when standing suggests mobility at the decreased lumbosacral segment and includes:
 - i. Disc disease ($L5-S1 > L4-L5$)
 - ii. Spinal stenosis ($L4-L5 > L5-S1$)
 - iii. Spondylolisthesis and spondylolysis ($L4-L5$ or $L5-S1$)
 - iv. Posterior ligament, articular facet or rarely sacrospinalis
 - v. Extension of the spine following flexion is difficult with lumbar disc disease
 - vi. Lateral bending:
 1. Ligament pathology or muscle strain:
 - a. Painful bending to the opposite side
 - b. Disc disease:
 - i. Bending to the opposite side is painful
 - vii. Straight leg raising:
 1. Positive with disc disease
 2. In spinal stenosis, there is often restriction but the maneuver is much less painful
 3. Very positive with all forms of spondylolisthesis
 - viii. Extension of the leg (patient lying on the stomach) is painful with:
 1. Fracture of the vertebral body or posterior elements
 2. Inflammatory processes
 3. Most helpful with upper lumbar root pathology
 - ix. Lateral decubitus position:
 1. Abduction against resistance of the upside leg causes sacroiliac joint pain
 2. Internal and external rotation induces intrinsic hip joint pain (easier to elicit with patient supine)
4. Palpation:
 - a. Percussion of the spine (to detect mechanical hypersensitivity)
 - i. Positive for any disc infection and metastatic disease of the vertebrae
 - ii. Less positive for inflammatory processes or infection
 - b. Tenderness over the interspinous ligament at L5–S1 suggests disc disease
 - i. Sacroiliac joint tenderness may be an early sign of ankylosing spondylitis
 - c. Pressure in the sciatic notch and posterior popliteal fossa suggests sensitization of the sciatic and posterior tibial nerve respectively. Tenderness of the gastrocnemius muscle often accompanies and is strong evidence of S1 root disease
 - d. Costovertebral angle tenderness occurs with genitourinary and adrenal disease as well as with fractures of the transverse processes of L1 and L2

- e. Examination of strength, atrophy, sensory loss and reflexes (including Babinski sign) completes the lower back examination

Almost all older patients have some combination of degenerative osteoarthritic changes in addition to nerve root and sclerotomal pain radiations.

Differential Diagnosis of Lumbar Radicular Pain

Congenital Lesions

1. Most congenital defects themselves do not cause compression of roots. However, bone metabolism is a dynamic molecularly driven process such that changes in loading forces on vertebrae or inflammatory conditions cause remodeling of bone by activation of osteoblasts, osteoclasts, the immune system and tissue transforming factor beta 1

Congenital Defects of the Lumbar Spine

1. Sacralization of L5
 - a. A fusion of the fifth lumbar vertebral body to the sacrum or separation of the first sacral segment (6 rather than 5 lumbar segments). There are no clinical consequences (other than rare localization difficulties on MRI for radiculopathies)
2. Spina bifida
 - a. Lack of fusion of the laminae of one or several lumbar or sacral vertebrae
 - i. Associated rarely with a subcutaneous mass, cutaneous hyperpigmentation or hypertrichosis over the defect
 - ii. Rare association with facet joint or pedicle anomalies
3. Asymmetric facet joints, narrow lateral recesses, and short pedicles may cause radicular involvement
4. Spondylolysis:
 - a. A congenital bony defect in the pars interarticularis (the junction is the pedicle and the lamina; often bound by cartilage)
 - b. Predisposition to fracture or disjunction with slight trauma such as stepping off a curb or jumping
 - c. Young patients may have aching in lumbar areas exacerbated by extension
 - d. Bilateral spondylolysis predisposes to spondylolisthesis. In this instance, the vertebral body, pedicles and superior facets slip forward. The degree of slippage is usually graded by the percentage of displacement relative to the lower vertebra
- e. Spondylolisthesis:
 - i. A common and severe problem that requires surgical intervention often with instrumentation when symptomatic
 - ii. Slippage in non-severe traumatic cases is L4 over L5 or L5 anteriorly to S1

- iii. Flexion and extension of the back are painful as in bending
- iv. Radicular pain is prominent primarily in L3–4 and root distributions
- v. Weakness of the gluteus maximus, anterior tibialis, and/or extensor hallucis longus is most prominent
- vi. Rare bladder involvement
- vii. Atrophy of the gluteus maximus is often prominent
- viii. Decreased ankle reflexes
- ix. Degenerative osteoarthritis (primarily spondylosis is causative in older patients)

Lumbosacral Trauma

1. Acute sprain and strain:
 - a. When there is severe pain and accompanying paraspinal muscle spasm, the segmental nerve roots have been stretched or otherwise injured
 - b. Trauma does not cause degenerative disc or bony structural disease but may exacerbate pain by compression of nerve roots against osteophytes in exit foraminal canals, increasing the bulge of an annulus fibrosus or mechanically stimulating the nervi nervorum of the nerve sheath and root sleeves or A-delta and C-fibers within the nerve root itself
 - c. Spasm of involved musculature localized low back pain and unusual splinting postures usually abate in less than a week:
 - i. Sacroiliac joint and ligamentous injury:
 1. Pain may radiate to the buttock and thigh; there is pain directly over the sacroiliac joint (an example of sclerotomal pain; injury to a component of an embryologic somite may radiate to dermatomes derived from the involved somite)
 2. Abduction of the thigh against resistance may cause pain radiation into the groin and symphysis pubis (sclerotomal radiation)

Recurrent Low Back Pain from Bony and Ligamentous Structures

1. Recurrent aching pain in lumbar areas. Some radiation into the buttocks and posterior thigh (never below the knee)
2. No weakness, sensory loss or reflex changes
3. Complaint of stiffness and aggravated by specific movements
4. CT and MRI frequently demonstrate mild disc desiccations and degenerative bony changes, but may be normal

Vertebral Fractures

1. Fractures of lumbar vertebra:
 - a. Result of flexion injuries
 - b. If patient falls and lands on his feet calcaneal and hip fractures may be associated

2. Specific fractures from severe injury (MVA, falls, skiing):
 - a. "Burst" fracture of a vertebral body (one or several)
 - b. Pedicle, lamina or spinous process (most often asymmetrical)
 - c. Loss of height of a vertebral body (wedge or compression; anterior border is most often involved with osteoporosis)

Differential Diagnosis of Pathologic Fractures

1. May occur spontaneously or with minimum trauma
2. Osteoporosis (women; thoracic anterior compression fracture)
3. Hyperparathyroidism (kidney disease)
4. Metastasis:
 - a. Pedicle involvement
 - b. Disc body
5. Corticosteroids
6. Myeloma (often multiple vertebrae)
7. Hemangioma (often with hemorrhage)
8. Various bone cysts
9. Prolonged heparin use (fish mouth endplate)

Clinical Features of Pathologic Fractures (Lumbar)

1. Immediate localized pain
 - a. Rare delayed onset of pain
2. Lower paraspinal muscle spasm:
 - a. Limitation of lumbar spine movement
 - b. Mechanical sensitivity

Clinical Features of a Transverse Process Fracture

1. Setting is almost always a high impact rotary injury of the spine
2. Associated paraspinal muscle injury with hematoma
 - a. If bleeding is retroperitoneal (or extends to this space from sacrospinalis or paraspinal muscle hemorrhage):
 - i. Severe pain, a local hematoma at the injury site
 - ii. A quiet patient whose position of comfort may be lying on a side with flexed legs
3. Groin pain
4. Proximal > distal leg weakness
5. Loss of the knee jerk on the affected side
6. After seven to ten days – Grey Turner's sign of blood breakdown products in the skin and subcutaneous tissue of the affected flank

Disc Disease (Lumbar)

1. L5–S1 herniations is the most common level of herniation followed by L4–L5 > L3–L4 > L1–L2 (rare)
2. L5–S1 is the primary motion segment of the lumbosacral spine while L5 is the primary load segment. If there is fu-

sion of L5–S1, then L4–L5 becomes the primary motion segment

3. Primary causes of disc herniation are not clear:
 - a. Degeneration of the annulus and the nucleus pulposus, as well as the posterior longitudinal ligament, has been posited. Rarely acute flexion injuries seem a likely cause of annulus pulposus tear
4. Nucleus pulposus fragments generally extend through degenerated areas of the annulus most often dorsolaterally and asymmetrically. Central and medial protrusions may involve descending nerve roots prior to entering the exit foramina. A far lateral protrusion compresses a single root at that level. Thus, a lateral protrusion at the interspace between L4–L5 will involve the L5 root. The L4 is spared as it exits above the protrusion. A medial protrusion at L4–L5 may involve the L5 root as well as sacral roots S1–S2 prior to their exit
5. The affected interspace may be mechanically sensitive to pressure. There may be a slight decrease of sensation 1½ inch laterally from the corresponding spinous process. The dorsal rami syndrome (discussed below) may be prominent
6. Mechanical stretch maneuvers are positive and exacerbated by Lasegue's maneuvers. This involves extension of the ankle with the leg extended
7. Tinel's signs are positive over the nerve that carries the affected roots. Tinel's sign (mechanical pressure on the nerve elicits pain) is positive in the sciatic notch and posterior popliteal fossa with L5–S1 root involvement
8. There is muscle tenderness of those muscles that are innervated by the sensitized roots (usually elicited by moderate squeezing). The root compression by the extruded disc material sensitizes the deep polymodal C-fiber and A-delta fiber afferent nociceptors such that mechanical pressure rather than tissue-destructive stimuli will depolarize them
9. Pain radiations are consistent but most often consist of a combination of dermatome and sclerotome patterns. The latter (pain from structures of the embryonic somite-vertebrae, facet joints and their capsules, periosteum, ligaments) often activates structures not often thought of as emanating from the affected roots
10. Bilateral symptoms and sphincter (overwhelmingly bladder) dysfunction most often occur with large midline disc extrusion that compresses the cauda equina

L2–L3 Disc Space

1. L3 root affected
2. Pain:
 - a. Anterior thigh
 - b. Top of the knee
3. Weakness of thigh adductors, quadriceps and iliopsoas muscles
4. Decreased knee jerk

L3–L4 Disc Space

1. L4 root affected
2. Pain:
 - a. Anterolateral thigh
 - b. Medial leg below the knee
3. Weakness of the anterior tibialis
4. Knee jerk decreased

L4–L5 Disc Space

1. L5 root affected
2. Pain
 - a. Posterolateral gluteal area, lateral thigh, lateral leg below the knee, dorsal foot to the lateral malleolus, great toe and 2nd and 3rd toes

Additional Radiations of L5 (Sclerotomal)

1. Hip
2. Top of the thigh:
 - a. Somatic referred pain possibly from the innervations of the annulus fibrosis (controversial mechanism but the radiation is helpful)
3. Dural innervations at L5; the innervations of the recurrent nerve of Spurling at this level
4. Scrotum
5. Rarely the anterior lower abdominal wall
6. Weakness of the extensor hallucis longus, extensor digitorum brevis, and anterior tibialis that cause partial foot drop. There is also weakness of invertors of the foot which does not occur in the foot drop of peroneal palsy
7. Ankle jerk is unaffected
8. Straight leg raising test and its variants are positive. Irritation of nociceptive afferents in the affected root or its sleeve synapse with Rexed layer VII interneurons that then depolarize Rexed layer IX flexor motor neurons that elicit hamstring muscle contraction which halts the further extension of the leg. This comprises a nocifensive reflex
9. Chronic disc disease causes atrophy of the anterior tibialis and the extensor digitorum brevis
10. Tenderness with compression over the fourth lumbar lateral process and between the fourth and fifth spinous space, the ligaments and laterally in the sciatic notch

L5–S1 Disc Space

1. The S1 root is affected
2. Classic pain radiations:
 - a. Mid gluteus maximus pain
 - b. Tenderness in the sciatic notch, posterior thigh, posterolateral leg, lateral foot, heel and lateral toes
 - c. Especially helpful is the radiation to the little toe
 - d. Low calf dull pain to the heel
3. Unusual pain radiations of S1 (components of the sclerotomal innervations):
 - a. Groin

- b. Tip of the penis
- c. Ipsilateral vagina
- d. Anus (controversial as there is evidence that this is an S5 root territory)
4. Weakness of plantar flexors, hamstring muscles, and the toes; abductor digiti (Vth metatarsal)
5. Depressed or absent ankle jerk
6. Positive straight leg raising test; tenderness of the sciatic notch, posterior popliteal fossa, and pain elicited by squeezing the gastrocnemius muscle; tenderness over the L5–S1 interspace; increased pain with walking on the heels but more difficulty walking on the toes due to plantar flexor muscle weakness

Visceral Association with L4, L5 and S1 Root Disease

1. Increased frequency of micturition
2. Slight decrease of bladder emptying (30cc residual urine) with S1 disease
3. Increased pain during menstruation (sciatic radiations). Convergent innervations from the uterus, fallopian tubes and ovary to L5, S1 DRG (somatic-visceral convergence) cause pain in these distributions

Exacerbating Factors for L4–S1 Radicular Pain

1. Flexion and extension posture; sitting; driving a car
2. Valsalva maneuvers
3. Sleep (veins that overlie the root compress the sensitized root; patients awaken with back pain at 4–5 AM. Inability to lie down suggests intraparenchymal spinal cord tumor (patients sleep upright in a chair). Awakening slightly earlier at night (3–4 AM) suggests a subarachnoid cyst that compresses the spinal cord)
4. The leg feels as if it will suddenly “give way” and will not support the patient’s body weight

Relieving Factors for L5–S1 Disc Disease

1. Rest; supine position with flexed knees (pillow behind the knees)
2. Heat over the affected interspace
3. Some patients improve with exercise (heat may decrease conduction in sensitized nerve roots)

Extreme Lateral Disc Protrusion

1. Unrelenting radicular pain without concomitant back pain (proximal portion of the intervertebral exit canal)
2. Pain is increased with extension and torsion toward the side of the extrusion
3. Intradural disc rupture with a free fragment may not cause sciatic pain as it may not impinge upon the cauda equina roots

Lower Sacral Radiculopathy

1. Usually, S2–S5 roots are involved concomitantly often from a large central disc herniation

2. Pain and sensory loss may be prominent in the perineal area
 - a. Usually asymmetrically
 - b. "Sudden anesthesia"
 - c. Prominent pain and numbness may also occur over the gluteus maximus, posterior thigh and if S1 is involved the calf and heel
3. Urinary incontinence and retention; rarely fecal incontinence
4. Loss of ankle jerks
5. Varying degrees of paraparesis
6. Severe back pain
7. Reduced or absent anal sphincter tone; decreased bulbocavernosus and anal wink reflexes with S1–S5 lesions

High Lumbar Root Disease

In general, the L1–L3 roots are not affected by disc disease as they are not motion segments.

They are involved by:

1. Diabetic plexopathy
2. Ilioinguinal
3. Genitofemoral nerve injury from:
 - a. Surgical procedures (hernia, catheterization of the femoral artery) and intra-abdominal surgical procedures
 - b. Lymphoma
 - c. Retroperitoneal hematoma
 - d. Autoimmune processes
4. Rarely the roots are involved in high impact injuries (MVA accidents, falls, and skiing injuries)

L1 root:

1. Pain and paresthesias of the inguinal area
2. Slight iliopsoas weakness

L2 root:

1. Pain referred to the lateral hip and anterolateral thigh pain
2. Weakness of the iliopsoas muscle
3. Differential diagnosis includes high lumbar plexopathy, meralgia paresthetica, or femoral neuropathy
4. In general, femoral neuropathy is associated with severe quadriceps weakness and a decreased or absent knee jerk

L3 radiculopathy:

1. Pain is in the anterior thigh to the kneecap
2. Iliopsoas and quadriceps weakness
3. A plexus lesion usually involves the hip adductor muscles and the obturator nerve
4. The knee jerk is depressed
5. The sensory loss overlaps the projected pain from the recurrent nerve of Spurling at L5 (the dural radiation from this level)
6. Diabetic amyotrophy frequently involves this root as a component of its plexopathy

L5 weakness:

1. Causes extensor hallucis longus and extensor digitorum brevis weakness along with mild weakness of the anterior tibialis and slight foot drop

2. Inversion of the foot is involved
3. There is no inversion weakness with a perineal neuropathy
4. Weakness of the gluteus minimus and medius localizes a lesion proximal to the formation of the sciatic nerve
5. L5 involvement could also be a component of a lumbosacral plexopathy

S1 weakness:

1. Primarily causes weakness of the gastrocnemius and soleus muscles > hamstring and glutes
2. Gluteus maximus weakness localizes a lesion prior to the formation of the sciatic nerve
3. Differential diagnosis includes:
 - a. Lumbosacral plexopathy and medical causes of radiculopathy:
 - i. Metastasis
 - ii. Autoimmune disorders
 - iii. Metabolic disorders (diabetes mellitus)
 - iv. Infectious diseases (HIV, CMV, and brucellosis)

Posterior Rami Syndrome

1. Also known as Maigne's syndrome or the dorsal ramus syndrome
2. Is due to activation or irritation of the primary division of a posterior ramus of a spinal nerve
3. Referred pain occurs in a tri-branched pattern:
 - a. Innervation of the groin or pubic region
 - b. Innervation of the lower back and upper gluteal region
 - c. Anterolateral thigh or trochanteric area
 - d. The affected posterior ramus ends cutaneously and may cause trophic skin changes:
 - i. Thickening or nodularity of the skin
 - ii. Hair loss
 - iii. Neurogenic edema
 - e. These are sclerotomal radiations and thus can originate from several levels. Patients should have facet and spinous processes palpated over a wide area

Differential Diagnosis of Low Back Pain

1. Spinal canal stenosis
 - a. Bone, joint and ligamentous changes that narrow the spinal canal and neural foramina:
 - i. The spinal roots are compressed by:
 1. The vertebral body anteriorly
 2. The facet joints laterally
 3. The ligamentum flavum posteriorly
2. Coccydynia:
 - a. The coccyx is composed of 3 to 5 vertebrae some of which may be fused
 - b. The coccyx attaches to the sacrum from two dorsal grooves being either a symphysis or as a true synovial joint
 - i. It also has attachments to the gluteus maximus muscle, the coccygeal muscle, and the anococcygeal ligament

- c. The mechanisms that cause coccydynia are:
 - i. Sudden impact due to a fall
 - ii. Childbirth pressure
 - iii. Partial dislocation of the sacrococcygeal synchondrosis
- d. Clinical manifestations
 - i. Pain at the end of the spine exacerbated by mechanical stimuli
3. Spondylolisthesis:
 - a. A prominent cause of L4–S1 radiculopathy in young patients
 - i. A pelvic tilt, atrophy of gluteal musculature and pain with extension and flexion
 - b. Older patients have degenerative spondylolisthesis, often forward slippage of L4 anteriorly over the L5 vertebra and L5 over S1 (spondyloptosis)
4. Vascular claudication:
 - a. Atherosclerosis of large and medium-sized blood vessels
 - i. Exercise-induced (intermittent) or ischemic rest pain
 - b. Thigh and calf muscles are predominantly involved
 - c. Leriche syndrome:
 - i. Distal aorta and iliac arteries are involved
 - ii. Hip and buttock claudication with walking
 - iii. Impotence
 - d. Burning and squeezing quality to the pain
 - e. Ischemic rest pain:
 - i. Primarily in the foot and toe
 - ii. Buerger's disease affects the medial foot
 - iii. Worse at night
 - iv. Relieved by dependency
 - v. Severe peripheral vascular disease
5. Facet syndrome:
 - a. Degenerative changes of the facet joint with tropism
 - i. The inferior or superior facet rotates into and compresses the nerve root in the canal
 - b. Not relieved by position
 - c. Back and radicular pain that is most often unilateral
6. Adhesive arachnoiditis:
 - a. The arachnoid is thickened over the cauda equina and its nerve roots
 - b. Clumping and adhesion of nerve roots
 - c. Burning pain and paresthesias predominate over motor weakness in the legs
 - d. Rare at present due to new water soluble myelography agents
7. Ankylosing Spondylitis:
 - a. HLA-B27 positive
 - b. Pain in the low back with radiation to the thighs
 - c. Limitation of spine movement is progressive and severe
 - d. Severe morning stiffness
 - e. Progressive flexion of the hips and flexion spine deformity
 - f. Severe late stages may cause cauda equina syndrome
 - g. Failure of chest expansion
 - h. Involvement of the hips may exacerbate gait difficulties and back pain
8. Metastatic disease:
 - a. Pain is often constant, dull, unrelieved by rest
 - b. Mechanically sensitive
 - c. Worse at night
 - d. Radicular pain with lateral extension or pedicle involvement
 - e. Osteoid osteoma may also involve the pedicle
9. Gynecologic processes with referred pain to the back
 - a. Uterosacral ligaments:
 - i. Pathologies include endometriosis or metastasis from uterine or cervical cancer
 - ii. Sacral radiations
 - iii. Endometrial tissue may deposit on lumbosacral roots that cause pain with menstruation
 - iv. Fibroid tumors may cause traction on uterosacral ligaments
10. Metastatic infiltration of pelvic nerve plexuses
 - a. Radiates to low back usually diffusely but may be in a dermatomal distribution
11. Iliopsoas region tumors:
 - a. Unilateral lumbar spine dull ache
 - b. Radiates to the groin, labia, and testicle
 - c. Involvement is frequently of the upper lumbar roots
12. Aneurysm of the abdominal aorta:
 - a. Pain at the segmental level
 - b. T10–L1 vertebral involvement
 - c. Erosion of the segmental vertebrae
13. Retroperitoneal bleed:
 - a. Severe back pain
 - b. Usual lumbar root involvement at times with a dermatomal radiation
 - c. A quiet patient lying in bed with flexed legs
14. Colon neoplasm:
 - a. Pain in the lower abdomen and mid lumbar areas
 - b. Belt-like radiation
 - c. Transverse colon or descending colon:
 - i. Central or left-sided abdominal pain
 - ii. Refers to second or third lumbar vertebrae
15. Inflammatory Processes Affecting the Cauda Equina
 - a. May produce back pain and bilateral L5–S1 pain radiations:
 - i. CMV in the HIV-infected patients
 - ii. Lyme's disease
 - iii. Herpetic infections
 - iv. Carcinomatosis of the meninges
 - v. Guillain-Barré syndrome
 - vi. Lumbosacral plexitis
16. Stenosis of the Lateral Recess:
 - a. A congenital cause of radiculopathy
 - b. Acquired from osteophytes

- c. Clear dermatomal pattern of sensory loss and weakness
- 17. Synovial cysts of the facet joint
 - a. Usually in association with severe degenerative spine and disc disease. Occurs in the proximal portions of the foraminal canal
 - b. Effects the exiting nerve root
- 18. Tarlov cysts
 - a. Dilatation of the perineural sheath; most often asymptomatic
 - b. Usually, sacral roots are involved
- 19. Piriformis syndrome
 - a. Peroneal trunk of the sciatic nerve; local and sciatic pain
 - b. Pain induced by flexion, adduction and internal rotation of the hip and compression
 - c. Etiologies include subarachnoid, subdural, epidural bleeding
 - d. Trauma, coagulopathy (usually warfarin), various arterial venous malformations and mechanical compression by sitting are the primary etiologies
- 20. Visceral Referred Pain Radiations to the Spine
 - a. Posterior gastric wall ulcer:
 - i. Pain radiates to the central thoracic spine
 - b. Pancreatic pain:
 - i. Straight through to the back; to the right of the spine if the head is involved and left of the spine if the body and tail are the source of pathology
- 21. Retroperitoneal neoplasms:
 - a. Thoracic pain or lumbar pain
 - b. Schwannoma
 - c. Radiates to lower abdomen, groin, anterior thigh or flank
 - d. Lymphoma, renal cell, sarcoma are characteristic neoplasm
- 22. Osteomyelitis of Vertebrae:
 - a. Involvement of the vertebral body and the disc. Cancer does not breach the disc space
 - b. Paravertebral mass
 - c. Tuberculosis of the spine is common in developing countries with areas of spinal involvement differing by ethnicity. Pott's disease and drainage sites may be prominent
 - i. Back pain without MRI evidence occurs with SBE
- 23. Epidural Abscess:
 - a. Most often caused by staphylococcal aureus infection
 - b. Hematogenous spread or surgical procedures are etiologic
 - c. Localized severe spine pain with leukocytosis and low-grade fever; may have a radicular component
 - d. May quickly affect the spinal cord with paralysis, sensory loss and sphincter dysfunction
- 24. Intraspinal Hemorrhage
 - a. Sudden onset of severe midline back pain with rapidly evolving signs of spinal cord

Cervical Disc Disease

1. General considerations:
 - a. A bulging disc extends beyond the margin of the endplate of the vertebral body, but the annulus fibrosis is intact
 - b. A disc extrusion is an extension of the nucleus pulposus through the annulus; usually, it remains anterior to the posterior longitudinal ligament (rarely it extrudes through the posterior longitudinal ligament)
2. Cervical spine roots exit horizontally from the spinal cord to the neural exit foraminal and entrap the root corresponding to the vertebral body directly below it
3. The ventral and dorsal roots join just distal to the DRG (which is in the vertebral foraminal exit canal) and form a spinal nerve
 - a. The dorsal ramus supplies the paraspinal muscles (its origin is just distal to the DRG) as well as the cutaneous innervations of 1½ to 2 inches lateral to the spinous process
4. Posterolateral disc herniation compresses the root that will exit one level below
5. Disc disease occurs at motion segments (C6–C7 > C5–C6)

Inspection and Palpation of Cervical Disc Disease

1. Limitation of neck movement due to pain is common with disc disease. Spurling's maneuver (extending and rotating the neck to the side of the lesion and then gently pressing the shoulder down) may irritate the involved root. Neck extension induces posterior disc bulging and lateral flexion and rotation narrows the ipsilateral neural foramina. A position of comfort for a patient with an acute cervical disc is to place the arm over the head, which decompresses the nerve root at its exit foramina. All patients with cervical spondylosis have limitation of neck movement to all planes. Extension may be most limited. Spondylolisthesis, rotary subluxation and jumped facets have specific clinical features. As spondylosis progresses, there are clear degenerative changes at segments C5–C7 which are similar to those that occur in the lumbar spine. These, in general, are most severe at C5–C6 and C6–C7
2. The neck is forward flexed with cervical spondylosis. Almost always, this is associated with some atrophy of the deltoid caps and spasm of the trapezius ridge
3. The head is splinted and often tilted to the side of an extruded disc
4. Spondylolisthesis patients are also splinted, and the neck is usually forward flexed
5. Subluxation at C2–C3 or C3–C4 is most often seen with severe rheumatoid arthritis. The intrinsic muscles of the hand are often concomitantly atrophic. There is ulnar deviation of the hand
6. Dystonic postures from movement disorders (cervical dystonia) have hypertrophy of the sternocleidomastoid muscles and may affect the ulnar nerve with pain and sensory

- loss of the lateral half of the fourth finger and the entire fifth finger. The ulnar nerve innervates a small ventral area (triangular) above the wrist
7. The upper trunk of the brachial plexus radiates pain clearly across the trapezius ridge and straight down the medial scapular border
 8. The lateral cord of the brachial plexus radiates pain to the thumb, index, and the radial part of the third finger. The medial cord encompasses the ulnar side of the third finger and the fourth and fifth finger as well as the medial forearm
 - a. Bilateral hand (rather than finger numbness) is common; occasionally the sensory loss is in the legs and feet (due to lamination of the dorsal columns and spinothalamic tract)
 - b. There may be a thoracic sensory level, usually several segments below the compression
 - c. Reflexes in the lower extremities may be enhanced, and a subtle Babinski sign may be elicitable

Intervertebral Disc Clinical Manifestations

Vertebral Disc C1–C2

1. There is no disc between C1–C2
2. Ligaments and joint capsules resist excessive motion at this level

Intervertebral Disc Space at C2–C3

1. Rarely trauma induces C2–C3 disc extrusion
2. Clinical manifestations include:
 - a. Non-specific neck and shoulder pain
 - b. Perioral hypesthesia
 - c. Radicular pain to pre-auricular areas and the lateral neck
 - d. A retro-odontoid disc may result from an upwardly migrating disc fragment
 - e. Concomitant cord injury may cause motor and sensory symptoms below the disc level

Intervertebral Disc Space at C3–C4

1. Disc herniations at this level are rare
2. May present with no or mild pain
3. A myelopathy may be caused
4. Hand numbness may be a prominent symptom

Clinical Manifestations of Cervical Disc Herniation

Intervertebral Disc Space at C4–C5

1. C5 root is affected
2. Pain is felt across the trapezius ridge to the shoulder
3. Weakness of the supra- and infraspinatus muscles, deltoid, and biceps muscle (slight)
4. Depressed biceps reflex

Intervertebral Disc Space at C5–C6

1. C6 root is affected
2. Pain across the trapezius ridge to the shoulder. Anterior and upper arm, thumb and index finger

3. A sequestered fragment is completely separated from the nucleus pulposus. This segment may migrate rostrally or caudally down the spinal canal
4. Weakness in the biceps, brachioradialis, extensor carpi radialis
5. Reflexes – diminished biceps and supinator jerk
6. Tenderness over the spine or scapula as well as the suprascapular area; paresthesias of the thumb and index finger

Intervertebral Disc Space at C6–C7

1. The affected root is C7
2. Pain in the shoulder, posterolateral arm, elbow and the middle finger and rarely the axilla
3. Weakness of triceps and wrist extensors
4. Diminished or absent triceps reflex
5. Tenderness down the medial scapular border and in the supraclavicular fossa; rarely the triceps; rarely patients complain of paresthesias of all fingers

Intervertebral Disc Space at C7–T1

1. C8 root is affected
2. Pain radiates to the medial forearm
3. There is weakness of the intrinsic hand muscles
4. Slight or no decrease in the triceps reflex
5. May be misdiagnosed as an ulnar palsy

Cervical Stenosis

General Characteristics

1. The confines of the cervical spinal canal are:
 - a. Laminae and ligamentum flavum posterolaterally
 - b. Pedicles anterolaterally
 - c. Discs and vertebral bodies anteriorly
 - d. The dimensions of the cervical spinal canal at:
 1. C1–C3 normally are (16–30 mm)
 2. C4–C7 (14–23 mm)
 - e. Extension of the neck reduces the canal 2–3 mm

Pathology of Cervical Canal Stenosis

1. Congenitally small canal
2. Disc herniation with concomitant facet and uncovertebral joint osteoarthritic overgrowth of bone
3. Hypertrophy and calcification of the posterior longitudinal ligament (more common in Asian patients) are rare; this is primarily a motor illness
4. Most often, there are depressed biceps and brachioradialis reflexes. The inverted radial reflex is often present (decreased biceps reflex with increased triceps and associated finger flexion)
5. Poor tandem gait; compression of the dorsal and ventral spinocerebellar tracts that are lateral in the spinal cord and carry cerebellar afferents from the legs. This occurs late in the course of the disease
6. Neurogenic bladder

Cervical Spondylolisthesis

- Occurs most frequently following trauma and may be associated with “jumped” lamina or rotator facet joint subluxation
- Extreme guarding with restriction of neck flexion and extension neck movements
- Bilateral enhanced reflexes at the appropriate level due to severe pain:
 - If the roots are compromised and there are arthritic changes in the neural exit foraminal canals, reflexes may be depressed
 - Brachial plexus lesions
 - Lesions of the shoulder joints and muscles (innervated by cervical nerve roots)

Cervical Spondylosis*General Characteristics*

- Mechanical signs:
 - Forward flexed neck (spondylitic posture) with restricted movement to all planes
 - Proximal > distal weakness in the upper extremities; this is a C5–C6, C6–C7 disease
 - Weakness and atrophy of the deltoid, supra- and infraspinatus muscles, the rhomboids are slightly weaker than the biceps and triceps
 - Trapezius ridge is often in spasm and tender; C8–T1 muscles are generally spared (almost always affected in motor neuron disease and peripheral neuropathy)
 - Prominent sensory loss at C5, C6, C7 from the spinal nerve
- Spinal segmental muscle weakness
- Atrophy of involved muscles
- Fasciculations of involved muscles may be evoked by gentle pressure or tapping
- Absent or depressed segmental reflexes:
 - Acutely with compressive or irritated lesion, the reflexes may be slightly enhanced; they are then decreased or lost
 - In the lower extremities, the knee and ankle jerks may be enhanced (although there is lumbar segmental pathology) because the spinal cord is disinhibited (higher compressive lesions, B12 deficiency, and spinal stenosis). There are putative inhibitory fibers in the ventral root that may be affected first with compressive root lesions

Differential Diagnosis of Cervical Root Disc Disease

- The major entities that comprise disease of the cervical roots are:
 - Disc degeneration
 - Immune processes
 - Traction injuries
- Clinically:
 - Lesions affecting the dorsal root entry zone (DREZ) are painful
 - Lesions peripheral to the DRG cause numbness

- Lesions of the posterior ramus (origin is prior to the DRG):
 - Have both medial and lateral branches
 - Cause numbness, paresthesias and pain approximately 1.5 inches from the spinal process laterally
 - These lesions may also cause segmental paraspinal atrophy, sclerotomal sensory alterations, and cutaneous lesions
- Meningeal branches (dural innervations of the meninges):
 - Recurrent nerves of Spurling occur at each level
 - Particularly relevant at the L4–L5 root level (interspace) affecting the L5 root as its referral pattern is to the top of the thigh
- Ventral Root Lesions (a component of the anterior rami) give rise to motor fibers prior to joining the sensory fibers that form the spinal nerve
- Dorsal Root Entry Zone Lesions of the Cervical Spine
 - Medial dorsal root afferent fibers are thickly myelinated and carry proprioception, vibration, light touch and mechanosensation
 - Lateral dorsal root fibers carry lancinating pain (A-delta thinly myelinated) fibers and cold; C-fibers carry heat and second pain (burning quality). Gentle pressure over the exit foramina is helpful in eliciting pain in sensitive roots, C5–C6 and C6–C7 are most easily accessible in the lateral neck. Pain in the supraclavicular fossa is most often severe with upper trunk brachial plexus lesions and with C5 and C6 root lesions. Pain in the infraclavicular fossa is most often from medial cord involvement. It may be associated with evoked pain in the distribution of the intercostobrachial nerve distribution. This pain is felt in the axilla and radiates down the lateral chest wall, under the breast to the midline
 - Muscle weakness and dermatomal sensory loss at disc levels (as noted above)
 - The inverted radial reflex is extremely helpful for C5–C6 lesions
 - Rotary subluxations of the facet joints are difficult to evaluate by neuroimaging but almost always are accompanied by a head tilt
- Klippel-Feil Anomaly
 - Congenital fusion of C4–C5 > C5–C6 (C8–C4 occurs but is rare)
 - Pain at the level of the affected root
 - Spinal stenosis may be concordant at the fused level or one segment rostral
 - Associated with Sprengel’s deformity:
 - Metameric abnormalities at the level of the fusion
 - Shoulder muscles and the scapular are poorly developed; the shoulder is elevated
- Syringomyelia is common in association with high cervical and skull base anomalies:
 - Atrophy of the muscles innervated by the involved roots

- b. Associated with Arnold-Chiari Type II malformations
- 9. Congenital Root disease
 - a. C1–C3 roots
 - b. Abnormal ossification of the odontoid process or the lateral masses of the atlas
 - c. Traction on C2 and C3; there is no somatic surface sensory representation of C1 (motor only)
- 10. Platybasia of the skull:
 - a. The angle formed by the intersection of the plane of the clivus and the plane of the anterior fossa is greater than 135 degrees; traction on C2 and C3
- 11. Basilar invagination:
 - a. An upward bulging of the occipital condyles above the plane of the foramen magnum
 - b. C2–C3 impingement or nerve traction
 - i. Arnold-Chiari malformation with traction on the posterior roots of C2 and C3 that causes pain; specifically cough or valsalva maneuvers may cause severe C2 lancinating pain and/or traction

Thoracic Disc Disease

General Characteristics

- 1. Rare approximately 0.5% of herniated discs
- 2. Affect primarily T8–T11
- 3. Falls on the heels and buttocks as well as lifting very heavy objects are etiologic
- 4. These are dangerous protrusions due to a small canal at these levels that favors spinal cord compression

Clinical Manifestations

- 1. Deep boring spine pain with a lancinating radicular component that may radiate to the thorax or abdomen
- 2. Valsalva maneuvers and downward pressure on the shoulders (increase disc extrusion with further pressure on the spinal cord) exacerbate radicular pain and myelopathy
- 3. Early leg weakness with sphincter involvement occurs if the cord is compressed
- 4. Bilateral Babinski signs with cord compression are concomitant with weakness, atrophy and loss of the specific segmental reflex
- 5. Ability to hop on the toes (without the heel touching the ground) is an excellent method of uncovering leg weakness
- 6. Lateral protrusion causes intercostal or radicular pain
- 7. C8–T1 discs may affect the ipsilateral sympathetic chain to cause a Horner's syndrome

Medical Causes of Thoracic Discs

- 1. Diabetes mellitus
- 2. Syphilis (denervated disc capsule and contiguous structures; a Charcot's joint)
- 3. Amyloid (painless joint; associated with small fiber neuropathy)
- 4. Ochronosis (homogentisic aciduria; pigmented discs; "Rugger Jersey" discs by x-ray)
- 5. Relapsing polychondritis
- 6. High impact trauma

Thoracic Outlet Syndrome

- 1. The major components of the thoracic outlet:
 - a. Sterno-costovertebral space:
 - i. Most proximal part of the thoracic outlet tunnel
 - ii. Anatomy:
 - 1. Anteriorly (sternum)
 - 2. Posteriorly (spine)
 - 3. Laterally (first rib)
 - iii. The subclavian artery and vein as well as the C4–T1 roots of the plexus transverse the space
 - iv. Nerve roots have exited the spine but have not formed trunks
 - v. Associated structures:
 - 1. Apex of the lung and pleura
 - 2. Sympathetic trunk
 - 3. Jugular vein
 - 4. Lymphatics of the neck
 - vi. Rarely, the space is congenitally narrowed
 - vii. The usual pathology in the sternocostovertebral space:
 - 1. Thyroid mass
 - 2. Enlarged thymus gland
 - 3. Parathyroid mass
 - 4. Lymph nodes
 - 5. Pancoast tumor (squamous or adenoma – carcinoma of the lung)

Scalene Triangle

- 1. Anatomy:
 - a. Anterior scalene muscle anteriorly
 - b. Middle scalene muscle posteriorly
 - c. The first rib forms the base
- 2. Anterior scalene muscle:
 - a. Origins are the transverse processes of C3–C6
 - b. Insertion on the scalene tubercle of the first rib varies; tubercle insertion is between the subclavian artery and vein and pleural dome
 - c. Variants of insertion:
 - i. Behind the artery
 - ii. Between the artery and the brachial plexus
 - iii. Entire base of the scalene triangle (traps the neurovascular bundle)
 - iv. Anterior insertion may merge with insertion of the middle scalene muscle (20% of patients)
 - v. The C5 and C6 roots may traverse the anterior scalene muscle rather than descend between the anterior and middle scalene muscles
- 3. Middle scalene muscles:
 - a. Origin is the transverse processes of C2–C7
 - b. Insertion is Chassaignac's retroarterial tubercle of the first rib
 - c. May insert on the fibrous septum of the pleural dome; lateral fibers insert on the second rib
 - d. The C8–T1 roots (individually or together is the lower trunk of the brachial plexus) are compressed by a more

anterior or forward insertion of the middle scalene muscle (its sharp anterior edge)

4. First rib:
 - a. Forms the floor of the scalene triangle
 - b. T1 is closest to the rib
 - c. Congenital rib anomalies, bony ridge, hypoplasia and inward curvature may compress the neurovascular bundle
5. Scalene triangle congenital variations:
 - a. The base of the triangle is 0.77 cm in men and 0.67 cm in women
 - b. C5, C6, and C7 roots emerge from the apex of the triangle; the fibers of the middle and anterior scalene muscles also merge at the apex. Patients with C5, C6, and C7 root involvement have a greater incidence of roots that emerge from the apex:
 - i. Interdigitation of anterior and middle scalene muscles occurs in 70% of symptomatic patients
 - ii. Adherence of C5 and C6 roots to the middle scalene muscle may occur and places these roots under traction when the arm is moved
6. Costoclavicular space (compresses the brachial plexus)
7. Pectoralis minor space (compresses the lateral and medial cords of the brachial plexus)

Cervical Ribs That Compress Cervical Roots

1. 0.17% to 0.74% (average 0.3%) of the general population (female > males, 2:1) have cervical ribs
2. Approximately 10% of patients with cervical ribs are symptomatic
3. Symptomatic patients often have suffered arm trauma or are in professions that require repetitive overhead arm movement
4. Aneurysmal dilatation or subclavian artery stenosis is most often associated with a rudimentary thoracic rib or a cervical rib
5. Neurological symptoms from cervical ribs are caused by nerve compression primarily of the lower trunk (composed of the C8, T1 roots)

Rib-Band Syndrome of Gilliat

1. A Roos type II band
2. Compression of the C8, T1 roots
3. Paresthesia of the 4th, 5th finger, medial forearm to the medial humerus
4. There is atrophy and wasting of intrinsic hand muscles

Other Structural Congenital Anomalies Affecting Cervical Roots

1. Hypoglossal duct cyst (involvement of C3, C4 roots)
2. Brachial cleft cysts (involvement of C2–C5 roots)
3. Short pedicle and block vertebral bodies:
 - a. Entrapment of the root under the pedicle and in the neural foramina exit canal
 - b. Achondroplasia (at all cervical levels); there are block vertebrae and often a foramen magnum stenosis

Trauma of Cervical Nerve Roots

1. Flexion-extension injury of the neck (whiplash)
 - a. Nerve traction injury (neuropraxis) rather than soft tissue, ligament, disc or joint injury is etiologic
 - b. C8–T1 is most often involved due to congenital anatomical predisposition
 - c. C5, C6 roots are injured either prior to or after having formed the upper trunk
 - d. The dorsal root of C2, C3, and C4 are frequently injured with whiplash trauma
 - e. There is immediate pain that worsens over time and may spread extrateritorially (peripheral and central sensitization)
 - f. Autonomic dysregulation occurs (usually adrenergic sympathetic over activity) particularly with C8, T1, T2 injury. The former carry sympathetic innervations to the face, and the T2 ganglion is the primary innervation of the arm
2. Damage to cervical roots occurs during transaxillary first rib resection:
 - a. C8, T1 is most frequently involved
 - b. C5, C6 roots are most often damaged with scalenectomy and neurolysis procedures (supraclavicular approach)
 - c. Flexion-extension injury may damage the ansa hypoglossi:
 - i. Causes slight weakness of the sternocleidomastoid muscle as most of its innervations are derived from the spinal component of cranial nerve XI. Spasm of the muscle may be severe
 - ii. Hyoid and omohyoid muscles may be involved
 - iii. Scalene and trapezius muscles may be slightly weak
3. Pain radiations:
 - a. Pre-auricular nerve territory (C2, C3 roots). The radiation overlaps with V2 and V3 radiations of the trigeminal nerve for which it is confused
 - b. Post auricular nerve territory (C3, C4 roots). This territory covers the ear, overlaps with C2 at the angle of the jaw and radiates to the parietal and occipital areas of the skull
 - c. Specific radiations of C2 in isolation are to the base of the occiput, angle of the jaw, parietal scalp and to the brow. The brow radiations are common with cough or valsalva maneuvers in the face of Chiari malformations and with severe cervical spondylosis
 - d. Greater and lesser occipital nerve distributions (C2, C3, C4) posterior roots. Primarily innervate the basiocciput and occipital areas of the scalp
4. Surgical trauma:
 - a. C5, C6, C7 roots are most often affected
 - b. Instrumentation that requires plates and pedicle screws
 - c. Arachnoiditis of the nerve sleeves or direct injury or irritation of the affected roots

- d. High impact trauma (MVA, falls, contact athletics)
 - i. Spondylolisthesis of cervical vertebrae
 - ii. Avulsion of nerve roots (a common motor cycle injury)
 - iii. Jumped laminae
 - iv. Rotary subluxation of a facet joint presents with:
 1. Pain at the segmental level in the neck with radiation into the affected segmental distribution
 2. Torticollis (to the affected side)
 3. Segmental weakness
 - v. Injury by epidural catheterization with bupivacaine >0.25% or trauma by the catheter itself

Complex Regional Pain Syndrome I and II (CRPS)

1. CRPS occurs most frequently after injury of small nociceptive afferents in soft tissue (Type I) or of a specific injured nerve (Type II)
2. Clinically it is manifested by:
 - a. Hyperalgesia and thermal and mechanical allodynia
 - b. Autonomic dysregulation:
 - i. Temperature change
 - ii. Hyper- or hypohidrosis
 - c. A movement disorder associated with atrophic changes in the affected areas
 - d. Severe spreading pain that involves multiple roots and hence is regional

Red Ear Syndrome

1. The C3 root is involved
2. Usually, one ear is involved but the process may be bilateral
3. The ear is beet red, slightly edematous and non-painful
4. The underlying pathology is thought to represent neurogenic edema. The irritated small fibers that innervate blood vessels of the ear and release vasoactive neuropeptides (principally substance P and calcitonin gene-related peptide). These peptides cause vasodilatation of the capillaries in the ear (CGRP) and leakage of the plasma through the endothelium (substance P)

Lax Ligament Syndrome (That Attach the Odontoid Process to the Atlas)

1. Four ligaments are involved:
 - a. A cruciate posterior ligament that attaches the odontoid process to the axis
 - b. Lateral ligaments that attach the odontoid process to the lateral mass of C1
 - c. The alar ligament from the tip of the odontoid process to the rim of the foramen magnum
2. Normal posterior odontoid displacement with neck flexion is:
 - a. 3–5 mm in children
 - b. 1–2 mm in adults
3. In abnormal displacement the C2 root is primarily involved with concomitant spinal cord compression

Differential Diagnosis of Cervical Ligament Disorders

1. Rheumatoid arthritis:
 - a. Frequently there is tingling of all fingers, the arms and the hands, most likely from cervical spinal cord compression
 - b. Subluxation at high cervical levels with spinal cord compression
 - c. The rheumatoid pannus erodes the cruciate ligament
2. Trisomy 21
3. Ehlers-Danlos syndrome (Type IV)
4. Marfan's syndrome
5. Trauma (flexion/extension) injury of the neck

Ligament Hypertrophy with Cervical Root Impingement

Differential Diagnosis

1. Acromegaly
2. Mucopolysaccharidosis:
 - a. Morquio's syndrome has concomitant absence or hypoplasia of the odontoid process
3. Posterior ligament ossification syndrome
4. IgG-4 syndrome – a form of pachymeningitis
5. Hirayama syndrome (ligament laxity at lower cervical levels with spinal cord compression)

Pachymeningitis with Cervical Root Compression

1. Syphilis
 - a. Dense fibrous dural thickening surrounding the roots and cervical cord
2. Sarcoid
3. Tuberculosis
4. IgG-4 syndrome and idiopathic pachymeningitis
5. Subarachnoid hemorrhage with consequent arachnoiditis
6. Hodgkin's and non-Hodgkin's lymphoma

Tumors of the Cervical Nerve Roots

1. Schwannoma:
 - a. Associated with neurofibromatosis (NFT) type I mutations on chromosome 17; Type II causes bilateral Schwannoma on the VIIIth nerve (the mutation is in chromosome 22)
 - b. May affect multiple nerve roots concomitantly
 - c. Root and plexiform involvement > in lumbosacral than brachial distributions
 - d. A dumbbell tumor; characteristically it involves the nerve which enlarges the nerve exit foramen and occupies the intradural extramedullary space with slowly progressive cord compression
2. Neurofibroma
3. Meningioma
 - a. Intradural extramedullary growth; concomitant nerve root compression
 - b. Plexiform (en-plaque growth)
4. Lymphoma (infiltration of nerve roots)
5. Leukemia:

- a. Hemorrhage into a nerve root (acute presentation)
- b. Infiltration of nerve roots (insidious presentation)
6. Carcinomatosis of the meninges:
 - a. Primary tumors are lung, breast, GI tract and prostate
 - b. Mental status alteration
 - c. Asymmetric cranial nerve and radicular presentation
 - d. Weakness, atrophy, sensory alterations, loss of reflexes in a segmental distribution
7. Chordoma:
 - a. Most common in the clivus and sacral vertebrae; rarely occur in the thoracic and cervical vertebrae (10%)
8. Osteogenic sarcoma is rare
9. Fibrosarcoma (degeneration of a neurofibroma)
10. Chondrosarcoma (rare)
11. Ewing's sarcoma
 - a. Greater than 5% occur in the axial vertebrae
12. Pancoast tumor:
 - a. Occur at the apex of the lung (adenoma or squamous carcinomas)
 - b. Involvement is primarily of lower nerve roots (C8–T1) in the sternocostovertebral space
 - c. Pain (usually burning in quality) along the medial forearm and into the 4th and 5th fingers
 - d. Horner's syndrome (involvement of the sympathetics at C8–T1)
13. Lymphomatous B-cells
 - a. Diffuse radiculopathies
14. Post x-ray treatment sarcoma:
 - a. Follows x-RT for breast cancer most frequently
 - b. Involves roots of the brachial plexus C8, T1 > C5, C6
 - c. May be delayed in onset from the last treatment by years
 - d. Associated with myokymia in the irradiated arm
 - e. Associated with skin changes that include hyperpigmentation, telangiectasia and proliferative endarteritis
 - f. MRI reveals hypertrophy and swelling of the trunks and cords of the plexus that enhance with contrast
15. Neuromyotonia with Hodgkin's disease
 - a. Rippling fasciculation in the innervated muscles of the affected nerve roots
 - b. Anti-TA antibodies may be detected in the serum
16. Mixed salivary gland tumors:
 - a. Infiltrate C1–C4 roots
 - b. "Sugar coated" roots
17. Parotid gland tumors:
 - a. VIIth nerve most frequently involved
 - b. Cervical C2–C4 roots are involved less frequently
 - c. Swollen parotid glands noted in diabetes mellitus, mumps, HIV, tumors, and uremia
18. Salivary gland cylindroma:
 - a. Cervical C1–C4 roots are infiltrated
 - b. May have concomitant cranial nerve involvement

Infection Involving Cervical Nerve Roots

Herpes Zoster

1. C5, C6 > C4, C5 > C8, T1 are the most commonly involved roots (cervical)
2. Clinical symptomatology:
 - a. Grouped vesicular eruption in a dermatomal distribution
 - b. Sensory loss in a dermatomal pattern to all modalities; severe pain in the affected dermatome
 - c. Atrophy, weakness much less than sensory alterations (subtle)
 - d. May have dermatomal sensory alterations for weeks to (occasionally) months prior to the vesicular eruption:
 - i. Sometimes there may not be an eruption (herpes sine herpetica)
 - ii. There is often burning pain in the affected dermatome

Post-Herpetic Neuralgia

1. Spontaneous lancinating pain
2. Deep continuous ache with lancinating exacerbations in the involved dermatome
3. Decreased sensory threshold to pinprick, touch or temperature of the dermatome
4. Allodynia to both static and dynamic mechano and thermal stimuli of the neighboring dermatomes but at times of the affected dermatome
5. Hyperalgesia of the involved dermatome
6. Neuroma in continuity along the root of the affected dermatome as well as central sensitization may be the mechanisms
7. Immune suppression is often concomitant

Herpes Simplex

1. A single or grouped vesicular eruption
2. Painful erythematous base
3. May be dermatomal but can be regional (several roots involved) pain

Brucella Mellitensis

1. Hyperhidrosis with fever
2. Non-pasteurized milk may be the source
3. Rare cervical root involvement (L5 is particularly involved)

Lyme's Disease

1. Unilateral or bilateral VIIth nerve palsy
2. C5, C6 cervical roots most often affected
3. Often arthralgia or erythema migrans is noted prior to neurologic symptoms

Staphylococcus Aureus

1. Contiguous spread from site of infection
2. Usually seen with IV drug abuse or following surgical procedures; hematogenous spread with SBE
3. Disc space involvement first; the nerves are compromised in the foraminal exit areas or laterally

Viral Infections

1. Parsonage Turner syndrome
 - a. The sudden onset of severe lancinating, burning, and deep pain
 - b. C5, C6 dermatomes are most often affected
 - c. A cause of neuralgic amyotrophy
 - d. May affect individual nerves (phrenic)
2. EBV
3. Hepatitis C (associated cryoglobulinemic neuropathy)
4. Poliomyelitis acute:
 - a. Usually groups of anterior horn cells are affected
 - b. Pain and deep ache in affected muscles
 - c. Isolated muscles affected (including fingers); asymmetric involvement; non-dermatomal distribution
 - d. Fasciculation and atrophy are prominent long after the infection
 - e. Post-polio syndrome follows in a significant percentage of patients and is characterized by:
 - i. Pain in affected muscles
 - ii. Weakness returns in formerly weak muscles; increased weakness may occur
 - iii. Enterovirus (polio-like syndrome) primarily motor
 - iv. Adenovirus
 - v. Coxsackie particularly 6 and 9 strains

Systemic Diseases Affecting Cervical Nerve Roots*Diabetes Mellitus*

1. Diabetic amyotrophy is much more common in L2–L4 roots
2. Putative involvement of the vasa vasorum in addition to axonopathy and demyelinating features of the polyneuropathy
3. May be bilateral; the second event occurs 6–8 weeks following the first

Acute Intermittent Porphyria

1. C5, C6 roots are most commonly involved
2. Overwhelmingly there is a motor neuropathy with severe atrophy and wasting of the involved muscles
3. Sensory symptoms more often than signs may be patchy; often out of a dermatomal distribution

Variegate Porphyria

1. Rare root involvement
2. May have associated skin rash

Post-X-RT Therapy

1. C5, C6 roots primarily are involved following cervical cord treatment
2. Myokymia may be prominent

*IgG4 Pachymeningitis**Sicca Complex*

1. Autoimmune

2. May have patchy anhidrosis and sensory loss out of a dermatomal distribution
3. Probable dorsal root ganglionopathy
4. May involve definable cervical roots

Amyloidosis

1. Familial amyloid
2. FOLMA (familial oculoleptomeningeal amyloidosis)
 - a. Meningeal involvement with nerve root compression

Isolated Angiitis of the CNS/PNS

1. Arteritis of the vasa vasorum that supply cervical nerve roots

Inflammatory Spondyloarthritis with Radiculopathy

1. Rheumatoid arthritis
2. Psoriasis
3. Ankylosing spondylitis
4. Crohn's disease
5. Ulcerative colitis
6. Behçet's disease

Vascular Disease of Cervical Nerve Roots*Arteriovenous Malformation*

1. Nerve root (on the root itself)
2. Dural AVM with accompanying compression of the nerve root

Dilated Vein Compressing the Nerve Root

1. Venous congestion from severe cervical spondylosis or an extruded disc
2. Concomitant venous congestion of the spinal cord (myelomalacia) and the nerve root
 - a. Postulated that veins over the nerve root cause mechanical pressure on the sensitized root that awakens patients with disc disease in the early morning

Foix-Alajouanine Syndrome

1. Arteriovenous malformation involving the anterior spinal artery
2. Cervical nerve roots and the spinal cord may be compressed

Weber-Klippel-Trenaunay Syndrome

1. Arteriovenous malformation of an extremity
2. Enlargement of the bone and soft tissue components of the extremity
3. Enlarged epidural veins and their tributaries may compress segmental nerve roots

Superficial Siderosis

1. Hemosiderin deposits on nerve roots
 - a. Radiculopathy
 - b. Cranial nerves I and VIII may be concomitantly involved

- c. Caused by repeated bleeding from aneurysms, cavernous hemangiomas or rarely telangiectasias
- d. Demonstrated by gradient ECHO or susceptibility weighted MRI sequences

Arachnoiditis

1. Clumping together and scar formation of nerve roots
 - a. Secondary to:
 - i. Multiple surgeries
 - ii. No longer seen from myelography due to the use of water-soluble contrast media
 - iii. Clinical manifestations
 1. Severe burning pain in several dermatomal distributions
 2. Usually a regional rather than a clear radicular pattern
 3. CT/myelography demonstrates clumping of nerve roots or a featureless dural sac
 4. MRI demonstrates gadolinium enhancement of the scar
 5. Minimal weakness; burning pain predominates
 6. Asymmetric reflex loss
 7. Rare bladder involvement

Rarely caused by aneurismal rupture of a vertebral or anterior spinal artery.

Differential Diagnosis of Cancer vs X-RT Involvement of Cervical Nerve Roots

1. Usually X-RT treatment of head and neck cancer
2. Signs and symptoms are often delayed from six weeks to three months

Cancer

1. Painful (burning quality)
2. C8, T1 roots are primarily involved
3. Horner's syndrome
4. Pancoast tumor of the lung apex (adenoma or squamous cell carcinomas)

Cervical X-RT

1. Dysesthesias or paresthesias of the involved roots
2. C5, C6 roots are primarily involved
3. No Horner's syndrome
4. Myokymia of the muscles in the involved dermatomes
5. X-RT of the breast, Hodgkin's disease, head and neck cancers are the most common systemic illnesses treated
6. Often missed by conventional x-ray; MRI for diagnosis
 - a. Segmental radiculopathy
 - i. Pain is usually the most prominent symptom
 - b. Burst fracture of the vertebral body:
 - i. Vertebral body star fracture (radiation of fracture lines from the center of the vertebral body)
 - ii. Bilateral radicular pain
 - iii. Fractured bone fragment may be displaced into the spinal canal or foraminal exit area

- iv. Concomitant spinal cord direct injury and compression

- c. Lateral vertebral body translocation:
 - i. Severe high impact trauma (most often MVA)
 - ii. Bilateral radicular pain
 - iii. Associated severe spinal cord injury

7. Anterior vertebral body compression fracture:
 - a. Middle-aged and elderly women

Thoracic Root Disease

Disc Disease

General Characteristics

1. Trauma
 - a. Severe trauma (high impact MVA, heavy lifting, direct spinal injury)
 - b. Dull boring midline ache with episodes of radicular lancinating pain
 - c. Intercostal or abdominal radiations
 - d. Exacerbated by specific movements
 - e. Radicular pain associated with signs of compressive myelopathy

Traumatic Thoracic Radicular Disease

General neuroimaging features:

1. Jumped facet joint:
 - a. Overriding of the inferior over the superior facet joint
 - b. Traction or direct injury of the segmental root
2. Rotary subluxation of the facet joint
 - a. Facet joint is twisted; synovial interfacet is breached with metabolic bone disease (osteoporosis)
 - b. Due most often to minimal trauma
 - c. Lancinating radicular pain at the involved segmental level

Rarer Causes of Thoracic Root Disease

Syrinx

1. Atrophy at the segmental level
2. Early hyperhidrosis followed by anhidrosis of the affected segments
3. Dissociated sensory loss at the segmental level (destruction of spinothalamic fibers as they decussate in the anterior ventral commissure)
4. Long tract motor and sensory signs below the syrinx

Post-Traumatic Syrinx

1. Further cystic degeneration of the spinal cord
2. Usually, there is a 2 to 3 segment loss of function above and below the level of injury
3. Bilateral root involvement at the involved segmental level

Chest Surgery

1. Open heart

2. Lung surgery
3. Retraction (neuropractic or direct radicular injury; post-thoracotomy syndrome)
4. Prolonged and often refractory neuropathic pain of the involved roots or intercostal nerves

Thoracic Nerve Root Involvement from Systemic Disease

Diabetes Mellitus

1. Infarction or ischemia of the thoracic nerve roots (vasa vasorum) or usual etiology of diabetic polyneuropathy occurs in:
 - a. Elderly type II diabetics
 - b. Associated with weight loss
 - c. Abrupt onset
2. Diabetic “dying back” neuropathy:
 - a. Shield sensory loss on the chest wall
 - b. Associated with distal dying back neuropathy of the extremities
 - c. Single or multiple dermatomal involvement of the chest or abdomen
 - d. Sensory loss is in the distribution of the anterior rami (dorsal root component) or posterior rami (paravertebral sensory territory); the sensory loss may be in various combinations of the territories of these rami

Amyloid Neuropathy

1. Associated with primary amyloid neuropathy; also the TTR met 30 mutation (transthyretin)
2. Familial oculoleptomeningeal amyloidosis (FOLMA)
3. Denervation of the segmental disc (rarely associated with a Charcot’s joint)
4. Radicular pain due to root irritation

Ochronosis

1. AR; homogentisic acid synthetase deficiency
2. Dark urine (homogentisic aciduria)
3. Calcification and degeneration of multiple thoracic discs
4. “Rugger-Jersey” x-ray evaluation (calcification of the discs)
5. Differential diagnosis of calcified thoracic discs
 - a. May be asymptomatic
 - b. Ankylosing spondylitis
 - c. Hyperparathyroidism
 - d. Toxins

Immune-Mediated Processes That Affect Thoracic Roots

1. Acute inflammatory demyelinating polyneuropathy (AIDP):
 - a. GMI, Gd1b, Gal-Nac-GD1a antibodies
2. Chronic inflammatory demyelinating polyneuropathy (CIDP)
3. Sjögren’s disease:
 - a. Primarily a dorsal root ganglionitis
 - b. Involvement of the dorsal primary ramus or its medial or lateral divisions

Sicca Complex

1. Dry eyes, mouth, serous membranes
2. Segmental and regional sensory loss
3. Segmental and regional anhidrosis
4. Radiculopathy with increased sed rate
 - a. Poorly defined process
 - b. Usually, the lumbosacral roots are involved

Cancer and Benign Tumors

1. Leukemia
2. Hodgkin’s disease and non-Hodgkin’s disease lymphoma
3. Carcinomatosis of the meninges
4. Metastatic cancers

Tumor

1. Anterior mediastinal tumors (rarely involve thoracic roots)
 - a. Thymoma and thymic carcinoma are usually locally invasive
 - b. Thymic carcinoid (associated with multiple endocrinopathy type I);
 - c. MEN (multiple endocrinopathy) associated with:
 - i. Thymic lipoma
 - ii. Hodgkin’s and non-Hodgkin’s lymphoma (NHL)
2. Primary mediastinal germ cell tumors:
 - a. Mature teratoma
 - b. Seminoma
 - c. Non-seminomatous germ cell tumors

Posterior Mediastinal Tumors

1. Peripheral nervous system benign and malignant neoplasms are more frequent in the posterior mediastinum
2. They develop from peripheral nerves, sympathetic and parasympathetic ganglia, as well as neural tube embryonic remnants and include:
 - a. Schwannoma
 - b. Neurofibroma
 - c. Melanotic Schwannoma
 - d. Ganglioneuroma
 - e. Granular cell tumor
 - f. Malignant melanocytic nerve sheath tumor
 - g. Neuroblastoma
 - h. Neurofibrosarcoma (non-Recklinghausen’s disease)

Metastatic Disease (to the Cervical Root)

1. Multiple myeloma
2. Osteoclastic myeloma
3. Plasmacytoma
4. Paget’s disease (sarcomatous degeneration)
5. Multiple myeloma (vertebral fractures with secondary radicular involvement)
6. GI cancer (sacral bone involvement with colon cancer; lumbar and sacral roots > thoracic root involvement)
7. Giant articular bone cyst (vertebral fracture)
8. Osteoid osteoma:

- a. Refractory to narcotics the pain responds to prostaglandin inhibitors
- b. Involve the posterior elements of the vertebral body (pedicles and facets)
- c. Radicular symptoms
9. Vertebral body sarcoma
10. Chondrosarcoma
11. Enchondroma
 - a. Involves the nerve root exit foramina
12. Chordoma:
 - a. Approximately 4% involve thoracic vertebrae
13. Brown bone cyst:
 - a. Occurs with hyperparathyroidism
 - b. Bone resorption, fracture and pain
14. Hemangioma of the vertebral body
 - a. Most often they are an incidental bone finding on MRI T2-weighted sequences
 - b. May weaken the vertebral body
 - c. The lesions are extremely vascular
 - d. May compress the exiting nerve root
15. Thoracic meningioma in women
 - a. Extremely rare location for meningioma in men
 - b. Increased growth of the tumor in pregnancy and with breast cancer
16. Schwannoma:
 - a. Typically enlarges the foramina nerve root exit canal
 - b. Scalloping of the affected vertebral body (a sign of chronic pressure)
 - c. A dumbbell tumor (both enlarging the nerve root and expanding in the intradural extramedullary space)
17. Neurofibroma
4. Gram-negative disc space infection following surgery:
 - a. Involvement and signs of infection may be delayed for up to six weeks from the procedure
 - b. Pain, swelling, erythema and edema at the operative site
 - c. Invariably high sediment rate and C-reactive proteins
5. Tuberculosis:
 - a. T4–T6, T11–T12, L1–L2, the usual location of the infection
 - b. The infection is more common in the cervical spine in Asian patients
 - c. Disc space is infected > than the vertebrae; bony sclerosis of the vertebral body and endplates on neuroimaging
 - d. Pott's disease
 - i. Acute kyphotic angulation
 - ii. Occurs from vertebral body collapse and loss of disc integrity
 - iii. May cause spastic paraparesis
 - e. Cold abscess may occur along the iliopsoas muscle; T10–T11 root may be involved; blurring of the psoas stripe on x-ray of the abdomen
6. Actinomycosis:
 - a. Extension of active lung infections into thoracic vertebrae
 - b. Abscess with radicular symptoms
 - c. Characteristic sulfur granules in the abscess
 - d. Rural population
7. Nocardia:
 - a. Occurs in immunocompromised patients
 - b. Epidural vein involvement
 - c. The fungus is often in a lung abscess
 - d. Associated with osteomyelitis

Infections Involving Thoracic Roots

1. HZ (Herpes Zoster)
 - a. Thoracic dermatomes are most commonly involved
 - b. Clinical symptoms (similar to that of cervical roots)
 - c. A dorsal root ganglionitis
 - d. Rarely a hemorrhagic spinal cord infarction is associated (paraparesis is most often at the T4–T6 level)
2. HIV
 - a. Usually, the cervical cord is involved
 - b. Vascular degeneration of the cord
 - c. Rare radicular complaints
3. Staphylococcus aureus
 - a. Young IV drug abusers; there are end arteries to the disc
 - b. The disc space is infected:
 - i. Enhancement of the disc with contrast on MRI
 - ii. The vertebral body is spared: there is often pre- and postvertebral ligament inflammation (enhancement with gadolinium on T1-weighted sequences)
 - iii. Disc space infection causes severe lancinating radicular pain; minimal movement initiates pain (touching the patient's bed)
 - iv. Spinal cord involvement by contiguous spread or by venous infarction

Lumbosacral Root Disease L1–L5; S1–S5

General Characteristics

1. Higher lumbar root pathology:
 - a. Autoimmune processes
 - b. Connective tissue diseases
 - c. Retroperitoneal processes (tumors, hemorrhage, fibrosis)
 - d. Diabetes mellitus
 - e. Vasculitis

Lower Root Involvement (L4–S1)

1. Degenerative disc disease
2. Lumbar spondylosis
3. Lumbar spondylolisthesis
4. Spinal stenosis
5. Facet hypertrophy and tropism
6. L5–S1 lateral recess syndrome
7. Surgical procedures

Combined Lumbosacral Root Disease

1. Tumors (metastatic)
2. Surgical and post-surgical complication
3. Arachnoiditis
4. Congenital abnormalities

Congenital Defects of Lumbosacral Roots*Scoliosis*

General Characteristics

1. Congenital scoliosis is the failure of normal vertebral development during the 4th to 6th week of gestation

Associated Conditions

1. May occur in isolation
2. Occurs with systemic anomalies in approximately 60% of patients that include:
 - a. Cardiac defects – 10%
 - b. Genitourinary defects – 25%
 - c. Spinal cord malformations
 - d. Associated with syndromes that include:
 - i. VACTERL syndrome
 - ii. Oculo Auricular Vertebral syndrome
 - iii. Jarcho-Levin syndrome/spondylocostal dysostosis
 - iv. Klippel-Feil syndrome
 - v. Alagille syndrome

Clinical Manifestations

1. Localized lumbar pain usually in the nerve roots on the contralateral side
2. Patients are more susceptible to further compression by disc, bone, or ligament

Neuropathology

1. A developmental defect in the formations of the mesenchymal component of the vertebra
2. Failure of formation:
 - a. A normal fully segmented hemivertebra (normal disc space above and below)
 - b. Semisegmental hemivertebra
 - i. Hemivertebra fused to the adjacent disc on one side
 - c. In segmented hemivertebra:
 - i. Hemivertebra fused to vertebra on each side
 - d. Incarcerated hemivertebra:
 - i. Fused within the lateral margins of the vertebra above and below
 - e. Unincarcerated hemivertebra:
 - i. Laterally positioned
 - f. Wedged vertebra
3. Failure of Segmentation:
 - a. Block vertebra:
 - i. Bilateral bony bars
 - b. Bar body:
 - i. Unilateral unsegmented bar is common
 - c. Mixed:
 - i. Unilateral unsegmented bar with contralateral hemivertebra
 1. Progresses the most rapidly

Neuroimaging

1. MRI:

- a. All patients with congenital scoliosis to evaluate the complete neuraxis to rule out associated other anomalies that occur in 20–40% of patients and include:
 - i. Chiari malformations
 - ii. Tethered cord
 - iii. Syringomyelia
 - iv. Diastematomyelia
 - v. Intradural lipoma
- b. 3D CT
 - i. Best delineation of posterior bony anatomy

Laboratory Evaluation

1. Renal ultrasound or MRI
2. Echocardiogram

Adult Scoliosis

General Characteristics

1. Definition: a spinal deformity with a Cobb angle of more than 10° in the coronal plane in a skeletally mature patient
2. Separated into 4 categories:
 - a. Type I (primary degenerative scoliosis)
 - i. Disc or facet joint arthritis that affects the spinal column asymmetrically
 - b. Type II (idiopathic adolescent scoliosis) which progresses to adulthood
 - i. Combined with secondary degenerations
 - ii. Surgical or no surgical treatment
 - c. Type III (secondary adult curves) in addition to:
 - i. Oblique pelvis due to leg length differences or hip pathology
 - ii. Idiopathic, neuromuscular, or congenital scoliosis
 - iii. Lumbosacral junction asymmetry anomalies
 - d. Context of metabolic bone disease (primarily osteoporosis) combined with asymmetric arthritic disease or vertebral fracture Type IV (no identifiable cause)

Clinical Manifestations

1. Low back pain
2. Signs of contra or lateral spinal stenosis
3. Radicular pain at the appropriate level
4. Claudication (neurogenic) symptoms

Neuropathology

1. Asymmetric degeneration leads to spinal load imbalance with bone remodeling and further degenerative changes
2. Destruction of facet joints, joint capsules, disc and ligaments
3. Multi-segmental instability

Neuroimaging

1. MRI and CT evaluation:

- a. Degenerative facet joint changes (hypertrophy and tropism); thickened ligaments

- b. Central and lateral spinal stenosis
- c. Disc desiccation with degeneration and loss of disc height

Laboratory Evaluation

- 1. Bone metabolism evaluation
- 2. Extensive medical evaluation of older patients prior to surgery

Lordosis

General Characteristics

- 1. Increased angulation of the spine, the anterior pelvic tilt angle

Clinical Manifestations

- 1. Postural pain
- 2. Radiculopathy at the segmental level (usually L3–L5)
- 3. Facet pain

Neuropathology

- 1. Increased compression of the apophyseal joint
- 2. Increased anterior shear force at the lumbosacral junction
- 3. Possible precursor to spondylolisthesis

Neuroimaging

- 1. MRI or CT:
 - a. Measurement of the lordosis angles in relation to the anterior pelvic tilt
 - b. A sharp angle of L5 in relation to S1; the closer to 180-degree plane > traction on L4, L5, and S1 nerve root

Conjoined Nerve Roots

General Characteristics

- 1. Two adjacent nerve roots that share a common dural envelope during their course from the dural sac
- 2. The incidence by CT, MRI and myelography vary widely 2–17% in patients studied with spine imaging

Clinical Manifestations

- 1. Straight leg raising test may be negative
 - a. A distinguishing clinical feature from disc herniation
- 2. Usual presentation is sciatic pain
- 3. The L5 and S1 roots are most frequently involved. L4 and L5 are next in frequency
- 4. Claudication pain rather than that of a fixed radiculopathy; radicular symptoms with rest pain are more common with disc herniation
- 5. Neurologic deficits (motor and sensory) are more common with disc disease

Neuropathology

- 1. The dorsal roots may be more commonly involved than the ventral roots
- 2. Bifurcation occurs close to the intervening pedicles; they then enter their respective foramina

- 3. Abnormal root anastomosis is caused from a connection of a band of nerve fibers or a distal union in a common sheath
- 4. There is decreased mobility of the root which increases its risk of neuropractic or direct injury during neurosurgical procedures

Neuroimaging

- 1. Features typical of conjoined roots include:
 - a. MRI:
 - i. Equal density of the nerve root anomaly and the thecal sac
 - b. Asymmetry of the subarachnoid space (pouching out) in the axial view at the level of the anomaly that may be above the intervertebral disc space
 - c. Possible specific MRI signs:
 - i. Asymmetric morphology of the anterolateral corner of the dural sac
 - ii. Intervening extradural fat between the asymmetric dura and the nerve root
 - iii. Visualization of the entire course of the nerve root at the disc level
 - iv. Focal lateral recess and foraminal stenosis

Perineural Cysts (Tarlov Cyst)

General Characteristics

- 1. Naba classification:
 - a. The cysts are located in the perineural space between the endoneurium and perineurium
 - b. Type I cyst:
 - i. Extradural meningeal cyst without spinal nerve root fibers
 - c. Type II
 - i. Spinal extradural meningeal cyst with spinal nerve roots
 - d. Type III
 - i. Spinal intradural meningeal cysts
- 2. Cystic dilatations of the lumbosacral roots at or distal to the junction of the posterior root or DRG
- 3. Incidence in adults is between 4–9%; there is no sex predilection
- 4. CSF filled

Clinical Manifestations

- 1. Most often they are asymptomatic
- 2. A ball valve mechanism from hydrodynamic CSF forces causes the perineural cyst to fill with CSF and expand
- 3. Back pain
- 4. Radicular pain
- 5. Rarely bowel and bladder dysfunction
- 6. Leg weakness
- 7. Sexual dysfunction
- 8. Infertility

Neuropathology

- 1. The cysts are frequently multiple

2. Arachnoidal proliferation around the lumbosacral involved root
3. Putative absence of dura mater during development
4. Possible hemorrhage with hemosiderin deposition leading to venous drainage into the perineurium
5. Lining of the cyst contains nerve fibers and/or ganglion cells; they have a synovial lining; pseudo-stratified columnar epithelium

Neuroimaging

1. MRI
 - a. Fluid filled lesion with low signal on T1-weighted sequences and high signal in T2-weighted images
2. May erode bone; particularly prominent with sacral cysts
3. There may be communication of the cysts with the subarachnoid space

Cysts of the Ligamentum Flavum

General Characteristics

1. Ligamentum flavum cyst is a juxtafacet cyst; synovial and ganglion cysts that are adjacent to facet joints or that arise from the ligamentum flavum
2. A classification of juxtafacet cysts by location has been proposed:
 - a. Flavum cyst
 - b. Facet cyst
 - c. Posterior longitudinal ligament cyst
3. The ligamentum flavum is attached above and below to the lamina and laterally to the articular facet
 - a. Dorsal in the intervertebral foramen
 - b. Fused with the capsule in the lateral surface of the superior articular process in the lumbar spine
4. Most common level is L4–L5 > L5–S1 > L3–L4

Clinical Manifestations

1. Usual presentation is that of radiculopathy
2. Often asymptomatic
3. Back pain

Neuropathology

1. Collagen fibers in the cyst wall without a synovial lining

Neuroimaging

1. MRI:
 - a. Isointense or variable intensity on T1-weighted sequences; isointense with T2-weighted sequences
2. No communication with the facet joint
3. May present with intraluminal hemorrhage or with air or gas in the cavity

Differential Diagnosis of Cystic Lesions of the Ligamentum Flavum

1. Granuloma
2. Intraligamentous amyloid deposition
3. Ossification

4. Myxomatous degeneration and hematoma
5. Perineural cyst
6. Intraspinal dermoid cyst
7. Neurofibroma
8. Hydatid cyst
9. Cysticercosis

Achondroplasia

General Characteristics

1. The most common form of non-lethal skeletal dysplasia
2. Genetics:
 - a. Mutation of the fibroblast growth factor receptor 3-gene (FGF R3); autosomal dominant
3. Prevalence is 0.36 to 0.6 per 10,000 live births
4. Defining clinical features are:
 - a. Short stature
 - b. Disproportionately shorter proximal limb bones
 - c. Narrow trunk
 - d. Macrocephaly
 - e. Prominent forehead and flattened midface
 - f. Short broad hands; trident fingers
5. General medical complications:
 - a. Musculoskeletal
 - b. Cardiorespiratory
 - c. Ear, nose, and throat
6. Neurological complications:
 - a. Cervicomedullary spinal cord compression
 - b. Sleep apnea
 - c. Disordered respiration
 - d. Myelopathy
 - e. Hydrocephalus
 - f. Ligament laxity

Clinical Manifestations (Lumbar Stenosis)

1. 80% of individuals are symptomatic by age 60
2. Radiculopathy with claudication
3. Compressive cervical myelopathy

Neuropathology

1. Narrow spinal canal
2. Short pedicles
3. Narrowed exit foramina
4. Block vertebra
5. Abnormal chondrocyte proliferation and differentiation in the growth plate

Neuroimaging

1. MRI evaluation of neuropathological bone changes as above
2. Foramen magnum stenosis
3. T11–T12 spinal stenosis

Laboratory Evaluation

1. Sleep studies to evaluate for sleep apnea
2. Evaluation for cervical medullary decompression emergent surgery if there is disorder breathing

Congenital Spinal Stenosis

General Characteristics

1. Developmental lumbar spinal stenosis is a maldevelopment primarily of the dorsal spinal elements
 - a. Short pedicles
 - b. Trefoil bony spinal cord

Clinical Manifestations

1. Similar clinical symptomatology as acquired stenosis but presents at an earlier age
2. Subtle clinical signs of spondylosis

Neuropathology

1. Multilevel involvement with L3, L4, and L5 most severely involved
2. Severe stenosis at L1, L2, and S1 is rare

Neuroimaging

1. Shorter pedicle length
2. Smaller cross-sectional spinal canal area
3. Block vertebra
4. Narrowed exit foramina

Lateral Recess Syndrome

General Characteristics

1. The lateral recess may be the principal site of pathology in lumbar canal stenosis
2. Anatomy:
 - a. Bordered laterally by the pedicles, posteriorly by the superior articular facet and ligamentum flavum and anteriorly by the vertebral body, endplate margin and disc margin
 - b. It is funnel shaped and is narrowest in its cranial extent at the superior portion of the pedicle

Clinical Manifestations

1. Radicular signs and symptoms
2. If the compression is in the intervertebral foramen, extension of the trunk in conjunction with ipsilateral side bending and rotation reproduces the symptoms

Neuropathology

1. Two morphologic forms cause root compression in the lateral recess:
 - a. A congenital trefoil-shaped lateral recess becomes smaller; the superior articular facet hypertrophies or the disc margin enlarges from an endplate spur or a disc bulge
 - b. Angular pinch-like encroachment of the lateral margin of the canal from facet endplate and disc margin alterations
 - c. Composition of osteophytes that cause lateral recess encroachment:
 - i. Fibrous and hyaline cartilage and cancellous bone
 - ii. Intramembranous bone formation possibly due to segmental instability

Neuroimaging

1. CT measurement of the posterior edge of the vertebral body and the anterior part of the articular facet in the pedicular slice at the level of the upper vertebral platform
 - a. Lateral recess stenosis occurs when the nerve root is trapped in the bony margins of the lateral recess or exit foramen

Tethered Cord

General Characteristics

1. Traction of the conus medullaris and cauda equina by a tight thickened filum terminale
2. Two clinical categories:
 - a. Asymptomatic in childhood and present for the first time in adult life
 - b. Patients with pre-existing static skeletal/neurologic abnormalities that progress in adult life

Clinical Manifestations

1. Pes cavus (uni- or bilateral)
2. Cutaneous stigmata (strawberry hemangioma; cutaneous dimple) over the sacrum
3. Back pain; may have anal and perianal pain; genital or diffuse leg pain
4. Motor and sensory radicular deficits of lumbar and sacral roots
5. Sphincter alterations
6. Symptomatic with specific positions; particularly the dorsal lithotomy position
7. Symptomatic following delivery or vaginal surgery (primarily due to the dorsal lithotomy position)
8. Urodynamic features:
 - a. Hyper-reflexia of the bladder (neurogenic bladder)
 - b. Internal and external detrusor dyssynergia
 - c. Decreased bladder sensation and compliance
 - d. Hypocontractility of the detrusor muscle
9. General hyper-reflexia of both upper and lower extremities
10. Associations with tethered cord:
 - a. Terminal syringomyelia (caudal 1/3 of the spinal cord)
 - b. Diastematomyelia
 - c. Lipoma of the conus and lipomyeloschisis
 - d. Unilateral pes cavus

Neuropathology

1. Combination of thickening of the filum terminale with:
 - a. Low or dilated conus medullaris
 - b. Spinal lipoma
 - c. Dermoid cyst
 - d. Diastematomyelia
 - e. Hydromyelin
 - f. Sacral agenesis

Neuroimaging

1. MRI:

- a. Tethered cord; tip of the conus medullaris is below the body of L2 instead of the L1–L2 disc space
- b. Most commonly associated with intra- or extradural lipoma

Classification of Lumbosacral Nerve Root Anomalies with a Tethered Cord

1. Type I and II
 - a. One or more nerve roots exit the thecal sac at a more cranial (Type I) or caudal (Type II) level
2. Type III
 - a. Two or more nerve roots emerge from the thecal sac through a closely adjacent dural opening
3. Type IV
 - a. Two or more roots emerge from the dural sac as one nerve trunk
4. Type V
 - a. Two or more nerve roots are connected by an anastomotic branch often exiting the dural sac

Clinical Characteristics of Congenital Nerve Root Anomalies

1. Anomalies occur primarily at L4–L5
2. 20% of patients have other lumbosacral anomalies; rarely congenital absence of a facet joint on the side of the anomaly
3. They may be asymptomatic
4. May be associated with failure of back surgery for herniated disc or spondylosis as they are less mobile
5. In association with lumbar spondylosis and foraminal stenosis
 - a. The affected roots are compressed between the transverse process of the last lumbar segment and sacral ala (S1) or in various relationships to the inner side of the pedicle and facet joint
6. Conjoined lumbosacral roots:
 - a. Are found in approximately 1% of lumbar disc operations
 - b. Most often at L5–S1
 - c. Often not associated with a herniated disc
 - d. Radiographic features:
 - i. Asymmetric subarachnoid space at the affected root level
 - ii. Widened nerve root sleeve
 1. Two or more individual nerve roots may be identified in the axillary pouch (3 Tesla MRI or CT myelography)

Differential Diagnosis of Degenerative Diseases Affecting Lumbosacral Nerve Roots

1. Degenerative disc disease (desiccated hard disc)
2. Spondylosis (degenerative disc disease in association with bone remodeling and osteophytes in the nerve root exit foramina)

3. Degenerative spondylolisthesis
4. Foraminal exit osteoarthritis (osteophytes)
5. Lateral recess syndrome
6. Facet hypertrophy (tropism and rotation)
7. Stenosis (disc; spondylosis; ligamentous hypertrophy)
8. Juxta facet joint cysts (cysts of the ligamentum flavum; synovial cysts)

Benign Bone Tumors Affecting Lumbosacral Nerve Roots

Osteoid Osteoma

General Characteristics

1. A primary benign bone lesion; it constitutes 10% of all primary benign bone tumors and 3% of all primary bone tumors

Clinical Manifestations

1. Most often they are seen in the first 3 decades; 3× more common in men
2. Predilection:
 - a. Long bones; particularly of the lower extremities
3. Major symptom is pain:
 - a. Localized and more severe at night
 - b. May be exacerbated or relieved by movement
 - c. Relieved by non-steroidal anti-inflammatory drugs (block prostaglandin activation of primary nociceptors in the lesion)
 - d. Scoliosis occurs in 70% of patients when it involves the spine:
 - i. The most common cause of painful scoliosis in adolescents particularly if located in the thoracic or lumbar spine
 - e. If located in a pedicle, it may involve the exiting nerve root

Neuropathology

1. A highly vascularized nidus or connective tissue surrounded by sclerotic bone
2. The nidus is approximately 10 mm in diameter which is smaller than that seen in an osteoblastoma

Neuroimaging

1. CT is the best diagnostic modality to visualize the nidus
2. MRI:
 - a. Increased signal intensity on T2-weighted sequences or enhanced T1-weighted sequences
 - i. Correlates with the degree of vascularity of the fibrovascular nidal stroma
 - ii. Correlates with the quantity of osteoid substance within the nidus
 - iii. Visualizes the soft tissue and bone marrow around the nidus

Differential Diagnosis

1. The major tumor to be differentiated is osteoblastoma

Osteoblastoma

General Characteristics

1. Rare benign osteoid-producing primary bone tumor
2. Affects the long bones
3. Males > females most often seen in the second decade
4. 36% occur around the spine

Clinical Manifestations

1. Cervical vertebrae are rarely affected
2. Similar clinical signs and symptoms to osteoid osteoma
3. More aggressive than osteoid osteoma and erosion into the vertebral artery has been reported; blindness has been reported from occlusion of the artery
4. May extend into the neuronal exit foramina

Neuroimaging

1. Similar to that of osteoid osteoma although a major differential point is these lesions are usually larger than 2 cm whereas osteoid osteomas are <2 cm

Osteochondroma

General Characteristics

1. The most common benign bone tumor
2. 35% to 50% of benign bone neoplasms and 10% to 15% of all primary bone tumors

Clinical Manifestations

1. Involvement of the spine occurs in 2 to 5% of patients; male > female 2.5:1
2. Spine involvement is often seen in the setting of multiple osteochondromatosis
3. Usual occurrences are in long bones
4. Usual spine predilection is for cervical or upper thoracic levels
5. Patients described at L4 and L5 with radicular involvement
6. Often asymptomatic

Neuropathology

1. A developmental enchondromatous hyperplasia
2. Formation of cartilage-capped bony protrusions from a bony focus

Neuroimaging

1. CT:
 - a. Differentiates the cartilaginous and bone components of the tumor
2. MRI
 - a. Demonstrates spinal cord or nerve root compression; a lobulated lesion
3. Conventional radiograph:
 - a. Enchondromas present as oval shaped, linear and/or pyramidal osteolytic lesions
 - b. Well defined margins
 - c. Metaphysis and/or diaphysis of long tubular and flat bones

Differential Diagnosis

1. Atypical cartilage tumor
2. Chondroblastoma
3. Chondromyxoid fibroma
4. Ollier disease:
 - a. Enchondromatosis
5. Maffucci syndrome:
 - a. Hereditary multiple exostoses
 - b. Associated multiple cavernous hemangiomas

Hemangioma

General Characteristics

1. Occur primarily in the thoracic spine
2. Usually, they are asymptomatic
3. Symptoms may occur from:
 - a. Epidural extension
 - b. Expansion of the involved vertebra
 - c. Spontaneous epidural extension
 - d. Pathologic burst fracture

Clinical Manifestations

1. Thoracic hemangiomas produce more cord compression than lumbar ones
2. Intracanalicular root compression from extraosseous extension
3. Spinal stenosis from vertebral bone expansion

Neuropathology

1. Hamartomatous proliferation of vascular tissue of endothelial origin
2. Most often in the vertebral body of thoracic and lumbar vertebrae; they may be multiple

Neuroimaging

1. Reduced bone density between denser vertical trabeculae
2. MRI:
 - a. Active lesions have low signal intensity on T1-weighted sequences with high signal intensity on T2-weighted sequences; quiescent lesions have high signal intensity in both sequences

Differential Diagnosis

1. Giant cell tumor
2. Aneurysmal bone cyst
3. Metastasis

Aneurysmal Bone Cyst

General Characteristics

1. A benign non-neoplastic expansile cystic bone lesion
2. Most common location is long bones but approximately 12–30% involve the spine
3. Lumbar spine is the most frequent location followed by the thoracic spine; 2% involve the cervical spine
4. Incidence is 114/100,000 people; age (1–59 years)

Clinical Manifestations

1. Most frequently encountered between 10–20 years of age
2. Most commonly found in the metaphyseal areas of long bone
3. Presenting symptoms:
 - a. Well defined somatic pain, stiffness, and swelling
 - b. Pathologic fracture may cause spinal cord compression and radiculopathy

Neuropathology

1. An expansible, tumor-like osteolytic lesion consisting of blood filled cavities separated by connective tissue septa; there is a surrounding thin cortical bone shell
2. May aggressively destroy and expand bone
3. Usually, a small lesion causes a pathologic fracture of a vertebra

Neuroimaging

1. Arise in the posterior elements of a vertebra and spreads in the pedicles and body
2. May involve the spinal canal
3. CT-3D reconstruction
 - a. Pedicle and vertebral body integrity
4. MRI:
 - a. Multilocular cysts that are fluid filled; T2-weighted sequences have high-intensity signal
 - b. Multiple cysts may have varying signal intensities on T1- and T2-weighted sequences due to different oxidation levels of blood and their breakdown products

Giant Cell Tumor (GCT)**General Characteristics**

1. Comprise approximately 5% of primary bone tumors and approximately 20% of benign bone tumors
2. Slightly higher incidence in females
3. Majority are seen in patients older than 20 years
4. Primary location is the long bones of the extremities; a small proportion occurs in the pelvis, skull and spine

Clinical Manifestations

1. Pain and swelling at the lesion site are the most common symptoms
2. The tumor may be locally aggressive and impinge on a nerve root
3. Skull lesions (often sphenoid and temporal bones, rarely the occiput) produce symptoms by their location

Neuropathology

1. Osteoclastic-like nuclear giant cells in a fibrohistiocytic stroma between osseous spicules
2. May also have foreign body-like giant cells
3. Histiocytes may be positive for CD68
4. Endochondral ossification

Neuroimaging

1. CT:

- a. Ground glass appearance; cystic lesion

- b. Expands bone

2. MRI:

- a. T1-weighted sequence equal intensity with muscle; T2-weighted sequence slightly intense signal

Differential Diagnosis

1. Chondroblastoma
2. Chondrosarcoma
3. Aneurysmal bone cyst
4. Dermoid cyst
5. Eosinophilic granuloma
6. Pigmented villonodular synovitis

Dermoid Cyst**General Characteristics**

1. Congenital non-neoplastic lesions that originate from totipotent ectodermal cells which remain within the developing neural tube
2. Between the 3rd and 5th weeks of gestation
3. In approximately 50% of patients, there is a dermal sinus tract

Clinical Manifestations

1. Cysts are usually intradural in the lumbar and sacral spine
2. Symptoms may occur from tethering of the spinal cord in association with congenital nerve root abnormalities
3. Rupture causes chemical arachnoiditis
4. Infection of the cyst or sinus tract causes meningitis
5. May occur at the site of meningocele repair
6. Rarely they develop after a lumbar puncture or trauma

Neuroimaging

1. MRI:
 - a. T1- and T2-weighted sequences demonstrate variable signal intensities according to the tissue in the cyst

Eosinophilic Granuloma**General Characteristics**

1. Eosinophilic granuloma (EG) is one of the Langerhans cell histiocytosis
2. Incidence of 1:150,000 people/year
3. The most common site is the skull; vertebral involvement is approximately 7%
4. EG is a self-limited disease

Clinical Manifestations

1. Most often patients are younger than 15 years of age
2. In addition to the skull and vertebrae, the pelvis, mandible and ribs may be involved
3. Thoracic vertebrae are most often affected followed by lumbar (35%) and cervical vertebrae (11%)
4. Male to female is 2–5:1
5. Usually, the neurologic deficits are rare:
 - a. Pain may occur at the site
 - b. Spinal cord compression may occur from cervical tumors
 - c. Radiculopathy

Neuropathology

1. Single or multiple skeletal lesions
2. Lung involvement
3. Accumulation of pathologic Langerhans cells
4. Anti-CD1a immunolabeling

Neuroimaging

1. Lytic lesion often with osteoblastic activity on X-ray and CT
2. PET evaluation has 90% sensitivity and a specificity of 65%–80%
 - a. False positive results occur from benign disease with an inflammatory component such as fibrous dysplasia or aneurismal bone cysts
 - b. Low-grade tumors

Rare Benign Bone Lesions That Can Affect the Axial Skeleton with Consequent Radiculopathy

1. Neurofibroma
2. Leiomyoma
3. Chondromyxoid fibroma
4. Fibrous histiocytoma
5. Differential points for malignancy or benignity:
 - a. Pedicle change with expansion is most often malignant
 - b. Normal marrow preservation of a collapsed vertebral body on T1-weighted MRI sequences is most compatible with an osteoporotic fracture

Malignant Bone Tumors of the Lumbosacral Spine**Chordoma****General Characteristics**

1. Rare tumors with an incidence of one/million people
2. Approximately 4% of primary malignant bone tumors and 20% of primary spine tumors
3. Divided into:
 - a. Clival (skull base)
 - b. Sacrococcygeal
 - c. Cervical, thoracic and lumbar
 - d. Almost equal distribution by site
4. Sacrococcygeal tumors have a male predominance of 2:1
5. Brachy gene in chordoma
 - a. A diagnostic marker that differentiates the tumor from myoepithelioma and chondrosarcoma
6. Classification:
 - a. Notochordal hamartomas
 - i. Benign counterpart of chordoma
 - b. Chondroid chordoma:
 - i. 5–15% of all chordomas
 - ii. Spheno-occipital areas of the skull base
 - c. Differentiated chordoma:
 - i. <10% of chordoma
 - d. There is a correlation between the histological characteristic of a chordoma and its ability to metastasize
 - i. Chondroid chordomas are the least aggressive while de-differentiated chordomas are the most aggressive

Clinical Manifestations

1. Sacral chordomas
 - a. May be associated with large exophytic soft tissue masses
 - b. Bowel and bladder dysfunction (sacral roots)
 - c. Severe back pain; painful sacral mass
 - d. Intralesional surgery has a high rate of recurrence

Neuropathology

1. Physaliferous cells are characteristic; foamy appearance of the cytoplasm that contains multiple vacuoles which ultra structurally are divided into smooth-walled and villous
2. Tumors stain for vimentin, the S100 protein, epithelial membrane antigen and low molecular weight cytokeratins
3. Chondroid chordomas:
 - a. Histological features of both chordoma and chondrosarcoma
 - i. Approximately 1/3 of cranial chordomas
 - ii. Express chordoma markers
4. De-differentiated chordoma:
 - a. Sarcomatous regions comprised of spindle-shaped polygonal cells
 - b. Metastasizes late

Neuroimaging

1. MRI:
 - a. T2-weighted sequences demonstrate a hypointense, non-enhancing, interosseous lesion

Liposarcoma**General Characteristics**

1. Liposarcoma is a common adult soft tissue sarcoma composed of three histologic subtypes:
 - a. Well- and de-differentiated
 - b. Myxoid/round cell
 - c. Pleomorphic
2. Z1C1 overexpression
 - a. A transcription factor important for neuronal development

Clinical Manifestations

1. Well-differentiated and de-differentiated liposarcomas occur:
 - a. Retroperitoneum > extremities > paratesticular areas and trunk
2. De-differentiated tumors may metastasize (lungs primarily)
3. Retroperitoneal tumors may be >30 cm and invade viscera and the lumbosacral plexus; local recurrence is common
4. Myxoid/round cell tumors:
 - a. Translocation of chromosome 12 and 16
 - b. Interferes with adipocyte differentiation
 - c. Present in younger patients and its primary location is the proximal lower extremities

- d. Metastasizes to the skeleton
- 5. Pleomorphic liposarcoma:
 - a. Chromosomal gains, losses, duplications, and rearrangements have been described
 - b. Usually, present with lower extremity involvement; rarely the retroperitoneum and mediastinum
- 6. All types may involve lumbar and sacral roots

Neuropathology

- 1. Dependent on subtype
- 2. Pleomorphic liposarcoma resembles a non-adipocytic soft tissue sarcoma (malignant fibrous histiocytoma)
- 3. Myxoid/round cell liposarcoma
 - a. Abundant extracellular myxoid tissue
- 4. Well and de-differentiated tumors:
 - a. Adipocytomas (WD Type)
 - b. DD Types have an adipocyte-rich region that is demarcated from highly cellular spindle cell area

Neuroimaging

- 1. Intradural lesion that may diffusely invade the vertebral bodies and encase the cauda equina

Ewing Sarcoma

General Characteristics

- 1. Primitive neuroectodermal tumors (PNET) and Ewing sarcoma are in the same family of malignant small, round cell neoplasms whose origin is soft tissue or bone
- 2. Usual sites for EWS-PNET are the chest wall, pelvis, and the extremities
- 3. Incidence rate is approximately 3 patients/1,000,000 people
- 4. Approximately 10% of EWS arise in extraskelatal soft tissue
- 5. Caused by rearrangements involving the EWS gene on chromosome 22q 12 and fusion partners from the ETS oncogene family; 95% of EW sarcoma family tumors have fusion of the central exons of the EWSR1 gene (Ewing Sarcoma Breakpoint Region 1)

Clinical Manifestations

- 1. The tumor may arise from the pedicles of L4–5, and L5 S1
- 2. Primarily involves lumbar and sacral roots in the spine
- 3. Cerebral and lung metastasis occur

Neuropathology

- 1. Poorly differentiated small round cell tumors
- 2. ES and PNET represent a single entity
- 3. Light microscopy reveals small round blue cells with hyperchromatic nuclei and minimal cytoplasm
- 4. EWS-PNETs coexpress:
 - a. CD99 (the glycoprotein MIC2) and vimentin

Neuroimaging

- 1. CT scan EWS-PNETs

- a. Heterogeneous masses that invade surrounding tissue including bone

2. MRI:

- a. The mass is isointense to muscle on T1-weighted sequences and hyperintense on T2-weighted sequences

Osteosarcoma

General Characteristics

- 1. Osteosarcoma is the most common primary malignant bone tumor in children and young adults
- 2. Older adults may usually be affected from sarcomatous transformation of Paget's disease of bone
- 3. Incidence of 1/100,000 people

Clinical Manifestations

- 1. Pain and a painful mass lesion
- 2. Pathologic fracture
- 3. Secondary causes include:
 - a. Ionizing radiation
 - b. Hereditary:
 - i. Retinoblastoma
 - ii. Paget's disease of bone
 - iii. Enchondromatosis
 - iv. Hereditary multiple exostoses
 - v. Fibrous dysplasia
- 4. Presents between 5 and 30 years of age; a second peak occurs in the fifth and sixth decade
- 5. Pathologic fracture of vertebrae and compressive myelopathy and radiculopathy

Neuropathology

- 1. A malignant spindle cell neoplasm that produces osteoid
- 2. Classified into 4 subtypes:
 - a. Osteoblastic
 - b. Fibroblastic
 - c. Chondroblastic
 - d. Telangiectatic
- 3. Classification is based on the predominant type of tumor matrix

Neuroimaging

- 1. Radiographs:
 - a. An ill-defined mixed sclerotic and lytic lesion that arises in the metaphyseal region of the involved bone
 - b. Destruction of the bone cortex
 - c. Soft tissue mass with ossification
 - d. Periosteal new bone formation with elevation of the cortex (Codman's triangle)
- 2. CT assessment is superior to MRI for assessment of new bone formation
- 3. MRI:
 - a. T1- and T2-weighted sequences with fat suppression for the extent of bone and soft tissue involvement
 - b. Macroscopic tumor emboli may be found in regional large vessels
 - c. Telangiectatic osteosarcoma may present as a sacral mass

Chondrosarcoma

General Characteristics

1. Less than 10% of chondrosarcomas are in children; 0.5% of low-grade tumors arise from benign chondroid lesions
2. They are 27% of all primary bone tumors
3. Central tumors arise in the medullary cavity or periosteum

Clinical Manifestations

1. Most patients present between 40–70 years of age
2. Patients with Ollier disease, Maffucci syndrome, and hereditary multiple exostoses have a higher incidence
3. Insidious worsening pain that is most pronounced at night
4. Approximately 20% present as a pathologic fracture
5. Primary sites are the shoulder, pelvis or proximal femur
6. Rare spinal compression from pathologic fracture or radiculopathy

Neuropathology

1. Chondrocytes with small to slightly enlarged dense nuclei on a background of chondroid stroma
2. Neoplastic chondrocytes are arranged in lobar cords and clumps which cause endosteal scalloping

Neuroimaging

1. Radiograph:
 - a. An expansile mixed sclerotic and centrally lucent lesion, with a narrow transitional zone and thin sclerotic margin
 - b. Arcs and Wings calcifications
2. CT:
 - a. Non-mineralized portion of the tumor is hypodense to muscle (high water content of hyaline cartilage)
3. MRI:
 - a. Low to intermediate signal intensity on T1-weighted sequences; T2-weighted sequences the lesion is hyperintense

Differential Diagnosis

1. May arise from an osteochondroma
2. Enchondroma (secondary chondrosarcoma)
3. Giant cell tumor
4. Bone cyst

Epidural and Vertebral Metastasis

General Characteristics

1. Metastatic tumors are the most common neoplasms of the intraspinal canal and nerve roots
2. Locations:
 - a. Epidural > leptomeningeal > intraspinal
3. Epidural metastases occur primarily from direct extension of metastatic vertebral tumors; rarely a metastasis grows through the intervertebral foramina or directly metastasizes to the epidural space

4. Radiculopathy is secondary to direct compression by the tumor, metabolic and cytokine expression or a pathologic fracture that compresses the cauda equina
5. Differential diagnosis of common tumors that metastasize to vertebrae:
 - a. Lung
 - b. Breast
 - c. Prostate
 - d. Ovary
 - e. Melanoma
 - f. Renal cell
 - g. Sarcoma
 - h. Multiple myeloma
6. The most frequent sites of metastases are: thoracic > 70%; lumbosacral > 20%; cervical 10%

Clinical Manifestations

1. Local pain is the initial symptom. It is particularly evoked by mechanical stimuli (first percussion over the involved vertebra)
2. Radicular pain:
 - a. Thoracic metastasis usually present with bilateral radicular pain
 - b. Lumbosacral roots most often have a unilateral presentation
 - c. Cervical spine:
 - i. C8–T1 (from Pancoast) tumor or metastasis may present with C8/T1 radicular pain, a Horner's syndrome and anhidrosis or hyperhidrosis
 - ii. C8–T1 innervates the eye and T2 is the level for extremity sympathetic innervations (irritation or destruction)
 - d. Herpes Zoster may be reactivated at the site of the lesion
 - e. Deep boring pain that is worse at night
 - f. Weakness, sensory loss, and atrophy with depressed or absent reflexes at the affected level

Neuroimaging

Solitary Vertebral Collapse

1. Malignant features by MRI:
 - a. Ill-defined lesion margin
 - b. Pedicle involvement
 - c. Heterogeneous enhancement pattern
 - d. Irregular nodular paravertebral soft tissue lesion
 - e. Erosion of the endplate
 - f. Star burst pattern of fracture is more likely traumatic

Benign CT Features of an Acute Vertebral Lesion

1. Cortical fractures of the vertebral body without cortical bone destruction
2. Retropulsion of a bone fragment of the posterior cortex of the vertebral body into the spinal canal
3. Fracture lines within the cancellous bone of the vertebral body

4. Intervertebral vacuum phenomena
5. Thin diffuse paraspinal soft tissue mass

Malignant Features of Spine Lesions by CT and SPECT

1. The posterior portion of the vertebral body is involved
2. Concomitant vertebral body and pedicle involvement
3. Extensive abnormalities that involve the vertebral body and vertebral arch, but spare the pedicle are benign
4. Destruction of the anterolateral or posterior cortical bone of the vertebral body
5. Destruction of the cancellous bone of the vertebral body

Specific Patterns of Metastasis by Tumor Type

Lung Cancer

1. Multiple vertebral levels are involved
2. The most common metastatic lesion
3. Thoracic vertebrae > lumbosacral > cervical spine
4. Cortical and cerebellar metastasis are often concomitant
5. A common cause of carcinomatosis of the meninges
6. Rarely anti-Yo antibodies with paraneoplastic cerebellar degeneration
7. Often bilateral lumbosacral roots are involved

Gastric and Colon Cancer

1. Colon cancer may destroy the sacrum and involve lower sacral roots
2. Kruckenberg metastasis (dropped metastases to the ovaries) from the stomach
3. Associated non-bacterial thrombotic emboli (NBTE) with stroke (mucinous adenocarcinoma is the most common tumor)
4. Extremely dense lesions on neuroimaging (mucin)
5. Hypercoagulable state may be associated

Lymphoma

1. Predilection for paravertebral lymph nodes
2. Intertwines with the lumbosacral roots
3. Often arises in the epidural space with consequent spinal cord compression
4. May be associated with a very dense vertebra

Breast Cancer

1. Multiple vertebral bodies are involved
2. Has been associated with thoracic meningioma (only in women)
3. Carcinomatosis of the meninges is prominent
4. May have delayed onset (years often a bilateral mastectomy)

Prostate Cancer

1. Osteoblastic and lytic bone destruction occur concomitantly
2. Multiple levels are involved
3. May metastasize through the paravertebral venous plexus (no valves; Bateson's plexus to the posterior fossa)

4. Most often radiculopathy and spinal cord compression are the neurological signs (lumbosacral roots)
5. Metastasizes to the petrous apex (Bateson's plexus)
6. Midline vertebral pain

Ovarian Cancer

1. L1–L3 nerve roots > L4–S1
2. Associated with peritoneal implantation (a marble vertebra)
3. L1–L3 > L5–S1 roots; the entire cauda equina may be involved
4. Rare associations:
 - a. Paraneoplastic neuropathy
 - b. Cerebellar degeneration
 - c. Limbic encephalopathy

Melanoma

1. Usually multiple cerebral metastases
2. Unusual adhesive qualities of the tumor allow it to metastasize to the cardiac and intestinal surfaces
3. Almost never solitary
4. Cord compression rather than radicular presentation

Intrinsic Spinal Cord Tumors That Involve the Lumbosacral Roots

Differential Diagnosis

1. Ependymomas (myxopapillary)
2. Glioma of the filum terminale
3. Neurofibroma of the cauda equine
4. Cauda equina tumors:
 - a. Hemangioblastoma
 - b. Paraganglioma
 - c. Ganglioneuroma
 - d. Schwannomatosis
 - e. Neurofibroma

Systemic Disease Affecting Lumbosacral Nerve Roots

1. Diabetes mellitus
 - a. Diabetic amyotrophy (femoral nerve or thoracolumbar plexitis from infarction)
 - b. Vasculopathy of the vasa vasorum
 - c. Clinical features:
 - i. Patients > 60 years of age
 - ii. Present with pain of neuropathic quality
 - iii. Prominent weakness
 - iv. Concomitant weight loss
 - v. Thoracoabdominal nerve root involvement
2. Sarcoid
3. Periarthritis nodosa:
 - a. Proximal L1–L3 nerve root involvement; all roots may be affected
 - b. Asymmetric involvement
4. Meningeal amyloid
5. Acute intermittent porphyria

6. Coproporphyrinuria
7. Variegate porphyria
8. Necrotizing arteritis
9. Hypertrophic pachymeningitis (IgG4)
10. All collagen vascular disease
11. Carcinomatosis of the meninges
12. Mixed collagen vascular disease

Immune-Mediated Processes That Affect Lumbosacral Roots

AIDP

1. May affect proximal, distal and terminal somatosensory afferents
2. May present with apparent radiculopathy

CIDP (Chronic Inflammatory Demyelinating Polyneuropathy)

1. L5–S1 roots may be initially affected

Multiple Sclerosis

1. Affects the dorsal root entry zone at a junction of central and peripheral myelin; anterior horn cell damage
2. Amyotrophy of the affected extremity (several segment involvement as occurring with NMO); gray matter lesions are common in the hemispheres (“black holes”)
3. Some major autoimmune epitopes:
 - a. GM1
 - b. MAG
 - c. GQ1b
 - d. GAL-NAc-GDT/1a
4. Radiculopathy with increased sed rate (usually at L5)
5. Post-vaccination
6. Post-viral infection
7. Acute disseminated encephalomyelitis (an overwhelmingly central demyelinating disease)

Infection Affecting Lumbosacral Roots

1. Herpes Zoster (thoracic; cervical and lumbosacral roots)
2. Brucellosis (L5 roots)
3. Lyme’s disease
 - a. *Borrelia burgdorferi* (spirochete) is the causative organism
 - b. Radiculopathy occurs early in the course of the illness
 - i. May be associated with cranial neuropathy (uni- or bilateral VII, rarely other cranial nerves and meningitis)
 - ii. Single or asymmetric multiple root involvement
4. Chronic radiculopathy:
 - a. Presents months after the initial infection
 - b. Mild motor and sensory loss; not associated with meningitis or VIIth nerve palsy
 - c. Distal paresthesia or radicular pain
5. CMV
 - a. General Characteristics

- i. Affects lumbar and sacral roots
- ii. Most commonly encountered in severely affected HIV patients (CD4⁺ count of <50 mm³)
- b. Clinical Manifestations
 - i. Rapidly progressive cauda equina syndrome
 - ii. Leg weakness, paresthesia and saddle region involvement, sphincter dysfunction that progresses to flaccid paralysis
 - iii. Severe low back pain
 - iv. Polymorphonuclear pleocytosis with elevated protein and viral titers in the CNS; positive PCR
 - v. Gadolinium enhancement on MRI of involved roots in 50% of patients
 - vi. If acute neurologic symptoms and signs need to rule out:
 1. Infection or many other lesions of the cauda equina and conus medullaris
 2. Lymphomatous infiltration of the lumbosacral roots
 3. Syphilis (in an HIV-infected patient)
 4. Herpes simplex (type II with sacral root involvement)
 5. HIV-related polyradiculopathy
 - vii. Herpes virus 8 (lumbar and thoracic roots)
 - viii. EBV (Isolated nerve roots)
 - ix. Tuberculosis (Cold abscess)
 1. L1–L3 roots
 2. Some ethnicities have primarily cervical root involvement (Asian patients)
6. Syphilis:
 - a. Dorsal root entry zone is the site of infection
 - b. Pachymeningitis cervicalis > lumbosacral involvement
 - c. Tabetic pain:
 - i. Thoracic > lumbosacral roots
 - ii. May simulate a thoracic or abdominal visceral emergency
7. HTLV-1:
 - a. Involvement is overwhelming in the cervical cord
 - b. Isolated roots may be involved
8. HIV: L5; sacral roots
9. Spinal epidural abscess
 - a. General characteristics:
 - i. Occurs in the thoracic > lumbosacral > cervical cord
 - ii. Chronic lesions occur in the thoracic cord
 - iii. Infecting organisms:
 1. *Staphylococcus aureus*
 2. Gram-negative rods
 3. Anaerobes
 4. Skin flora (spinal operations)
 5. *Mycobacterium*
 6. Fungi
 - b. Risk factors:
 - i. IV drug abuse
 - ii. Spinal surgery

- iii. Diabetes mellitus
- iv. Epidural steroids:
 - 1. Recent fungal contaminant of steroid injections
- v. Epidural catheters:
 - 1. Prolonged use for neuropathic pain patients
- vi. Immunocompromised patients
- c. Clinical Manifestations
 - i. Onset often occurs with severe back pain; delayed from the onset of the infection
 - ii. Spinal cord compression, infarction or parenchymal infection
 - iii. Deep boring midline pain in the spine with sudden radicular component
 - iv. Cauda equina involvement
 - v. Fever, leukocytosis and elevated sed rate
 - vi. MRI may demonstrate gadolinium enhancement of the involved roots
- a. Severe trauma (often motorcycle accidents)
- b. Most often cervical nerve roots and the brachial plexus are injured
- c. MVA affect lumbosacral roots and the lumbosacral plexus
- 9. Plate fixation and pedicle screw displacement
- 10. Complications of epidural and spinal anesthesia
 - a. General Characteristics
 - i. Toxic effects of anesthetic (usually 0.25% bupivacaine)
 - ii. Direct injury by needle or catheter
 - iii. Subarachnoid injection of anesthetic during epidural procedures
 - iv. Contamination of anesthetics with detergents, chemicals or organisms (bacteria or fungal)
 - v. Epidural abscess
 - vi. Risk of epidural anesthesia is increased with:
 - 1. Lumbar spinal stenosis ("Pooling") of bupivacaine around nerve roots
 - 2. Inadvertent subarachnoid injection of high volume of anesthetic
 - 3. A combination of general and epidural anesthesia
 - 4. Advanced age
 - b. Clinical Manifestations
 - i. Radicular pain and weakness
 - ii. Lower extremity myoclonus and severe spasm
 - iii. Cauda equina syndrome
 - iv. May clear after days to weeks (the cauda equina are peripheral nerves and have regenerative capacity)

Miscellaneous Involvement of Lumbosacral Roots

- 1. Endometriosis
 - a. Endometrial tissue is adherent to pelvic nerve roots (L5–S5)
 - b. Catamenial cyclical pain with bleeds from the aberrant tissue and irritation of the lumbosacral roots
- 2. Laparoscopy for pelvic and abdominal processes
 - a. L1–L3 > involvement than L5–S1 roots
- 3. Epidural catheter trauma
 - a. Prolonged exposure to bupivacaine (directly toxic to the nerve root)
 - b. Direct trauma to the root during catheter insertion
- 4. Arachnoiditis
 - a. General Characteristics
 - i. Clumped scarred nerve roots in the dorsal sac (MRI evaluation)
 - ii. Occurs following multiple surgeries or hemorrhage during myelography with pantopaque. Water-soluble contrast has eliminated this cause
 - b. Clinical Manifestations
 - i. Severe burning pain in several root distributions > motor weakness
 - ii. No exacerbating or relieving factors
 - iii. Asymmetric reflex loss
 - iv. Neurenteric cyst (usually asymptomatic)
- 5. Spina Bifida
 - a. May be associated with congenital defects of the pedicles, facets, and foraminal exit canals
 - b. Conjoined nerve roots
- 6. Myxopapillary Ependymoma
 - a. Asymmetric lumbosacral nerve root involvement
 - b. Lower extremity weakness
 - c. Bowel, bladder, and sexual dysfunction
- 7. Dropped Metastasis
 - a. Medulloblastoma
- 8. Traumatic nerve root avulsion

Differential Diagnosis of Radiculopathy

Differential Diagnosis of Cervical Radiculopathy

- 1. Congenital Defects:
 - a. Abnormalities of the odontoid process ossification centers (C1–C2 roots)
 - b. Failure of odontoid tip fusion (C1–C2)
 - c. Morquio syndrome (atresia of the odontoid process)
 - d. Platybasia (C1–C3)
 - e. Basilar impression (C1–C4)
 - f. Klippel-Feil syndrome (C4–C7)
 - g. Sprengel's deformity with Klippel-Feil syndrome (C4–C7)
 - h. Roos' cervical bands (C4–T1)
 - i. Cervical ribs (C8–T1)
 - j. Thoracic outlet syndrome:
 - i. C5–C6 components of the upper trunk
 - ii. C8–T1 major components of the lower trunk
 - k. Congenital defects of the spinal canal and posterior elements:
 - i. Stenosis of the canal

- ii. Shortened block vertebra
- iii. Vertebral fusions
- iv. Lateral recess trefoil configuration
- 1. Chiari malformation
 - i. High cervical roots suffer a neuropractic injury
- 2. Lax ligaments (hypermobility of the odontoid process) with neuropractic injury of cervical roots and spinal cord compression
 - a. Rheumatoid arthritis
 - b. Trisomy 21
 - c. Marfan's syndrome
 - d. Ehlers-Danlos syndrome
 - e. Type VI collagen defects
 - f. Trauma (rupture of ligaments and odontoid fracture from high impact flexion/extension injuries)
- 3. Ligament Hypertrophy (all cervical roots may be involved)
 - a. Acromegaly
 - b. Mucopolysaccharidoses
 - c. Posterior ligament ossification syndrome
- 4. Pachymeningitis
 - a. Syphilis (now rare; cervical > lumbar > thoracic)
 - b. IgG4 syndrome (a component of idiopathic pachymeningitis)
 - c. Lymphoma (all roots are involved, but predominance is lumbosacral)
 - d. Sarcoid (cervical > lumbar > thoracic)
 - e. Tuberculosis (root site of involvement depends on ethnicity; Asian populations cervical roots > lumbosacral)
 - f. Subarachnoid hemorrhage (lumbar > cervical > thoracic)
 - g. Arachnoiditis (lumbar > cervical)
- 5. Degenerative disease
 - a. Cervical spondylosis (C5–C7)
 - b. Spondylolisthesis (C4–C7)
 - c. Spinal stenosis (C4–C7)
 - d. Disc disease (C4–C5, C5–C6, C6–C7)
 - e. Foraminal exit osteophytes (C3–C4 – C8–T1)
 - f. Facet hypertrophy (uncovertebral joints); C3–T1
- 6. Tumors of Cervical Nerve Roots
 - a. Schwannoma
 - b. Neurofibroma
 - c. Meningioma
 - d. Hemangioma
 - e. Aneurysmal bone cyst
 - f. Osteoid osteoma
 - g. Osteochondroma
 - h. Chordoma
 - i. Ewing's sarcoma
 - j. Osteosarcoma
 - k. Chondrosarcoma
 - l. Pancoast tumor (squamous and adenoma cancer of the lung)
 - m. Lymphoma
 - n. Salivary gland (adenocarcinoma)
 - o. Metastatic (carcinomatosis)
 - p. Post-X-RT (sarcoma of plexus/roots)
 - q. Hodgkin's/non-Hodgkin's lymphoma
 - r. Leukemia (acute with hemorrhage into a root)
 - s. Lymphomatous B-cell
- 7. Immune-mediated radiculopathies of Cervical Roots
 - a. AIDP
 - b. CIDP
 - c. Post-vaccination
 - d. Demyelinating disease (dorsal root entry zone DREZ; components of neuropathy)
 - e. ADEM (acute disseminated encephalomyelitis; overwhelming CNS demyelination rarely DREZ lesions)
 - f. Specific epitopes:
 - i. GM1
 - ii. GAL-NAc-GDT1a
 - iii. GQ1b
 - iv. Gd1b
 - g. Hangman's fractures
 - h. Spondylolisthesis
 - i. Plate fixation/screw displacement
 - j. Epidural catheter trauma (mechanical and from prolonged 0.25% bupivacaine)
 - k. Avulsion of nerve roots (C5–C6; C8–T1)
- 8. Trauma of the Cervical Spine
 - a. "Jumped" facet joints (C3–T1)
 - b. Rotary facet subluxation
 - c. Disc disease (rare; usually degenerative)
 - d. Burst vertebral fracture
 - e. Anterior compression fracture
 - f. Jefferson fracture
 - g. Odontoid fracture (dens) C2
 - h. Atlanto-occipital dislocation
- 9. Infection of Cervical Roots
 - a. HIV
 - b. HTLV-1 I (mixed HTLV-1 and concomitant HIV infection)
 - c. Herpes Zoster
 - d. Herpes simplex
 - e. Brucella (usually L5)
 - f. Bacterial infection (overwhelmingly in the context of epidural abscess or meningitis)
 - g. Staphylococcus aureus (IV drug abuse)
 - h. Gram-negative bacilli (post-surgical procedures)
 - i. Fungal infection:
 - i. Immunocompromised patients
 - ii. Aspergillus
 - iii. Cryptococcus immitis
 - iv. Coccidiomycosis
 - v. Mucormycosis
 - j. Parsonage Turner syndrome (C5–C6) putatively viral
 - k. Poliomyelitis (neuronopathy)
 - l. Enterovirus >1

- m. Coxsackie serotype 6 and 9
- n. West Nile Virus
- o. Hepatitis C
- p. EBV
- q. Adenovirus
- 10. Systemic Diseases that Affect Cervical Nerve Roots
 - a. Diabetes mellitus
 - b. Acute intermittent porphyria
 - c. Variegate porphyria
 - d. Coproporphyrinuria
 - e. IgG4 (pachymeningitis)
 - f. Sicca complex
 - g. Wegener's disease
 - h. SLE
 - i. PAN
 - j. Amyloidosis: FOLMA/FAP-1
 - k. Necrotizing angitis
 - l. Mixed connective tissue disease
 - m. Sarcoid (dural involvement)
 - n. Hyperparathyroidism (vertebral collapse)
- 11. Vascular disease of Cervical Nerve Roots
 - a. AVM involving the nerve root
 - b. Dural AVM
 - c. Dilated vein (overlying the nerve root) with compression
 - d. Klippel-Weber-Trenaunay
- 12. Miscellaneous Disorders that Affect Cervical Nerve Roots
 - a. Plasmacytoma
 - b. Paget's disease (degenerates to osteosarcoma)
 - c. Toxins
 - d. Ankylosing spondylitis

Differential Diagnosis of Thoracic Root Disease

- 1. Trauma
 - a. Compression fracture (Osteoporosis; anterior wedge)
 - b. Burst fracture (thoracolumbar)
 - c. Chance fracture:
 - i. Thoracolumbar
 - ii. Fracture through facets and posterior elements
 - d. Chest surgery
 - e. Jumped facet
 - f. Rotary subluxation of the facet joint
 - g. Chronic regional pain syndrome
 - h. Trauma to T1 and T2
 - i. Spinal cord injury with syrinx
- 2. Infection:
 - a. HZ
 - b. HIV
 - c. Bacterial infection
 - d. In conjunction with epidural abscess
 - e. Tuberculosis (T12–L2)
 - f. Nocardia (immunosuppression)
 - g. Actinomyces (extension from the lung)

- h. Herpes simplex
 - i. Surgical disc space
 - j. Poliomyelitis (neuronopathy)
 - k. Enterovirus
 - l. West Nile Virus
 - m. Coxsackie serotype 6 and 9
 - n. Adenovirus
- 3. Systemic Diseases:
 - a. Diabetes mellitus
 - b. Amyloid
 - c. Sicca complex (Sjögren's disease)
 - d. Homogentisic aciduria (ochronosis)
- 4. Tumor:
 - a. Meningioma
 - b. Neurofibroma
 - c. Schwannoma
 - d. Malignant and benign tumors of bone similar to cervical root disease
 - e. Metastatic disease
 - f. Leukemia and lymphoma
 - g. Carcinomatosis of the meninges
- 5. Immune-Mediated:
 - a. AIDP
 - b. CIDP
 - c. Post-vaccination
 - d. Post-viral infection
 - e. Autoimmune epitopes (similar to cervical root disease)

Differential Diagnosis of Lumbosacral Root Disease

- 1. Congenital Defects
 - a. Conjoined nerve roots
 - b. Scoliosis/kyphosis
 - c. Achondroplasia
 - d. HSM I, III, V (compression of hypertrophied roots)
 - e. Perineural cysts (all lumbar and sacral roots may be affected)
 - f. Congenital spinal stenosis:
 - i. Small canal
 - ii. Short pedicles
 - iii. Trefoil shape
 - g. Lateral recess stenosis (L4–L5; L5–S1)
 - h. Congenital dermoid cyst with paravertebral dermal sinus
 - i. Deep lordotic curve (neuropraxis of L4–L5 roots)
 - j. Meningomyelocele (lumbosacral roots)
 - k. Diastematomyelia (T10–T12)
 - l. Reduplicated cord (L1–S5 roots)
 - m. Achondroplasia (L1–S5)
 - n. Spondylolysis (pars interarticularis defect (L4–L5; L5–S1)
 - o. Sacral agenesis; caudal regression syndrome (L4–S5)
- 2. Degenerative disease Affecting Lumbar and Sacral Roots
 - a. Disc disease (desiccation; hard discs)

- i. Rarely a free fragment extrudes through the posterior longitudinal ligament
 - ii. Schmorl's node (erosion of the midline vertebral vertebrae)
- b. Lateral recess syndrome (osteophyte)
- c. Spinal stenosis (Spondylosis, ligament hypertrophy, facet hypertrophy, vacuum disc disease, bulging annulus fibrosis)
- d. Facet hypertrophy (superior facet that rotates into the foraminal exit canal)
- e. Juxta-articular cysts:
 - i. From the synovium
 - ii. Ligamentum flavum
- f. Osteophyte formation in the foraminal exit canal
- g. Degenerative spondylolisthesis
3. Bone Tumors of Lumbosacral Vertebrae:
 - a. Osteoid osteoma
 - b. Enchondroma
 - c. Osteochondroma
 - d. Aneurysmal bone cyst
 - e. Hemangioma/hemangioblastoma
 - f. Brown tumor (hyperparathyroidism)
 - g. Dermoid
 - h. Giant cell tumor
 - i. Chordoma
 - j. Osteosarcoma (evolution from Paget's disease of bone)
 - k. Chondrosarcoma
 - l. Liposarcoma
 - m. Ewing's sarcoma
 - n. Metastatic disease
4. Cancer Affecting Lumbosacral Nerve Roots:
 - a. Carcinomatosis of the meninges (possible with all cancer)
 - b. Leukemia:
 - i. Acute (hemorrhage into a nerve root)
 - ii. Chronic (infiltration)
 - c. Hodgkin's and non-Hodgkin's lymphoma
 - d. Liposarcoma
 - e. Myxopapillary ependymoma
 - f. Dropped metastasis (medulloblastoma)
 - g. Metastasis from any solid tumor
5. Systemic disease:
 - a. Diabetes mellitus
 - i. Amyotrophy (partial femoral nerve infarction)
 - b. Vasculitis (primarily L2, L3, L4)
 - c. Connective tissue disease (similar to cervical and thoracic roots)
 - d. Amyloid
 - e. Acute intermittent, variegate and coproporphyrinuria
 - f. Endometriosis
 - g. Sarcoid
 - h. Retroperitoneal hemorrhage (trauma, bleeding diathesis and anticoagulation)
6. Immune disease (Similar to Cervical Root disease)
7. Toxins/Anesthesia
 - a. Epidural anesthesia (bupivacaine 0.25%; usually prolonged epidural catheter for severe pain of at least 3 days duration)
 - b. Pantopaque contrast (rarely relevant today due to water soluble contrast agents used for myelography)
 - c. Metronidazole (contrast)
8. Trauma of Lumbosacral Roots
 - a. Chance fracture (thoracolumbar)
 - b. Compression fracture (Wedge)
 - c. Burst/fracture (thoracolumbar)
 - d. Sacrum ala compression
 - e. Laparoscopic procedures (higher L1–L3 roots > L5–S1)
 - f. Instrumentation (plate and pedicle screw placement)
 - g. Obstetrical and GYN Surgery (retraction injury of upper lumbar roots)
 - h. Hip replacement surgery (L4–S1)
 - i. Decompressive laminectomy
9. Vascular disease (similar to cervical and thoracic roots)
10. Infection
 - a. Cytomegalic virus infection of the lumbosacral roots in late stage HIV patients
 - b. Brucellosis (L5 root)
 - c. Lyme's disease (L5 root)

Chapter 6

Plexus

Cervical Plexus

Overview

The cervical plexus is derived from the anterior primary rami of C1–C4. It lies behind the sternocleidomastoid muscle and anteriorly to the scalenus medius and levator scapulae muscles. It forms anastomotic loops that are related to the spinal accessory (XI) and hypoglossal nerves (XII).

Its terminal cutaneous branches are:

1. The greater occipital nerve (C2) which innervates the skin of the posterior scalp
2. The lesser occipital nerve that innervates the mastoid process and lateral head; the mastoid innervations overlap that of the sensory innervation from cranial nerve VII
3. The greater auricular nerve (C2–C3) which innervates:
 - a. The skin of the lower cheek and the mandible (overlaps V2, V3)
 - b. The auriculotemporal and buccinator terminal nerves of cranial nerve V
 - c. It also innervates the neck below the external ear
4. The cutaneous branches of the transverse colli nerves (C2–C3) which innervate the neck (primarily anteriorly)
5. The supraclavicular nerve (C3–C4) which innervate the skin of the supraclavicular fossa (immediately above the clavicle)
6. C1 is a purely motor root
7. Anatomical variants include:
 - a. Great auricular nerve communication with the mandibular nerve
 - b. Spinal accessory nerve communication with C2

The innervations of the muscular branches of the cervical plexus include:

1. A loop formed by C1 which curves with the hypoglossal nerve and joins the fibers from C2 and C3 roots that innervate infrahyoid muscles:
 - a. Sternohyoid
 - b. Omohyoid
 - c. Sternothyroid
 - d. Thyrohyoid
 - e. Geniohyoid

These muscles are synergistic in head flexion and swallowing physiology:

1. The phrenic nerve which innervates the diaphragm (C3–C5); C4 is the dominant root
2. Branches to the middle scalene (C3–C4) that affects:
 - a. Lateral neck flexion
 - b. Levator scapulae muscles (C3–C4); rotation of the scapula
3. Branches to the spinal accessory nerve that include:

- a. C2 to the sternocleidomastoid muscle
 - b. C3–C4 to the trapezius muscle
 - c. These branches course with CNXI
4. Swallowing function
 - a. Hyolaryngeal complex

Hyolaryngeal Complex

An important component of the pharyngeal phase of swallowing is the elevation of the hyolaryngeal complex. This is accomplished by the submental muscles (mylohyoid, geniohyoid and anterior digastric and the thyrohyoid muscles). Hyolaryngeal elevation displaces the larynx above the food bolus, shortens the pharynx and opens the upper esophageal sphincter. The hyolaryngeal complex is comprised of the hyoid bone, thyrohyoid membrane and the laryngeal cartilages that are the attachment site for the cricopharyngeus muscle; the cricopharyngeus muscle forms the upper esophageal sphincter. Other muscles that may contribute to the elevation of the hyolaryngeal complex are the posterior digastrics, stylohyoid, and long pharyngeal muscles.

Anatomically, an anterior and posterior sling of muscles suspends the hyolaryngeal complex and along with the thyrohyoid muscle, elevates it during swallowing. The anterior component of the sling is composed of the mylohyoid, geniohyoid, and anterior digastric muscles that insert on the hyoid bone. The posterior digastricus and stylohyoid may also contribute to the anterior sling. The posterior ring is composed of the long pharyngeal muscles that include the stylopharyngeus, salpingopharyngeus and palatopharyngeus muscles that are stabilized by the levator veli palatini. The distal posterior ring muscles insert on the posterior edge of the thyroid cartilage and lateral pharyngeal walls proximal to the upper esophageal sphincter. The thyrohyoid muscle is intrinsic to the hyolaryngeal complex and approximates the thyroid and hyoid bone.

In summary, the submental muscles (mylohyoid, geniohyoid, and anterior digastric) and the thyrohyoid muscle primarily elevate the hyolaryngeal complex that opens the upper esophageal sphincter during the pharyngeal phase of swallowing. The ansa hypoglossi of the cervical plexus is pivotal in the innervations of many of the muscles required for the pharyngeal phase of swallowing.

Clinical Presentations of the Sensory Components of C2–C4 Branches of the Cervical Plexus

The Greater Occipital Nerve

General Characteristics

1. Innervates the skin of the occiput (posterior scalp)

Clinical Manifestations

1. Pain and paresthesias in the cutaneous territory it innervates
2. Severe C2 irritation:
 - a. Pain projected to the brow and behind the eyes
 - b. A frequent trigger of unilateral migraine headaches

Neuropathology

1. Entrapped by the semispinalis and trapezius muscle
2. Neurofibroma
3. Direct trauma

Neuroimaging

1. Ultrasound

*The Lesser Occipital Nerve***General Characteristics**

1. Pain and paresthesias of the mastoid, lateral and posterior head and lower portion of the occiput

Clinical Manifestations

1. Often symptoms in the C2 distribution primarily

Neuropathology

1. Associated with flexion-extension or rotary injury of the neck (motor vehicle accidents, falls, and athletic injuries)
2. Very frequently associated with upper trunk (C5–C6) brachial plexus traction injuries
3. Lacerations
4. Surgical procedures of the posterior triangle of the neck

*The Great Auricular Nerve C2–C3***General Characteristics**

1. Roots are C2–C3; overlaps the auriculotemporal nerve of the Vth cranial nerve as well as components of V2 and V3

Clinical Manifestations

1. Paresthesias and pain in the lower cheek, lower pinna of the external ear (overlaps the auriculotemporal nerve of the Vth cranial nerve)
 - a. Irritation of this nerve causes:
 - i. Neurogenic inflammation and vasodilation of the pinna; the probable genesis of the “red ear” syndrome (C3 root is involved)
 - ii. C-fibers within the nerve release substance P (which interacts with mast cells that release histamine) and calcitonin gene-related peptide. The former (SP) causes endothelial plasma leakage and the latter (CGRP) vasodilation of the affected vessels

Neuropathology

1. Damaged during surgical procedures to the neck or face:
 - a. Facelift
 - b. Parotid surgery
 - c. Carotid endarterectomy
 - d. Traction injury from MVA
 - e. Lacerations

Neuroimaging

1. Ultrasound guided

*Transverse Colli Nerves***General Characteristics**

1. Innervation of the anterior and upper neck (C2–C3 roots)

Clinical Manifestations

1. Pain in the anterior and upper neck

Neuropathology

1. Trauma (flexion, extension, and rotary neck injuries)
2. Surgical procedures in the neck

Neuroimaging

1. Ultrasonography

*Supraclavicular Nerves***General Characteristics**

1. Innervate the supraclavicular fossa and clavicle
2. May innervate the anterior chest wall to T2

Clinical Manifestations

1. Paresthesia and pain in its innervations territory
2. May give a false level following spinal cord injury

Neuropathology

1. Flexion-extension and rotary neck injuries (MVA and falls)
2. Biopsy of lymph nodes
3. Supraclavicular approach for first rib removal or neurectomy of the upper trunk of the brachial plexus in thoracic outlet surgery

Neuroimaging

1. Ultrasonography

Injury of the Motor Roots of the Cervical Plexus (Ansa Hypoglossi)*Ventral Root of C2***Clinical Manifestations**

1. Inability to elevate the hyolaryngeal complex during the pharyngeal component of swallowing:
 - a. Failure to adequately open the upper esophageal sphincter
 - b. Aspiration pneumonia
 - c. Weakness of infrahyoid muscles
2. Middle scalene muscle weakness
 - a. Decreased anterior and lateral head flexion
3. Weakness of the sternocleidomastoid muscle:
 - a. Depressed rotation of the head contralaterally
4. Weakness of the trapezius muscle:
 - a. Depressed shoulder elevation

*The Phrenic Nerve***General Characteristics**

1. Spinal accessory component (C2 innervation) involvement weakens the lateral half of the diaphragm
2. An anatomic variant in which the phrenic nerve receives an anatomic branch from the subclavian nerve; the diaphragm may be normal in this instance with a proximal phrenic nerve lesion

Clinical Manifestations

1. Unilateral paralysis causes dyspnea on exertion but not at rest
2. Bilateral phrenic nerve paralysis causes severe dyspnea on exertion and may lead to alveolar hypoventilation and hypercarbia

Neuropathology

1. May be involved with viral infections that include Parsonage-Turner syndrome or neuralgia amyotrophica
2. Rarely involved with traction injury but not infrequently damaged with scalenectomy and neurolysis procedures in thoracic outlet surgery (lies adjacent to the middle scalene muscle)
3. Aortic aneurysm (compression)
4. Intrathoracic neoplasm (infiltration)
5. Enlarged mediastinal lymph nodes
6. Subclavian vein or internal jugular vein catheterization (direct trauma)
7. Central vein catheter placement
8. Breast cancer (neck metastasis); if associated with damage to the sympathetic chain and recurrent laryngeal nerve it is Payne syndrome
9. Injured during coronary by-pass surgery (neuropraxis or dissection of the internal mammary artery)
10. Clipped in association with the inferior vena cava during liver transplantation
11. Amyotrophic lateral sclerosis
12. Diabetes mellitus
13. Critical care neuropathy (difficulty removing a patient from mechanical ventilation)
14. Mediastinal X-RT
15. Herpes Zoster
16. AIDP
17. Hypophosphatemia

Neuroimaging

1. X-ray
 - a. Elevated diaphragm on the affected site
2. The diaphragm paradoxically moves upward with inspiration (fluoroscopy)

Pharyngeal Plexus*General Characteristics*

1. Lies in the retropharyngeal space between:
 - a. Anteriorly:
 - i. Superior and middle pharyngeal constrictor muscles
 - b. Posteriorly:
 - i. Longus capitis and colli muscles
 - ii. Prevertebral fascia
 - iii. Second and third cervical vertebrae
2. Composed of:
 - a. Sensory fibers of IX and X
 - b. Motor fibers of IX and X

3. Experimental information suggests:

- a. Stimulation of the pharyngeal plexus elicits vocal cord adduction
- b. Glottic closure reflex is affected (in porcine model) by the inferior superior laryngeal nerve. Some studies reveal that the external branch of the superior laryngeal nerve, the communicating nerve of Galen and the recurrent laryngeal nerve also may play a role in the innervations of the thyroarytenoid muscle (pivotal in the glottic closure reflex)
- c. The lingual branches of the glossopharyngeal nerves are thickened and course through a slit between the constriction pharyngis superior and medius muscles, where they may be compressed

Clinical Manifestations

1. Failure of the glottic closure reflex affected by the thyroarytenoid muscle (reflex)
2. Complaints that food gets stuck in the back of the throat and difficulty initiating deglutition

Neuropathology

1. Direct injury from surgical and dental procedures
2. Head and neck X-RT for malignancy
3. Associated with brachial plexus and cervical plexus neuropractic injuries

Neuroimaging

1. MRI (primarily utilizing defined landmarks rather than direct visualization of the plexus)

The Brachial Plexus*Overview*

The brachial plexus derives from the anterior primary rami of spinal segments C5, C6, C7, and T1. It is approximately 0.5 cm long in adults and extends from the spinal column to the axilla. Its detailed anatomy in this course is important as to which of its components are injured or affected by its varied pathologies. It is divided into roots, trunk, division, cords and branches. The C5–C6 roots coalesce to form the upper trunk; the C7 primary anterior ramus forms the middle trunk and the anterior primary rami of C8–T1 the lower trunk. In approximately 60% of patients, the C4 spinal root is a component of the upper trunk. In this instance, the plexus is prefixed, as all of the spinal root contributions are placed up one level. In this situation, the T1 spinal root of the lower trunk is less prominent. In approximately 7% of patients, C5 contributes minimally to the plexus and spinal roots are shifted down one level. If this occurs, T2 contributes to the lower trunk and C7 to the upper trunk.

The C5–C6 roots course downward and coalesce to form the upper trunk between the scalenus medius and scalenus anterior muscles. The anterior division of the upper and middle

trunk fuses and forms the lateral cord, while the anterior division of the lower trunk becomes the medial cord. The three posterior divisions of the upper, middle, and lower trunks form the posterior cord.

The brachial plexus is in close proximity to mobile components of the neck and shoulder that make it susceptible to traction injuries. The trunks are superficial in the supraclavicular fossa. The lower trunk is adjacent to the subclavian artery and the apex of the lung. The divisions of the plexus are retroclavicular and lie between the clavicle and the first rib. Infraclavicularly, the cords surround the axillary artery and are close to the proximal humerus and the glenohumeral joint. Cords are situated below the clavicle in the axilla and are the longest components of the plexus. There are anatomic variations between the cords.

The spinal nerves derived from the cords and trunks may be purely sensory, motor or mixed sensory motor. The nerves that arise directly from spinal roots include the dorsal scapular nerve, the long thoracic nerve and a branch to the phrenic nerve. The subclavian and suprascapular nerves arise from the upper trunk. The subscapular and thoracodorsal nerves arise from the posterior cord that terminates as the axillary and radial nerves. The proximal medial cord gives rise to the motor branch that innervates the pectoral muscle. The distal medial cord gives rise to the medial brachial and medial antebrachial cutaneous nerves. The medial cord gives a small branch to the median nerve and makes up the ulnar nerve. The proximal portion of the lateral cord gives rise to the lateral pectoral nerve. The termination of the lateral cord is the musculocutaneous nerve. It also gives off a lateral branch that joins the branch from the medial cord to form the median nerve.

The median, ulnar, radial, axillary nerves take origin in the peripheral axilla. The proximal portions of the median, ulnar and radial nerves are adjacent to the proximal humerus and the axillary artery. Plexus trunks form at the lateral border of the anterior and middle scalene muscles.

The major blood supply of the brachial plexus derives from the subclavian artery. The supraclavicular components of the plexus are supplied by the ascending cervical, deep cervical and the superior intercostal arteries. The roots are supplied by branches from the vertebral artery. The infraclavicular plexus and cords are supplied by the subclavian, axillary, and subscapular vessels.

Terminal Nerves That Arise from the Cervical Roots

1. The phrenic nerve
 - a. As noted earlier, the major root that innervates the diaphragm is C4. It receives contributions from C3 and C5. The phrenic nerve crosses the anterior scalene muscle to enter the thorax
2. Dorsal Scapular Nerve: Arises from the C5 nerve root immediately after it emerges from the intervertebral foramen, courses between the middle and posterior scalene muscle to innervate the levator scapular and the major and minor rhomboid muscles

3. The long thoracic nerve arises from the C5, C6 and C7 roots, descends along the lateral chest wall to innervate the serratus anterior muscle

Nerves That Arise from Brachial Plexus Trunks

Suprascapular Nerve

1. The suprascapular nerve arises from the upper trunk, descends posteriorly between the omohyoid and the trapezius muscle, through the scapular notch to innervate the supra- and infraspinatus muscles
2. Nerve to the subclavius muscle: May arise from the C5 root or the upper trunk to innervate the subclavius muscle that lies between the clavicle and the first rib
3. Medial pectoral nerve: Arises from the medial trunk whose major roots are C8 and T1. It innervates the pectoralis major and minor muscles

Nerves That Arise from the Brachial Plexus Cords

Lateral Pectoral Nerves

The major roots contributing to the nerve are C5, C6, and C7. The nerve usually arises from the lateral cord.

Anatomic variations occur and include:

1. Origin from the anterior division of the upper and middle trunks

Subscapular Nerves

The primary roots of the nerves are C5 and C6. The upper and lower subscapular nerves arise from the posterior cord in the axilla. The subscapularis nerve innervates the subscapularis muscle; the lower subscapular nerve innervates both the subscapularis and the teres major muscles.

Thoracodorsal Nerve

The major roots comprising the nerve are from C5–C7. The primary root is C7. The nerve takes origin from the posterior cord to innervate the latissimus dorsi muscle.

Anatomic variants include origins from:

1. The radial nerve
2. The axillary nerve

Medial Cutaneous Nerve of the Arm

The nerve originates from the medial cord to innervate the medial upper arm above the elbow.

Medial cutaneous nerve of the forearm usually arises from the medial cord. An anatomic variant is an origin from the medial cutaneous nerve of the arm. It innervates the medial forearm to the wrist.

Musculocutaneous Nerve

The musculocutaneous nerve is the termination of the lateral cord. It innervates the coracobrachialis, biceps brachii, and the brachialis muscles. Its major contributing roots are C5 and C6. In some patients, there is a contribution from C7. It terminates as the lateral cutaneous nerve of the lateral forearm from the elbow to the wrist.

A lateral branch fuses with a branch from the medial cord to form the median nerve.

An anatomic variant in a small number of patients includes:

1. An origin of the nerve from the anterior division of the upper trunk
 - a. In this instance, the lateral branch to the median nerve arises from the middle trunk

Axillary Nerve

The axillary nerve is one of the terminal branches of the posterior cord and is primarily composed of the C5 and C6 spinal nerves. It transverses the quadrilateral space (teres major inferiorly, triceps laterally, the humerus medially, and the teres minor superiorly). It innervates the teres minor and deltoid muscles. Its cutaneous branches innervate the lateral proximal arm over the deltoid muscle.

Radial Nerve

The spinal nerves that comprise the radial nerve are from C5–C8. T1 contributes in approximately 10% of patients. It is the termination of the posterior cord. A branch arises in the axilla, the posterior cutaneous nerve, which innervates the posterior upper arm to the elbow. In the upper arm, it descends medially to the humerus between the medial and long heads of the biceps muscle in the spiral groove. Its branches in the upper arm innervate the medial, lateral, and long heads of the triceps brachii and the anconeus muscle. At the lateral aspect of the upper arm (often exiting the spiral groove), it innervates the brachioradialis, extensor carpi radialis longus and a small component of the brachialis muscle (whose main innervation is the musculocutaneous nerve). It gives off the posterior antebrachial cutaneous nerve that innervates the posterior forearm. At the elbow, it divides into the sensory superficial radial nerve and the motor posterior interosseous nerve. The posterior interosseous nerve transverse the radial tunnel at the elbow that is composed of the radius, the capsule of the radiocapitular joint and the tendons of the biceps brachii and brachialis muscles medially and the brachioradialis, extensor carpi radialis and the extensor carpi ulnaris that form the anterior and lateral walls. A fibrous band around the superficial head of the supinator muscle forms the Arcade of Frohse that is the end of the radial tunnel. The superficial radial nerve travels into the forearm underneath the brachioradialis muscle outside of the radial tunnel. The nerve innervates the extensor surfaces of the hand and fingers (with the exception of the fingertips that are innervated by the median and ulnar nerves) as well as the medial dorsal hand and medial fingers that are innervated by the dorsal ulnar cutaneous nerve. The posterior interosseous nerve courses through the radial tunnel and descends under the Arcade of Frohse. It innervates the supinator, extensor digitorum communis, extensor digiti minimi, extensor carpi ulnaris, abductor pollicis longus, extensor pollicis longus and brevis and the extensor indicis proprius.

Median Nerve

The median nerve is composed of spinal nerves C5–T1 and is formed from the fusion of branches of the medial and lateral cords. Its sensory components are primarily derived from spinal segments C6 and C7. Rarely the C5 spinal segment is a component of the nerve. Sensory fibers arise from the upper and middle trunks to the lateral cord. Motor fibers course through all of the trunks and the medial and lateral cords. The median nerve reaches the antecubital fossa through the anterior compartment of the upper arm. It passes through the two heads of the pronator teres muscle and between the flexor digitorum superficialis and profundus muscles to reach the wrist. It innervates the pronator teres, flexor carpi radialis, palmaris longus, and flexor digitorum superficialis from branches given off in the forearm. It gives off the purely motor anterior interosseous nerve that innervates the flexor digitorum profundus 1 and 2, flexor pollicis longus and the pronator quadratus muscle. Prior to entering the carpal tunnel at the wrist, it gives off the palmar cutaneous nerve that innervates the thenar eminence. The nerve then enters the carpal tunnel that is composed of the carpal bones and a dorsal transverse ligament. It also contains nine flexor tendons to the fingers as well as the median nerve. Either within or just distal to the tunnel the recurrent branch of the nerve arises to innervate the abductor pollicis brevis, opponens pollicis, and the superficial head of the flexor pollicis brevis. The nerve supplies the first and second lumbrical muscles and digital branches to the volar and dorsal tips of the thumb index and long finger as well as the medial one-half of the ring finger.

Ulnar Nerve

The ulnar nerve is comprised primarily of spinal nerves C8 and T1, but in over 50% of patients, there is a contribution from the C7 spinal nerve that innervates the flexor carpi ulnaris muscle. This innervation derives from a branch of the lateral cord. The nerve is the termination and then continuation of the medial cord. It descends anteriorly to the teres major and latissimus dorsi muscles to enter the upper arm. It courses down the posterior compartment of the upper arm to the ulnar groove of the elbow. The ulnar groove comprises the medial epicondyle of the humerus and the olecranon process of the ulna. The ulnar collateral ligament bounds it inferiorly. Distal to the ulnar groove (1–2.5 cm), the nerve courses under a fibrous aponeurosis that connects the humeral and ulnar heads of the flexor carpi ulnaris muscle. The ulnar groove and the aponeurosis form the cubital tunnel. There are no branches from the ulnar nerve in the upper arm. The nerve traverses between the flexor carpi ulnaris and flexor digitorum profundus to the wrist. Its forearm branches innervate the flexor carpi ulnaris and the flexor digitorum profundus III and IV. The dorsal ulnar cutaneous nerve innervates the dorsum of the medial hand and fourth and fifth fingers. Prior to entering Guyon's canal at the wrist, it gives off the palmar branch that gives sensory innervation to the hypothenar eminence and innervates the palmaris brevis muscle. Guyon's

canal is formed radially by the hook of the hamate bone and the pisiform bone on its ulnar side, the pisohamate ligament inferiorly and the transverse carpal ligament superiorly. Either within or immediately distal to Guyon's canal the ulnar nerve gives off its terminal branches. The superficial sensory branch innervates the volar components of the fifth finger and the ulnar half of the fourth finger as well as the dorsal distal aspects of these digits. The deep motor branch of the ulnar nerve innervates the hypothenar muscles, the third and fourth lumbricals, the interossei, adductor pollicis and the deep head of the flexor pollicis brevis muscle.

Clinical Manifestations of Brachial Plexus Disorders

1. Supraclavicular Level:
 - a. Supraclavicular lesions present in myotomal and dermatomal distributions
 - b. Cervical root derived terminal nerves:
 - i. Phrenic nerve (C3–C5); C4 is the predominant root
 - ii. Dorsal scapular nerve:
 1. Arises from the C5 root as it exits the intervertebral foramen
 2. Innervates the major and minor rhomboid muscles and the levator scapuli
 3. The muscles pull the scapulae medially, rotate it and hold it against the chest wall
 - iii. Long thoracic nerve:
 1. Arises from C5, C6 and C7 spinal nerves
 2. Innervates the serratus anterior muscle
 3. Function:
 - a. Pulls the scapula forward around the thorax to achieve anteversion of the arm
 - b. Compresses the scapula against the wall of the thorax
 - c. Assists with elevation of the ribs with respiration
 - d. A component of arm elevation
 - e. Protraction of the scapula
 - f. Role in upward rotation of the scapula in synchrony with the trapezius muscle
 - c. Upper trunk lesions:
 - i. Suprascapular nerve
 1. Arises from the upper trunk immediately after it forms
 2. Function:
 - a. Abducts the arm at the shoulders, it is the main agonist of this movement for the first 10–15 degrees of its arc. Beyond 30 degrees the deltoid muscle is the primary arm abductor
 - b. Stabilizes the shoulder joint by effecting pressure medially that helps to hold the humeral head in the glenoid fossa
 - c. Provides sensory innervations to the acromioclavicular and glenohumeral joints

- d. The infraspinatus muscle:
 - i. Externally rotates the humerus
 - ii. Stabilizes the shoulder joint
- e. Diagnostic points:
 - i. Lesions at the level of the formation of the trunks:
 1. The serratus anterior and the rhomboids are normal
 2. Lesions at mid or upper trunk segments:
 - a. The supra- and infraspinatus muscles are normal

Lateral Cord Lesions

1. Lateral pectoral nerves:
 - a. Most often arise from the lateral cord. Anatomic variants are its origin from the anterior division of the upper and middle trunks
 - b. Function:
 - i. Innervates the pectoralis major muscle that is also innervated from the medial pectoral nerve
 - ii. Flexion and adduction of the humerus
 - iii. Rotates the humerus medially
 - iv. Sensory innervations of the anterior chest wall

Musculocutaneous Nerve

1. Most often is the termination of the lateral cord:
 - a. Gives off a branch that combines with a branch from the medial cord that forms the median nerve
 - b. Its major spinal nerves are C5 and C6 although there is a contribution from C7 in greater than 50% of patients
2. It innervates:
 - a. Coracobrachialis
 - b. Biceps brachii
 - c. Brachialis
 - d. Forms the lateral cutaneous nerve of the forearm
3. Function:
 - a. Coracobrachialis:
 - i. Flexes and adducts the arm
 - ii. Medial rotation of the humerus
 - iii. Stabilization of the humeral head within the glenoid fossa
 - b. Biceps brachii:
 - i. Supination of the forearm
 - ii. Flexion of the forearm
 - iii. Minor functions:
 1. Forward flexion of the shoulder
 2. Aids abduction of the arm
 3. Short head contributes to adduction of the arm
 4. Stabilization of the shoulder
 - iv. Lateral cutaneous nerve of the forearm
 1. Sensation from the lateral elbow to the wrist (laterally)

Medial Cord

1. Medial pectoral nerve:

- a. Innervates both the pectoralis major and minor muscles
- b. Function:
 - i. Adduction and medial rotation of the arm
 - ii. Poland syndrome (congenital absence of the muscle) may be asymptomatic
- 2. Medial cutaneous nerve of the arm
 - a. Provides sensation to the medial upper arm to the elbow
- 3. Medial cutaneous nerve of the forearm:
 - a. May arise from the medial cutaneous nerve of the arm
 - b. Function:
 - i. Innervates the medial forearm to the wrist

Posterior Cord

- 1. Thoracodorsal Nerve:
 - a. Most often arises from the posterior cord. Rarely its origin is the radial or axillary nerves
 - b. Its major spinal nerve is C7, but it receives contributions from C5 and C6
 - c. Function:
 - i. Extension and adduction of the arm
 - ii. Horizontal abduction of the arm
 - iii. Internal rotation
 - iv. Flexion from an extended position
 - v. Synergistic for extension and lateral flexion of the lumbar spine
- 2. Suprascapular nerves:
 - a. The upper suprascapular nerve innervates the subscapularis muscle. Derived from C5, C6 spinal nerves
 - b. Function:
 - i. Rotates the head of the humerus medially
 - ii. Draws the humerus forward and downward if the arm is raised
 - iii. Prevents displacement of the humerus

Lower Subscapular Nerve

- 1. Supplies the lower part of the subscapularis muscle as well as the teres major
- 2. Its spinal nerves are C5 and C6
- 3. Function:
 - a. The subscapularis is the major and most powerful muscle of the rotator cuff
 - b. Stabilizes the glenohumeral joint

Axillary Nerve

- 1. One of the terminal branches of the posterior cord. Its spinal nerves are C5 and C6. It innervates the teres minor and deltoid muscles. Its sensory innervation is the lateral proximal arm over the deltoid muscle
- 2. Function of the deltoid muscle:
 - a. Anterior fibers:
 - i. Shoulder abduction
 - ii. Medial rotation of the humerus
 - b. Posterior fibers:
 - i. Transverse extension
 - ii. Lateral rotation

- c. Lateral fibers:
 - i. Shoulder abduction
 - ii. Stabilizes the humeral head
- 3. Teres minor muscle:
 - a. Part of the rotator cuff that stabilizes the humeral head in the glenoid fossa
 - b. Is synergistic with the posterior fibers of the deltoid to laterally rotate the humerus
 - c. Transverse adduction and extension of the arm

Radial Nerve

- 1. The continuation of the posterior cord following branching of the axillary nerve. Its major spinal nerves are C5–C8 although approximately 10% of patients have a contribution from T1
- 2. Innervates:
 - a. The long, medial and lateral head of the triceps and the anconeus muscle
 - b. Brachioradialis, extensor carpi radialis longus and the brachialis (major innervations is from the lateral cord)
 - c. In the axilla, it gives off the posterior cutaneous nerve that innervates the posterior arm to the elbow. The posterior antebrachial cutaneous nerve innervates the posterior forearm. The superficial radial nerve innervates the extensor surface of the hand and fingers except for the distal fingertips. The dorsal ulnar cutaneous nerve supplies the dorsal medial hand and medial fingers
 - d. In the forearm it innervates the extensor carpi radialis brevis, supinator, extensor digitorum communis, extensor digiti quinti, extensor carpi ulnaris
 - e. Above the wrist branches innervate the abductor pollicis longus, extensor pollicis longus and brevis and the extensor indicis
 - f. In the hand, it gives off dorsal digital nerves
 - g. At the elbow the motor posterior interosseous nerve

Function of the Radial Nerve

Triceps Muscle

- 1. Primary extensor of the elbow joint
- 2. Fixates the elbow when the hand is used
- 3. Long head:
 - a. Used for sustained force
 - b. Synergistic for control of the shoulder and elbow
 - c. Retroversion and adduction
- 4. Lateral head
 - a. High-intensity force
- 5. Medial head:
 - a. Used during low force precise hand movements

Anconeus Muscle

- 1. Assists in elbow extension and supports the elbow in full extension
- 2. Protects the elbow joint capsule in the olecranon fossa during extension of the elbow
- 3. Abducts the ulna

Brachioradialis Muscle

1. One of the few muscles that receives innervations directly from the radial nerve (the triceps, anconeus, and extensor carpi radialis are the others). The other radial nerve innervated muscles receive their innervations from a deep branch of the nerve
2. Function:
 - a. Flexes the forearm at the elbow
 - b. Stabilizes the elbow during rapid flexion and extension
 - c. Synergistic with the brachialis and biceps muscles

Supinator Muscle

1. Curved around the upper 1/3 of the radius and innervated by the deep branch of the radial nerve
2. Function:
 - a. Supinates the forearm

Extensor Carpi Radialis Longus

1. Innervated by the radial nerve. All other major extensor muscles in the superficial layer of the posterior compartment of the forearm are innervated by the posterior interosseous nerve and include:
 - a. Extensor digitorum
 - b. Extensor carpi radialis brevis
 - c. Extensor carpi ulnaris
 - d. Extensor digiti minimi
2. Function:
 - a. Extension of the wrist
 - b. Radial abduction of the hand at the wrist

Extensor Carpi Radialis Brevis

1. Innervated by the posterior interosseous nerve
2. Function:
 - a. An extensor and abductor of the hand at the wrist

Extensor Digitorum Communis

1. Innervated by the posterior interosseous nerve
2. Function:
 - a. Principal action is extension of the proximal phalanges, the middle and terminal phalanges are extended by the interossei and lumbricals
 - b. Extends the phalanges, the wrist and the elbow (weak)

Extensor Carpi Ulnaris

1. Innervated by a deep branch of the radial nerve (C7, C8 spinal segments)
2. Function:
 - a. Extends and adducts the wrist

Extensor Indicis, Extensor Pollicis Longus and Brevis, Extensor digiti quinti

1. Innervated by the posterior interosseous nerve
2. Function:
 - a. Extension of the thumb (metacarpophalangeal and interphalangeal joints)
 - b. Extension of the index finger and wrist (extensor indicis) and extension of the little finger at all joints (extensor digiti quinti)

Median Nerve

1. Formed by fusion of branches from the medial and lateral cords (spinal segments C6–T1)
 - a. Motor fibers arise primarily from C6–T1 spinal segments
 - b. Sensory fibers from C6–C7 spinal segments
 - c. The sensory fibers transverse the upper and middle trunks to the lateral cord
 - d. Motor fibers traverse all of the trunks to both the medial and lateral cords
 - e. In the forearm the median nerve innervates:
 - i. Pronator teres
 - ii. Flexor carpi radialis
 - iii. Palmaris longus
 - iv. Flexor digitorum superficialis

2. Pronator Teres:

- a. A forearm pronator (C6–C7)

3. Flexor carpi radialis (C6–C7)

- a. A radial flexor of the hand

4. Palmaris longus (C7–T1)**5. Flexor digitorum superficialis (C7–T1)**

In its descent and after it passes between the two heads of the pronator teres the purely motor anterior osseous nerve takes origin to innervate:

1. Flexor pollicis longus (C7–C8)
2. A flexor of the terminal phalanx or the thumb
3. Flexor digitorum profundus and (C7–C8)
 - a. A flexor of the terminal phalanges of the second and third fingers
4. Pronator quadrates (C7–C8)
 - a. A forearm pronator

The median nerve divides into its terminal branches at the distal end of the carpal tunnel. The motor branches innervate the first and second lumbricals and the thenar muscles.

1. First and second lumbricals (C8–T1):
 - a. Flexors of the proximal and extensors of the two distal phalanges of the second and third fingers
2. Abductor pollicis brevis (C8–T1):
 - a. An abductor of the metacarpal of the thumb (possibly the best muscle to test for median nerve weakness)
3. Opponens pollicis (C8–T1)
 - a. Brings the metacarpal of the thumb into opposition
4. Superficial head of the flexor pollicis brevis (C8–T1)
 - a. Flexes the proximal phalanx of the thumb

Variations in the Innervation of Intrinsic Hand Muscles

1. Riche-Cannieu Anastomosis
 - a. Anastomosis between the motor branch of the median nerve and the deep ulnar nerve branch in the radial aspect of the hand
2. Adductor pollicis and first dorsal interosseous muscles may be exclusively supplied by the median nerve in 2% of patients
3. The abductor pollicis brevis and flexor pollicis brevis may be supplied exclusively by the ulnar nerve in 2% of individuals

Ulnar Nerve

The ulnar nerve derives from the C7, C8, and T1 spinal nerves and is the main branch of the medial cord. In its descent into the arm, it traverses the axilla beneath the pectoralis minor muscle and lies medial to the brachial artery in the upper arm. The C7 component arises from a branch of the lateral cord to innervate the flexor carpi ulnaris muscle. It enters a groove in the distal arm between the medial humeral epicondyle and the olecranon process. The dorsal component of this osseous fibrous canal is an aponeurosis between the olecranon and medial epicondyle. It is bound inferiorly by the medial ligament of the elbow joint. This canal is the cubital tunnel. Distal to the elbow joint originate its first two muscular branches.

1. The flexor carpi ulnaris (C7–T1)
 - a. Flexor of the wrist
2. Flexor digitorum profundus III and IV (C7–C8)
 - a. A flexor of the terminal phalanges of the fourth and fifth fingers

In the distal forearm, it gives off the palmar cutaneous branch that innervates the skin of the hypothenar eminence. Shortly thereafter, it gives off the dorsal cutaneous branch that innervates the dorsal ulnar hand and the dorsal components of the fifth finger and one-half of the fourth finger. The ulnar nerve proper enters the wrist lateral to the tendon of the flexor carpi ulnaris muscle and gives off the superficial terminal branch. This sensory branch innervates the distal ulnar palm and the volar aspect of the fifth and one-half of the fourth finger. The nerve then traverses Guyon's canal whose medial component is the piriform carpal bone and the hook of the hamate carpal bone laterally to become the deep muscular branch.

It innervates intrinsic muscles of the hand that includes:

1. Palmaris brevis (C8–T1)
 - a. Tenses the skin of the palm on the ulnar side of the hand to deepen the hollow of the palm
2. Abductor digiti minimi (C8–T1)
 - a. An abductor of the fifth finger
3. Opponens digiti minimi (C8–T1)
 - a. An opposer of the fifth finger
4. Flexor digiti minimi (C8–T1)
 - a. A flexor of the fifth finger at the metacarpophalangeal joint
5. Lumbricals III and IV (C9–T1)
 - a. Flexors of the metacarpal phalangeal joints and extensors of the proximal interphalangeal joints of the fourth and fifth fingers
6. Interosseous muscles:
 - a. Flexors of the metacarpophalangeal joints and extensors of the proximal interphalangeal joints. The four dorsal interossei muscles are finger abductors. The three palmar interossei muscles are finger adductors
 - i. Variants are:
 1. Innervation of the first dorsal interosseous by the median nerve (1% of individuals)
 2. First dorsal interosseous is innervated by the radial nerve (Froment-Rauber nerve)

7. Adductor pollicis (C8–T1)
 - a. An adductor of the thumb
 - b. It receives median nerve innervations in approximately 2% of individuals
8. Deep head of the flexor pollicis brevis (C8–T1)
 - a. A flexor of the first phalanx of the thumb

Clinical Manifestations

1. Total Brachial Plexus Paralysis:
 - a. There is paralysis of the entire arm that hangs limply at the patient's side. There is severe atrophy of all muscle groups
2. Anesthesia of the arm distal to a line extending obliquely from the tip of the shoulder to the medial arm approximately $\frac{1}{2}$ way to the elbow
3. Areflexia of the upper extremity

Upper Plexus Lesions

Most commonly involve the C5 and C6 spinal nerves of the upper trunk of the plexus.

1. Motor signs:
 - a. C5–C6 spinal nerve innervated muscles are paretic or paralyzed and atrophic. These muscles include:
 - i. Deltoid
 - ii. Biceps
 - iii. Brachioradialis
 - iv. Brachialis
 - b. If the lesion is very proximal the supraspinatus, infraspinatus and subscapularis may be involved. The arm is internally rotated and adducted and the forearm is extended and pronated. The palm faces out and backward. There is weakness of:
 1. Shoulder abduction:
 - a. Deltoid and supraspinatus
 2. Elbow flexion:
 - a. Biceps brachioradialis and brachialis
 3. External rotation of the arm:
 - a. Infraspinatus
 4. Forearm supination:
 - a. Biceps
 5. Very proximal lesions involve the rhomboids, levator scapulae, serratus anterior and scalene muscles
2. Sensory signs:
 - a. Sensation is often intact
 - b. Sensory loss does occur over the lateral/upper arm and the deltoid muscle in some patients
3. Reflex signs
 - a. Depression of the biceps and brachioradialis reflexes

Middle Plexus Lesions

1. Lesions of the middle trunk or the individual anterior primary ramus of C7 are involved
2. Motor signs:
 - a. Involvement of C7 innervation to the radial nerve is primarily involved which causes weakness or paralysis of extension of the forearm, hand, and fingers

- b. The paretic or paralyzed muscles are:
 - i. Triceps
 - ii. Anconeus
 - iii. Extensor carpi radialis and ulnaris
 - iv. Extensor digitorum
 - v. Extensor digiti minimi
 - vi. Extensor pollicis longus and brevis
 - vii. Abductor pollicis longus
 - viii. Extensor indicis
- c. Forearm flexion is maintained by the brachioradialis and brachialis (C5–C6 spinal nerves)
- 3. Sensory signs:
 - a. Patchy sensory deficit over the extensor surface of the forearm and the dorsum of the hand
- 4. Reflexes:
 - a. Triceps reflex is depressed or absent

Lower Plexus Lesion

- 1. Primary injury involves the C8–T1 spinal nerves or the lower trunk of the plexus
- 2. Motor signs:
 - a. Musculature supplied by the C8–T1 spinal nerves is affected. There is weakness of wrist and finger flexion and in the intrinsic hand muscles. There is usually severe hand atrophy leading to the “claw” hand deformity
- 3. Sensory signs:
 - a. Decreased sensation of the medial arm and forearm and the ulnar side of the hand
- 4. Reflex signs:
 - a. Loss of finger flexion
- 5. If T1 is damaged, sympathetic fibers to the superior cervical ganglia are interrupted which causes a Horner’s syndrome. If T2 is damaged, there is an interruption of the sympathetic innervation of the arm

Lesions of the Lateral Cord

Usually, result in weakness of the muscles innervated by the musculocutaneous and lateral head of the median nerve.

- 1. Motor signs
 - a. Weakness of the biceps brachii and brachialis
 - i. Flexion of the elbow
 - b. Coracobrachialis:
 - i. Supination of the forearm
 - c. Median nerve innervated muscles:
 - i. Pronator teres
 - 1. Pronation of the forearm
 - ii. Flexor carpi radialis:
 - 1. Radial wrist flexion
 - iii. Palmaris longus:
 - 1. Flexion of the wrist
 - iv. Flexor digitorum superficialis:
 - 1. Flexion of the middle phalangeal joints (second through fourth digits)
 - v. Flexor digitorum profundus I and II:

- 1. Flexion of the distal phalanges of the second and third fingers
- vi. Pronator quadratus:
 - 1. Pronation of the forearm
- 2. Sensory signs
 - a. Loss of sensation in the distribution of the lateral cutaneous nerve of the forearm:
 - i. Sensory loss in the lateral forearm
 - ii. Branch of the musculocutaneous nerve
- 3. Reflexes
 - a. Depression or absence of the biceps reflex

Lesions of the Medial Cord

- 1. Cause weakness of the muscles innervated by the ulnar nerve and the medial component of the median nerve
- 2. Ulnar innervated muscles that are weak include:
 - a. Flexor carpi ulnaris:
 - i. Ulnar flexion of the wrist
 - b. Flexor digitorum III and IV:
 - i. Flexion of the terminal digits of the fourth and fifth fingers
 - c. All of the ulnar innervated small intrinsic hand muscles
- 3. Median innervated muscles include:
 - a. Abductor pollicis brevis
 - i. Metacarpal abduction of the thumb
 - b. Opponens pollicis:
 - i. Opposition of the thumb
 - c. Superficial head of the flexor pollicis brevis:
 - i. Flexion of the proximal phalanx of the thumb
 - d. Lumbricals I and II:
 - i. Flex the first two metacarpophalangeal joints and extend the digits of the second and third fingers
- 4. Sensory Signs
 - a. Loss of sensation of the medial arm and forearm due to injury of the medial cutaneous nerves of the arm and forearm
- 5. Reflexes
 - a. Loss of the finger flexor reflex

Proximal Lesions of the Medial Cord

- 1. Injury of the medial anterior thoracic nerve
 - a. Weakness of the lower sternocostal portion of the pectoralis major muscle and the pectoralis minor muscle

Lesions of the Posterior Cord

Posterior cord lesions cause weakness in the muscles innervated by the subscapular thoracodorsal, axillary and radial nerves.

- 1. Motor signs:
 - a. Subscapular nerve innervated muscles:
 - i. Weakness of the teres major and subscapularis muscles
 - 1. Internal rotation of the humerus
 - b. Thoracodorsal innervated muscles:
 - i. Latissimus dorsi weakness:

1. Extension, adduction, transverse extension (horizontal abduction), flexion from an extended position and internal rotation of the shoulder joint
2. Synergistic role (therefore weakness) in extension and lateral flexion of the lumbar spine
- c. Axillary nerve innervated muscles:
 - i. Deltoid:
 1. Arm abduction
 - ii. Teres minor:
 1. Lateral rotation of the shoulder joint
 - iii. Sensory loss:
 1. Distribution of the lateral cutaneous nerve of the arm that includes a diminished sensation of the lateral arm

Radial Nerve

1. Weakness of elbow extension, wrist extension, supination of the forearm and finger extension. There is a minimal contribution to elbow flexion. Proximal lesions cause triceps reflex loss
2. Sensory signs: sensory loss in the extensor surface of the arm and forearm, dorsum of the hand and first four fingers distribution
3. Reflexes:
 - a. Depression of triceps and radial reflexes

Neuropathology of Nerve Injuries

Neuropraxis

1. Neuronal dysfunction due to transient conduction block
2. Compression of a nerve may cause segmental ischemia. If of short duration there may only be a reversible physiologic conduction block that lasts for minutes to hours. There may also be paranodal and then segmental demyelination. In this instance, recovery may take several weeks and is effected by remyelination

Axonotmesis

In this instance, the axon is interrupted, but the epineurium is preserved. The axon distal to the lesion degenerates over 7–10 days. Regenerating nerve sprouts from the proximal portion of the injured nerve attempt regeneration. The intact epineurium enhances the chance of reinnervation. Axons grow at a rate of 1 mm/day, so this process may require months to over a year.

Neurotmesis

1. The axon and epineurium are interrupted. The difference between axonotmesis and neurotmesis can only be determined by direct vision (surgery). Scarring from overlying tissue damage often prevents reinnervation

Neuropathology

1. Dependent on the particular process affecting the plexus

Neuroimaging

1. Primarily high resolution MRI
2. Ultrasound is useful for focal neuropathies

Laboratory Evaluation

1. EMG:
 - a. The EMG is essential in evaluating radiculopathy, plexopathy, and mononeuropathy
 - b. Combined with motor and sensory NCVs, it supports the localization determined by the clinical examination

Traumatic Brachial Plexus Injury

Overview

1. The longitudinal excursion of the brachial plexus is 15.3 mm
2. The greater the traction on the plexus, the greater the injury (neuropraxia, axonotmesis to neurotmesis)
3. The primary roots are the most susceptible to traction injury (they are arranged in parallel bundles rather than a lattice structure and therefore have decreased tensile strength)
4. Shoulder depression and lateral head flexion contralaterally injure the upper and middle trunk
5. Traction on the hyperabducted arm causes traction on the lower > middle > upper trunk
6. Preganglionic injuries are usually caused by avulsion of the root
7. Traction injuries may affect all or a portion of the plexus to a varying degree
8. C5 and C6 rupture occur close to the exit foramina. C8–T1 rupture is often closer to the spinal cord
9. The pathology is categorized as neuropraxic axonotmesis and neurotmesis
10. Treatment (surgical intervention) is dependent on the type and severity of the injury:
 - a. Most closed injuries are neuropraxic or axonometric that may recover spontaneously
 - i. Upper trunk lesions usually demonstrate signs of recovery in 2–3 months
 - ii. Four to five months are required for recovery in middle and lower trunk lesions
 - b. High impact injuries and those causing near total paralysis need to be evaluated earlier for possible surgery (3 weeks to 3 months)
 - c. Injuries that more likely sever nerves such as lacerations or gunshot wounds need to be evaluated for possible surgical repair within 72 hours
 - d. Associated conditions that cause neurological worsening after injury:
 - i. Hematoma
 - ii. Concomitant bone and vascular injury
 - iii. Compartment syndromes

Avulsion Injury

General Characteristics

1. C5–C6 root lesions after severe trauma

- a. 27% avulsions; 33% ruptures
- 2. Most often are caused by high impact trauma
 - a. MVA (motorcycle injuries are the most common)
 - b. Football, skiing, mountain climbing accidents and falls
- 3. C8–T1 root lesions:
 - a. 98% are avulsion, and 1–2% are ruptures

Clinical Manifestations

1. Total plexopathy may occur with high impact trauma:
 - a. Avulsion is greater in C8–T1 roots > C5, C6 and C7 roots
2. Early severe burning pain in an otherwise anesthetic hand; most severe proprioceptive loss if any sensation is present
3. Horner's syndrome is present in C8–T1 avulsion
4. Paralysis of the serratus anterior, rhomboids, infra- and supraspinatus muscles
5. Negative supraclavicular Tinel's sign
6. May have associated spinal cord symptoms and signs

Neuropathology

1. Neurotmesis of the roots

Neuroimaging

1. Traumatic meningocele
2. Fracture of a transverse process
3. Flattening of the root sleeve
4. Extravasation of contrast through the torn root sleeve during myelography
5. High resolution MRI may demonstrate the lesions and is now more commonly used than myelography
6. Ultrasound is used for focally associated neuropathies

Laboratory Evaluation

1. EMG:
 - a. Sensory, motor and mixed sensorimotor nerve conduction studies
 - b. SNAP (sensory nerve action potentials) are normal if the lesion is distal to the dorsal root ganglion
 - i. It requires 7–10 days for SNAPs to disappear with a completely severed nerve
 - c. Positive sharp-wave and fibrillation potentials in affected muscles and paraspinal muscles:
 - i. May require one week to appear in paraspinal muscles and three weeks following axonal injury
 - ii. The MUAPs voluntarily recruited are immediately affected

Obstetric Complications

General Characteristics

1. Incidence ranges from 0.38 to 2% per 1000 live births
2. Three types of injury occur:
 - a. Diffuse plexopathy
 - b. Upper trunk plexopathy (Erb's)
 - c. Lower trunk plexopathy (Klumpke's)
3. Risks for brachial plexus injury during childbirth:

- a. Diabetic, multiparous, obese mothers
- b. Greater than 4500 gram fetuses
- c. Mothers that are short
- d. Breech presentation
- e. Long and difficult labor
- f. Forceful downward traction of the head

Clinical Manifestations

1. Erb's palsy (C5–C6 roots; upper trunk)
2. The most common obstetrical brachial plexus injury:
 - a. Stretch of the upper trunk
 - b. Severe traction may avulse the C5 and C6 spinal nerves
 - c. Occurs with shoulder dystocia in a vertex presentation or the aftercoming head in a breech presentation
 - d. Upper trunk lesions cause weakness of muscles that include:
 - i. Supra- and infraspinatus
 - ii. Deltoid
 - iii. Biceps brachii
 - iv. Teres minor
 - v. Brachioradialis
 - vi. Extensor carpi radialis/longus/brevis
 - vii. Supinator
 - e. Weakness of the diaphragm or serratus anterior suggests root avulsion (proximal to the upper trunk)
 - f. Sensory loss < motor deficit

Klumpke's Paralysis (C8–T1 Roots)

1. Face presentation with hyperextension of the neck or with a breech delivery with hyperabduction of the arm
2. Weakness of hand muscles
3. Sensory loss < motor deficit

Neuropathology

- a. Primarily axonotmesis and neurotmesis (with avulsion)

Neuroimaging

- a. To assess for associated humeral or clavicular fracture; diaphragmatic paralysis
- b. MRI:
 - i. To assess for nerve root avulsion

Laboratory Evaluation

- a. EMG:
 - i. Determines the site and severity of the lesion

Thoracic Outlet Syndrome

Overview

The major components of the thoracic outlet are the sternocostovertebral space that forms the most proximal part of the thoracic outlet tunnel and is bound:

1. Anteriorly by the sternum
2. Posteriorly by the spine
3. Laterally by the first rib

The subclavian artery, subclavian vein, and C4 to T1 spinal nerves traverse this space. Associated structures include the apex of the lung and pleura, sympathetic trunk, jugular vein and lymphatics of the neck. It may be congenitally narrowed. The usual pathology of the sternocostovertebral space includes thyroid masses, an enlarged thymus, parathyroid mass, lymph nodes or lung tumors that cause the Pancoast syndrome (squamous or adenocarcinoma of the lung). The scalene triangle is bound by the anterior scalene muscle anteriorly, the middle scalene posteriorly with the first rib forming its base. The origins of the anterior scalene muscle are the transverse processes of C3–C6. The insertion of the anterior scalene muscles on the scalene tubercle of the first rib varies between the subclavian artery and vein and the pleural dome.

Variants of this insertion include:

1. Behind the artery
2. Between the artery and the brachial plexus
3. The entire base of the scalene triangle (which traps the neurovascular bundle). The anterior insertion may merge with the insertion of the middle scalene muscle in 20% of patients. The C5–C6 spinal nerves may traverse the anterior scalene muscle rather than descend between the anterior and middle scalene muscles

The origin of the middle scalene muscle is the transverse processes of C2–C7. It inserts on the retroarterial tubercle of the first rib (Chassaignac's tubercle). It may insert on the fibrous septum of the pleural dome in which case its lateral fibers insert on the second rib. The C8–T1 spinal nerves as the lower trunk of the plexus may be compressed by a more anterior or forward insertion (its sharp anterior edge). Rarely, congenital fibromuscular bands are noted along the anterior edge of the muscle that may also compress the C8–T1 spinal nerves.

The first rib forms the floor of the scalene triangle. The T1 spinal nerve is closest to the rib. Congenital rib anomalies, bony ridges, hypoplasia or inward curvature may compress the neurovascular bundle. There are congenital variations in the size of the base of the scalene triangle that may cause compression of components of the plexus. Its usual size is approximately 0.77 cm in men and 0.67 cm in women. The C5–C7 spinal nerves emerge from the apex of the triangle in association with interdigitation of the anterior and middle scalene muscles. This anatomical feature is noted in a large percentage of patients with neurogenic thoracic outlet syndrome. Adherence of the C5–C6 spinal nerves to the middle scalene muscle may also irritate these nerves and cause pain. Pathology in the costoclavicular and pectoralis minor space compresses the brachial plexus with various arm positions.

Anatomical Variations of the Thoracic Outlet

1. Bone defects:
 - a. Cervical rib
 - b. Abnormal or rudimentary first rib
2. Congenital bands or ligaments
3. Pectoralis minor insertion variations (hyperabduction syndrome)

4. Large subclavius muscle
5. Tight thoracic inlet
6. Scalene triangle congenital defects:
 - a. Narrow scalene triangle
 - b. Proximity of anterior and middle scalene muscles
 - c. High emerge of spinal nerves from the triangle
 - d. Interdigitated muscle fibers between the middle and anterior scalene muscles
 - e. Adherence of spinal nerves C5–C6 to the anterior scalene muscle
7. Congenital narrowness of the costoclavicular space
8. Clavicle anomalies (acromial head depression compresses the costoclavicular space)
9. A tight pectoralis minor space (below the insertion of the pectoralis minor tendon into the coracoid process); hyperabduction of the arm closes the space

Neurogenic Thoracic Outlet Syndrome

General Characteristics

1. The most frequent cause of TOS (hotly debated between neurologists, EMG specialists and thoracic and specific groups of orthopedic surgeons)
2. High percentage of patients has an underlying anatomical variant:
 - a. The four anatomical spaces of the thoracic outlet:
 - i. Sternocostovertebral space
 - i. Scalene triangle (most frequently involved)
 - ii. Costoclavicular space
 - iii. Pectoralis minor space
 - b. Congenital bands (12 types)
 - c. Cervical ribs
 - d. Long neck droopy shoulder
 - e. Tight thoracic inlet
 - f. Abnormal insertions of the anterior, middle or minimus scalene muscle

Clinical Manifestations

1. Abnormal posture of the affected extremity forward flexed and dropped shoulder as the position of comfort (weakness of the lower components of the trapezius muscle and the levator scapulae). There is often associated pathology of the ventral components of C2–C4
2. Positive stretch of maneuvers
 - a. Roos' abduction stress maneuver is positive in approximately 60–70% of patients in one minute; Wright's maneuver is also frequently positive. These maneuvers evoke heaviness and paresthesia in specific plexus sensory radiations within 1–2 minutes. Control patients can maintain these postures (surrender position of the arms) for at least three minutes
3. Positive Tinel's signs:
 - a. Erb's point (supraclavicular plexus)
 - b. Pectoralis minor space (lateral infraclavicular fossa)
 - c. Compression of the neurovascular bundle (against the proximal humerus)

- d. At the cubital tunnel (ulnar nerve)
- e. At the Arcade of Frohse (dorsal radial sensory fibers). This Tinel's sign is invariably misdiagnosed as "tennis elbow"
- f. Pronator canal (median nerve)
- g. Occasionally the carpal tunnel and Guyon canal areas are mechanically sensitive
- h. Sensory loss in specific plexus distributions:
 - i. Upper trunk
 1. Trapezius ridge, deltoid and medial scapula border (C5–C6 sensory radiations)
 2. Pain or tenderness at the tip of the scapula is notalgia and is a C6 sensory nerve radiation, not T6
 - ii. Lower trunk:
 1. Medial arm and forearm distributions (brachial and antebrachial cutaneous nerve distributions)
 2. Radiation into the complete 4th finger (the ulnar nerve splits the fourth finger and supplies a small triangular area above the wrist). The lower trunk innervates the entire medial forearm and arm. The lower trunk radiations are often misdiagnosed as ulnar nerve lesions
 3. Proximal lesions may be associated with a Horner's syndrome
 4. Lower trunk lesions are a common cause of chronic regional pain syndrome Type I and II that has severe somatosensory, motor, and autonomic features
 - iii. Lateral cord:
 1. Pain or paresthesia in the lateral forearm (lateral antebrachial cutaneous nerve) distribution
 2. Thumb, index and radial side of the third finger have decreased sensation or paresthesias
 - iv. Medial cord:
 1. Medial forearm (territory of the medial antebrachial cutaneous nerve); rarely the brachial cutaneous nerve territory of the medial proximal upper arm is involved
 2. The ulnar side of the third finger and the complete 4th and 5th finger comprise the medial cord sensory topology
 3. There is frequent involvement of intercosto-brachial nerve concomitantly with medial cord injury; this causes pain in the anterior chest wall (T1–T3) and the lateral chest wall (anterior axillary line); paresthesia and pain may radiate under the breast to the middle of the epigastrium at the xiphoid process. These radiations are often misdiagnosed as visceral pain radiations
 - v. Posterior cord:
 1. Paresthesias of the triceps muscle and back of the arm
 2. Radiations to the dorsal forearm and base of the thumb and parts of the dorsal hand (posterior antebrachial radial cutaneous nerve)
 - vi. Muscle weakness:
 1. Occurs in various components of the involved plexus; subscapularis, teres major, latissimus dorsi, deltoid, teres minor, triceps brachii, brachioradialis, extensor of the fingers and wrist, supinator and extensor and abductor muscles of thumb
 - vii. Reflexes:
 1. Most often they are normal
 2. They may be increased if CRPS I or II has supervened which is more common with lower trunk lesions (sympathetic hyperactivity induces contraction of the intrafusal muscle fibers of the nuclear bag of the muscle spindle complex)

Neuropathology

1. Neurogenic thoracic outlet syndrome comprises approximately 90% of all patients suffering the syndrome
 - a. Most patients have suffered trauma with flexion-extension injuries of the neck ("whiplash")
 - b. Repetitive movements commonly initiate the process
 - i. Falls on the outstretched arms are common
 - c. Most often, the process is neuropractic and recovers spontaneously. However, a small percentage of patients become chronic
 - d. Secondary concomitant CRPS I and II may be caused by lower trunk trauma most often
2. Specific anatomic causes of neurogenic TOS:
 - a. Cervical ribs: The incidence of cervical ribs in the population is estimated to be 0.3%
 - b. Women are affected two times more frequently than men are
 - c. Approximately 10% of patients with cervical ribs are symptomatic. Usually, symptoms are initiated by trauma
 - d. The Gruber classification of cervical ribs:
 - i. Type I – Protrudes slightly beyond the transverse process and attaches to the first rib by a tight fibrous band
 - ii. Type II – 2.5 cm in length:
 1. Attaches to the first rib by a tight fibrous band
 2. Rib and band lie within or on the medial border of the middle scalene muscle
 3. This configuration narrows the scalene triangle
 - iii. Type III:
 1. A complete rib with a fibrous connection to the first rib
 - iv. Type IV:
 1. A complete rib with a cartilaginous joint at the first rib

2. The complete rib causes the neurovascular bundle to arch over the rib
3. The neurovascular bundle is compressed when the shoulder girdle is depressed

Ligaments and Fibrous Bands That Compress Cervical Spinal Nerves

1. Twelve different fibrous structures can compromise the thoracic outlet
2. The most significant ligaments are:
 - a. Transverse process of C7 to the first rib
 - b. Tip of the cervical rib that inserts on the first rib
 - c. Ligaments that are within the body or on the anterior surface of the middle scalene muscle may affect C8–T1 spinal nerves of the lower trunk
 - d. Common anomalies:
 - i. Incomplete cervical rib on a long transverse process of C7 from which a tight band inserts on the first rib

Roos' Congenital Bands and Ligaments

1. Type I:
 - a. Tip of an incomplete cervical rib ligament that inserts posteriorly to the scalene tubercle
2. Type II:
 - a. The origin of the ligament is from the transverse process of C7 and inserts on the scalene tubercle
3. Type III:
 - a. A ligament that originates and inserts on the first rib; the origin is posterior and the insertion is anterior
4. Type IV:
 - a. The ligament originates within the middle scalene (C2–C7)
 - b. Courses on the anterior edge of the middle scalene
 - c. Inserts with the muscle on the first rib
 - d. The ligament is adjacent to C8–T1 spinal nerves
5. Type V:
 - a. Scalenus minimus muscle is the Vth band
 - b. Origin is in the anterior scalene muscle (lower fibers)
 - c. Courses behind the subclavian artery in front of the plexus to insert on the first rib
6. Type VI:
 - a. Scalenus minimus insertion into Sibson's fascia over the cupola of the lung rather than the first rib
7. Type VII:
 - a. A fibrous cord that courses on the anterior surface of the anterior scalene muscle
 - b. Inserts on the costochondral junction of the sternum
 - c. The band lies behind the subclavian vein that it may compress
8. Type VIII:
 - a. Origin of the ligament is the middle scalene muscle
 - b. Courses under the subclavian artery and vein
 - c. Inserts on the costochondral junction
9. Type IX:
 - a. A web of muscle and fascia that fills the posterior curve of the first rib

The Rib-Band Syndrome of Gilead

General Characteristics

1. Primarily a lower trunk plexopathy
2. Women are more often affected than men

Clinical Manifestations

1. Paresthesia of the 4th and 5th fingers, medial forearm to the medial humerus
2. Atrophy of the thenar > than hypothenar muscles of the hand

Neuropathology

1. A sharp fibrous band from the tip of an elongated C7 transverse process of true cervical rib to the first rib
2. A neuropraxic injury of the proximal lower trunk

Neuroimaging

1. Plain x-ray:
 - a. Prominent transverse process at C7
 - b. Cervical rib
 - c. The band cannot be appreciated by MRI

Laboratory Evaluation

1. EMG:
 - a. The median CMAP and medial antebrachial cutaneous SNAP amplitudes are reduced to a greater extent than the ulnar SNAP and CMAP
 - i. Ulnar studies primarily assess C8 fibers

Brachial Plexus Injuries

Brachial Plexus Surgery for Neurogenic Plexopathy

General Characteristics

1. No gender difference
2. Young and middle-aged patients are affected

Clinical Manifestations

1. Weakness of the intrinsic muscles of the hand noted immediately
2. Pain may be the predominant symptom
3. Lower trunk involvement is often associated with Type II complex regional pain syndrome

Neuropathology

1. Most lesions occur during transaxillary first rib resection; less frequently with scalenectomy and neurolysis of the upper trunk in the supraclavicular fossa
2. Direct surgical injury as traction (neuropraxis) plexus injury
3. Phrenic nerve may be involved concomitantly (particularly if the procedure involves the middle scalene muscle)
4. Site of the lesion:
 - a. Proximal lower trunk
 - b. C8–T1 spinal nerves

*Orthopedic Surgical Procedures That Injure the Plexus***General Characteristics**

1. Most common procedures are those for:
 - a. Recurrent anterior shoulder dislocation
 - b. Shoulder joint replacement
 - c. Arthroscopy of the shoulder
 - d. Surgical procedures that compromise the costoclavicular space
 - e. Direct trauma from arteriography and cannulas
 - f. Percutaneous cannulation of the subclavian and internal jugular vein
 - g. Percutaneous brachial plexus block

Clinical Manifestations

1. Chronic recurrent anterior shoulder dislocation:
 - a. Putti-Platt; Bristow procedures
 - b. During surgery:
 - i. Direct trauma to the musculocutaneous nerve is the most frequent injury
 - ii. Median, ulnar, radial, and axillary nerves may be injured with clinically expected motor and sensory deficits
 - c. Concomitant damage to the axillary artery and vein
 - d. Delayed onset of plexopathy following the modified Bristow procedure:
 - i. The bone screw that attaches the coronoid process to the glenoid rim works loose
 - ii. Axillary artery may be pierced with pseudoaneurysm formation that compresses the infraclavicular plexus

Shoulder Joint Replacement

1. Direct trauma to the axillary nerve and the supraclavicular plexus

Arthroscopy of the Shoulder

1. Direct trauma to the infraclavicular nerves:
 - a. Musculocutaneous
 - b. Axillary
 - c. Ulnar
 - d. Radial
2. Neuropraxis injuries of these nerves

Surgical Procedures That Compromise the Costoclavicular Space

1. Operations to correct Sprengel deformity
2. Midportion of the clavicle surgery (fracture repair or to obtain access to subclavian vessels); regeneration of the lateral clavicle with excess callus formation that compresses the upper trunk

Direct Trauma from Arteriography and Cannulas

1. Trauma to the infraclavicular brachial plexus:
 - a. Cords of the plexus are adjacent to the second segment of the axillary artery; the median nerve is on the surface of the artery

- b. Leakage of blood from the puncture site that causes direct compression of the terminal nerves: median > ulnar > radial
- c. Most often, there is a combination of median and ulnar nerve trauma
- d. Pain, paresthesia, and arm weakness in characteristic patterns
 - i. Onset of symptoms may be delayed for up to two weeks
- e. Nerve lesions may occur from pressure (hematoma) in the medial brachial fascial compartment that:
 - i. Extends from the axilla to the elbow
 - ii. Formed by the medial intramuscular septum and the surface of the medial upper arm
 - iii. Encloses the neurovascular bundle and fascial axillary sheath
- f. Percutaneous cannulation of the subclavian and internal jugular vein:
 - i. Direct instrumentation induced trauma
 - ii. Hematoma compression
 - iii. Rarely axillary mononeuropathy
 - iv. Rarely upper trunk plexopathy
- g. Percutaneous brachial plexus block:
 - i. Injuries may be caused by:
 1. The block itself
 2. Tourniquet-induced ischemia
 3. Post-operative casting
 4. The surgical procedure
 - ii. Axillary block approach causes more injuries than interscalene blocks
 - iii. Usual symptoms are paresthesia in the median and ulnar nerve distributions; usually slight weakness of the involved nerves
 - iv. May have delayed onset (up to two days) following the procedure:
 1. Bupivacaine at 0.25% may demyelinate nerves

*Median Sternotomy***General Characteristics**

1. Median sternotomies:
 - a. Primarily open heart surgeries
 - b. Thoracotomy
2. Affects up to 5% of patients that undergo the procedure

Clinical Manifestations

1. Primarily affects the lower trunk
2. Sensory loss of the medial forearm and hand
3. Weakness of intrinsic hand muscles

Neuropathology

1. Neuropraxis injury of the lower trunk; usually recovers in months

Neuroimaging

1. Ultrasound evaluation of the plexus

2. MRI not effective in visualizing lesions that are neuropractic
3. EMG:
 - a. Usually, demonstrates a lower trunk lesion

Post-Anesthesia Brachial Plexopathy

General Characteristics

1. Follows surgical procedures usually under general anesthesia
2. Abdominal operation (usually cholecystectomy or hysterectomy; now changing due to minimally invasive surgery)

Clinical Manifestations

1. Upper plexus more often involved than lower plexus; usually unilateral
2. Weakness and paresthesia are the predominant signs and symptoms
3. Rarely patients complain of pain
4. Rarely a Horner's syndrome
5. Recovery usually begins 2–3 weeks after onset and may require several months to be complete:
 - a. Sensory loss recovers first followed by lower plexus, then upper plexus and lastly motor function

Neuropathology

1. A neuropractic injury
2. Positions associated with post-operative paralysis:
 - a. Supine
 - b. Trendelenburg (steep and prolonged)
 - c. Abduction of one or both arms to 90 degrees or greater
 - d. Extension and external rotation
 - e. Rotation and lateral flexion of the head to the contralateral side
 - f. Lower shoulder and arm compressed
 - g. Flexed and prone position (back procedures)
 - h. Excessive abduction and arm flexion

Neuroimaging

1. MRI/MRA:
 - a. To evaluate soft tissue and vascular components in the surgical field
 - b. Ultrasonography to evaluate terminal nerves

Post-Operative Brachial Plexopathy

General Characteristics

1. Surgery for neurogenic brachial plexopathy particularly performed without a clear anatomic target such as a cervical rib is fraught with complications

Clinical Manifestations

1. First rib transaxillary resection:
 - a. Weakness and wasting in a lower trunk distribution
 - b. Paresthesias and burning pain in the 4th and 5th fingers and medial forearm
 - c. Less commonly:

- i. Flail arm with numbness and pain of the entire upper extremity
- ii. This pattern may evolve into a medial cord distribution of weakness

2. Anterior scalenectomy and neurolysis:

- a. Pain across the trapezius ridge and down the medial scapular border
- b. Minimal weakness of the rhomboids, supra- and infraspinatus and biceps muscles
- c. Occasional paresthesia of the lateral deltoid and the lateral forearm
- d. Occasional weakness of the ipsilateral phrenic nerve

Neuropathology

1. Neuropractic, axonotmesis, and neurotmesis

Neuroimaging

1. MRI:
 - a. To evaluate the surgical field for hematoma or bone defects (difficult to distinguish brachial plexus components with 1.5 Tesla magnet strength)
2. Ultrasonography to evaluate terminal nerves

Laboratory Evaluation

1. EMG:
 - a. After 14–21 days to evaluate the level and extent of the operative injury

Gunshot Wounds/Laceration Injuries

General Characteristics

1. Gunshot wounds:
 - a. 85% are in males; the average age is 28 years

Clinical Manifestations

1. 80% of injuries affect the cords or terminal nerves
2. Majority of patients have plexus lesions in continuity
3. Laceration injuries:
 - a. Knife injury or glass (fall through a glass window); propeller blades; chainsaw
 - b. Clinical manifestations:
 - i. Associated damage to blood vessels of the neck, axilla, and upper lung
 - ii. 33% of injuries the brachial plexus is in continuity
 - iii. Knife or glass injury tend to be focal

Neuropathology

1. Neuropractic (less often)
2. Usually neurotmesis injury

Neuroimaging

1. MRI/MRA
2. Ultrasonography

Laboratory Evaluation

1. EMG after 21 days demonstrates denervation in the injured components of the plexus

*Backpack Palsy***General Characteristics**

1. Noted in military personnel and civilians using improperly positioned heavy backpacks
2. Males affected more often than females
3. Related to backpack design and weight; multiple mechanical and time-dependent features
4. Possible congenital structural or prior trauma as predisposing factors

Clinical Manifestations

1. Preceded by transient episodes prior to the fully developed syndrome
2. Muscle weakness of the shoulder, arm or forearm > pain
3. Upper trunk > middle plexus innervated muscles are involved; the deltoid may be the most severely involved muscle
4. Sensory loss and reflex changes are less apparent

Neuropathology

1. Neuropractic and axonometric injury

Neuroimaging

1. MRI:
 - a. To rule out congenital defects and prior traumatic injury (excessive callus formation from a fractured clavicle)
2. Ultrasonography

Laboratory Evaluation

1. EMG:
 - a. To evaluate the location and severity of the injury

*Shoulder Injuries with Concomitant Brachial Plexus Involvement***General Characteristics**

1. Brachial plexus involvement is often overlooked in the context of shoulder pathology. Weakness is often ascribed to pain and joint pathology
2. The usual injuries are:
 - a. Humeral fracture or dislocation
 - b. Scapular fracture
 - c. Rotator cuff tear

Clinical Manifestations

1. Rotator cuff tear:
 - a. Approximately 30% of these injuries are associated with brachial plexopathy
 - b. All components of the plexus may be injured
 - c. Posterior cord and middle trunk > than upper trunk and lateral cord
2. Humeral fractures and dislocation:
 - a. Ischemic or a vascular compressive lesion
 - b. Posterior cord and middle and lower trunk may have the greatest deficit
 - c. Trunks and cords, as well as terminal nerves, may be involved with reductions of shoulder dislocations

3. Clavicular fractures with plexopathy:
 - a. Excess motion of the clavicle at the fracture site
 - b. Exuberant callus formation
 - c. Tight figure of eight brace
 - d. Delayed onset (months to years)
 - e. Anterior division and upper trunk involvement with weakness of the innervated muscles
 - f. Upper arm pain exaggerated by arm elevation

Neuropathology

1. Primarily neuropractic and axonometric injury

Neuroimaging

1. MRI (local pathology)
2. Ultrasonography (terminal nerves)

Laboratory Evaluation

1. EMG:
 - a. To evaluate location and extent of the injury

*Burner/Stinger Syndrome***General Characteristics**

1. Usual contact sports injury (shoulder trauma; face mask injury in football)

Clinical Manifestations

1. Severe pain and paresthesia in the arm without motor loss
2. Recovery within minutes

Neuropathology

1. Neuropractic
2. Neuroimaging and EMG
 - a. Not necessary unless symptoms persist

*Arterial Vascular Thoracic Outlet Syndrome***General Characteristics**

1. Extremely rare
2. May be seen in individuals that perform repetitive overhead/arm movements (butchers, using saws; pitchers in baseball)

Clinical Manifestations

1. Adson's maneuver less often positive than in patients with true neurogenic thoracic outlet syndrome
2. Ischemia of the hands and fingers rather than specific neurogenic plexopathy is most common; some patients complain of heaviness and weakness of the arm in abduction; primarily upper trunk distribution
3. May have severe ischemic pain

Neuropathology

1. Bony abnormalities of the clavicle and first rib cause post stenosis dilatation then aneurysm formation of the subclavian or axillary artery
2. Distal emboli from thrombi in the artery to the fingers

Neuroimaging

1. MRI:

- a. Evaluation of the local anatomy with particular reference to bony and congenital anomalies
2. MRA:
 - a. Evaluation of the arterial supply to the arm to rule out aneurysm of the subclavian or axillary arteries

Laboratory Evaluation

1. EMG:
 - a. Evaluation of the location and extent of any brachial plexus involvement

Effort Venous Thrombosis of the Upper Extremity (Paget-von Schroetter Disease)

General Characteristics

1. Thrombosis of the subclavian and axillary vein

Clinical Manifestations

1. Abrupt presentation
2. Upper extremity swelling cyanosis and livedo reticularis
3. Dilated venous collaterals over the chest and shoulder
4. Brachial plexus is not involved

Neuropathology

1. Prolonged compression of the axillary vein on a hard surface (arm outside of the window and resting on the door of a car)
2. May follow extreme exercise of the arm

Neuroimaging

1. MRA and MRV to evaluate the circulation to the arm

Immune-Mediated Brachial Plexopathy

General Characteristics

1. Terminology:
 - a. Acute brachial plexitis
 - b. Neuralgic amyotrophy
 - c. Parsonage-Turner syndrome
2. Evidence suggesting an immune basis includes:
 - a. May develop after an infection or vaccination
 - b. Following bone marrow transplantation
 - c. During treatment with immunomodulating agents
 - i. Interferons
 - ii. Interleukin 2
 - iii. Tumor necrosis factor alpha blockers
 - d. Antibodies against peripheral nerve myelin and soluble terminal complement complexes
 - e. Response to steroids
 - f. In association with some autoimmune diseases

Clinical Manifestations

1. Immune brachial plexus neuropathy usually presents with acute shoulder pain or forearm pain that is exacerbated by movement:
 - a. The intense pain may last for days to weeks but usually evolves to a dull ache that may be persistent for several years

2. Weakness is evident as pain dissipates and depends on the components of the plexus that is involved (trunks, divisions, cords or terminal nerves)
3. Patterns of weakness:
 - a. The most common pattern of weakness involves muscles innervated by the upper trunk or multiple mono-neuropathies that include:
 - i. Suprascapular nerves
 - ii. Long thoracic nerves
 - iii. Axillary nerves
 - b. There may be concomitant involvement of the phrenic and interosseous nerves. These nerves may be involved in isolation
 - c. Rarely cranial nerves IX, X, XI and XII can be involved
 - d. Isolated spinal accessory involvement has been described

Neuropathology

1. Biopsy of IBPN reveals:
 - a. Perivascular perineural and endoneurial inflammatory infiltrates
2. Antigens have not been identified, but electrodiagnostic studies suggest they are axonal rather than epitopes of myelin

Neuroimaging

1. MRI:
 - a. May demonstrate increased T2-weighted signal intensity of the plexus that suggests inflammation with edema

Laboratory Evaluation

1. CSF:
 - a. Approximately 10% of patients have increased spinal fluid protein with or without pleocytosis
2. EMG:
 - a. Electrodiagnostic studies depend on the component of the plexus that is involved
 - b. Nerve damage may be multifocal and is usually axonal
 - c. The upper trunk is primarily involved:
 - i. Median and ulnar motor studies are positive in approximately 15% of patients; median and brachial SNAPs may be abnormal
 - d. 50% of patients demonstrate:
 - i. Decreased CMAP from the deltoid, biceps, and serratus anterior muscles
 - ii. Decreased SNAPs of the lateral, antebrachial, cutaneous and median sensory nerves
3. CSF:
 - a. Slightly increased CSF protein with mid pleocytosis

Differential Diagnosis

1. Asymmetric form of chronic inflammatory demyelinating neuropathy
2. Multifocal acquired motor and sensory demyelinating neuropathy
3. Multifocal motor neuropathy

Hereditary Neurologic Amyotrophy

General Characteristics

1. AD; gene maps to chromosome 17q 25.3 (SEPT9)
 - a. Encodes the septin-9 protein
2. Severe form of hereditary neuralgic amyotrophy without SEPT9
3. A novel locus on chromosome 21q21

Clinical Manifestations

1. A history of one or more sudden onset painful attacks that involve the neck, shoulder or arm
2. Weakness in various affected components of the plexus
3. Associated features:
 - a. Hypertelorism
 - b. Occasional cleft palate:
 - i. Skin folds or creases on the neck or forearm
 - ii. Short stature
 - iii. Syndactyly

Neuropathology

1. Septins are involved in cytokinesis and cellular trafficking
2. Septin-9 protein localizes with other septins and with septin-intermediate filaments that interact with actin microfilaments and microtubules

Neuroimaging

1. MRI to rule out other causes of brachial plexopathy
2. Sonography

Laboratory Evaluation

1. EMG:
 - a. Similar to idiopathic brachial plexus neuropathy

Hereditary Neuropathy with Liability to Pressure Palsies

General Characteristics

1. PMP22 gene deletion; AD but gene de novo mutations occur; the gene is on chromosome 17p11.2
2. The deletion of the 1.5 MB region is the same that is duplicated in CMT
3. Prevalence of 7.3/100,000 to 16/100,000 people

Clinical Manifestations

1. Age of onset is the second and third decade (but has been described to the 8th decade)
2. 60–70% of patients present with a single, focal acute neuropathy
3. Rare cranial nerve involvement that includes V, VII, XII and components of X
4. Brachial plexus involvement (12–27%)
 - a. Possibly causative of backpack neuropathy
5. Painless recurrent plexopathy
6. Scapuloperoneal presentation (Davidenkov phenotype)
7. Muscle weakness and atrophy
8. Numbness in affected plexus distributions
9. Reduced or absent deep tendon reflexes (primarily ankle jerks)
10. Episodes may be preceded by minor compression of the affected nerve or the plexus

Neuropathology

1. Nerve biopsy demonstrates segmental demyelination with varying large-fiber loss
2. Tomacula:
 - a. Redundant or over folding layers of the myelin sheath of variable thickness are present
3. The 1.5 Mb deletion on chromosome 17p11.2 is found in approximately 85–90% of patients that are clinically affected
4. Mouse model demonstrates focal axonal constriction within tomacula

Neuroimaging

1. MRI:
 - a. CNS white matter lesions occur in isolated patients
 - b. Sonography reveals hypertrophy at entrapment sites
2. EMG:
 - a. Increase in distal motor latencies especially of the median and peroneal nerves
3. EMA:
 - a. Focal motor slowing at entrapment sites
 - b. NCV may be normal in some segments
 - c. Sensory nerve conduction velocities may be decreased with decreased SNAP amplitudes

Laboratory Evaluation

1. DNA testing for the deletion of the PMP22 gene
2. Focal motor slowing at entrapment sites
3. NCV may be normal in some segments
4. Sensory nerve conduction velocities may be decreased with decreased SNAP amplitudes

Neoplasms Affecting the Brachial Plexus

General Characteristics

1. Benign tumors:
 - a. Neuronal sheath tumors:
 - i. 60–80% of brachial plexus tumors are neuronal sheath tumors
2. Include:
 - a. Schwannoma
 - b. Neuroma
 - c. Neurofibroma

Clinical Manifestations

1. Present as mass lesions in the supraclavicular fossa or axilla
2. Pain and paresthesia are early symptoms (distortion of nerve fibers without conduction block, demyelination, or destruction of axons)
3. Later motor and sensory loss

Schwannoma

General Characteristics

1. Approximately 5% of benign and soft tissue neoplasms
2. Approximately 20% of tumors of the brachial plexus

Clinical Manifestations

1. Solitary
2. An adult tumor
3. Affects the upper plexus
4. Most often presents as a supraclavicular or axillary mass
5. May affect any organ and region including:
 - a. Nasal septum
 - b. Cervical sympathetic chain
 - c. Gingiva
 - d. All cranial nerves; may be plexiform
 - e. Base of the tongue
 - f. Cecum and gastric mucosa
 - g. Sublingual area
6. Affects the upper plexus most often
7. Sensory signs:
 - a. Tender to palpation; radiating paresthesia is common
8. Later mild motor and sensory deficit referable to the involved dermatome and myotome of the nerve

Neuropathology

1. Benign and well encapsulated
2. Usually, affect the proximal components of the plexus
3. Degenerative changes and variable admixture of spindle (Antoni A) areas and hypocellular microcytic (Antoni B) areas with macrophages and collagen fibers; located near vessels and have a well formed collagenous capsule
4. Express S100 protein and pericellular collagen type IV
5. Plexiform Schwannoma:
 - a. A subtype that occurs in superficial cutaneous or subcutaneous locations
 - b. Intraneuronal pattern of growth
 - c. Associated weakly with NF2 and Schwannomatosis (approximately 5% of patients); usually Antoine A pattern and is less encapsulated than classic Schwannomas

Neuroimaging

1. MRI:
 - a. Homogeneously isointense on T1-weighted sequences and hyperintense on T2 images
 - b. Cystic degeneration may be noted in the usual Schwannoma

Neurofibroma**General Characteristics**

1. Growth pattern is well-demarcated intraneural or diffuse infiltration of soft tissue at extraneural sites
2. Variants:
 - a. Based on architectural growth and include localized, diffuse and plexiform subtypes
 - i. Localized cutaneous neurofibroma is the most common
 1. May involve a major nerve to cause a fusiform expansion of the nerve trunk (intraneural subtype)
 2. Diffuse neurofibromas cause a plaque-like enlargement (usually in the head and neck region)

- ii. 10% of neurofibromas are seen with neurofibromatosis type I

Clinical Manifestations

1. Interdigitate more with nerve fibers within the nerve fascicle
2. In association with neurofibromatosis, they are often multiple and may affect a large portion of the brachial plexus
3. Demonstrate motor and sensory deficits depending on which component of the plexus is affected
4. Neurofibromas associated with NFI:
 - a. Occur both supra- and infraclavicularly
 - b. Are frequently multiple and plexiform
 - c. Present at an earlier age than Schwannomas
 - d. May extend intraspinally (dumbbell tumor) in the intradural extramedullary compartment
 - e. Equal male and female incidence

Neuropathology

1. Neoplastic proliferation with Schwann cell differentiation:
 - a. Wavy nuclear contours
 - b. S100 protein expression
2. Incorporate non-neoplastic peripheral nerve components that include axons, perineural cells, fibroblasts, mast cells, and lymphocytes

Neuroimaging

1. Plain films may demonstrate enlargement of an intraforaminal exit canal
2. MRI:
 - a. Bag of worms appearance from diffuse involvement along a nerve segment
 - b. Few flow voids within the lesion are seen in T2-weighted images
 - c. Plexiform neurofibromas may present on imaging with an intermediate signal compared to muscle on T1-weighted images and with a hyperintense signal on T2-weighted sequences

Perineuroma**General Characteristics**

1. Advanced perineural differentiation
2. Two types of tumor have been described:
 - a. Intraneural
 - b. Soft tissue

Clinical Manifestations

1. Localized solitary expansion of peripheral nerve due to involvement of one or more nerve fascicles
2. Remain stable over time or progress slowly

Neuropathology

1. Perineurial cell proliferation that extends into the endoneurium that surrounds individual nerve fibers and capillaries that produce "pseudo-onion bulbs"
2. Soft tissue perineuromas lack an associated nerve
3. The most commonly utilized immunohistochemical marker is epithelial membrane antigen (EMA)

Neuroimaging and Electrodiagnostic Features Have Not Been Delineated

Differential Diagnosis

1. Localized reactive Schwann cell proliferation (intraneural form)
2. Low-grade fibromyxoid sarcoma (soft tissue form)

Hybrid Benign Nerve Sheath Tumors

General Characteristics

1. Some arise in the setting of inherited syndromes the most common of which is NFI

Clinical Manifestations

1. A solitary painless nodule
2. Equal male to female incidence
3. Approximately 70% arise in the second to fifth decade
4. Wide distribution over the extremities and trunk

Neuropathology

1. Usually well circumscribed; features of Schwannoma and soft tissue perineuroma
2. Encapsulated and composed of spindle cells
3. EMA and S100 are histological markers
4. Neuroimaging and electrodiagnostic features have not been well delineated

Differential Diagnosis of Benign Non-Neural Sheath Plexus Tumors

1. Lipoma
2. Ganglioneuroma
3. Myoblastoma
4. Lymphangioma
5. Dermoid

Malignant Nerve Sheath Tumors That May Involve the Brachial Plexus

General Characteristics

1. Approximately 15% of neural sheath tumors are malignant
2. They are primarily neurogenic sarcoma and fibrosarcoma
3. Malignant transformation of benign neural sheath tumors:
 - a. Most common in von Recklinghausen's disease
 - b. Late transformation (20–40 years) to sarcoma in patients who have been irradiated for breast cancer or Hodgkin's disease

Metastatic Brachial Plexus Tumors

General Characteristics

1. Two-thirds originate from the lung or breast
2. Other metastatic lesions occur from:
 - a. Larynx
 - b. Pancreas
 - c. Colon
 - d. Bladder
 - e. Testes
 - f. Thyroid

- g. Esophagus
- h. Lymphoma
- i. Melanoma
- j. Ewing's sarcoma

3. Metastatic tumors have often metastasized extensively prior to plexus involvement

Clinical Manifestations

1. Known malignant disease (rare for plexus involvement as a presentation)
2. A long latency from treatment of the primary tumor is not uncommon
3. Pain in the arm and shoulder is often the first manifestation; weakness and sensory loss occur later
4. Associated extradural spread with cervical cord compression
5. Many breast cancer patients have received X-RT that involved the plexus prior to a metastatic disease presentation
6. Pancoast syndrome
 - a. Direct spread from the apex of the lung (superior sulcus or thoracic inlet tumor)
 - b. Usually, the syndrome is caused by a squamous cell carcinoma (rarely in the scar of a prior tuberculous infection) or an apical adenocarcinoma
 - c. Pain in the shoulder, scapula or 4th and 5th finger that is often burning in quality
 - d. Weakness wasting and sensory loss in the lower trunk distribution
 - e. Horner's syndrome
7. Primary lymphoma:
 - a. Arising from the cervical or axillary lymph nodes may infiltrate the plexus

Neuropathology

1. Metastatic lesions may grow along the components of the plexus
2. Symptomatology may derive from expression of inflammatory cytokines as well as direct invasion of the tumor

Neuroimaging

1. Demonstrates thickening of plexus components; often contrast enhancement is noted
2. 18-FDG-SPECT
 - a. May demonstrate primary and other metastatic sites; useful in following the course of treatment
3. Sonography

Laboratory Evaluation

1. Electrodiagnosis:
 - a. Dependent upon the components of the plexus that is affected

Radiation-Induced Brachial Plexopathy

General Characteristics

1. Women irradiated for breast cancer is the most frequent cause followed by lung cancer and lymphoma

2. Dosimetric considerations that induce lesions:
 - a. Field size
 - b. Amount of tissue irradiated:
 - c. Time period of the irradiation
 - d. Number of fractions delivered
 - e. Dose of each fraction
 - f. Total dosage
3. Latent period of 0 to 34 years may occur after x-ray treatment

Clinical Manifestations

1. Paresthesias in the C5–C6 spinal nerve, lateral cord, and median nerve distributions
2. Pain may develop late and is usually of moderate severity
3. Weakness of intrinsic hand muscles
4. All parts of the plexus may be involved, but the supraclavicular components of the plexus usually have greater involvement than the infraclavicular
5. Edema of the extremity may develop
6. Most patients have a progressive course although some patients plateau
7. Rare clinical manifestations:
 - a. Severe edema (possible compartment syndrome)
 - b. An acute onset ischemic process:
 - i. Injury to the subclavian artery
 - ii. Associated with painless weakness and sensory loss
 - iii. Segmental occlusion of the subclavian artery
 - c. Reversible Plexopathy:
 - i. Develops 2–14 months after X-RT
 - ii. Hand and forearm paresthesia; shoulder pain; mild hand weakness
 - iii. Chemotherapy after X-RT may be causative or associated

Neuropathology

1. Extensive demyelination
2. Proliferative endarteritis of the vasa vasorum
3. Progressive fibrosis in the irradiated field

Neuroimaging

1. MRI with three Tesla magnet field strength which develops 3D isotropic sequences
2. Gadolinium enhancement is positive for tumor

Laboratory Evaluation

1. EMG:
 - a. Myokymic discharges

Differential Points Between X-RT Damage and Recurrent Tumor

1. Tumor:
 - a. Primarily the C8–T1 roots or the lower trunk is affected; rapidly progressive
 - b. Severe burning pain and intrinsic hand muscle wasting
 - c. Horner's syndrome

- d. MRI:
 - i. May demonstrate thickening or mass in these plexus components
 - ii. Enhances with gadolinium
2. X-RT
 - a. Occurs primarily in the C5–C6 root or spinal nerve distribution
 - b. Greater paresthesias than pain and weakness
 - c. MRI:
 - i. Fibrosis of the plexus and surrounding tissue
 - ii. No enhancement with gadolinium
 - d. EMG:
 - i. Myokymic discharges

Lumbosacral Plexus Lesions

Overview of Lumbosacral Plexopathy

Upper lumbar plexus lesions demonstrate various combinations of deficits in the iliohypogastric, ilioinguinal, genitofemoral, femoral and obturator nerve distributions. Weakness is seen in hip flexion, knee extension (concomitant inability to lock the leg on standing) and adduction of the thigh. Sensory loss is noted in the lower abdominal wall, inguinal, labial, and scrotal areas as well as the thigh and medial lower leg. An absent or a depressed knee reflex is noted.

Lower lumbar sacral plexus lesions cause deficits within the innervation territories of the gluteal, sciatic, tibial, and peroneal nerves. Weakness occurs in hip extension, and abduction, knee flexion, and all intrinsic foot musculature. Sensory loss occurs in the posterior thigh, anterior and posterior aspects of the lower leg below the knee and most of the foot. There are diminished or absent ankle reflexes. Gluteal and sciatic nerve weakness localizes a lesion to the sacral plexus.

Plexopathies are recognized when motor, sensory, and reflex deficits occur in multiple nerve and segmental distributions that affect one extremity. Localization is often difficult due to the pathologies of the region, but usually in a broad sense can be divided into:

1. Lumbar plexopathy
2. Sacral plexopathy
3. Lumbosacral trunk lesions
4. Pan-plexopathy

In general, lumbar plexopathies evolve in a stepwise and dissociated manner.

In localization of lumbosacral plexopathies pathology of the cauda equina and conus medullaris has to be considered. Rarely, motor neuron disease may simulate plexopathy if deficits are without pain or sensory loss. Intraspinal lesions (lower spinal cord) tend to be bilateral with early bowel and bladder dysfunction rather than motor weakness. Cauda equina lesions are painful, and bladder dysfunction is seen early.

Differential points in the history or examination include:

1. Pain in the following territories define specific sensory roots and nerves:

- a. Hip (sclerotoma radiation of L5)
 - b. Buttock (L5–S1 root); often have tenderness in the sciatic notch
 - c. Proximal thigh laterally (L5); also may be caused by bursitis of the tensor fascia lata
 - d. L1, L2, L3 roots innervate the dorsal thigh; this is also the sclerotomal distribution of the recurrent nerve of Spurling of L5. The usual problem is disc herniation radiating to the dorsal thigh rather than its somatic dermatomal distribution
 - e. The medial thigh is innervated by the ilioinguinal nerve (L1, L2 roots)
 - f. The groin is innervated by T12 and L1. It may also have a projected sclerotomal radiation from S1. Thus S1 root irritation may radiate to the groin. This invariably is diagnosed as hip disease or an inguinal hernia
 - g. The straight leg raising test causes sciatic nerve pain (L5–S1 roots); the reverse SLR test stretches the femoral nerve (L2–L3 sensory roots are involved; often concomitant inguinal pain)
 - h. In plexopathy, the valsalva maneuver does not elicit pain as it frequently does with radiculopathy
 - i. In peroneal nerve neuropathy with foot drop:
 - i. Inversion of the foot is normal
 - ii. Toe flexion and hip abduction are normal
 - iii. The ankle reflex is preserved
 - j. Differential signs to distinguish lumbosacral trunk lesions from an L5 radiculopathy:
 - i. The lumbar trunk is formed primarily by the L5 spinal nerve with a contribution from L4; peroneal sensation is normal which favors a trunk lesion
 - ii. If the pattern of weakness is hip adductors, iliopsoas, and quadriceps a lumbar plexopathy rather than femoral or obturator nerve lesions is more likely
 - k. Simultaneous involvement of the lumbar and sacral roots is usual with external trauma; iatrogenic injury more often involves individual L5 plexus components
4. Sensory nerves of the lumbar plexus:
 - a. Iliohypogastric (L1 spinal root)
 - b. Ilioinguinal nerve (L1 root) innervates:
 - i. Upper medial thigh
 - ii. Base of the penis and labia majora
 - c. Genitofemoral nerve (L1–L2 root)
 - i. Innervates the upper anterior thigh
 - ii. Scrotum and labia majora
 - d. Lateral cutaneous nerve of the thigh (L2–L3)
 5. Lesions of the entire lumbosacral plexus:
 - a. Rare; most are incomplete
 - b. Paralysis or paresis of the entire lower extremity with hypo or areflexia
 - c. Sensory abnormalities that involve the entire lower extremity
 6. Lesions of lumbar segments:
 - a. Usually, are incomplete
 - b. Paresis and atrophy in the distribution of the femoral and obturator nerves:
 - i. Iliopsoas:
 1. Weakness of thigh flexion
 - ii. Quadriceps:
 1. Weakness of leg extension
 - iii. Sartorius:
 1. Weakness of thigh eversion
 - iv. Adductor muscles:
 1. Weakness of thigh adduction
 - c. Sensory signs:
 - i. Sensory loss in the inguinal area and over the genitalia
 1. Iliohypogastric, ilioinguinal, and genitofemoral nerves are involved
 - ii. Lateral thigh:
 1. Lateral femoral cutaneous nerve
 - iii. Medial thigh:
 1. Obturator nerve
 - iv. Anterior thigh:
 1. Femoral nerve
 - v. Medial part of the lower leg:
 1. Saphenous nerve that is derived from the femoral nerve

Anatomical Relationship of the Lumbar and Sacral Plexus

1. The L1, L2, L3 ventral rami are the primary components of the lumbar plexus with contributions from T11 and T12
 - a. They traverse the posterior portion of the psoas muscle anterior to the vertebral transverse processes:
 - i. Femoral nerve (L2–L4 primary spinal nerves) also supplies sensation to the thigh and leg by:
 1. Medial and intermediate nerve of the thigh
 2. Saphenous nerve which provides sensation to the medial calf
2. Obturator nerve (L2–L4 spinal nerves)
 - a. Innervates the adductor muscles of the thigh
 - b. Provide cutaneous innervations to the medial thigh
3. Muscular branches that derive directly from the plexus:
 - a. Iliopsoas (L2–L3 spinal nerves)
 - b. Iliacus (L2–L3 spinal nerves)

Reflexes

1. Depressed or absent patellar reflex:
 - a. Femoral nerve
2. Loss of cremasteric reflex:
 - a. Genitofemoral nerve

Sacral Plexus

General Characteristics

1. S1–S3 ventral rami are the major roots:
 - a. Contribution from L4–L5 and S4–S5 roots
2. The plexus overlies the lateral sacrum and the posterior lateral pelvic wall
3. Sciatic nerve (spinal nerves L4, L5, S1–S3):

- a. Innervates the hamstrings; all muscles below the knee
- b. All sensation below the knee except that supplied by the saphenous nerve (medial lower leg):
- c. At the sciatic notch it divides into the common peroneal and tibial nerves
- 4. Superior gluteal nerve (L4, L5, S1 spinal nerves):
 - a. Innervates the gluteus medius and minimus muscles
- 5. Inferior gluteal nerve (L5, S1, S2 spinal nerves):
 - a. Innervates the gluteus maximus muscles
- 6. Posterior femoral cutaneous nerve (S1, S2, S3):
 - a. Innervates the buttocks, perineum, posterior thigh
 - i. The cuneal branch innervates the posterior upper thigh and inferior buttock

Lesions of the Sacral Plexus

Complete Lesion

1. Motor signs:
 - a. Paralysis or paresis of muscles innervated by the superior gluteal, inferior gluteal and the sciatic nerves
 - i. “Flail foot” from paralysis of both the dorsal and plantar foot musculature
 - b. Weakness:
 - i. Knee flexion:
 - 1. Hamstrings
 - ii. Foot eversion:
 - 1. Peroneal
 - c. Foot inversion (L4–S1 spinal roots):
 - i. Tibialis anterior and posterior tibial nerve
 - d. Plantar flexion of the toes:
 - i. Medial plantar nerves (II–V digits)
 - ii. Tibial nerve innervates the flexor hallucis longus
 - e. Extension of the toes:
 - i. Peroneal nerve innervates the extensor hallucis longus; L5–S1 roots
 - ii. Deep fibular nerve (Extensor hallucis longus muscle – EHL)
 - f. Abduction and internal rotation of the thigh:
 - i. Superior gluteal nerve
 - g. Hip extension:
 - i. Inferior gluteal nerve

Sensory Signs

1. Loss of sensation in the sciatic nerve distribution
 - a. Outer leg
 - b. Dorsum, sole and inner aspect of the foot
2. Posterior thigh and popliteal fossa
 - a. Posterior femoral cutaneous nerve

Reflexes

1. Decreased Achilles reflex
 - a. Sciatic nerve
2. Depressed bulbocavernosus reflex

Sphincter Signs

1. Loss or dysfunction of bladder and bowel control
 - a. Pudendal nerve

Differential Diagnosis Features Between Root and Lumbosacral Plexus Lesions

1. Positive mechanical signs favor a root lesion:
 - a. Straight leg raising test (sciatic nerve and S1 root)
 - b. Reverse SLR (places traction on the femoral nerve); the leg is extended with the patient lying on his stomach
 - c. Valsalva maneuver that causes pain:
 - i. Root greater than plexus involvement
2. Warm dry and red foot:
 - a. Indicative of a plexus lesion
 - b. Involvement of the retroperitoneal lumbar sympathetic nerves
3. Proximal > distal leg muscle weakness suggests a plexus lesion
4. Gluteus muscle innervations arise directly from the plexus
5. Iliopsoas muscle is not involved in a femoral nerve lesion because its innervation is directly from the plexus

Trauma of the Lumbosacral Plexus

General Characteristics

1. The lumbosacral plexus is often injured with trauma to the pelvic ring:
 - a. Double fracture dislocation
 - b. Traction injury from dislocation of the hip joint
2. Femoral nerve compression due to position:
 - a. Occupies the gutter between the psoas and iliopsoas muscle above the inguinal ligament
 - i. Surgical retraction (medially)
 - ii. Injured laterally by a hematoma between the iliacus fascia and the nerve
3. The lumbosacral cords are vulnerable to compression at the:
 - a. Pelvis brim by the fetal head
 - b. Obstetric forceps
4. Aneurysm of the common iliac or hypogastric arteries in the presacral areas
5. The femoral nerve is compressed by:
 - a. Angulation under the inguinal ligament
 - b. Prolonged flexion abduction of the thigh (dorsal lithotomy position under anesthesia)
6. Fixation points of the common peroneal nerve are at the sciatic notch and fibular neck:
 - a. Vulnerable to traction injury

Clinical Manifestations

1. Fracture:
 - a. Double vertical fracture dislocations of the pelvic bony ring:
 - i. 50% of patients suffer neurologic deficits
 - b. The injury is usually ipsilateral to the iliac joint damage
 - c. The lumbosacral plexus cord level is affected by consequent compromise of L5–S1 spinal nerve innervated muscles
2. Rupture, compression and traction injuries affect:
 - a. Lumbosacral trunk:

- i. Primarily L4 and L5 spinal nerves (L5 primarily)
 - ii. The spinal nerves are contiguous with the sacrum adjacent to the sacroiliac joint
- b. Obturator and/or superior gluteal nerves are often concomitantly injured
- c. L5–S3 anterior rami may be affected
- d. Concomitant vertebral body rupture
3. Intra-arterial injections
 - a. Injections into the buttock:
 - i. Ischemic injury due to vasoactive drugs that are injected into the inferior gluteal artery causing ischemia of the sciatic nerve
 - ii. Weakness, pain, and sensory loss in the sciatic nerve distribution occur minutes to a few hours after the injection
 - iii. Widespread lumbar plexus injury may occur due to retrograde extension of gluteal artery spasm to branches of the internal iliac artery
 - iv. Buttock skin may be painfully swollen, cyanotic and develop gangrene
 - v. Painless lumbosacral plexopathy may follow cisplatin injection into the iliac artery
4. Obstetric and gynecologic procedures that damage the lumbosacral plexus:
 - a. Risk factors:
 - i. Short women with large babies
 - ii. Prima gravida
 - b. Post-partum weakness
 - i. Lumbosacral trunk injury (primarily L5 spinal nerve) compression at the pelvic brim over the sacroiliac joint:
 1. Cephalic pelvic disproportion
 2. Protracted labor
 3. Mid pelvic forceps delivery
 - c. Involvement of the quadriceps muscles:
 - i. Bilateral in 25% of patients
 - ii. Concomitant with an obturator neuropathy
 - d. Causes of peripheral femoral neuropathy:
 - i. Lithotomy position under anesthesia during vaginal delivery (compression under the inguinal ligament)
 - ii. Separation of the symphysis pubis with direct compression of the nerve by the fetal head
 - iii. Epidural anesthesia:
 - iv. Paracervical block that affects the posterior femoral nerve (pain may be delayed by several days)
 - v. Lumbosacral plexus compressed at the pelvic brim by a uterine leiomyoma (accelerated growth during pregnancy)
 - vi. Intrapelvic Schwannoma
 - e. Catamenial sciatic nerve pain:
 - i. Implantation of endometrial tissue either intra-abdominally or at the sciatic notch
 - ii. Endometrial deposits in the sciatic notch may be associated with an outpouching of a pocket of peritoneum
 - iii. Perimenstrual pain in the buttock or posterior thigh

Clinical Manifestations

1. Weakness, sensory loss, and reflex changes are dependent on the lumbosacral component or the terminal nerve that is affected
 - a. Motor, sensory and reflex deficits are evident in multiple nerves or segmental distributions in the affected extremity

Neuropathology

1. Neuropractic and axonometric injury occur with compression and traction injuries
2. Neuromeric injury is primary with high impact trauma and some surgical procedures

Neuroimaging

1. Ultrasonography of the plexus
2. MRI:
 - a. To evaluate the plexus and soft tissue
3. CT
 - a. To evaluate bone at the site of injury

Surgical Trauma of the Lumbosacral Plexus

1. Laterally placed retractor blades compress the femoral nerve between the iliac and psoas muscle during:
 - a. Vaginal hysterectomy
 - b. Modified lithotomy position (under anesthesia)
 - c. Pelvic procedures (ovarian tumors and cysts)
2. Hip joint replacement
 - a. Approximately 0.7–1% of hip replacement surgeries are complicated by femoral, obturator or sciatic palsies
 - b. Subclinical nerve damage occurs from:
 - i. Preoperative stretch injury due to hip dislocation
 - ii. Retroperitoneal hemorrhage
3. Other surgical complications
 - a. Heat
 - b. Toxicity from methyl methacrylate bone cement
 - c. Direct trauma and that from retractor blades
 - d. Post-operative aneurysm formation
4. Aneurysm of the iliac or hypogastric artery:
 - a. Rectal examination reveals a firm pulsatile mass
 - b. Surgical repair has been associated with ischemic plexus lesions
 - c. Hemorrhage from an aortic, iliac or a hypogastric aneurysm may compress the femoral nerve
 - d. Retroperitoneal hematoma occurs from abdominal aortic aneurysm leakage

Tumors of the Lumbosacral Plexus

General Characteristics

1. Occur in less than 1% of patients with neoplasms
2. Direct extension from the tumor occurs in approximately 75% of patients while metastasis from extra-abdominal sites in approximately 25%
3. In approximately 15% of patients, lumbosacral plexopathy is the initial presentation

4. The lumbar plexus is affected in approximately 1/3 of patients; the sacral plexus in 50% and the remainder both plexus bilateral involvement is seen in 25% of patients

Clinical Manifestations

1. Severe unilateral pain radiating into L1–L4 sensory root distributions or the costovertebral angle
2. Weakness of the iliopsoas and quadriceps muscle (L1–L4 ventral roots)
3. Lower extremity edema
4. A warm dry and red foot if the sympathetic chain is involved paravertebrally
5. Lymphomas and lymphosarcoma may attain a large size and present as an abdominal mass

Neuropathology

1. Tumors that involve the lumbosacral plexus:
 - a. Colorectal, prostate, cervical, ovarian are the primary tumors
 - b. They invade by local extension
2. Metastatic lesions:
 - a. Breast
 - b. Lymphoma
 - c. Sarcoma
 - d. Lung
 - e. Thyroid (rare)
 - f. Melanoma
 - g. Testicular
 - h. Multiple myeloma
3. Primary pelvic plexus tumors:
 - a. Neurofibroma
 - b. Schwannoma
 - c. Sarcoma (degenerations of a benign neurofibroma)
4. Benign tumors
 - a. Dermoid of the omentum
 - b. Uterine leiomyoma

Neuroimaging

1. CT scan and MRI are positive more than 80% of patients by the time of clinical presentation
2. Sacral bone involvement is often a sign of colorectal cancer

Radiation Therapy (X-RT)

General Characteristics

1. Median time to the onset of symptoms is variable; the usual is five years; in some patient, symptoms may appear 20–30 years after treatment
2. There is no apparent relationship between the amount of X-RT and the latent period to symptoms
3. Signs rarely occur with less than 40 Gy rads

Clinical Manifestations

1. Bilateral or unilateral slowly progressive leg weakness
2. Starts distally usually in the L5–S1 roots; muscle wasting and absent reflexes

3. Numbness and paresthesia may be the presenting symptoms
4. Mild pain as a late symptom (approximately 50% of patients); aching, burning and lancinating in character
5. May arrest after several years (usually five years)
6. Often associated bowel and bladder symptomatology treatment

Neuropathology

1. The usual cancers that are irradiated are:
 - a. Lymphoma
 - b. Testicular
 - c. Ovarian
 - d. Uterine
 - e. Cervical
2. X-RT may induce:
 - a. Malignant nerve sheath tumors
 - b. Post-irradiation lower motor neuron syndrome
3. A dose above 1 Gy effects can be seen in:
 - a. Schwann cells
 - b. Fibroblasts
 - c. Vascular and perineural cells
4. Injury may occur after:
 - a. External beam photon therapy
 - b. Intestinal or intracavitary radiation implants
 - c. Combined photon and proton beam
5. The effect is dose dependent:
 - a. Animal experiments demonstrate that the threshold dose is 20–25 Gy
 - b. Accumulated doses below 40 Gy with conventional fractionation of 1.8–2.0 Gy are considered to have a low risk of injury to nervous tissue
6. Late effects include proliferative endarteritis and fibrosis in the plexus and soft tissue; vascular permeability and venous exudation

Neuroimaging

1. MRI:
 - a. Demonstrates thickening of the plexus with tumor and atrophy with X-RT; no enhancement with gadolinium with X-RT
2. Diffusivity measurements differentiate malignant lesions from irradiation injury

Laboratory Evaluation

1. CSF:
 - a. CSF protein may be slightly elevated
2. EMG:
 - a. Myokymia may be demonstrated in approximately 60% of patients

Radiation vs. Tumor Invasion of the Lumbosacral Plexus

Radiation Plexopathy

1. Insidious onset and progression
 - a. Sensory symptoms may begin at two months; may resolve after several months

- b. Presenting symptoms and signs may be weakness
- c. Bilateral involvement
- d. Distal muscle weakness (L5–S1 roots)
- e. Atrophy and no enhancement on MRI; less diffusivity on DWI
- f. EMG may be normal or demonstrate myokymia and fasciculation

Tumor Invasion

- 1. Rapid onset and progressive course
- 2. Pain may be the initial symptom
- 3. Unilateral involvement
- 4. Proximal weakness (L1–L4 roots)
- 5. Enhancing mass on MRI (with gadolinium); destruction of bone

Post-Irradiation Lower Motor Neuron Syndrome

- 1. X-RT of the lower thoracic and lumbar spine
- 2. Painless wasting and fasciculation of leg muscles
- 3. May have a delayed onset from the end of treatment (months to years)
- 4. Sphincter function is normal
- 5. EMG:
 - a. Sensory nerve action potentials are normal
 - b. Denervation is seen in the affected muscles

Medical Causes of Lumbosacral Plexopathy

Diabetic Radiculoplexus Neuropathy

General Characteristics

- 1. Involves the nerve roots and the lumbosacral plexus most often in a setting of diabetic length-dependent neuropathy
- 2. Approximately 8% prevalence in type I and II diabetic patients
- 3. Rarely the presenting feature of diabetes
- 4. Often seen in Type I diabetic patients controlled by diet and oral hypoglycemic agents
- 5. Most common onset is the sixth to seventh decade
- 6. Rare to have concomitant nephropathy, retinopathy, or history of coma

Clinical Manifestations

- 1. Hip and anterior thigh pain are often the initial presenting symptoms
- 2. Leg weakness supervenes within a few days to weeks
- 3. Weakness predominates in a lumbar plexus distribution that affects:
 - a. Hip flexion
 - b. Adduction
 - c. Knee extension
- 4. Approximately 2/3 of patients have weakness in the L5 myotome; 50% are weak in the S1 dermatome in addition to the proximal muscles innervated by L1–L4 roots. L5 and S1 innervated muscle weakness may occur without involvement of proximal muscle weakness

- 5. Sensory loss is common but often not noticed due to pain and weakness
- 6. A small percentage of patients have neuropathy of the trunk
- 7. Approximately 50% of patients have involvement of the autonomic nervous system that includes:
 - a. Orthostatic hypotension
 - b. Urinary dysfunction
 - c. Impotence
 - d. Constipation or nocturnal diarrhea
- 8. 75% of patients have concurrent length-dependent neuropathy
- 9. There may be gradual improvement of weakness over months, and the pain diminishes over weeks; proximal muscles are more likely to recover

Neuropathology

- 1. Microvasculitis:
 - a. Epineural and perivascular inflammation
- 2. Multifocal fiber loss is demonstrated on nerve biopsy
- 3. The process is frequently bilateral
- 4. Impaired glucose tolerance has been demonstrated in a large percentage of patients with idiopathic plexopathy

Neuroimaging

- 1. MRI:
 - a. An early screen to r/o other pathologies
 - b. If malignant infiltration of the plexus is suspected CT should be added to imaging parameters as up to 40% of patients have epidural tumor extension

Laboratory Evaluation

- 1. EMG and nerve conduction velocities to evaluate the level and extent of the plexopathy as well as the often concurrent length-dependent neuropathy
- 2. Sed rate is elevated in 20% of patients
- 3. CSF:
 - a. Protein may be elevated (120 mg% suggests root involvement)

Idiopathic Lumbosacral Plexitis

General Characteristics

- 1. Phenotype is similar to that of diabetic radiculoplexus neuropathy
- 2. Lumbar plexus is more often affected than the sacral although pan-plexopathies occur
- 3. Age of onset is 30 months to 81 years of age
- 4. It is usually monophasic and mild but may be recurrent and have a progressive course
- 5. Bimodal incidence:
 - a. Prior to age 20 years of age
 - b. Between 40–60 years of age
- 6. Mild trauma, vaccination and viral illness have been reported to precede the illness in some patients
- 7. Children, in general, have a monophasic course; adults may have recurrences

Clinical Manifestations

1. Abrupt onset of unilateral pain in the anterior thigh (lumbar plexitis) and posterior thigh and buttock (sacral plexitis); some patients have a more prolonged onset with recurrent bouts of pain
2. Muscle weakness is observed within 5–10 days of onset of the pain; it may progress for days to weeks; the pain resolves as the weakness supervenes
3. Muscle weakness of L1–L4 roots is most common and is associated with a positive femoral reverse SLR nerve test and absent quadriceps reflex
4. Lower plexus involvement:
 - a. Positive Tinel's sign at the sciatic notch and popliteal fossa
 - b. Weakness of the anterior and posterior tibialis, everters of the ankle, foot flexors, and extensors
 - c. Absent Achilles reflex
5. The process may be bilateral
6. Recovery is often prolonged (over months) and is incomplete

Neuropathology

1. Impaired glucose tolerance has been reported in some patients
2. Nerve biopsy demonstrates demyelination and axon loss similar to diabetic patients
3. Probable microvasculitis; possibly immune-mediated

Neuroimaging

1. MRI:
 - a. To rule out compressive or invasive lesions
 - b. Gadolinium-enhanced lumbar and sacral roots, and trunks may be demonstrated

Laboratory Evaluation

1. EMG/NCV:
 - a. To delineate the location and severity of the process
2. HbA1c (must be negative)
3. Sed rate elevated in some patients
4. CSF:
 - a. Slight increase in protein has been demonstrated in some patients

Differential Diagnosis of Medical Causes of Lumbosacral Plexus Lesions**Vasculitis****General Characteristics**

1. Usually a necrotizing vasculitis

Clinical Manifestations

1. Develops acutely
2. Painful; weakness with fixed sensory loss
3. Progresses in a step-wise manner
4. Constitutional symptoms are associated that include:
 - a. Fatigue and weight loss

b. Associated conditions:

- i. Granulomas of the respiratory tract
- ii. Retinitis
- iii. Purpura
- iv. CNS involvement
- v. Eosinophilia

c. Specific entities:

- i. Diabetic microvasculitis
- ii. SLE
- iii. Periarteritis nodosa
- iv. Sarcoid
- v. Steroid responsive lumbosacral plexopathy
- vi. Wegener's granulomatosis
- vii. Hereditary temperature sensitive plexopathy (AD)

Infections Affecting the Lumbosacral Plexus**1. Abscess:**

- a. Bacterial abscess whose origin is in the psoas or paraspinal musculature

b. Perirectal abscess:

- i. Immunocompromised patients
- ii. Prior rectal surgery
- iii. Fever in association with groin, abdominal or back pain
 1. Usually sciatic nerve radiation
 2. L4–S2 motor/sensory deficits

2. Anogenital Herpes Simplex

- a. Less than 1% of women with primary anogenital infection develop plexopathy
- b. Most frequent incidence is in males with herpetic proctitis
- c. HS type 2 greater than type 1
- d. The primary anogenital lesion may be on the cervix
- e. Rare plexopathy with recurrent attacks
- f. Clinical features:
 - i. Dermatomal leg weakness and sensory loss
 - ii. Paresthesias and sensory loss in the perineum, buttocks, and posterior thigh
 - iii. Urinary retention, constipation, and erectile dysfunction
 - iv. Reduced tone of the anal sphincter; sensory loss in sacral dermatomes; loss of the bulbocavernosus reflex
 - v. May involve lower motor neurons of the sacro-coccygeal plexus
 - vi. Mild meningeal irritation
 - vii. Symptoms and signs last 10 days to 3 weeks often with good recovery

g. Laboratory evaluation:

- i. Diagnosis is confirmed by PCR
- ii. CSF may demonstrate a lymphocytic pleocytosis

3. Cytomegalic virus:

- a. Lumbosacral plexus noted in severely ill HIV patients
 - i. CD4⁺ count of <200 mm³
- b. Severe pain, paresthesia and weakness in a wide distribution

- c. Associated retinitis
- 4. Herpes Zoster:
 - a. L5–S1 roots
- 5. Tuberculosis:
 - a. Cold abscess; involves the psoas and iliacus muscle; (T12–L4 roots)
- 6. Pyelonephritis:
 - a. Upper > lower plexus
- 7. Appendicitis:
 - a. Upper roots of the lumbar plexus
 - b. Characteristic iliopsoas spasm
- 8. Iliacus muscle abscess:
 - a. Following laparoscopy
 - b. Upper plexus involvement
- 9. Lyme's disease:
 - a. L5 root most often affected
- 10. Brucellosis:
 - a. L5 root is most often affected
- 11. Syphilis:
 - a. Dorsal root entry zone; meninges are involved particularly involving cervical root
 - b. HIV-associated
- 12. Epidural abscess:
 - a. Surgery
 - b. Catheters (anesthesia for pain)
 - c. Osteomyelitis
- 13. IV drug abuse:
 - a. Pyogenic organisms
 - b. Staph aureus is most common
 - c. Affects the disc space (end arterial supply)
 - i. Severely painful (vibration of the bed causes pain)
 - ii. Very positive meningeal stretch signs
 - d. MRI:
 - i. Involvement of both the anterior and posterior longitudinal ligaments
 - ii. Enhancement of the disc space, the nerve roots, and the paravertebral muscle
 - e. Contiguous spread of infection to nerve roots from osteomyelitis is the most common route of infections
- 14. EBV Infection:
 - a. Upper lumbar plexus involvement

Retroperitoneal Hemorrhage

General Characteristics

1. The lumbar plexus may be compressed within the iliopsoas muscle
2. Femoral nerve in isolation may be compressed by an iliacus hematoma or hemorrhage (trauma or retractor)

Clinical Manifestations

1. Femoral nerve
 - a. The iliacus fascia is lighter than the psoas fascia; smaller hematomas produce femoral compression more frequently than diffuse lumbar plexopathy

2. Pain in the groin radiating to the anterior thigh and medial lower leg (primarily L3–L4 roots and the saphenous nerve)
3. Position of comfort is a flexed upper leg
4. Positive reverse straight leg raising test
5. Minimally painful Patrick's maneuver (internal/external rotation of the upper leg)
6. Weakness of the quadriceps; loss of sensation in the femoral nerve territory; loss of the quadriceps reflex
7. Grey-Turner's sign in approximately 5–10 days over the costovertebral angle (purple blood breakdown products)
8. Clinical manifestations of psoas muscle hematoma
 - a. Severe groin and lower abdominal pain
 - b. The upper leg is not usually flexed at the hip:
 - c. Negative reverse SLR test (forced upper leg extension)
 - d. Rarely hip flexion with external rotation of the leg is painful
 - e. No palpable hematoma; rarely a groin mass is palpable
 - f. Thigh adductor muscle weakness (obturator nerve)

Neuropathology

1. Iliacus and psoas hemorrhage; occur most often in anticoagulated patients
 - a. May be associated with an abrupt drop in hemoglobin
 - b. Rarely bilateral
 - c. Heparin has a greater incidence than Coumadin; the never anticoagulants have not yet been reported
 - d. Often there is no preceding trauma
 - e. Most often a neuropractic nerve injury

Neuroimaging

1. Loss of the psoas shadow on a routine abdominal flat plate
2. MRI demonstrates the hemorrhage

Differential Diagnosis of Hemorrhagic Plexus Lesions

1. Athletic injury; hyperextension and avulsion of the iliacus muscle from the ileum
2. Localized blunt trauma; pelvic fracture
3. Disseminated intravascular coagulation
4. Hemophilia and other clotting disorders
5. Leukemia
6. Aneurysmal rupture
7. Anticoagulation

Immune-Mediated Causes of Lumbosacral Plexopathy

1. AIDP (acute inflammatory demyelinating plexopathy) may involve the proximal plexus
2. CIDP (distal nerve involvement to a greater degree than proximal nerve roots)
3. Specific epitopes:
 - a. GMI
 - b. Gal-NAC-GTdla
 - c. Gd1b
 - d. MAG
 - e. SGPG
 - f. Anti-sulfatide

4. Paraneoplastic Antibodies
 - a. Anti-Hu
 - b. Anti-Yo
 - c. Anti-MA
 - d. Anti-TA
5. Post-vaccination
6. Post-serum infusion with anti-venoms antibody preparations

Toxins/Anesthetics

1. Lidocaine/bupivacaine
 - a. 0.25% or greater concentration usually delivered by epidural catheter for severe neuropathic pain; demyelinating lesions of the roots
 - b. Benzyl alcohol adjuvant of anesthetics
 - c. Heroin (IV drug abuse); the adulterants may be talc or quinine to which there is an autoimmune response
 - i. May have a delayed onset of symptoms and signs (1–2 days after infusion)
 - ii. Diffuse lower extremity pain
 - iii. Minimal weakness or sensory loss
 - iv. Pain clears prior to recovery of motor function
 1. May be associated with transverse myelitis of ten at T4

Differential Diagnosis of Gadolinium Enhancement of the Lumbosacral Plexus

1. Carcinomatous meningitis
2. AIDP
3. CIDP
4. Arachnoiditis
5. Infections (CMV in particular)
6. Sarcoid
7. Leukemia/lymphoma
8. Tumor invasion

Differential Diagnosis of Unusual Lumbosacral Plexus Lesions

1. Acute aortic occlusion:
 - a. Level of the lesion may be:
 - i. Conus medullaris
 - ii. Cauda equina
 - iii. Proximal nerve trunks
 - iv. Lumbosacral plexus
 - b. Clinical manifestation
 - i. Acute lower extremity monoplegia

Neuromuscular Choristoma

General Characteristics

1. Rare congenital lesions
 - a. Differentiated muscle intertwined with peripheral nerve and the lumbosacral plexus

Clinical Manifestations

1. Undergrowth of the affected limb
2. Primarily in the sciatic nerve:

- a. Progressive neuropathy
 - b. Shortened atrophic limb
 - c. Pes cavus
3. Undergrowth of bone with hip dysphasia

Neuropathology

1. Normal differential muscle within the affected nerve or plexus

Neuroimaging

1. Smoothly tapering fusiform enlargement of the sciatic nerve or brachial and/or lumbar plexus
2. T1 and T2 signal characteristics of muscle
 - a. Longitudinal bands of loss of T1 and T2 signal
3. Nerve fascicle thickening results in coccyx cable root presentation

Chapter 7

Peripheral Neuropathy

Overview

The differential diagnosis of peripheral neuropathies can be based on the determination of the signs and symptoms of:

1. The predominant fiber size in the nerve that is affected
2. The patterns of motor or sensory loss
3. The time course of the illness
4. Associated medical conditions
5. Exposure to toxins and medications
6. Most importantly the individuals' genetic background

Approximately 30% of peripheral neuropathies remain undiagnosed after a sophisticated evaluation. This percentage will steadily decrease with modern techniques of high throughput genetic testing.

The patient's predominant symptoms and neurologic examination suggest the fiber size that is involved in the neuropathy that focuses the examination on the physical findings subserved by that fiber size. It is important to realize that damage to peripheral nerves cause dynamic changes in both the peripheral and central nervous system such that modality-specific sensory information such as touch may be perceived as pain. These changes are complex and involve responses of the injured nerve to its microenvironment (that includes immune cells, tachykinins, protons, and other proteins) with consequent changes at all levels of the peripheral and central nervous system. These changes from afferent input may activate genes that in turn induce structural changes in the central nervous system.

The smallest unmyelinated fibers are C-fibers (that are polymodal) and autonomic fibers that are approximately 1 μ in size. The predominant symptoms expressed by patients with involvement of these fibers are distal extremity burning pain and autonomic dysregulations.

Secondary signs and symptoms of C-fiber involvement may be:

1. Mechanical allodynia in which an innocuous stimulus (touch) is perceived as painful
2. Hyperalgesia in which a normally painful stimulus is amplified
3. Hyperpathia where the stimulus threshold to elicit pain is increased but once exceeded reaches maximal intensity too rapidly, is overwhelming, and is not stimulus bound

C-fibers are primarily involved in neuropathic pain but are also involved in other aspects of sensation such as pleasurable touch. A-delta thinly myelinated fibers may also be considered small fibers and mediate well-localized fast lancinating pain, the sensation of cold and deep muscle ache. Allodynia to mechanical and thermal stimuli, hyperalgesia and hyperpathia, characterize neuropathic pain which is a major symptom of many neuropathies.

Recent studies of mechanical allodynia reveal that after nerve injury:

1. Neurokinin-1 receptor expressing pain projection neurons of lamina I in the dorsal horn receive excitatory afferent input from somatostatin-containing interneurons via a pre-existing polysynaptic pathway
2. These somatostatin interneurons also receive input from nociceptors
3. This pathway under normal conditions is inhibited by dynorphin/GAD67 interneurons located in lamin II of the dorsal horn
4. These inhibitory GABA-ergic interneurons are normally modulated by polysynaptic projections from AB fibers as well as A-delta and C-fiber nociceptors
5. A-beta (touch fibers) are also linked to lamina I NKIR pain projecting neurons through PKC (phosphokinase C gamma/somatostatin) interneurons, central cells and somatostatin interneurons in outer lamina II of the dorsal horn
6. This pathway is modulated by glycinergic and dynorphin expressing interneurons. As noted above sensory processing in the dorsal horn is exceedingly complex and is not fully understood

It is clear that after a nerve injury touch and mechanical afferent input is relayed to nociceptive circuits in lamina I and II of the dorsal horn that are involved in mechanical allodynia.

Autonomic fiber symptomatology (unmyelinated fibers) derives from:

1. Autonomic dysregulation manifested by postural hypertension
2. Obstipation
3. Sexual dysfunction
4. Micturition abnormalities
5. Hypo- or hyperhidrosis
6. Pupillary alterations

Characteristically, small fiber neuropathies have decreased pain and temperature thresholds, minimal weakness, and atrophy with retained reflexes.

Large fiber neuropathies (12–22 μ fiber size) have deficits in motor, vibratory, proprioceptive, and discriminative touch. Patients demonstrate sensory ataxia, distal and proximal weakness, a positive Romberg sign, poor balance, and loss of reflexes.

In general, both large and small fibers are involved in neuropathies (recently small fiber deficits have been shown in Charcot-Marie-Tooth disease (CMT)) and demonstrate motor, sensory, and autonomic features to various degrees. Frequently sensory abnormalities are noted initially with the gradual development of motor and autonomic phenomena. Coldness of the effected extremities with sweating deficits are common symptoms and signs of autonomic involvement in a mixed peripheral neuropathy.

The distribution of the sensory loss is extremely important in differential diagnosis. Axonal metabolic dying back neuropathies (length dependent dying back neuropathy) affect

the longest axons initially. Patients develop deficits in the toes and distal legs initially, and the fingers become involved when the process crosses the knees. The center part of the chest is affected in a shield distribution. The dorsal root ganglia that subserve the central chest are in the thoracic spine and their most distal axons (that subserve the central chest) degenerate initially. Similarly, in the face, when the cervical nerve roots are affected, the chin and midface may be numb or dysesthetic prior to areas near the ear (C2 distribution). In general, these neuropathies progress symmetrically although initially, they may be slightly asymmetric. Some polyneuropathies demonstrate a proximal symmetric pattern of weakness. These include Guillain-Barré syndrome, acute intermittent porphyria, diabetes, and chronic inflammatory demyelinating polyneuropathy (CIDP). Rarely patients may have a proximal accentuation of weakness superimposed on distal weakness (from a distal length-dependent process such as occurs with diabetes and HIV).

Focal neuropathies occur with entrapments in various tunnels, mononeuritis multiplex from infarction or nerve compression. These may be genetic as is the case with hereditary neuropathy with compression palsy (deletion of chromosome 17) or mechanical from trauma, anesthesia, alcohol or coma. Mononeuritis multiplex (sequential involvement of large nerves) has recently been described as presenting as a distal symmetric polyneuropathy. Monoradiculopathies, polyradiculopathies, and plexopathies are distinguished by their characteristic patterns of involvement. Differential diagnosis becomes more difficult in situations where there are several simultaneous processes such as diabetes and multiradiculopathies from cervical and lumbar spondylosis. Almost all older patients have some degree of osteoarthritic involvement at C5–C6 and L4–L5 and L5–S1 levels. Shoulder trauma and repetitive movements may damage the brachial plexus, individual nerves, and nerve roots. Commonly diabetic and HIV-infected patients have nerve involvement at several levels. Almost all patients with complex regional pain syndrome (CRPS I/II) have multiple nerve, plexus and root components that maintain the illness.

As a general rule in the upper extremities, root disease is primarily felt proximally and rarely radiates to the fingers. The exception is C6 that radiates to the lateral forearm, thumb, and index finger. The C7–T1 spinal nerve almost never gets injured as this is a non-movement segment. Brachial plexus and upper extremity nerve problems radiate to the hand. In the lower extremities, the reverse is true. Radicular pain frequently radiates to the leg and foot while lumbosacral plexus problems are experienced proximally. Nerve pathologies are experienced both proximally and distally. At times, polyradiculopathies at L4–L5 and L5–S1 may simulate a neuropathy but most patients have had prior back, buttock and posterior thigh radiations at some point in their course. The examination demonstrates the particular motor and sensory deficits of the involved roots. Multifocal neuropathies may have characteristic distributions such as cold

parts of the body in leprosy (ear lobes, nose and dorsal aspects of extremities) and a regional distribution as in CRPS I.

The temporal profile of a neuropathy is extremely helpful in differential diagnosis and may be divided into:

1. Acute (progressing over days to weeks)
2. Subacute (6 months to one year)
3. Chronic (6 months to years)

Within the time frame, the process may be monophasic, intermittent or progressive.

Acute neuropathies are generally autoimmune mediated, toxic exposures, in the setting of critical care or metabolic as exemplified by acute intermittent porphyria. Subacute neuropathies may be autoimmune, paraneoplastic, metabolic or due to vitamin deficiency. Chronic neuropathies are often hereditary or metabolic (uremia, diabetes, liver failure).

Axonal neuropathies are characterized by digital muscle weakness, atrophy, and at times, fasciculation whereas demyelinating neuropathies demonstrate weakness and loss of deep tendon reflexes out of proportion to atrophy.

Hereditary neuropathies are suggested by pes cavus, a foreshortened foot and intrinsic foot muscle atrophy. The insertions of the gastrocnemius muscles in the lower extremities are too high, and there is often distal 1/3 of the quadriceps muscle atrophy. The patients' wrists and ankles are thin. Associated medical conditions include kyphoscoliosis, ataxia, cardiomyopathy and other dysmorphisms. The process evolves slowly. Patients may note that it was always difficult for them to stand in one place without shifting weight due to a deep ache in the legs. They may have had difficulty running and were clumsy in their adolescent years. Approximately 10% of hereditary neuropathies have abnormally flat or "rocker bottom feet." These patients along with those that have pes cavus suffer an undue number of twisted ankles due to peroneal muscle weakness. Family members are often affected but are unaware of the condition.

Almost all acquired neuropathies have a seminal feature that leads to a clinical diagnosis.

Hereditary Peripheral Neuropathies Charcot-Marie-Tooth Disease (CMT)

General Characteristics

1. Hereditary neuropathies comprise approximately 50% of undiagnosed neuropathies
2. CMT is the most common type of hereditary neuropathy and is classified by:
 - a. Nerve conduction velocity
 - b. Demyelinating or axonal primary pathology
 - c. Mode of inheritance:
 - i. Autosomal dominant
 - ii. X-linked
 - iii. AR
 - iv. Sporadic

- d. Age of onset
- e. Identification of the causative gene mutation
3. CMT1 is the demyelinating form and CMT2 is characterized by axonal degeneration
4. Overlapping phenotypes exist; CMT1 patients show signs of secondary axonal degeneration
5. Patients within each subtype may be unequally affected in regard to motor and sensory deficits
6. The genotype is heterogeneous, and there is complexity of phenotype/genotype correlation; greater than 900 mutations in various genes have been described
7. Clinical groups overlap and the same phenotype can be caused by mutations in different genes
8. CMT occurs in approximately 1:2500 individuals

Clinical Manifestations of CMT1

1. Ratio of CMT1 to CMT2 is approximately 2:1
2. Onset is usually from the first to third decade although a few patients may remain asymptomatic into later life
3. They are initially distally weak with an early predilection for the anterior compartment peroneal muscles with consequent foot drop; they suffer frequent falls and ankle sprains
4. Steppage gait
5. Rare complaints of numbness or tingling although patients may have difficulty standing still without muscle ache. Positive early sensory complaints are a strong differential point for an acquired neuropathy. There is decreased sensation to all modalities and recent studies demonstrate a small fiber component to the sensory loss
6. Muscle weakness and atrophy is severe below the knee and often effects the distal 1/3 of the quadriceps; rarely there is pseudohypertrophy of the calves which is asymmetric
7. Pes cavus or a foreshortened foot with hammer toes is most common; a small proportion has a flattened foot with no arch, a "rocker bottom" foot
8. Approximately 2/3 of patients have intrinsic hand muscle weakness and atrophy that may become severe in some patients in later stages of the illness; over time there is slight to moderate proximal muscle weakness
9. Respiratory difficulties rarely occur from phrenic nerve involvement
10. Reflexes are usually unobtainable
11. Hypertrophy of nerve roots rarely compresses the spinal cord or cauda equina
12. Nerve hypertrophy may be palpitated in the great auricular nerve, the supraclavicular nerves, ulnar and the peroneal nerve at the fibular head
13. Rare associated findings:
 - a. Deafness
 - b. Adie's pupil
14. Roussy-Levy essential tremor occurs in approximately 1/3 of patients

Neuropathology

1. Nerve biopsy:
 - a. Loss primarily of large diameter fibers
 - b. Diminished axon diameter with neurofilaments within atrophic axons
 - c. Recurrent demyelination and remyelination result in decreased intermodal length
 - d. Schwann cell proliferation causes the formation of onion bulbs
 - e. Loss of myelinated fibers in the posterior columns of the spinal cord

Neuroimaging

1. MRI:
 - a. Predominant early atrophy of the anterior compartment muscles

Laboratory Evaluation

1. EMG:
 - a. By 3–5 years of age, the nadir of nerve conduction velocity is reached and remains stable for the rest of the patient's life
 - b. Compound motor action potential amplitude (CMAP) progressively decreases over time (axonal loss)
 - c. Distal motor latencies increase until approximately ten years of age at which time they plateau
 - d. Motor nerve conduction velocities:
 - i. Motor NCV are less than 38 m/s; usually, they range between 20–25 m/s
 1. Point mutations in peripheral myelin protein 22 (PMP22) and those with mutations in myelin protein zero (MPZ) have NCV 10 m/s or less
 2. There is no conduction block or temporal dispersion
 3. Prolonged distal motor latencies
 4. F-waves latencies are usually absent or are extremely prolonged
 5. Sensory nerve action potentials (SNAPs) are unobtainable or of low amplitude; NCVs are very slow
2. Evoked potentials:
 - a. Somatosensory evoked potentials demonstrate slow central conduction
 - b. Visual evoked potentials reveal slow conduction in central optic pathways (in some CMTs)
3. Cerebrospinal fluid (in general)
 - a. Increased protein

Clinical Variants of CMT

CMT1A

General Characteristics

1. Approximately 85% of patients with CMT1A have a duplication within chromosome 17p11.2-12 in the PMP22 gene (3 gene copies)

- a. Patients with deletion of this chromosome segment (one gene copy remains) have hereditary neuropathy with liability to pressure palsies (HNPP)
- b. Most de novo duplications are paternally inherited
- c. Point mutations in the PMP22 gene
 - i. Phenotypically resemble Dejerine-Sottas

Clinical Manifestations

1. Classic features as described for CMT1

Neuropathology

1. Duplication of one of the alleles of the PMP22 gene
2. Toxic effect of PMP22 overexpression
3. Enlarged nerves with Schwann cell proliferation, loss of myelinated fibers (large diameter fibers), decreased internodal length
4. Disruption of multiple types of cell junction complexes in peripheral nerve with increased permeability of myelin and impaired action potential propagation
5. Increases in endoneurial extracellular matrix volume (synthesized by Schwann cells)
6. Abnormalities in fibronectin and tenascin
7. Increase in endoneurial collagen

Neuroimaging

1. MRI:
 - a. Anterior compartment (leg) muscle atrophy initially
2. Peripheral nerve ultrasound (in pediatric patients)
 - a. Increased cross-sectional area (1.9–3.5 fold increase compared to controls)
 - b. Disease severity correlated with cross-sectional area and age

CMT1B

General Characteristics

1. Approximately 20% of patients with CMT1 have CMT1B
2. Genetics:
 - a. Mutations in the MPZ gene are located on chromosome 1q22-23
3. MPZ is an integral myelin protein
4. Some mutations are associated with a severe demyelinating CMT3 phenotype (early onset); the later onset form is suggestive of the CMT2 axonal form

Clinical Manifestations

1. A severe early onset form with delayed walking (NCV < 10 m/s)
2. Later onset form with more axonal pathology
3. More commonly associated with Adie's pupil

Neuropathology

1. MPZ is an integral myelin protein that is a member of the immunoglobulin superfamily
2. Localizes to the tight, compact regions of myelin possibly maintaining tight compaction by forming links between adjacent myelin layers

3. Rarely tomaculae and uncompacted myelin are demonstrated

Neuroimaging

1. Similar to CMT1A

Laboratory Evaluation

1. Greater axonal characteristics on EMG than CMT1A

CMT1X

General Characteristics

1. The second most common form of CMT
2. Genetics:
 - a. Mutation of the gap junction protein beta 1 (GJB1) gene:
 - i. Encodes connexin 32 (CX32)
 - ii. Located on the X-chromosome
 - iii. There is no male to male transmission and males are more affected than females
 - iv. All amino acid mutations are pathogenic
 - v. Females have a spectrum of deficits putatively due to X-inactivation

Clinical Manifestations

1. Peripheral manifestations are similar to CMT1A and 1B characterized by progressive weakness, atrophy, and sensory abnormalities distally more often than proximally
2. A subgroup of patients has mild deafness and abnormalities on brainstem evoked potentials
3. Weakness and atrophy develop in the hands. Thenar atrophy and positive sensory symptoms and loss are more evident than in CMT1A
4. Males are clinically affected by ten years of age
5. CMT1X is an X-linked dominant trait:
 - a. It affects female carriers
 - b. Affected women have a later onset than men and have a milder phenotype
 - c. Women may be completely asymptomatic but obligate carriers have electrophysiological evidence of peripheral neuropathy

Neuropathology

1. Prominent features are age-related loss of myelinated fibers and regenerated axon clusters
2. Myelin sheaths are inappropriately thin for the axonal diameter which supports:
 - a. Segmental demyelination and remyelination
 - b. Remyelination after axonal regeneration

Laboratory Evaluation

1. EMG:
 - a. Men with CMT1X mutations demonstrate "intermediate" nerve conduction velocities with mildly prolonged distal motor and F-wave latencies

- b. Forearm motor NCV in males are 30–40 m/s and 30–50 m/s in females
- c. Conduction slowing in CMT1X is less uniform among nerves and dispersion is greater than in CMT1A
- d. Electrophysiological evidence of distal axonal loss

CMT1C

General Characteristics

1. Genetics:
 - a. Autosomal dominant, which is unusual for CMT, as most other forms are recessive
 - b. Mutations in the gene SIMPLE (also named LITAF, EET1, and PIG7) the small integral membrane protein of the lysosome/late endosome causes CMT1C
 - c. A putative role in endosomal regulation and vesicular trafficking which is fundamental for cargo entry, export and intracellular transport in cells
 - d. SIMPLE is secreted by the endosome pathway
 - e. The percentage of CMT1 with this mutations is 0.6%

Clinical Manifestations

1. Chronic CMT1 phenotype

Neuropathology

1. SIMPLE is an early endosomal protein rather than a late lysosomal/late endosomal protein
2. In genetically altered mice there is myelin unfolding that originates from paranodal regions near Schmidt-Lanterman clefts
3. The illness is caused by dominant effects of the mutant protein rather than haploinsufficiency of SIMPLE protein
4. Nerve biopsy of one patient demonstrated onion bulb formation

CMT1D

General Characteristics

1. Comprises less than 1% of molecularly defined cases of CMT1
2. Genetics:
 - a. Missense mutations in the early growth response 2 gene (also called Knox 20) located on chromosome 10
 - b. EGR2 is a transcription factor that is involved in the transcriptional regulation of myelin genes in Schwann cells
3. Localization with SOX10 genes

Clinical Manifestations

1. CMT1 phenotype

Neuropathology

1. Mutations interfere with the expression of genes required for myelination by Schwann cells

CMT1E

General Characteristics

1. Allelic to CMT1A
2. Point mutation in the PMP22 gene

Clinical Manifestations

1. CMT1 phenotype
2. Associated deafness

CMT1F

General Characteristics

1. Mutations in the neurofilament light chain gene NF-1
2. Located on chromosome 8p13-21
3. CMT1 phenotype

Laboratory Evaluation

1. EMG evaluation:
 - a. May be associated with low amplitude CMAPs and normal or only slightly slow NCVs and thus is often classified as CMT2F
 - b. Some patients have conduction velocities in the mid-twenties which classify them as CMT1F

Hereditary Neuropathy with Liability to Pressure Palsies (HNPP)

General Characteristics

1. Also known as tomaculous neuropathy is autosomal dominant
2. Caused by a 1.5 Mb deletion in chromosome 17p16.2
3. De novo deletions are paternally inherited
4. May also be rarely caused by mutations in myelin protein zero (MPZ)
5. The mutation affects peripheral myelin protein 22 (PMP22) the same region that is duplicated in CMT1A

Clinical Manifestations

1. Manifests within the second or third decade; rarely presents in the first decade and some patients remain asymptomatic
2. The usual presentation is painless numbness and weakness in the distribution of a peripheral nerve; rarely, there are cranial neuropathies and multiple mononeuropathies
3. Precipitants are most often trivial compression of a nerve or repetitive movements
4. The mononeuropathies usually resolve over weeks to months
5. The most common site of compression is the carpal tunnel, cubital tunnel, spiral groove and the fibular head. The brachial plexus may be involved from carrying a heavy load or clavicular pressure from a backpack

6. Rarely patients may suffer a progressive or relapsing sensorimotor peripheral neuropathy that may be misdiagnosed as a CMT or chronic inflammatory demyelinating polyneuropathy (CIDP)
 7. There is often sensory loss to all modalities primarily affecting large fibers, decreased reflexes throughout and pes cavus
 8. HNPP is approximately 6% of patients with CMT
- d. Proteins involved in lipid metabolism:
 - i. MTMR2, RAB7, SPTLC1, SPTLC2
 - ii. These genes are ubiquitously expressed and have pleiotropic functions:
 1. Chaperone activity
 2. Autophagy
 3. Vesicular transport
 4. Protein and lipid biosynthesis

Neuropathology

1. Focal globular thickening of the myelin sheath that resembles a sausage (tomacula). These are redundant loops of myelin
2. There is a decrease in large myelinated fibers, segmental demyelination and remyelination and axonal atrophy and degeneration
3. Patients have only one copy of the PMP22 gene
4. De novo deletions arise from unequal crossing over during meiosis
5. De novo mutations of female origin are from intrachromosomal rearrangement
6. Mutation within the PMP22 gene may cause the illness putatively by a loss of function of the gene

Laboratory Evaluation

1. EMG:
 - a. Sensory and motor NCVs (nerve conduction velocities) demonstrate prolonged distal latencies and slightly slow NCVs with normal or reduced amplitudes
 - b. Across entrapment sites, there is slowing of NCVs, conduction block, and temporal dispersion
 - c. There may be distal accentuation of slowing without compression
 - d. Asymptomatic family members may demonstrate slowing of NCVs

CMT2 Autosomal Dominant Axonal Neuropathies

General Characteristics

1. The axonal forms of CMT comprise approximately 50% of the illness which have been linked to over 15 gene mutations
2. The genes are involved in four major physiologic functions:
 - a. Neuron-specific:
 - i. Cytoskeletal organization
 - ii. Axonal transport
 - iii. NEFL, GAN1, and KIF1B
 - b. Code for heat shock proteins
 - i. HSPB1, HSPB3, HSPB8
 - c. Aminoacyl-tRNA synthetase
 - i. GARS, YARS, AARS, HARS, KARS

3. The canonical roles of heat shock proteins are:
 - a. Protein folding under stress conditions
 - b. Cytoskeletal regulation
 - c. Apoptosis
 - d. Autophagy
 - e. Oxidative stress

Clinical Manifestations of CMT2

1. CMT2, in general, has later onset than CMT1
2. Onset is usually in the second decade although some patients are asymptomatic until adulthood
3. Less severe involvement of the intrinsic hand muscles than patients with CMT1
4. CMT1 has more severe involvement of the peroneal, anterior tibialis, gastrocnemius and soleus muscles than patients with CMT2
5. Generalized areflexia is common in CMT1 and rare in CMT2
6. CMT1 may have tremor (Roussy-Levy syndrome)
7. 50–70% of CMT2 patients have decreased light touch, pain, joint position and vibration sensibility. Recent work has demonstrated small fiber sensory loss by quantitative sensory testing in CMT1 patients
8. Both CMT1 and CMT2 have loss of ankle jerks
9. Pes cavus and hammer toes are more severe in CMT1 patients
10. Approximately 25 to 30% of CMT2 patients have identified mutations

Seminal Manifestations of the Clinical Variants of CMT2

CMT2A2

General Characteristics

1. Is caused by mutations in the mitofusin 2 gene that is located on chromosome 1p36
2. It is the most common form of CMT2 and comprises approximately 20% of CMT2 patients
3. MFN2 mutation may account for 79% of severely impaired patients with CMT2
4. Associated neurologic findings include:
 - a. Optic atrophy
 - b. Pyramidal tract deficits
 - c. Hearing loss
 - d. Vocal cord paralysis (patients with severe disability)

Neuroimaging

1. MRI:
 - a. Subcortical white matter hyperintensities
 - b. A subgroup with spinal cord atrophy with or without hydromyelia

CMT2B*General Characteristics*

1. Mutations in the Rab7 gene have been identified as causative
 - a. Rab7 is a small G-protein that is involved in vesicular transport to late endosomes and lysosomes in the endocytic pathway
 - b. The mutant Rab7 proteins have impaired GTPase activity
 - c. Mutations in the SPTLC1 gene may also be causative

Clinical Manifestations

1. Foot ulcers and amputations of the toes on a background of sensory loss, distal muscle, and atrophy

CMT2B1*General Characteristics*

1. The disease is caused by a homozygous missense mutation at the LMNA locus at chromosome 1q21.2-q21.3
2. Patients come from Northwestern Africa (northwest of Algeria and east of Morocco)
3. The inheritance is autosomal recessive
4. Lamins A and C are allelic to limb-girdle muscular dystrophy
5. Other mutations in the lamins A and C protein cause:
 - a. Emery-Dreifuss muscular dystrophy
 - b. Fiber type disproportion
 - c. Limb-girdle muscular dystrophy
 - d. Dilated cardiomyopathy with conduction defect
 - e. Different forms of lipodystrophy and progeria

Clinical Manifestations

1. The age of onset is between 6 to 27 years
2. The cause can be variable with rapid progression of a proximal and distal muscle weakness and sensory loss or a milder phenotype that evolves slowly

CMT2C*General Characteristics*

1. The illness is caused by mutations in gene encoding the calcium-permeable ion channel TRPV4 (transient receptor potential vanilloid 4)
2. The TRPV spectrum disorders are autosomal dominant and show variable disease expression and reduced penetrance
3. The TRPV4 disorders are grouped into six neuromuscular disorders and skeletal dysplasia

4. The three neuromuscular disorders are:
 - a. CMT2C
 - b. Scapuloperoneal spinal muscular atrophy
 - c. Congenital distal spinal muscular atrophy (CDSMA)
5. There are six skeletal muscle dysplasias

Clinical Manifestations of CMT2C

1. The age at onset is variable and can begin in infancy
2. Disease in infancy:
 - a. Breathing difficulties and stridor
 - b. Phrenic nerves may be affected
 - c. In adults, vocal cord paralysis is evident which may begin with hoarseness
 - d. There is severe atrophy of the distal limbs, but proximal weakness may develop
 - e. Sensory loss to all modalities
 - f. Reduced or absent deep tendon reflexes
 - g. Some patients develop pes cavus but not to the same degree as is seen with CMT1, CMT2A or CMT2B
 - h. Patients have been reported as having hereditary distal spinal muscular atrophy with vocal cord paralysis
 - i. Patients may manifest skeletal dysplasia and peripheral neuropathy

CMT2D*General Characteristics*

1. Autosomal dominant inheritance
2. Mutations in the glycyl-tRNA synthetase (GARS) gene
 - a. 13 GARS mutations have been associated with CMT disease
 - b. Loss of function mutations
3. Patients with Silver syndrome from mutations in the BSCL2 gene can present similarly

Clinical Manifestations

1. Age of onset is between 12 to 36 years
2. The hands are more affected than the distal legs; there is prominent first dorsal interosseous wasting
3. The course is slowly progressive
4. There is distal sensory loss to all modalities
5. Areflexia slowly supervenes
6. One patient described with a GARS mutation had facial and respiratory muscle involvement
7. A subgroup of patients may develop pes cavus, hammer toes and scoliosis
8. The disorder is allelic to distal spinal muscular atrophy type B

CMT2E*General Characteristics*

1. The disease is caused by mutations in the neurofilament light chain NEFL gene; chromosome 8p21
2. Autosomal dominant inheritance
3. The phenotypic spectrum has not been fully elucidated

Clinical Manifestations

1. Manifests in the second and third decade
2. Distal leg weakness
3. Deafness in some patients
4. Sensory loss to all modalities
5. Pes cavus
6. Areflexia
7. One patient had post-partum exacerbation

CMT2F*General Characteristics*

1. Caused by mutations in the HSPB1 gene that encodes a small heat shock protein 27; chromosome 7q11-q21
2. Autosomal dominant inheritance demonstrated in a large multigenerational Russian family

Clinical Manifestations

1. Symmetric weakness and atrophy of distal leg muscles that is more severe than the arms
2. Onset is between 15 to 25 years

Neuroimaging

1. MRI evaluation:
 - a. A proximal to distal gradient of muscle involvement in male patients; less impairment of distal thigh muscles (3/5 patients)
 - b. Minimal or no muscle abnormalities were detected in female patients (2/5 patients)

CMT2G*General Characteristics*

1. The disease is caused by mutation the gene HSPB8 located in chromosome 12q12-q13.3
2. Evaluated in a Spanish kinship

Clinical Manifestations

1. Age of onset between 9 to 76 years
2. Most patients became symptomatic in the second decade of life (mean age of 29)
3. Classic CMT2 phenotype
4. Maybe allelic to CMT4H

CMT2H*General Characteristics*

1. Possibly allelic to CMT4A

CMT2L*General Characteristics*

1. The disease is caused by mutations in the gene HSPB8 which encodes heat shock protein 22:
 - a. The mutations are primarily in the Lys 141 residue; clinical heterogeneity occurs in patients with the Lys 141 mutation

2. Mutations (K141N and K141E) that occur in the α -crystallin domain of HSP22 cause distal hereditary motor neuropathy or CMT2L
3. The stress-induced molecular chaperones:
 - a. Assist in the correct folding of denatured proteins
 - b. Prevent aggregation of misfolded proteins

Clinical Manifestations

1. Distal limb atrophy, sensory loss (axonal loss in large myelinated fibers)
2. Areflexia
3. Classic CMT2 phenotype
4. The same genetic defect is noted in distal hereditary neuropathy 2A (dHMN2A)

Neuroimaging

- a. MRI imaging:
 - i. Lower extremity MRI reveals similarity between HSPB8 and HSPB1 in 1 patient

CMT2I/2J*General Characteristics*

1. The disease is caused by mutations in the myelin protein zero (MPZ gene)
2. MPZ:
 - a. Is an essential structural protein that is required for peripheral nerve myelination
 - b. It has a single extracellular transmembrane and cytosolic domain which bind to adjacent molecules that form tetramers which link to opposing tetramers on adjacent wraps of myelin
 - c. Mutations are dominant-negative (frameshift, missense or nonsense)
3. There are two major forms:
 - a. Early childhood onset
 - b. Late adult onset

Clinical Manifestations

1. Early onset form:
 - a. Presents in infancy with hypotonia and delayed motor milestones
 - b. Nerve conduction studies demonstrate severe slowing of less than 15 m/s
 - c. There may be a slight elevation of CSF protein
2. The demyelinating phenotype CMT1B presents in the first decade with gait abnormalities ("steppage"), falls and pes cavus
3. The adult form (CMT2I, CMT2J)
 - a. Presents usually between 18 to 50 years of age
4. CMT2J
 - a. In addition to phenotypic CMT2 axonal neuropathy has:
 - i. Adie's pupil
 - ii. Hearing loss
5. CMT2I
 - a. Electrophysiology is more associated with a demyelinating pattern

*Neuropathology***Mechanism 1**

1. Length-dependent axonal loss with/without segmental demyelination
2. Pathogenesis of MPZ neuropathies:
 - a. The mechanism of MPZ mutations is failure of the protein to reach the plasma membrane
 - b. The protein accumulates within the cytoplasm or endoplasmic reticulum
 - c. The abnormal aggregates decrease protein translation, activate protein degradation and may induce apoptosis

Mechanism 2

1. MPZ mutation
 - a. Protein reaches the plasma membrane but fails to adhere to adjacent MPZ molecules

Mechanism 3

1. The mutated protein reaches the plasma membrane, adheres to adjacent molecules but fails to maintain normal Schwann cell-axon interactive

CMT2K*General Characteristics*

1. Mutations in ganglioside-induced differentiation associated protein 1 (GDAP1)
2. It is allelic to CMT4A
3. Most often causes autosomal recessive demyelinating, axonal and intermediate forms
4. There is a rare AD form

Clinical Manifestations

1. Usually manifests in childhood
2. May have vocal cord paralysis; the AD form has a milder phenotype, and this sign is usually absent
3. Nerve conduction velocities may be axonal or demyelinating

Neuropathology (CMT2K)

1. A generalized decrease in myelinated fibers more evident in large myelinated fibers
2. Wallerian degeneration and signs of regeneration (small clusters of thinly myelinated fibers) are seen
3. Onion bulb formation is not prominent
4. Electron microscopy of CMT2A may have an abnormal accumulation of mitochondria
5. CMT2E has giant axons packed with disorganized neurofilament

Laboratory Evaluation

1. EMG:
 - a. Sensory NCS have reduced or absent SNAP amplitudes in both upper and lower extremities
 - b. Conduction velocities are normal or only slightly slow; greater than 38 m/sec
 - c. Distal sensory latencies may be slightly prolonged

- d. Distal extremity muscles may show fasciculation and fibrillation potentials
- e. Rare patients with CMT2 have continuous motor unit action potential firing that is abolished by neuromuscular blockade
- f. Recruitment is decreased in weak muscles

Dominant Intermediate CMT**Overview**

There are subgroups of CMT in which NCVs (nerve conduction velocities) overlap the axonal and demyelinating range of 25–45 m/s; axonal neuropathies > 38 m/sec. There are axonal and demyelinating characteristics on nerve biopsies.

The three intermediate types of CMT that have been identified are:

1. CMTA on chromosome 10q24.1-25.1
2. D1-CMTB (19p 12-p13.2)
3. D1-CMTC (1p34-p35), CMT1X, CMT2E, late onset CMT1B and CMT4A have patients that may qualify for this category
 - a. Clinical features are similar to those described in CMT1 and CMT2

DI-CMTB*General Characteristics*

- a. Mutations in the DNM2 gene lead to dynamin 2 protein alterations that cause AD centronuclear myopathy and dominant intermediate CMT type B
- b. Dynamin 2 is a large GTPase whose best-known function is related to membrane scission during vesicle budding from plasma or Golgi membranes
- c. Pleiotropic functions include:
 - i. Synaptic vesicle recycling
 - ii. Postsynaptic receptor internalization, neurosecretion, actin assembly and centrosome cohesion
- d. The major function of dynamin 2 in peripheral neuropathy has been proposed to be clathrin-mediated endocytosis which may be pivotal in myelination

DI-CMTC*General Characteristics*

1. DI-CMTC is caused by mutations in tyrosyl and glycyl-tRNA synthetase (YARs and GARs)
 - a. Aminoacyl-tRNAs are ubiquitously expressed and charge tRNAs with their cognate amino acids
2. They are localized in axon terminals
3. Mutations do not impact charging function and thus may not be primary in disease mechanisms

Congenital Hypomyelinating Neuropathy, Dejerine-Sottas Disease*General Characteristics*

1. CMT3 is genetically heterogeneous with most patients having PMP22, MPZ or ERG2 gene point mutations

2. Loss of function mutations in periaxin has recently been linked to autosomal recessive Dejerine-Sottas disease
3. There is a wide spectrum of clinical phenotypes, electrophysiological characteristics and neuropathology with these gene mutations

Clinical Manifestations (CMT3)

1. Presentation is at birth or in early childhood
2. Infantile form:
 - a. Have hypotonia and distal contractures (arthrogryposis multiplex)
 - b. Severe patients suffer respiratory distress, poor suck and swallow reflexes; many die in several months
 - c. In children that are ambulant:
 - i. Distal muscles are more affected than proximal; weakness may progress to patients becoming wheelchair-bound
 - d. Peripheral nerves are palpably enlarged
 - e. There is sensory loss in all sensory modalities most severe in vibration and proprioceptive domains
 - f. There is generalized areflexia
 - g. Unusual features are sensorineural hearing loss and pupillary abnormalities
 - h. Patients often have pes cavus and kyphoscoliosis

Neuropathology

1. Patients may have hypomyelination with basal lamina
2. Classic onion bulbs or amyelination
3. The nerve fasciculi are enlarged in the face of reduced myelinated fibers. There is less involvement of unmyelinated fibers
4. Hypomyelination with basal lamina onion bulbs is the most common pathology
5. Onion bulbs are composed of layers of basement membranes with minimal Schwann cell lamella in the outer ring
6. Congenital amyelinating neuropathies have few nerve fibers and minimal myelin

Laboratory Evaluation

1. EMG:
 - a. Motor NCV are typically 5–10 m/s
 - b. Distal motor latencies are markedly increased with low amplitudes
 - c. Sensory responses are not obtainable
 - d. There is increased insertional activity, positive sharp waves, and fibrillation potentials; there is decreased recruitment of MUAP (motor unit action potentials)
 - e. If there is some reinnervation there are large amplitude, long duration and polyphasic MUAPs; in severe patients with minimal reinnervation, MUAPs are small
 - f. CSF protein is often moderately elevated

CMT Disease Type 4

General Characteristics

1. Less than 10% of CMT patients in Europe and North America have autosomal recessive CMT

2. In areas with a high percentage of consanguineous marriages such as the Mediterranean basin and parts of the Middle East ARCTM may comprise 30 to 50% of patients with CMT

Clinical Manifestations

1. Childhood onset
2. Usually more severe than the classic CMT phenotype
3. They are most often demyelinating

CMT4A

General Characteristics

1. Caused by mutations in the GDAP1 (ganglioside induced differentiation protein) that is located on chromosome 8q13-q21
2. Expressed in both Schwann cells and neurons
3. Is located in the mitochondrial outer membrane
4. A component of the mitochondrial network
5. The autosomal dominant mutation causes CMT2K

Clinical Manifestations

1. Distal extremity weakness usually occurs before age two; there is developmental delay, and proximal weakness supervenes by the end of the first decade
2. A subgroup of patients is wheelchair bound by the third decade
3. Vocal cord paralysis and diaphragm weakness may occur
4. Mild sensory loss
5. Areflexia
6. Scoliosis and pes cavus occur
7. Autosomal dominant (CMT2K)
 - a. May begin late even at the 6th decade
 - b. Mild clinical course (axonal neuropathy)

CMT4B

General Characteristics

1. CMT4B is caused by mutations in the genes that encode:
 - a. The lipid phosphatase myotubularin-related protein 2 CMTMR2; CMT4B1
2. MTMR13 (CMT4B2); chromosome 11p15
 - a. Phosphoinositides (PI) 3-phosphatases that dephosphorylate phosphatidylinositol 3-phosphate
 - i. Lipids that regulate endolysosomal membrane traffic
 - ii. MTMR2 is catalytically active and associates with inactive MTMR13
 - iii. MTMR13 loss causes axonal degeneration and is associated with myelin outfoldings
 - iv. MTMR2 and MTMR13 are localized to punctuate compartments in Schwann cell cytoplasm
 - v. MTMRs and MTMR13 are physically codependent for normal protein expression

Clinical Manifestations

1. Distal greater than proximal weakness; legs more than arms

2. Weakness occurs at birth or the first year of life; rarely it may be initiated in the third decade
3. Motor milestones are delayed
4. There is primarily large fiber sensory loss
5. Weakness is slowly progressive which may lead to loss of ambulation
6. Reflexes are absent
7. Scoliosis occurs

Neuropathology

1. Focally folded myelin sheaths are noted on nerve biopsy

CMT4C

General Characteristics

1. CMT4C is due to mutations in the SH3TC2 gene
2. The gene maps to chromosome 5q23-q33 and is AR
3. Most patients are from families around the Mediterranean basin but also has been described in a European Gypsy kindred
4. There is significant clinical variation between families

Clinical Manifestations

1. The mean age of onset was in the 4th decade
2. Scoliosis may be the presenting manifestation
3. The early onset form may be characterized by delayed walking, foot deformities and scoliosis by age 5; distal greater than proximal extremity weakness
4. Sensory impairment is primarily in large fiber myelinated afferents and is often manifest in those patients with severe weakness
5. Reflexes are reduced or absent
6. Enlarged nerves may be apparent
7. Cranial VIII involvement with severe vestibular deficits may be prominent; cranial nerve VII and XII may be involved in isolation, or there may be combined involvement of cranial nerves IX and X
8. A subgroup of patients may have proximal muscle weakness

Neuropathology

1. Demyelinating fibers surrounded by excess Schwann cell lamellae that form basal lamina onion bulbs
2. Abnormally long and attenuated Schwann cell processes

Laboratory Evaluation

1. A subgroup of patients demonstrates conduction block and temporal dispersion

CMT4D

General Characteristics

1. An autosomal recessive demyelinating neuropathy
2. Due to R148 X mutations in the N-myc downstream-regulated gene 1 (NDRG1)
3. Probably allelic to hereditary motor and sensory neuropathy with deafness-Lom (HSMNL)

Clinical Manifestations

1. Exclusively found in gypsies kindred's
2. An early demyelinating phenotype with deafness
3. A subgroup of patients with copy number variation (3 Turkish patients)
 - a. Severe distal and mild proximal weakness
 - b. Distal extremity loss of light touch, vibration, and proprioceptive loss
 - c. Kyphoscoliosis, pes cavus, hammer toes and claw hands

Laboratory Evaluation

1. EMG:
 - a. Absence of sensory nerve action potentials
 - b. CMAPs are unobtainable in some patients
2. Moderate sensorineural hearing loss primarily in low frequencies

Neuroimaging

1. White matter hyperintensities (primarily subcortical) seen in a subgroup of patients

CMT4E

General Characteristics

1. Also known as congenital hypomyelination neuropathy
2. Mutations are in PMP22, MPZ or ERG2 genes

Clinical Manifestations

1. CMT3 phenotype

CMT4F

General Characteristics

1. Associated with periaxin (PRX) mutations; chromosome 19q 13.13-q13.2:
 - a. Periaxin protein forms tight junctions between myelin loops and the axon
 - b. Maintenance of normal myelin structure

Clinical Manifestations

1. In general, starts in early childhood but late onset patients have been described
2. Walking is usually late (>3 years); patients may become wheelchair bound in their mid-twenties
3. Associated signs include:
 - a. Restrictive respiratory syndrome due to severe scoliosis (after age 12)
 - b. Strabismus, glaucoma, and myopia
 - c. Pes cavus

Neuropathology

1. Demyelinating neuropathy

Laboratory Evaluation

1. EMG:

- a. Motor conduction velocities are slow; prolonged motor latencies

CMT4G

General Characteristics

1. Mutations that are primarily in the European Roma population are CMT4C, CMT4D, and CMT4G
2. The gene mutations in NDRG1 causes CMT4D
3. HK1 gene mutation causes CMT4G:
 - a. A > C change in a novel alternative untranslated exon in the HK1 gene causes CMT4G/HMSN-Russe
 - b. Hexokinase 1 blocks apoptotic signals at the mitochondria

Clinical Manifestations

1. Severe weakness and sensory loss in a CMT phenotype of the distal extremities
2. A dominant mutation in HK1 causes retinitis pigmentosa

Laboratory Evaluation

1. EMG:
 - a. Motor nerve conduction velocities are in the demyelinating or intermediate range

CMT4H

General Characteristics

1. CMT4H is caused by mutations in the FGD4 gene/Frabin located on chromosome 12p11.21-q13.11
 - a. Encodes a small RHO GTPases with guanine nucleotide-exchange factor Frabin
 - b. Experimental evidence (genetically altered mice) support a role for the protein both in nerve development and myelin maintenance
 - c. Frabin/FGD4 regulates Schwann cell endocytosis

Clinical Manifestations

1. A demyelinating phenotype

CMT4J

General Characteristics

1. Mutations in FIG4 cause the Yunis-Varon syndrome and CMT4J
2. The FIG4 phospholipid phosphatase controls the generation and level of phosphatidylinositol (3,5) P2 phosphoinositide
 - a. Phosphatidylinositol (3,5) P2 regulates membrane and protein trafficking in the endosome-lysosome pathway
 - b. Deficits from FIG4
 - c. Losses cause enlargement of late endosome-lysosomes and cytosolic vacuolization

Clinical Manifestations

1. The Yunis-Varon syndrome

- a. Autosomal recessive inheritance
- b. Skeletal and structural brain abnormalities
- c. Facial dysmorphism
- d. Seizures
2. FIG4 mutations in the syndromes are missense or nonsense that abolish FIG4 enzyme activity
3. CMT4J
 - a. Demyelinating phenotype with AR inheritance
 - b. Late-onset patients may initially have a predominantly motor asymmetric neuropathy with rapid progression

Neuropathology

1. Severe demyelination with axonal loss
2. Onion bulb formation
3. Polymicrogyria

Laboratory Evaluation

1. Both early-onset and late-onset CMT4J demonstrate decreased nerve conduction velocities

HINT1

General Characteristics

1. HINT1 (histidine triad nucleotide binding protein 1)

Clinical Manifestations

1. Progressive distal muscular atrophy and weakness
2. Clinical myotonia

Laboratory Evaluation

1. EMG:
 - a. Neuromyotonia associated with severe predominantly axonal neuropathy

Summary of Neuropathology in CMT Type 4

1. CMT4A:
 - a. Decreased myelinated fibers with hypomyelination
 - b. Basal lamina onion bulbs
2. CMT4B:
 - a. Hypomyelination
 - b. Loss of myelinated fibers
 - c. Basal lamina onion bulbs
 - d. Fibers with excessively folded myelin sheaths (tomacula)
3. CMT4C:
 - a. Decreased large diameter myelinated fibers with less involvement of small and intermediate fibers
 - b. Axons are thinly myelinated and are surrounded by Schwann cells that form classic onion bulbs
4. CMT4F:
 - a. Severe axonal loss; remaining axons are hypomyelinated and associated with onion bulbs
 - b. Tomacula with focal myelin thickening
 - c. Alterations in paranodal myelin loops
 - d. Absence of paranodal septate-like junctions between the terminal loops and the axon

X-Linked CMT Disease**Genes Associated with ARCMT1 (Demyelinating Form)**

1. GDAP1
2. MTMR2
3. SBF2
4. NDRG1
5. EGR2
6. SH3TC2
7. PRX
8. FGD4
9. FIGA

Genes Associated with ARCMT2 (Axonal Form)

1. LMNA
2. MED25
3. HINT1
4. GDAP1
5. LRSAM1
6. NEFL
7. HSPB1
8. MFN2
9. PLEKHG5

CMT1X*General Characteristics*

1. CMT1X is the second most common form of CMT
2. CMT1X is caused by mutations in the GJB1 gene that encodes Cx32
3. Autosomal dominant and maps to chromosome xq13

Clinical Manifestations

1. Motor and sensory neuropathy in affected males
2. No symptoms in carrier females
3. Sensorineural hearing loss and central symptoms in some families
4. Men with CMT1X
 - a. Present in the first two decades of life; usually, male patients present by age 10
 - b. Initial symptoms may include difficulty running and sprained ankles
 - c. Distal weakness of the extremities progresses and involve the gastrocnemius and soleus muscles
 - d. Weakness in the hands is clear in intrinsic muscles, with particular involvement of the thenar eminence
 - e. Pes cavus, hammer toes, and claw hand deformities are common

Sensory loss to all modalities is demonstrated on examination but is usually not a patient complaint. It is more prominent than in CMT1A.

1. Obligate women carriers:
 - a. Females are less affected due to X inactivation, whereby only a fraction of their myelinating Schwann cells expresses the mutant GJB1 allele

- b. Women may be asymptomatic
- c. In those that are affected, the onset of the neuropathy is often in the second decade and has a milder phenotype
- d. Rarely patients may have transient CNS symptoms

Neuropathology

1. Cx32 is expressed by Schwann cells
2. Forms gap junction (GJ) through which there is diffusion of ions and small molecules that include second messengers
3. The diffusion across apposed cell membranes directly connects Schwann cell perinuclear cytoplasm with the adjacent cell compartment inside the myelin sheath
4. Gap junctions (GJs) formed by Cx32 are pivotal in homeostasis of myelinated axons
5. Most Cx32 mutations cause loss of function due to inability to form functional gap junctions (intercellular channels)
6. More than 400 mutations have been described to date; it accounts for approximately 12% of CMT
7. Sensory nerve biopsy:
 - a. Demonstrates a loss of myelinated nerve fibers, primarily of large diameter
 - b. Axonal degeneration and atrophy occur
 - c. Clusters of thinly myelinated regenerated fibers; occasional Schwann cell proliferation with onion bulbs may surround remaining thinly myelinated fibers
 - d. There is a mixture of demyelination and remyelination

Laboratory Evaluation

1. EMG:
 - a. NCS demonstrate characteristics of demyelinating and axonal degeneration that are more severe in affected men than affected women
 - b. SNAPs are absent most often (or reduced) but if obtainable have prolonged distal latencies
 - c. Men usually have intermediate slowing of nerve conduction velocities with mildly prolonged distal motor and F-wave latencies
 - d. Forearm motor NCV are 30–40 m/s in affected males and 30–50 m/s in affected females
 - e. Conduction slowing is less uniform among different nerves, and dispersion is more pronounced than with CMT1A
 - f. There is electrophysiological evidence of distal axonal loss
 - g. Reduction of motor units correlates with clinical severity

CMT2X*General Characteristics*

1. Associated with mutations in Xq24-Xq25; X-linked recessive

Clinical Manifestations

1. Early childhood initiation
2. Distal limb weakness, atrophy, and sensory loss
3. Males have sensorineural hearing loss; some develop cognitive dysfunction
4. Female carriers are asymptomatic

Neuropathology

1. Axonal motor and sensory neuropathy

LRSAM1*General Characteristics*

1. LRSAM1 (leucine-rich repeat and sterile alpha motif-containing protein D is a ubiquitin protein)
2. Mutations in LRSAM1 cause an autosomal dominant axonal CMT (3 families studied)
3. The protein functions in sorting internalized cell-surface receptor proteins and endocytosis
4. The mutation causes the loss of a splice donor site that results in the inclusion of 63 additional base pairs of intronic DNA into the aberrant transcript
5. The gene maps to chromosome 9q33-q34

Clinical Manifestations

1. Distal weakness and atrophy of the lower extremities are the initial manifestations
2. Loss of sensory modalities primarily of large fiber function; areflexia
3. Pes cavus and hammer toes
4. May have late occurrence in adulthood

Neuropathology

1. Sural nerve biopsy
 - a. Severe axonal degeneration

Laboratory Evaluation

1. Severe axonal neuropathy
2. Absent sural nerve sensory action potentials
3. Mildly reduced motor NCVs
4. Severe distal neurogenic features by needle EMG

PLEKHG5*General Characteristics*

1. Mutations in the Pleckstrin homology domain-containing family G member 5 (PLEKHG5) cause an autosomal recessive intermediate CMT
2. PLEKHG5 is expressed in the peripheral nervous system
3. Suggested to have a role in the activation of the RHOA exchange factor and NF-KB signaling pathways that are important in neuronal cell differentiation
4. Loss of function in the NF-KB transduction pathway and aggregate formation of mutant PLEKHG5 may be pathogenic

Clinical Manifestations

1. Onset in childhood
2. Weakness of the distal lower extremities with atrophy
3. Pes cavus and steppage gait
4. Loss of sensation to all modalities, but more large fiber deficits
5. Reflexes are absent in the lower extremities

Neuropathology

1. Loss of large and medium-sized myelinated fibers
2. Electron microscopy reveals that small myelinated fibers have occasional focal folding of myelin with minimal regeneration
3. Unmyelinated fibers demonstrate clustering and atrophy
4. Endoneurial fibroblast proliferation with collagen deposition

Neuroimaging

1. MRI:
 - a. T1-weighted sequences revealed severe muscle atrophy and fatty replacement of the lower leg
 - i. Selective involvement of the anterior and lateral compartment
 - ii. A pattern of length-dependent axonal degeneration

Laboratory Evaluation

1. EMG:
 - a. Median nerve conduction velocities ranged from 24.7 m/s to 29.3 m/s; prolonged motor latencies
 - b. Absent SNAP
 - c. Needle EMG demonstrated severe degeneration
 - d. CPK is modestly elevated

Differential Diagnosis of CMT

1. Autosomal dominant demyelinating neuropathy:
 - a. CMT1A:
 - i. Classic CMT phenotype
 - ii. EMG NCVs are uniformly slowed (20 m/s)
 - iii. Demyelination with onion bulbs
 - iv. Duplication on chromosome 17p11.2 affecting PMP22
 - b. CMT1B:
 - i. Mutations in myelin protein zero (MPZ)
 - ii. Severe early onset form (NCV less than 10 m/s) and a late onset axonal neuropathy
 - iii. Mutations in EGR2 and LITAF/SIMPLE are less than 1% of these patients
2. Hereditary neuropathy with liability to pressure palsies (HNPP):
 - a. Gene deletion in chromosome 17p11.2 that includes PMP22
 - b. Recurrent episodes of focal compression of nerves or plexi with focal motor and sensory deficits
 - c. Tomacula on nerve biopsy
3. X-linked CMT1:

- a. Mutations in the gap junction protein beta; the gene is GJB1 on the X-chromosome
- b. Encoded protein is connexin (CX32)
- c. NCVs are in the intermediate range (25–40 m/s)
- d. Males have greater impairment than females
- e. Mild deafness
- 4. CMT2X:
 - a. The gene has not been identified; mutations are in Xq24-Xq25
 - b. CMT phenotype with cognitive impairment
 - c. Axonal motor and sensory neuropathy
- 2. ARCMT possibly 30–50% of all CMT patients
- 3. Polymorphisms are frequent
- 4. ARCMTs are usually demyelinating and are usually severe:
 - a. CMT4B1 (MTMR2) and CMT4B2
 - i. Focally misfolded myelin
 - b. CMT4D and CCFDN:
 - i. Congenital cataracts
 - ii. Facial dysmorphism
 - iii. Neuropathy
 - iv. Primarily in the Balkan Roma population
 - c. CMT4C (SH3TC2 mutations):
 - i. Most common in European and North American patients
 - ii. Pivotal for myelination and maintenance of the node of Ranvier
 - iii. Severe early scoliosis
 - d. LMNA mutations
 - i. Associated with cardiomyopathy muscular dystrophies, mandibuloacral dysplasia, and restrictive dermopathy
 - e. GDAP1
 - i. Maps to chromosome 8q21.11
 - ii. It is an integral membrane protein of the outer mitochondrial membrane
 - iii. Most often autosomal recessive inheritance but less severe autosomal dominant form has been described

CMT2 Autosomal Dominant Axonal Neuropathies

General Characteristics

- 1. Most present with the classic phenotype of CMT
- 2. Greater range of onset than CMT1A
- 3. NCVs in the upper extremities are greater than 38 m/s with decreased CMAPs (unobtainable in severely affected patients)
- 4. CMT2A:
 - a. Mutations in the mitofusin 2 gene in chromosome 1p36
 - b. Severe early-onset axonal neuropathy; may comprise >90% of severely affected CMT2 patients
 - c. Associated optic atrophy, pyramidal tract, and other CNS deficits
 - d. Approximately 3–4% of genetically defined patients in North America
- 5. CMT2B:
 - a. Mutations in the RAB7 gene or SPTLC1 gene
 - b. Profound sensory loss with ulceration and amputations of toes in the lower extremities
 - c. Minimal weakness
- 6. CMT2D:
 - a. Mutations in the glycyl-tRNA synthetase gene (GARs)
 - b. Weakness with no or minimal sensory loss
 - c. Silver syndrome patients may have a similar presentation (mutation in the BSCL2 gene)
 - d. Severe hand weakness prior to leg weakness
- 7. CMT2C:
 - a. Mutations in the TRPV4 gene that maps to chromosome 12q24.11:
 - i. Great phenotypic variability
 - ii. Scapuloperoneal dystrophy to sensorimotor neuropathy
- 8. CMT2 mutations that present with the classic phenotype include:
 - a. CMT2E (NEFL mutation)
 - b. CMT2F (HSP27 mutation)
 - c. CMT2G and CMT2L (HSP22 mutations)
 - d. CMT2I (MP2 mutations)

Autosomal Recessive CMT4 (ARCMT)

- 1. Most frequently seen in populations with a high percentage of consanguineous marriages

Differential Diagnosis of Intermediate CMT

These are CMT neuropathies whose NCVs overlap the axonal and demyelinating range (25–45 m/s) and whose pathogenesis may affect both Schwann cells and axons.

- 1. Linkage to chromosome 10q24.1-25.1 (DI-CMTA)
- 2. Dynamin 2 (DI-CMTB)
- 3. YARS (DI-CMTC)
- 4. PLEKHG5 (autosomal recessive)

Differential Diagnosis by Pathologic Mechanism

- 1. Gene dosage:
 - a. Duplication of the 11.4-mb region on chromosome 17 that contains the PMP22 gene CMT1A
 - b. HNPP is caused by deletion of the same gene region
- 2. Schwann cell-axonal interaction. Axonal degeneration is seen in all forms of demyelinating CMT and may have a major role in the demyelinating process. Mutations in GJB1 and GDAP1 cause both demyelinating and axonal types of CMT which suggest that primary Schwann cell pathology disrupts myelin-axon interaction to cause axonal degeneration
- 3. Protein misfolding and impaired membrane trafficking:
 - a. Mutant MPZ accumulates in the endoplasmic reticulum to induce apoptosis (cell-based studies)
 - b. Defects of lysosomal transport or degradation:
 - i. CMT1C (LITAF/SIMPLE) mutations

- ii. CMT2B (Rab7) mutations
- c. Disruption of phosphoinositide-mediated trafficking within the cell
 - i. Mutations of myotubularin-related proteins (MTMR2 and 13 and FIGA mutations cause:
 1. CMT4B1
 2. CMT4B2
 3. CMT4J

Impaired Mitochondrial Physiology

Mitochondrial transport is pivotal for the energy supply of distal axons. They undergo fission and fusion that is partially regulated by mitofusin 1 and 2, which are nuclear encoded outer mitochondrial membrane proteins.

1. Suspected defects in mitochondrial function may be involved in CMT2A (MFN2) and CMT4A
2. Defects in PNS-specific proteins:
 - a. PMP22
 - b. MPZ
 - c. Periaxin
3. Defects in widely expressed proteins:
 - a. GARS
 - b. HSP27
 - c. CX32
4. Disruption of protein synthesis with predominant motor neuropathy:
 - a. GARS
 - b. YARS
5. Stress response:
 - a. HSP22 and HSP27
6. Axonal transport:
 - a. HSP27
7. Primarily sensory neuropathy:
 - a. RAB7
 - b. HSP27

Other Hereditary Motor and Sensory Neuropathies

Proximal Hereditary Motor and Sensory Neuropathy/Neuronopathy

General Characteristics

1. Linked to chromosome 3p14.1-q13; autosomal dominant
2. Primarily described early from Okinawa, Japan, but now in many other countries

Clinical Manifestations

1. Resembles Kennedy's disease
2. Muscle cramps are early symptoms, followed by proximal muscle weakness, atrophy, and fasciculation in the legs greater than the arms
3. Facial muscles are slightly weak, but neck flexors and extensors are only slightly involved

4. Dysphasia and dysarthria are rare although the tongue may be slightly weak
5. Bulbar and respiratory weakness may be late signs
6. Patients may be wheelchair bound 5 to 20 years after onset
7. Loss of all sensory modalities with a large fiber predominance occurs in the extremities
8. Reflexes are diminished or absent
9. Neurogenic tremor is common

Neuropathology

1. Loss of large and small myelinated fibers with preserved unmyelinated fibers
2. Loss of anterior horn cells
3. Loss of neurons in the dorsal root ganglia

Laboratory Evaluation

1. Serum creatine kinase levels are mildly elevated
2. EMG:
 - a. SNAPs are unobtainable or are reduced in amplitude
 - b. CMAP amplitudes are reduced with minimal prolongation of distal latencies and NCVs
 - c. Needle EMG reveals diffuse fasciculation and fibrillation potentials
 - d. Decreased recruitment of large amplitude, long duration polyphasic MUAPs

Hereditary Neurologic Amyotrophy

General Characteristics

1. HNA is caused by mutations in the SEPT9 gene located on chromosome 17q25; AD
2. Putative functions involve formation of the neuronal cytoskeleton and cell division

Clinical Manifestations

1. Initiated in childhood
2. Attacks are similar to those that occur with the Parsonage-Turner syndrome (idiopathic brachial neuritis)
3. Usually of sudden onset
4. Recurrent attacks of pain, weakness, and sensory loss in brachial plexus distributions
5. There is usually complete or partial recovery over weeks or months
6. Associated neurologic manifestations include:
 - a. Hypotelorism
 - b. Epicanthal folds
 - c. Cleft palate and uvula (bifid)
 - d. Syndactyly
 - e. Micrognathia
 - f. Facial asymmetry
 - g. Short stature
7. Distinguished from HNPP because of severe pain and no history of nerve compression
8. Episodes are triggered by:
 - a. Infections
 - b. Immunization
 - c. Puerperium
 - d. Stress

Neuropathology

1. There is a founder haplotype in some kindreds with SEPT9; others have heterogeneous tandem duplications; the duplicated regions contain a conserved 645 bp exon within SEPT9 where missense mutations have been shown
2. Axonal degeneration in nerves distal to the plexus injury

Neuroimaging

1. MRI:
 - a. In some instances, there is gadolinium enhancement on T1-weighted sequences in affected components of the brachial plexus

Laboratory Evaluation

1. EMG:
 - a. Reduced amplitudes of SNAPs and CMAPs in all affected components of the plexus (trunks, cords, division and nerves)
 - b. Decreased recruitment of MUAPs
 - c. Positive sharp waves and fibrillation potentials in affected muscle groups associated with decreased recruitment of MUAP
 - d. An axonal process localized to the brachial plexus
 - e. HNPP is demyelinating and is generalized

Scapuloperoneal Neuropathy*General Characteristics*

1. The genetic basis of scapuloperoneal atrophy is heterogeneous
 - a. Inheritance may be autosomal dominant or recessive
2. Alterations in the ankyrin domain of the TRPV4 gene may cause:
 - a. Congenital distal SMA
 - b. Scapuloperoneal SMA
 - c. HMSN2C
3. One family with AD inheritance of scapuloperoneal SMA has been linked to chromosome 12q24.1-q24.31
4. One patient has been linked to a 17p11.2 deletion (Davidenkow phenotype)

Clinical Manifestations

1. Heterogeneous manifestations depending on the genetic background
2. Scapuloperoneal pattern of weakness may be seen in:
 - a. Myofibrillar myopathy
 - b. Scapuloperoneal neuropathy (Davidenkow's syndrome)
 - c. Spinal muscular atrophy
3. Scapuloperoneal neuropathy:
 - a. The disease starts in the second or third decade
 - b. Insidious onset of foot drop with tripping and recurrent ankle sprains
 - c. Gradual onset of proximal hip and shoulder girdle weakness becomes apparent; the involved muscles include:

- i. Pectoralis, serratus anterior, rhomboids, supra- and infraspinatus, trapezius, deltoid and brachioradialis
- ii. Peroneal innervated muscles of the lower extremity are atrophic and weak
- iii. Distal arm muscles are spared
- iv. The distinguishing clinical pattern of weakness in the scapuloperoneal syndromes is upper extremity proximal weakness and lower extremity distal weakness
- v. Sensation may be normal or decreased primarily in large fiber afferents
- vi. Reduced muscle stretch reflexes
- vii. Pes cavus and hammertoes are common

Neuropathology

1. Sural and superficial peroneal nerve biopsy:
 - a. Axonal degeneration
2. Anterior horn cell loss (atrophy)
3. Muscle biopsy reveals signs of denervation with small angulated fibers, type grouping, and atrophy

Laboratory Evaluation

1. Normal median and ulnar nerve CMAPs and NCS; peroneal CMAPs are reduced in amplitude with normal distal latency and CV
2. Reduced SNAPs in the arms and legs but with otherwise normal sensory studies
3. Weak muscle group demonstrates reduced recruitment of large amplitude, long duration polyphasic MUAPs

Hereditary Sensory and Autonomic Neuropathies**Overview**

The hereditary sensory autonomic neuropathies (HSAN) are characterized by sensory and autonomic dysfunction to a greater degree than weakness.

Hereditary Sensory Autonomic Neuropathy 1 (HSAN1)*General Characteristics*

1. HSAN1 is the most common HSAN and has AD inheritance
2. The illness presents in the second through fourth decades, which distinguishes it from other HSANs whose onset is in infancy or childhood
3. HSAN1 is caused by mutations in serine palmitoylation transferase long chain subunit C1 (SPTLC1 gene) located on chromosome 9q22.31
4. Serine palmitoylation transferase is pivotal in the biosynthesis of sphingolipids
5. There may be genetic heterogeneity:
 - a. Both an AR inheritance form and an X-linked form have been described with a similar phenotype
 - b. HSAN1B

- i. Linked to chromosome 3p22-p24
 1. Clinical manifestations are cough, gastroesophageal reflux, and length-dependent neuropathy

Clinical Manifestations of HSN1

1. Late onset presentation in the second through fourth decades
2. Insidious loss of pain and temperature sensation in the feet and hands
3. Severe dystrophic features supervene:
 - a. Dermal ulcerations that become infected
 - b. Osteomyelitis of affected extremities
 - c. Charcot joints
 - d. Severe foot and hand deformities
 - e. Amputated digits
4. Burning, aching and lancinating pain in the extremities
5. Bladder dysfunction and hyperhidrosis of the lower extremities
6. Reduced sensation to all modalities primarily C-fiber and A-delta fibers (slow burning pain C-fibers, A-delta, cold appreciation and lancinating pain)
7. Distal arm and leg weakness progressively develop over time, although a subgroup of patients may have early distal weakness
8. Absent ankle stretch reflexes, but reflexes may be normal in the upper extremities
9. Pes cavus and hammer toes are common

Neuropathology

1. Predominant loss of thinly myelinated fibers (A-delta fibers) and unmyelinated fibers (C-fibers)
2. Reduced density of all fiber sizes
3. Muscle biopsy demonstrates denervation
4. Degeneration of dorsal root ganglion cells and posterior columns
5. Transmission electron microscopy demonstrates:
 - a. Swollen mitochondria with abnormal crystal clustered around the nucleus
 - b. Some mitochondria are wrapped in rough endoplasmic reticulum (ER) membranes
 - c. Observations support a mechanism in which SPTLC1 mutations cause mitochondrial abnormalities and ER stress in HSN1 sensory neurons

Laboratory Evaluation

1. EMG:
 - a. Sensory NCS are normal or demonstrate mildly decreased amplitudes, normal distal latencies and conduction velocities
 - b. Near-nerve recordings demonstrate decreased A-delta and C potentials
 - c. Slightly reduced amplitudes and slowing of conduction velocities develop over time in motor NCS
 - d. Needle EMG supports chronic reinnervation with large MUAPs in addition to positive sharp waves and fibrillation potentials

2. Sympathetic skin responses may be lost
3. CSF examination is normal
4. Serum IgA levels may be elevated

Hereditary Sensory Autonomic Neuropathy Type 2A (HSAN2A)

General Characteristics

1. HSAN2A is autosomal recessively inherited and is caused by mutations in the WNK1 gene on chromosome 12p13.3:
 - a. The mutations are confined to exon "HSN2" of the WNK1 (with-no-lysine kinase 1) serine-threonine kinase gene
 - b. These are truncating mutations in the neuron-specific exon of HSN2 gene that lead to a loss of function of the WNK1 kinase
 - i. A loss-of-function mutation in WNK1 induces an overexpression of neuronal potassium chloride co-transporter KCC2, which putatively is important for peripheral sensory nerve development

Clinical Manifestations

1. Manifests at birth or early childhood
2. Severe sensory loss to all modalities; there is lancinating pain which differentiates it from HSN1
3. Impaired sweating, bladder dysfunction, and impotence; rare to manifest postural hypotension
4. Slightly impaired distal motor strength
5. Scoliosis
6. Sensory loss, most severe to touch-pressure/vibration, which causes:
 - a. Pressure ulcers
 - b. Charcot joints
 - c. Osteomyelitis
 - d. Bone reabsorption
 - e. Amputation of extremity digits

Neuropathology

1. Almost complete absence of myelinated fibers
 - a. Mild loss of small myelinated fibers

Laboratory Evaluation

1. Absent SNAPs
2. Normal to mildly decreased CMAPs amplitude
3. Quantitative sensory thresholds
 - a. Severely abnormal vibratory thresholds
4. Needle EMG:
 - a. Positive sharp waves and fibrillation potentials
 - b. Reduced recruitment of large polyphasic MUAPs, most severe in the distal legs

Hereditary Sensory Autonomic Neuropathy Type 2B (HSAN2B)

General Characteristics

1. HSAN2B is AR and is caused by a homozygous mutation in the FAM134B gene that maps to chromosome 5p15.1

Clinical Manifestations

1. Early childhood onset
2. Distal sensory impairment
3. Hyperhidrosis
4. Urinary incontinence
5. Gait impairment (some patients)
6. Mutilating ulcerations of the hands and feet

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of myelinated fibers

Laboratory Evaluation

1. Sensorimotor axonal neuropathy

Hereditary Sensory Autonomic Neuropathy Type 3 (HSAN3 or Riley-Day Syndrome)*General Characteristics*

1. HSAN3, also known as familial dysautonomia or Riley-Day syndrome, is caused by:
 - a. Mis-splicing of exon 20 from an intrinsic mutation in the inhibitor of kappa light chain polypeptide gene enhancer in B-cells, kinase complex-associated protein (IKBKAP), that maps to chromosome 9q31.3
 - b. That encodes IKK complex-associated protein (IKAP)/elongator protein (LIPI)
 - c. Mis-splicing of IKBKAP causes decreased tRNA modification
2. AR inheritance; most patients are of Ashkenazi Jewish ethnicity

Clinical Manifestations

1. HSAN3 starts in infancy
2. Infants have:
 - a. Poor suck and cry
 - b. Cry without tears
 - c. Livedo reticularis of the skin
 - d. Fluctuations in body temperature and blood pressure
 - e. Vomiting
3. Specific autonomic features:
 - a. Esophageal and gastrointestinal dysmotility
 - b. Hyperhidrosis
 - c. Tonic pupils
 - d. Postural hypotension
4. Recurrent pulmonary infections
5. Developmental delay
6. Seizures may occur
7. Cognitive function is normal
8. Decreased pain and temperature sensation > proprioception and vibration loss
9. Absence of fungiform papillae of the tongue
10. Decreased taste
11. Muscle strength is normal
12. Reduced or absent muscle stretch reflexes; often absent corneal reflexes
13. Occasional Charcot joints occur

Neuropathology

1. Loss of neurons in the cervical and thoracic sympathetic ganglia as well as the Vth nerve nucleus
2. Decreased unmyelinated fibers in sural nerve biopsies (5–15% of the normal fiber density) and a loss of up to 50% of myelinated fibers
3. Elp1 is a subunit of the heterohexameric transcriptional elongator complex
4. Studies in conditional knockout mice demonstrate:
 - a. No impairment in migration, proliferation or survival of sympathetic and sensory neural crest cells
 - b. Ablation of Elp1 in post-migratory sympathetic neurons causes:
 - i. Abnormal target tissue innervations
 - ii. Abnormal neurite outgrowth and branching
 - iii. Alteration of soluble tyrosinated tubulin
 - c. Defects in Elp1 cause:
 - i. Failed target tissue innervations
 - ii. Alteration of cytoskeletal regulation

Laboratory Evaluation

1. EMG:
 - a. SNAPs have slightly reduced amplitude and slow CVs
 - b. CMAPs are normal
2. Sympathetic skin responses are obtainable
3. Quantitative sensory testing (QST) demonstrates altered thresholds to heat, cold and vibration modalities

Hereditary Sensory Autonomic Neuropathy Type 4 (HSAN4)*General Characteristics*

1. HSAN4 is caused by loss of function mutations in the NTRK1 gene (tyrosine kinase A/nerve growth factor TrkA/NGF) gene that is located on chromosome 3q; AR inheritance
2. NGF is a trophic factor essential for the survival of nociceptive neurons and postganglionic sympathetic neurons

Clinical Manifestations

1. Is initiated in infancy or childhood
2. Insensitivity to pain
3. Anhidrosis
4. Self-mutilation
5. Cognitive impairment
6. Severe loss of pain and temperature sensation, and loss of large myelinated proprioceptive and vibratory fibers
7. Preserved strength and muscle stretch reflexes

Neuropathology

1. Sural nerve biopsy:
 - a. Absence of A-delta (1–4 μ) and C fibers (1 μ unmyelinated fibers)
 - b. Reduction of large myelinated fibers to approximately 50% of normal fiber density

2. Mutations in NTRK1 cause the selective loss of NGF-dependent neurons (nociceptive and sympathetic postganglionic neurons)
3. TrkA-NGF complex is internalized into the nucleus of target neurons and induced genes that are pivotal for maintenance and survival of sensory neurons derived from the neural crest

Laboratory Evaluation

1. EMG:
 - a. Normal or slightly diminished SNAPs, CMAP amplitudes and conduction velocities
2. QST:
 - a. Markedly increased thresholds to heat, cold and pinprick; less involvement of mechano and vibration thresholds

Hereditary Sensory Autonomic Neuropathy Type 5 (HSAN5)

General Characteristics

1. HSAN5 is caused by missense mutations in the NGF gene located on chromosome 1p11.2-p13.2; it is autosomal-recessively inherited

Clinical Manifestations

1. Manifests at birth
2. Self-mutilation involves the teeth, lips, tongue, eyes, nose and fingers
3. Bone fractures may be asymptomatic
4. Patients have an indifference to pain. They do not recognize or react to painful stimuli
5. They have normal sensory thresholds to other modalities
6. Normal strength and muscle stretch reflexes

Neuropathology

1. Subgroups of patients have a small reduction of myelinated and unmyelinated fibers, while other patients have normal sural nerve biopsies

Laboratory Evaluation

1. Motor and sensory NCVs, QST and autonomic testing are normal

Rare Hereditary Neuropathies

Metachromatic Leukodystrophy (MLD)

General Characteristics

1. MLD is caused by mutations in the ARSA gene on chromosome 22q13.31; inheritance is AR
2. ARSA encodes arylsulfatase A, which catalyzes the hydrolysis of sulfatide, the sulfate ester of cerebroside
3. In MLD, arylsulfatase A and prosaposin enzymes metabolize galactosyl sulfatide, a glycolipid of myelin membranes

4. The enzyme deficiencies cause an accumulation of sulfatides in Schwann cells and oligodendrocytes (primarily galactosylceramide)

Clinical Manifestations

1. Disease manifestations are characterized by the age at onset:
 - a. Late infantile onset (18–24 months):
 - i. Onset between 1–2 years of age
 - ii. Progressive weakness
 - iii. Cognitive impairment
 - iv. Dysarthria (bulbar)
 - v. Children become cortically blind, quadriparetic and may have seizures
 - vi. Hypotonia, Babinski sign and loss of reflexes develop
 - b. Juvenile onset (4–10 years):
 - i. Presents in late childhood or adolescence
 - ii. Similar phenotype to the late infantile form
 - iii. Peripheral neuropathy may be present in the early stages of the disease:
 1. Decreased peripheral nerve conduction velocities
 - c. Adult onset (3rd to 4th decade):
 - i. Patients develop a slowly progressive dementia
 - ii. Often a psychosis
 - iii. Spasticity
 - iv. Ataxia
 - v. Extrapyramidal signs
 - vi. Visual loss

Neuropathology

1. Degeneration of myelin (often frontal lobe predominant) in the subcortical white matter
2. Nerve biopsy:
 - a. Decrease of myelinated fibers with evidence of remyelination
 - b. Accumulation of metachromatic inclusions in Schwann cell cytoplasm
 - c. Electron microscopic evaluation:
 - i. Inclusions are laminated bodies within Schwann cells

Neuroimaging

1. Abnormal subcortical white matter may have a pattern of radiating stripes
2. Confluent periventricular white matter (T2-weighted sequences); spares accurate fibers
3. Cranial nerve enhancement occurs; rarely there is enhancement of peripheral nerves

Laboratory Evaluation

1. Decreased arylsulfatase A can be demonstrated in the urine, leukocytes or cultured fibroblasts
2. Cerebrospinal fluid protein is markedly elevated (100–300 mg/dl)

3. EMG:
 - a. Motor nerve conduction studies (NCS) reveal:
 - i. Reduced amplitude and prolonged distal latencies
 - ii. Conduction velocities of 10–20 m/s in the legs and 20–40 m/s in the arms
 - iii. Rare temporal dispersion; no conduction block
 - iv. Usually unobtainable sensory NCS
4. All evoked potentials (visual, brainstem and somatosensory) are delayed

Krabbe's Disease

General Characteristics

1. Krabbe's disease is an autosomal recessive disease caused by mutation in the β -galactosidase gene (GALC) that maps to chromosome 14q 24.3-q 32.1:
 - a. Encodes β -Galactosidase which metabolizes galactocerebroside to ceramide and galactose
 - b. Hydrolyzes psychosine

Clinical Manifestations

1. Presents in early infancy or adulthood
2. Infantile form:
 - a. Usually, presents between 3–8 months; infants appear normal at birth
 - b. Irritability and hypersensitivity evolve with feeding difficulties, vomiting and generalized clonic-tonic seizures
 - c. Progressive weakness, spasticity, blindness and deafness supervene
 - d. Gradual loss of reflexes occurs with a developing neuropathy;
 - i. Babinski sign remains
 - ii. Death supervenes by the age of 2
3. Adult onset:
 - a. Progressive dementia
 - b. Spasticity and paraparesis
 - c. Hemiparesis
 - d. Cerebellar ataxia
 - e. Optic atrophy
 - f. Cortical blindness

Neuropathology

1. Cortical atrophy (may be parietal lobe predominant)
2. Macrophages filled with galactocerebroside (globoid cells) are demonstrated
3. Sural nerve biopsy:
 - a. Segmental demyelination or hypomyelination as well as loss of myelinated fibers
 - b. Globoid cells
 - c. Electron microscopy demonstrates:
 - i. Electron-dense granules and tubular crystalloid inclusions in the cytoplasm of macrophages

Neuroimaging

1. MRI:
 - a. Cortical atrophy (parieto-occipital predominant)
 - b. Peripheral nerves may enhance
 - c. Corticospinal tract demyelination

Laboratory Evaluation

1. Decreased β -galactosidase in leukocytes and cultured fibroblasts
2. 50% of patients have increased CSF protein
3. EMG:
 - a. Motor NCS (nerve conduction studies)
 - i. Mild to moderate decrease of CMAP amplitude
 - ii. Moderately prolonged distal latencies
 - iii. Moderately slow NCVs
 - iv. Delayed or absent F-waves
 - b. Sensory NCS:
 - i. Absent SNAPs or severely reduced amplitudes and distal latencies and slow CV if obtained

Fabry's Disease

General Characteristics

1. Fabry's disease (angiokeratoma corporis diffusum):
 - a. Caused by mutations in the galactosidase gene that maps to chromosome Xq21-22
 - b. A multisystemic lysosomal storage disorder that presents with phenotypic and genotypic variability among affected male and female patients
 - c. Globotriaosylceramide (Gb3) and galactosylceramide (Ga2) isoforms and analogs have been identified by mass spectroscopy in the urine of Fabry's disease patients

Clinical Manifestations

1. Most prominently affects males in childhood or adolescence
2. Affected individuals often present with neuropathic extremity pain
3. Angiokeratomas (reddish purple maculopapular lesions) are seen in a bathing suit distribution; angioectasias may be seen in the nail beds mucosa and conjunctiva
4. Systemic manifestations:
 - a. Hypertension
 - b. Myocardial infarction
 - c. Renal failure
 - d. Small vessel CNS disease
 - e. Heat intolerance
 - f. Severe atherosclerotic changes
 - g. Women most often suffer the neuropathy

Neuropathology

1. Sural nerve biopsy:
 - a. Reduction of thinly myelinated and unmyelinated nerve fibers
 - b. Glycolipid granules are found in ganglion cells of the peripheral and sympathetic nervous system as well as perineural cells
 - c. Skin biopsy:
 - i. Decreased epidermal fiber density
 - ii. Globotriaosylceramide (Gb3) and analogs, as well as galactosylceramide (Ga2) isoforms/analogues

are demonstrated in the vascular endothelium, nerve, cardiomyocytes, renal glomerular and tubular epithelial cells

- iii. Gb3 isoforms that contain saturated fatty acids are the most abundant

Neuroimaging

1. Ischemic stroke
2. White matter hyperintensities
3. Vertebrobasilar dolichoectasia
4. Pulvinar sign

Laboratory Evaluation

1. Low galactosidase activity in leukocytes and cultured fibroblasts
2. Ga2 and Gb3 and respective isoforms and analogs can be found in the urine
3. EMG:
 - a. Mildly decreased amplitudes of motor and sensory NCS
4. QST:
 - a. Small fiber deficits

Adrenoleukodystrophy/Adrenomyeloneuropathy

General Characteristics

1. Adrenoleukodystrophy and adrenomyeloneuropathy are allelic linked dominant diseases
 - a. Caused by mutations in the peroxisomal transmembrane adenosine triphosphate binding cassette ABCD1 transporter gene that is located on chromosome q28
2. ABC transporter protein:
 - a. Is a member of the peroxin family of proteins
 - b. Peroxin proteins are involved in the transport, biogenesis and proliferation of peroxisomes:
 - i. In brain capillary endothelial cells, they also function as ATP-driven efflux pumps for xenobiotics and metabolites
 - ii. Mutations in the ABC transporter gene cause:
 1. Impaired transport of very long chain fatty acids (VLCFA) as well as VLCFA CoA synthetase into peroxisomes that cause decreased beta oxidation of VLCFA

Clinical Manifestations

1. Onset between 4 to 8 years of age in X-linked dominant ALD
2. Male patients have progressive:
 - a. Dementia
 - b. Optic atrophy
 - c. Cortical blindness
 - d. Hearing loss
 - e. Seizures
 - f. Spasticity
 - g. Adrenal insufficiency

Clinical Manifestations of Late Onset

1. Onset in adolescence or adulthood
2. Phenotype is similar but with a much slower progression
3. Late-onset patients may present with symptoms suggestive of schizophrenia

Clinical Manifestations of Adrenomyeloneuropathy (AMN)

1. Occurs in approximately 30% of patients with adrenoleukodystrophy
2. Onset is in the third to fifth decade
3. Progressive spastic paraplegia develops with a mild to moderate peripheral neuropathy
4. The degree of muscle stretch reflex sensitivity depends on the neuropathy (normal to reduced)
5. A subgroup of patients may develop dementia in the later course of the disease
6. Adrenal insufficiency occurs in approximately 2/3 of patients
7. Rarely patients may present with an adult onset spinocerebellar phenotype or with isolated adrenal insufficiency
8. Women may develop a myelopathy in their thirties

Neuropathology

1. In the CNS:
 - a. Demyelination and perivascular inflammation occur predominantly in the parietal and occipital lobes
 - b. The spinal cord shows bilaterally symmetric long tract degeneration in a drying back pattern
2. Sural nerve biopsy:
 - a. Loss of all myelinated fiber sizes as well as unmyelinated fibers
 - b. Electron microscopy reveals:
 - i. Lamellar inclusions in the cytoplasm of Schwann cells

Neuroimaging

1. MRI:
 - a. Adrenoleukodystrophy demonstrates an elevated diffusion pattern
 - i. An apparent diffusion coefficient (ADC) maps in ADL
 - b. Subcortical white matter confluent demyelination occurs in ADL
 - c. Similar MRI patterns of demyelination occur in approximately 50% of AMN patients late in the course of the disease

Laboratory Evaluation

1. Elevated very long chain fatty acids (C24, C25, C26), are demonstrated in the urine
2. Approximately 85% of obligate female carriers have elevated urinary VLCFA levels
3. Many patients have laboratory evidence of adrenal insufficiency
4. EMG:

- a. ALD has normal nerve conduction studies
- b. AMN demonstrates:
 - i. Sensory and motor slightly reduced amplitudes, prolonged distal latencies, and slightly slow CVs
 - 1. Most compatible with a primary axonopathy with secondary demyelination
 - 2. Rarely some patients have electrophysiological features of a primary demyelinating process
- 5. Somatosensory evoked potentials
 - a. Evidence of central slowing

Refsum's Disease

General Characteristics

- 1. Refsum's disease is an autosomal recessive peroxisomal disorder
- 2. Classic Refsum's disease is caused by mutations in PAHX that is located on chromosome 10p13:
 - a. Encodes phytanoyl-CoA hydroxylase that catalyzes the oxidation of phytanic acid
- 3. Less commonly mutations in the PRX7 gene located on chromosome 6q22-24 cause the disease
 - a. Encodes peroxin7 receptor protein

Clinical Manifestations

- 1. May manifest in infancy to adulthood; usually in late childhood
- 2. Classic tetrad:
 - a. Retinitis pigmentosa (often the earliest sign)
 - b. Peripheral neuropathy
 - c. Cerebellar ataxia
 - d. Elevated CSF protein
- 3. Other signs and symptoms include:
 - a. Anemia
 - b. Ichthyosis
 - c. Cardiac arrhythmia (conduction defects)
 - d. Deafness
 - e. Very late-onset cognitive decline and leukoencephalopathy
- 4. Over time patients develop:
 - a. Distal numbness and paresthesias in the legs (in their early twenties)
 - b. Atrophic, weak distal leg musculature and foot drop
 - c. Proximal shoulder and pelvic girdle weakness evolve
 - d. Sensory loss is primarily in a length-dependent manner with large myelinated fiber predominance
 - e. Generalized absence of muscle stretch reflexes
 - f. The neuropathy may fluctuate
 - g. Nerves become hypertrophic

Neuropathology

- 1. Phytanic acid is branched chain fatty acid that accumulates in many tissues
 - a. When it exceeds a millimolar range, it leads to severe symptoms

- 2. Degradation of phytanic acid is accomplished by alpha-oxidation inside of peroxisomes. A decrease in its breakdown results from:
 - a. General peroxisomal dysfunction
 - b. A defect in one of the enzymes involved in alpha-oxidation
- 3. Phytanic acid reduces histone acetylation, which induces cell death in an experimental cell culture system
- 4. Sural nerve biopsy:
 - a. Demonstrates loss of myelinated nerve fibers; remaining axons are thinly myelinated and are associated with onion bulb formation

Laboratory Evaluation

- 1. Elevated serum phytanic acid levels
- 2. Elevated CSF protein
- 3. EMG:
 - a. Sensory nerve conduction studies (NCS):
 - i. Reduced amplitudes, prolonged latencies, and slow CVs
 - ii. Motor NCS
 - 1. Normal or moderately reduced amplitudes, prolonged distal latencies and slowing of CV (10–30 m/s)

Tangier Disease

General Characteristics

- 1. Tangier disease is an autoimmune disorder caused by mutations in the ABCA1 gene that maps chromosome 9q22-31
- 2. ABCA1 is pivotal in the secretion of cellular free cholesterol and phospholipids to an intracellular acceptor apolipoprotein A1 which forms nascent high-density lipoprotein (HDL)
- 3. ABCA1 is pleiotropic and is important for:
 - a. Plasma membrane remodeling
 - b. ApoA1 binding to the cell surface
 - c. Unfolding of the N-terminal of ApoA1 on the cell surface which is followed by lipidation of ApoA1 and the release of nascent HDL

Clinical Manifestations

- 1. It may present as:
 - a. An asymmetric mononeuropathy multiplex
 - b. A slowly progressive, symmetric polyneuropathy that is more severe in the legs than the arms
 - c. A pseudosyringomyelia phenotype in the arms in which there is dissociation between loss of pain and temperature with retained position and vibration sense
- 2. Swollen yellowish orange enlarged tonsils
- 3. Splenomegaly and lymphadenopathy occur

Neuropathology

- 1. Extremely low levels of plasma high-density lipoprotein cholesterol

2. Accelerated atherosclerosis
3. Accumulation of cholesterol in many body tissues
4. Impaired cholesterol efflux from affected tissues
5. Sural nerve biopsy:
 - a. Axonal degeneration with demyelination and remyelination
 - b. Electron microscopy:
 - i. Abnormal accumulation of lipid in Schwann cells predominately those associated with thinly myelinated fibers

Laboratory Evaluation

1. Severe reduction of serum high-density lipoprotein cholesterol
2. Increased levels of triacylglycerol levels
3. EMG:
 - a. Some patients have moderately reduced amplitudes, prolonged distal latencies and slow CV in motor and sensory nerves

Cerebrotendinous Xanthomatosis (Cholestanolosis) CTX

General Characteristics

1. A rare autosomal recessive lipid storage disease
2. CTX is caused by mutations in the CYP27A1 gene:
 - a. Encodes the mitochondrial enzyme sterol 27-hydroxylase
 - b. The CYP27A1 gene maps to chromosome 2q333-qter
 - c. The mutations lead to decreased synthesis of bile acid, an excess production of cholesterol with its accumulation in tissues

Clinical Manifestations

1. The onset of CTX is usually after the second decade
 - a. Average age at diagnosis is 35 years of age
2. Adult onset of:
 - a. Ataxia
 - b. Dementia
 - c. Seizures
 - d. Psychiatric disorders
 - e. Spasticity
 - f. Mild sensory neuropathy
 - g. Mild myopathy
3. Non-neurologic manifestations:
 - a. Tendon xanthomas
 - b. Childhood-onset cataracts
 - c. Infantile onset diarrhea
 - d. Premature atherosclerosis
 - e. Osteoporosis
 - f. Respiratory insufficiency

Neuropathology

1. Premature atherosclerosis
2. Multiple dispersed lipid crystal clefts
3. Perivascular accumulation of foamy macrophages

4. Sural nerve biopsy:
 - a. Loss of myelinated nerve fibers with evidence of demyelination and onion bulb formation
 - b. Lipid inclusions are seen in Schwann cells

Neuroimaging

1. MRI:
 - a. A generalized decrease of both gray and white matter
 - b. Bilateral symmetric hyperdense lesions in the dentate nuclei on both T1- and T2-weighted images
2. PET imaging:
 - a. Decreased metabolic activity in both the frontal and temporal lobes

Laboratory Evaluation

1. Increased serum levels of cholesterol
2. EMG: (depends on degree of neuropathy)
 - a. Motor and sensory NCS may reveal absent amplitudes with slightly prolonged distal latencies and decreased CVs
 - b. Compatible with a sensorimotor axonal polyneuropathy

Hereditary Ataxias with Neuropathy

Overview

The hereditary ataxias are progressive neurodegenerative disorders with involvement of:

1. The cerebral cortex
2. Basal ganglia
3. Cerebellum
4. Brainstem
5. Spinocerebellar and corticospinal tracts
6. Motor neurons
7. Peripheral nerves

The CNS manifestations predominate, although, in Friedreich's ataxia and inherited vitamin E deficiency, peripheral nerve manifestations may be significant.

Friedreich's Ataxia

General Characteristics

1. An autosomal recessive disease caused by a GAA trinucleotide repeat of the first intron of the frataxin gene located in chromosome 9q13
2. Ninety-seven percent of patients have an expanded GAA triplet repeat in both alleles (100 to 1700 repeats; normal 40 or less triplet repeats); the remaining 3% have an expanded GAA repeat in one allele and a point mutation in the other:
 - a. The gene encodes the mitochondrial protein frataxin
 - b. Dysregulation of iron metabolism is a pivotal component of the disease, which is characterized by:
 - i. Mitochondrial iron accumulation

- ii. Decreased activity of iron-sulfur cluster enzymes
- iii. Frataxin has a primary role in iron-sulfur cluster biogenesis

Clinical Manifestations

1. Usually presents between 2–16 years of age; late onset cases occur
2. Gait ataxia and clumsiness are often the presenting signs
3. Progressive neurologic manifestations include:
 - a. Dysarthria
 - b. Optic atrophy
 - c. Nystagmus
 - d. Hearing loss
 - e. Pyramidal signs
 - f. Motor neuronal loss
 - g. Distal extremity atrophy
 - h. Prominent loss of proprioception and vibration sensitivity
 - i. Pes cavus
 - j. Loss of muscle stretch reflexes
 - k. Rare dementia
 - l. Babinski sign

Non-Neurologic Manifestations

1. Pigmentary retinal degeneration
2. Cardiomyopathy
3. Scoliosis
4. Diabetes mellitus

Neuropathology

1. Role in protection against free radical damage and mitochondrial DNA replication
2. Marked atrophy of the posterior columns and dorsal roots
3. Sural nerve biopsy:
 - a. Loss of large myelinated fibers

Neuroimaging

1. MRI:
 - a. MRI of the brain is usually normal
 - b. Atrophy of the cervical spinal cord

Laboratory Evaluation

1. Genetic testing for the gene mutations
2. Electrocardiogram:
 - a. Low voltage QRS complexes
 - b. Non-specific ST and T-wave changes
 - c. Deep Q waves
 - d. Conduction defects
3. EMG:
 - a. Sensory nerve conduction studies (NCS):
 - i. Absent or reduced amplitudes
 - ii. H-reflexes are unobtainable
 - b. Motor NCS:
 - i. Moderately affected
 - c. Magnetic stimulation studies:
 - i. Slow central motor conduction
 - d. Somatosensory evoked potentials:
 - i. Slow central motor conduction

Vitamin E Deficiency

General Characteristics

1. Rare autosomal recessive disease due to mutations in the tocopherol transfer protein gene (TTPA gene) that is located in chromosome 8q13:
 - a. The gene encodes alpha-TTP, a cytosolic liver protein that putatively functions in the intracellular transfer of alpha-tocopherol
 - b. Defects in the transfer protein cause reduced incorporation of vitamin E into serum very low-density lipoproteins (VLDL) which in turn causes its rapid elimination and consequent low levels in the CNS and PNS

Clinical Manifestations

1. Onset in hereditary patients is between 5 and 10 years of age
2. Slowly progressive ataxia, dysarthria, decreased vibration, and proprioceptive sensitivity occur
3. Pes cavus, Babinski sign, generalized weakness with decreased or absent muscle stretch reflexes are common signs
4. Acquired vitamin E deficiency may have:
 - a. Ophthalmoplegia
 - b. Optic neuropathy
 - c. Retinitis pigmentosa
 - d. Above are not seen in the hereditary patients

Neuropathology

1. Severe loss of dorsal root ganglion cells
2. Degeneration of the posterior column
3. Loss of cells in the cuneate and gracile nuclei
4. Myelin sheath vacuoles and disrupted Schmidt-Lanterman incisures occur in the peripheral nerve

Laboratory Evaluation

1. Isolated low vitamin E serum levels
 - a. Patients who have malabsorption deficits (acquired vitamin E deficiency) have concomitant:
 - i. Low serum cholesterol
 - ii. VLDL
 - iii. Vitamin A
 - iv. Vitamin C levels
2. EMG:
 - a. Sensory NCS:
 - i. Absent or slowed with low amplitudes
 - b. Motor conduction velocities are usually normal although some patients demonstrate slightly prolonged conduction velocities

Homozygous Hypobetalipoproteinemia (HHBL)

General Characteristics

1. HHBL is caused by mutations in the APOB gene (both alleles) that causes homozygous hypobetalipoproteinemia that maps to chromosome 2p

Clinical Manifestations

1. Malabsorption of lipid-soluble vitamins in the disease that causes:
 - a. Retinal degeneration
 - b. Coagulopathy
 - c. Peripheral neuropathy

Laboratory Evaluation

1. Increased distal latencies and slowed NCVs

Abetalipoproteinemia (ABL) (Bassen-Kornzweig Disease)*General Characteristics*

1. ABL is inherited in an autosomal dominant manner and is caused by mutations in the large subunit of microsomal triglyceride transfer protein (MTP) that maps to chromosome 4q 22-24:
 - a. Encodes the large subunit of MTP (97-KDa subunit)
 - b. This subunit forms a heterodimer with the endoplasmic reticulum enzyme protein disulfide isomerase (PPI)
 - c. MTP is a chaperone that is pivotal in the transfer of lipids into apolipoprotein B (apoB)

Clinical Manifestations

1. Multisystem manifestations include:
 - a. Fat malabsorption
 - b. Acanthocytosis
 - c. Low serum cholesterol
 - d. Deficiency of serum apoB
 - e. Steatorrhea

Neurological Manifestations

1. Presentation within the first two decades is often ataxia and night blindness
2. Ataxia is progressive and leads to loss of ambulation by the fourth or fifth decade
3. Patients have short stature, pes cavus, and hammer toes
4. Severely decreased vibration and proprioception sensibility that also causes sensory ataxia
5. Mild distal extremity atrophy and weakness
6. Muscle stretch reflexes are decreased or absent
7. Rarely there is ophthalmoparesis

Neuropathology

1. Degeneration of the posterior columns and ventral spinocerebellar pathways
2. Sural nerve biopsy:
 - a. Axonal degeneration with a predominant loss of large diameter myelinated fibers; demyelination with remyelination

Laboratory Evaluation

1. Acanthocytes are demonstrated on blood smear
2. Decreased serum of:
 - a. Cholesterol

b. VLDLs

c. Chylomicrons

d. Vitamin A, E, and K

3. EMG:

- a. Sensory SNAPs are absent or if obtainable reveal reduced amplitudes with slowing of conduction velocities with normal or slightly prolonged distal latencies
- b. CMAPs may be slightly reduced with mild reduction of distal latencies and CVs
- c. Brainstem auditory evoked potentials are normal as opposed to reduced in Friedreich's ataxia

Disorders of Defective DNA Repair**Ataxia Telangiectasia***General Characteristics*

1. Ataxia telangiectasia is an autosomal recessive disorder that is caused by mutations in the ataxia telangiectasia mutated gene (ATM gene) that maps to chromosome 11q23:
 - a. The mutated ATM protein functions primarily as a nuclear protein that is involved in the early recognition and response to double-stranded DNA breaks
 - b. It is a high molecular weight phosphoinositol kinase
 - c. Its other roles include:
 - i. Phosphorylation of protein substrates that activate and coordinate signaling pathways for:
 - a. Cell cycle checkpoints
 - b. Nuclear localization
 - c. Gene transcription
 - d. The response to oxidative stress
 - e. Apoptosis
 - ii. Mutations in the ATM gene alter DNA repair

Clinical Manifestations

1. Cutaneous telangiectasia
2. Cerebellar ataxia
3. Conjunctival telangiectasia
4. Oculomotor dyspraxia
5. Sinopulmonary infections
6. Children develop choreoathetosis and dysarthria within the first decade
7. Distal motor weakness
8. Severe loss of proprioception and vibration sensitivity

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large myelinated fibers
2. High cancer risk (lymphoma and leukemia)
3. Adverse reactions to radiation and chemotherapy
4. Immunodeficiency
5. Glucose transporter aberrations
6. Insulin resistant diabetogenic response
7. Chromatin and chromosomal changes
8. Mitochondrial deficiencies that cause inefficient respiration and cellular metabolism

Laboratory Evaluation

1. Decreased serum levels of IgA and IgG
2. Increased serum alpha-fetoprotein
3. EMG:
 - a. Absent or reduced SNAPs amplitudes
 - b. Mild reduction of NCVs
 - c. Slightly prolonged distal sensory latencies
 - d. Similar but less severe changes are seen on motor NCS

Xeroderma Pigmentosa (XP)*General Characteristics*

1. Xeroderma pigmentosa is a rare autosomal recessive disease
2. It is caused by mutations in seven genes (XPA-XPG) that cause a defect in nucleosides excision repair (NER)
 - a. The eighth gene causes a defect in polymerase activity
3. It causes greater than 1000 fold increase in the frequency of all forms of major skin cancer due to hypersensitivity to (UV) radiation and carcinogenic agents

Clinical Manifestations

1. Intense cutaneous photosensitivity
2. Poikiloderma
3. Actinic keratosis
4. Erythema
5. Hyperpigmented lentiginous macules
6. Malignant lesions in sun-exposed areas

Clinical Manifestations of Gene Mutation of XPA, XPB, XPD, and XPG

1. Onset between 1 and 2 years of age
2. Microcephaly
3. Cognitive impairment
4. Seizures
5. Deafness
6. Cerebellar ataxia
7. Dystonia
8. Choreoathetosis
9. Primary sensory neuropathy

*Neuropathology**Sural nerve biopsy:*

1. Loss of myelinated and unmyelinated fibers
2. Sensory fibers are affected to a greater degree than motor fibers

*Laboratory Evaluation**EMG:*

1. Decreased SNAPs
2. Slowing of motor and sensory NCVs

Cockayne Syndrome*General Characteristics*

1. The majority of patients (approximately 80%) carry mutations in CSB/ERCC6 that maps to chromosome 10q11:

- a. Encodes a SWI/SNF family DNA translocase
 - i. The other major gene, CSA/ER CC8, that is mutated encodes a ubiquitin ligase
2. The major function of these genes is in transcription-completed nucleotide excision repair
3. XPD, XPB, and XPG mutations are described in a small number of patients
4. CSB affects the expression of thousands of genes many of which are neuronal in the absence of DNA damage

Clinical Manifestations

1. Children appear normal at birth but by 12 months they demonstrate slow growth and signs of aging
2. At age between 4 and 10 they show evidence of:
 - a. Progeria-like facial dysmorphism
 - b. Cognitive deficits
 - c. Ataxia
 - d. Sensorineural hearing loss
 - e. Loss of muscle stretch reflexes
 - f. Photosensitivity
 - g. Pigmentary retinopathy
 - h. Dwarfism

Neuropathology

1. There is evidence that the defects seen in Cockayne syndrome (CS) are due to dysregulation of gene regulatory networks rather than from aberrations in DNA repair
2. Sural nerve biopsy:
 - a. Segmental demyelination and Schwann cell inclusions

Laboratory Evaluation

1. EMG:
 - a. Moderate reduction of NCVs and prolonged distal latencies in motor and sensory nerves

Other Hereditary Neuropathies**Giant Axonal Neuropathy***General Characteristics*

1. Recessive mutations in the GAN that maps to chromosome 16q23
 - a. Encodes gigaxonin protein
2. Changes in peripheral nerves that are similar to CMT type 2 (may be a continuum)
3. Evidence supports disorganization of the intermediate filament network

Clinical Manifestations

1. Presents in the first decade of life
2. Children are normal at birth and complete early milestones
3. At approximately two years of age, they become ataxic and by age 4 they have a sensorimotor polyneuropathy
4. Sensory loss is demonstrated in all sensory modalities in a length dependent phenotype

5. Mild distal muscle atrophy and weakness
6. Loss of muscle stretch reflexes in the legs and decreased reflexes in the arms
7. Babinski sign is present
8. Patients have curly or kinky hair

Neuropathology

1. Sural nerve biopsy:
 - a. Segmental demyelination with loss of myelinated axons
 - b. Giant axonal swellings are noted
2. Electron microscopy:
 - a. Axonal swellings are composed of abnormal density packed intermediate neurofilaments which are most prominent distally and in paranodal areas
 - b. Degeneration of central CNS tracts is demonstrated in postmortem pathology

Laboratory Evaluation

1. Gigaxonin is reduced due to both mRNA and protein instability mechanisms
2. EMG:
 - a. Absence or reduced amplitudes of SNAPs and CMAPs
 - b. Mildly slow CVs
 - c. Prolonged distal latencies of motor and sensory nerves

Porphyria

General Characteristics

1. There are three forms of porphyria that are associated with both peripheral neuropathy and CNS signs and symptoms:
 - a. Acute intermittent porphyria
 - b. Variegate porphyria
 - c. Hereditary coproporphyria
2. The porphyrias are autosomal dominant diseases of both the peripheral and central nervous systems

Clinical Manifestations

1. A photosensitive rash is encountered with variegate porphyria and hereditary coproporphyria but not with acute intermittent porphyria
2. The neurologic symptomatically is similar in all three forms of disease
3. Attacks of porphyria are initiated by specific drugs (primarily those metabolized by the p450 cytochrome system)
 - a. Thorazine, penicillin, gabapentin and diazepam are safe
4. Other triggers include:
 - a. Pregnancy
 - b. Luteal phase of the menstrual cycle
 - c. Alcohol
 - d. Fasting
5. Neurologic manifestations include:

- a. Severe abdominal pain (most often without guarding) i.e. a soft abdomen; often associated with prior surgical scars
- b. Agitation, hallucinations and at times psychotic behavior
- c. Major motor seizures occur
- d. Episodes of cortical blindness; some associated with seizures and others due to posterior reversible encephalopathy
- e. A Guillain-Barré phenotype:
 - i. Motor weakness can be asymmetric and proximal
 - ii. Sensory impairment is much less dramatic than motor involvement but occur as radicular pain between attacks
 - iii. Motor involvement may affect arms or legs preferentially
 - iv. Rarely cranial nerves may be affected most commonly VII and XII
 - v. Muscle stretch reflexes are usually absent although ankle jerks may be retained
 - vi. Autonomic dysregulation is common and manifests during an acute attack with:
 1. Hypertension (rarely hypotension) and pupillary dilatation
 2. Tachycardia
 - vii. Between attacks patients may complain of:
 1. Constipation
 2. Urinary retention
 3. Incontinence

Neuropathology

1. Sural nerve biopsy
 - a. Axonal degeneration

Laboratory Evaluation

1. The urine is often brownish due to the high concentration of porphyrin metabolites
2. The diagnosis is made by determining in the urine or stool specific intermediary precursors of heme:
 - a. Acute intermittent porphyria:
 - i. Deficiency of porphobilinogen deaminase
 1. Increased porphobilinogen in the urine or stool
 - b. Variegate porphyria:
 - i. Deficiency of protoporphyrinogen oxidase
 1. Increased protoporphyrinogen IX in the urine or stool
 - c. Hereditary coproporphyria:
 - i. Increased coproporphyrinogen III in the stool or urine
3. X-linked sideroblastic anemia, ALAD deficient porphyria, erythropoietic protoporphyria, and congenital erythropoietic porphyria
 - a. Can cause an axonal neuropathy
4. There is no neuropathy with porphyria cutanea tarda
5. Other laboratory features:
 - a. CSF protein may be normal or slightly elevated

- b. Liver enzymes may be slightly elevated, and there may be slight anemia
- c. Cholesterol levels may be slightly elevated
- d. Inappropriate antidiuretic hormone occurs and produces a low serum sodium
- e. Delta-aminolevulinic acid is often elevated with AIP during exacerbations
- 6. Specific enzyme assays can be obtained from erythrocytes or leukocytes
- 7. EMG:
 - a. Sensory NCS demonstrate normal conduction velocities and distal sensory latencies, but with slightly reduced amplitudes
 - b. CMAPs are reduced (marked)
 - c. Motor NCVs are reduced and distal motor latencies are minimally prolonged
 - d. Needle EMG demonstrates reduced recruitment, positive sharp waves and fibrillation potentials

Neuroimaging

- 1. MRI:
 - a. White matter involvements and cortical involvement
 - b. A subgroup demonstrates predominant involvement of the caudate, putamen and thalamus

Erythromelalgia

General Characteristics

- 1. May occur as an inherited autosomal dominant condition, or it can be acquired
- 2. It is caused by mutations in the SCN9 gene that maps to chromosome 2q24
 - a. Encodes the Nav 1.7 protein
 - b. Missense mutations cause a gain of function that promotes neuronal hyperexcitability
 - c. The channel is expressed in nociceptive neurons of the dorsal root ganglia and in sympathetic neurons
 - d. Mutations alter voltage dependence, the kinetics of deactivation, and steady-state slow inactivation
 - e. Mutations of the Nav 1.7 channel also cause "paroxysmal extreme pain disorder" (PEPD)
 - f. Deficiency of the Nav 1.7 channel causes congenital indifference to pain

Clinical Manifestations

- 1. Episodic erythema with intense burning pain and warmth of the extremities
- 2. The edema and increased blood flow to the extremities is a feature of neurogenic edema produced by the release of vasoactive neuropeptides that include substance P and calcitonin gene-related peptide from unmyelinated C-fibers
- 3. The acquired form occurs from small fiber neuropathies (neurogenic inflammation) chemotherapy, myeloproliferative and autoimmune disease
- 4. Symptoms may begin at any age in the inherited type

- 5. Clinical manifestations of paroxysmal extreme pain disorder (PEPD)
 - a. Severe burning pain in the rectum (most commonly), eye, or jaw regions

Neuropathology

- 1. Electrophysiological studies show that inherited erythromelalgia mutations enhance activation, whereas those that cause paroxysmal extreme pain disorder alter fast inactivation
- 2. The changes in sodium channel gating arise from:
 - a. Alterations in conformation (affects all gating characteristics)
 - b. Voltage sensing charge (affects activation)
 - c. Interaction within the protein (binding to the inactivation links)
 - d. Interaction with other proteins (generation of resurgent sodium currents)
- 3. Skin biopsies:
 - a. May be normal
 - b. Reduced epidermal nerve fiber density
 - c. Rarely observed is perivascular inflammation and thickening of arteriolar basement membrane and smooth muscle hyperplasia

Guillain-Barré Syndrome and Its Variants

Overview

Guillain-Barré syndrome (GBS) is an immune-mediated polyneuropathy mediated by autoreactive leukocyte infiltration of specific components of the peripheral nervous system. The process induces neuroinflammation, demyelination, and an axonal degenerating polyneuropathy (AIDP). A bacterial protein is the epitope presented by a macrophage to a T-cell that after penetrating the blood vessel endothelium (peripheral blood-nerve barrier) recognizes a cross-reactive antigen and releases cytokines that activate endoneurial macrophages. Endoneurial macrophages in turn secrete enzymes and nitric oxide radicals and infiltrate compact myelin concomitantly with activated T-cells.

Mechanisms of demyelination include:

- 1. Release of cytokines
- 2. Activated T-cells interact with B-cells to produce antibodies which cross the damaged blood-nerve barrier
- 3. The antibodies interact with epitopes on Schwann cell and axonal surfaces which fix complement that:
 - a. Destroy and damage Schwann cells
 - b. Produces vesicular dissolution of myelin

In acute motor axonal neuropathy (AMAN):

- 1. The process is antibody-mediated
- 2. There is little or no inflammatory infiltrate
- 3. There is cross-reactivity from an epitope of the infective agent with an epitope of the peripheral nerve. The most likely epitopes of the peripheral nerves in AMAN are:

- a. GM1
- b. GM1b
- c. GD1a
- d. GALNAc-CD1a which is expressed on the motor nerve axolemma

A large component in the pathogenesis of GBS is humeral immunity that is demonstrated by:

1. The demonstration of immunoglobulin and complement on peripheral nerves
2. The therapeutic benefit of plasmapheresis and intravenous immunoglobulin (IVIG)
3. The existence of antibodies against peripheral nerve in GBS sera
4. The experimental demonstration that some patient IgM antibody or serum produces complement-dependent demyelination of peripheral nerve
5. In GBS patients:
 - a. Activated complement components are detected in serum and the cerebral spinal fluid
 - b. Anti-myelin antibodies rise before activated complement that supports an antibody-mediated complement attack on peripheral nerve myelin
6. Several infectious agents have been identified in association with GBS attacks, which include:
 - a. *Campylobacter jejune*
 - b. Cytomegalovirus
 - c. Epstein-Barr virus
 - d. *Mycoplasma*
 - e. *Campylobacter jejune* has been the most intensively studied and appears to be conclusive as a triggering agent
7. The mechanism for GBS with strong support is that of molecular mimicry between lipopolysaccharide of the bacterial wall and ganglioside-like epitopes on nerve cells, which causes cross-reactivity of the immune response following exposure to the infective agent. In the molecular mimicry hypothesis of *C. jejune* antecedent infection and the immunopathogenesis of GBS, several mechanistic aspects remain poorly understood:
 - a. Several *C. jejune* strains that express GM1 ganglioside-like epitopes fail to induce anti-ganglioside antibodies
 - b. Patients develop different GBS variants after exposure to the same epitope
 - c. Susceptibility genes may predispose patients to develop GBS after specific infecting agent exposure (i.e., bacterial vs. viral)
 - d. Host factors that include cytokines and toll-like receptors (TLRs) in addition to molecular mimicry are pivotal in the production of cross-reactive antibodies seen in GBS patients

The Role of Toll-Like Receptors (TLRs) and Cytokines in GBS Pathogenesis

Toll-like receptors are structurally related receptors that recognize specific components of micro-organisms and endogenous ligands that are associated with cell damage. They re-

cognize pathogen-associated molecular patterns (PAMPs). Their activation induces expression of proinflammatory cytokines (IL1, IL6, and TNF) which are a component of T-cell differentiation and the host immune response.

Cytokines are small proteins secreted by a variety of immune cells that are involved in inflammation as well as the recruitment and amplification of leukocyte infiltration into the peripheral nervous system after specific stimulation. They have pleiotrophic functions which include the regulation of cellular replication, differentiation, and activation. Th1 cytokines (IFN-gamma and IL12) induce autoimmune processes, while Th2 cytokines (IL4) are primarily involved in antibody-mediated autoimmune diseases. In GBS, cytokines are produced by infiltrating monocytes and Schwann cells in AIDP and by macrophages in the axonal form of the disease. Cascades of immune-mediated inflammatory responses are initiated by immune recognition receptors that involve lymphocytes, monocytes, and cytokines that cause peripheral nerve demyelination. Cytokines are pivotal in the disruption of the blood-nerve barrier, allowing the infiltration of immune cells to access peripheral myelin and Schwann cells. One cytokine TNF-alpha that is produced by infiltrating Th1 cells is directly myelin toxic and decreases the synthesis of myelin protein and glycolipids.

Interferon-gamma, which is produced by Th1 cells, has pleiotrophic effects that include:

1. Activation of endothelial cells, macrophages and T-cells
2. Increases the expression of major histocompatibility complex II that enhances the antigen presenting capacity of macrophages
3. Induces the differentiation of T-cells to a Th1 phenotype
4. B-cell class switching
5. Apoptosis of T-cells
6. Enhances the production of other inflammatory cytokines such as TNF-alpha, IL1-B and IL5
7. IFN-gamma inhibits Th2 cells

Experimental studies have demonstrated that Th1 cytokines are associated with immune-mediated disease progression early in the course of illness due to their role in neuroinflammation. Th2 mediated immune responses are characteristic of later phases of recovery. IL23 in conjunction with IL6 and TGFB1 stimulate naïve CD4⁺ T-cells to differentiate into Th17 which further enhance the production and secretion of IL1B and IL6 from monocytes which amplifies the inflammatory cascade. IL17 levels in the CSF have been correlated with GBS severity. Toll-like receptors are transmembrane proteins that are pattern recognition receptors (PRRs). They are critical for the initiation of both innate and adaptive responses against microbial organisms by activating the NF-KB inflammatory pathway. Excessive signaling has been implicated in atherosclerosis and autoimmune disease by activating self-reactive T- or B-cells. TLRs have also been shown to activate antigen presenting cells through MyD88 (myeloid differentiation primary-response gene) dependent or independent transduction pathways. TLR2 has been demonstrated

to deliver co-stimulatory signals to antigen-activated T-cells and to enhance T-cell proliferation, survival, effect, or function.

At present, a widely accepted theory for the initiation of GBS in the case of *C. jejune* is that of molecular mimicry between liposaccharides (LPS) on its cell envelope and ganglioside epitopes on peripheral nerves that induce a cross-reactive immune response.

Special Conditions That Cause GBS

1. After seroconversion in HIV (lymphocytosis in the CSF)
2. Vaccinations (swine flu)
3. Lymphoma
4. Bone marrow transplantation
5. Graft-versus-host disease
6. Following the use of immunomodulating drugs (TNF-alpha antagonists)

Acute Inflammatory Demyelinating Polyradiculoneuropathy (AIDP)

General Characteristics

1. AIDP is the most common cause of acute generalized weakness whose annual incidence is 1–4/100,000 persons
2. The peak age of onset is approximately 40 years of age; there may be a slight male predominance
3. Preceding conditions include:
 - a. Infections
 - b. Surgery
 - c. Trauma
 - d. Immune dysfunction
 - e. Systemic illness
4. Infections:
 - a. Approximately 60–70% of patients with AIDP have a history of preceding infection (usually within 10–14 days)
 - b. *Campylobacter jejune* is the most common infection and accounts for approximately 30% of patients
 - c. CMV accounts for approximately 15% of patients:
 - i. Younger patients
 - ii. Severe course
 - iii. Respiratory failure
 - iv. Cranial nerve involvement
 - v. Subgroup of patients with GM2 antibodies
 - d. EBV (10% of patients):
 - i. Mononucleosis
 - ii. Pharyngitis and hepatitis may be associated
 - e. *Mycoplasma* (approximately 5% of patients):
 - i. Fever
 - ii. Headache with a dry cough
 - iii. Cold agglutinin in the serum

Clinical Manifestations

1. Sensory symptoms:
 - a. Early distal numbness and paresthesias

- b. Minimal sensory deficit but large fiber predominant with proprioception and vibratory loss greater than pain and temperature
- c. Severe muscle, back and extremity pain occurs in 50% of patients; over time it may be reported by 80% of patients
- d. Rarely back and radicular pain precedes weakness
- e. Occasionally there is a sensory level on the trunk but no analgesia below the level; there is a variant with transverse myelitis in association with the classic pattern in which there is profound sensory loss
2. Weakness:
 - a. The usual pattern is mild distal weakness that may progress to complete quadriparesis
 - b. The weakness is first noted in the legs, then ascends to include the trunk, arms, head, and neck. This pattern is usually symmetrical
 - c. 10% of patients have upper extremity weakness greater than lower extremity weakness
 - d. In 60% the lower extremities are weaker than the upper extremities
 - e. Approximately 30% upper and lower extremities are equally affected
 - f. Descending weakness occurs in approximately 14% of patients
 - g. Proximal weakness may be greater than distal weakness
 - h. Rarely fasciculation or myokymia is noted

Cranial Nerve Involvement

1. Symmetrical peripheral facial weakness is appreciated in 60–70% of severe patients; rarely it is unilateral in association with asymmetric motor weakness; quadriparesis without facial weakness is rare
2. 10–20% of patients have partial or complete ophthalmoplegia or ptosis
3. Respiratory paralysis occurs in approximately 30% of patients within two weeks

Sphincter Involvement

1. Urinary retention for 1–2 days occurs in approximately 2% of patients; often associated with spinal type paresthesias
2. Fecal incontinence occurs in 1% of patients

Autonomic Dysregulation

1. Common
2. Occurs most commonly with quadriparesis and during ventilator support
3. Manifestations:
 - a. Sinus bradycardia
 - b. Sinus arrest
 - c. Variety of supraventricular arrhythmias
 - d. Paroxysmal hypertension or hypotension
 - e. Vagal episodes:
 - i. Bronchorrhea, bradycardia, and hypotension

- f. Ileus
- g. Peripheral vasomotor instability, cyanosis and livedo reticularis
- 4. Areflexia most often occurs within one week; diminished or absent reflexes in a paretic limb by three days
- 5. Course of the illness:
 - a. Average time to nadir is approximately 17–20 days
 - i. It occurs after the first week in 40% of patients
 - ii. 80% after the second week
 - iii. 90% by the third week

Unusual Features within the Classic Presentation

1. Unilateral paralysis
2. Radicular pain and weakness at onset
3. Severe neck, back and extremity pain; deep ache, mechanical and thermal allodynia; hyperalgesia (the “meningitis variant”)
4. Central features (associated with peripheral manifestations):
 - a. Optic neuritis
 - b. Babinski sign
 - c. Conjugate recovery of ophthalmoplegia:
 - i. Recovery of upgaze earlier than horizontal gaze
 - ii. Preservation of Bell’s phenomenon with impaired voluntary gaze
5. Severe generalized burning pain (peripheral C-fiber mediated)
6. Early and almost pure respiratory failure (often associated with deltoid muscle and flexor and extensor neck muscle weakness)
7. Early severe vibration and position sense loss (sensory ataxia)
8. Preserved triceps reflex
9. Increased intracranial pressure:
 - a. Bilateral papilledema
 - b. Increased CSF protein
 - c. Cytotoxic intracranial edema (Joynt hypothesis)
 - d. Blockage of the Pacchionian granulations (Denny-Brown hypothesis)
 - e. Respiratory paralysis; $PCO_2 > 70$ mm/Hg
10. Severe ataxia (Richter’s variant):
 - a. Primary involvement of large peripheral nerve fibers, A-beta and A-alpha fibers; heavily myelinated afferents that carry proprioception and vibratory sensibility to the dorsal root ganglia (DRG)
 - b. Severe ataxia of the upper and lower extremities
 - i. The ataxia is evident through all components of the movement rather than the terminal 1/3 which is characteristic of cerebellar disease
 - c. In Richter’s variant there is less loss of proprioceptive position sense than expected; it is hypothesized that the primary defect is abnormal spindle afference to the cerebellum
11. Transverse myelitis (concomitant with the peripheral demyelination):

- a. Occurs concomitantly with the onset of the peripheral neuropathy
- b. A clear sensory level (usually at T4–T6)
- c. Bowel and bladder are involved
- d. Reflexes in the arms may be greater or more active than those of the legs
- 12. Miller-Fisher syndrome:
 - a. Ophthalmoplegia
 - b. Ataxia
 - c. Areflexia
 - d. Anti-GQ1b antibody
 - e. May present with only two components of the triad
 - f. Excellent prognosis
- 13. Bickerstaff’s brainstem encephalitis:
 - a. Acute ophthalmoplegia and ataxia
 - b. Alterations in mental status
 - c. Babinski sign
 - d. Hemisensory loss
 - e. Most likely on a continuum of Miller-Fisher syndrome
 - f. A significant proportion of patients demonstrates anti-GQ1b IgG

Designated GBS Variants

1. Miller-Fisher syndrome
2. Bickerstaff’s encephalitis
3. Idiopathic cranial neuropathy
4. Pharyngeal-cervical-brachial (descending variant)
5. Transverse myelitis
6. Acute sensory neuropathy/ganglionopathy (Richter’s variant)
7. Acute small fiber neuropathy (C-fiber mediated generalized burning pain)
8. Acute autonomic neuropathy
9. Severe back and neck pain (“meningitis form”)

Neuropathology

1. Perivascular mononuclear cell infiltration of macrophages and lymphocytes; early predisposition for nerve roots in areas of peripheral nerve root entrapment and motor nerve terminals
2. Nodes of Ranvier demonstrate alteration of paranodal myelin and demyelination of internodal segments
3. In severe cases, polymorphonuclear cells may be concomitantly seen with monocytes in areas of axonal degeneration
4. Recovery demonstrates remyelination with reduced myelin to axon ratio associated with an increased number of internodes

Laboratory Evaluation

1. Cardiac arrhythmias:
 - a. Occur in 10–80% of patients:
 - i. Sinus tachycardia (30–60%)
 - ii. Sinus bradycardia (10–30%)
 - iii. Premature atrial and ventricular contractions

- iv. Ventricular tachycardia and asystole are rare except in the autonomic variant
- b. EKG:
 - i. Abnormalities occur in 50–80% of patients
 - ii. Depressed ST segments
 1. Inverted T-waves: varying QT intervals
 - iii. Mild or asymptomatic glomerulonephritis
 - iv. Inappropriate ADH occurs in 7–25% of patients (the usual serum sodium is between 120–130 meq/dl)
 - v. Diabetes insipidus is very rare
 - vi. Ileus and gastric retention occur in >40% of patients
 - vii. Compression mononeuropathy is seen primarily in the peroneal and ulnar nerves
 - viii. Pseudotumor cerebri occurs in 1–3% of patients
 - ix. Pulmonary emboli (dramatically decreased incidence with the use of compression boots)
- c. EMG evaluation:
 - i. Prolonged distal motor latencies early in the course of the disease
 - ii. Conduction block with >20% progressive reduction of CMAP (30% of patients)
 - iii. Slowing of motor nerve conduction with dispersion of the alpha waveform; conduction velocities may decrease during recovery due to remyelination (some patients)
 - iv. Slowed sensory nerve conduction velocities occur by three weeks of illness in 75% of patients; decreased sensory amplitudes
 - v. Median and ulnar sensory potentials are decreased when the sural nerve may be normal
 - vi. Positive sharp waves and fibrillation potentials are usually demonstrated within the first four weeks in approximately 20–60% of patients
 - vii. Fisher variant:
 1. Reduced or absent sensory potentials with normal motor studies
 - viii. Abnormal spontaneous activity is noted in affected muscles in 2 to 4 months
 - ix. Myokymia may be seen in the face and extremities early in the course of the illness
 - x. Approximately 15 to 20% of patients may have normal nerve conduction velocities
 - xi. Conduction velocities may remain normal for several weeks in a small number of patients
2. CSF abnormalities:
 - a. Cytoalbuminologic dissociation occurs in 80–90% of patients
 - b. In general, five lymphocytes or less/mm³ are seen; rarely up to 20 lymphocytes/mm³
 - i. The more cells that are seen, the more likely another problem such as lymphoma, carcinomatosis of the meninges, or leukemia is involving the nerve roots
 - ii. HIV, Lyme's disease, and sarcoidosis are the exception and may demonstrate >40 lymphocytes/mm³
 - c. Protein elevation:
 - i. Starts approximately on day 3 to 10
 - ii. The usual levels that are attained are between 100–180 mg/dl; it is extremely rare to note levels greater than 500 mg/dl (this level suggests a spinal block; Froin's reaction)
 - d. Autoimmune antigenic targets at the node of Ranvier:
 - i. Approximately 30% of patients with acute or chronic inflammatory demyelinating polyneuropathy have autoantibodies that are demyelinating
 - ii. Specific antigens are identified in approximately 13% of patients
 - iii. Autoantibodies identified at the node of Ranvier include:
 1. Neurofascin 186
 2. Gliomedin and moesin in the nodal domain
 3. Paranodal domain:
 - a. Contactin-1
 - b. Caspr-1
 - c. Neurofascin 155

Axonal GBS (AMASN)

General Characteristics

1. Clinically and early EMG findings are similar to AIDP

Clinical Manifestations

1. There is sensory loss early in the hands and feet to all modalities
2. Patients have a more rapid course over days, rather than 1–2 weeks as is more typical of AIDP
3. Ophthalmoplegia, dysphagia, and respiratory muscle weakness can occur
4. Autonomic dysregulation with blood pressure variation and cardiac arrhythmias occur
5. There is loss of segmental motor stretch reflexes
6. Recovery is less complete than in AIDP

Neuropathology

1. Sensory and motor nerve biopsies have demonstrated demyelination rather than a primary axonopathy in patients with inexcitable motor and sensory electrodiagnostic studies
2. A subgroup of patients appears to have a primary axonopathy
3. Demyelination and lymphocytes are absent or minimal on nerve biopsy
4. Axonal degeneration affects the dorsal and ventral roots as well as peripheral nerves
5. Three autopsied patients who succumbed early in the course of the illness demonstrated macrophages in the periaxonal space of myelinated internodes as well as rare intra-axonal macrophages; these changes are seen in AMAN but rarely in AIDP

6. AMSAN may follow *C. jejune* infection; there is some support for “molecular mimicry” between GM1 or GM1a on the nodal axolemma and pathogens in the immune response

Laboratory Evaluation

1. CSF cytoalbuminologic dissociation is usual
2. GM1 antibodies concordant with *C. jejune* infection is common
3. EMG:
 - a. Decreased amplitudes or absent CMAPs are demonstrated within 7–10 days
 - b. Distal latencies of the CMAP and nerve conduction velocities, if obtainable, are minimally affected
 - c. Decreased recruitment
 - d. In time (weeks) needle EMG demonstrates fibrillation potentials and positive sharp waves most marked in distal regions of affected muscles

Acute Motor Axonal Neuropathy (AMAN)

General Characteristics

1. Identified in patients with seasonal acute flaccid paralysis in Northern China; has now been identified worldwide
2. An antecedent infection (most often gastrointestinal) occurs in 30 to 85% of patients
3. 67% to 92% of patients have serological evidence of *C. jejune* infection associated with the illness
4. Not uncommon in both Asians and Central and South Americans

Clinical Manifestations

1. Occurs in both children and adults, and presents as a sudden onset of generalized weakness
2. Distal muscles are more severely affected than proximal muscles
3. Approximately 1/3 of patients have cranial nerve deficits and respiratory failure
4. There are no sensory signs or symptoms
5. Cardiac arrhythmias, hyperhidrosis, and blood pressure fluctuations occur
6. Muscle stretch reflexes may be normal or absent and occasionally are exaggerated during the recovery phase
7. AMAN progresses more rapidly and has an earlier peak than demyelinating forms; recovery time is similar to AIDP

Neuropathology

1. Lengthening of nodal gaps occurs early in the illness
2. Deposition of IgG and complement activation factors (C3d and C5,6–9) occurs in nodal and internodal axolemma of motor fibers
3. Macrophages are noted in the affected nodes of Ranvier and periaxonal space
4. Axon retracts from the Schwann cell due to macrophage migration through the Schwann cell basal lamina

and dissects beneath the myelin sheath to the periaxonal space

5. If axons degenerate, the innermost myelin sheath (adaxonal lamina) may remain intact
6. Degeneration of large myelinated intramuscular nerve fibers is noted
7. Pathogenesis:
 - a. Lymphocytes and autoantibodies that link to GM1 or GD1 gangliosides located at the nodes of Ranvier activate complement which alters sodium channel clusters and axonal junctions

Laboratory Evaluation

1. Cytoalbuminologic dissociation in the CSF is seen. Lack of pleocytosis is a distinguishing point from poliomyelitis
2. Serological evidence of recent *C. jejune* infection is seen in the majority of patients
3. Elevation of GM1 and GD1a antibodies occurs commonly
4. EMG:
 - a. Nerve conduction studies reveal low amplitude CMAPs with normal SNAPs when obtainable
 - b. CMAP distal latencies and conduction velocities are slow, as are F-waves
 - c. Rarely, conduction block without other features of demyelination occurs
 - d. Sural sparing occurs
 - e. Needle EMG reveals positive sharp waves, fibrillation potentials, and decreased recruitment of MUAPs
 - f. Autonomic studies are less impaired than in AIDP

GBS Variants

Miller-Fisher Syndromes

General Characteristics

1. There is a spectrum between Miller-Fisher syndrome and Bickerstaff's encephalitis which includes alterations in consciousness and hemisensory loss as well as ophthalmoplegia, ataxia, and areflexia
2. There is a 2:1 male predominance and it occurs in children
3. In more than 2/3 of patients, there is a preceding infection

Clinical Manifestations

1. The mean age of onset is in the fourth decade
2. Diplopia is usually the first symptom followed by:
 - a. Sensory ataxia and incoordination
 - b. Complete ophthalmoplegia with ptosis; pupillary involvement is rare
 - c. Facial weakness, dysarthria, and dysphagia occur in a significant proportion of patients
 - d. Limb weakness occurs in approximately 1/3 of patients
 - e. Paresthesia of the face and distal extremities in approximately 50% of patients; delayed facial weakness
 - f. Generalized weakness may supervene
3. Patients start to recover in approximately two weeks, and a full recovery may be seen by six months

Neuropathology

1. Demyelination and inflammatory infiltrates in cranial nerve III, IV, VI
2. Inflammation in the sensory ganglia of peripheral nerves
3. GQ1b antibodies directed against oculomotor nerves and sensory ganglia

Laboratory Evaluation

1. Cytoalbuminologic dissociation is seen in the CSF (in approximately 60% of patients)
2. Serologic evidence of recent infection with *C. jejune*
3. Anti-GQ1b antibodies are noted in a significant number of patients (approximately 80%); they peak in the first week. The profile is similar in Bickerstaff's variant
4. EMG:
 - a. NCS reveal decreased amplitudes of SNAPs that is out of proportion to prolongation of distal latencies or sensory conduction velocities
 - b. CMAPs in the extremities are usually normal
 - c. In >50% of patients, there is mild to moderate decrease of facial CMAPs
 - d. Sural nerve sparing

Idiopathic Sensory Neuropathy*General Characteristics*

1. Proposed to be an autoimmune process directed against the dorsal root ganglia (DRG)
2. Known diseases with prominent DRG pathology include:
 - a. Paraneoplastic syndromes (anti-Hu antibodies)
 - b. Sjögren's syndrome
 - c. Toxins
 - d. Infections (Herpes Zoster and simplex)

Clinical Manifestations

1. Age of onset is between 18 and 81 years
2. There may be an abrupt onset, or symptoms may evolve over days and even years; the course can be chronically progressive or relapsing as well as monophasic
3. Rare antecedent infections are reported (Epstein-Barr virus)
4. Presentation is numbness and tingling of the extremities, face, and trunk
5. Symptoms begin asymmetrically in the upper extremities in more than 50% of patients; most often the sensory symptoms are generalized, but they can remain localized
6. Radicular symptoms may occur and are often painful
7. Decreased large myelinated fiber afference; vibration and proprioception are affected to a greater degree than pain and temperature
8. Sensory ataxia is prominent
9. Pseudoathetosis of the outstretched upper extremities may be evident
10. Positive Romberg sign
11. Muscle stretch reflexes are decreased or unobtainable:

- a. There may be proximal progression of sensory loss over days to months; the face is frequently affected early with paresthesias around the mouth
 - b. There is no weakness or respiratory failure
12. Most often there is improvement of sensory parameters within 1–2 months after onset

Neuropathology

1. Sensory nerve biopsy:
 - a. Preferential loss of large myelinated fibers (12–22 μ) as opposed to small thinly myelinated (1–4 μ A-delta fibers) or unmyelinated 1 μ fibers
 - b. Mild perivascular inflammation
 - c. No segmental demyelination
2. One autopsy (five weeks after onset of the illness) revealed:
 - a. Inflammation of sensory and autonomic ganglia with loss of neurons and Wallerian degeneration
 - b. Normal motor roots and neurons
 - c. Consistent with a CD8⁺ T-cell mediated process directed against DRG neurons

Laboratory Evaluation

1. Most often the CSF protein is normal or only slightly elevated; high proteins have been reported
2. Rare pleocytosis
3. A subgroup of patients has an IgM, IgG or IgA monoclonal gammopathy as well as increased GD1b antibodies
4. Antifibroblast growth factor receptor 3 antibodies have been identified in a subgroup of patients in whom an autoimmune pathogenesis was suspected
5. EMG:
 - a. SNAPs are often unobtainable; in those that can be studied, there are normal distal sensory latencies and conduction velocities or slightly prolonged latencies or decreased CVs
 - b. Differential EMG parameters:
 - i. An absent or abnormal blink reflex supports a non-paraneoplastic etiology of sensory neuropathy
 - ii. The masseter reflex is abnormal in patients with a sensory neuropathy but is normal with sensory neuronopathy

Acute Small Fiber Sensory Neuropathy*General Characteristics*

1. Many of these neuropathies are idiopathic. The most common well-described small fiber neuropathies include:
 - a. Diabetes mellitus
 - b. Amyloidosis
 - c. Sjögren's syndrome
 - d. Transthyretin-met 30 gene mutations
 - e. Antisulfatide antibody neuropathy
 - f. Some paraneoplastic antibodies
 - g. Hereditary sensory and autonomic neuropathies

Clinical Manifestations

1. The usual small fiber neuropathies present insidiously with burning pain and autonomic dysregulation in the extremities, with preserved strength and reflexes
2. In autoimmune small fiber neuropathy:
 - a. Presentation may be acute
 - b. The pattern may or may not be length dependent
 - c. An antecedent infection is common
 - d. Pain and temperature modalities are primarily affected
 - e. Normal or brisk muscle stretch reflexes are demonstrated
 - f. Strength is maintained
 - g. Burning and dysesthesia usually abate by four months, but objective sensory loss may last longer

Neuropathology

1. Skin biopsy:
 - a. Reduced intraepidermal nerve fiber density
 - b. Alterations in sweat glands

Laboratory Evaluation

1. CSF evaluation often demonstrates cytoalbuminologic dissociation
2. EMG:
 - a. Motor and sensory conduction velocities are normal
3. Alterations in autonomic nerve testing
4. QST:
 - a. Increased thermal thresholds as well as cold pain thresholds

Autoimmune Autonomic Neuropathy*General Characteristics*

1. Autoimmune autonomic ganglionopathy is a pure autonomic disorder which affects both cholinergic and adrenergic function
2. This is a heterogeneous neuropathy in regards to onset, specific autonomic deficits, and the presence of somatic involvement

Clinical Manifestations

1. The onset may be abrupt, or insidious and chronic
2. Approximately 20% of patients may have selective cholinergic dysfunction, while the vast majority demonstrate widespread sympathetic and parasympathetic dysfunction
3. Approximately 80% of patients have orthostatic signs and symptoms
4. Gastrointestinal dysfunction occurs in approximately 70% of patients
5. Heat intolerance and hypohidrosis is very common
6. Blurred vision
7. Dry mouth and sicca signs
8. Urinary retention or incontinence
9. Approximately 1/3 of patients have numbness, dysesthesia of the distal extremities

10. Impotence may be severe and an early sign
11. The course is most often monophasic, with a plateau phase that is followed by partial recovery

Neuropathology

1. Nerve biopsy:
 - a. Decreased density of small diameter myelinated nerve fibers (1–4 μ)
 - b. Stacks of empty Schwann cell profiles and collagen pockets
 - c. Mild epineural perivascular inflammation
 - d. Autopsy material:
 - i. Neuronal loss in thoracic sympathetic and dorsal root ganglia

Laboratory Evaluation

1. Cytoalbuminologic dissociation (slightly elevated protein)
2. Decreased standing plasma norepinephrine levels
3. Approximately 20% of patients have elevated serum levels of ganglionic acetylcholine receptor autoantibodies
4. EMG:
 - a. Routine motor and sensory nerve conduction studies and needle EMG evaluation are normal
 - b. QST:
 - i. Alteration in thermal thresholds
 - c. Autonomic evaluation:
 - i. In greater than 60% of patients, there is reduced variability of the heart rate with deep breathing
 - ii. Abnormalities in the Valsalva maneuver include:
 1. Exaggerated fall of the blood pressure during early phase II of the response
 2. Absent recovery of the systolic and diastolic blood pressure during late phase II
 3. Reduced or absent overshoot of the systolic and diastolic blood pressures during phase IV
 - iii. Absent sympathetic skin responses
 - iv. Thermoregulatory sweat test:
 1. Areas of anhidrosis are seen between 12 to 97% of patients
 - v. Abnormalities of gastrointestinal motility throughout the GI tract

Pharyngeal-Cervical-Brachial Variant (Munsat's Variant)*General Characteristics*

1. A regional pattern of involvement; descending paralysis occurs in approximately 10% of patients who develop GBS

Clinical Manifestations

1. Weakness is limited early to pharyngeal and neck muscles that spread to the upper extremities; the legs are spared
2. Ptosis is common
3. Severe swallowing and respiratory compromise may occur
4. Approximately 30% of patients have an antecedent infection caused by C. jejune
5. AIDP, Miller-Fisher syndrome, and Bickerstaff's encephalitis overlap

Neuropathology

1. Axonal neuropathy

Laboratory Evaluation

1. Anti-GT1a IgG antibodies are positive in approximately 50% of patients; anti-GQ1b IgG antibodies are positive in approximately 40% of patients; IgG antibodies to GM1, GM1b, GD1a and GalNAC-GD1a1 serological markers for axonal GBS are detected in 27% of patients
2. 5% of descending GBS (pharyngeal cervical brachial variant) have anti-GT1a IgG antibodies which may cross react with GQ1b antibodies; the IgG GQ1b antibodies seen in Fisher syndrome almost always cross react with GT1a
3. EMG:
 - a. NCV are normal early; demyelinating features may be noted later in the upper extremities
 - b. Slightly elevated CSF protein

Paraparetic Variant*General Characteristics*

1. In one large study (492 patients) 8% had paraparesis

Clinical Manifestations

1. Presentation with paraparesis without arm or hand weakness; normal upper extremity strength was maintained throughout period of illness in 77% of patients
2. These patients have a milder phenotype than those with quadriparesis:
 - a. Less cranial nerve involvement
 - b. Milder leg weakness
3. 50% of patients have arm sensory deficits
4. 73% have absent arm reflexes

Neuropathology

1. Not determined

Laboratory Evaluation

1. MRI:
 - a. Lumbar spinal roots may demonstrate gadolinium enhancement
2. EMG:
 - a. Demyelinating features
 - b. NCV studies include arm as well as leg involvement in approximately 80% of patients who have cauda equina or spinal cord involvement

The Differential Diagnosis of AIDP**Overview**

In general, the differential diagnosis of AIDP is very straightforward, although subtypes and variants form a spectrum with overlapping features. The basic pathophysiology is autoimmune, and in most instances there is a history of upper

respiratory or gastrointestinal illness (particularly *C. jejune*), a monophasic disease course, and symmetrical extremity and cranial nerve weakness. Delayed facial weakness occurs in AIDP and the Miller-Fisher variants. There are pure motor and sensory axonal forms, and there is overlap between the Fisher and Bickerstaff variants. Rarely the process is descending with severe cranial-pharyngeal weakness. Several studies have demonstrated white matter hyperintensities on MRI with variable signs during the course of AIDP. Spinal cord involvement with both long and short segment MRI documented myelitis is seen. The Miller-Fisher variant and Bickerstaff's brainstem encephalitis (now primarily thought to be a spectrum) may be misdiagnosed as a brainstem stroke, botulism, or myasthenia gravis. Bickerstaff's encephalitis may appear similar to Wernicke's encephalitis due to its alteration in consciousness. The reflexes in AIDP may remain normal or are increased in approximately 10% of patients. Experimental studies suggest that there are inhibitory fibers in the ventral roots that when affected primarily may increase reflexes. Alternatively, demyelination of the cortical spinal tracts anywhere in their course would disinhibit muscle stretch reflexes below the level of the lesion. The paraparetic form may be misdiagnosed as a CMV infection in a patient with HIV. Chronic inflammatory demyelination polyneuropathy and a severe aggressive episode of multiple sclerosis have clinical signs that resemble AIDP. Complicating the diagnosis, however, are patients who present without an obvious history of prior infection, or with associated neurological or medical problems that alter their mental status.

A high cervical spinal cord injury causes flaccid quadriplegia, loss of bowel and bladder control, hypothermia (97° Fahrenheit) and hypotension. If it is acute and severe, males may ejaculate or have an erection. Acute inflammatory myopathy may be associated with sore muscles, rare diaphragmatic weakness, depressed but not absent muscle stretch reflexes, and no bowel or bladder dysfunction. Metabolic muscle disease, periodic paralysis, hypophosphatemia and hypercalcemic states spare the cranial nerves and bowel and bladder. Myasthenia gravis usually affects the extraocular muscles more than extremity musculature, but both can be affected concomitantly during exacerbations. There is no sensory loss, muscle stretch reflexes are maintained, and the pupils are clinically normal. Hyperkalemic periodic paralysis may present with generalized weakness, normal mentation, some myotonic features, no bowel or bladder dysfunction, and absent myotatic and muscle stretch reflexes. Toxic neuropathies that cause acute paralysis often have concomitant CNS involvement.

Acute Peripheral Neuropathies**Toxic Neuropathies***General Characteristics*

1. History of exposure
2. Involvement of other organ systems

Clinical Manifestations

1. Thallium (hair loss, distal extremity pain)
2. Arsenic (hyperkeratosis, GI symptoms)
3. Lead (encephalopathy, hypertension, abdominal pain)
4. N-hexane (encephalopathy; industrial exposure)

Acute Demyelinating Neuropathies

1. Amiodarone (painful; skin changes)
2. Perhexiline (lumbosacral roots)
3. Gold (rash; wasting of intrinsic hand muscles)
4. Alcohol (painful, associated with neuropathy from pan-tothenic acid deficiency and concomitant B12 deficiency)

Drugs

1. Vincristine/vinblastine
2. Cisplatin
3. Paclitaxel
4. Gold
5. Chloroquine (concomitant muscle involvement)
6. Mervacor (all cholesterol lowering agents) usually a painful symmetrical distal neuropathy but rarely a GBS presentation
7. Disulfiram
8. Nitrofurantoin
9. Isoniazid
10. Emetine

Infections

1. Diphtheria (pharyngeal muscles)
2. Tick paralysis (ataxia is often more prominent than weakness)
3. Poliomyelitis
4. Enteric viruses
5. Lyme's disease
6. HIV
7. CMV

Metabolic

1. Porphyria (AIP, variegate and coproporphyria)
2. Hypermagnesemia
3. Hypophosphatemia (concomitant muscle involvement; proximal > distal)
4. Hyperkalemia, potassium level > 6 mg/dl
5. Renal tubular acidosis
6. Secondary hypokalemic periodic paralysis
7. Hyperaldosteronism

Toxins

1. Organophosphate insecticides
2. Hydrocarbons
3. Buckthorn
4. Toluene
5. Solvents

Autoimmune Diseases

1. Demyelinating disease (MS, ADEM, acute hemorrhagic leukoencephalitis)
2. CIDP
3. Vasculitis (SLE, Sjögren's, Periarteritis nodosa)

Acute Quadriparesis

1. Hypokalemic periodic paralysis (severe hypokalemia with fewer EKG changes than the very low potassium produces in other circumstances; lid retraction; no myotatic reflexes)
2. Tick paralysis:
 - a. Ataxia precedes weakness and low muscle stretch reflexes
3. Organophosphate poisoning:
 - a. Miosis
 - b. Hyperhidrosis
4. Botulism:
 - a. Ptosis
 - b. Pupillary dilatation
 - c. Pharyngeal paralysis
 - d. GI symptoms
5. Myasthenia gravis:
 - a. Cranial nerve involvement
 - b. Muscle stretch reflexes are spared
6. Polymyositis:
 - a. Painful swollen muscles (particularly with severe rhabdomyolysis)
 - b. Retained reflexes
7. Critical care neuropathy:
 - a. Usually at least 2 to 3 weeks in the ICU
 - b. Concomitant large fiber myopathy
 - c. Multi-organ involvement
 - d. Concomitant sepsis
 - e. Difficulty in weaning off a respirator

Acute Quadriparesis with Severe Pain

1. Acute intermittent porphyria:
 - a. Acute severe abdominal pain that is accompanied by a soft abdomen
 - b. Autonomic dysregulation (arrhythmia, paroxysmal hypo- and hypertension)
 - c. Non-dermatomal patchy sensory loss
 - d. Retained ankle muscle stretch reflexes
2. Arsenic poisoning:
 - a. Distal extremity weakness
 - b. Painful extremities
 - c. Hyperkeratosis of palms and soles
 - d. Mees lines in the fingernails
3. Vasculitic neuropathy:
 - a. Distal extremity weakness and sensory loss
 - b. Associated underlying medical conditions (SLE, PAN, Sjögren's syndrome)
 - c. Asymmetric extremity involvement
 - d. Asthma
 - e. Eosinophilia

4. Mononeuritis multiplex:
 - a. Underlying autoimmune cause; quadriceps pain with femoral nerve infarction

Acute Neuropathy with Prominent Sensory Abnormalities

1. Autoimmune:
 - a. Functional loss of the dorsal columns; large myelinated fiber modalities affected
2. Rabies:
 - a. Simulates the pharyngeal-cervical-brachial GBS variant
 - b. Pharyngeal spasms
 - c. Severe muscle pain
 - d. A motor neuropathy upon examination
3. Vasculitic neuropathies:
 - a. Mononeuritis multiplex
 - b. Approximately 15% of patients have distal symmetrical involvement; often not symmetrical by EMG evaluation
4. Ciguatera toxin:
 - a. Generalized burning pain
 - b. Large joint arthritic pain
 - c. The mouth is often involved
 - d. Paradoxical temperature perception (cold is felt as hot)
5. Thallium:
 - a. Distal pain
 - b. Alopecia
6. Arsenic poisoning:
 - a. Burning distal extremity pain
 - b. Hyperkeratosis of palms and soles
 - c. Vascular collapse
7. Perhexiline
 - a. Lumbosacral root involvement
8. Paralytic shellfish ingestion:
 - a. Domoic acid
 - b. Small fiber neuropathy
 - c. GI Symptoms

Increased CSF Protein and Acute Neuropathy

1. Carcinomatous meningitis
2. Leukemic and lymphomatous meningitis
3. Arsenic
4. Lead
5. Vincristine
6. Perhexiline
7. Thallium

Disorders of the Neuromuscular Junction Simulating AIDP

1. Myasthenia gravis:
 - a. Severe cranial nerve involvement, particularly the extraocular muscles with pupillary sparing
 - b. Muscle stretch reflexes are retained
2. Botulism:
 - a. Internal ophthalmoplegia (pupils are involved); nasopharyngeal weakness > ophthalmoplegia
3. Snake envenomation (neurotoxic):

- a. Pain at the site of envenomation
 - b. Perioral numbness
 - c. Pharyngeal paralysis
 - d. Toxin may be mixed; if hemotoxic component disseminated intravascular coagulation can be initiated
4. Hypermagnesemia:
 - a. No myotatic reflexes
 - b. Cranial nerves are spared
 - c. Usually occurs during the treatment of toxemia
 5. Aminoglycosides:
 - a. In the setting of gram-negative sepsis
 - b. Less cranial nerve involvement
 6. Tetanus:
 - a. Opisthotonus
 - b. Pharyngeal and masseter spasm
 - c. Extreme sensitivity to startle and sound
 7. Succinylcholine:
 - a. Prolonged exposure
 - b. Failure to move after surgery
 - c. May occur in an undiagnosed myasthenia patient (during surgery)

Acute Myopathy Simulating AIDP

1. Polymyositis:
 - a. No VIIth nerve involvement
 - b. Reflexes are relatively preserved
2. Acute rhabdomyolysis:
 - a. Severe edema of affected muscles
 - b. Tight, thin-appearing skin, often with blisters
 - c. Lumbar quadratus may be the first large muscle involved
 - d. Severe pain (mechanical hyperalgesia)
3. Critical care myopathy:
 - a. Associated with axonal neuropathy
 - b. May have diaphragmatic involvement
 - c. Usually patients have had a prolonged ICU stay associated with multiple medical complications

CNS Abnormalities Simulating AIDP

1. Acute transverse myelitis
 - a. Simulating the paraparetic variant
2. Cervical cord intrinsic pathologies:
 - a. Cavernous hemangioma bleed
 - b. Acute MS or ADEM
 - c. Metastasis
3. Rhombencephalitis:
 - a. Simulates the spectrum of Fisher syndrome and Bickerstaff's encephalitis
 - b. Herpes simplex (in HIV-infected patients)
 - c. CMV (lumbosacral root involvement in a terminally ill AIDS patient; CD4 T-cells < 50/mm³)
 - d. Listeria brainstem infection:
 - i. Dorsal pons involvement
 - ii. Occurs in pregnancy, immune suppression, and after ENT procedures

4. Locked-in syndrome:
 - a. Quadriplegia or -plegia
 - b. Vertical gaze and consciousness intact
 - c. No horizontal eye movements
5. Basilar artery infarction:
 - a. Pinpoint pupils (<0.5 mm)
 - b. Herald hemiparesis
 - c. May have prominent sensory loss
 - d. Pharyngeal muscle and horizontal gaze center involvement
2. There are four major patterns of progression:
 - a. Chronic monophasic (15%)
 - b. Fluctuating over weeks or months (approximately 30% of patients)
 - c. Stepwise (>30%)
 - d. Chronically progressive (15%)
3. The relapsing form presents in the second to third decade
4. Increased prevalence in men
5. Triggers include:
 - a. Infection
 - b. Vaccination
 - c. Surgery
 - d. Trauma

Distinguishing Acute-Onset CIDP from Fluctuating Guillain-Barré Syndrome

1. Treatment-related fluctuations of GBS
 - a. Occur within eight weeks
2. Chronic inflammatory polyneuropathy with acute onset:
 - a. Less severely affected than patients with AIDP and treatment-related fluctuations
 - b. Do not require mechanical ventilation
 - c. Rare cranial nerve involvement
 - d. CIDP EMG evaluation
 - e. Acute-onset CIDP is a high differential when a patient thought to have AIDP deteriorates after eight weeks from onset, as there are usually three or more episodes of neurologic deterioration

Chronic Inflammatory Demyelinating Polyneuropathy and Related Autoimmune Neuropathies

CIDP

General Characteristics

1. These are a heterogeneous group of inflammatory neuropathies that have overlapping clinical pathologic and electrodiagnostic features but a distinct pathogenesis
2. The entities include:
 - a. Chronic inflammatory demyelinating polyneuropathy (CIDP)
 - b. Distal acquired demyelinating sensorimotor neuropathy (DADS)
 - c. Multifocal acquired demyelinating sensory and motor neuropathy (MADSAM)
 - d. Multifocal motor neuropathy (MMN)
 - e. Multifocal acquired motor axonopathy (MAMA)
3. CIDP represent approximately 10 to 30% of undiagnosed peripheral neuropathy in referral centers
4. The course must be progressive for at least eight weeks which distinguishes it from AIDP; a variant, subacute demyelinating polyneuropathy, may have an onset over 4–8 weeks which can remit and thus would be AIDP or, if progressive, CIDP

Clinical Manifestations

1. The peak incidence is between 40 to 60 years of age

6. Infection has been identified as antecedent to relapse or exacerbation in 20–30% of patients; pregnancy may also trigger a relapse
7. Progressive symmetrical proximal and distal weakness of the extremities is most common; early distal extremity numbness and weakness may be prominent
8. 80% of patients manifest both motor and sensory involvement
 - a. Approximately 10% have a pure motor or sensory (5–10%) presentation
9. Numbness in the extremities occurs in 70–80% of patients; painful paresthesias occur in 15–50%
10. Large fiber modality deficits (vibration and proprioception) are found primarily on examination, and when severe, may cause sensory ataxia
11. There is loss or depression of muscle stretch reflexes
12. Facial muscles are rarely affected but can be, causing ophthalmoparesis, dysarthria, dysphagia, and sensorineural hearing loss; neck extensor weakness can cause a dropped head syndrome
13. Autonomic involvement is uncommon
14. Papilledema has been described in a subgroup of patients with a POEMS phenotype (polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy, skin changes)
15. Intercostal and diaphragmatic involvement is uncommon in classic CIDP
16. Approximately 3% of patients demonstrate CNS demyelination

Associated Medical Conditions

1. HIV
2. Inflammatory bowel disease
3. SLE
4. Diabetes mellitus
5. Monoclonal gammopathy
6. Paraneoplastic syndromes
7. Graft-versus-host or rejection following bone marrow transplantation
8. Neurotoxins

Neuropathology

1. Nerve biopsy:

- a. Segmental demyelination and remyelination
2. Proliferation of Schwann processes that form “onion bulbs” and nerve hypertrophy
3. Demyelination patterns include:
 - a. Segmental with remyelination (20–40%)
 - b. Axonal degeneration (20–40%)
 - c. Mixed demyelination and axonal degeneration (12%)
 - d. Normal evaluation (20–40%)
4. Endoneurial and perineurial edema
5. Inflammatory cell infiltrates in the epineurium, perineurium or endoneurium; most often is perivascular
6. Inflammatory cells include:
 - a. Macrophages
 - b. CD3⁺ activated T-cells (CD8⁺ and CD4⁺ lymphocytes)
 - c. Dendritic cells
7. Overexpression of matrix metalloproteinases by T-cells
8. Electron microscopy:
 - a. Cellular infiltrates:
 - i. Penetrate the basement membrane
 - ii. Lyse the superficial myelin lamellae
 - iii. Penetrate along intraperiod line
 - iv. Endocytosis disrupts myelin
 - v. Recruited Schwann cells remyelinate the demyelinated internodes
 - vi. Failure of regulatory T-cells mechanisms may be causative

Laboratory Evaluation

1. An elevated CSF protein is documented in 80–95% of patients; mean protein is 135 mg/dl but levels >1000 mg/dl often occur with POEMS
2. The cell count is most often normal, but approximately 10% of patients have >5 lymphocytes/mm³. High cell counts in the CIDP setting suggest:
 - a. HIV
 - b. Lyme’s disease
 - c. Neurosarcoidosis
 - d. Carcinomatosis of the meninges
 - e. Lymphoma/leukemia
3. CSF oligoclonal bands are found in approximately 65% of patients
4. IgA, IgM or IgG monoclonal gammopathy occurs in 25% of patients
5. A subgroup of patients has demonstrated antibodies against GM1, P0, and P2 myelin proteins

Neuroimaging

1. MRI:
 - a. Demonstrates hypertrophy and enhancement of nerve roots and peripheral nerves
2. EMG:
 - a. Reduction in conduction velocity in two or more nerves
 - b. Partial conduction block or abnormal temporal dispersion in one or more motor nerves
 - c. Prolonged distal latencies in two or more nerves

- d. Absent F-waves or prolonged minimum F-wave latencies

Differential Diagnosis

1. If weakness is distal throughout the course:
 - a. Rule out hereditary demyelinating neuropathies
2. Sensory signs out of proportion to muscle weakness:
 - a. Rule out IgM monoclonal gammopathy with or without antibodies against myelin-associated glycoprotein (MAG)
 - b. Pure sensory neuropathy:
 - i. A small group of CIDP patients with “chronic sensory demyelinating neuropathy”
 - ii. Sjögren’s syndrome
 - iii. Sensory ganglionitis of paraneoplastic origin
3. Differential points between chronic demyelinating sensory polyradiculopathy versus sensory ganglionitis and anti-MAG induced neuropathies include:
 - a. Decreased or absent reflexes
 - b. Normal sensory SNAPs
 - c. Abnormal H-reflexes and somatosensory evoked potentials (proximal demyelination of sensory roots)
 - d. Papilledema and respiratory insufficiency:
 - i. Occurs most often in the setting of CIDP POEMS
 - ii. Rule out underlying plasmacytoma or lymphoma
 - e. Approximately 3% of CIDP patients have clinical, MRI or electrodiagnostic features of CNS demyelination
 - i. CIDP can precede or follow attacks of central demyelination
 - f. Rare diabetic patients have:
 - i. Asymmetric proximal and distal arm and leg weakness
 - ii. An elevated CSF protein
 - iii. Characteristic demyelination on electrodiagnostic studies
 - g. CIDP phenotype may be produced by toxins which include:
 - i. Cyclosporine
 - ii. Tacrolimus
 - iii. Tumor necrosis factor alpha (TNF-alpha) blockers
 - h. The most common malignancies associated with CIDP include:
 - i. Melanoma
 - ii. POEMS syndrome (Plasmacytoma)
 - iii. Lymphoma
 - iv. Castleman’s disease
 - v. Waldenström’s macroglobulinemia
 - vi. Carcinoma of the lung, pancreas, colon, and choriocarcinoma

Distal Acquired Demyelinating Symmetric Polyneuropathy (DADS)

General Characteristics

1. The phenotype is based on the pattern of weakness in patients with features of CIDP
2. DADS patients have only distal signs and symptoms

Clinical Manifestations

1. Mild symmetric distal weakness
2. Distal and symmetric sensory loss
3. Decreased or absent muscle stretch reflexes

Neuropathology

1. Elevated IgM (primarily anti-MAG); rare GM1 antibodies
2. Demyelinating and remyelinating characteristic on nerve biopsy; IgM deposition in paranodal areas
3. Decreased claudin-5 protein levels in microvascular endothelial cells

Laboratory Evaluation

1. Monoclonal proteins are detected in more than 50% of patients
2. In those patients with IgM-DADS neuropathy, 2/3 have MAG antibodies
 - a. These patients are older than those with idiopathic DADS neuropathy or CIDP; their mean age is 62 years
3. EMG:
 - a. CMAPs:
 - i. Demyelinating features with no conduction block
 - ii. Abnormal SNAPs
4. CSF protein: elevated

Multifocal Motor Neuropathy (MMN)*General Characteristics*

1. Prevalence range from 0.3–3 patients in 100,000 people
2. Males > females at 3:1
3. Is associated with the use of tumor necrosis factor blockers
4. The weakness is in the distribution of peripheral nerves whereas in ALS it is in the distribution of myotome

Clinical Manifestations

1. In 80% of patients, the onset is less than 50 years of age (mean age 40 with range between 20 and 70 years)
2. The onset is asymmetric and often in the upper extremity
3. The ulnar, median, and radial nerves are most commonly affected
4. There may be differences in the severity of involvement of different muscles supplied by the same nerve
5. In approximately 66% of patients, weakness starts in the distal upper limb with wrist and finger extension involvement
 - a. In approximately 25% of patients symptoms occur in the lower extremity initially; rarely it may start in the proximal muscles of an upper extremity
6. The onset is insidious as weakness progresses over years
7. Weakness is associated with cramps and fasciculations
8. Early in its course the weakness is not accompanied by muscle atrophy; rarely affected muscle groups are hypertrophied (possibly due to myokymia)
9. There may be vague sensory symptoms, numbness
10. Rare cranial nerve involvement

11. Muscle stretch reflexes are variable in unaffected muscles; weak and atrophic muscles have depressed reflexes
12. There are no corticospinal signs
13. There is usual involvement of two or more nerves, but monofocal motor neuropathy may be an early presentation

Neuropathology

1. MMN is characteristically associated with increased levels of IgM antibodies against ganglioside GM1
2. The association of GM1 antibody and a motor phenotype is also seen in acute motor axonal neuropathy (AMAN)
3. Autopsied patients reveal:
 - a. Immunoglobulin deposition and inflammatory demyelination in motor roots
 - b. There is more GM1 ganglioside in motor than sensory roots
 - c. Treatment with infliximab may cause a similar phenotype but with more rapid progression
4. GM1 is localized to both the axolemma and myelin of peripheral nerves:
 - a. Primarily at the nodes of Ranvier and adjacent paranodes
 - b. GM1 concentrates in the cholesterol enriched domains of the plasma membrane which stabilizes the paranodal area and modulates ion channel clustering by maintenance of tight junctions
5. Experimental studies support an autoimmune attack with complement activation that is effected by membrane attack complexes (MAC) that compromise the plasma membrane and nodal regions. The result is nodal disruption and sodium channel dispersion as well as axonal damage
6. Autoantibodies to neurofascin-186 and gliomedin may be found in MMN and may contribute to conduction block and motor weakness

Laboratory Evaluation

1. CSF is usually normal (differential point from CIDP and MADSAM)
2. Approximately 20 to 80% of patients have IgM serum antibodies against GM1 ganglioside; antibodies are also noted against asialo-GM1 and GM2; monoclonal proteins are rare
3. EMG:
 - a. Demyelinating features
 - b. Prominent conduction block
 - c. Normal SNAPs
 - d. Reduction in CMAP may occur in chronic patients due to secondary axonal degeneration
 - e. Motor NCS also demonstrate
 - i. Prolonged distal latencies
 - ii. Prolonged or absent F-waves
 - iii. Demyelinating features are more often found in the arms
 - iv. Electrophysiological deficits may occur in nerves that innervate normal muscles

Differential Diagnosis

1. Diagnostic points in favor of MMN versus amyotrophic lateral sclerosis:
 - a. MMN is predominant in the upper extremities
 - b. Lacks bulbar and respiratory muscle involvement
 - c. Less atrophy in weak muscles (at least early in the illness)
 - d. Cramps and fasciculations are less prominent than in motor neuron disease (occurs in approximately 50% of patients with MMN)
 - e. No upper motor neuron signs
 - f. Characteristic conduction block on EMG
 - g. MMN can have brisk reflexes in 8% of patients, or they can be normal in approximately 20% of patients
 - h. Rarely the phrenic nerve can be involved with associated respiratory embarrassment:
 - i. MMN is more asymmetric than CIDP and does not evolve into generalized weakness as rapidly
 - ii. Multifocal acquired demyelinating sensory and motor neuropathy (MADSAM may affect single nerves but has both clinical and electrodiagnostic features of sensory involvement)
2. Multifocal motor acquired motor axonopathy (MAMA)
 - a. A subgroup of rare patients has the clinical phenotype of MMN:
 - i. Only axonal features on electrodiagnostic studies
 - ii. Most patients lack GM1 antibodies
 - iii. May respond to immune therapies

MADSMA (Lewis-Sumner Syndrome)*General Characteristics*

1. A multifocal demyelinating neuropathy with persistent conduction block

Clinical Manifestations

1. A male predominance
2. A mononeuritis multiplex clinical picture
3. Weakness in the distribution of individual peripheral nerves
4. Mild wasting
5. Cramps and fasciculations
6. Partial loss of muscle stretch reflexes
7. Stepwise course
8. Lower limb involvement at onset is frequent but spread to the upper extremities is common in later stages of the disease
9. Cranial nerve involvement occurs with MNN
10. Mixed sensory and motor involvement occurs in approximately 50% of patients
11. Pain is seen in 20% of patients; oculomotor, facial and trigeminal are reported

Neuropathology

1. Sensory nerve biopsy:
 - a. Thinly myelinated nerve fibers are involved

- b. Endoneurial edema
- c. Occasional perivascular inflammatory infiltrates
- d. Asymmetric loss of large myelinated nerve fibers between and within fascicles
- e. Demyelinating and remyelinating feature

Laboratory Evaluation

1. CSF protein is usually increased
2. Rare monoclonal protein
3. GM1 antibodies are rare
4. EMG:
 - a. Demyelinating features
 - b. Conduction block
 - c. Abnormal SNAPs

Chronic Immune Sensory Polyradiculopathy (CISP)*General Characteristics*

1. Most probably a restricted variant of CIDP

Clinical Manifestations

1. Insidious onset of progressive numbness and paresthesias
2. Sensory ataxia
3. Presentation may be asymmetric; modalities of sensation that are affected are proprioception and vibration
4. Normal muscle strength
5. Absent or reduced muscle stretch reflexes

Neuropathology

1. Biopsy of lumbar sensory rootlets demonstrates:
 - a. Decreased density of large myelinated fibers
 - b. Demyelinated axons
 - c. Endoneurial edema
 - d. Onion bulb formation

Laboratory Evaluation

1. CSF has elevated protein with a normal cell count
2. No GM1, GD1b, GQ1b, Ro, or anti-La serum antibodies
3. EMG:
 - a. Routine motor and sensory NCS, as well as needle EMG, is normal
 - b. Reflexes are abnormal
4. Somatosensory evoked potential interpeak latencies show decreased conduction in proximal nerve segments
5. MRI:
 - a. Thickening and enhancement of nerve roots

Idiopathic Perineuritis*General Characteristics*

1. A non-specific inflammation and thickening of the perineurium most often associated with:
 - a. Diabetes mellitus
 - b. Ulcerative colitis
 - c. Connective tissue disease
 - d. Vasculitis

- e. Cryoglobulinemia
 - f. Lymphoma
 - g. Malignancies
2. It is idiopathic if it occurs without an underlying disease

Clinical Manifestations

1. Variable presentation:
 - a. A subgroup of patients develops sensory loss, hyperpathia, dysesthesia in a multiple nerve distribution
 - b. A group that is indistinguishable from AIDP or CIDP with generalized symmetric motor and sensory loss
 - c. Some patients complain of migratory sensory loss
 - d. May have a remitting and relapsing course
 - e. Examination may reveal positive Tinel's sign over peripheral nerves as well as hyperesthesia or hyperpathia in affected areas
 - f. Large fiber sensory modalities are less affected than small fiber modalities of pain and temperature
 - g. Usually, muscle strength is preserved, but generalized weakness has been noted
 - h. Normal muscle stretch reflexes

Neuropathology

1. Nerve biopsy:
 - a. Thickening and fibrosis of the perineurium with macrophage and lymphocyte infiltration
 - b. Axonal degeneration with loss of myelinated fibers
 - c. Mild perivascular inflammation

Laboratory Evaluation

1. Normal CSF, ANA, liver function profile, serum protein and electrophoresis
 - a. Abnormal laboratory profile suggests a specific underlying disease
2. EMG:
 - a. NCS demonstrate multifocal or generalized decrease in SNAP amplitudes or they are unobtainable
 - b. Normal motor nerve EMG and NCS

Vasculitic Neuropathy

General Characteristics

There are several different classifications of vasculitis that are based on:

1. The size of the affected blood vessel
2. Whether it is primary or secondary to a systemic disease or if it is systemic or isolated to the peripheral nervous system
 - a. All are immune-mediated pathologies; the attack being directed to blood vessels

Nomenclature Based on the 2012 Revised International Chapel Hill Consensus Conference

Large Vessel Vasculitis (LVV)

This is a vasculitis that affects the aorta and its major branches, although any size artery may be affected. The two major LVVs are Takayasu's arteritis and giant cell arteritis (GCA).

Medium Vessel Vasculitis (MVV)

This vasculitis predominantly affects medium-sized arteries, the main visceral arteries, and their branches. Any sized artery may be affected concomitantly. The two major diseases in this category are periarteritis nodosa (PAN) and Kawasaki disease (KD).

Small Vessel Vasculitis (SVV)

This vasculitis group of is divided into anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis and immune complex SVV. ANCA-associated vasculitis is necrotizing with minimal immune deposits that predominantly affects small vessels. The prefix indicates ANCA reactivity, i.e., MPO-ANCA (myeloperoxidase), or PR3-ANCA (anti-proteinase 3). The ANCA specificity identifies distinct disease categories.

ANCA-associated vasculitis is divided into:

1. Microscopic polyangiitis (MPS)
2. Granulomatosis with polyangiitis (Wegener's)
3. Eosinophilic granulomatosis with polyangiitis (Churg-Strauss)

Immune Complex Small Vessel Vasculitis

Immune complex SVV is a vasculitis in which there is moderate or extensive immunoglobulin deposition and complement factors that predominately affect small vessels. Glomerulonephritis is the most frequent pathology.

This category includes:

1. Anti-glomerular basement membrane disease (anti-GBM)
2. Cryoglobulinemia vasculitis (CV)
3. IgA Vasculitis (Henoch-Schönlein)
4. Hypocomplementemic intracranial vasculitis (HVV) (anti-Clq vasculitis)

Variable Vessel Vasculitis (VVV)

In this vasculitis, there is no predominant vessel size or type (arteries, veins, capillaries) that are affected. Behçet's disease and Cogan's syndrome comprise this category.

Single Organ Vasculitis (SOV)

This is a vasculitis in a single organ that is not an expression of a systemic vasculitis. The involved vessel type includes cutaneous small vessel vasculitis, testicular arteritis, and central nervous system vasculitis.

Clinical Manifestations

Peripheral nervous system vasculitis presents in 3 basic patterns:

1. A mononeuropathy or mononeuropathy multiplex
2. Overlapping mononeuropathies
3. Distal symmetric polyneuropathy

The mononeuropathy pattern usually evolves asymmetrically and affects multiple nerves. In overlapping mononeuropathies, different nerves on both sides of the body are affected to varying degrees, which leads to generalized but

asymmetric involvement. In progressive involvement of peripheral nerves, a generalized pattern of involvement develops that mimics a distal symmetric polyneuropathy. Between 6 to 70% of patients present with mononeuropathy or mononeuropathy multiplex. Approximately 30 to 40% of patients present with an asymmetric distal peripheral neuropathy. Patients with mononeuropathy or multiple mononeuropathies usually complain of burning or paresthesias in the affected nerve distribution. Examination reveals appropriate weakness and sensory loss. Rarely patients may have pure sensory loss. Muscle stretch reflexes are variable depending on the degree of nerve involvement.

Neuropathology

1. The most commonly biopsied sensory nerves are:
 - a. The sural
 - b. The superficial sensory branches of the peroneal
 - c. The radial sensory nerves
2. The diagnostic yield is improved if both muscle and nerve can be examined. This combination is most commonly obtained with superficial peroneal nerve and peroneus brevis biopsy
3. Transmural inflammatory cell infiltration is seen
4. Necrosis of the vessel wall occurs
5. Immunocytochemistry may reveal:
 - a. IgM and/or IgG
 - b. Complement
 - c. Membrane attack complex deposition on the affected vessel walls
6. Fiber loss between and within nerve fascicles
7. Axonal degeneration
8. Immunostaining of the epi- and endoneurial vessels, the perineum and monocytes may demonstrate:
 - a. Receptor for advanced glycosylation end products (RAGE)
 - b. Nuclear factor-kappa B
 - c. Interleukin 6 expressed by CD4⁺, CD8⁺ and CD68⁺ cells that invade peripheral nerves and strongly support the autoimmune mechanisms hypothesized as the cause of these illnesses
 - d. Skin biopsies may demonstrate a loss of epidermal nerve fibers in some patients

Systemic Vasculitis That Affect Large and Medium-Sized Vessels

Giant Cell Vasculitis

General Characteristics

1. Giant cell arteritis and Takayasu's disease are the two categories of large vessel arteritis. There is no peripheral neuropathy with Takayasu's disease
2. Affects large and medium-sized vessels primary of the aortic arch, internal and external carotid arteritis; rarely the vertebral arteries are affected

Clinical Manifestations

1. General neurological signs and symptoms:
 - a. Headache; often a burning scalp with associated mechanical allodynia is seen
 - b. Jaw and tongue claudication
 - c. Rarely palpable nodules are noted in the temporal artery
 - d. Tongue lesions (resembling squamous cell cancer) and a perforated nasal septum are noted
 - e. Ischemic optic neuropathy
 - f. Stroke
- g. Peripheral nervous system manifestations:
 - i. 10 to 15% of patients develop:
 1. Multiple mononeuropathies
 2. Radiculopathies
 3. Brachial plexopathies
 4. Generalized sensorimotor peripheral neuropathy

Neuropathology

1. Thrombosis of the ophthalmic and posterior ciliary arteries
2. Intense granulomatous or "giant cell" arteritis is seen in approximately 2/3 of patients

Neuroimaging

1. Ultrasound of the artery may reveal thickening
2. Contrast material enhanced magnetic resonance imaging (MRI) of superficial cranial arteries has a sensitivity of 78% and a specificity of 90%

Polyarteritis Nodosa

General Characteristics

1. The most common form of the necrotizing vasculitis
2. Primarily involves small and medium-sized blood vessels in multiple organs
 - a. The incidence is 2–9/million of the population

Clinical Manifestations

1. Presents between 40 to 60 years of age
2. Involved organs:
 - a. Long medullary arteries of the kidney
 - b. Bowel, skin and testes
 - c. Lobar liver infarction
 - d. Weight loss
 - e. Fever similar to that which occurs with lymphoproliferative disease
3. Multiple mononeuropathies
4. The sciatic nerve (peroneal or tibial branches) are the most commonly involved peripheral nerves
5. In less than 2% of patients, the cranial nerves or CNS is involved
6. Myalgias and arthralgias are seen in 30 to 70% of patients
7. Skin involvement is manifest by petechiae, livedo reticularis, subcutaneous painful nodules, and distal gangrene
8. Severe hypertension (occasional ICH) occurs with renal involvement

Neuropathology

1. Involvement of small nutrient arteries of peripheral nerves occurs in approximately 75% of patients (autopsy series)
2. A necrotizing arteritis primarily affecting medium-sized vessels
3. Fibrinoid necrosis of all 3 coats of the vessel wall; infiltrating eosinophils may be prominent
4. Muscle biopsy:
 - a. Perivascular inflammation and necrosis
5. Spared pulmonary circulation
6. Nerve biopsy:
 - a. Transmural infiltration of CD8⁺ T-cells, macrophages, and polymorphonuclear cells
7. Blood vessels may demonstrate IgM, IgG, complement components and membrane attack complexes
8. Aneurysms of the long medullary arteries of the kidney occur

Laboratory Evaluation

1. Approximately 1/3 of patients have evidence of Hepatitis B infection; may also be associated with hepatitis C and HIV
2. ESR is elevated in most patients

Churg-Strauss Syndrome (CSS)*General Characteristics*

1. Rarest subtype of anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis
2. Has the lowest frequency of ANCA-positivity (approximately 30%)
3. HLA-DRB4 association has been documented
4. Approximately 1/3 the incidence of PAN

Clinical Manifestations

1. A clinical overlap occurs between PAN, Churg-Strauss syndrome, and Hypereosinophilic syndrome
2. Rhinitis and asthma may be longstanding prior to onset
3. Later in the course of asthma there may be marked eosinophilia and an eosinophilic pneumonitis
4. The neuropathy is usually preceded by fever and weight loss
 - a. Acute painful mononeuropathy multiplex
5. Signs of systemic vasculitis usually are seen by three years after the onset of asthma. Late onset asthma in patients older than 35 years of age is a seminal feature
6. Approximately 20 to 50% of patients may develop a necrotizing glomerulonephritis (ischemic nephropathy occurs with PAN)
7. Several patients have used leukotriene antagonists after being weaned from corticosteroids. A few patients have been associated with macrolide antibiotic use

Neuropathology

1. Nerve biopsy: Necrotizing vasculitis similar to PAN; CD8⁺ T-cytotoxic lymphocytes, CD4⁺ cells, and eosinophilic infiltrates in the nerve are demonstrated

2. Intravascular and extravascular granulomas are rarely seen around affected blood vessels
3. Although the disease is usually considered Th2 mediated, recent evidence supports roles for Th1 and Th17 responses
4. HLA-DRB4 association has been described; CD4⁺ T-cells secrete IL4, IL5 and IL13 which are involved in allergic and eosinophilic processes
5. Eotaxin-3 and CCL17 that are secreted by endothelial and epithelial cells may amplify the immune response. FL5 is of particular interest as a mediator of eosinophilia
6. End organ damage may be caused by vasculitis or eosinophilic infiltration

Laboratory Evaluation

1. Eosinophilia, leukocytosis and elevated ESR
2. Increased C-reactive protein, rheumatoid factor and serum IgG and IgE levels are commonly detected
3. Approximately 2/3 of patients have positive anti-neutrophil antibodies primarily myeloperoxidase or p-ANCA
4. Approximately 50% of patients have pulmonary infiltrates by chest x-ray

Wegener's Granulomatosis (Granulomatosis with Polyangiitis)*General Characteristics*

1. The new designation is granulomatosis with polyangiitis
2. Necrotizing vasculitis which primarily affects medium- to small-sized blood vessels
3. Prevalence is 3/100,000 persons in the USA
4. More common in Caucasian ethnicity and slightly more common in men in European population

Clinical Manifestations

1. Granulomatous vasculitis of the upper and lower respiratory tract
2. Glomerulonephritis
3. Pulmonary involvement occurs in greater than 75% of patients
4. Orbital vasculitis occurs in approximately 50% of patients:
 - a. Inflammation of ocular structures include:
 - i. The globe
 - ii. Orbital fat
 - iii. Orbital nerves
 - iv. Extraocular muscles
 - v. Lacrimal gland
 - vi. Optic nerve
 - b. Signs and symptoms of orbital involvement:
 - i. Ocular pain
 - ii. Erythema and edema of the eyelids
 - iii. Conjunctival injection
 - iv. Nasolacrimal duct obstruction
 - v. Epiphora

- vi. Limitation of extraocular muscle movement
 - vii. Afferent pupillary defect
 - viii. Proptosis
 - ix. Diplopia
 - x. Loss of vision
5. Dermatologic involvement occurs in approximately 50% of patients
 6. Asymmetrical multiple mononeuropathies
 7. Mononeuropathies of the lower cranial nerves as they exit the skull and pass through the retropharyngeal tissue
 8. The peroneal nerve may be the most commonly affected nerve
 9. Symmetrical distal polyneuropathy occurs in 10–20% of patients;
 - a. Neuropathy may be more common in patients with severe renal involvement
 10. The frequency of peripheral nerve involvement is less than in the other vasculitides
 - c. Sinus metastatic breast cancer (although the eye may be retracted with scirrhous breast cancer)

4. Orbital Inflammatory Diseases:
 - a. Idiopathic sclerosing orbital inflammation (CD3⁺ T-cells)
 - b. Thyroid orbitopathy:
 - i. Inferior rectus may be preferentially involved whereas the superior rectus muscle may be primarily involved with lymphoma
 - ii. Most often, all muscles are involved
 - c. Sarcoidosis (usually affects the meninges surrounding the optic nerve)
 - d. Temporal arteritis (primarily affects the ophthalmic and posterior ciliary arteries)
 - e. IgG4-related disease
 - f. Rarely polyarteritis nodosa and Kawasaki disease, as well as Churg-Strauss syndrome, may involve orbital tissues

Neuropathology

1. A primary necrotizing vasculitis of small to medium-sized vessels
2. Large vessel involvement has been described with luminal stenosis, occlusion or wall thickening; the abdominal aorta is the most commonly affected vessel
3. Classic triad is vasculitis, tissue necrosis, and granulomatous inflammation
4. Granulomas consist of collections of epithelioid histiocytes; lung, kidney, and sinuses are involved

Laboratory Evaluation

1. The majority of patients have ANCA directed against proteinase-3 in the serum with a specificity of 98% and 95% sensitivity
2. Absence of peripheral eosinophilia distinguishes it from Churg-Strauss disease

Neuroimaging

1. An orbital mass from GPA is suggested by:
 - a. Sinus involvement
 - b. Paranasal bone erosion

Differential Diagnosis of Orbital Granulomatous Polyangiitis

1. The basic conditions to be differentiated are infectious, neoplastic and other orbital inflammatory conditions
2. Infections:
 - a. Mycobacterial
 - b. Invasive fungus infection (aspergillus and mucormycosis)
 - i. Primarily in immune suppressed patients
 - ii. Diabetes
3. Primary and Secondary Neoplasms
 - a. Extranodal marginal zone B-cell lymphoma
 - b. Non-Hodgkin's and Hodgkin's lymphoma

Microscopic Polyangiitis

General Characteristics

1. The incidence is approximately 1/3 that of PAN which it resembles clinically
2. Primarily a disease of small blood vessels, the absence of granulomas and minimal or no immune deposits on blood vessels

Clinical Manifestations

1. Average age of onset in 50 years
2. Glomerulonephritis is common
3. There is involvement of the lungs and GI tract in approximately 50% of patients
4. There may be eye vascular involvement
5. The spleen and muscle are involved in 20–30% of patients
6. Polyneuropathy occurs in approximately 15–35% of patients

Neuropathology

1. A necrotizing vasculitis with minimum immune complex deposition in the vasculature
2. Capillaries, vessels, and arterioles are primarily involved; there may be some involvement of small- and medium-sized arteries
3. Pulmonary capillaritis is common
4. Necrotizing glomerulonephritis is seen in a majority of patients

Laboratory Evaluation

1. ANCA are directed primarily against myeloperoxidase (MPO-ANCA) but in a minority of patients there is an antibody response directed toward proteinase 3 (PR3-ANCA)
2. Rheumatoid factor is noted in approximately 50% of patients
3. Rarely there is decreased complement
4. Hepatitis B, C antibodies may be detected

Behçet's Disease*General Characteristics*

1. The illness is primarily seen in the Middle East, India, and Japan
2. Men are slightly more affected than women
3. Small to medium-sized vessels are involved

Clinical Manifestations

1. Oral and genital ulcers (well circumscribed and often painful)
2. Painful oral aphthous ulcers are more common than genital ulcers
3. Anterior or posterior uveitis
4. Retinal vasculitis; iridocyclitis
5. Associated erythema nodosa
6. Thrombophlebitis
7. CNS manifestations:
 - a. Sinus thrombosis
 - b. Aseptic meningitis
 - c. Stroke (ischemic)
 - d. Dementia/psychosis
 - e. Brainstem presentation
 - f. Purely ocular presentation
 - g. Meningoencephalitis
8. Peripheral nervous system manifestations:
 - a. Sensorimotor neuropathy (distal demyelination)
 - b. Mononeuropathy multiplex
 - c. Motor predominant polyradiculoneuropathy
 - d. Lumbosacral polyradiculitis
 - e. Neurologic signs and symptoms may clear over weeks

Neuropathology

1. Anti-Th1 and lymphocytes and IL-6 as well as TNF
2. The gut microbiota has a specific signature:
 - a. Decreased genera Roseburia and Subdoligranulum
 - b. A significant decrease in butyrate production has been noted:
 - i. Butyrate promotes the differentiation of T-regulatory cells
3. Perivascular and meningeal infiltrates of lymphocytes
4. Sinus thrombosis
5. Vasculitic arterial lesions

Laboratory Evaluation

1. CSF:
 - a. Lymphocytic pleocytosis
 - b. Moderately elevated protein
 - c. Normal glucose

Secondary Systemic Vasculitides***Vasculitis Associated with Connective Tissue Disease****General Characteristics*

1. Incidence varies by disease

2. The major entities include:

- a. SLE
- b. Rheumatoid arthritis
- c. Mixed collagen vascular disease
- d. Scleroderma (systemic sclerosis)
- e. Sjögren's syndrome

Clinical Manifestations

1. Fever, weight loss
2. Anorexia
3. Skin rash, renal, lung, gastrointestinal involvement depending upon the illness
4. Specific neurologic features dependent upon the disease

Neuropathology

1. Similar to PAN

Laboratory Evaluation

1. Disease specific
2. In general, an increase of biomarkers of autoimmune disease

Vasculitis Associated with Infection*General Characteristics*

1. The most common infections associated with vasculitic neuropathy are:
 - a. HIV
 - b. Hepatitis B and C
 - c. Cytomegalovirus
 - d. Epstein-Barr virus

Clinical Manifestations

1. Disease specific
2. Directly related to treatment

Neuropathology

1. Disease specific

Laboratory Evaluation

1. Disease specific

Malignancy Related Vasculitis*General Characteristics*

1. Various cancers are associated with vasculitic neuropathies
2. The most common malignancies associated with various vasculitic neuropathies are:
 - a. Small cell carcinoma of the lung
 - b. Lymphoma
 - c. Leukemia/myeloproliferative disorders
3. Rarely carcinoma of the kidney, prostate, bile duct and stomach are associated with vasculitic neuropathy

Clinical Manifestations

1. Symmetric distal neuropathy

2. Mononeuropathy multiplex
3. Lymphoma and leukemia may directly infiltrate nerves

Neuropathology

1. Non-specific transmural or perivascular inflammation of small blood vessels is seen rather than a necrotizing vasculitis
2. Lymphoma may induce vasculitic neuropathy

Laboratory Evaluation

1. Disease specific

Drug-Induced Hypersensitivity Vasculitis

General Characteristics

1. Cutaneous manifestations are predominant

Clinical Manifestations

1. Internal organs may be involved that includes:
 - a. Glomerulonephritis
 - b. Gastrointestinal and myocardial involvement
2. Distal symmetric polyneuropathy
3. Self-limited

Neuropathology

1. Capillaries, arterioles, and venules are involved
2. Leukocytoclastic mechanism
3. Amphetamines, cocaine, and opioids have been reported as causing both CNS and PNS vasculitis

Laboratory Evaluation

1. Increased ESR > 50% of patients
2. Rheumatoid factor in approximately 100% of patients
3. ANA positivity in approximately 15% of patients

Vasculitis Associated with Essential Mixed Cryoglobulinemia

General Characteristics

1. Cryoglobulins:
 - a. Are circulating immune complexes
 - b. They are immunoglobulins directed against immunoglobulins
 - c. They are categorized as:
 - i. Type I cryoglobulins:
 1. IgM monoclonal immunoglobulins directed against polyclonal IgG
 - a. Occur with plasma cell dysplasia
 - ii. Type II cryoglobulins:
 1. A combination of monoclonal IgM and polyclonal immunoglobins directed against polyclonal IgG
 - iii. Type III cryoglobulins:
 1. A mixture of polyclonal IgM, IgG, and IgA immunoglobulins
 2. Directed against polyclonal IgG

- iv. Type II and Type III cryoglobulins:

1. Occur in patients with mixed cryoglobulinemia and are detected in connective tissue diseases as well as hepatitis B and C
2. Essential mixed cryoglobulinemia is designated when mixed cryoglobulinemia is detected without an underlying disease. It may occur with viral hepatitis:
 - a. Most patients with essential mixed cryoglobulinemia have hepatitis C antigen in the serum

Clinical Manifestations

1. Raynaud's phenomena
2. Bleeding diathesis (platelet dysfunction)
3. Retinal hemorrhage
4. Arthralgias
5. Malaise
6. Weakness
7. Skin ulcers
8. Blue cyanotic extremities (primarily fingers and toes)
9. Peripheral neurologic manifestations:
 - a. Painful distal symmetric sensory or sensorimotor polyneuropathy
 - b. Mononeuropathy multiplex
 - c. Rare small fiber neuropathy

Neuropathology

1. Cooling precipitates IgG and IgM immunoglobulins that redissolve on heating
2. Necrotizing vasculitis; occlusive microangiopathy
3. Involvement of small arteries, arterioles, capillaries and venules
4. Nerve biopsy:
 - a. Wallerian degeneration:
 - i. Perivascular mononuclear cell infiltration
 - ii. Center of the nerve fascicle may be more involved than the periphery
 - iii. Perivascular mononuclear cell infiltration
 - iv. Lack of local HCV replication in the biopsied nerve:
 1. Putative mechanism of the neuropathy is a virus-triggered immune-mediated process
 2. Ischemia from hyperviscosity
 3. Immune complex deposition in the vasa vasorum that occludes the nutrient blood supply of the nerve

Laboratory Evaluation

1. Hepatitis C is detected in greater than 80% of patients
2. Rheumatoid factor is increased in 80% of patients
3. Decreased complement is detected in greater than 75% of patients
4. ANA is elevated in approximately 20% of patients
5. ANCA detected in approximately 5% of patients
6. EMG:
 - a. Similar to PAN

Isolated PNS Vasculitis (Non-Systemic)

General Characteristics

1. Necrotizing vasculitis is restricted to the peripheral nervous system
2. Inflammatory and connective tissue biomarkers are absent; a few patients demonstrate anti-neutrophil cytoplasmic antibodies (ANCA)
3. 60% of vasculitic neuropathies are restricted solely to peripheral nerves
4. Incidence: 5/million of the population/year
5. Primarily a disease of adults, but childhood patients are well documented

Clinical Manifestations

1. Usually, presents as a subacute symmetrical or asymmetrical polyneuropathy (45% of patients)
2. Overlapping episodes of mononeuropathy multiplex (40% of patients)
3. Solely mononeuropathy multiplex is detected in approximately 40% of patients

Neuropathology

1. Involvement of the small- and medium-sized arteries of the epineurium and perineurium
2. Immune complex deposition occurs in affected vessels
3. Up-regulation of metalloproteinase-2 and -9 in affected nerves
4. Vasculitis may be demonstrated on muscle biopsy

Laboratory Evaluation

1. ESR may be mildly elevated as are ANA titers
2. EMG may demonstrate conduction block early in the course
3. Positive sharp waves and fibrillation potentials are detected in affected muscle

Differential Diagnosis of Vasculitic Neuropathy by Signs and Symptoms

Overview

The suspicion of a systemic vasculitic neuropathy occurring in the face of a known systemic vasculitis is raised with the onset of an asymmetric neuropathy that may evolve over time into a symmetric distal motor sensory neuropathy due to overlapping mononeuropathies (nerve infarctions) of specific peripheral nerves. Early trigeminal nerve involvement and mononeuropathy multiplex are seminal features of these diseases (Sjögren's disease, systemic sclerosis). The specific features of each entity identify the underlying cause of the vasculitis.

In SLE, the neuropathy usually occurs in the face of established disease. Central nervous features usually predominant with stroke, seizure, psychosis as major signs. A trans-

verse myelitis usually at T4–T6 (or from a dropped cervical level) in many instances may be confused with neuropathy if bladder involvement is not prominent. Serosal surface involvement, arthralgia, malar skin rash are usually evident when the sensorimotor or sequential mononeuropathies begin. The major differential considerations at this stage are toxic, metabolic, or nutritional causes and often immune suppressive drugs and biologic anticytokine agents. Proximal myopathy is common, which may further complicate the clinical picture. A GBS picture that may evolve in patients with systemic signs of weight loss, anorexia, and slight anemia is more suggestive of PAN. The important considerations if the process presents a GBS pattern of weakness are cervical spinal cord inflammation, cavernous hemangioma, compression, mitosis, or infection (SBE is often at the T4–T6 level in IV drug addiction). In later stages of a GBS presentation from systemic autoimmune processes, a CIDP pattern may be noted which must be differentiated from lymphoma, HIV, Castleman's disease, graft-versus-host disease, osteosclerotic myeloma (POEMS) and monoclonal gammopathies. The DADs, MADSAM (Lewis-Sumner variant) and multiple motor nerve with conduction block are readily differentiated on clinical and EMG parameters. A vasculitic sensorimotor neuropathy is suggested by an asymmetric onset, stuttering course, and significant motor involvement.

The major differential features that are problematic for making the diagnosis of Sjögren's syndrome are distinguishing it from other processes associated with the SICCA complex. These disorders are sarcoid, graft-versus-host disease, amyloidosis, hepatitis C, HIV, and HTLV-1 disease. In sarcoid, bilateral VIIth nerve involvement rather than Vth nerve involvement is classic (Heerfordt's disease). Dural enhancement associated with intracranial lesions in the posterior hypothalamus and pituitary regions are diagnostic. Severe mucous ulcerative inflammation is characteristic of graft-versus-host disease whereas Sjögren's is primarily glossitis and has conjunctival symptomatology. Dissociated sensory loss (small fiber modality loss), autonomic neuropathy in association with a primary loss of reflexes, cardiac and renal disease, supports a diagnosis of amyloid neuropathy. HTLV-1 is a long-standing myelopathy with severe spasticity and bladder involvement. Hepatitis C and cryoglobulinemic neuropathy is suspected in patients with severe Raynaud's phenomenon, livedo reticularis and, rarely, gangrene and cyanosis of the fingers and toes. HIV most commonly is associated with a distal symmetrical neuropathy (with or without treatment with highly effective retroviral agents) parotid hypertrophy (cyst formation on MRI) and severe periventricular demyelination with global atrophy on MRI. Paraneoplastic sensory neuropathy can present with a severe sensory ataxia. Prominent dorsal column large fiber proprioceptive and vibratory deficits are common. It may also present with the burning pain of a small fiber (C-fiber) neuropathy with associated autonomic features. Idiopathic chronic ataxic neuropathy does not have autonomic involvement that is common in both Sjögren's and

paraneoplastic syndromes. Anti-Hu antibodies are found in the majority of paraneoplastic syndromes.

Other immune-mediated ataxic sensory polyneuropathies include:

1. Miller-Fisher variant of GBS
2. Myelin-associated glycoprotein neuropathy (MAG)
3. Pure sensory CIDP
4. Immunoglobulin associated paraproteinemias (particularly IgM)
5. Neuropathy with anti-sulfatide antibodies
6. SICCA complex
7. Syphilis (may cause proliferative endarteritis at the dorsal root entry zone or possible immune dysfunction at the level of the DRG with consequent death of large myelinated afferents that comprise the posterior column)
8. Herpes zoster (most often causes proprioceptive neuronal destruction by direct invasion in the DRG; the virus is activated during immune suppression)

The hypersensitivity vasculitides are diagnosed by their characteristic leukocytoclastic skin reactions. These skin reactions may occur with cryoglobulinemic neuropathies which are most often secondary to hepatitis C and rarely to hepatitis B infection. Henoch-Schönlein purpura occurs primarily in children in association with GI pain and arthralgias as well as the seminal purpura. The sensorimotor neuropathy is a minor part of the symptom complex. Hypersensitivity vasculitis most often occurs from an autoimmune reaction to drugs that contain sulfa or penicillin and may present with dramatic swelling and burning of the fingers and toes. Temporal arteritis usually presents in elderly patients with systemic signs of weight loss, anorexia, and proximal muscle pain as well as a low-grade headache and tender scalp. It most often involves the external carotid vascular system that affects the watershed between the posterior ciliary arteries and the central retinal artery with concomitant ischemia of the optic nerve head and visual loss. Rarely, the arch of the aorta, carotid, and subclavian arteries are affected. Sensorimotor peripheral neuropathy and neuropathy multiplex occur.

Polyarteritis nodosa is overwhelmingly a disease of the peripheral nervous system. It should always be suspected in a middle-aged man who has developed late onset asthma, eosinophilia, liver, kidney or testicular infarction. Microaneurysms of the long medullary arteries of the kidney are diagnostic. In this setting, overlapping mononeuropathies and an asymmetrical peripheral neuropathy may present as GBS. Raised palpable nodules from infarction of skin arterioles often in the quadriceps muscle should be sought. Mononeuropathy and asymmetrical peripheral neuropathy is common. CNS stroke is rare. Microscopic polyangiitis (MPA) primarily affects the kidney, but vasculitis may also be seen in the eyes, lung, muscle and, rarely, the brain. ANCA antibodies are detected in the serum of >90% of patients. A sensorimotor neuropathy in the setting of severe renal involvement should suggest this diagnosis. Decreased complement and increased rheumatoid factor are supportive. The lungs are in-

involved in approximately 50% of patients, and the neuropathy does not cause burning feet which helps to separate it from uremic neuropathy.

Churg-Strauss sensorimotor neuropathy is suggested in patients with eosinophilia and interstitial lung disease. The pituitary is occasionally involved. The IgE is increased in the serum in 75% of patients and ANCA antibodies are present in 50–75% of patients.

Wegener's granulomatosis (renamed granulomatous polyangiitis) invariably attacks the sinuses (greater than 90% of patients). It is also associated with granulomatous lung disease. Orbital and Vth cranial nerve involvement are caused by direct extension of the granulomatous process. Mononeuropathies are more common than an asymmetric, stuttering, slowly progressive distal predominant sensorimotor neuropathy.

The idiopathic eosinophilic syndrome is a heterogeneous group of disorders in which there is a persistent and extreme degree of eosinophilia (often > 20,000/mm³). There is eosinophilic infiltration of many organ systems. Neuropathy occurs in approximately 50% of patients, may concomitantly affect cranial nerves and is usually a diffuse painful sensorimotor axonal neuropathy. Mononeuropathy multiplex may also occur. Diffuse eosinophilic involvement of the nerves rather than a vasculitic process is thought to be its mechanism.

Rheumatoid arthritis often involves the carpal tunnels symmetrically and less commonly the tarsal tunnels. In patients with severe longstanding disease, (ulnar deviation of the hands; forward flexed frozen neck) hand paresthesias may occur from subluxation of C1–C2 (pannus destruction of the cruciate and transverse ligaments). Severe intrinsic hand muscle atrophy out of proportion to the arthropathy may also be a presentation. A high sediment rate (ESR) and increased levels of rheumatoid factor are seen in greater than 90% of patients. Low-level eosinophilia, and ANA and ANCA antibody response with decreased complement are supportive. Rarely, mononeuropathy and an asymmetric peripheral neuropathy occur.

Scleroderma is easily diagnosed from its distinctive physical findings. Often not appreciated is its penchant for trigeminal or mental nerve involvement ("numb chin" syndrome; also seen with sickle cell disease and breast cancer). Carpal tunnel syndrome is common in its early inflammatory stage. Later in its course, a sensorimotor neuropathy may develop. It should always be suspected in patients with early severe Raynaud's phenomena. The CREST syndrome (calcinosis, Raynaud's phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasia) is associated with a sensorimotor neuropathy. Raynaud's phenomena is often severe in SLE and rheumatoid arthritis. Scleroderma presents no difficulty in differentiation from other connective tissue diseases or vasculitic neuropathies. Realizing that the Vth nerve, carpal and tarsal tunnel and a vasculitic neuropathy may occur is what is overlooked.

Mixed connective tissue disease has features of scleroderma, SLE, and polymyositis. It frequently presents with trigeminal neuropathy. Rarely a sensorimotor neuropathy is present. High antibody titers of ANA antibodies to extractable nuclear RNP ribonuclease-VI are detected in the serum.

Behçet's disease primarily affects the CNS with anterior and posterior uveitis, optic neuritis, a brainstem syndrome or vasculitic stroke. Its seminal feature is aphthous ulceration of the mouth and genitals. Occasionally patients have a well demarcated extragenital, erythematous ulcer on the body that is extremely painful. Large joint and GI involvement occur. Venous thrombosis of the cortical veins and sinuses is increasingly recognized. Rarely patients have a concomitant distal predominant sensorimotor polyneuropathy.

Relapsing polychondritis may present with erythematous, sudden painful ears. Ochronosis (homogentisic aciduria) and uremia may also involve the pinna. This inflammatory autoimmune disease of cartilage causes tracheal stenosis, saddle nose deformity and heart valve inflammation. Optic neuritis, vestibulopathy, and conductive hearing loss from eustachian tube involvement are the seminal central features. Rarely, patients have a concomitant distal predominant sensorimotor polyneuropathy.

The major differential diagnostic problem occurring in the diagnosis of vasculitic neuropathy lies not in differentiating one connective disease from another in which it may occur, but rather diagnosing in the absence of systemic features.

Differential Diagnosis of Vasculitic Peripheral Neuropathy

Secondary Vasculitis

1. Connective tissue disease
2. Malignancy
3. Infection
4. Cryoglobulinemia
5. Hypersensitivity reactions

Primary Vasculitis

1. Giant cell (temporal arteritis)
2. Takayasu's (extremely rare)
3. Polyarteritis nodosa
4. Churg-Strauss syndrome
5. Wegner's granulomatosis (granulomatous polyarteritis; GPA)
6. Microscopic polyarteritis (MPS)
7. Idiopathic eosinophilic syndrome (possibly vasculitic)
8. Isolated peripheral nerve vasculitis

Differential Diagnosis of Mononeuropathy Multiplex

1. Traumatic compression neuropathy
2. Compression neuropathy superimposed on peripheral nerve disease
3. Hereditary liability to pressure palsy (HNPP)

4. Multifocal acquired demyelinating sensory and motor neuropathy
5. Multifocal motor neuropathy
6. Chronic inflammatory demyelinating polyneuropathy
7. Sensory perineuritis
8. Isolated peripheral nerve vasculitis
9. Periarthritis nodosa
10. Granulomatous polyarteritis
11. Churg-Strauss syndrome
12. Microscopic polyangiitis
13. Systemic lupus erythematosus
14. Rheumatoid arthritis
15. Relapsing polychondritis
16. Mixed connective tissue disease
17. Sjögren's
18. Cryoglobulinemia
19. Leukemia/lymphoma infiltration
20. Intravascular lymphoma
21. Isolated (non-systemic) vasculitis
22. Paraneoplastic vasculitis
23. Leprosy
24. Herpes zoster
25. Lyme's disease
26. HIV
27. CMV
28. Hepatitis B and C
29. Sarcoid
30. Lymphomatoid granulomatosis
31. Diabetes mellitus
32. Amyloidosis
33. Neoplastic infiltration
34. Atherosclerotic vascular diseases
35. Amphetamines
36. Cocaine
37. Heroin
38. Lumbosacral/brachial plexopathy

Neuropathies of Systemic Disease

Sjögren's Syndrome

General Characteristics

1. A chronic inflammatory process that involves the exocrine glands
2. If it occurs alone it is primary Sjögren's syndrome, or in association with other autoimmune diseases, it is secondary Sjögren's
3. Extra glandular manifestations of the disease are divided into two groups that involve:
 - a. Lung
 - b. Kidney (interstitial nephritis)
 - c. Liver
 - d. Due to lymphocytic invasion of epithelial tissue
4. Skin vasculitis, peripheral neuropathy, CNS manifestations, glomerulonephritis

- a. Due to immune complex deposition
- b. Low C4 levels
- c. High lymphoma risk

Clinical Manifestations

1. The sicca complex is a seminal feature and comprises:
 - a. Xerophthalmia (dry eyes)
 - b. Xerostomia (dry mouth)
 - c. Dryness of mucous membranes
2. More common in females than males
3. Age of onset is in middle years
4. CNS complications include:
 - a. Transverse myelitis or dorsal column spinal cord degeneration
 - b. Diffuse white matter hyperintensities simulating demyelinating disease (CNS; rare)

Peripheral Neuropathy

General Characteristics

1. Evident in 10 to 20% of patients
2. May be the presenting sign of the disease and may be evident without signs of the sicca complex
3. Patterns of peripheral neuropathy:
 - a. Length-dependent axonal sensorimotor neuropathy
 - b. Small fiber neuropathy
 - c. Autonomic involvement
 - d. Vasculitic pattern with multiple mononeuropathy multiplex
- e. Trigeminal nerve involvement is prominent
- f. Sensory neuropathy/ganglionopathy manifest by:
 - i. Progressive numbness and paresthesias of the extremities, trunk and face in a non-length dependent manner
 - ii. Signs and symptoms may be asymmetric, and the arms may be more involved than the legs
 - iii. Severe large myelinated fiber involvement with proprioceptive and vibratory loss that may cause pseudoathetosis; Romberg sign is prominent in patients with lower limb involvement
 - iv. Autonomic involvement is seen by:
 1. Orthostatic hypotension
 2. Adie's pupil
 3. Anhidrosis
 4. Fixed tachycardia
 5. Strength may be maintained
 6. Reduced or absent muscle stretch reflexes

Neuropathology

1. Nerve biopsy (sensorimotor neuropathy):
 - a. Axonal degeneration with some segmental demyelination
 - b. Rare perivascular inflammation of perineural and endoneurial blood vessels
 - c. Rare necrotizing vasculitis

2. Biopsy of patients with sensory neuropathy/ganglionopathy:
 - a. Loss of large myelinated fibers (dorsal column spinal cord degeneration)
 - b. CD8⁺ T-cell perivascular inflammation and degeneration of large sensory neurons of the dorsal root ganglia
3. Skin biopsy (patients with small fiber neuropathy)
 - a. Decreased nerve fiber density
4. Growing evidence supports a mechanism of disease involving B-cells, cytotoxic T-cells, and T-helper cells in chronic inflammation which alters the expression of proinflammatory cytokines
5. Dysfunction of co-inhibitory and co-stimulatory immune checkpoint inhibitors that regulate T-cell activation has been postulated as a pivotal mechanism

Laboratory Evaluation

1. Serum antibodies to SS-A/Ro, SS-B/LA, and anti-nuclear (ANA) antibodies may be detected
2. CSF is most often normal
3. Salivary gland, lip, and parotid biopsy may reveal lymphocytic infiltration
4. Schirmer's test is positive for keratoconjunctivitis
5. EMG:
 - a. Decreased or absent SNAPs in patients with the sensory neuropathy phenotype
 - b. Motor nerve conduction velocities and needle EMG are usually normal

Rheumatoid Arthritis

General Characteristics

1. Peripheral neuropathy occurs in approximately 50% of patients; 50% of the neuropathies are vasculitic
2. Systemic features of anemia and weight loss occur in severely affected patients; adenopathy, pericarditis, interstitial lung disease, glomerulonephritis and serosal surfaces may be involved in severely involved patients; small joint involvement is the seminal feature

Clinical Manifestations

1. Entrapment neuropathies that may be bilateral: median nerve in the carpal tunnel; digital, ulnar, anterior and posterior interosseous nerves; ulnar entrapment in the cubital tunnel or Guyon's canal; sciatic nerve entrapment in the posterior popliteal fossa; tarsal tunnel syndrome
2. Distal symmetric polyneuropathy:
 - a. Insidious onset of paresthesias and decreased sensibility in both upper and lower extremities
 - b. Minimal motor deficits
 - c. Hands are often severely wasted
3. Mononeuropathy or mononeuropathy multiplex:
 - a. May have an acute or subacute onset that evolves into a severe distal sensorimotor neuropathy
 - b. Cranial nerve involvement is rare

Neuropathology

1. Arteritis primarily of small vessels of the fibrinoid type
2. Immune globulins may be detected on the vessel walls
3. Rare transmural inflammatory cell infiltrate
4. Vasculitis may be initiated by anti-TNF-alpha or biological agents

Laboratory Evaluation

1. Elevated ESR, rheumatoid factor, and anti-nuclear antibodies are seen in the serum
2. A few patients develop ANCA antibodies
3. EMG:
 - a. Absent or reduced amplitudes of SNAPs
 - b. Usually normal nerve conduction velocities

Systemic Lupus Erythematosus*General Characteristics*

1. Prevalence of 1/2000 in the population
 - a. More common in women than men
 - b. Possibly more prevalent in black than Caucasian patients
2. Multiple organ system involvement
3. Approximately 2–27% of patients develop a peripheral neuropathy
 - a. CNS involvement is much more common than that of the peripheral nervous system

Clinical Manifestations

1. Concomitantly with nervous system involvement, the joints, serosal surfaces, heart, lung, kidney, skin, and muscles are affected
2. Patterns of neuropathy:
 - a. Slowly progressive sensory loss starting in the feet
 - b. Pure small fiber phenotype
 - c. Multiple mononeuropathies that may fuse with long-standing disease that causes a symmetric generalized axonal sensorimotor polyneuropathy
 - d. AIDP or CIDP pattern
3. Cranial neuropathy:
 - a. Occurs in 5 to 10% of patients
 - b. Involves cranial nerves II, III, V, VI, and X (laryngeal component)
4. Rare neuropathies:
 - a. CTS
 - b. Acute sensory ataxic neuropathy
 - c. Neuromyotonia

Neuropathology

1. Nerve biopsy:
 - a. Endoneurial mononuclear inflammatory infiltrate
 - b. Increased expression of class II antigens within nerve fascicles and on endothelial cells
 - c. Upregulation of metalloproteinases-3 and -9 within blood vessel walls

d. Skin biopsy:

- i. Decreased density of intra-epidermal C-fibers
2. Mounting evidence supports dysregulated microRNA network from interference with the miRNA expression profile
 - a. MicroRNAs regulate the differentiation and function of immune cells that leads to autoimmune disease. MicroRNA-1246 that regulates B-cell activation may be particularly relevant in the pathogenesis of SLE
 3. Small- and medium-sized vessels are primarily involved with a necrotizing vasculitis
 4. Vasculopathy > true vasculitis occurs in cerebral vessels; scattered perivascular inflammatory cells are noted
 5. Dorsal root ganglion (autopsy material):
 - a. Cytotoxic/suppressor CD8⁺ T-cells surround neurons
 - b. Arterioles, capillaries, and venules may be involved

Laboratory Evaluation

1. ANA positive antibodies occur in >95% of patients
2. Double-stranded DNA positive antibodies are seen in approximately 70% of patients
3. Anti-Ro and La antibodies are detected in >25% of patients
4. ANCA antibodies are detected in approximately 10% of patients
5. Rheumatoid factor (RF) is positive in >75% of patients
6. Cryoglobulins are found in approximately 15% of patients
7. EMG:
 - a. Overlapping mononeuropathies (later stages of the illness)
 - b. NCS most commonly show a length dependent axonal sensory neuropathy

Scleroderma*General Characteristics*

1. Fibrosis of the skin and visceral organs from the deposition of extracellular matrix proteins that consist of interstitial collagens (type I and III), cellular fibronectin, basement membrane proteins (laminins and others) and cellular fibronectin
2. Activation of myofibroblasts, which include actin (ACTA2), express smooth muscle proteins, are contractile which contributes to the distortion of parenchymal architecture
3. Scleroderma limited to the skin rarely causes neuropathy (linear scleroderma, morphea, diffuse cutaneous scleroderma)
4. The incidence is 10–15/million of the population; there are important ethnic differences
5. Peak incidence is in the third to fifth decades
6. The ratio of women to men is 3:1
7. The CREST variant includes:
 - a. Calcinosis
 - b. Raynaud's phenomenon

- c. Esophageal dysmotility
- d. Sclerodactyly
- e. Telangiectasia
- f. CREST may be associated with a vasculitic neuropathy

Clinical Manifestations

1. Raynaud's phenomenon is seen in 95% of patients
2. Slowly progressive skin and systemic organ involvement occur over years; visceral involvement primarily occurs in the GI tract, kidney, and lung
3. Sensorimotor neuropathy:
 - a. Complicates 5 to 67% of long standing patients
 - b. Asymmetric at onset
 - c. Later stages become symmetrical
 - d. Motor greater than sensory involvement occurs in <10% of patients
4. Entrapment neuropathies:
 - a. Carpal tunnel syndrome is seen in 10% of patients, most prominent in the early inflammatory stages of the illness
 - b. May have pressure palsies of other major nerves
5. Trigeminal inflammatory ganglionitis:
 - a. Affects 3% of scleroderma patients
 - b. Bilateral and asymmetrical in 60% of patients
 - c. Rare involvement of the VIIth and IXth nerve; mental nerve involvement causes the "numb chin" syndrome
6. Multiple mononeuropathies have been described in rare patients with CREST

Neuropathology

1. Fibroblasts and myofibroblasts are key fibrosis effectors in many organs; synthesize extracellular matrix proteins
2. TGF-1B cascade plays a major role in fibrosis
3. Nerve biopsy:
 - a. Axonal sensory > motor polyneuropathy
 - b. Increased endoneurial and perineural tissue
 - c. Rare vasculitis
4. Microvascular alterations:
 - a. Perturbation of endothelial cells
 - b. Neointimal formation
 - c. Pericyte activation
 - d. Perivascular inflammation
 - e. Capillary dilation and capillary atrophy are noted in the nail-fold
5. Small arteries and arterioles (50–500 μ m) demonstrate concentric fibrous intimal lesions that obliterate the lumen

Laboratory Evaluation

1. Positive anti-Scl-70 and anti-centromere antibodies are detected in greater than 60% of patients
2. Anti-nucleolar anti-RNA polymerase I, II and III antibodies; anti-ribonucleoprotein (RNP) antibodies are increased in some patients
3. Elevations of VEGF, PDGF, FGF-2 and DIGF in the plasma

Mixed Connective Tissue Disease (MCTD)

General Characteristics

1. A disease with a clinical overlap of SLE, scleroderma, and polymyositis
2. Presence of antibodies against the U1 small nuclear ribonucleoprotein autoantigen (U1-snRNP)
3. Women are affected more than men
4. Severe pulmonary hypertension a cause of death in some patients

Clinical Manifestations

1. Mild distal axonal sensorimotor polyneuropathy occurs in approximately 10% of patients
2. Trigeminal neuropathy
3. CTS (carpal tunnel syndrome)
4. Autonomic features

Neuropathology

1. Axonal neuropathy

Laboratory Evaluation

1. Elevated ESR
2. Hypergammaglobulinemia
3. Anti U1-snRNP antibodies
4. EMG:
 - a. Axonal features; some patients with mixed axonal-demyelinating characteristics
 - b. Rare polyradiculopathy presentation
5. MRI:
 - a. Patients have been described with cauda equina enhancement

Relapsing Polychondritis

General Characteristics

1. Inflammation of cartilaginous and proteoglycan rich structures
2. Peak incidence is in the fifth decade
3. Involved structures include:
 - a. Ear, nose, articular and tracheobronchial tree
 - b. Less frequently involvement of:
 - i. Cardiac valves
 - ii. Eye (episcleritis, conjunctivitis, uveitis, keratitis)

Clinical Manifestations

1. Optic neuritis (rare)
2. Sensorineural hearing loss in greater than 30% of patients
3. Vestibular involvement
4. Rare involvement of cranial nerves III, IV, V, and VI
5. Rare sensorimotor neuropathy and mononeuropathy
6. May have a coexistent autoimmune disorder

Neuropathology

1. Development of autoimmunity against cartilage that includes type II, IV, and XI collagen and constituent proteins such as matrilin-1

2. Interferon-gamma, interleukin 12 and IL-2 increase during disease activity, suggesting Th1 dysregulation
3. There may be an increased risk of myelodysplastic disease
4. Coincidence with Behçet's disease is designated MAGIC syndrome (mouth and genital ulcers with inflamed cartilage)
5. Renal disease and parenchymal lung involvement occur

Laboratory Evaluation

1. Increased interferon-gamma, IL-2 and IL-12
2. Rare ANCA-associated vasculitis

Sarcoidosis

General Characteristics

1. A granulomatous multisystem disease of unknown etiology
2. Neurosarcoidosis is usually seen with other forms of the disease but may be isolated in 1% of patients
3. Adult onset is usually between 30 to 40 years of age
4. Most frequently seen in Northern Europe, Japan and the east coast of the USA
5. African-American patients have an incidence 4× greater than Caucasian patients
6. Possible incidence is 10/100,000 in the population

Clinical Manifestations

1. The presenting symptoms are often fever, weight loss, arthralgias and fatigue
2. Erythema nodosa and enlarged lymph nodes may occur
3. Mucosal lesions of the nose and sinuses are common
4. Uveitis is often severe
5. The disease most often affects the lungs and mediastinal lymph nodes, but the heart (conduction defects) and the kidney are frequently affected
6. The peripheral and central nervous systems are affected in approximately 5% of patients
 - a. The most common cranial nerve that is involved is VII. The second cranial nerve may be compressed by meningeal infiltration. Any cranial nerve may be involved but the VIIth, VIIIth, and II are primary
 - b. Meningeal involvement
 - c. The posterior hypothalamus and pituitary are often involved, but infiltrates may be seen anywhere in the cortex

Peripheral Nervous System Involvement

1. Radiculopathy or polyradiculopathy
2. Acute sensory ataxia with sphincter involvement (rare)
3. Multiple mononeuropathies
4. Slowly progressive sensory > motor polyneuropathy
5. Pure small sensory neuropathy

Neuropathology

1. Nerve biopsy:

- a. Necrotizing granulomas that infiltrate the endoneurium, perineurium, and epineurium
2. Lymphocytic necrotizing angitis
 3. A combination of demyelination and axonal degeneration are seen in the nerve
 4. Muscle biopsy:
 - a. Noncaseating granulomas in the endomysium
 5. Skin biopsy:
 - a. Loss of intraepidermal nerve fibers in patients with the phenotype of small fiber neuropathy
 6. Recent studies support the contribution of heat shock proteins that act as DAMPs (tissue damage associated molecular patterns) or other microbial heat shock proteins that are recognized by pattern recognition receptors; these proteins may induce sarcoid inflammation

Laboratory Evaluation

1. Elevation of angiotensin converting enzyme in the serum (particularly in patients with lung disease) and in the CSF in those with CNS involvement
2. EMG:
 - a. Reduced or absent SNAPs are seen in the phenotype with sensorimotor neuropathy
 - b. In the lower extremities, there may be reduced or absent CMAPs, with borderline CMAPs in the upper extremities
 - c. Radiculopathy or polyradicular EMG pattern
 - d. QST:
 - i. Altered thermal thresholds

Celiac Disease (CD)

General Characteristics

1. A chronic small intestinal immune-mediated enteropathy precipitated by exposure to dietary gluten in genetically predisposed individuals
2. Gluten is a protein in wheat and its products
 - a. The classic disorder is defined with signs and symptoms of malabsorption, diarrhea, weight loss or growth failure
3. Clinical and laboratory diagnosis requires:
 - a. Malabsorption
 - b. Alterations of jejunal villi
 - c. Clinical and histologic improvement seen with a gluten free diet
 - d. Approximately 10% of patients have neurologic complications

Clinical Manifestations

1. The neuropathies include:
 - a. Generalized sensorimotor polyneuropathy
 - b. Autonomic neuropathy
 - c. Motor neuropathy
 - d. Multiple mononeuropathies
 - e. Neuromyotonia

2. Neurological examination reveals:
 - a. Loss of large fiber sensory modalities (often leading to ataxia in association with the neuropathy)
 - b. Mild distal extremity muscle weakness
 - c. Diminished or absent muscle stretch reflexes
 - d. Ataxic gait
 - e. Less frequent signs of a small fiber neuropathy

Neuropathology

1. Inflammation in celiac disease:
 - a. Increased intraepithelial lymphocyte count (>25/100 cells)
 - b. An adaptive T-cell mediated response to gluten (the protein component of wheat, rye, and barley, but not oats) that occurs in HLA-DQ2/DQ8-positive patients
2. Nerve biopsy:
 - a. Loss of myelinated fibers
3. Autopsy material:
 - a. Loss of Purkinje cells in the cerebellum
 - b. Degeneration of the spinal cord posterior columns and corticospinal tracts
 - c. Loss of neurons throughout the neuraxis in conjunction with cortical atrophy
 - d. Some features suggest malabsorption of B12 and vitamin E

Laboratory Evaluation

1. Presence of specific endomysial antibodies (EMA); anti-tissue transglutaminase antibodies (TTG a-tTG, TTA) and/or disassociated antigliadin antibody
2. Requires biopsy of the duodenum when patients are on a gluten free diet
3. EMG:
 - a. NCS reveal reduced SNAP amplitudes with minimally reduced NCVs or mildly prolonged distal latencies
 - b. Motor CVs are mildly reduced with normal distal motor latencies and CMAP amplitudes
 - c. Rare neuromyotonic discharges have been reported
 - d. Alterations in autonomic parameters may be detected in patients with autonomic features

Inflammatory Bowel Disease (IBD)

General Characteristics

1. Extraintestinal manifestations occur in approximately 1/3 of patients with ulcerative colitis and Crohn's disease (the major inflammatory bowel diseases)
2. These extraintestinal manifestations may occur several years prior to the onset of gastrointestinal symptoms
3. Immunosuppressant and biological therapies for IBD may be a component mechanism of the pathology of neurological complications
4. Neurological complications occur in approximately 3% of patients with IBD

Clinical Manifestations

1. Patterns of peripheral neuropathy:
 - a. Acute and chronic demyelinating neuropathies
 - b. Multifocal motor neuropathy
 - c. Axonal sensory or sensorimotor polyneuropathy
 - d. Multiple mononeuropathies

Neuropathology

1. Patients treated with biologics for a prolonged period:
 - a. PML a. Only reported in IBD patients treated with natalizumab as well as a few patients treated with anti-TNF therapy
 - b. CNS vasculitis
 - c. Posterior reversible encephalopathy syndrome (PRES)
 - d. Exacerbations of MS on TNF-alpha blocker therapy
 - e. Anti-TNF associated neuropathy:
 - i. Encompasses both a T and humoral attack directed against peripheral nerve myelin epitopes as well as disruption of trophic support for axons
 - f. Both Miller-Fisher variant and GBS have been described in patients undergoing treatment with TNF-alpha antagonists
 - g. Other neuropathology in patients with IBD include:
 - i. Toxicity of treatment with metronidazole
 - ii. B12 deficiency
 - h. Associated neurologic diseases:
 - i. Myasthenia gravis
 - ii. Inflammatory muscle disease

Laboratory Evaluation

1. Anti-GM1 antibodies in 50% of patients with multifocal motor neuropathy with conduction block
2. Evidence of anti-nuclear antibodies and anti-ds-DNA autoantibodies in patients with CNS vasculitis that are under anti-TNF-alpha therapy
3. EMG:
 - a. Multiple conduction blocks noted in some patients undergoing anti-TNF therapy
 - b. Demyelinating and axonal features in those with the appropriate phenotype

Primary Biliary Cirrhosis (PBC)

General Characteristics

1. Primary biliary cirrhosis is a chronic immune-mediated liver disease with progressive cholestasis, biliary fibrosis that may lead to cirrhosis
2. The primary autoimmune attack is against the biliary ducts in the liver
3. PBC may be associated with Sjögren's syndrome, myasthenia gravis, Lambert-Eaton syndrome, and myositis

Clinical Manifestations

1. A predominantly large fiber peripheral neuropathy
2. A CIDP clinical syndrome has been described

Neuropathology

1. Loss of large myelinated nerves without segmental demyelination
2. Autoimmune attack against biliary epithelia:
 - a. B-cells, cytotoxic and helper T-cells are involved in the chronic inflammation mediated by altered expression of proinflammatory cytokines

Laboratory Evaluation

1. Elevated liver function tests
2. Antimitochondrial antibodies are detected in a subgroup of patients
3. EMG:
 - a. Reduced or absent SNAPs; needle EMG and motor conduction velocities are usually normal
 - b. One patient has been reported with slow conduction velocities and conduction blocks

Henoch-Schönlein Syndrome*General Characteristics*

1. A systemic small vessel vasculitis that most often presents in childhood
2. Often self-limiting, although approximately 20% of patients suffer permanent sequelae

Clinical Manifestations

1. Erythematous macules that become papules; urticarial purpuric and necrotic lesions occur on the external portions of limbs and buttocks
2. Abdominal pain, joint and renal involvement
3. Severe hypertension may supervene
4. CNS manifestations:
 - a. Focal neurologic deficits
 - b. Altered level of consciousness
5. Peripheral neuropathies:
 - a. Mononeuropathy multiplex
 - b. Peripheral VIIth nerve palsy
 - c. Brachial plexopathy
 - d. Guillain-Barré syndrome

Neuropathology

1. Leukocytoclastic reaction in the skin
2. IgA vascular deposits
3. Arterioles, capillaries, and venules are primarily affected

Laboratory Evaluation

1. Occasional eosinophilia
2. Elevated IgA is detected in 50% of patients
3. EMG:
 - a. Mononeuropathy multiplex
 - b. Demyelinating feature in a subgroup of patients
4. Factor XIII deficiency (rare)
5. Decreased complement (rare)
6. Increased ESR in approximately 20% of patients

Hypereosinophilic Syndrome (HES)*General Characteristics*

1. Eosinophilic disorders that are characterized by chronic blood eosinophilia for more than six months, characterized by eosinophilic mediated damage to organs
2. Myeloproliferative HES has interstitial deletions on chromosome 4q12
3. Lymphocytic HES:
 - a. A primary lymphoid disorder characterized by a non-malignant expansion of a T-cell population that produces eosinophilopoietic cytokines
 - b. Other variants have not been molecularly identified

Clinical Manifestations

1. Associated skin, cardiac, hematologic or gastrointestinal manifestations are defined
2. Patterns of peripheral neuropathy:
 - a. Generalized peripheral sensorimotor neuropathy; radiculopathy
 - b. Mononeuropathy multiplex
 - c. Neuropathies occur in approximately 6 to 14% of patients
3. Associated neurologic involvement:
 - a. Inflammatory myopathy
 - b. Ataxia
 - c. Cerebral infarction
 - d. Leptomeningeal dissemination
 - e. Cognitive dysfunction
 - f. Ophthalmologic involvement

Neuropathology

1. Myeloproliferative variant that includes chronic eosinophilic leukemia
2. Deficits are secondary to toxic components of eosinophils

Laboratory Evaluation

1. Elevated levels of eosinophilia for more than six months (often as high as 20,000 cells/mm³)
2. EMG:
 - a. Features of axonal sensorimotor neuropathy

Uremic Neuropathy*General Characteristics*

1. Approximately 60% of patients with renal failure develop neuropathy
2. Glomerular filtration rates <12 ml/minute
3. In adults, peripheral neuropathy occurs in 50 to 60% of patients on dialysis
4. Evidence supports the contribution of diabetes, advanced age, low creatinine and urea to the neuropathy
5. Nerve damage may occur from toxins associated with uremia

Clinical Manifestations

1. Most commonly there is a length dependent numbness, tingling, and mechano-allodynia

2. Cramping of the calves may be prominent at the initiation of the neuropathy
3. Restless legs are common
4. Large fiber sensory modalities are most frequently involved
5. There is mild distal > proximally weakness and loss of muscle stretch reflexes
6. An AIDP phenotype occurs with rapidly progressive weakness and sensory loss
7. Mononeuropathies are documented:
 - a. May be related to hemodialysis equipment with a cuprophane membrane which incompletely removes beta-2 microglobulin that is catabolized by the kidney; this protein may be deposited in the transverse ligament of the carpal tunnel as well as the cubital tunnel and at the fibular level. An ischemic median neuropathy may occur from the shunt; the radial and ulnar nerves may rarely be similarly affected as well

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large myelinated nerve fibers
 - b. Axonal degeneration
 - c. Segmental and paranodal demyelination
2. Autopsy material:
 - a. Chromatolysis of anterior horn cells
 - b. Degeneration of the fasciculus gracilis
3. Two phases of recovery after transplantation
 - a. Dramatic early improvement with protracted recovery over time
4. Excitability studies have demonstrated a correlation between hyperkalemia and nerve dysfunction
5. Nerve damage may occur from guanidine compounds, parathyroid hormone and myoinositol molecules in the range of 300–2000 daltons

Laboratory Evaluation

1. Sensory studies demonstrate reduced or unobtainable SNAP amplitudes; slow conduction velocities and prolonged distal latencies are usual
2. Prolonged or absent H-reflexes
3. Somatosensory evoked potentials reveal slow peripheral and central conduction

Liver Disease

General Characteristics

1. Peripheral neuropathy occurs in between 20 to 80% of patients with chronic liver failure by EMG evaluation
2. Major confounders in association with liver disease that may be etiologic in the neuropathy are alcoholism and viral etiologies of the cirrhosis

Clinical Manifestations

1. Numbness and paresthesias of the distal, lower extremities with minimal weakness is the most common presentation
2. Autonomic alterations occur in approximately 50% of patients

Neuropathology

1. Sural nerve biopsy:
 - a. Segmental demyelination and axonal degeneration

Laboratory Evaluation

1. NCS reveal decreased SNAP amplitudes with usually normal motor studies
2. QST:
 - a. Abnormal mechanical and thermal thresholds

Whipple's Disease

General Characteristics

1. Tropheryma whipplei is the causative agent of Whipple's disease
2. The bacterium is transmitted among humans via oro-oral or feco-oral routes
3. The classic features of large joint arthropathy, diarrhea, and weight loss are rare
4. Asymptomatic carriage of T. whipplei is common but overt disease is rare

Clinical Manifestations

1. The clinical spectrum of disease includes:
 - a. An acute self-limiting disease in children
 - b. Localized forms that affect cardiac valves
 - c. Involvement of the CNS and PNS
2. A complicated Whipple's disease causes a T. whipplei endocarditis and may accompany immunosuppression, particularly with TNF-alpha blockade
3. CNS manifestations:
 - a. Dementia
 - b. Supranuclear ophthalmoparesis
 - c. Myorhythmia:
 - i. Rhythmic repetitive slow (1–4 Hz) movements that affect cranial and limb muscles; may be oscillatory or jerky
 - ii. Oculomasticatory myorhythmia is more typically associated with Whipple's disease:
 1. Slow, repetitive, and asymmetrical
 2. Facial and ocular movements are prominent
 - d. Convergence nystagmus
 - e. Myoclonus
 - f. Hyperphagia, insomnia, and polydipsia may occur in the disorder
4. Peripheral manifestations:
 - a. Sensorimotor polyneuropathy

Neuropathology

1. Peripheral lymphadenopathy accompanied by enlargement of the celiac, mesenteric and periaortic lymph nodes
2. May present as an acute infection that includes gastroenteritis, pneumonia and/or bacteremia
3. Jejunal biopsy:
 - a. Macrophages filled with periodic acid-Schiff positive organisms

4. PAS-positive histiocytes may be seen in the CSF; periventricular areas, hypothalamus and scattered diffusely through the brain
5. There are no reports of nerve histology

Laboratory Evaluation

1. CSF:
 - a. Pleocytosis of polymorphonuclear cells and macrophages; rarely PAS-positive histiocytes
2. Specific quantitative PCR of saliva and stool specimens may be diagnostic
3. MRI:
 - a. Gadolinium enhancement of the ependyma
4. EMG:
 - a. NCS of sensory and motor nerves reveal reduced amplitudes and mildly slow conduction velocities

Critical Illness Polyneuropathy

General Characteristics

1. Increased survival of critically ill patients has revealed the syndrome of ICU-acquired weakness
2. The most common neuromuscular cause is polyneuropathy, although many authorities suggest that critical illness myopathy may be equally frequent; prolonged neuromuscular blockade also may cause severe weakness
3. The illness of critical care polyneuropathy and myopathy most often occurs in a setting of multi-organ failure and sepsis. It prolongs mechanical ventilation and hospitalization time and increases mortality and disability

Clinical Manifestations

1. The neuropathy usually develops after 2–3 weeks, but the often altered sensorium precludes accurate assessment of sensory loss. Sepsis, multi-organ failure, and severe burns are significant confounds to pathogenesis. A systemic inflammatory response syndrome has been implicated
2. Presentation is often difficulty in weaning the patient from mechanical ventilation
3. The neuropathy is primarily motor that varies from just an electrodiagnosis without clinical deficits to quadriplegia with respiratory insufficiency
4. Sensory symptoms and signs are variable, but often mild and hard to document due to confounding mental status alterations
5. Cranial nerves are most often not affected
6. Little or no autonomic dysfunction

Neuropathology

1. Nerve biopsy:
 - a. Axonal degeneration
2. Autopsy material demonstrates:
 - a. Chromatolysis of anterior horn cells, loss of dorsal root ganglion cells, as well as degeneration of motor and sensory nerve axons

3. Muscle biopsy:
 - a. Features of neurogenic atrophy that include target or core-like lesions
 - b. Loss of myosin thick filaments

Laboratory Evaluation

1. Serum creatine kinase is usually normal (high values would indicate critical illness myopathy)
2. EMG:
 - a. Reduced amplitudes or absent CMAPs with normal motor conduction velocities and distal latencies
 - b. SNAPs are reduced in amplitude or absent (may be due to age, diabetes, uremia, or other underlying illness)
 - c. Needle EMG:
 - i. Positive sharp waves and fibrillation potentials
 - ii. Decreased MUAPs; if recruited they may be small and polyphasic; early recruitment small duration polyphasic MUAPs suggest myopathy
3. Screening for neuropathy with single nerve conduction studies reveals decreased amplitudes
4. Another method to distinguish critical neuropathy from myopathy is the ratio of nerve stimulation evoked CMAP to direct muscle stimulation CMAPs
 - a. Expected is 1:1 (>.9) in myopathy and zero (.1 μ V) with neuropathy or neuromuscular junction disorder

Amyloid Polyneuropathy

Overview

Amyloid is a 10 to 20 nm non-branching protein fibril which when aggregated forms β -pleated sheets that are resistant to proteolytic degradation. It causes proteinaceous deposition in the kidney, heart, liver, and GI tract, as well as in muscle and peripheral nerves. It has genetic forms and can be acquired. Genetic forms are autosomal dominant and are caused by mutations in the transthyretin (TTR), apolipoprotein A-I (APOA1) or gelsolin genes. Primary AL amyloidosis causes deposition of immune globulin light chains and occurs with multiple myeloma, Waldenström's macroglobulinemia, lymphoma, plasmacytomas, and lymphoproliferative disease. It may be idiopathic. Approximately 10% of patients that have amyloid light-chain (AL) amyloidosis are thought to have a genetic form.

AA amyloidosis, also known as "secondary amyloidosis," may be associated with rheumatoid arthritis and other chronic inflammatory conditions, deposits in visceral organs, but is not associated with a polyneuropathy.

In peripheral nerves, amyloid deposition occurs in the endoneurium, perineurium, epineurium, and around blood vessels. There may be a concomitant inflammatory cell infiltrate. Muscle biopsy demonstrates amyloid deposition that encases muscle fibers.

The variety of amyloid is determined by immunohistochemistry in which antibodies distinguish light chains, apolipoprotein A, gelsolin, and TTR. Genetic testing is optimal for distinguishing the various forms of familial amyloidosis.

Primary or AL Amyloidosis*General Characteristics*

1. Primarily associated with multiple myeloma and other myeloproliferative disease
2. Formerly known as “primary amyloidosis”
3. The amyloid is most often derived from a circulating para-protein which is cleared by macrophage enzymes
4. The cleared light chains aggregate and deposit in visceral organs, peripheral nerves, and muscle
5. In light chain disease, plasma cells produce light chains directly
6. Lambda light chains are more often seen in idiopathic disease, while kappa light chains are predominant in multiple myeloma

Clinical Manifestations

1. AL (light chain) amyloidosis is primarily a disease of older men (55–65 years of age)
2. Has a more rapid course than occurs in hereditary forms
3. Presenting signs and symptoms may be due to visceral involvement which includes:
 - a. Nephrotic syndrome
 - b. Congestive heart failure and cardiac arrhythmia
 - c. Gastrointestinal dysmotility
 - d. Bleeding into the skin
 - e. Constitutional symptoms of fatigue and weight loss

Neuropathology

1. Approximately one-third of patients develop a peripheral neuropathy
2. Initially, it presents as numbness or paresthesias, but a significant proportion of patients develop neuropathic pain and thermal sensitivity changes (small fiber modalities). The pain and autonomic involvement are helpful in differential diagnosis from paraprotein neuropathies
3. Weakness occurs initially in distal leg muscles but evolves to affect the hands and arms
4. Later in the course, large sensory fiber modalities are affected
5. The trunk may be involved
6. In approximately 20% of patients, it presents as mononeuropathy multiplex
7. Carpal tunnel syndrome is present in 25% of patients, from amyloid infiltration of the flexor retinaculum
8. There may be preferential involvement of:
 - a. Lumbar roots
 - b. Plexus
 - c. Motor nerves
 - d. Amyloidomas may involve single nerves (such as the sciatic or trigeminal)
9. Autonomic involvement may be severe and may present early in the illness; signs and symptoms include:
 - a. Alterations of gastrointestinal motility
 - b. Bowel and bladder dysfunction

- c. Impotence
 - d. Decreased sweating
 - e. Pupillary light-near dissociation
10. Rarely, enlarged peripheral nerves can be palpated
 11. Associated features of the general exam include:
 - a. Macroglossia
 - b. Hoarse voice (vocal cord infiltration)
 - c. Peripheral lower extremity edema
 - d. Hepatomegaly
 12. Infiltrative amyloid myopathy is rare
 - a. Enlargement and indurations of muscles (including the tongue)
 13. Nerve biopsy:
 - a. Axonal degeneration
 - b. Loss of small myelinated and unmyelinated fibers; less density of large myelinated fibers
 14. Congo red stains reveal:
 - a. Amyloid deposition of either globular or diffuse pattern in the endoneurium, epineurium, and perineum
 - b. Blood vessel walls
 - c. Other sites that may be biopsied to demonstrate amyloid deposition are:
 - i. Rectum
 - ii. Salivary glands
 - iii. Abdominal fat pad
 - iv. Kidney
 - v. Stomach
 - vi. Liver

Laboratory Evaluation

1. Serum monoclonal proteins are composed of IgG, IgM, or IgA; only free Lambda or K-light chain (more common in multiple myeloma) can be seen
2. Initial screen of the urine and serum for an abnormal paraprotein
3. Only a small subgroup of genetic amyloid patients have a monoclonal gammopathy
4. Immunoelectrophoresis or immunofixation of the serum and urine are sensitive for detecting light chains (more sensitive than serum or urine electrophoresis)
5. Hypogammaglobulinemia, renal failure, increased liver enzymes are frequently associated
6. Elevated CK occurs if there is concomitant myopathy
7. CSF has slightly elevated protein without pleocytosis
8. EMG:
 - a. Sensory nerve amplitudes are reduced or absent; distal latencies and conduction velocities are only minimally affected
 - b. Motor conduction velocities are less affected than sensory; distal motor latencies are more prolonged in the lower than upper extremities
 - c. CMAP amplitudes are slightly reduced in the early course of the disease and are not as severely involved as SNAPs
 - d. Carpal tunnel is common

- e. Needle EMG:
 - i. Signs of denervation in affected muscles
 - ii. Patients with myopathy may demonstrate:
 - 1. Myotonic discharges
 - 2. Myopathic MUAPs

Differential Diagnosis of Acquired Amyloid Neuropathy

1. Familial forms of amyloid
2. Small fiber neuropathies
3. Myeloproliferative neuropathies
4. Paraneoplastic disease
5. Diabetic neuropathy
6. Sjögren's disease
7. Idiopathic small fiber neuropathy

Secondary Amyloidosis or AA Amyloidosis

General Characteristics

1. Is caused by chronic infection or chronic inflammatory disease
2. Formerly known as "secondary amyloidosis"
3. Generally, is not associated with neuropathy

TTR-Related Amyloidosis (FAP Type I and II)

General Characteristics

1. Transthyretin (TTR) amyloidosis is characterized by extracellular deposition of amyloid fibrils composed of TTR (transthyretin)
2. TTR is a plasma transport protein for thyroxine and vitamin A
3. It is produced in the liver, dissociates from its usual tetramer, is misfolded, and aggregates into amyloid fibrils
4. TTR amyloidosis is the most common form of familial amyloidosis; the mutations destabilize the TTR protein
5. TTR amyloid also causes senile systemic amyloid, which is acquired and primarily affects men over 60 years of age, and results from deposition of wild-type TTR amyloid

Genetics

1. There are more than 80 mutations that have been identified in the TTR gene which maps to chromosome 18q 11.2-12.1
 - a. Mutation at position 30 (Val 30 Met) is the most common mutation associated with FAP I
 - b. The most common mutations for FAP II involve serine at position 84 and histidine at position 58
 - c. There is variability within families regarding age of onset and severity in those with the Val 30 Met mutations
 - d. Endemic areas for TTR-FAP mutations are Portugal, Sweden, Japan, Brazil, and Majorca
 - e. Incidence in the USA is 1/100,000 individuals

Clinical Manifestations

1. There are two major clinical forms of TTR mutations:
 - a. FAP I (severe)

- b. FAP II (milder phenotype)
2. Onset is usually between the second and fourth decades
 - a. Associated with variations across different populations
 - b. Portuguese and Japanese patients have an early onset mean age of 33 years, whereas Swedish patients have a near age of onset at 56 years
 3. Pattern of neuropathies:
 - a. Typical insidious onset of numbness and painful paresthesias in the distal lower extremities; small fiber sensory modality loss predominates
 - b. Carpal tunnel syndrome is not common, as opposed to AL primary amyloidosis
 - c. Autonomic involvement is often severe:
 - i. Postural hypotension
 - ii. Constipation or continual diarrhea
 - iii. Erectile dysfunction
 - iv. Dyshidrosis
 - d. Distal extremity weakness and atrophy evolve
 - e. Cranial nerve involvement occurs
 - f. Visceral involvement from amyloid deposition occurs in the heart, liver, kidneys and cornea
 - g. Symptoms may be similar in patients with different genotypes; phenotypes may not be uniform, and the same point mutation may produce different phenotypes
 - h. Clinical manifestations of Val 30 Met TTR-FAP differ according to specific endemic foci
 - i. Patients usually succumb to the illness 10 to 15 years after onset, from cardiac and renal involvement

Clinical Manifestations of Type II FAP

1. Originally described in families from Indiana and Switzerland
2. Early carpal tunnel syndrome
3. Later stages of the disease patients develop a mild generalized sensorimotor polyneuropathy
4. Accompanied by vitreous opacities that also occur with TTR-FAP Type I
5. Severe autonomic dysfunction is unusual
6. Rare development of cardiac or renal complications
7. Patients with Val 30 Met TTR-FAP from non-endemic foci usually have onset of disease after the age of 60 years, are predominantly male and have a sporadic presentation
8. FAP II usually has a long survival

Neuropathology

1. Multifocal (or diffuse) deposition of amyloid within the endoneurium, epineurium, or perineurium
2. Amyloid deposition within and around blood vessels
3. Amyloid deposits around blood vessels in the autonomic ganglia and peripheral nerves
4. Predominant loss of thinly myelinated and unmyelinated nerve fibers
5. Axonal degeneration and segmental demyelination occur
6. Other organ involvement:

- a. Cardiac disease occurs in approximately 50% of patients
- b. Ocular involvement causes:
 - i. Vitreous opacity
 - ii. Dry eyes
 - iii. Glaucoma
 - iv. Light-near pupillary dissociation

Laboratory Evaluation

1. Biopsy of the abdominal fat pad; rectal mucosa
2. Deposits of amyloid in nerve biopsies
3. Genetic testing:
 - a. In contrast to acquired forms, there are no monoclonal gammopathies and there is no immunostaining for light chains
4. EKG:
 - a. Bundle branch block, AV and sinoatrial block
 - b. Abnormalities in the long-axis function of both ventricles on tissue Doppler imaging

Leptomeningeal TTR Amyloidosis

General Characteristics

1. Induced by point mutations in the TTR gene and is also seen in advanced Val 30 Met TTR-FAD
2. The source of the TTR in leptomeningeal amyloidosis is thought to be the choroid plexus

Clinical Manifestations

- a. Cerebral amyloid angiopathy
- b. Ocular amyloidosis
- c. CNS manifestations include:
 - i. Infarction of:
 1. Medium-sized and small arteries
 2. Cerebral hemorrhage
 3. Hydrocephalus
 4. Focal neurologic deficits
 5. Dementia
 6. Amyloid deposition in the vitreous bodies and other tissues of the eye

Neuropathology

1. Amyloid deposition in the media and adventitia of medium-sized and small arteries, arterioles, and veins of the cortex and leptomeninges
2. TTR Val 30 Gly mutation was associated with refractory bilateral intermediate uveitis and elevated intraocular pressure with meningeal amyloid

Laboratory Evaluation

1. Ocular findings of uveitis
2. Meningeal biopsy that demonstrates amyloid
3. MRI:
 - a. Familial amyloid patients with the ATTRY114C mutations revealed gadolinium enhancement from the brainstem to the spinal cord

Apolipoprotein A1 Related Amyloidosis (Type III FAP or the Van Allen Type)

General Characteristics

1. FAP type III is caused by mutations in the apolipoprotein A1 gene on chromosome 11q23-qter that cause an arginine substitution for glycine at position 26
2. High-density lipoproteins and their major protein apolipoprotein A-1 (apo A-1) promote vascular health by removing excess cellular cholesterol. In FAP III amyloidosis non-variant full-length apo A-1 deposits as fibrils

Clinical Manifestations

1. Onset of neuropathy is in the fourth decade
2. Neuropathy usually starts in the distal lower extremities with paresthesias and painful dysesthesia. It evolves over time to affect the upper extremities that may involve proximal muscles
3. Autonomic neuropathy is usually not severe
4. Patients usually succumb 12–15 years after onset of the illness from renal failure

Neuropathology

1. N-terminal fragments of variant apo A-1 deposit in vital organs as well as the peripheral nerve

Laboratory Evaluation

1. Biopsy of the abdominal fat pad or peripheral nerve
2. Genetic testing

Gelsolin-Related Amyloidosis (FAP Type IV, Finnish)

General Characteristics

1. Type IV amyloidosis results from mutations in the gelsolin gene that maps to chromosome 9q32-q34
2. Gelsolin is a widespread binding protein that can be recovered from plasma and leukocytes

Clinical Manifestations

1. Onset of the disease is usually in the third decade
2. Primary clinical manifestations are:
 - a. Lattice corneal dystrophy
 - b. Severe facial and bulbar weakness
 - c. A mild generalized sensorimotor polyneuropathy without autonomic dysfunction

Neuropathology

1. Deposition of gelsolin amyloid in vascular walls and perineural sheaths
2. Nerve roots are more severely affected than distal nerves
3. Large myelinated fibers are preferentially involved

Laboratory Evaluation

1. Ophthalmologic evaluation of the distinctive corneal lattice degeneration
2. Genetic testing

Neuropathies Associated with Infections

Leprosy (Hansen's Disease)

Overview

The disease is caused by the acid-fast bacteria *Mycobacterium leprae* and *Mycobacterium lepromatosis*. It is a common cause of infectious peripheral neuropathy in Southeast Asia, Africa, and South America. The spectrum of disease ranges from tuberculoid leprosy, an intermediate form, to lepromatous leprosy. The clinical manifestations are dependent on the host's immunological response to the infection.

Tuberculoid Leprosy

General Characteristics

1. The cell-mediated immune response is intact

Clinical Manifestations

1. The skin lesions are well circumscribed, scattered hypopigmented patches with raised erythematous borders. They may have a plaque-like morphology
2. The cutaneous nerves are affected, which causes loss of sensation in the center of the skin lesions
3. Cooler regions of the body (face, ears, nose, and limbs) are most often affected
4. Other sites of nerve involvement include:
 - a. The ulnar nerve at the elbow (medial epicondyle)
 - b. The median nerve near in the distal forearm
 - c. The superficial radial nerve at the wrist
 - d. The peroneal nerve at the fibular head
 - e. The greater auricular nerve
 - f. The nerve involvement causes mononeuropathy or mononeuropathy multiplex; pure neuritic leprosy occurs; the nerves are often palpable

Neuropathology

1. There is granuloma formation by macrophages and Th1 cells that are surrounded by Th2 cells
2. Caseation may occur; the lesions extend throughout the dermis
3. The Fite stain is negative for bacteria
4. Cell-mediated immunity is intact:
 - a. Th1 > Th2 lymphocytes
 - b. Increased cytokine expression
 - c. IL-2

Laboratory Evaluation

1. Lepromin test is positive (>5 mm of induration)
2. Bacterial index 0
3. Morphological index is low

Lepromatous Leprosy

General Characteristics

1. Cell-mediated immunity is decreased, which causes extensive bacterial infiltration and hematogenous spread

Clinical Manifestations

1. Confluent and symmetrical rash that is anesthetic and anhidrotic
2. Predilection for cooler areas of the body; older lesions form plaques and nodules
3. Loss of eyebrows and eyelashes
4. Skin infiltration exaggerates natural skin folds causing "leonine facies"
5. The superficial cutaneous nerves of the skin and distal extremities are often involved
6. A slowly progressive symmetric sensorimotor polyneuropathy evolves:
 - a. Distal extremity weakness occurs
 - b. Relative sparing of large myelinated sensory afferents
 - c. Muscle stretch reflexes are relatively spared
 - d. Facial neuropathy
 - e. Mononeuropathies may be superimposed on the generalized neuropathy
 - f. No pure neuritic phenotype

Neuropathology

1. Infiltrating bacilli, Th2 lymphocytes, and macrophages with bacilli are noted
2. Electron microscopy of bacilli reveals the bacillus to be a dense osmophilic rod surrounded by a clear halo
3. Fite stain is positive
4. Cell-mediated immunity is markedly depressed or absent
 - a. Th2 > Th1 lymphocytes
 - b. IL4, IL5 and IL10 are the expressed cytokines

Laboratory Evaluation

1. Lepromin test is negative (0–2 mm of indurations)
2. Bacterial index is high (5–6)
3. Morphological index is high (0–10)

Borderline Leprosy

General Characteristics

1. The most common form with neuropathy
2. Associated with both the clinical and histological features of both the tuberculoid and lepromatous forms of the disease
3. There is partial spread of disease that provokes an inflammatory response
4. The clinical picture may shift toward the tuberculoid or lepromatous form of the disease depending on the immunological status of the patient

Clinical Manifestations

1. Skin lesions are intermediate between those seen in the tuberculoid or lepromatous form of the disease
2. Generalized symmetric sensorimotor polyneuropathy
3. Mononeuropathy
4. Mononeuropathy multiplex
5. Brachial plexopathy

Effects of Treatment

1. Immunologic interactions during the course of treatment may affect the course of the disease and the patient's subsequent disability
2. The three types of immunologic reactions with leprosy are:
 - a. Reversal reaction (type 1):
 - i. Most commonly seen in borderline leprosy
 - ii. Occurs at any time during treatment and is due to an increase in cellular immunity
 - iii. Associated with increased levels of tumor necrosis factor alpha (TNF- α), gamma interferon 2 and interleukin 2:
 1. New granulomas may form
 2. Exacerbation of the rash and worsening of the neuropathy
 - b. Nodosum leprosum (type 2):
 - i. Most commonly occurs during treatment
 - ii. Erythematous, painful nodules (subcutaneous) are seen that may be associated with worsening of the neuropathy
 - iii. Most likely the result of new antigen exposure from degenerating bacilli (Toll-like receptor response from the newly released antigens)
 - c. Lucio phenomenon:
 - i. A rare form of lepra reaction
 - ii. Tender nodules with ulceration and necrotic areas
 - iii. A cutaneous vasculitis involving medium- and small-sized vessels

Neuropathology

1. Granulomas contain epithelioid cells but no giant cells
2. Lymphocytes are scant, but if seen are diffusely infiltrating
3. Usually, there is evidence of cell-mediated immunity

Laboratory Evaluation

1. Lepromin reaction (2–5 mm of induration)
2. Bacterial index (2–4)
3. Morphologic index is moderate

Pure Neuritic Leprosy**General Characteristics**

1. Most patients have the tuberculoid or borderline phenotype

Clinical Manifestations

1. Patients have isolated peripheral neuropathy without skin lesions

Laboratory Evaluation for All Forms of Leprosy

1. EMG:
 - a. The pattern of involvement on both needle EMG and NCS is that of mild to moderate active denervation
 - b. Sensory nerve conduction velocities are usually de-

creased in the lower extremities and are reduced in amplitude in the arms

- c. Motor NCS are usually normal, but a subgroup of patients may have reduced NCVs
- d. The pattern of involvement is generally a symmetrical polyneuropathy, mononeuropathy or multiple mononeuropathies
- e. Evaluation of leprosy by NCS may be independent of the patient's degree of infection

Lyme's Disease**General Characteristics**

1. Lyme neuroborreliosis is the designation of the neurologic syndromes caused by the spirochete *Borrelia burgdorferi* (Bb)
2. The deer tick (*Ixodes* genus) is the responsible vector
3. The three stages of Lyme's disease are:
 - a. Early infection characterized by localized erythema migrans
 - b. Disseminated infection
 - c. Late stage infection

Clinical Manifestations

1. Stage I:
 - a. In general, approximately one month after the tick bite, an circular erythematous lesion appears which expands. The center clears giving it a bull's-eye appearance. The rash clears within a month. Some patients with Lyme's disease do not develop erythema migrans
2. Stage II:
 - a. Dissemination of the spirochete occurs throughout the body
 - b. Systemic symptoms of fever, chills, localized adenopathy, fatigue, and myalgia are common, and may be associated with additional skin lesions
 - c. Associated cardiac involvement (conduction blocks and pericarditis), as well as small and large joint infection, may occur
3. Neurologic manifestations start in the second and third stages and include:
 - a. Unilateral and bilateral VIIth nerve palsies; occurs in approximately 50% of patients
 - b. Painful sensory radiculitis
 - c. Multifocal motor radiculopathy
 - d. May present with GBS phenotype
 - e. Meningitis signs and symptoms are more frequent in children than adults
 - f. Approximately 4–8% of patients develop cardiac complications, 11% develop neurologic manifestations, and 45–60% have an inflammatory arthritis
4. In late stage disease:
 - a. Destructive joint inflammation
 - b. Distal extremities may become cyanotic, associated with paresthesia and weakness with large fiber sensory loss and decreased muscle stretch reflexes

- c. Cognitive decline is controversial
- d. Rare inflammatory myopathy

Neuropathology

1. Nerve biopsy:
 - a. Perivascular infiltration of plasma cells and lymphocytes around the blood vessels that supply the endoneurium, perineurium, and epineurium
 - b. Axonal degeneration with secondary demyelination
 - c. Root inflammation and dorsal root ganglia pathology are seen

Laboratory Evaluation

1. Immunofluorescence enzyme-linked immune absorbent assay
2. Western blot analysis confirms a positive enzyme-linked immune absorbent assay
3. Patients with CNS involvement, polyradiculitis, and facial nerve involvement demonstrate CSF lymphocytic pleocytosis with moderately increased protein elevation
4. EMG:
 - a. Electrodiagnostic studies are most consistent with a primary axonopathy
 - b. Patients with mononeuropathy demonstrate:
 - i. Reduced compound muscle action potentials (CMAP) and SNAP amplitudes
 - ii. Demonstrated abnormalities are most often asymmetric
 - iii. Fibrillation, positive sharp waves, and decreased recruitment of neurogenic MUAPs are seen in affected muscles
 - iv. In late stage disease, a subgroup of patients may develop an inflammatory myopathy

Diphtheria

General Characteristics

1. Diphtheritic polyneuropathy is caused by an exotoxin-producing strain of *Corynebacterium diphtheriae*
2. Spread by respiratory secretions and cutaneous lesions (human-to-human contact)
3. The disease is vaccination preventable; the last reported patient in the USA was in 2003

Clinical Manifestations

1. Diphtheria is a biphasic illness:
 - a. Patients may initially present with a low-grade fever, sore throat, neck swelling and some degree of palatal paralysis within 7 to 10 days of exposure
 - b. A whitish membranous exudate in the pharynx may occur with or without lymph node involvement
 - c. Cardiac involvement causes arrhythmias and hypotension
 - d. Approximately 3 to 4 weeks after the initial infection, patients develop:
 - i. Decreased pharyngeal sensation
 - ii. Dysphagia, dysarthria, and hoarseness
 - iii. Diplopia (adductor function of the IIIrd nerve) initially
 - iv. Pupil responds to light but fails accommodation
 - v. Respiratory weakness

- e. Diphtheritic polyneuropathy:
 - i. Is caused by hematogenous dissemination of intracellular toxin A
 - ii. Occurs 2–4 months following the initial infection
 - iii. Characteristic polyneuropathy with numbness, paresthesias, and extremity weakness; all sensory modalities are affected with distal > proximal weakness
 - iv. Muscle stretch reflexes are reduced or absent
 - v. Autonomic dysfunction of bowel and bladder is rare

Neuropathology

1. Nerve biopsy:
 - a. Segmental demyelination and axonal degeneration are evident
 - b. There is involvement of nerve roots and the dorsal root ganglia
 - c. The diphtheria toxin binds to Schwann cells and inhibits myelin protein synthesis

Laboratory Evaluation

1. CSF protein is often elevated, with or without a lymphocytic pleocytosis
2. EMG:
 - a. Sensory NCS demonstrates absent SNAPs
 - b. Motor NCS reveal moderately prolonged distal latencies with decreased nerve conduction velocities
 - c. NCS abnormalities are generally noted by two weeks following the onset of symptoms and reach maximum intensity between 5–8 weeks
 - d. NCS improvement frequently lags behind clinical recovery, which usually occurs after several months

Human Immunodeficiency Virus (HIV)

General Characteristics

1. The global prevalence of HIV infection is approximately 37 million people (as of the end of 2014)
2. Combination antiretroviral therapy (cART) has greatly expanded life expectancy to almost normal ranges
3. HIV sensory neuropathy affects between 27% to 57% of ambulatory patients; approximately 38% to 90% of patients with sensory neuropathy have neuropathic pain
 - a. The prevalence of HIV-sensory neuropathy is approximately 40% even in patients with no exposure to dNRTI (nucleoside reverse transcriptase inhibitors)
 - b. Recent cART-era populations and gene association studies have identified additional patient-related risk factors which include:

- i. Ethnicity
- ii. Elevated plasma triglycerides
- iii. Association with genes involved in inflammation and mitochondrial function

Clinical Manifestations

1. Patterns of neuropathy:
 - a. Distal symmetric polyneuropathy
 - b. Inflammatory demyelinating polyneuropathy (phenotype similar to AIDP and CIDP)
 - c. Multiple mononeuropathies (Vasculitis and CMV-related)
2. Polyradiculopathy (usually lumbar and sacral) that is CMV-related
3. Autonomic neuropathy
4. Sensory ganglionitis
5. Associated with retroviral treatment

HIV-Related Distal Symmetric Polyneuropathy (DSP)

General Characteristics

1. The most common form of peripheral neuropathy associated with HIV infection, most often seen in patients with AIDS

Clinical Manifestations

1. Numbness and paresthesias of the distal extremities
2. There is usually slight distal muscle weakness, which may evolve to proximal leg weakness and moderate distal arm weakness
3. Asymptomatic patients may have sensory loss in the extremities to all modalities on examination
4. Reduced muscle stretch reflexes in the ankles, but usually spared at the knee and in the upper extremities
5. Many patients have moderate to severe burning pain in a stocking and glove distribution, most often in patients being treated with dideoxynucleoside reverse transcription inhibitors (d-drugs)
6. May affect 50% of all HIV-infected patients

Neuropathology

1. Two major mechanisms have been proposed for the neuropathy:
 - a. Neurotoxicity from the virus and its products
 - b. Neurotoxic effects of medications used in its treatment
2. Nerve biopsy:
 - a. Axonal degeneration, with loss of both myelinated and demyelinated axons
 - b. Loss of neurons in the dorsal root ganglion, with secondary degeneration in the posterior columns
 - c. Minimal perivascular inflammation, with macrophages and T-lymphocytes
3. Increased levels of proinflammatory cytokines
4. A subset of patients has vitamin B12 deficiency
5. Skin biopsy:
 - a. Reduced density of small myelinated epidermal nerve fibers

Laboratory Evaluation

1. CSF:
 - a. Mild lymphocytic pleocytosis with moderate protein elevation
2. EMG:
 - a. Nerve conduction studies are consistent with a symmetric axonal sensory greater than motor polyneuropathy

HIV-Related Inflammatory Demyelinating Polyradiculopathy

General Characteristics

1. AIDP most often develops at the time of seroconversion, while CIDP occurs at any point during the infection

Clinical Manifestations

1. Similar to idiopathic AIDP and CIDP

Neuropathology

1. Nerve biopsy: similar to AIDP and CIDP

Laboratory Evaluation

1. CSF:
 - a. Lymphocytic pleocytosis
 - b. Elevated protein
2. EMG:
 - a. Similar to idiopathic AIDP and CIDP

CMV-Related Progressive Polyradiculopathy

General Characteristics

1. Most often seen in severely affected AIDS patients (CD4⁺ counts of less than 200 cells/mm³)

Clinical Manifestations

1. Severe leg radicular pain and numbness that is usually asymmetric
2. Loss of perineal sensation
3. Bowel and bladder incontinence
4. Moderate to severe weakness of the legs; weakness of the arms may evolve during the course of the illness
5. Cranial nerves may be involved
6. Decreased or absent muscle stretch reflexes in the legs; reduced reflexes in the arms
7. CMV retinitis is frequently a concomitant infection
8. Plantar responses are flexor if the infection is relegated to the lumbosacral roots; Babinski sign occurs with CMF myelitis

Laboratory Evaluation

1. CSF:
 - a. Decreased glucose concentration
 - b. Neutrophilic pleocytosis
 - c. Increased protein
2. CMV can be cultured from the CSF, urine, and blood
3. EMG:
 - a. Decreased amplitudes of SNAPs and CMAPs
 - b. Denervation with fibrillation potentials and positive sharp waves in the affected muscles

Neuropathology

1. Lumbosacral axonal loss in both dorsal and ventral roots
2. Inflammatory infiltrates
3. Rare cranial nerve inflammation, often associated with myelitis
4. CMV may be demonstrated in endothelial cells and macrophages (with the nerve biopsy)
5. Ischemic vasculitis and direct CMV infection are putatively causative

HIV-Related Multiple Mononeuropathies*General Characteristics*

1. Mononeuropathies may develop in AIDS patients

Clinical Manifestations

1. Weakness, sensory loss and pain occur in the distribution of affected nerves

Neuropathology

1. Axonal degeneration
2. Necrotizing vasculitis
3. Perivascular inflammation
4. Vasculitis may occur from the deposition of HIV antigen-antibody complexes on vascular walls, or from concomitant CMV or hepatitis B or C infection

Laboratory Evaluation

1. CSF:
 - a. Mononuclear cell pleocytosis
 - b. Elevated protein
2. EMG:
 - a. Reduced amplitudes of motor and sensory potentials
 - b. Symmetry of amplitudes
 - c. Distal latencies are normal or slightly prolonged
 - d. Conduction velocities are normal or only slightly reduced
 - e. Denervation changes in affected muscle

HIV-Related Autonomic Neuropathy*General Characteristics*

1. Distal symmetric polyneuropathy (DSP) is often associated with autonomic impairment
2. The composite autonomic severity score (CASS) in patients with autonomic impairment with HIV correlated with:
 - a. Increased total neuropathy score (TNS)
 - b. Age
 - c. Viral load
 - d. Hypertension
 - e. Use of medications, primarily anticholinergic
3. There was no correlation with:
 - a. Antiretroviral treatment
 - b. CD4⁺ count
 - c. HIV duration
 - d. Metabolic factors
 - e. CNS diseases

Clinical Manifestations

1. Orthostatic hypotension
2. Impaired sweating
3. Bladder dysfunction
4. Impotence
5. Diarrhea
6. Autonomic dysfunction may develop insidiously

Neuropathology

1. Distal axonal degeneration
2. Neuronal loss in DRG and autonomic ganglia
3. Inflammatory cell infiltration
4. Reduced epidermal nerve fiber density (ENFD)
5. Pathogenesis:
 - a. Glycoprotein (Gp) 120 expressed on the surface of the HIV envelope
 - b. Gp 120 may activate macrophages to release TNF-alpha and IL-1; induces Schwann cells to release RANTES that induces DRG cells (possibly autonomic ganglia cells) to release TNF-alpha, which induces cell death through TNF receptor 1-mediated neurotoxicity
6. Mitochondrial damage appears most severe in patients with NRT1 exposure. A proposed mechanism is inhibition of mitochondrial DNA polymerase

Laboratory Evaluation

1. Cerebrospinal fluid:
 - a. Lymphocytic pleocytosis is present in greater than 50% of asymptomatic HIV patients, usually up to 50 cells/mm³ in seropositive patients
 - b. CSF protein is elevated in both seronegative and seropositive patients (50–80 mg%)
 - c. DSP and mononeuropathy multiplex patients may demonstrate a mild mononuclear pleocytosis
 - d. CSF glucose is normal in HIV patients
 - e. A low glucose (30–40 mg%), high PMN pleocytosis (as high as 2000 cells/mm³); high protein up to 1 gram/dl has been reported in CMV lumbosacral plexitis
 - f. CMV detection of DNA by PCR is important as culture is only positive in 50% of patients
2. EMG:
 - a. Similar to that seen with DSP
 - b. Abnormal autonomic testing

HIV-Related Sensory Neuropathy/Ganglionopathy*General Characteristics*

1. Dorsal root ganglionitis during HIV infection is rare
2. Occasionally it is the presenting peripheral nerve presentation

Clinical Manifestations

1. Sensory ataxia
2. Large myelinated fiber deficits cause proprioception and vibration loss
3. Decreased or absent motor stretch reflexes
4. Preserved strength

Neuropathology

1. Inflammatory cell infiltrates of the dorsal root ganglia
2. Loss of large dorsal root ganglia neurons
3. Degeneration of myelinated nerve fibers in peripheral nerves

Laboratory Evaluation

1. Decreased-amplitude or unobtainable SNAPs

Differential Diagnosis of HIV Distal and Sensory Polyneuropathy

1. Concomitant diseases that cause neuropathy in AIDS patients:
 - a. Diabetes mellitus
 - b. Uremia
 - c. Drug abuse (ethanol)
 - d. Standard HAART therapy
 - e. B12 deficiency
 - f. Diffuse infiltrative lymphocytosis syndrome that consists of:
 - i. Painful distal neuropathy
 - ii. Acute onset
 - iii. Primarily motor involvement
 - iv. May be asymmetric and restricted to the arms

Differential Diagnosis of HIV Polyradiculopathy

1. CMV
2. Mechanical bone and disc compression of the cauda equina
3. Lymphomatosis of the meninges
4. Syphilis

Differential Diagnosis of Neuropathy in Late HIV Infection

1. Superimposed CMV infection
 - a. Patient is not responding to therapy as expected
 - b. A rapidly progressive course
 - c. Associated myelitis and retinitis
 - d. CD4⁺ count of fewer than 200 lymphocytes/mm³
2. Diffuse infiltrative lymphocytosis syndrome

HTLV-1*General Characteristics*

1. Human T-lymphotropic virus type 1 (HTLV-1)-associated myelopathy/tropical spastic paraparesis is a chronically progressive myelitis that dominates symptomatology
2. There is an associated axonal sensorimotor polyneuropathy
3. Approximately 20 million people are affected worldwide with approximately 0.3–0.4% destined to get TSP/HAM
4. Endemic areas are Southern Japan, the Caribbean, Africa and some areas of South and Central America
5. The incidence is 2 patients/100,000 people in endemic areas

Clinical Manifestations

1. Slowly progressive severe spastic paraparesis with sphincter involvement
2. The neuropathy can occur in the absence of the myelopathy
3. A myositis may occur
4. A sensory greater than motor axonal length-dependent polyneuropathy is characteristic

Neuropathology

1. Sural nerve biopsy:
 - a. Axonal degeneration with secondary demyelination associated with inflammatory infiltrates
 - b. The HTLV-1 proviral DNA and mRNA activated T-cells CD8⁺ specific for Tax protein that up-regulates proinflammatory cytokines

Laboratory Evaluation

1. HTLV-1 proviral DNA and mRNA are increased in the CSF
2. EMG:
 - a. Characteristics of an axonal sensory greater than motor neuropathy

Cytomegalovirus Virus*General Characteristics*

1. One of the most important opportunistic infections in AIDS patients (usually with CD4⁺ counts <200/mm³)

Clinical Manifestations

1. Retinitis
2. Encephalitis
3. Polyradiculopathy (particularly of lumbosacral roots) often associated with myelitis
4. Multifocal neuropathy (radial, ulnar, and peroneal nerves)
5. Cranial nerves may be involved

Neuropathology

1. Patients with AIDP after CMV infection demonstrate serum autoantibodies against moesin (membrane-organizing extension spike protein)
2. Moesin:
 - a. Expressed in Schwann cell process at the nodes of Ranvier
 - b. Pivotal for myelination
 - c. Possible antigen in CMV AIDP

Laboratory Evaluation

1. EMG:
 - a. Characteristic of polyradiculopathy
2. Mononeuropathy of ulnar, radial, and peroneal nerves
3. PCR positive for CMV in the CSF
4. MRI:
 - a. May demonstrate gadolinium enhancement of the cauda equina

Herpes Varicella-Zoster*General Characteristics*

1. Ubiquitous neurotropic herpes virus
2. The primary infection causes varicella (chicken pox), after which the virus becomes latent in dorsal root ganglia along the entire neuraxis
3. A decline in cell-mediated immunity with age or immunosuppression causes virus reactivation
4. Approximately 95% of the USA population is infected
5. Reactivation is common in HIV patients and those undergoing chemotherapy
6. Transmission is respiratory or by direct contact

Clinical Manifestations

1. Radicular distribution of severe lancinating pain:
 - a. 50% of patients have a thoracic dermatome distribution
 - b. 20% lumbosacral distribution
 - c. 30% cervical distribution
 - d. The diaphragmatic innervations can be affected
2. Decreased threshold to primary modalities of cold and pin-prick in affected dermatomes
3. Mechanical dynamic and static allodynia in the affected dermatomes
4. There may be secondary mechano-hyperalgesia in the dermatomes above and below the affected dermatome with analgesia in the zone of the affected root
5. Sensory symptoms (usually bring pain) may occur prior to the skin eruption; at times greater than 2–3 months; herpes sine herpette
6. Weakness of muscles in the affected dermatome occurs in 5 to 30% of patients, usually within the first 14 days after the skin eruption, but can be delayed up to a month
7. Cranial nerve involvement is infrequent:
 - a. Ophthalmoplegia is rare
 - b. IIIrd cranial nerve is most frequently involved if cranial nerve involvement occurs
 - c. VI cranial nerve involvement is often associated with meningoencephalitis
8. Rarely optic neuritis occurs
9. VII–VIII involvement with vesicles in the external auditory canal constitutes the Ramsay Hunt syndrome
10. Other HZV neurologic complications include:
 - a. Post-herpetic neuralgia
 - b. Meningoencephalitis (particularly with VI involvement)
 - c. VZV temporal arteritis
 - d. VZV vasculopathy may occur in large or small cerebral arteries; cerebral aneurysms and hemorrhage may develop from viral invasion of vessels
 - e. Myelopathy
 - f. Retinal necrosis
 - g. Delayed MCA stroke is associated with VI infection

Neuropathology

1. The virus, when reactivated, migrates down sensory fibers that originate in the dorsal root ganglia to invade the skin and subcutaneous tissue in a dermatomal distribution
2. Axonal degeneration with secondary segmental demyelination
3. Necrosis of dorsal root ganglion cells
4. Loss of dorsal column spinal cord fibers

Laboratory Evaluation

1. Cerebral spinal fluids:
 - a. RBC may be seen (40–50 RBC/mm³)
 - b. Increased protein occurs in 50% of patients
 - c. Normal glucose; rarely glucose is less than 40 mg%
2. Rarely, detection of the virus by PCR is more successful in the serum than the CSF
3. EMG:
 - a. Sensory NCS demonstrate reduced or absent SNAPs
 - b. Motor NCS are normal or have reduced CMAP amplitudes
 - c. Needle EMG of affected muscles reveal positive sharp waves, fibrillation potentials, decreased recruitment and neurogenic MUAPs
4. MRI:
 - a. Meningoencephalitis if VIth nerve is involved with dural enhancement
 - b. Delayed carotid or MCA stroke if VIth nerve is involved

Differential Diagnosis of Radicular Pain on the Thorax Without Rash

1. Cancer of the lung
2. Diabetic neuropathy
3. Disc disease
4. Lymphoma
5. Vascular malformation of a nerve root
6. Sjögren's syndrome

Hepatitis B*General Characteristics*

1. Hepatitis B has extrahepatic complications that include the skin, renal, hematological, and nervous system

Clinical Manifestations

1. Hepatitis B-related vasculitic mononeuritis multiplex
 - a. The course is subacute to chronic
 - b. Rarely, the course may be acute and present as a distal symmetric sensorimotor polyneuropathy
 - c. Associated with mixed cryoglobulinemia
 - d. Acute AIDP and CIDP occur

Neuropathology

1. Immune complexes on nerves
2. Vasculitis
3. Demyelinating features and axonal degeneration on nerve biopsy

4. Exacerbation of neuropathy during alpha-interferon therapy

Hepatitis C

General Characteristics

1. Chronic hepatitis C virus infection is associated with a wide spectrum of extrahepatic manifestations, primarily immunologic and rheumatologic
2. Hepatitis C virus-associated neuropathy is most often associated with mixed cryoglobulinemia and vasculitis

Clinical Manifestations

1. Primary axonal neuropathies include:
 - a. Sensorimotor polyneuropathy
 - b. Large or small fiber sensory neuropathy
 - c. Mononeuritis multiplex
 - d. Rare AIDP and CIDP
2. Peripheral demyelinating disorders include:
 - a. CIDP
 - b. Lewis-Sumner syndrome
 - c. Cryoglobulin-associated polyneuropathy
 - d. Pegylated interferon treatment associated central and peripheral demyelination
 - e. Approximately 20% have components of autonomic neuropathy

Neuropathology

1. Nerve biopsy
 - a. Inflammatory vascular lesions that include:
 - i. Necrotizing arteritis
 - ii. Small-vessel vasculitis of either lymphocytic or leukocytoclastic type
 - b. Perivascular inflammatory infiltrates
 - c. Tissues demonstrating vasculitis may contain intracellular HCV
 - d. Cryoglobulin deposition in the vasa vasorum

Laboratory Evaluation

1. Detection of cryoglobulins and mixed cryoglobulins in the serum
2. Evidence of cirrhosis in a subset of patients
3. Positive PCR identification

Epstein-Barr Virus

General Characteristics

1. Acute Epstein-Barr virus (EBV) may be associated with both central and peripheral neurologic complications

Clinical Manifestations

1. Mononeuropathy
2. Mononeuropathy multiplex
3. Autonomic neuropathy
4. Polyradiculopathy
5. Brachial plexopathy
6. Lumbosacral radiculoplexopathy
7. Cranial neuropathy
8. Sensory neuropathy

Neuropathology

1. Nerve biopsy:
 - a. Axonal degeneration from leukocytoclastic vasculitis
2. Immune-mediated
 - a. Successful immunosuppressant treatment of a patient with EBV-positive T/natural killer cell lymphoproliferative disease

Laboratory Evaluation

1. Positive serological tests for EBV virus antibodies
2. EMG:
 - a. Consistent with mononeuropathy multiplex
 - b. Brachial plexopathy characteristics in both adult and pediatric patients

Toxic Neuropathies

Misonidazole

General Characteristics

1. Used as an adjuvant in the treatment of malignancies

Clinical Manifestations

1. After 3 to 5 weeks of treatment subgroups of patients develop:
 - a. Painful paresthesias
 - b. Distal length-dependent weakness
 - c. Usually, the total dose prior to symptoms is 18 grams
 - d. Loss of vibratory and temperature sensibilities
 - e. Improvement occurs after discontinuation of the drug

Neuropathology

1. Sural nerve biopsy:
 - a. Axonal degeneration and segmental demyelination primarily of large myelinated fibers
 - b. Remyelination
2. Electron microscopy:
 - a. Neurofilament accumulation with axonal swelling

Laboratory Evaluation

1. EMG:
 - a. Sensory nerve conduction studies demonstrate reduced or unobtainable amplitudes in the legs, with less involvement in the arms
 - b. Motor conduction velocities are normal; slightly reduced amplitudes of CMAPs

Metronidazole

General Characteristics

1. Nitroimidazole antibiotic with activity against protozoa and most gram-negative and gram-positive anaerobic bacteria
2. Used for prophylaxis and treatment of Crohn's disease

Clinical Manifestations

1. Length-dependent sensorimotor neuropathy

2. Painful paresthesias
3. Both large and small fiber sensory modulated neurons are affected
4. Slight distal weakness

Neuropathology

1. Nerve biopsy:
 - a. Axonal degeneration
 - b. Loss of myelinated fibers

Laboratory Evaluation

1. EMG:
 - a. Decreased-amplitude or absent SNAPs
 - b. Normal CMAPs

Chloroquine and Hydroxychloroquine

General Characteristics

1. Chloroquine and hydroxychloroquine are 4-aminoquinoline compounds used as antimalarial and immune suppressants, and as disease-modifying antirheumatic drugs
2. Newer uses are for treatment of SLE, rheumatoid arthritis, primary Sjögren's disease, sarcoidosis, and antiphospholipid syndrome
3. Chloroquine analogs are being evaluated for their effects on metabolic, cardiovascular, antithrombotic and neoplastic diseases

Clinical Manifestations

1. Length-dependent loss of small and large fiber sensory modalities
2. Distal extremity weakness from the neuropathy; proximal weakness may be concomitant from a superimposed myopathy
3. Decreased muscle stretch reflexes
4. The usual dose required for muscle and nerve toxicity is 500 mg/day for greater than one year

Neuropathology

1. Nerve biopsy:
 - a. Autophagic vacuoles and Schwann cell inclusions
 - b. Vacuolar myopathy occurs in muscle cells
2. The hydrophilic and hydrophobic amphiphilic properties of the drug allow interaction with ionic phospholipids of cell membranes and organelles; the drug-lipid complex, resistant to lysosomal enzymes, form autophagic vacuoles whose myeloid debris may be neurotoxic
3. The drugs reduce T-cell and B-cell hyperactivity and proinflammatory cytokine gene expression
4. Axonal degeneration associated with autophagic vacuoles
5. Hydroxychloroquine:
 - a. Absent vacuoles on nerve and muscle biopsy
 - b. Electron microscopy
 - i. Abnormal accumulation of myeloid and curvilinear bodies in Schwann cells and muscle

Laboratory Evaluation

1. Sensory NCS reveal decreased or absent SNAPs

2. Normal or reduced CMAP amplitudes
3. Needle EMG:
 - a. Distal denervation
 - b. Myopathic MUAPs in proximal muscles in patients with concomitant myopathy

Amiodarone

General Characteristics

1. Amiodarone toxicity affects:
 - a. Lungs
 - b. Thyroid gland
 - c. Skin
 - d. Liver
 - e. Nervous system
 - f. Optic nerves
 - g. Parotid gland hypertrophy occurs

Clinical Manifestations

1. Greater than 90% of patients develop corneal micro deposits; less than 5% report halo vision; 2% develop visual loss from optic neuropathy; usually, ocular symptoms occur after one year of use
2. Weakness is both proximal and distal, worse in the legs than arms
3. Distal paresthesias and burning pain
4. Sensory loss is to all modalities
5. Associated depression of muscle stretch reflexes

Neuropathology

1. Nerve biopsy:
 - a. Axonal degeneration and segmental demyelination
 - b. Electron microscopy:
 - i. Lamellar or dense inclusions in Schwann cells, pericytes, and endothelial cells
 - c. Muscle biopsy:
 - i. Autophagic vacuoles
 - ii. Neurogenic atrophy

Laboratory Evaluation

1. Sensory NCS:
 - a. Reduced amplitudes and mild to moderately slow conduction velocities
 - i. Prolonged distal latencies
 - b. Motor NCS are affected similarly but not to the same degree
 - c. Needle EMG:
 - i. Positive sharp waves and fibrillation potentials
 - ii. Mixture of myopathic and neuropathic MUAPs; rare myotonic discharges

Colchicine

General Characteristics

1. Primarily disrupts inflammation activation; modulates multiple pro- and anti-inflammatory pathways

Clinical Manifestations

1. Presentation is usually a proximal myopathy with concomitant distal numbness and paresthesias of the extremities; distal weakness
2. Length-dependent loss of vibration and proprioception sensory modalities
3. Decreased to absent muscle stretch reflexes

Neuropathology

1. Colchicine effects:
 - a. Prevents microtubule assembly
 - b. Disrupts inflammation activation
 - c. Disrupts microtubule-based inflammatory cell chemotaxis
 - d. Decreases generation of leukotrienes and cytokines
 - e. Decreases phagocytosis
 - f. Inhibits polymerization of tubulin in microtubules; decreased axoplasmic flow
2. Nicotine protects against colchicine-induced apoptosis through the P13-kinase-AKT pathways
3. Nerve biopsy:
 - a. Axonal degeneration
4. Muscle biopsy:
 - a. Focal myofibrillar disorganization with accumulation of autophagic vacuoles in muscle fibers

Laboratory Evaluation

1. Serum CK levels may be increased if there is concomitant myopathy
2. EMG:
 - a. Low amplitude SNAPs
 - b. Normal or reduced CMAPs
 - c. Myopathic MUAPs (in patients with concomitant myopathy)
 - d. Neurogenic MUAPs in distally affected muscles
 - e. Positive sharp waves and fibrillation potentials

Podophyllin*General Characteristics*

1. The primary condition treated with podophyllin was anogenital warts (condylomata acuminata)
2. Systemic side effects of podophyllin include:
 - a. Gastrointestinal paresis
 - b. Urinary retention
 - c. Pancytopenia
 - d. Liver and renal dysfunction
3. Due to severe toxicity, podophyllin has been removed from treatment options in favor of podophyllotoxin-derived products

Clinical Manifestations

1. Both CNS and PNS toxicity:
 - a. Psychosis
 - b. Altered mental status

2. Length-dependent peripheral neuropathy characterized by:
 - a. Slowly progressive distal weakness
 - b. Paresthesias
 - c. Reduced muscle stretch reflexes
 - d. Autonomic dysregulation:
 - i. Nausea and vomiting
 - ii. Constipation
 - iii. Orthostatic hypotension
 - iv. Urinary retention
 - v. Tachycardia
 - vi. "Slide" is common; the neuropathic side effects may continue after the medication has been discontinued
 - vii. Improvement occurs over months; urinary deficits are common

Neuropathology

1. Nerve biopsy: axonal degeneration
2. Podophyllin disrupts microtubular function and possibly axoplasmic flow

Laboratory Evaluation

1. CSF: elevated protein
2. Pancytopenia
3. Evidence of liver and renal involvement
4. EMG:
 - a. Sensory NCS:
 - i. Reduced-amplitude or unobtainable SNAPs
 - ii. Reduced amplitudes of CMAPs

Thalidomide*General Characteristics*

1. Thalidomide is primarily used in the USA to treat multiple myeloma (often with bortezomib, which also causes neuropathy), graft-versus-host, and other autoimmune disorders. It is used extensively in leprosy treatment protocols

Clinical Manifestations

1. Approximately 20 grams of thalidomide are required for neurotoxicity, which is dose related
2. Primarily a length-dependent sensory neuropathy with paresthesias, numbness, and burning pain
3. Distal muscle weakness with minimal neurogenic atrophy
4. Loss of large fiber sensory modalities greater than small fibers (occasionally can be seen with an accumulative dose of 12 grams)
5. Hypo or absent muscle stretch reflexes

Neuropathology

1. Nerve biopsy:
 - a. A greater loss of large fiber myelinated fibers than small
 - b. Axonal degeneration

2. Loss of large diameter DRG neurons
3. The incidence of neuropathy with thalidomide treatment varies from 25% to 75% and is dose-dependent
4. Reduces levels of proinflammatory cytokines (TNF-alpha; interleukin-1B (IL-1B), IL-6); malondialdehyde and myeloperoxidase (MPO) activity

Laboratory Evaluation

1. EMG:
 - a. Reduced amplitudes of SNAPs; normal sensory conduction velocities
 - b. Motor NCS are usually normal

Adjunctive Therapy with Bortezomib

1. Used in conjunction with thalidomide in multiple myeloma treatment:
 - a. Incidence of sensory neuropathy is 40%
 - b. Reversible in greater than 60% of patients with discontinuance of the medication
2. Mechanism of toxicity is putatively disruption of calcium homeostasis, or proteasome inhibition by bortezomib increasing IL-8 expression, which is proinflammatory as a neutrophilic chemoattractant and inducer of leukocyte-mediated inflammation

Disulfiram

General Characteristics

1. Primarily used for the treatment of alcohol abuse and dependence
2. Some studies suggest its benefit for cocaine dependence
3. Mechanism of action for its use in alcohol abuse:
 - a. Inhibits liver aldehyde dehydrogenase, preventing the breakdown of acetaldehyde, a product of ethanol metabolism, causing a severe "instant hangover" on drinking alcohol
4. Disulfiram is metabolized to carbon disulfide, which is toxic to both the central and peripheral nervous system

Clinical Manifestations

1. Induced Parkinsonism
2. Frontal lobe syndrome
3. May cause adverse events at less than the daily dose of 500 mg
4. Disulfiram neuropathy usually occurs after 5 to 6 months of use; progression of deficits is steady
5. Peripheral neuropathy is consistent with a length-dependent axonal neuropathy:
 - a. Distal weakness
 - b. Sensory loss, large fiber greater than small myelinated fibers; sensory deficits may appear as early as 10 days after initiation of therapy

Neuropathology

1. The CNS and PNS toxicities are correlated with the production of carbon disulfide, a metabolite of disulfiram

2. Sural nerve biopsy:
 - a. Loss of predominately large diameter myelinated fibers to a greater degree than of thinly myelinated fibers
 - b. Axonal degeneration and segmental demyelination
 - c. Electron microscopy:
 - i. Axonal swellings from the accumulation of neurofilament debris within both myelinated and unmyelinated axons
3. Bilateral lentiform lesions

Laboratory Evaluation

1. EMG:
 - a. Unobtainable SNAPs generally; in those that can be studied low amplitude is noted
 - b. CMAP amplitudes are normal or may be slightly reduced

Dapsone

General Characteristics

1. Dapsone is primarily used for:
 - a. Treatment of leprosy
 - b. Dermatologic conditions that include:
 - i. Acne conglobate
 - ii. Dermatitis herpetiformis
 - iii. Pemphigoid
 - iv. Pemphigus
 - v. Behçet's disease
 - vi. Polychondritis
 - vii. Leukocytoclastic vasculitis

Clinical Manifestations

1. The onset of peripheral neuropathy is variable, and may be seen as early as 5 days to as long as several years
2. Distal weakness of arms and legs is initially seen, and may progress to proximal muscles
3. Rarely there are paresthesias and sensory symptoms without weakness
4. The neuropathy usually occurs after prolonged therapy; cumulative doses that have been reported with neuropathy are from 25–600 mg
5. Signs and symptoms usually resolve after 12 months from cessation of the drug

Neuropathology

1. Axonal atrophy and Wallerian degeneration of distal motor nerve terminals
2. Sural nerve biopsy:
 - a. Loss of myelinated fibers (segmental demyelination and axonal degeneration)

Laboratory Evaluation

1. EMG:
 - a. CMAPs are unobtainable or demonstrate low amplitude
 - b. Normal or minimally reduced SNAP amplitudes

Leflunomide*General Characteristics*

1. Leflunomide is converted into A771726 in the liver which inhibits dihydroorotate dehydrogenase
2. The enzyme is required for biosynthesis of pyrimidine nucleotides by T-lymphocytes
3. The drug is used primarily for the treatment of rheumatoid arthritis
4. Other adverse effects of the drug are:
 - a. Diarrhea
 - b. Liver toxicity
 - c. Alopecia
 - d. Rash
 - e. Hypertension
 - f. Drug-induced pneumonia

Clinical Manifestations

1. Length-dependent peripheral neuropathy
2. Distal numbness and paresthesias
3. The median duration of treatment prior to the onset of neuropathy is 7.5 months; rarely, it may start within three weeks

Neuropathology

1. Not known

Laboratory Evaluation

1. EMG:
 - a. Low amplitude SNAPs with normal or slightly reduced CMAPs
2. Quantitative sensory testing
 - a. Higher cold detection threshold

Nitrofurantoin*General Characteristics*

1. Primary use is the treatment of urinary tract infection
2. Elderly patients and those with renal compromise have the highest risk

Clinical Manifestations

1. Acute GBS presentation has been described
2. Distal extremity numbness and paresthesias that may be painful
3. Absent or reduced muscle stretch reflexes

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large myelinated fibers
 - b. Autopsy material:
 - i. Degeneration of spinal roots, dorsal greater than ventral
 - ii. Chromatolysis of anterior horn cells
 - c. Skin biopsy: (2 patients)
 - i. Clustered terminal nerve swellings without nerve fiber degeneration; nerve conduction studies were normal

Laboratory Evaluation

1. EMG:
 - a. Reduced-amplitude or absent SNAPs and CMAPs
 - b. Axonopathy pattern

Pyridoxine (Vitamin B6 Toxicity)*General Characteristics*

1. A coenzyme for transformation and decarboxylation reactions
2. Doses of greater than 100 mg/day may cause neurotoxicity

Clinical Manifestations

1. Loss of large diameter myelinated fiber modalities of proprioception and vibration
2. The neuropathy may begin in the arms
3. Sensory ataxia with an associated wide-based unsteady gait
4. Muscle stretch reflexes are reduced or absent

Neuropathology

1. Nerve biopsy:
 - a. Axonal loss in all fiber diameters
 - b. Loss of DRG cells (experimental studies)
 - c. Glutamate carboxypeptidase inhibition has been protective (experimental evidence in rats)

Laboratory Evaluation

1. Toxic levels in the serum (usually by excessive vitamin supplementation)
2. EMG:
 - a. NCS reveal absent or reduced SNAPs with normal or slightly reduced CMAPs

Isoniazid*General Characteristics*

1. Primarily used for the treatment of tuberculosis
2. Neuropathy develops in approximately 17% of patients taking high doses (6 mg/kg/d) and in 2% of patients taking the standard 3–5 mg/kg/d
3. Increased risk of neuropathy occurs in elderly, malnourished, and slow drug acetylators
4. Usually, the neuropathy begins after six months on the usual doses

Clinical Manifestations

1. Usual presentation is paresthesias and numbness in the distal extremities
2. With continued use, proximal weakness may occur
3. There is sensory loss to all modalities, and sensory ataxia may develop in severely affected patients
4. Distal muscle atrophy
5. Reduced or absent muscle stretch reflexes
6. An isolated motor neuropathy has been described
7. Isoniazid-induced myopathy may occur concomitantly with the neuropathy; rarely there may be an isolated myopathy

Neuropathology

1. Inhibition of pyridoxal phosphokinase, causing pyridoxine deficiency, is the major mechanism of toxicity
2. Patients who are “slow acetylators” have higher serum concentrations of the medication
3. Sural nerve biopsy:
 - a. Axonal degeneration
 - b. Loss of myelinated and unmyelinated fibers
 - c. Loss of neurons in the DRG with secondary dorsal column degeneration

Laboratory Evaluation

1. EMG: Reduced SNAPs and CMAPs amplitude

Ethambutol*General Characteristics*

1. Ethambutol is primarily used in the treatment of tuberculosis; it is frequently combined with isoniazid for treatment of multi-drug-resistant disease
2. Its most common complication is toxic optic neuropathy characterized by a decrease in visual acuity, deficits in color vision and centrocecal scotoma

Clinical Manifestations

1. Neurotoxicity is seen with prolonged therapy with doses of 20 mg/kg/day or greater
2. Patients develop severe optic neuropathy
3. A sensory neuropathy develops in the extremities with numbness and minimal weakness
4. Loss of large fiber modalities of proprioception and vibration
5. Reduction or loss of distal muscle stretch reflexes
6. May exacerbate the neuropathy of CMT2A2 and possibly other neuropathies with mitochondrial fusion defects

Neuropathology

1. Nerve biopsy:
 - a. Axonal degeneration with secondary loss of myelinated fibers

Laboratory Evaluation

1. Decreased amplitude of SNAPs with normal distal latencies and conduction velocities
2. Normal motor conduction velocities

Chloramphenicol*General Characteristics*

1. Chloramphenicol is a broad-spectrum antibiotic rarely used in the USA, but still utilized in developing countries
2. Severe bone marrow toxicities:
 - a. Dose-dependent toxicity that causes anemia and is reversible
 - b. Idiosyncratic reaction causing irreversible aplastic anemia

Clinical Manifestations

1. Severe optic neuropathy
2. A sensory neuropathy affecting all modalities
3. Absent or reduced deep tendon reflexes, primarily in the legs

Neuropathology

1. Nerve biopsy: Not reported

Laboratory Evaluation

1. EMG: Not reported

Nucleoside Analogues (Dideoxycytidine, Dideoxyinosine, Stavudine, Lamivudine)*General Characteristics*

1. Nucleoside analogs and antiretroviral nucleoside reverse transcriptase inhibitors are used to treat HIV
2. Most often there is subacute onset of neuropathy (mean of 16 weeks with dideoxycytidine)

Clinical Manifestations

1. Sensory length-dependent peripheral neuropathy
2. Hyperpathia of the extremities that is usually symmetrical
3. Loss of pin-prick and temperature modalities greater than large myelinated fiber modalities
4. Decreased muscle stretch reflexes in the legs greater than in the arms
5. Mild distal muscle weakness and slight atrophy in the intrinsic foot muscles
6. “Coasting effect” for approximately one month after the drug (ddc) is discontinued; improvement occurs after several months

Neuropathology

1. Nucleoside analogs inhibit mitochondrial DNA
2. Possible deficit of acetylcarnitine may contribute to the neuropathy
3. Axonal neuropathy

Laboratory Evaluation

1. EMG:
 - a. Decreased SNAPs with normal sensory conduction velocities and distal sensory latencies
 - b. Motor NCS are usually normal
2. QST:
 - a. Impaired temperature and vibratory thresholds

Phenytoin*General Characteristics*

1. Genetic polymorphisms of CYP2C9 may lead to interindividual variations of drug level, adverse drug reactions, and toxicity

Clinical Manifestations

1. Generally a sensory neuropathy

2. Decreased light touch, vibration and proprioception primarily in the distal leg
3. Minimal weakness
4. Decreased ankle muscle stretch reflexes

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large myelinated axons
 - b. Segmental demyelination

Laboratory Evaluation

1. Rare megaloblastic anemia
2. EMG:
 - a. Decreased amplitude of SNAPs with normal sensory conduction velocities and distal latencies
 - b. Approximately 20% of patients may have slightly reduced conduction velocities and amplitude of SNAPs

Lithium

General Characteristics

1. CNS side effects are much more common than peripheral neuropathy and include:
 - a. Myoclonus
 - b. Tremor
 - c. Dysarthria
 - d. Altered mental status
 - e. Seizures
 - f. Hyperhidrosis
2. Renal and thyroid toxicity

Clinical Manifestations

1. Peripheral neuropathy is characterized by slight weakness and primarily large fiber modality sensory loss
2. Reduced muscle stretch reflexes

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large myelinated fibers
 - b. Axonal degeneration

Laboratory Evaluation

1. EMG:
 - a. Low amplitude SNAPs
 - b. Normal or reduced CMAPs

Acrylamide

General Characteristics

1. Acrylamide is a "type-2-alkene", which is a vinyl monomer
2. Absorption occurs through the skin, gastrointestinal tract (contaminated with water) or lungs
3. It is used industrially as a flocculating and grouting agent

Clinical Manifestations

1. Contact dermatitis

2. CNS manifestations include:
 - a. Confusion and irritability
 - b. Ataxia and dysarthria
 - c. Hallucinations
3. A distal symmetrical polyneuropathy
 - a. Loss of large fiber modalities of touch, vibration, and proprioception
 - b. Minimal loss of temperature and pain
 - c. Positive Romberg sign
 - d. Mild distal muscle atrophy and weakness
 - e. Decreased muscle stretch reflexes

Neuropathology

1. Putative mechanisms of toxicity:
 - a. Inhibition of kinesin-based fast axonal transport
 - b. Alteration of neurotransmitter levels
 - c. Direct inhibition of neurotransmission
2. Sural nerve biopsy:
 - a. Axonal degeneration with loss of large myelinated fibers
 - b. Experimental studies reveal:
 - i. Early paranodal accumulation of 10 nm neurofilaments at the distal terminal arbors of peripheral nerves
 - ii. Distal axons enlarge and degenerate
3. Autopsy material demonstrates
 - a. Demyelination of the dorsal columns, spinocerebellar tracts, optic tracts, corticospinal tracts and the mammillary bodies

Laboratory Evaluation

1. EMG:
 - a. Decreased SNAP amplitude with normal sensory distal latencies and conduction velocities
 - b. Slightly reduced CMAPs; high levels of exposure may be associated with temporal dispersion of CMAPs

Carbon Disulfide

General Characteristics

1. Carbon disulfide is a widely used industrial solvent in the vulcanization of rubber, rayon, cellophane, and adhesives
2. It can be absorbed through the skin and lungs
3. CNS alterations from higher levels of exposure cause psychosis and Parkinsonism

Clinical Manifestations

1. Reflexes
2. Presentation is usually numbness and tingling distally in the extremities
3. Loss of all sensory modalities
4. Minimal distal muscle weakness and atrophy
5. Decreased muscle stretch reflexes

Neuropathology

1. Experimental studies reveal:

- a. Accumulation of 10 nm neurofilaments and axonal swelling
- 2. Low levels of chronic exposure cause a length-dependent sensorimotor symmetrical polyneuropathy

Laboratory Evaluation

- 1. Reduced amplitude of SNAPs and CMAPs
- 2. Slowing of sensory greater than motor conduction velocities

Ethylene Oxide

General Characteristics

- 1. Primarily used to sterilize heat sensitive materials (surgical packs)
- 2. Associated with:
 - a. Dermatological lesions
 - b. Inflammation of mucosal membranes
 - c. Altered sensorium
 - d. Nausea and vomiting

Clinical Manifestations

- 1. Peripheral neuropathy characterized by:
 - a. Distal numbness and paresthesias
 - b. Mild distal weakness
 - c. Sensory ataxia
 - d. Decreased muscle stretch reflexes

Neuropathology

- 1. Sural nerve biopsy:
 - a. Loss of large diameter greater than small diameter myelinated fibers

Laboratory Evaluation

- 1. EMG:
 - a. Low amplitude SNAPs
 - b. Normal or reduced CMAP amplitudes

Organophosphates

General Characteristics

- 1. Used for insecticides, in the plastics industry and petroleum products
- 2. Affects both the central and peripheral nervous systems
- 3. Basic mechanism of toxicity is cholinergic neuronal excitotoxicity induced by irreversible ACHE (acetylcholinesterase) inhibition

Clinical Manifestations

- 1. CNS effects include:
 - a. Emotional lability and anxiety
 - b. Altered mental status
 - c. Seizures
 - d. Ataxia
- 2. Muscarinic effects include:
 - a. Nausea, vomiting, abdominal cramping and pain

- b. Diarrhea
- c. Pulmonary edema
- d. Bradycardia
- 3. Nicotinic side effects include:
 - a. Generalized weakness
 - b. Fasciculations
- 4. Peripheral neuropathy:
 - a. A distal sensory motor delayed polyneuropathy (OPIDP)
 - b. Evolves after several weeks from the initial exposure
 - c. Early symptoms include:
 - i. Cramping in calf muscles
 - ii. Paresthesias and burning of the feet
 - iii. Distal extremity weakness of the feet which over time evolves to affect the hands
 - iv. Hyperreflexia and increased tone develop from concomitant CNS involvement

Neuropathology

- 1. Nerve biopsy:
 - a. A distal axonopathy
 - b. Autopsied patient who died from Sarin poisoning:
 - i. Loss of myelinated and unmyelinated fibers in the sural and sciatic nerves
 - ii. Degeneration of fasciculus gracilis and the corticospinal tracts
- 2. Organophosphates inhibit neuropathy target esterase (NTE)
 - a. The cleavage of a side chain of NTE, which leads to neurotoxicity (requires time from the initial exposure)

Laboratory Evaluation

- 1. In the acute phase:
 - a. Repetitive firing of CMAPs from a single stimulus
 - b. Decrementing response to low rates of stimulation that may persist for 4 to 11 days
- 2. During OPIDPI
 - a. Decreased amplitudes of SNAPs and CMAPs most consistent with an axonal sensorimotor neuropathy

Hexacarbons (N-Hexane, Methyl-N-Butyl Ketone/Glue Sniffer's Neuropathy)

General Characteristics

- 1. N-Hexane and methyl-n-butyl ketones are industrial organic solvents
- 2. Inhalation is the usual route of exposure although they can be absorbed through the skin
- 3. Many patients have been exposed by glue sniffing

Clinical Manifestations

- 1. A subacute onset over 4 to 6 weeks of a severe sensorimotor neuropathy
- 2. The presentation is with numbness and tingling of the feet that evolves proximally to affect the upper and lower extremities

3. Progressive weakness of the extremities occurs; respiratory muscles are not affected
4. Loss of muscle stretch reflexes
5. High dose exposure has been associated with muscle wasting, weakness, foot drop, and spasticity

Neuropathology

1. Sural nerve biopsy:
 - a. Severe loss of myelinated fibers
 - b. Giant axonal swelling with secondary demyelination; giant axons demonstrate an accumulation of 10 nm neurofilaments
 - c. Hexacarbons putatively lead to cross-linking between axonal neurofilaments, aggregation and disrupted axonal transport

Laboratory Evaluation

1. EMG:
 - a. Prolongation of distal latencies, slowing of nerve conduction velocities and conduction block with temporal dispersion in some severely affected patients
2. "Coasting" occurs over 2 to 3 months followed by a slow recovery over 1 to 2 years

Styrene (Vinyl Benzene)

General Characteristics

1. Vinyl benzene is a colorless, oily liquid that is a component of paints, plastics, and resins

Clinical Manifestations

1. Altered mental status occurs with inhaled exposure over extended periods
2. Along with other organic solvents causes:
 - a. Corneal ulcers
 - b. Ventricular enlargement
 - c. Visual field deficits
 - d. Retinal lesions
 - e. Decreased visual acuity
 - f. Acquired dyschromatopsia
3. A primarily sensory neuropathy characterized by:
 - a. Burning pain and paresthesias in the legs
 - b. Loss of pain and temperature modalities, with only slight involvement of large fiber modalities
 - c. Strength is preserved
 - d. Muscle stretch reflexes are slightly depressed

Neuropathology

1. Nerve biopsy:
 - a. Axonal degeneration

Laboratory Evaluation

1. Slight reduction of motor nerve conduction velocities in the lower extremities
2. Features of a mixed axonal and/or demyelinating sensorimotor neuropathy

Lead

General Characteristics

1. Industrial lead exposure (burning batteries) and exposure to lead-containing products occur in adults
2. Children may be exposed by ingestion of lead-based paints in old buildings

Clinical Manifestations

1. In children who have been exposed, encephalopathy with increased intracranial pressure and seizures may be the presentation
2. Lead is associated with a primarily motor neuropathy:
 - a. Insidious onset of weakness
 - b. Early predilection for the wrist-finger extensors and wrist extensors that give the appearance of a radial palsy. It most often occurs in the dominant arm (acute intermittent porphyria also may appear first in the dominant arm)
 - c. May also cause foot drop
 - d. Weakness is frequently asymmetric
 - e. Sensation is most often preserved
 - f. Autonomic involvement is common with constipation and rarely severe hypertension
 - g. Decreased muscle stretch reflexes occurs
 - h. A lead line (bluish discoloration of the gums) is now rarely seen

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large myelinated axons
2. A possible toxic mechanism is its ability to substitute for other polyvalent cations, particularly divalent cations, such as calcium or zinc
3. Membrane ion channels and their signaling systems may be disrupted

Laboratory Evaluation

1. High serum lead levels
2. Microcytic hypochromic anemia with basophilic stippling of erythrocytes
3. Elevated serum coproporphyrin level
4. Urinary levels are elevated
5. EMG:
 - a. Denervation
 - b. Reduced CMAP amplitudes with normal SNAPs

Mercury

General Characteristics

1. Mercury neurotoxicity occurs from exposure both to organic or inorganic mercurials
2. Organic mercurials are methyl- or ethylmercury
3. Inorganic mercury is used primarily in industry and is composed of mercury salts that are ingested or inhaled
4. Methylmercury poisoning occurs from high consumption of seafood or primarily consumption of marine mammals from Arctic regions

Clinical Manifestations

1. Organic mercury intoxications causes:
 - a. Dysarthria
 - b. Ataxia
 - c. Decreased cognition
 - d. Visual and hearing loss
2. Peripheral neuropathy is characterized by:
 - a. Paresthesias of the distal extremities that evolves proximally and may involve the face and tongue
3. Inorganic mercury poisoning:
 - a. Entry may be inhalation or ingestion
 - b. Gastrointestinal symptoms and the nephritic syndrome predominate
 - c. Encephalopathy
 - d. Sensorimotor polyneuropathy

Neuropathology

1. Nerve studies:
 - a. Axonal degeneration
2. Autopsy studies (Minamata Bay series):
 - a. Cortical and cerebellar cortex degeneration
 - b. Loss of cells in the dorsal root ganglia
3. Amyloid protein aggregation in the cell nucleus may be a pathway for Hg-bio-interactions
 - a. Purified protein aggregates, spliceosomal components, and the nucleoskeletal protein lamin B1 constitutes components of an Hg-induced nuclear aggregate network; Hg enhances proteasomal activity in the nucleus; experimental evidence suggests that these interactions may be a component of Hg toxicity

Laboratory Evaluation

1. EMG:
 - a. Sensory NCS demonstrate slow low amplitude SNAPs and minimally slow conduction velocities
 - b. Motor conduction is normal or demonstrates borderline velocities
 - c. Needle EMG:
 - i. May demonstrate positive sharp waves or fibrillation potentials

Thallium*General Characteristics*

1. May be monovalent or trivalent
2. Primarily a rodenticide; food poisoning has been reported

Clinical Manifestations

1. First week of exposure:
 - a. Pigmentation of the hair
 - b. Arciform malar rash
 - c. Hyperreflexia
2. Second and third weeks following exposure:
 - a. Autonomic instability with varying heart rate and blood pressure

- b. Alopecia may only occur after the fourth week in a subset of patients
3. CNS manifestations include:
 - a. Increased thirst
 - b. Sleep alterations
 - c. Psychotic behavior
4. Burning paresthesias of the feet associated with abdominal pain and vomiting may be acute or appear after a few days
5. The peripheral neuropathy is characterized by:
 - a. Loss of pain and temperature

Laboratory Evaluation

1. EMG:
 - a. Early after exposure NCS may be normal
 - b. After 1 to 2 weeks there are low amplitude SNAPs and normal or decreased CMAP amplitudes

Arsenic*General Characteristics*

1. Industrial and agricultural exposure; chronic exposure a common problem in parts of South East Asia

Clinical Manifestations

1. System signs and symptoms:
 - a. Dermatologic involvement (exfoliative changes in palms and soles)
 - b. Mees lines in the nails (after 1–2 months of exposure)
 - c. Hepatomegaly occurs in approximately 1/3 of patients with chronic exposure
 - d. Alopecia in approximately 10% of patients with chronic exposure
 - e. Lung involvement in approximately 20% of patients with chronic exposure
2. Acute exposure:
 - a. Abdominal pain with nausea and vomiting, diarrhea
3. Peripheral neuropathy:
 - a. Starts 5 to 10 days after exposure
 - b. Burning pain in the distal extremities
 - c. Distal weakness evolves; after severe intoxication proximal muscles and cranial nerves are involved which can simulate Guillain-Barré syndrome
 - d. There may be respiratory compromise requiring ventilation
 - e. Muscle stretch reflexes are decreased or absent
 - f. Autonomic involvement occurs

Neuropathology

1. Sural nerve biopsy:
 - a. Axonal degeneration
 - b. Loss of large and small diameter myelinated fibers
 - c. Rare “onion bulb” formation
 - d. Loss of anterior horn cells

Laboratory Evaluation

1. Arsenic levels are increased in the urine, hair, and nails

2. Bone marrow depression with anemia and pancytopenia
3. Stippled erythrocytes
4. Increased CSF protein without pleocytosis
5. EMG:
 - a. Characteristics of an axonal neuropathy; some features of demyelination have been reported
 - b. Sensory NCS demonstrate low amplitude SNAPs with relative preserved distal latencies and conduction velocities
 - c. Conduction block and prolongation of F-wave latencies
 - d. Progressive deterioration of CMAPs with slowing of conduction velocities
6. Needle EMG:
 - a. Positive sharp waves and fibrillation potentials in distal muscles
 - b. Decreased number of motor units

Gold

General Characteristics

1. Gold salts have been primarily used for treatment of rheumatoid arthritis
2. Neuropathy usually occurs following several months of therapy

Clinical Manifestations

1. Rash and pruritus often are associated with the neuropathy
2. Presentation is usually with distal extremity paresthesias
3. Loss of all sensory modalities
4. Loss of muscle stretch reflexes
5. Myokymia and fasciculations may be prominent

Neuropathology

1. Sural nerve biopsy:
 - a. Axonal degeneration with segmental demyelination

Laboratory Evaluation

1. EMG:
 - a. Low amplitude or absent SNAPs
 - b. Myokymia and fasciculations may be demonstrated

Neuropathies Associated with Cancer

Overview

Peripheral neuropathies that occur in a setting of cancer may be caused by:

1. Metastasis
2. Primary tumors of the nerve or its sheaths
3. X-RT associated
4. Effects of chemotherapy
5. Dysproteinemic states
6. Paraneoplastic effects
7. Immune-mediated:
 - a. Immunosuppressive drugs

- b. Associated bone marrow transplantation
- c. Graft-versus-host disease

The incidence of peripheral neuropathy in patients suffering from cancer is estimated at between 15 to 30%. However, it is dramatically increased with electrophysiological testing and effects may be seen in between 30 to 40% of patients.

Paraneoplastic neuropathy is a possibility in all patients with malignancy and can occur at any stage of the illness, including after chemotherapy, radiation or stem cell transplantation. They are rare. The neuropathy may occur as an isolated finding or in combination with involvement in other areas of the peripheral or central nervous system. Loss of dorsal root ganglion cells due to CD8-positive cytotoxic T-cells that mediate the classic subacute sensory neuropathy. Patients may present with Guillain-Barré syndrome, chronic inflammatory demyelinating polyneuropathy as well as brachial and lumbosacral plexopathy, vasculitic neuropathy, autoimmune autonomic ganglionopathy and chronic intestinal pseudo-obstruction. Multiple onconeural antibodies that include anti-Hu, CV2/CRMP-5 and anti-ganglionic acetylcholine receptor are associated with these neuropathies. Neurologic signs and symptoms may precede the effects of the primary tumor. A paraneoplastic sensorimotor neuropathy may be similar to other forms of an axonal polyneuropathy.

Paraneoplastic Sensory Neuronopathy/Ganglionopathy

General Characteristics

1. Small cell cancer of the lung is most often the cause of paraneoplastic encephalomyelitis (PEM)/sensory neuronopathy (SN)
2. Other tumors associated with the syndrome include:
 - a. Esophageal
 - b. Breast
 - c. Ovarian
 - d. Kidney
 - e. Lymphoma

Clinical Manifestations

1. PEM/SN is most often seen in the sixth or seventh decade
2. There is a 2:1 ratio of women to men
3. The syndrome may precede the diagnosis of the underlying cancer; in general, the underlying cancer is diagnosed within 4–12 months after the onset of the neurological symptoms but, rarely, it may be several years before diagnosis
4. Presentation is most often with numbness and paresthesias of the distal extremities
5. In more than 50% of patients, symptoms may begin in the hands
 - a. Maybe asymmetric in 30–40%
6. The onset may be acute, but is most often insidiously progressive
7. All fiber modalities of sensation are affected and when severe proprioceptive loss causes sensory ataxia with

- pseudoathetosis to a greater degree than proprioception and vibration sensibility
8. Distal muscle atrophy and weakness evolve
 9. Loss of distal muscle stretch reflexes
 10. Other concomitant paraneoplastic syndromes may cause weakness and include:
 - a. Myelitis
 - b. Lambert-Eaton syndrome
 - c. Motor neuronopathy
 11. May be associated with components of autonomic neuropathy
 12. CNS signs and symptoms occur concomitantly in 20% of patients and include:
 - a. Memory loss, altered mental status, seizures
 - b. Brainstem dysfunction
 - c. Cerebellar signs occur in approximately 30% of patients
 - d. Cranial nerve involvement occurs in 15%; VIIIth nerve is often involved
 - e. Oculomotor abnormalities are seen in approximately 30% of patients
 - f. Myelitis occurs in approximately 15%

Neuropathology

1. Sural nerve biopsy:
 - a. Perivascular infiltration of T- and B-cells, macrophages and plasma cells
 - b. Degeneration of DRG sensory neurons and secondary degeneration of the posterior columns of the spinal cord
 - c. Inflammation of autonomic ganglia and the myenteric plexus
 - d. Deposition of anti-Hu antibodies
2. Putative mechanism is antigenic mimicry between proteins expressed on the surface of tumor cells and sensory neurons of the DRG and central neurons
3. There is correlation of high titer of anti-Hu antibodies in the CSF and serum titer correlates with the sensory neuropathy
 - a. Human studies suggest that the pathology is an antigen-driven cytotoxic T-cell response

Laboratory Evaluation

1. IgG polyclonal antineuronal antibodies are directed against a protein or a complex of proteins and are detected in the serum and CSF
2. Serum antibodies correlate with the sensory neuropathy; CSF antibodies correlate with paraneoplastic sensory neuropathy
3. CSF may demonstrate lymphocytic pleocytosis and elevated protein
 - a. Oligoclonal bands and IgG may be demonstrated in most patients

Neuroimaging

1. MRI:

- a. A subset of patients with concomitant paraneoplastic neuropathies have increased T2-weighted signal in the temporal and frontal lobes as well as periventricularly. There is frontal, temporal and cerebellar atrophy
2. EMG:
 - a. Low amplitude SNAPs
 - b. In the absence of motor neuronopathy or Lambert-Eaton syndrome, the CMAPs are normal

Differential Diagnosis of Sensory Neuropathy/Ganglionopathy

1. Anti-Hu paraneoplastic syndrome
2. Sjögren's syndrome
3. HIV
4. Chemotherapy (particularly cisplatinum)
5. Pyridoxine deficiency or excess
6. Anti-nucleoside toxicity
7. Guillain-Barré syndrome (Richter's variant)
8. Idiopathic sensory neuronopathy (possibly autoimmune)

Differential Diagnosis of Antibodies Associated with Sensory Neuronopathy

1. Anti-Hu
2. Anti-CV2
3. ANNA-3
4. Anti-Ma
5. Amphiphysin

Paraneoplastic Sensorimotor Polyneuropathy

General Characteristics

1. Associated with anti-CV2/CRMP antibodies (collapsing/response-mediating protein, CRMP-5)
2. CV2 antigen is found in the cytoplasm of oligodendrocytes
3. Most often seen with small cell cancer of the lung and thymoma

Clinical Manifestations

1. CNS involvement causes:
 - a. Limbic encephalitis
 - b. Cerebellar ataxia
 - c. Chorea
 - d. Uveo/retinal involvement
2. Peripheral neuropathy:
 - a. Primarily sensorimotor with moderate distal weakness
 - b. Motor involvement is greater in the lower than upper extremities
 - c. The peripheral neuropathy may be isolated in 30% of patients
 - d. Mononeuropathies occur (probably associated with vasculitis)

Neuropathology

1. Sural nerve biopsy:
 - a. Perivascular inflammation

- b. Loss of all sizes of myelinated fibers
- c. An axonal polyneuropathy has been described with CV2/CRMP-Ab
- d. Rare necrotizing vasculitis

Laboratory Evaluation

1. EMG
 - a. Low amplitude SNAPs with borderline slowing of conduction velocities; prolonged distal latencies
2. Motor NCS may be normal or only slightly involved
3. A demyelinating neuropathy has been described with melanoma

Differential Diagnosis Between Anti-Hu and Anti-CV2/CRMP Antibody Syndromes

1. CV2/CRMP
 - a. More frequent chorea, ataxia, uveo/retinal involvement and myasthenic symptoms
2. Anti-Hu antibody syndrome
 - a. More frequent brainstem encephalitis and peripheral neuropathy
3. Limbic encephalitis was similar

Paraneoplastic Autonomic Neuropathy

General Characteristics

1. Pandysautonomia may occur:
 - a. As an isolated phenomenon or associated with peripheral and CNS signs, due to the spectrum of anti-Hu immunity
2. Pandysautonomia is often severe, rare, and may present as an acute, subacute or chronic syndrome
3. Most commonly associated with small cell lung cancer, but has also been described with breast, ovarian, testicular, pancreatic and lymphoma malignancies

Clinical Manifestations

1. Orthostatic hypotension
2. Gastroparesis (when severe may cause pseudo-obstruction)
3. Urinary retention
4. Dry eyes and dry mucosal surfaces
5. Pupillary dysfunction
6. Hypohidrosis

Neuropathology

1. Inflammatory T-cell infiltrate in the DRG and autonomic ganglia (myenteric plexus)
2. Neuronal loss in autonomic ganglia
3. Antiganglionic acetylcholine receptor antibodies
4. CRMP-5 may be associated with an isolated neuropathy
5. Autoantibodies have been detected against a nuclear antigen of the myenteric neurons

Laboratory Evaluation

1. Detected autoantibodies including anti-Hu, anti-CRMP, anti-acetylcholine receptor, anti-neuronal (neurons of the myenteric plexus) and anti-VGKC
2. Abnormal autonomic testing

Idiopathic Sensory or Sensorimotor Polyneuropathy Associated with Cancer

General Characteristics

1. More common than paraneoplastic neuropathies
2. Most often associated with small cell cancer of the lung, but can be seen in a wide range of malignancies

Clinical Manifestations

1. Slowly progressive distal numbness in the lower extremities that evolves to affect the hands
2. All sensory modalities are affected
3. Minimal distal extremity weakness
4. Distal loss of muscle stretch reflexes

Neuropathology

1. Sural nerve biopsy:
 - a. Axonal degeneration with secondary segmental demyelination

Laboratory Evaluation

1. Anti-Hu, anti-CV2 and ANNA-3 antibodies have been detected
2. EMG:
 - a. Characteristics of a length dependent axonal, sensory or polyneuropathy
 - b. Decreased SNAP and CMAP amplitudes
 - c. Minimally prolonged distal latencies and reduced conduction velocities
 - d. Needle EMG:
 - i. Minimal distal muscle denervation

Tumor Infiltration of Peripheral Nerve

Leukemia

General Characteristics

1. Leukemic infiltration of peripheral nerve is rare and is designated as neuroleukemiosis
2. Peripheral neuropathy occurs in 5% of patients with leukemia

Clinical Manifestations

1. Symmetric sensorimotor polyneuropathy is rare
2. Mononeuropathy may present acutely, and mononeuropathy multiplex has been described
3. Brachial and lumbar plexopathy

Neuropathology

1. Axonal degeneration and segmental demyelination is the usual nerve pathology
2. Vasculitic neuropathy may occur with hairy cell leukemia
3. Root infiltration by leukemic cells
4. Acute hemorrhage occurs into nerves

Laboratory Evaluation

1. EMG:
 - a. Characteristics of a multifocal axonal sensorimotor neuropathy
 - b. Setting of chronic lymphocytic leukemia is most common; cases with myeloid and hairy cell leukemia have been described
- c. CSF:
 - i. Leukemic cell pleocytosis is seen with a moderate increase in protein
- d. Neuroimaging
 - i. Fluorodeoxyglucose (FDG) uptake that is useful for diagnosis and monitoring treatment

Large Cell Lymphoma*General Characteristics*

1. Intravascular large B-cell lymphoma is a rare extranodal lymphoma with exclusive intravascular tumor growth
2. In a third of patients, the disease starts with involvement of the nervous system; during the course of the illness, 2/3 of patients develop neurological signs

Clinical Manifestations

1. Peripheral nervous system involvement includes:
 - a. Progressive sensorimotor neuropathy
 - b. Guillain-Barré presentation
 - c. Focal peroneal or sciatic neuropathy
 - d. Relapsing neuropathy
 - e. Cauda equina syndrome
 - f. Multiple cranial neuropathies
 - g. 25% of patients develop a radiculopathy or polyradiculopathy
2. Approximately 50% of patients will demonstrate widespread systemic lymphoma

Neuropathology

1. Sural nerve biopsy:
 - a. Greater than 80% of patients demonstrate lymphomatous infiltrations, endoneurial involvement is greater than that in the perineum

Laboratory Evaluation

1. Absence of malignant cells in the peripheral blood or lymph nodes
2. Diagnosis is secured by demonstration of endoneurial lymphocytic B-cell infiltration

Differential Diagnosis of Lymphoma Related to Non-Tumor Associations

1. Irradiation
2. Chemotherapy
3. Paraneoplastic syndrome
4. Vasculitis
5. Immune antibody mechanisms

Lymphomatoid Granulomatosis (LYG)*General Characteristics*

1. Lymphomatoid granulomatosis is a rare angiocentric Epstein-Barr virus-associated B-cell lymphoproliferative disorder due to dysregulated immune surveillance of EBV

Clinical Manifestations

1. LYG may present with bilateral pulmonary nodules (same series 100% of patients)
2. Subcutaneous skin nodules
3. Renal nodules
4. Peripheral and cranial neuropathies
5. Peripheral nerve involvement:
 - a. Occurs in 10–15% of patients and is characterized by:
 - i. Distal symmetric polyneuropathy
 - ii. Mononeuropathy multiplex
 - iii. Polyradiculoneuropathies
 - iv. Cranial neuropathies (including optic neuropathy)

Neuropathology

1. Epstein-Barr virus (EBV), a member of the γ -herpes virus family, is pivotal in the pathology of some lymphomas and lymphoproliferative diseases. These include B-cell, T-cell, and NK cell processes
2. LYG is an angiocentric and angi destructive EBV-associated B-cell lymphoproliferative disorder. Its putative mechanism is dysregulated immune surveillance of the EBV
3. Almost all patients have had post EBV exposure, demonstrated by serologic testing, and carry a low median viral load
4. The angiocentric lesions demonstrate T-cells, large atypical B-cells and are positive for EBV
5. Sural nerve biopsy:
 - a. Perivascular infiltrates of the above cells in the epineurium
 - b. Necrosis and thrombosis of the vasa vasorum
 - c. Loss of axons between and within nerve fascicles due to ischemia

Laboratory Evaluation

1. Chest x-ray; almost 100% of patients have pulmonary nodules
2. Lesions biopsied demonstrate EBV and large atypical B-cells
3. EMG:
 - a. Demonstrate a multifocal axonal sensorimotor neuropathy

Infiltrating Tumors**Carcinomatosis of the Meninges***General Characteristics*

1. Results from diffuse or focal infiltration of the leptomeninges by malignant cells that originate from an extrameningeal primary tumor

2. Carcinomatosis of the meninges occurs in 5–10% of patients with solid tumors
3. The most common types of tumors seen with this form of metastasis are lung, breast, and melanoma. It has been seen in almost all type of tumors

Clinical Manifestations

1. Approximately 10 to 25% of patients with lung cancer may have leptomeningeal metastasis
2. The median survival is 4 to 6 weeks after diagnosis
3. Polyradiculopathy:
 - a. Radicular pain and sensory loss (may involve the trunk)
 - b. Weakness of specific roots
 - c. Most often there are decreased muscle stretch reflexes
4. Generalized spread can simulate a sensorimotor neuropathy
5. Concomitant spinal cord compression can lead to hyperreflexia and upper motor neuron signs
6. Cranial nerve involvement:
 - a. Metastasis most often involves the VIth, IIIrd, Vth, and VIIth cranial nerves
 - b. Nasopharyngiomas most commonly involve the Vth and VIth cranial nerves
 - c. “Numb chin” syndrome may occur with breast metastasis, from invasion of the mental or inferior alveolar nerves that derive from the mandibular branch of V
 - d. Most patients are lethargic; a subgroup that maintains consciousness have clear leptomeningeal involvement by neuroimaging
 - e. Central signs:
 - i. Headache (85%)
 - ii. Nausea and vomiting (58%)

Laboratory Evaluation

1. Classic CSF pattern is:
 - a. Pleocytosis of cancer cells
 - b. Elevated protein (80–150 mg/dl)
 - c. Sugar depressed, usually to 30–40 mg/dl
 - d. Neuroimaging:
 - i. MRI with gadolinium enhancement may have a sensitivity of greater than 90%
 - e. NMR metabolomics:
 - i. Myoinositol, creatine, lactate, alanine, and citrate are elevated in the nuclear magnetic spectra
 - f. The concentrations of CYFRA 21-1, NSE, and CEA in the CSF are indicators of meningeal carcinomatosis from lung cancer

Brachial Plexus Involvement by Cancer

General Characteristics

1. The brachial plexus is commonly involved in cancer due to the spread of local tumors, primarily lung, and breast
2. Delayed plexopathy occurs from radiation treatment
3. Sarcoma involving the brachial plexus may occur secondarily from regional breast irradiation

4. Anatomical spread of tumors is most often from the lymphatics to the lateral group of axillary lymph nodes to involve the divisions that form the lower trunk

Clinical Manifestations of Pancoast Tumors

1. Pancoast tumors (superior sulcus or apical lung tumors) involve the C8–T1 nerve roots, lower trunk of the plexus, the sympathetic chain, and often the stellate ganglion
2. The initial complaint is paresthesia or burning pain in the shoulder, and from the medial forearm to the fourth and fifth fingers
3. Weakness and atrophy of the hand evolves
4. A Horner’s syndrome (miosis, partial ptosis, anhidrosis of the face, and apparent enophthalmos) is common
5. The arm may be swollen from a combination of lymphedema and neurogenic edema (release of vasoactive neuropeptides and sympathetic nerve involvement)
6. Upper and middle trunk brachial plexus involvement is rare and is most often from the epidural extension of the tumor
7. The most common cause of Pancoast tumor is bronchogenic carcinoma of the lung

Radiation Plexitis

General Characteristics

1. XRT doses often exceed 6000 rads

Clinical Manifestations

1. The C5–C6 roots are most commonly involved
2. Paresthesias are the rule rather than pain; occurs in approximately 15% of patients
3. There is no Horner’s syndrome
4. Approximately 70% of patients have upper plexus involvement, and in 20%, diffuse involvement occurs
5. Symptoms are delayed from three months to years (mean of six years)

Neuropathology

1. Direct extension of cancer cells that encase the nerve roots, trunks, and cords of the plexus
2. Perineural spread of tumor cells
3. In patients treated with XRT, components of the plexus demonstrate demyelination and there is a proliferative endarteritis of the vasa vasorum

Laboratory Evaluation

1. MRI and CT:
 - a. Demonstrate anatomical abnormalities of the plexus and enhancement with gadolinium
 - b. Magnetic resonance neurography is able to differentiate neurogenic and non-neurogenic neoplasms
2. EMG:
 - a. Motor and sensory NCS demonstrate decreased amplitudes of SNAPs and CMAPs

- b. Myokymic discharges are noted in patients who have been irradiated

Lumbosacral Plexopathy from Cancer

General Characteristics

1. Perineural spread has been demonstrated from the prostate bed to the lumbosacral plexus; distal spread to the sciatic nerve and lumbosacral roots as well as intradural spread occurs
2. Bilateral neoplastic lumbosacral plexopathy may occur, utilizing the dural sac as a bridge to connect opposite sacral roots
3. There are multiple reports of carcinomatous involvement of the lumbosacral plexus, sciatic, obturator, pudendal, and spinal nerves. Recently reported patients with rectal cancer and perineural spread of cancer to the inferior hypogastric plexus by the conduits of the pelvic and sacral splanchnic nerves have been described
4. The most common tumors that affect the lumbosacral plexus are:
 - a. Colorectal
 - b. Cervical
 - c. Prostate
 - d. Breast
 - e. Lymphoma
 - f. Sarcoma
5. Distribution of lumbosacral involvements:
 - a. Lumbar plexus in 31%
 - b. Lumbosacral trunk in 5%
 - c. The entire lumbosacral plexus in 18%

Clinical Manifestations

1. Initiated by an insidious onset of pain, numbness, and paresthesias in root and nerve distributions of a lower extremity
2. Weakness and edema of the extremity evolve
3. 25% of patients have bilateral involvement
4. Bowel, bladder, or sexual dysfunction occurs in approximately 10% of patients

Radiation-Induced Plexopathy of the Lumbosacral Plexus

Clinical Manifestations

1. Delayed onset of between 1–3 years (mean is 5 years)
2. Insidious onset of a slowly progressive weakness of the affected muscle distribution, with appropriate loss of muscle stretch reflexes
3. Pain occurs in less than 50% of patients
4. Symmetric involvement of the lower extremities with distal > proximal muscle weakness
5. Bowel and bladder involvement occurs from both root and nerve injury, as well as radiation-induced proctitis or cystitis

Neuropathology

1. Radiation-induced demyelination and proliferative endarteritis of the vasa vasorum

Laboratory Evaluation

1. MRI or CT:
 - a. Enlargement of nerve roots and nerves from the infiltrating tumor
 - b. Gadolinium enhancement
 - c. Extension of tumor into the epidural space
2. EMG:
 - a. Paraspinal muscles demonstrate fibrillation potentials and positive sharp waves
 - b. Myokymic discharges are demonstrated in approximately 50% of patients

Secondary Non-Infiltrative Peripheral Neuropathies Associated with Lymphoproliferative Disorders and Plasmacytomas

Overview

1. Monoclonal gammopathies are detected in patients with peripheral neuropathy
2. Approximately 10% of patients with idiopathic peripheral neuropathies have monoclonal proteins, while only 2.5% of identified neuropathies (cause known) have these antibodies
3. The association of IgA and IgG antibodies to peripheral neuropathy is not clear
 - a. These antibodies are not deposited on nerve sheaths in patients with neuropathy, although they may be detected in the serum
4. IgM gammopathy is associated with a demyelinating sensorimotor polyneuropathy
5. Myeloproliferative disorders that may demonstrate a monoclonal gammopathy are:
 - a. Waldenström's macroglobulinemia
 - b. Osteosclerotic myeloma
 - c. Plasmacytoma
 - d. Multiple myeloma
 - e. Lymphoma
 - f. Leukemia
 - g. Cryoglobulinemia
6. Most patients with monoclonal gammopathies have no underlying myeloproliferative disorder and are designated monoclonal gammopathy of undetermined significance (MGUS)
7. Approximately 20% of patients with a monoclonal gammopathy may develop leukemia, lymphoma, myeloma, or plasmacytoma
8. Serum and urine protein electrophoresis are the screening tests for monoclonal gammopathies. In those patients in whom a myeloproliferative disorder is suggested, the more

sensitive immunoelectrophoresis or immune fixation studies are employed in the laboratory evaluation

Lymphoma

General Characteristics

1. Approximately 8% of lymphoma patients have clinical signs of neuropathy or radiculopathy, which is increased to 35% with electrophysiological testing
2. Neurolymphomatosis (NL) is the direct invasion of cranial or peripheral nerves or plexi by subtypes of non-Hodgkin's lymphoma
3. Hodgkin's and non-Hodgkin's lymphoma cause sensorimotor polyneuropathies
4. Lymphomas may affect any part of the nervous system, and can occur at any stage of the disease

Clinical Manifestations

1. The course may be acute, subacute, chronic progressive, or relapsing and remitting
2. Neuropathy patterns:
 - a. Sensorimotor (most common)
 - b. Pure sensory or motor
 - c. Rarely, severe autonomic features occur
 - d. CIDP pattern
 - e. Sensory ganglionopathy
 - f. Vasculitic neuropathy
 - g. Paraneoplastic neuropathy
 - h. Multiple mononeuropathies
 - i. Pain suggests neurolymphomatosis

Neuropathology

1. Sural nerve biopsy:
 - a. Neurolymphomatosis with direct invasion of lymphoma cells into the nerve is more prominent in the proximal portions of the nerve trunk
 - i. Demyelination without macrophage invasion, and associated axonal degeneration distal to the site of demyelination
 - b. Endoneurial inflammation
 - c. Features of chronic inflammatory demyelinating polyneuropathy

Laboratory Evaluation

1. CSF:
 - a. Lymphocytic pleocytosis (frequently 50–100 cells/mm³)
 - b. Increased protein
2. EMG:
 - a. Reduced amplitudes of SNAPs and CMAPs with normal conduction velocities
 - b. CIDP pattern:
 - i. Prolonged distal and F-wave latencies
 - ii. Slow conduction velocities
 - iii. Temporal dispersion
 - iv. Conduction block

Multiple Myeloma

General Characteristics

1. Multiple myeloma-related peripheral neuropathy may occur in up to 54% of patients, due to the disease or as a complication of treatment
2. New antimyeloma medications can trigger or exacerbate a pre-existing neuropathy (occurs in 3–13% of untreated patients, although up to 40% may show a subacute neuropathy by electrodiagnostic testing)

Clinical Manifestations

1. Multiple myeloma occurs primarily in the fifth through seventh decade
2. Systemic signs and symptoms include:
 - a. Bone pain
 - b. Fatigue
 - c. Anemia
 - d. Hypercalcemia
3. Peripheral neuropathy patterns:
 - a. Distal axonal sensory or sensorimotor polyneuropathy
 - b. Chronic demyelinating polyneuropathy
 - c. May be associated with amyloid polyneuropathy that is suggested by:
 - i. Loss of small fiber modalities of pain and temperature
 - ii. Painful paresthesias of the distal extremities
 - iii. Autonomic dysfunction
 - iv. Carpal tunnel syndrome
 - v. Enlarged plasmacytoma that can involve cranial nerves, spinal roots and occasionally intracranial structures

Neuropathology

1. Sural nerve biopsy:
 - a. Amyloid deposition occurs in 2/3 of patients
 - b. Axonal degeneration and segmental demyelination

Laboratory Evaluation

1. Monoclonal protein abnormalities detected in the serum or urine
2. Mild to moderate anemia and hypercalcemia
3. Osteolytic lesions of the spine and long bones; may have collapsed vertebrae with spinal cord compression (three or more contiguous vertebral body involvement suggests multiple myeloma rather than metastasis)
4. Bone marrow biopsy demonstrates at least 10% plasma cells
5. EMG:
 - a. Sensory and motor NCS reveal decreased amplitudes with normal or minimally prolonged distal latencies and conduction velocities
 - b. Common carpal tunnel median nerve compression
6. 18F-FDG PET is excellent for diagnosis and monitoring treatment

POEMS Syndrome (Osteosclerotic Myeloma)*General Characteristics*

1. POEMS syndrome (polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy, and skin changes) is a multisystemic disorder associated with osteosclerotic myeloma (a variant of plasma cell dyscrasia)
2. POEMS is seen in approximately 3% of myelomas
3. Approximately 50% of patients develop a peripheral neuropathy, which may be the presenting symptom
4. Most patients do not have all the features of the disease
5. The syndrome can occur with Castleman's disease, although the great majority of patients have osteosclerotic myeloma. It has been described with Waldenström's macroglobulinemia, extramedullary plasmacytoma, and rarely with no discovered malignancy
6. The major criteria include:
 - a. Polyradiculoneuropathy
 - b. Clinical plasma cell disorder (PCD)
 - c. Sclerotic bone lesions
 - d. Elevated vascular endothelial growth factor (VEGF)
 - e. Presence of Castleman's disease
7. Minor criteria:
 - a. Organomegaly
 - b. Endocrinopathy
 - c. Skin changes
 - d. Papilledema
 - e. Extravascular overload
 - f. Thrombocytosis

Clinical Manifestations

1. Systemic signs:
 - a. Hepatosplenomegaly
 - b. Cutaneous pigmentation
 - c. Hypertrichosis
 - d. Severe edema
 - e. Pericardial and pleural effusions
 - f. Clubbing
 - g. Gynecomastia
 - h. Testicular atrophy
 - i. Amenorrhea
 - j. Diabetes mellitus
 - k. Hypothyroidism
 - l. Endocrinopathy (hyperprolactinemia)
2. Pattern of peripheral neuropathy:
 - a. Symmetric distal lower extremity paresthesias, numbness, and weakness
 - b. Gradual spread to proximal-distal upper extremity muscles
 - c. Primarily affects large fiber sensory modalities
 - d. Loss of muscle stretch reflexes
 - e. Cranial nerves and muscles of respiration may be affected
 - f. Papilledema occurs in 30–55% of patients
 - g. Patients may develop an inflammatory myopathy or a proximal myopathy from hypothyroidism

Neuropathology

1. Sural nerve biopsy:
 - a. Combination of segmental demyelination and axonal degeneration
 - b. Endomysial perivascular cell infiltration
 - c. High expression of VEGF in blood vessels and non-myelin-forming Schwann cells
 - d. Increased thickness of the basal lamina of the vasa vasorum
 - e. Electron microscopy:
 - i. Proliferation of endothelial cells
 - ii. Separation of tight junctions
 - iii. Demonstration of uncompacted myelin

Laboratory Evaluation

1. The monoclonal gammopathies are usually of immunoglobulin (Ig) type A with lambda light chain restriction (in multiple myeloma (MM) the light chains are of the kappa type)
2. Rare Bence-Jones protein in the urine (common with MM)
3. Bone marrow biopsy reveals less than 5% plasma cells
4. The monoclonal protein is low and is best demonstrated with immunofixation; in 15% of patients, it is not detected, although biopsy of a sclerotic lesion may be positive
5. Increased levels of VEGF and IL1B, TNF-alpha and IL-6
6. In 20% of patients, erythropoietin clonal protein is detected in the urine but not in the serum
7. CSF:
 - a. Greatly elevated protein (greater than in CIDP)
8. Skeletal X-ray survey:
 - a. Lesions are usually found in the vertebral bodies and ribs; occasionally in the pelvis
 - b. In 50% of patients, there are multiple lesions (focal plasmacytomas)
 - c. X-ray evaluation of bone lesions:
 - i. A radiolucent central component ringed by a sclerotic margin (pure osteolytic lesion in MM)
 - ii. Lesions may precede clinical symptoms; rare cranial lesions
9. EMG:
 - a. NCS are similar to CIDP but with less conduction block
 - b. Characteristics of a demyelinating neuropathy or a mixed axonal and demyelination neuropathy

Castleman's Disease (Angiofollicular Lymph Node Hyperplasia)*General Characteristics*

1. Castleman's disease is a rare lymphoproliferative disorder characterized by enlarged hyperplastic lymph nodes that mimic lymphoma
2. It has several histologic variants that include:
 - a. Hyaline vascular plasma cell

- b. Plasma cell
- c. Mixed types

Clinical Manifestations

1. Localized or unicentric form: indolent
2. Multicentric systemic form: usually involves the plasma cell variant
3. Systemic manifestations include:
 - a. Diffuse lymphadenopathy
 - b. Hepatosplenomegaly
 - c. Fever
 - d. Night sweats
 - e. Fatigue
4. CNS complications:
 - a. Intracranial extra-axial lesions that simulate meningiomas and may cause seizures; one report of limbic encephalitis; rare optic neuropathy
 - b. Associated with POEMS syndrome:
 - i. Similar but less severe peripheral neuropathy; usually a mild sensory predominant neuropathy
 - c. Associated with:
 - i. Paraneoplastic pemphigus
 - ii. Systemic lupus erythematosus
 - iii. Rheumatoid arthritis
 - iv. Myasthenia gravis

Neuropathology

1. Herpes virus 8 has been associated with the plasmablastic variant
2. These patients are at risk for Kaposi sarcoma, lymphoma, and follicular dendritic cell tumors
3. Polyclonal lymphocyte and plasma cell proliferation induced primarily by IL-6
4. Human herpes virus 8 (HHV-8) drives the hypercytokinemia in most HIV-positive patients and a subgroup of HIV-negative patients
5. Reactivated HHV-8, in immunosuppressed patients, induces IL-6 that stimulates B-cell proliferation and lymphoid hyperplasia

Laboratory Evaluation

1. Increased VEGF and IL-6 in the serum
2. No osteosclerotic lesions on skeletal survey
3. EMG:
 - a. Similar to POEMS (but less severe)
4. Differences from lymphoma by CT:
 - a. Calcification (with Castleman's disease) in 30%
 - b. Heterogeneous enhancement in 20%
5. MRI:
 - a. Nodes are hypointense to isointense on T1-weighted sequences; isointense to hyperintense on T2-weighted images. All patients demonstrate homogeneous enhancement with gadolinium F¹⁸-2DG
 - i. Nodes were avid

Waldenström's Macroglobulinemia and IgM-MGUS

General Characteristics

1. Defined by WHO and the revised European-American Lymphoma Association as a bone marrow infiltrated lymphoplasmacytic lymphoma and IgM paraproteinemia
2. Occurs in approximately 2% of patients with monoclonal gammopathies
3. Approximately 80% are associated with a K light chain
4. Waldenström's macroglobulinemia is differentiated from IgM myeloma by:
 - a. Absence of lytic lesions in bones
 - b. No hypercalcemia
 - c. Evidence of hepatosplenomegaly and lymphadenopathy
 - d. There are similarities to IgM-MGUS

Clinical Manifestations

1. Age of onset is between 50 to 70 years in men > women
2. Systemic symptoms include:
 - a. Progressive fatigue
 - b. Weight loss
 - c. Lymphadenopathy
 - d. Hemorrhages (nose bleeds; petechial hemorrhages below the knees; platelet dysfunction due to coating by IgM protein)
 - e. Hepatomegaly and splenomegaly
3. Peripheral neuropathy:
 - a. Insidious onset of paresthesias in the distal lower extremities which evolves proximally, and goes on to involve the distal upper extremities
 - b. Sensory ataxia
 - c. Minimal distal extremity weakness
 - d. Loss of muscle stretch reflexes
 - e. Gait instability and loss of fine movements in the fingers due to sensory loss

Neuropathology

1. Sural nerve biopsy:
 - a. IgM deposition on the outer myelin membranes
 - b. Rare deposition in the periaxonal space; no deposition on compact myelin
2. Neuropathy may be associated with concurrent:
 - a. POEMS
 - b. Secondary amyloidosis
 - c. Vasa vasorum ischemia due to serum hyperviscosity
 - d. Neurolymphomatosis

Laboratory Evaluation

1. Serum IgM monoclonal protein in a concentration greater than 3 g/L
2. Antibodies against myelin-associated glycoprotein (MAG) or sulfatide occur in some patients
3. Bone marrow biopsy:
 - a. Infiltrated by lymphoplasmacytic lymphoma

4. EMG:
 - a. Usually, features of a demyelinating sensorimotor neuropathy are demonstrated
 - b. An axonal sensorimotor neuropathy is sometimes seen

Monoclonal Gammopathy of Undetermined Significance (MGUS)

General Characteristics

1. Monoclonal gammopathy of undetermined significance (MGUS) is a common premalignant condition
2. It affects approximately 3.5% of the population older than 50 years of age
3. IgG and IgA MGUS are defined:
 - a. An M protein less than 30 g/L
 - b. Bone marrow plasma cell percentage of less than 10%
 - c. Absence of signs and symptoms of other lymphoproliferative malignancies that include:
 - i. Multiple myeloma
 - ii. Waldenström's macroglobulinemia
 - iii. Immunoglobulin light-chain (AL) amyloidosis
 - iv. Chronic lymphocytic leukemia
 - v. B-cell lymphoma
4. IgA or IgG MGUS have an increased risk of progression to multiple myeloma
5. IgM-MGUS may progress to Waldenström's or other lymphoproliferative disorders
6. Light-chain MGUS may progress to light-chain multiple myeloma; it has a prevalence of 0.7–0.8% in persons over 50 years of age
7. Progression of MGUS to MM is approximately 1% per year
8. The disappearance of the M-protein occurs in approximately 2–5% of patients with MGUS
9. Secondary MGUS:
 - a. Refers to the emergence of a new monoclonal gammopathy of an isotype distinct from the original multiple myeloma (MM) during its course; it occurs in 10–73% of MM patients after autologous stem cell transplantation and 1.6–33% of non-transplant patients

Clinical Manifestations

1. Neuropathies associated with an IgM monoclonal protein are primarily demyelinating
2. IgA or IgG monoclonal gammopathies can be either axonal or demyelinating
3. Demyelinating neuropathies:
 - a. May present with proximal and distal weakness
 - b. Primarily large fiber sensory modality loss
 - c. Similar to CIDP
 - d. Distal symptoms similar to DADS (distal acquired demyelinating sensory neuropathy)
4. Numbness, paresthesias and tingling distally, in both upper and lower extremities that evolve proximally
5. IgM-MGUS has weakness of primarily the distal extremities

6. IgG and IgA have more symmetrical proximal and distal weakness
7. Muscle stretch reflexes are depressed or absent throughout
8. Axonal neuropathy patients are indistinguishable from idiopathic sensorimotor polyneuropathies
9. Length-dependent sensory neuropathy

Neuropathology

1. Nerve biopsy:
 - a. Primarily loss of large diameter myelinated fibers, with minimal involvement of thinly myelinated and unmyelinated fibers
 - b. A subgroup of patients demonstrates demyelination and remyelination
 - c. IgM-MGUS:
 - i. Immunoglobulin deposition on the outer myelin membranes, minimal involvement of the periaxonal spaces, and no deposition on compact myelin
 - ii. Electron microscopy:
 1. Separation of myelin sheaths with IgM deposits in areas of myelin splitting

Associated MGUS Medical Conditions

1. Possibly related to MGUS by clone-related alterations in the bone marrow microenvironment:
 - a. Suppression of normal plasma cells
 - b. Depressed osteoblast activation
2. Infection:
 - a. Increased risk of bacterial and viral infection
 - i. Relative immune deficiency due to low levels of normal immunoglobulins
 - ii. Lower absolute number of CD4⁺ and CD8⁺ T-cells
3. Osteoporosis:
 - a. MGUS patients have an increased risk of fractures
 - b. The prevalence of MGUS is higher in patients that present with acute vertebral fractures from osteoporosis
 - c. Altered bone microstructure:
 - i. Biochemical markers of bone formation are reduced, and markers of resorption are increased
 - ii. Possibly related to elevated levels of DKK1 (a Wnt pathway inhibitor) that decrease bone formation
4. Progression to malignancy:
 - a. There is a 2 to 8 fold risk of progression to myeloid malignancies that include:
 - i. Myelodysplastic syndrome
 - ii. Acute myeloid leukemia
 - iii. Polycythemia vera
 - b. Risk factors:
 - i. M-protein > 15 mg/L
 - c. MGUS patients have a slightly higher risk of developing non-hematologic malignancies
5. Thrombosis:
 - a. MGUS patients have a 2 to 3 times higher risk of developing deep vein thrombosis and pulmonary emboli

- b. Possible increased risk of arterial thrombosis:
 - i. Increased factor VIII and von Willebrand factor levels are similar to those of MM
- c. The increased prothrombotic risk is only seen in IgG and IgA isotypes

M-Protein Related Medical Complications

1. Clonal MGUS may cause organ damage by:
 - a. Production of an M-protein with autoantibody characteristics
 - b. Deposits of the protein in tissues that occur with:
 - i. AL amyloidosis
 - ii. Monoclonal immunoglobulin deposition disease
 - iii. Type I cryoglobulinemia

Laboratory Evaluation

1. Approximately 50% of patients with IgM-MGUS neuropathy have antibody titers against myelin-associated glycoprotein (MAG)
2. M-protein concentration of 15 g/L helps to discriminate between MM and non-myeloma patients
3. Bone lesions are rare with IgG or IgA isotypes on skeletal survey
4. Bone marrow examination is suggested for patients with IgA and IgM M-proteins
5. CT of the chest, abdomen, and pelvis for IgM-MGUS
6. Elevated CSF protein may be seen with IgM-MGUS
7. EMG:
 - a. IgM neuropathies demonstrate demyelinating features:
 - i. Prolonged distal latencies
 - ii. Moderately slow conduction velocities
 - b. NCS in patients with IgG or IgA MGUS may be axonal or demyelinating

Differential Diagnosis of Peripheral Neuropathies with Monoclonal Protein

1. Cryoglobulinemia (mixed):
 - a. Raynaud's phenomena
 - b. Acrocyanosis
 - c. Subacute painful multiple mononeuropathies
 - d. Positive for hepatitis C-virus
2. AL amyloidosis:
 - a. Insidious onset of a symmetric painful autonomic and sensorimotor neuropathy
3. POEMS:
 - a. Insidious demyelinating polyradiculopathy
 - b. Diabetes, hypothyroidism, testicular atrophy, amenorrhea
 - c. Skin and nail changes
 - d. Severe peripheral extremity edema
4. IgM-MGUS:
 - a. Insidious painless distal sensory ataxic neuropathy
 - b. Demyelinating
5. Waldenström's macroglobulinemia:

- a. Numbness of the distal lower extremities
- b. Tumor (sensory loss)
- c. Positive Romberg sign
- d. Bleeding disorder; nosebleeds and petechiae in the distal lower extremities
- e. More axonal than demyelinating features on EMG; IgM-MGUS demonstrates greater demyelinating features

Graft-Versus-Host Disease

General Characteristics

1. Graft-versus-host disease (GVHD) is a systemic immune-mediated disease
2. The leading morbidity after allogeneic hematopoietic stem cell transplantation
3. Neurological complications may occur in as many as 64% of long-term survivors of allo-HSCT, and are associated with:
 - a. Long-term immunosuppression
 - b. GVHD
 - c. Chemotherapy
 - d. Infection
 - e. Radiation
 - f. Autoimmunity

Clinical Manifestations of GVHD

1. Cranial neuropathies (often loss of taste and smell)
2. Sensorimotor polyneuropathy
3. Multiple mononeuropathies
4. Guillain-Barré syndrome
5. CIDP and brachial plexopathy
6. Peripheral neurologic involvement usually has a delayed onset
 - a. Occurs most commonly in setting of chronic GVHD
7. May be associated with muscle cramps

Neuropathology

1. Sural nerve biopsy:
 - a. Vasculitis
 - b. Infiltration of T-cells and immunoglobulin deposits
 - c. Perineural fibrosis
 - d. Loss of myelinated fibers

Laboratory Evaluation

1. EMG:
 - a. NCS may demonstrate demyelinating, axonal, or mixed characteristics

Chemotherapy-Induced Peripheral Neuropathy (CIPN)

Overview

The primary chemotherapeutic agents used in practice cause toxic peripheral neuropathy and include taxanes, platinum

compounds, vinca alkaloids and proteasome inhibitors, and anti-angiogenic immunomodulatory agents. Only a proportion of chemotherapy-treated patients develops persistent CIPN, which is greater in patients with pre-existing neuropathic, diabetes and Charcot-Marie-Tooth disease. CIPN is often dose limiting and can persist and worsen long after cessation of chemotherapy. CIPN often affects the DRG (a less stringent blood-nerve barrier) but also affects nerve terminals as well as the axon. Clinical features depend on the chemotherapeutic agent and its site of action.

Taxanes (Paclitaxel)

General Characteristics

1. Paclitaxel (Taxol®) is more neurotoxic than docetaxel
2. It has an incidence of up to 85% of a subclinical or mild neuropathy often to 3 to 7 cycles of Taxol at doses of 135–200 mg/m²; doses between 250 and 350 mg/m² patient may be symptomatic after the first or second cycle
3. Approximately 70% of patients have a severe neuropathy; only 2% develop severe neuropathy with ten doses
4. Risk factor for developing a severe neuropathy are:
 - a. A cumulative dose of 1500 mg/m²
 - b. A pre-existing neuropathy
 - c. Concurrent exposure to neurotoxic agents
5. The neurotoxic threshold for paclitaxel is 1000 mg/m²
6. Duration of infusion (1 to 3 hours per 24 hours)

Clinical Manifestations

1. Paresthesias, numbness, and at times, neuropathic pain, develop in a length-dependent manner
2. Loss of large myelinated fiber modalities of sensation
3. Minimal distal extremity weakness
4. Loss of muscle stretch reflexes
5. Signs and symptoms usually improve with cessation of chemotherapy

Neuropathology

1. Final nerve biopsy:
 - a. Primary loss of large diameter myelinated nerve fibers
 - b. Axonal degeneration with secondary demyelination and remyelination
 - c. Disruption of microtubule-based axonal transport by:
 - i. Increasing microtubule assembly by inducing polymerization
 - ii. Aggregation and accumulation of bundles of microtubules in DRG sensory neurons, axons, and Schwann cells
 - d. Nociceptor Beta 11, delta and epsilon isoforms of PKC differentially mediate paclitaxel in clinical spontaneous evoked pain
 - e. Paclitaxel is also associated with the induction of chemokine monocytes chemoattractant protein-1 (MCP-1) and its receptor CCR2 in primary sensory nerves of the DRG

Laboratory Evaluation

1. Electron microscopy:
 - a. Accumulation of tubercular and membranous structure within axons

Docetaxel (Taxotere®)

General Characteristics

1. Docetaxel is a semisynthetic analog of Taxol
2. Utilized for a wide range of malignancies
3. Cumulative dose of 400 mg/m² is the neurotoxic threshold

Clinical Manifestations

1. Primarily a sensory neuropathy that is less severe than that seen with Taxol
2. Pain in the extremities
3. Lhermitte's sign
4. Large fiber sensory modalities are primarily affected
5. Decreased or absent ankle reflexes
6. Between 5 to 19% of patients have mild distal extremity weakness
7. Many patients improve after 1 to 2 months following treatment, but "slide" (continuing worsening) can occur

Neuropathology

1. Serial nerve biopsy
 - a. Loss of large diameter myelinated fibers
 - i. Axonal degeneration

Laboratory Evaluation

1. NCS studies reveal decreased SNAPs and CMAPs with minimal slowing of conduction velocities

Platinum Compounds

General Characteristics

1. Cisplatin has evidence of peripheral neuropathy in approximately 60% of patients that receive a cumulative dose of 225–500 mg/m²
2. The combination of cisplatin/paclitaxel is additive in causing neuropathy

Clinical Manifestations

1. Predominant sensory neuropathy involving large myelinated fibers and primarily affecting proprioception and vibration in sensibilities
2. Distal extremity paresthesia and hypoaesthesia
3. Gait ataxia and pseudoathetosis
4. Approximately 2% of patients develop weakness
5. Approximately 40% of patients demonstrate Lhermitte's sign
6. Onset of symptoms may be delayed as long as 8 weeks after cessation of therapy and "coasting" can occur for up to six months
7. Generalized loss of muscle stretch reflexes

Neuropathology

1. Sural nerve biopsy:

- a. Predominant loss of large diameter myelinated fibers
- b. Axonal degeneration with sign of sprouting
- c. Segmented demyelination
- d. Ganglionopathy with loss of large sensory neurons
- e. Autopsy studies:
 - i. The DRG is primarily affected by deposition of platinum compounds
 - ii. Suggested mechanism of toxicity:
 1. Alteration of the tertiary structure of DNA:
 - a. Formation of intrastrand adducts
 - b. Interstrand crosslinks
 2. Neuronal apoptosis of sensory neurons in the DRG induced by oxidative stress, mitochondrial dysfunction or by increased activation of p53, p38 and ERK 1/2

Laboratory Evaluation

1. EMA:
 - a. Low amplitude or unobtainable SNAPs
 - b. Normal or slightly prolonged distal latencies
 - c. Normal CMAPs
 - d. Minimal prolonged sensory latencies and slowed conduction velocities
2. QST
 - a. Abnormal vibrating thresholds

Oxaliplatin

General Characteristics

1. There are two distinct forms of toxicity:
 - a. Acute or chronic
 - b. Due to specific aspects of neurotoxicity
2. The vast majority of patients treated with oxaliplatin-based regimens that have between 85–130 mg/m² exposure develop some form of neurotoxicity
3. Severe acute OXLIPN (oxaliplatin-induced peripheral neuropathy) occurs in approximately 22% of patients
 - a. Major risk factors are:
 - i. Cold temperature
 - ii. Time of the infusion
4. Chronic oxaliplatin-induced neurotoxicity is found in 60 to 70% of patients that are treated with oxaliplatin-based regimens that include:
 - a. FOLFOX4
 - b. FOLFOX6
 - c. XELOX
5. Risk factors for chronic oxaliplatin neuropathy are:
 - a. Cumulative dose
 - b. Time of infusion
 - c. Prior peripheral neuropathy
 - d. Chemotherapy regimen

Clinical Manifestations

1. Signs and symptoms of acute OXLIPN may start during or within 1 to 2 days of the infusion

2. Primarily, there are distal and perioral cold-induced paresthesias and dysesthesias
3. Clinical symptoms include:
 - a. Shortness of breath
 - b. Jaw spasm
 - c. Fasciculations
 - d. Cramps
 - e. Difficulty swallowing
 - f. Voice and visual changes
 - g. Ptosis and pseudolaryngospasm

Neuropathology

1. Chronic sensory form:
 - a. Due to degeneration of sensory neurons in the DRG from local deposition and accumulation of oxaliplatin
2. Acute form:
 - a. Dysfunction of nodal axonal voltage-gated sodium channels due to oxalate chelating effects on Ca²⁺ and Mg²⁺

Laboratory Evaluation

1. EMG:
 - a. Repetitive CMAPs
 - b. High-frequency discharge of motor unit
 - c. Neuromyotonia

Suramin

General Characteristics

1. Suramin is a hexasulfonated naphthyl urea
2. The most common dose-limiting side effects are fatigue, anorexia, and peripheral neuropathy
3. 1440 mg/m² appears to be the maximal tolerated dose
4. Peripheral neuropathy occurs in 25 to 90% of patients

Clinical Manifestations

1. Distal axonopathy form of toxicity:
 - a. Distal numbness and paresthesias
 - b. Mild weakness of the distal extremities
 - c. Reduced light touch pain, vibration, and proprioceptive sensibility
 - d. Diminished or absent ankle reflexes
 - e. This form of the neuropathy is reversible
2. A subacute sensorimotor demyelinating neuropathy:
 - a. More severe than axonal neuropathy
 - b. Develops in 10 to 20% of patients
3. Different protocols for administration are used; neuropathy occurs with:
 - a. Usually 1 to 5 months of treatment
 - b. Peak plasma concentrations of >300 mg/m² or exposure to 200 mg/m² for more than 25 days a month
 - c. Cumulative dose of 40,000 mg-h/L
 - d. Presentation is numbness and paresthesias of the distal extremities and face
 - e. Proximal > distal extremity weakness

- f. Absent muscle or stretch reflexes throughout
- g. Weakness progresses and a significant number of patients require mechanical ventilation
- h. The neuropathy can “coast” for approximately one month following cessation therapy
- i. Recovery occurs to some degree over months often with residual deficits

Neuropathology

1. Sural nerve biopsy:
 - a. Patients with demyelination neuropathy:
 - i. Loss of both large and small myelinated fibers
 - ii. Demyelination and remyelination with secondary axonal degeneration
 - iii. Mononuclear inflammatory infiltrates of the epi and endoneurium
 - iv. Glycolipid lysosomal inclusions in axons (produced in experimentally exposed animals)
 - v. Competition between the agent and nerve growth factor at the high-affinity NGF receptor

Laboratory Evaluation

1. CSF:
 - a. Elevated protein access with the subacute demyelinating polyradiculoneuropathy
 - b. Minimal reduction of distal latencies and conduction velocities
2. EMG:
 - a. In patients with axonal form:
 - i. Decrease SNAPs and CMAPs amplitudes
 - ii. Minimal reduction of distal latencies and conduction velocities
3. QST of axonal pathology
 - a. Abnormal vibration and cooling thresholds
4. Needle EMG:
 - a. Positive sharp waves, fibrillation potentials and neurogenic MUAPs are demonstrated in affected distal musculature
5. Subacute demyelinating polyradiculoneuropathy:
 - a. Slow conduction velocities
 - b. Prolonged distal latencies including F waves
 - c. Temporal dispersion
 - d. Conduction block
6. QST
 - a. Increased vibratory and cold thresholds

Etoposide (VP-16®)

General Characteristics

1. VP-16 is a semisynthetic derivative of podophyllotoxin whose effect may be due to nucleolar disruption and apoptosis due to individual DNA damage
2. Approximately 4 to 10% of patients suffer a neuropathy

Clinical Manifestations

1. Length-dependent primarily sensory axonal neuropathy

2. Severe autonomic neuropathy associated with orthostatic hypotension and gastrointestinal symptomatology

Neuropathology

1. Experimental models demonstrate loss of neurons in the DRG
2. Blockage of RNA polymerase-1-driven transcription
3. Acts as a topoisomerase inhibitor
4. The DNA damage induced by the drug has been suggested to cause reduced ribosomal biogenesis

Laboratory Evaluation

1. EMG:
 - a. JNCs demonstrate low amplitude SNAPs and CMAPs

Vinca Alkaloids

General Characteristics

1. Toxic effects of vincristine are usually evident after a cumulative dose of 12 mg; however, the neuropathy has been reported as early as two weeks after a single 2 mg/m² dose
2. “Coasting” often occurs in 24 to 30% of patients for several weeks following cessation of therapy
3. Symptoms remain for approximately three months following therapy

Clinical Manifestations

1. Initially, patients suffer numbness and paresthesias in the distal extremities. The upper extremity may be affected first
2. In 25 to 35% of patients, there is distal extremity weakness with accumulating dosage
3. Autonomic neuropathy is common and causes:
 - a. Orthostatic hypotension
 - b. Gastrointestinal symptomatology
 - c. Urinary retention
 - d. Impotence
4. Cranial neuropathies are uncommon but include:
 - a. Optic neuropathy
 - b. Oculomotor dysfunction
 - c. VIIth cranial nerve paralysis
 - d. Laryngeal weakness
5. A subset of patients has painful paresthesias and hyperesthesia
6. There is generalized diminution or loss of muscle stretch reflexes

Neuropathology

1. Serial nerve biopsy:
 - a. Loss of myelinated and unmyelinated nerve fibers
 - b. Axonal degeneration with clusters of regenerating axonal sprouts
2. Interferes with both fast and slow axonal transport at the level of the cell body and alters cellular microtubular structure; binds to tubulin

Laboratory Evaluation

1. NCS demonstrate:

- a. Axonal sensorimotor peripheral neuropathy
- b. Decreased amplitude of SNAPs and CMAPs
- c. Normal or minimally prolonged latencies and mildly slow nerve conduction velocities
2. Needle EMG:
 - a. Positive sharp waves and fibrillation potentials in affected muscles
3. QST:
 - a. High vibration threshold
4. Inherited polymorphism of the promoter of CEP72 may cause increased risk of neuropathy

Vinorelbine

General Characteristics

1. Vinorelbine is a semisynthetic vinca alkaloid that is used most often in combination for a variety of cancers
2. Causes a dose-related peripheral neuropathy in 20 to 50% of patients
3. Less neurotoxic than vincristine
 - a. A severe neuropathy has been described in 1% of patients

Clinical Manifestations

1. Usual presentation is a distal sensory loss with paresthesias
2. Distal muscle weakness may occur after 3 to 6 months of treatment
3. Autonomic neuropathy may occur but is less severe than that which occurs with vincristine
4. Usually, there is diminution of muscle stretch reflexes with their loss at the ankles

Neuropathology

1. Nerve biopsy results are not available

Laboratory Evaluation

1. Decreased SNAP and CMAP amplitudes
2. Normal distal latencies and conduct in velocities

Cytosine Arabinoside

General Characteristics

1. Cytarabine (ara-C) is an antimetabolite used in the treatment of leukemia and lymphoma and is often combined with other chemotherapeutic agents
2. Its intrathecal use has been associated with myelopathy and cauda equine syndrome
3. Cumulative doses of 60 mg/m² to 36 g/m² have caused peripheral neuropathy

Clinical Manifestations

1. Rarely patients may have an RBS presentation or bronchial plexopathy
2. Primarily a sensory neuropathy

3. The neuropathy may begin within hours or be delayed for several weeks
4. Central effects following intrathecal administration often with methotrexate include:
 - a. Cauda equina syndrome
 - b. Myelopathy
 - c. Diffuse cerebral vasospasm rarely occurs in children

Neuropathology

1. Small nerve biopsy:
 - a. Loss of myelinated nerve fibers
 - b. Axonal degeneration with segmented demyelination
 - c. No inflammation

Laboratory Evaluation

1. CSF:
 - a. In patients with a GBS phenotype, the protein is elevated
2. EMG:
 - a. NCS may be compatible with a demyelinating or primary axonal sensorimotor polyneuropathy

Ifosfamide

General Characteristics

1. Ifosfamide is a cyclophosphamide analog metabolized by the cytochrome P450 system to its active form ifosfamide mustard
2. Ifosfamide is used in the treatment of several solid tumors and hematologic malignancies
3. It is associated with a polyneuropathy after a total dose of 14 g/m²

Clinical Manifestations

1. Approximately 10 to 14 days after treatment, patients experience numbness and painful paresthesias in the hands and feet
2. The onset is rarely in the hands rather than the feet, which occurs with a ganglionopathy
3. Systemic manifestations:
 - a. Bone marrow suppression
 - b. Alopecia
 - c. Nausea and vomiting
4. If combined with aprepitant for nausea and vomiting (a neurokinin-1 inhibitor), there may be a higher incidence of neurotoxicity
5. Ifosfamide may be associated with neuropsychiatric toxicity

Neuropathology

1. A well-known systemic complication is renal dysfunction that may be progressive and permanent
2. In a patient with encephalopathy:
 - a. Increased excretion of glutaric acid and sarcosine suggestive of a defect in the mitochondrial fatty acid oxidation that results from defective electron transfer to flavoproteins

Laboratory Evaluation

1. There are no available electrodiagnostic studies

Bortezomib (Velcade®)*General Characteristics*

1. Bortezomib is a proteasome inhibitor primarily utilized in the treatment of multiple myelomas that has been relapsed or with refracting or primary therapies
2. The risk of neuropathy is associated with increasing dosage and in patients with pre-existing neuropathy or comorbidities for peripheral nerve damage
3. The estimates of peripheral neuropathy in patients treated vary widely 37 to 75%. The accumulated neurotoxic dose may be 80 mg/m²

Clinical Manifestations

1. Length-dependent paresthesias, burning dysesthesias and numbness
2. Burning dysesthesias suggest a small fiber component clinically
3. Distal sensory loss to all modalities including proprioception
4. Muscle stretch reflexes are reduced or absent
5. Predominant motor polyradiculoneuropathy (one patient)

Neuropathology

1. Nerve biopsy (one reported patient)
 - a. Microvasculitis
2. Experimental studies suggest:
 - a. Metabolic dysfunction from bortezomib accumulation in dorsal root ganglia cells
 - b. Mitochondrial-mediated dysregulation of Ca²⁺ homeostasis
 - c. Proteasome inhibitor
 - d. Increased alpha-tubulin polymerization
 - e. Endoplasmic reticulum damage
 - f. Dysregulation of neurotrophins through inhibition of NFκB activation
 - g. Specific functional alterations in A-delta and C fibers
 - h. Increase density of TRPV1 and CGRP labeled neurons after treatment that suggest bortezomib treatment selectively affects pain processing cells in the DRG

Laboratory Evaluation

1. EMG:
 - a. Characteristic of an axonal sensory neuropathy with primarily small fiber involvement
2. QST:
 - a. Increased temperature thresholds
 - b. Abnormal autonomic function

Thalidomide*General Characteristics*

1. Thalidomide is most often used in cancer therapy for relapsed multiple myelomas; it has often been combined with proteasome inhibitors

2. Thalidomide monotherapy may lead to a peripheral neuropathy in 44% of patients with relapsed multiple myelomas; severe neuropathy occurs in approximately 6% of patients
3. There are no established risk factors for thalidomide neurotoxicity
4. Lenalidomide, an analog, is less toxic and causes peripheral neuropathy in approximately 3% of patients
5. Pomalidomide:
 - a. Used in multiple myeloma patients who have received and failed at least two prior treatments that have included lenalidomide and bortezomib
 - b. Neuropathy occurs in approximately 9% of patients

Clinical Manifestations

1. Neuropathic pain in and paresthesias in the distal extremities
2. The sensory loss to all modalities
3. Depressed motor stretch reflexes throughout
4. Orofacial neuropathy has been reported
5. CNS manifestations
 - a. Treatment with the immunomodulatory drugs utilized for multiple myelomas (thalidomide, lenalidomide, and pomalidomide) have caused:
 - i. Reversible coma
 - ii. Amnesia
 - iii. Expressive aphasia
 - iv. Dysarthria

Neuropathology

1. Lenalidomide and pomalidomide are more potent, anti-inflammatory, and immunomodulatory than thalidomide
2. Cereblon (cerebral protein with ion protease; CRBN) has recently been shown to be the primary target of thalidomide teratogenicity
3. These small molecule immunomodulators (thalidomide, lenalidomide, and pomalidomide) are involved in the degradation of transcription factors
4. A-delta, C-fibers, and proprioceptive fibers, as well as sensory DRG cells, are involved in thalidomide neurotoxicity

Laboratory Evaluation

1. EMG:
 - a. Similar findings as those seen with bortezomib
 - b. Characteristics of a sensory axonal neuropathy with primarily small fiber involvement

Endocrinopathies Associated with Neuropathy**Diabetes Mellitus (DM)***General Characteristics*

1. The estimated prevalence of DM in the USA in the population 40 to 70 years of age is 12%

2. If children are included, DM may occur in 1 to 4% of the population
3. Approximately 2/3 of both insulin dependent DM (IDDM) and non-IDDM have subclinical or clinical peripheral neuropathy
4. Approximately 50% of diabetic patients have a symmetrical polyneuropathy:
 - a. 25% carpal tunnel syndrome
 - b. 5% autonomic neuropathy
5. Risk factors for diabetic neuropathy:
 - a. Duration of disease
 - b. Poor glycemic control
 - c. Retinopathy and nephropathy
6. Diabetes mellitus diagnostic criteria:
 - a. AIC $> 6.5\%$
 - b. FPG ≥ 126 mg/dl (7.0 mm/l)
 - c. Two hour plasma glucose ≥ 200 mg/dl during an oral glucose tolerance test
 - d. Symptomatic hyperglycemia or hyperglycemic crisis
 - i. A random glucose of ≥ 200 mg/dl

Diabetic Distal Symmetric Sensory and Sensorimotor Polyneuropathy (DSPN)

General Characteristics

1. DSPN is the most common form of diabetic neuropathy (approximately 50% of diabetic neuropathies)

Clinical Manifestations

1. Primarily a length-dependent sensory neuropathy with minimal motor weakness
2. Sensory loss initially starts in the feet and toes; as it progresses above the knees patients complain of numbness and paresthesias in the upper extremities
3. Severely affected patients develop intercostal nerve neuropathy and complain of sensory loss or paresthesias in the chest and abdomen
4. Hypesthesia may be accompanied by tingling, paresthesias, lancinating pain (A-delta fibers), burning pain (C-fiber mediated) or a deep ache
5. Severe denervation and sensory loss lead to ulceration, secondary infection and Charcot joints (a destroyed, degenerative joint; most often the shoulder)
6. Patients may develop autonomic dysregulation from small fiber involvement (impotence, gastroparesis, orthostatic hypertension)
7. There may be loss of all modalities of sensation or primarily small fiber sensibility (pain and temperature)
8. Loss of muscle stretch reflexes is common with large myelinated fiber loss but may be retained if the process involves primarily small fibers
9. Foot intrinsic muscles may be weak and atrophy observable (particularly EDB)

Neuropathology

1. Sural nerve biopsy:
 - a. Axonal degeneration and segmental demyelination
 - b. Clusters of small regenerating axons
 - c. Asymmetric loss of axons between and within nerve fascicles
 - d. Endothelial hyperplasia of epi- and endoneurial arterioles (vasa vasorum)
 - e. Redundant basement membranes around arterioles
 - f. Thickness of the basement membranes or perineurial cells
 - g. Occasional perivascular infiltrate of CD8⁺ T-cells
 - h. Patients with the small fiber phenotype may have a normal nerve biopsy; however skin biopsy reveals a less dense intraepidermal innervation
 - i. Frank DM patients have more involvement of large diameter myelinated fibers; patients with impaired small fiber phenotype are more likely to demonstrate impaired glucose tolerance

Laboratory Evaluation

1. Impaired glucose tolerance test
2. AIC $\geq 6.5\%$
3. EMG:
 - a. Reduced SNAPs amplitudes and slow sensory conduction velocities (in 50% of DM patients)
 - b. 80% of patients with symptomatic neuropathy have abnormal NCS
 - c. Motor NCS are less severely involved than sensory studies but frequently demonstrate low amplitude CMAPs, slightly prolonged latencies and mildly decreased NCVs
4. Needle EMG:
 - a. Positive sharp waves, fibrillation potentials, and large motor unit action potentials (MUAP) may be seen in affected distal muscles
5. QST evaluation
 - a. Higher temperature thresholds

Diabetic Autonomic Neuropathy

General Characteristics

1. Autonomic diabetic neuropathy most frequently occurs concomitantly with DSPN
2. Autonomic neuropathy is an under-recognized complication of diabetes (may be severe in 5% of patients)
3. Aggressive glycemic control, particularly in the face of peripheral neuropathy, may increase the risk of sudden death
4. In adults, cardiovascular autonomic neuropathy is an independent predictor of mortality due to cardiovascular disease, neuropathy and hypoglycemia
5. Overt autonomic neuropathy is rare in childhood and adolescence, but subclinical autonomic dysfunction is common soon after diagnosis
6. Risk factors for autonomic neuropathy in young patients include:
 - a. Duration of diabetes

- b. Poor glycemic control
- c. Possibly polymorphism in the aldose reductase gene (AKR1B1); the Z-2/Z-2 genotype

Clinical Manifestations

1. Hypo- or hyperhidrosis
2. Alteration in thermoregulation
3. Dry eyes and mouth
4. Pupillary abnormalities
 - a. Light-near disassociation
5. Gastrointestinal dysfunction:
 - a. Chronic and nocturnal diarrhea
 - b. Gastroparesis
 - c. Postprandial bloating
6. Impotence
 - a. Retrograde ejaculation
7. Cardiac autonomic neuropathy:
 - a. Resting tachycardia
 - b. Postural hypotension
 - c. Orthostatic bradycardia and orthostatic tachycardia (POTS)
 - d. Exercise intolerance
 - e. Decreased hypoxia-induced respiratory drive
 - f. Loss of baroreceptor sensitivity
 - g. Enhanced intraoperative or perioperative cardiovascular lability
8. Increased incidence of asymptomatic ischemia, myocardial infarction and congestive heart failure

Neuropathology

1. Degeneration of sympathetic and parasympathetic neurons
2. Inflammatory infiltrates of the sympathetic and parasympathetic systems

Laboratory Evaluation

1. Sensory and motored NCS are similar to those seen with DSPN
2. Abnormal qualitative sudomotor axon reflexes
3. Decreased sympathetic skin response
4. Heart rate variability during:
 - a. Deep breathing
 - b. Standing
 - c. Valsalva maneuver
 - d. Allows a quantitative measure of cardiac sympathetic and parasympathetic parameters
5. Spectral analysis of heart rate variability (HRV); variability is measured as a function of frequency
 - a. Sympathetic system modulates to low frequency components while the parasympathetic system modulates the high frequency component

Diabetic Neuropathic Cachexia (DNC)

General Characteristics

1. Although DNC is rare it can be the presenting manifestation of diabetes

2. More common in men than women and is associated with poor glycemic control
3. The disorder can affect both type one and type two diabetes and occurs irrespective of the duration of the illness; it generally occurs in the sixth or seventh decade

Clinical Manifestations

1. An abrupt onset of severe generalized paresthesias that involves the extremities and trunk
2. Severe weight loss occurs concomitantly
3. The cause is usually monophasic but can be recurrent
4. Examination reveals profound emaciation of fat and lean mass
5. Mild sensory loss
6. A subset of patients develop distal weakness and muscle atrophy
7. Muscle stretch reflexes are decreased or lost
8. The neuropathy may spontaneously improve usually preceded by weight gain

Neuropathology

1. Sural nerve biopsy
 - a. Severe axonal degeneration with relative sparing of thinly myelinated fibers or unmyelinated C-fibers

Laboratory Evaluation

1. CSF:
 - a. Increased protein
2. EMG:
 - a. Absent or low amplitude SNAPs
 - b. Normal or slightly reduced CMAPs with slight slowing of motor NCVs

Differential Diagnosis of DNC

"Insulin Neuritis"

General Characteristics

1. Preceded by a period of rapid glycemic control
2. Occurs in both type one and type two diabetes that has been treated with insulin or oral hypoglycemic drugs

Clinical Manifestations

1. Acute severe distal limb pain that may concurrently be associated with trunk involvement
2. Autonomic deregulation

Neuropathology

1. Proposed mechanisms include:
 - a. Endoneurial ischemia
 - b. Microvascular neuronal damage
 - c. Spontaneous discharge of regenerating C-fibers
2. Carcinomatosis
3. Acute alcoholic neuropathy
4. Acute intermittent porphyria
5. CIDP

Diabetic Amyotrophy*General Characteristics*

1. The most common form of polyradiculopathy or radiculoplexus neuropathy
2. Affects type two older patients primarily but can affect type one patients
3. In approximately one third of patients, it can be the presenting feature of DM

Clinical Manifestations

1. Presents most often with severe pain in the low back, hip, and thigh in one leg (often confused with a herniated disk)
2. Most patients have DSPN
3. Rarely, it is initiated bilaterally simultaneously; usually asymmetrically
4. Atrophy of both proximal and distal leg muscles with appropriate weakness
5. Approximately 50% of patients complain of numbness and paresthesias (often in femoral nerve or L5–S1 distributions)
6. The contralateral leg is often affected six weeks to several months later
7. The polyradiculopathy can be preceded or accompanied by severe weight loss
8. The weakness may progress gradually or stepwise over weeks or several months
9. Some patients have thoracic intercostal nerve involvement with weakness and sensory loss in the appropriate distributions
10. Rarely associated cervical polyradiculoneuropathy and brachial plexopathy are concurrent

Neuropathology

1. Nerve biopsies including the sural, lateral femoral cutaneous and superficial peroneal nerve demonstrate:
 - a. Loss of myelinated nerve fibers asymmetrically between and within nerve fascicles
 - b. Axonal degeneration with clusters of small thinly myelinated regenerating fibers may be seen
 - c. Perivascular inflammation
 - d. Vasculitic changes of the epineurial and perineurial blood vessels
 - e. Possible mechanism:
 - i. Immune-mediated microangiopathy

Laboratory Evaluation

1. CSF:
 - a. Increased protein with no pleocytosis
 - b. Increased ESR (erythrocyte sediment rate)
2. EMG:
 - a. Low amplitude SNAPs and CMAPs of the affected roots and plexi
 - b. Characteristics of multifocal axonal damages

- c. Conduction velocities normal or only slightly reduced
3. Needle EMG:
 - a. Positive sharp waves, fibrillation potentials and decreased recruitment of affected muscles
 - b. After reinnervation occurs, there are large amplitude long duration polyphasic MUAPs

Radiculoplexus Neuropathy (LRPN)*General Characteristics*

1. Progressive, often painless, symmetrical weakness of the legs > arms
2. Affects both proximal and distal muscles in a pattern that resembles CIDP
3. Occurs in both type one and type two diabetes

Clinical Manifestations

1. Weakness is usually symmetrical and involves both proximal and distal muscles; the legs are more severely involved than the arms with distal > proximal weakness
2. The onset is not accompanied by back and leg pain
3. A subset of patients has weight loss
4. Distal dysesthesia and numbness occur, some patients have pain in affected root and/or plexus distributions
5. Reduced or absent muscle stretch reflexes in affected areas

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large and small myelinated fibers
 - b. Axonal degeneration with clusters of small regenerating fibers
 - c. Rarely demyelinated fibers demonstrate onion bulb formation associated with infiltration of perivascular mononuclear cells in the peri- and epineurium

Laboratory Evaluation

1. CSF:
 - a. Elevated protein without pleocytosis
2. EMG:
 - a. Reduced or absent SNAPs and CMAPs amplitudes
 - b. Slow NCVs with prolonged distal latencies
 - c. Absent or prolonged F-wave latencies
 - d. Rare conduction blocks and temporal dispersion
3. Needle EMG:
 - a. Fibrillation potentials and positive sharp waves in affected muscles and associated paraspinal musculature
4. Autonomic evaluation
 - a. Alterations in sudomotor, cardiovagal, and adrenergic physiology

Diabetic Cervical Radiculoplexus Neuropathy*General Characteristics*

1. Review of the Mayo Clinic series of 85 patients
 - a. Mean age of 62 years (range of 32 to 85 year of age)
 - b. Primarily in type two diabetes

Clinical Manifestations

1. Major presenting complaint was pain and numbness
2. Upper, middle and lower brachial plexus segments were equally involved; pain plexopathy occurred in approximately 20% of patients
3. Approximately 50% of patients had signs and symptoms in another body region including the thorax and lumbosacral plexus
4. Recurrent attacks occurred in approximately 10% of patients

Neuropathology

1. Nerve biopsy:
 - a. Ischemic injury with axonal degeneration and multifocal fiber loss
 - b. Focal perineurial thickening
 - c. Epineurial perivascular inflammation
 - d. Microvasculitis

Laboratory Evaluation

1. CSF:
 - a. Elevated protein (median 70 mg/dl)
2. EMG:
 - a. An axonal neuropathy
 - b. Paraspinal denervation
3. Alteration in autonomic function
4. MRI:
 - a. All patients demonstrate brachial plexus pathology

Diabetic Cranial and Peripheral Mononeuropathies*General Characteristics*

1. Cranial Nerve involvement:
 - a. VIIth nerve is most commonly involved
 - b. IIIrd nerve palsy:
 - i. Pupil is usually not involved
 - ii. Light-near dissociation occurs
 - iii. The ptosis may be more severe than that seen with an aneurysm compressing the IIIrd nerve
 - c. VIth nerve palsy
 - d. Rarely the IVth nerve is involved
 - e. V and VII cranial nerves may be involved concomitantly from ischemia of the lateral trunk of the external carotid artery
 - f. Diabetic pseudotabes
 - i. Severe symmetric loss of cutaneous and deep pain sensation including proprioception
 - ii. Tabetic gait, positive Romberg sign
 - iii. Absent reflexes
 - iv. Foot ulcers and arthropathy
2. Diabetic patients are vulnerable to pressure and chemotherapy. Most of the mononeuropathies that are seen occur in a background of DSPN. The most common mononeuropathies occur:
 - a. Median nerve at the carpal tunnel

- b. Lateral femoral cutaneous nerve (compressed under the femoral ligament in the groin and associated with meralgia paresthetica)
- c. Peroneal nerve at the fibular head
- d. Rarely, the sciatic nerve at the level of the piriformis muscle
- e. Plantar nerve in the tarsal tunnel

Hypoglycemic Neuropathy*General Characteristics*

1. Hypoglycemic neuropathy has been associated with early stages of treatment for DM or persistent hypoglycemia from an insulinoma
2. Hypoglycemia is common in type one diabetes mellitus
 - a. 1 of 6 patients has at least one severe episode/year
3. The incidence rate of hypoglycemia is higher in patients with:
 - a. Previous severe hypoglycemia
 - b. Existing peripheral neuropathy
 - c. Long duration of DM (>20 years)
 - d. Polypharmacy

Clinical Manifestations

1. Progressive numbness and paresthesias of the hands and feet
2. Distal muscle weakness evolves over time. Multiple episodes occur prior to anterior horn cell involvement
3. Decreased muscle stretch reflexes
4. Classic triad of an insulinoma:
 - a. Progressive encephalopathy
 - b. Intractable seizures
 - c. Peripheral neuropathy
5. Isolated VIth nerve palsy has been reported

Neuropathology

1. Wallerian-like axonal degeneration that is initiated at the nerve terminal and spreads to the proximal axon; motor axons may be more affected than sensory axons
2. Nerve biopsy:
 - a. Axonal degeneration primarily of large myelinated fibers

Laboratory Evaluation

1. EMG:
 - a. Reduced amplitude or absent SNAPs; CMAPs are slightly reduced
 - b. Conduction velocities may be mildly decreased
2. Needle EMG:
 - a. Positive sharp waves and fibrillation in potentials
 - b. In reinnervating muscles, there is decreased recruitment of large polyphasic MUAPs

Acromegaly*General Characteristics*

1. 35% of patients suffer CTS which is often apparent at presentation

- a. 35% to 45% have a sensorimotor peripheral neuropathy
2. CTS may be the presenting complaint
3. Enlarged sinuses, cardiac failure, severe arthropathy, myelopathy and radiculopathy (due to bony encroachment of the foraminal exit canals) may be concomitant medical complications
4. The pituitary gland is usually not enlarged as the morphological facial features of the endocrinopathy may lead to an early diagnosis. The optic neuropathy is usually a result of surgery and X-RT

Clinical Manifestations

1. Patients with generalized neuropathy:
 - a. Have paresthesias of the hands and feet; legs are more affected than the hands
 - b. Decreased light touch, vibration, and proprioception
 - c. Rare distal muscle wasting
 - d. Absent or reduced muscle stretch reflexes
 - e. Concomitant proximal myopathy
 - i. Type 2 fiber atrophy
 - f. Severe CTS often precedes the diagnosis
 - g. Rare compression of the optic chiasm or nerve; usual involvement is from surgery and X-RT
 - h. Tarsal tunnel syndrome

Neuropathology

1. Bone overgrowth may narrow the spinal canal with consequent spinal cord compression
2. Similarly, there may be encroachment from bone overgrowth in the exit foramina of nerve roots with consequent radiculopathy
3. Nerve biopsy:
 - a. Increase of endoneurial and subperineurial connective tissue
 - b. Loss of myelinated and unmyelinated nerve fibers
4. Acromegaly occurs in 20% of patients with the McCune-Albright syndrome (poly/monostotic fibrous dysplasia, café-au-lait spots, and hyperfunctioning endocrinopathies)

Laboratory Evaluation

1. EMG (in patients with the generalized neuropathy):
 - a. Reduced amplitudes of SNAPs with prolonged distal latencies and slow conduction velocity
 - b. CMAPs are frequently normal but may demonstrate reduced amplitudes and prolonged distal latencies
 - c. Slightly slowed motor nerve conduction velocities
2. Increased insulin-like growth factor
3. Growth hormone > 1.0 ng/dl
4. Increased somatostatin C

Hypothyroidism

General Characteristics

1. Concurrent hypothyroid myopathy (Hoffman's Syndrome)

- a. Pseudohypertrophy; proximal weakness
2. Hyperexcitability of the sarcolemmal membrane (lumping phenomenon with mechanical percussion of its muscle)
3. Associated central nervous system signs and symptoms:
 - a. Decreased mentation
 - b. Cranial nerve V involvement (pain)
 - i. Laryngeal sensory neuropathy
 - c. Sensorineural hearing loss from VIIIth nerve involvement
 - d. Cerebellar ataxia (Purkinje cell dysfunction)
4. Peripheral neuropathy manifestations:
 - a. Distal sensory loss (all modalities)
 - b. Burning and lancinating distal pain
 - c. Leg muscle cramps
 - d. Distal leg muscle weakness
 - e. Concomitant CTS with hand paresthesias
 - f. Delayed relaxation phase of the ankle muscle stretch reflex as well as other reflexes
 - g. Hoarseness (mucopolysaccharide deposition in the vocal cords)

Neuropathology

1. Sural nerve biopsy:
 - a. Myelinated fiber loss: large > small fibers
 - b. Axonal degeneration with segmental demyelination
 - c. Occasional "onion bulb" formation

Laboratory Evaluation

1. Hemoglobin of 12 grams; monocytic anemia
2. CSF
 - a. Increased protein; without pleocytosis
3. TSH levels (thyrotropin)
 - a. Euthyroidism:
 - i. Thyrotropin (TSH) levels 0.45–4.49 mIU/L with normal thyroxine levels
4. EMG:
 - a. Carpal tunnel NCS is the most common abnormality
 - b. Patients with generalized neuropathy
 - i. Reduced SNAP amplitudes with slightly prolonged distal latencies
 - ii. CMAPs may have slightly reduced amplitude
 - iii. Slowing of conduction velocities and slight prolongation of distal latencies

Hyperthyroid Neuropathy

General Characteristics

1. CNS neurologic dysfunction predominates:
 - a. Cognitive dysfunction
 - b. Apathetic hyperthyroidism (associated with slow atrial fibrillation)
 - c. Davidoff syndrome:
 - i. Nystagmus
 - ii. Hyperactive muscle stretch reflexes
 - iii. Babinski signs

2. Proximal myopathy
 - a. Iliopsoas often severely involved; wasting of the rhomboid muscles
3. Thyroid storm
 - a. Fever to 105° Fahrenheit, atrial fibrillation; wide pulse pressure; hypotension; most are associated with increased T4; rarely increased T3 with a normal T4

Clinical Manifestations

1. Neuropathy:
 - a. Sensory loss is mild
 - b. Proprioceptive large myelinated > small fiber phenotype
2. Basedow's paraplegia:
 - a. Proximal and distal leg weakness
 - b. Hypotonia
 - c. Areflexia in the legs
3. Thyroid ophthalmopathy
4. Associated with (other diseases):
 - a. Myasthenia gravis
 - b. Hypokalemic periodic paralysis

Neuropathology

1. Nerve biopsy
 - a. Not well defined
2. Muscle biopsy
 - a. Denervation of distal muscles

Laboratory Evaluation

1. EMG
 - a. NCS slightly slow motor and sensory conduction velocities

Nutritional Deficiencies and Neuropathy

Overview

Dietary nutritional deficiency in the developed world is most often secondary to alcoholism, patients with chronic illness, those with restricted or unusual diets, malabsorption syndromes, gastrectomy and obesity surgery, sprue and intestinal surgery. Medications may interfere with vitamin metabolism that occurs with B6 deficiency (isoniazid). In cases of malnutrition and those patients with malabsorption, multiple vitamin deficiencies occur.

Thiamine Deficiency (Vitamin B1)

General Characteristics

1. Occurs in the setting of starvation, alcoholism, prolonged vomiting, post-gastric stapling, dialysis and a diet of carbohydrates without vitamin supplementation
2. Vitamin B1 is absorbed in the small intestine by passive diffusion and active transport; it is phosphorylated in the jejunum to thiamine pyrophosphate
3. Vitamin B1 is involved in the decarboxylation of alpha-keto acids that are metabolized to alpha ketols
4. It may develop with total parenteral nutrition

Clinical Manifestations

1. Presents in two forms:
 - a. Wet beriberi:
 - i. The neuropathy is associated with congestive heart failure and significant peripheral edema most severe in the lower extremities
 - b. Dry beriberi patients have no congestive heart failure
2. Presents as a symmetrical sensorimotor neuropathy
3. Evolves over weeks to months; it may rarely develop over several days
4. A subgroup of patients develops a small fiber phenotype
5. Patients frequently complain of paresthesia of the extremities; all sensory modalities are affected
6. Associated Wernicke-Korsakoff syndrome
7. Distal weakness with loss of ankle motor stretch reflexes
8. Rare involvements:
 - a. Vagus and recurrent laryngeal nerves
 - b. Tongue and facial weakness
9. Central and centrocecal scotoma may develop

Neuropathology

1. Sural nerve biopsy:
 - a. Primarily loss of large myelinated fibers
 - b. Autopsy evaluation:
 - i. Chromatolysis of anterior horn cells
 - ii. Loss of DRG cells
 - iii. Axonal degeneration with secondary demyelination of the posterior columns
 - c. Thiamine deficiency:
 - i. Decreases thiamine-dependent enzymatic activity
 - ii. Alters mitochondrial function
 - iii. Impairs oxidative metabolism
 - iv. Selective neuronal death
 - v. No defined mutations in three thiamine carrier genes:
 1. SLC19A2
 2. SLC19A3
 3. SLC25A19
 - vi. Two patients have demonstrated an increase of vascular endothelial growth factor in the serum

Laboratory Evaluation

1. Erythrocyte transketolase activity and the percentage increase of activity after the addition of thiamine pyrophosphate is an accurate assay
2. EMG:
 - a. Absent or reduced SNAP amplitudes
 - i. Minimally affected distal sensory latencies and conduction velocities
 - b. Motor NCS is normal or demonstrates slightly reduced CMAP amplitudes

Vitamin B6

General Characteristics

1. Associated with:

- a. Polynutritional deficiencies
- b. Isoniazid
- c. Hydralazine
- d. Duodenal infusion of levodopa in severe Parkinson's disease:
 - i. Low B12 levels
 - ii. High homocysteine and methylmalonic acid are associated
 - iii. The levodopa infusion has been reported to cause an acute GBS syndrome
- 2. Toxic doses of B6 are >200 mg/day
- 3. Inhibits the conversion of pyridoxal phosphate

Clinical Manifestations

- 1. May be seen in patients on peritoneal dialysis
- 2. Malnutrition of chronic alcoholism
- 3. Peripheral neuropathy:
 - a. Distal burning paresthesias in the feet and hands
 - b. Severe deficiency has been associated with sensory ataxia
 - c. Sensory > motor polyneuropathy

Neuropathology

- 1. Axonal degeneration

Laboratory Evaluation

- 1. EMG:
 - a. Features of an axonal sensorimotor neuropathy
- 2. B6 levels can be determined by direct assay

Cobalamin (Vitamin B12) Deficiency

General Characteristics

- 1. B12 deficiency is common in patients over the age of 65 years
 - a. Possible prevalence of 10 to 20% but only 5–10% are symptomatic
- 2. The main causes of cobalamin deficiency are pernicious anemia and food-cobalamin malabsorption
- 3. Characteristics of food-cobalamin malabsorption:
 - a. A disorder in which there is an inability to release cobalamin from food or its binding proteins
 - b. The syndrome is most often caused by atrophic gastritis that is related or unrelated to *Helicobacter pylori* infection, long-term ingestion of antacids and biguanides
- 4. Mutations in genes that encode endocytic receptors that are involved in ileal absorption and uptake of cobalamin are responsible for some patients with hereditary megaloblastic anemias
- 5. Cobalamin is in meat, fish, and dairy products but not in fruits, vegetables and grains:
 - a. It requires the transport molecule – intrinsic factor which is synthesized and secreted by gastric parietal cells for its absorption
 - b. Intrinsic factor deficiency may be caused by:
 - i. Autoimmune destruction of gastric parietal cells
 - ii. Gastrectomy

- 6. Other causes of vitamin B12 deficiency include:
 - a. Vegan diet (lack of intake)
 - b. Inflammatory bowel disease (malabsorption)
 - c. Blind loop syndrome (*diphyllobothrium latum* overgrowth)
 - d. Nitrous oxide anesthesia (acute)
 - e. In association with another autoimmune disease (parietal cell antibodies)
 - f. Severe steatorrhea (malabsorption)
 - g. Infestation of the fish tapeworm
 - h. May accompany folic acid deficiency; if the folate deficiency is treated without B12 replacement, hematologic abnormalities may clear, but neurologic deficits may be exacerbated

Clinical Manifestations

- 1. Both CNS and PNS neurological deficits occur with B12 deficiency which may or may not be associated with megaloblastic anemia and pancytopenia
- 2. Peripheral neuropathy:
 - a. It is an active large fiber neuropathy that may be initiated with paresthesias and burning in the hands and feet
 - b. Sensory ataxia may occur due to the loss of proprioceptive sense in the nerve and dorsal column degeneration
 - c. Romberg sign may be present
 - d. Due to associated spinal cord involvement, the hands may be more affected than the feet
 - e. Spasticity with distal muscle weakness
 - f. Muscle stretch reflexes may be lost at the ankle (from the neuropathy) and increased throughout due to the myelopathy
 - g. Babinski sign is present
 - h. CNS signs and symptoms include:
 - i. Cranial I and II involvement
 - ii. Characteristic myelopathy:
 - 1. Spasticity
 - 2. Posterior column dysfunction
 - 3. Bilateral Babinski sign
 - iii. Frontal lobe dysfunction
 - 1. Euphoria
 - 2. Psychiatric manifestations
 - iv. Cerebellar ataxia

Neuropathology

- 1. Nerve biopsy:
 - a. Loss of large diameter myelinated fibers
 - b. Axonal degeneration
 - c. Secondary segmental demyelination
- 2. Cobalamin is necessary for the demethylation of methyl-tetrahydrofolate; the tetrahydrofolate produced is required for the synthesis of folate coenzymes pivotal for DNA synthesis. Other possible mechanisms include:

- a. Decreased methylation of myelin phospholipids
- b. Accumulation of methylmalonic and propionic acids that may be substrate for fatty acid synthesis that causes aberrant myelination
- 3. White matter demyelination in many brain areas including projections to the frontal lobe
- 4. Autopsy material
 - a. Degeneration of cortical spinal tracts and the dorsal columns

Laboratory Evaluation

- 1. Vitamin B12 may be directly assayed but is not sensitive
- 2. Large hypersegmented neutrophils; low platelets and a macrocytic anemia that may be severe (<2 grams/dl) may develop gradually
- 3. Increased urinary methylmalonic acid concurrently with increased homocysteine
- 4. Detection of intrinsic factor and parietal cell antibodies
- 5. Schilling test is utilized to detect pernicious anemia
- 6. Elevated gastrin and antiparietal cell antibody are specific and sensitive for pernicious anemia
- 7. EMG:
 - a. SNAP amplitudes are reduced or absent
 - b. CMAPs amplitudes may be normal or only slightly reduced
 - c. Minimal abnormalities of motor and sensory distal latencies and conduction velocities
- 8. Somatosensory-evoked potentials and transcranial magnetic stimuli often reveal slowed central conduction times

Clinical Points

- 1. Nitrous oxide anesthesia:
 - a. Inactivates methylcobalamin
 - b. Causes both neuropathy and subacute combined degeneration of the spinal cord
 - c. Generally appears more quickly than the progression of the natural disease
 - d. Primarily affects patients with low or borderline B12 levels
 - e. Similar in all spheres to B12 deficiency
- 2. High vitamin B12 levels (350–1,200 pmol/L) are associated with hematological and hepatic disorders as well as malignancy
- 3. Intestinal (duodenal infusion of levodopa) has been associated with B12 deficiency

Folate Deficiency

General Characteristics

- 1. Folate is in fruit, vegetables, and liver
- 2. Folate is absorbed in the proximal jejunum
- 3. Isolated deficiencies occurs:
 - a. Rarely
 - b. In the elderly that are malnourished
 - c. Alcoholic malnutrition

- d. Partial gastrectomies
- e. Duodenojejunal resections
- f. Celiac disease
- 4. Cerebral folate deficiency:
 - a. Definition:
 - i. A neuropsychiatric condition associated with low CSF N5-methyl tetrahydrofolate (MTHF) with normal folate levels outside of the CNS
 - b. Caused by serum autoantibodies of the blocking type that are directed against folate receptor-alpha (FR-alpha) that are attached to the plasma side of choroid plexus epithelial cells:
 - i. The blocking FR antibodies inhibit MTHF transport across the choroid plexus
 - ii. Progressive dystonia or schizophrenic syndromes develop during adolescence

Clinical Manifestations

- 1. Characteristics of the peripheral neuropathy:
 - a. Slowly progressive polyneuropathy predominant lower extremity involvement
 - b. Sensory > motor with large fiber rather than small fiber phenotype
- 2. Other neurologic deficits are similar to those seen with B12 deficiency:
 - a. Subacute combined degeneration of the spinal cord
 - b. Psychiatric disease

Neuropathology

- 1. Other drugs that can interfere with folate metabolism are:
 - a. Phenytoin
 - b. Phenobarbital
 - c. Sulfasalazine
 - d. Colchicine
- 2. Sural nerve biopsy
 - a. Large fiber-predominant axonal degeneration without segmental demyelination
- 3. Low serum folate levels
- 4. Megaloblastic anemia
 - a. Rare for hemoglobin levels to drop below 10 g/dl
- 5. EMG:
 - a. Consistent with an axonal neuropathy
 - b. Sensory and motor NCS may be similar to B12 deficiency

Vitamin E Deficiency Neuropathy

General Characteristics

- 1. Vitamin E is found in vegetable oils and wheat germ
- 2. Vitamin E is most often in the alpha-tocopherol form
- 3. It is a lipid-soluble antioxidant that is present in the lipid bilayer of the cell membrane
- 4. There are three major mechanisms that cause vitamin E deficiency:
 - a. Fat malabsorption:

- i. Cystic fibrosis
- ii. Short bowel syndrome
- iii. Chronic cholestasis and hepatobiliary disorders
- iv. Intestinal lymphangiectasia
- b. Alteration of fat transport:
 - i. Abetalipoproteinemia (Bassen-Kornzweig disease)
 - ii. Hypobetalipoproteinemia
 - iii. Normotriglyceridemic abetalipoproteinemia
 - iv. Chylomicron retention disease
- c. Genetic forms of the disease:
 - i. Alpha-tocopherol transfer protein gene mutations on chromosome 8q13
 - ii. The majority of patients are homozygous for the 744 del A mutation

Clinical Manifestations

1. May occur several years after the onset of the deficiency
2. A common presentation is difficulty walking and poor coordination of fine movements in the hands
3. Severe loss of proprioception and vibration sensibilities
4. Limb ataxia
5. Truncal ataxia with head titubation
6. Resembles a spinocerebellar ataxia with a polyneuropathy
7. Ophthalmoparesis and dysarthria
8. A subset of patients has dystonia and bradykinesia
9. Generalized diminution or absence of muscle stretch reflexes
10. Proximal muscle weakness
11. Pigmentary retinopathy with visual loss
12. Rare patients may have an isolated polyneuropathy while in a Tunisian cohort 50% of patients had no neuropathy (a hereditary form)

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large diameter myelinated fibers
 - b. Axonal degeneration with regenerating clusters
 - c. Rare vacuoles of the myelin sheath and disruption of Schmidt-Lanterman incisures
2. Autopsy material:
 - a. Swelling and degeneration of axons in the dorsal columns and spinocerebellar pathways
 - b. Neuronal loss in posterior column nuclei
3. After absorption from the small intestine, alpha-tocopherol is incorporated into chylomicrons and is transported to the liver where it is incorporated into low-density lipoproteins
4. In the hereditary form, autosomal recessive, there are mutations in the TTPA gene that encodes the alpha-TTP protein. Its putative function is intracellular alpha-tocopherol transport
5. Vitamin E is an important free radical scavenger and appears to be important in cell membrane physiology

Laboratory Evaluation

1. Vitamin E levels can be measured in the serum; hyperlipidemia may cause erroneous readings
2. EMG:
 - a. Absent SNAPs and reduced amplitudes in those that are obtainable
 - b. Sensory nerve conduction velocities may be normal or are only slightly slow
 - c. Motor NCS are normal
3. Somatosensory evoked potentials
 - a. Slowing of central conduction

Copper Deficiency

General Characteristics

1. Copper is an essential trace element involved in multiple enzymatic processes throughout the body
2. Almost 90% of patients have combined hematologic and neurologic signs and symptoms at presentation; approximately 20% may present with only hematologic dysfunction
3. A significant number of patients have high serum zinc concentrations ($>18 \mu\text{m/L}$) from zinc-containing dental fixatives
4. Deficiency may occur from the duodenal switch operative procedure and Roux-en-Y gastric bypass procedures

Clinical Manifestations

1. Weakness, spasticity, gait difficulties from a myelopathy
2. Bilateral Babinski signs
3. Large fiber proprioceptive and vibratory sensibility loss
 - a. Some patients also lose components of light touch, pinprick and temperature sensibility concurrently
4. Reflexes are increased (due to the myelopathy)

Neuropathology

1. Sural nerve biopsy
 - a. Axonal degeneration
2. Other causes of copper deficiency include:
 - a. Malnutrition
 - b. Prematurity
 - c. Total parenteral feeding
 - d. Copper chelating agents
3. Zinc (a component of dental fixtures) upregulates enterocyte metallothionein which decreases copper absorption from the stomach and proximal jejunum

Laboratory Evaluation

1. Anemia, thrombocytopenia, and neutropenia; microcytic anemia
2. Low serum copper levels; high zinc levels in those with zinc dental fixatives
3. Bone marrow biopsy:
 - a. Multilineage dysplasia
 - b. Excess blasts

- c. A subset of patients with myelodysplasia
- 4. CSF:
 - a. Normal or minimally elevated protein
 - b. Some patients demonstrate an increased immunoglobulin synthesis rate
- 5. EMG:
 - a. Consistent with a sensorimotor axonal polyneuropathy
- 6. Somatosensory evoked potentials
 - a. Decreased conduction in central pathways
- 7. MRI:
 - a. Multifocal T2 hyperintense signal foci in subcortical white matter
 - b. Atrophy of the cerebrum and cerebellum
 - c. Signal change in the posterior columns of the cervical and thoracic cord

Bariatric Surgery

General Characteristics

1. In the USA approximately 150,000 bariatric procedures are performed annually
2. Approximately 5% of patients suffer neurologic complications from the procedure which are seen at all levels of the neuroaxis
3. The most common deficiencies from the surgery include:
 - a. Thiamine
 - b. B12
 - c. Copper
 - d. Folate
 - e. Zinc
 - f. Vitamins A and E

Clinical Manifestations

1. Characteristics of the peripheral neuropathy:
 - a. Usually, occurs in a setting of significant weight loss or recurrent prolonged vomiting
 - b. The sensory loss may be acute or subacute
 - c. Burning feet associated with distal weakness
 - d. GBS-like syndrome
 - e. Mononeuropathy
 - f. Radiculoplexus neuropathy
 - g. The neuropathy usually occurs within the first 1½ years following surgery
 - i. The latency has been documented for months or years in some patients operated on for total or partial gastrectomy due to ulcer or cancer
 - h. Wernicke-Korsakoff syndrome may occur concomitantly

Neuropathology

1. Sural nerve biopsy:
 - a. Active axonal degeneration
 - b. Some perivascular, endoneurial and epineurial inflammatory cell infiltrate

Laboratory Evaluation

1. EMG:
 - a. Most often consistent with an axonal neuropathy
 - b. Patients with GBS demonstrate a demyelination pattern
2. Deficits and laboratory values reflect the specific vitamins that have been malabsorbed

Hypophosphatemia

General Characteristics

1. Intravenous glucose administration is the most common cause of hypophosphatemia in hospitalized patients. It usually is asymptomatic
2. Major other causes of hypophosphatemia include:
 - a. Severe diabetic ketoacidosis
 - b. Parenteral alimentation
 - c. Burn patients
 - d. Antacids
 - e. Diuretics
 - f. Steroids
 - g. Biphosphonates
3. Severe hypophosphatemia is a serum phosphorus less than or equal to 0.48 mmol/L or ≤ 1.5 mg/dl
4. Often neurological recovery obtains with rapid restoration of phosphorous concentrations

Clinical Manifestations

1. Characteristics of the neuropathy:
 - a. Hypophosphatemia may be associated with a subacute severe sensorimotor peripheral neuropathy
 - b. Patients first note paresthesias in the feet which ascend to affect the entire body
 - c. Patients suffer generalized weakness
 - d. Decreased sensation to all modalities
 - e. Ataxia
 - f. Loss or depression of muscle stretch reflexes
 - g. The weakness may be severe enough to cause respiratory embarrassment that requires mechanical ventilation

Neuropathology

1. Sural nerve biopsy (one patient):
 - a. Mild axonal degeneration
 - b. Moderate subperineurial edema
 - c. Phosphatonins are being investigated as a mechanism that regulates phosphorus metabolism along with parathormone and vitamin D. Fibroblast growth factor 23 (FGF-23) may be pivotal

Laboratory Evaluation

1. A phosphorus level of < 1.5 mg/dl
2. EMG:
 - a. Absent SNAPs; reduced CMAP amplitudes with slightly slow conduction velocities
 - b. Some patients have absent F-waves

Alcoholic Neuropathy

General Characteristics

1. Alcoholic neuropathy occurs in 10 to 30% of hospitalized patients and is seen in >80% of patients with Wernicke-Korsakoff syndrome
2. Men and women are equally susceptible
3. It usually requires 100 grams daily for a prolonged period of time
4. The neuropathy may occur in a setting of severe weight loss over the preceding several months

Clinical Manifestations

1. The usual presentation is a slowly progressive, generalized sensorimotor peripheral neuropathy
2. Rarely, a more acute GBS-like presentation has been described
3. Loss of all sensory modalities; the insidious onset of numbness, paresthesias and burning pain in the feet
4. There are mild distal leg weakness and atrophy; strength in proximal muscles and the upper extremities is usually maintained
5. Alcoholic myopathy may occur with proximal muscle weakness
6. Distal loss of motor stretch reflexes in the ankles that progresses proximally
7. Autonomic dysfunction is often subtle
8. Central nervous system manifestations:
 - a. Dementia
 - b. High incidence of chronic subdural hematoma and chronic traumatic brain encephalopathy
 - c. "Marionette" gait occurs from anterior vermal atrophy (trunk is held in extension; stiff legged)
 - d. Central pontine myelinolysis

Neuropathology

1. Sural nerve biopsy:
 - a. Loss of large diameter and thinly myelinated fibers
 - b. Wallerian degeneration and secondary segmental demyelination
2. Skin biopsy:
 - a. Decreased end nerve fiber densities (ENFD)
3. Ethanol may be directly neurotoxic via its metabolite acetaldehyde and may induce oxidative stress in peripheral nerves
4. May activate protein kinase C epsilon in primary afferent nociceptors which lowers their firing threshold
5. May cause cytoskeletal dysfunction and inhibits antegrade and retrograde axonal transport
6. Is also frequently seen in association with deficiencies of B vitamins and folate

Laboratory Evaluation

1. EMG:
 - a. Characteristics of a generalized axonal sensory or sensorimotor polyneuropathy

2. QST

- a. Phenotype of a small fiber neuropathy with altered pain and temperature thresholds
- b. Decreased RBC transketolase activity

Tumors of Peripheral Nerves

Overview

Peripheral nerve tumors are rare types of soft tissue tumors. In a large series of 397 peripheral neural sheath tumors, 91% were benign. A large subgroup of patients with benign lesions was in the brachial plexus: 54 schwannomas (38%) and 87 neurofibromas (62%). In the breakdown of the neurofibromas, 63% were solitary, and 37% were type I (NF-1 associated neurofibromas); a supraclavicular location was predominant. A much smaller subgroup of patients had benign peripheral nerve sheath tumor in the pelvic plexus, 62% of which were neurofibromas and 38% were schwannomas. Twenty-eight of the 397 peripheral neural sheath tumors were malignant. Approximately 7% comprised neurogenic sarcomas in 28. In 36 others, tumors included fibro, spindle cell, synovial and perineurial types.

In general, the majority of tumors were benign peripheral nerve sheath tumors originating in the brachial plexus area. Neurofibromas in all locations comprised the majority of peripheral nerve sheath tumors (PNST); the predominant form being a solitary tumor. Neurofibromas are primarily in the upper extremity whereas schwannomas were distributed equally between upper and lower extremities.

The most common symptoms include:

1. Tumor mass (100%)
2. Tinel's sign (sensitivity to a mechanical stimulus) in 95% of patients
3. Paresthesias (over 90%)
4. Sensory deficit (approximately 90%)
5. Motor deficit in approximately 40% of patients

Tumors occurred almost equally in major peripheral nerves and small nerve branches. The mass may be displaced at right angles to the course of the nerve. The tumor's mechanosensitivity is demonstrated by paresthesias when it is mechanically compressed. It is not possible to distinguish clinically between a neurofibroma, schwannoma, or malignant tumor.

Schwannoma (Neurilemmoma)

General Characteristics

1. Schwannomas are benign tumors derived from nerve sheath Schwann cells
2. They occur between the third to fifth decades
3. There is no racial or gender difference
4. They usually develop as a solitary mass of 1.5 to 3 cm diameter at presentation. They are rarely large and multiple
5. Schwannomas are located in the upper extremity in 12 to 19% of patients and the lower extremity in 13.5 to 17.5% of patients

6. They are well encapsulated and have a non-infiltrating growth pattern

Clinical Manifestations

1. Positive Tinel's sign (paresthesias elicited by mechanical stimulation of the tumor in the distribution of the affected nerve) is often elicited
2. Rarely, presents as a neurologic deficit of the affected nerve
3. Most common nerves affected are:
 - a. Supra- greater than infraclavicular components of the brachial plexus
 - b. Axillary and musculocutaneous nerves may rarely be affected
 - c. The tibial nerve is more often affected than the sciatic nerve in the thigh
 - d. Median > ulnar > radial nerve are affected; the proximal portions of the nerve are more often affected than the distal

Neuropathology

1. A well encapsulated growth that displaces adjacent nerve fascicles laterally
2. Antoni Type A (hypercellular compact or palisading regions) is the predominant pathology
3. A plexiform Schwannoma is a rare variant that accounts for 5% of all Schwannomas; it can be associated with neurofibromatosis type 2 or Schwannomatosis
4. Sox-10 is a marker for Schwannian and melanocytic neoplasms

Neuroimaging

1. Well circumscribed mass by MRI neurography
2. Intermediate signal intensity on T2-weighted sequences
3. Ultrasonography can adequately delineate the tumor
4. Differentiation of malignant soft tissue tumors from a peripheral Schwannoma
 - a. In Schwannomas:
 - i. Split fat sign
 - ii. Bright rim sign
 - iii. Lobular shape and peritumoral edema are more common with malignant soft tissue tumors

Variant Schwannomas

Cellular Schwannoma

General Characteristics

1. Comprise approximately 10% of schwannomas
2. Primarily located in paravertebral paraspinal locations in association with autonomic or spinal nerves
3. Slightly more prevalent in females 1.4 to 1.6:1
 - a. Usually occur in the fifth decade

Clinical Manifestations

1. Mass in a paravertebral location
2. Pain in affected root distribution
3. Rare intracranial locations compress associated structures

Neuropathology

1. Variable hemorrhage
2. High cellularity Antoni type A pattern
3. Antoni type B zones are seen in 2/3 of tumors
4. Dense pericellular reticulin staining and strong S100 protein immunoreactivity

Neuroimaging

1. MRI:
 - a. Inhomogeneous T2-weighted signal in areas of cystic change
 - b. T1-weighted sequences demonstrate well encapsulated lobular mass

Melanotic Schwannoma

General Characteristics

1. The melanotic schwannoma is the least common variant
2. The age at presentation is a mean of 35 years with a female to male ratio of 1.2:1
3. Approximately 50% are associated with the Carney complex: myxomas, spotty pigmentation and nodular adrenocortical disease (Cushing's syndrome), pituitary adenoma (acromegaly) and large cell calcifying sertoli tumors
4. Tumors may involve the GI tract, retroperitoneum, liver, bone, chest wall and soft tissue of the chest and trunk

Clinical Manifestations

1. May involve spinal nerve root with accompanying weakness, sensory loss or pain
2. Rare involvement of the Vth nerve

Neuropathology

1. Tumor cells may be extremely melanotic
2. Cytoarchitecture includes:
 - a. Spindled and dendritic forms
 - b. Fusiform cells
 - c. Epithelioid cells

Neuroimaging

1. MRI:
 - a. 20% of patients have multiple tumors
 - b. Low signal T1-weighted sequence calcified bodies that resemble psammoma bodies
 - c. Circumscribed, lobulated tumors
 - d. High intensity signal in areas of cystic degeneration on T2-weighted sequences

Neurofibromas

General Characteristics

1. Solitary neurofibromas are the most common tumor of peripheral nerves
2. Tumors develop from the second to fourth decade; cutaneous forms may occur in childhood and adolescence
3. Cutaneous nerves, deep nerves, and visceral autonomic fibers are the most often affected; spinal nerve roots are

frequently affected; intracranial sites are rare (as opposed to schwannomas)

4. Neurofibromas may undergo malignant transformation which occurs in 5 to 10% of the plexiform variant; patients with neurofibromatosis type 1 (NF1) have a 10% lifetime risk of developing a malignant nerve sheath tumor

Neurofibroma Not Associated with Von Recklinghausen's Disease

General Characteristics

1. Females are affected more than males
2. Occur as localized mass; may involve a long segment of the nerve
3. Most often there is no cleavage plane; total removal may require nerve section

Clinical Manifestations

1. Arise from the motor more often than the sensory portion of the nerve
2. The nerve can be displaced side to side but not longitudinally
3. More painful than Schwannomas
4. Fusiform > plexiform
5. Tinel's sign is nearly universal
6. R > L side of the body
7. Location:
 - a. Supraclavicular > infraclavicular brachial plexus compartments 4:1
 - b. Axillary nerve > the radial nerve
 - c. Pelvic plexus > sciatic nerve in the thigh
 - d. Sciatic nerve in the buttock, peroneal and tibial nerve have equal incidences
 - e. Painful particularly if partially resected

Neuropathology

1. A classification divides neurofibromas into intraneural and diffusively infiltrative variants
2. Intraneural lesions are solitary, fusiform or less commonly multinodular with involvement of many branches
 - a. A plexiform growth pattern is pathognomonic of neurofibromatosis type I
3. Histopathologic features:
 - a. Spindle shaped, wavy Schwann cells that are arranged in loose bundles
 - b. Matrix of collagen and mucopolysaccharide
 - c. There are scattered perineurial cells and fibroblasts
 - d. Myelinated and non-myelinated nerve fibers are within the tumor
 - e. Arise from the perineurial fibroblast

Neuroimaging

1. Irregular T2-weighted and gadolinium enhanced signals
2. The tumors are usually not encapsulated and grow into adjacent tissue; rarely a tumor is confined beneath the epineurium

3. Solitary tumors diffusely expand into endoneurial spaces across perineurial lines; they appear as globoid masses with a fusiform enlargement of the affected nerve and diffusely spread individual nerve fibers
4. Plexiform neurofibromas:
 - a. Involve multiple nerve fascicles with thickening of nerve branches

Neurofibromas Associated with Von Recklinghausen's Disease

General Characteristics

1. Autosomal dominant with full penetrance; chromosome 17 mutation; 50% are new mutations
2. Incidence of 1/3000 persons; often patients have few symptoms
3. Tumors are found in nerve endings in the skin as well as proximal nerves
4. An approximate 10% chance of malignant degeneration

Clinical Manifestations

1. Patients present at an earlier age than those with isolated neurofibromas
2. Both motor and sensory symptoms
3. There is anesthesia in the center of a small neurofibroma whose origin is from a small intraepidermal nerve
4. Painful Tinel's sign is usually present in affected nerves location:
 - a. Supraclavicular > infraclavicular in the brachial plexus at 3:1
 - b. Axillary nerve > musculocutaneous nerve
 - c. Ulnar > median > radial nerve involvement
 - d. Tibial > peroneal > saphenous nerve involvement
 - e. Radicular signs and symptoms

Neuropathology

1. Similar to that of an isolated neurofibroma
2. Plexiform neurofibroma is diagnostic of NF-1

Neuroimaging

1. Tumors of the CNS:
 - a. Optic nerve glioma
 - b. Gliomas and astrocytomas
 - i. Midline location
 - c. Non-tumoral white matter lesions:
 - i. Unidentified bright objects (UBO)
 - ii. Typical location is the basal ganglia and posterior fossa structures
 - iii. The lesions are most prevalent in childhood and fade with age; a rare malignant transformation has been documented
 - d. Plexiform variants most frequently involve the lumbosacral plexus
 - e. Hydrocephalus

- f. Neurofibromas are homogeneous oval or nodular tumors that may extend into the spinal canal (intradural extramedullary spinal compartment)
- g. Dural sac abnormalities may be associated with meningocele formation
- h. Neurofibrosarcoma:
 - i. May develop de novo
 - ii. Sarcomatous degeneration of a pre-existing plexiform neurofibroma occurs
 - iii. A large heterogeneous tumor that invades adjacent structures
- i. Osseous lesions with NF-1 include:
 - i. Thoracic scoliosis
 - ii. Vertebral anomalies (posterior scalloping)
 - iii. Long bone anomalies with bowing of the tibia; may cause pseudoarthrosis
 - iv. Rib anomalies (ribbon ribs)
- j. Vasculopathy that may be associated with aneurysm formation and hypertension

Intraneural Perineuroma

General Characteristics

1. There are two major forms of perineuroma:
 - a. Intraneural
 - b. Extranural
2. It is a benign neoplasm composed exclusively of well-differentiated whorls of perineural cells surrounding nerve fibers well circumscribed within the confines of a peripheral nerve
3. Extranural perineuroma is also composed of perineural cells which are found in soft tissue and skin
4. Perineural cells surround nerve fascicles and constitute a component of the blood-nerve barrier
5. They create tight junctions in association with endothelial cells
6. One patient had a clonal expansion associated with chromosome 22 abnormalities

Clinical Manifestations

1. Median age of onset of neurological symptoms was 14 years (6 months to age 55)
2. Chief complaint on presentation is weakness and atrophy; a few patients (<10%) have numbness and pain as the presenting symptom
3. Motor weakness in the distribution of the affected nerves has been detected in almost all patients
4. Approximately 2/3 of patients have sensory loss in the distribution of the affected nerve
5. Muscle stretch reflexes are diminished or absent in the affected nerve
6. The most common nerves affected are the sciatic nerve or its branches
7. Other affected nerves and plexuses include:
 - a. Brachial plexus

- b. Radial nerve
- c. Ulnar nerve
- d. Median nerve
- e. Femoral nerve
- f. Trigeminal nerves
- g. Lumbosacral plexus
- 8. Most common pattern of involvement is a mononeuropathy; approximately 15% have plexopathy; rare to have bilateral disease

Neuropathology

1. Perineural cells are immunoreactive for EMA (epithelial membrane antigen), CD34, Glut1 and claudin-1 which are diagnostic markers
2. Nerve biopsy:
 - a. The tumor cells form a whirling arrangement into a fasciculated or laminated pattern
 - b. The cytoarchitecture of the tumor cell is a fusiform shape with bipolar cellular processes and a spindled nucleus
 - c. Layers of spindle shaped cells surround a central nerve fiber

Laboratory Evaluation

1. The majority of patients have a normal CSF protein. There is no pleocytosis and a few patients demonstrate slight increase of protein
2. EMG:
 - a. Axonal degeneration is the characteristic finding
 - b. Needle EMG:
 - i. Fibrillation potentials and large motor unit potentials
 - c. In a majority of patients, there is reduction or absence of SNAPs
3. QST:
 - a. Increased thresholds to all modalities in affected nerves

Neuroimaging

1. MRI:
 - a. Fusiform nerve enlargement
 - b. Isointense on T1-weighted sequences; avid enhancement with gadolinium

Differential Diagnosis of Rare Benign Neural Sheath Tumors

1. Hybrid peripheral nerve sheath tumors:
 - a. Demonstrate hybrid features of more than one cell type:
 - i. Schwannoma/perineuroma
 - ii. Neurofibroma/perineuroma
 - iii. Granular cell tumor/perineuroma
2. Neurothekeoma:
 - a. Occurs in patients less than 30 years of age
 - b. Commonly misdiagnosed as Schwannoma

- c. Soft mobile tumor of the dermis
 - d. Schwann cell or perineural origin
 - e. Tumor cells in fascicles circumscribed by a myxoid stroma
3. Nerve sheath myxoma:
- a. Myxoma may have a superficial resemblance to a neurofibroma
 - b. Occurs on the face and upper extremities of young women
 - c. A loose aggregation of spindle, stellate and ovoid cells in a myxomatous matrix

Differential Diagnosis of Benign Non-Neural Sheath Tumors

- vii. Normal fatty tissue; genetic HMGA2 rearrangement is characteristic of soft tissue lipoma
6. Lipohamartoma:
- a. Intrinsic to nerve
 - b. Involves the median nerve at the wrist or in the palm and causes its dysfunction
 - c. Composed of normal fatty tissue that may envelope the nerve
7. Hemangiopericytoma:
- a. Most often arises in the cerebellum often in the setting of Von Hippel-Lindau syndrome
 - b. Rarely arises at peripheral sites
 - c. May arise from spinal nerves and within a nerve
 - d. Usually arises in the mediastinum and may compress the brachial plexus
 - e. All tumors have a complex network with large thin-walled vessels
 - f. Tumors express neurospecific endolase, S100 protein GLUT-1
8. Hemangioma:
- a. They are benign neoplasms that closely resemble normal tissue
 - b. May be found in all organs of the body
 - c. High or low flow characteristics by MR angiography
 - d. May be intrinsic to peripheral nerves
9. Ganglions:
- a. In most instances they arise from joints and may compress contiguous nerves
 - b. They often present as pain and paresthesias of the affected nerve
 - c. Compress adjacent nerves at the following levels:
 - i. Thenar sensory branch of the median nerve
 - ii. Ulnar palmar branch
 - iii. Median and ulnar major trunks
 - iv. Radicular junction (posterior interosseous nerve)
 - v. Knee (peroneal nerve)
 - vi. Ankle (posterior tibial nerve)
 - vii. Shoulder (brachial plexus); suprascapular nerve at the scapular notch
 - viii. Elbow > radial > median > ulnar nerves
 - ix. Ganglions without joint connections
 - 1. Intraneural ganglions:
 - a. Extend great distances with the nerves
 - b. Cause motor and sensory nerve deficits
10. Epidermoids cysts:
- a. Congenital epidermoid cysts are common in aberrant spinal cord closure (dysraphisms)
 - b. Often they are associated with filum terminal defects and lipomas; they may occur in many areas of the neuraxis and intracranially
 - c. Acquired epidermoid cysts may occur following lumbar puncture
 - d. In peripheral nerve compression the sciatic nerve is affected at the sciatic notch and in the posterior popliteal fossa

Malignant Peripheral Nerve Sheath Tumors (MPNST)

Overview

Malignant peripheral nerve sheath tumors are spindle cell sarcomas that arise from a nerve or a pre-existing benign nerve sheath tumor. They may be a sarcoma that demonstrates nerve sheath differentiation. Most MPNSTs are malignant degenerations of neurofibromas. Malignant transformation of a schwannoma is extremely rare. Malignant degeneration of neurofibroma in patients with NF-1 is 4.0 to 4.6% (usually from the plexiform variant). There is a slight male predominance in NF-1. Approximately 10% of all soft tissue sarcomas are MPNST. Malignant peripheral nerve tumors may occur following X-RT. They may, as noted, rarely arise from malignant transformation of Schwannomas and ganglioneuromas.

The tumors are most often associated with major nerve trunks. They are most often located in the proximal extremities, trunk, and occasionally in the head and neck. Extremely rarely, they will affect a cranial nerve. NF-1 associated tumors tend to be centrally located. Multifocal tumors are also rare. The clinical presentation is one of an expanding mass that is painful and is associated with motor and sensory deficits of the affected nerve. The tumor may be firmer than benign neural sheath tumors and is often adherent to adjacent structures. There is a rapid increase in size. Patients may present with metastases to lung, bone or the liver. The recurrence rate after treatment with X-RT and chemotherapy is high. The five-year survival rate with tumors arising in the setting of NF-1 is approximately 16% versus 53% in those that are sporadic.

The histologic features vary although the majority of patients demonstrate densely cellular fascicles of spindle cells (herringbone or storiform patterns). Necrosis is common. Patients with NF-1 may demonstrate heterologous differentiation that includes rhabdomyosarcomatous features (malignant triton tumor): these include skeletal muscle, bones, cartilage, epithelial and neuroendocrine components.

MPNST with Rhabdomyoblastic Differentiation (Malignant Triton Tumors)

General Characteristics

1. Malignant triton tumor defines those that demonstrates rhabdomyoblastic differentiation
2. Approximately 70% of these tumors are seen in patients with NF-1

Clinical Manifestations

1. Occur in young patients
2. May arise anywhere in the peripheral somatic nervous system including the head, neck, and trunk
3. Rarely occur in cranial nerves; the most frequent nerve involved is VIII
4. A poor five years survival rate of 12%

Neuropathology

1. The distinctive feature of the tumor is rhabdomyoblast distribution throughout the tumor
2. There are areas of necrosis
3. Immunohistochemical stains are positive for desmin and myoglobin within the rhabdomyoblasts
4. S100 protein is positive within the normal Schwann cells

Epithelioid MPNST

General Characteristics

1. More common in superficial sites
2. MPNST that arises from pre-existing Schwannoma are epithelial in type

Clinical Manifestations

1. Similar to that of Schwannoma but less often arise from nerve trunks
2. Deficits of motor and sensory function of the involved peripheral nerve

Neuropathology

1. Epithelioid cells have granular abundant eosinophilic cytoplasm that is arranged in nests or cords
2. The tumors express S100 protein
3. The differential diagnosis of epithelioid MPNST tumor includes melanoma, clear cell sarcoma, epithelioid sarcoma, and carcinoma

Differential Diagnosis of MPNST

1. NF-1
2. Schwannoma
3. Variety of sarcomas
4. Adult-type fibrosarcoma
5. Synovial sarcoma
6. Rhabdomyosarcoma
7. Leiomyosarcoma
8. De-differentiated liposarcoma
9. Clear cell sarcoma

Traumatic and Compressive Neuropathies

Overview

1. Peripheral nerve injuries occur in 2 to 3% of patients admitted to level 1 trauma centers; the addition of root and plexus injuries increases this figure to 5%
2. Definitions for injuries:
 - a. Neuropraxia: axons are intact but fail to conduct action potentials due to focal demyelination or loss of ion channels and paranodal proteins
 - b. Axonotmesis: transection of axons but the nerve trunk is intact
 - c. Neurotmesis: a transected nerve trunk

3. Sunderland Classification of Peripheral Nerve Injury
 - a. First degree: disruption of the myelin sheath with intact axon and stroma
 - b. Second degree: transection of axons with intact stroma
 - c. Third degree: transection of axons and the endoneurium; the perineurium is intact
 - d. Fourth degree: transection of the axons, endoneurium, and perineurium; fascicular transection occurs; the epineurium is intact
 - e. Fifth degree: transection of the nerve trunk
4. Prognosis after peripheral nerve injury depends upon:
 - a. The degree of injury
 - b. Distance from the muscle and area of sensory innervations
 - c. Activation of the genetic pathways that control the process of Wallerian degeneration and repair

Dorsal Scapular Nerve

General Characteristics

1. Arises directly from the C5 spinal nerve after it exits the intervertebral foramen. It courses between the middle and posterior scalene muscle to innervate the major and minor rhomboid muscles and the levator scapulae
2. The rhomboids adduct the scapula to the midline; the levator scapulae lift and slightly rotate the scapula forward

Clinical Manifestations

1. The superior portion of the scapula is deviated laterally; the shoulder sags (levator involvement)
2. Interscapular pain

Neuropathology

1. Usually a compression injury from improper backpack loading
2. Rarely trauma

Long Thoracic Nerve

General Characteristics

1. Derived from the C5, C6, C7 spinal nerves prior to the origin of the brachial plexus
2. Innervates the serratus anterior muscle

Clinical Manifestations

1. Paralysis of the serratus anterior muscle with scapular winging (primarily the ventral and tip of the scapula)
2. Shoulder stabilization is decreased
3. There is no cutaneous innervation
4. The inferior scapular border is rotated medially; the vertebral border is more prominent when the arm is extended against resistance

Differential Diagnosis

1. Neuralgia amyotrophica:

- a. Probable viral origin that may damage the nerve or its component roots in isolation
 - b. Severe shoulder pain for days to weeks
 - c. Difficulty with shoulder movement (destabilization and pain)
2. Intercostobrachial nerve damage from the medial cord of the brachial plexus:
 - a. This is a purely sensory nerve that innervates the lateral and upper anterior chest wall and radiates under the breast to the midline
 3. Limb-girdle muscular dystrophy
 - a. Muscle disease is almost always symmetrical (congenital forms)
 4. The long thoracic nerve is a major component of scapular winging that may be caused by:
 - a. Injury (usually traction)
 - b. Periscapular and soft tissue abnormalities
 - c. Brachial plexus injury
 - d. Facioscapulohumeral dystrophy and other myopathies
 - e. The long thoracic nerve may be injured during first rib resection
 - f. Subscapular osteochondroma
 - g. Rupture of the rhomboid and trapezius muscles
 5. The long thoracic nerve may be injured in isolation due to breast cancer surgery or cosmetic breast surgery (implants)

Suprascapular Nerve

General Characteristics

1. C5–C6 are its roots of origin; it arises from the upper trunk of the brachial plexus and traverses the suprascapular notch
2. Rarely, anomalous branches may contribute to innervations of axillary nerve territory

Clinical Manifestations

1. Impingement at the suprascapular notch causes shoulder pain
2. There are no cutaneous innervations; sensory innervations are in the deep tissues (muscles of the capsule of the glenohumeral joint)
3. There may be deep throbbing pain along the superior border of scapula toward the shoulder (exacerbated by stretching the adducted arm across the chest)
4. If there is entrapment in the suprascapular notch there is a weakness of both supra- and infraspinatus muscles; if an injury occurs at the lateral border of the spine, the infraspinatus muscle is involved in isolation
5. Weakness of the first 30 degrees of abduction occurs with supraspinatus weakness; external rotation of the arm is compromised with infraspinatus weakness
6. Infraspinatus injury at the spinoglenoid notch is painless and may only involve this muscle
7. Pain may be severe at the suprascapular notch

Differential Diagnosis

1. Entrapment usually occurs at the suprascapular notch; rarely the nerve may be compromised at the spinoglenoid notch
2. Repetitive overhead movements (baseball pitchers; meat cutters)
3. Ganglion cysts
4. Sarcoma
5. Metastatic disease
6. Positioning during surgical procedures (knee-chest position)
7. Weightlifting (shoulder abduction and protraction)
8. Volleyball, dancing, baseball pitchers (the injury is distal often at the spinoglenoid notch)
9. Associated with neuralgia amyotrophica (along with other shoulder girdle nerves)

Differential Diagnosis of Supra- and Infrascapular Nerve Lesions

1. Musculoskeletal pain around the shoulder that is generated from:
 - a. Subacromial bursitis
 - b. Bioccipital tendonitis
 - c. Acromioclavicular joint arthritis or separation (typical football injury)
 - d. Pericapsular fibrosis
 - e. Rotator cuff injury (no weakness)
 - f. C5, C6 radiculopathy; refers pain to the deltoid cap (C5); C6 (thumb and lateral forearm); often pain in this instance radiates to the upper arm; weakness of the biceps, depressed biceps, and brachioradialis muscle stretch reflexes
 - g. Brachial neuritis (Parsonage-Turner syndrome; neuralgia amyotrophica)
 - i. Abrupt onset of pain and weakness of other muscles innervated by the plexus; may be bilateral
2. Brachial plexus traction injury (neuropraxic):
 - a. Tinel's sign at the supra- and infraclavicular fossa
 - b. Mechanical allodynia of the neurovascular bundle when compressed against the humerus
 - c. Tinel's signs at the Arcade of Frohse and pronator canal
 - d. Positive Roos abduction stretch maneuver (the arms are held in a surrender position) which induces trunk and cord sensory loss and weakness

Nerve to the Subclavius Muscle*General Characteristics*

1. Arises from the C5 root or upper trunk of the brachial plexus
2. Innervates the small subclavius muscle between the clavicle and the first rib
3. One of the destinations of the C4 ventral ramus that forms the prefixed brachial plexus

Clinical Manifestations

1. Variation of the subclavius muscle
 - a. Attaches medially to the first rib by a tendon and to the clavicle by fibrous bands
 - b. Possible component of thoracic outlet syndrome

Medial Pectoral Nerve*General Characteristics*

1. The spinal nerves innervating the muscles are C8 and T1; it arises from the medial trunk of the brachial plexus to innervate the pectoralis major and pectoralis minor muscles
2. The nerve innervates the pectoralis major and minor muscles that are a component of adduction flexion and extension and medial rotation of the shoulder joint
3. The muscle also contributes to the stabilization of the glenohumeral joint

Clinical Manifestations

1. Loss of muscle functions as noted; if the muscle is denervated the shoulder is abducted, laterally rotated, retracted and elevated (compensatory from antagonistic muscles)

Differential Diagnosis

1. The nerve is injured during mastectomy (modified radical mastectomy) and during breast reconstruction
2. The nerve may be injured during breast augmentation surgery
3. Severe trauma (motor vehicle accidents; contact sports)
4. In association with brachial plexus pathology
5. The pectoral nerves may be used as donors to the musculocutaneous, axillary long thoracic and spinal accessory nerves during reconstruction procedures

Lateral Pectoral Nerves (LPN)*General Characteristics*

1. Arise primarily from the lateral cord of the brachial plexus; it may arise from the anterior division of the upper and middle trunk prior to the formation of the lateral cord
2. It is innervated by C5–C7 spinal nerves
3. The medial and lateral pectoral nerves are most frequently connected distally to the thoracoacromial artery by the ansa pectoralis
4. The LPN supplies the upper portions of the pectoralis major muscle

Clinical Manifestations

1. Major functions that are compromised by injury are protraction and depression of the scapula
2. The nerve may be injured by:
 - a. Direct trauma
 - b. Hypertrophic muscle compression
 - c. Axillary node dissection
 - d. Breast surgery for cancer and reconstruction
 - e. Cosmetic breast surgery
 - f. Utilized for nerve transfers

Spinal Accessory Nerve

General Characteristics

1. The component of the nerve from the medulla supplies the soft palate; the cranial component merges with the vagal nerve
2. In the majority of people, the spinal component originates in the upper cervical spinal cord to C5
3. The spinal component has a long course as it ascends between the dentate ligament and posterior spinal nerve roots to enter the skull foramen and exits through the jugular foramen; the nerve descends posterior to the digastric and stylohyoid muscles to innervate the sternocleidomastoid and trapezius muscles

Clinical Manifestations

1. The ability to tip the head and rotate the cranium contralaterally is decreased or lost with a sternocleidomastoid injury
2. The trapezius muscle has several scapular functions that include elevation of the shoulder. It also is a component of arm abduction
3. The nerve may be surgically injured from medical procedures (surgery) of the head and neck. A common procedure that injures the nerve is a simple posterior triangle lymph node biopsy. The distal part of the nerve is most often injured
4. Lymphoma, neck cancers and severe trauma (spinal cord injury) injure the nerve

Phrenic Nerve

General Characteristics

1. The major spinal nerve comprising the phrenic nerve is C4. It receives contributions from C3 and C5
2. The nerve descends obliquely in association with the internal jugular vein across the anterior scalene muscle deep to the prevertebral layer of the deep cervical fascia and across the transverse cervical and suprascapular arteries. On the left side, it crosses the initial part of the subclavian artery while on the right, it crosses the anterior scalene muscle and traverses the second component of the subclavian artery. Bilaterally it is posterior to the subclavian vein and passes anteriorly to the root of the lung. It lies between the fibrous and parietal layers of the pericardium. The nerve passes through the vena cava hiatus at the level of T8
3. The motor components of the phrenic nerve innervate the diaphragm while sensory fibers innervate the fibrous pericardium, mediastinal pleura, and the diaphragmatic peritoneum

Clinical Manifestations

1. Rapid respiratory failure is accompanied by:
 - a. Anxiety
 - b. Tachypnea

- c. Tachycardia
 - d. Diaphoresis
2. Paradoxical respiration may occur:
 - a. The abdominal wall retracts during inspiration due to the inability of the diaphragm to contract while a negative intrathoracic pressure is generated by the intercostals and accessory muscles of respiration
 - b. Respiratory alternans may occur, in which the diaphragm descends only on alternate breaths (most often seen with airway obstruction)
 - c. These patterns of respiration are seen in acutely ill patients when the vital capacity is approximately 10% of normal (500 ml in an average-sized man)
 3. Patients with weakness of respiratory muscles may have $p\text{CO}_2 > 40$ torr (in acute respiratory failure $p\text{CO}_2$ may be > 70 torr) which can cause:
 - a. Daytime somnolence
 - b. Early morning headache
 - c. Rarely papilledema
 4. Patients with only one diaphragm affected are most often normal at rest but become dyspneic too easily with exertion
 5. Irritation of the phrenic nerve often initiates the hiccup reflex:
 - a. A hiccup is a spasmodic contraction of the diaphragm that causes inhalation of air against the closed folds of the larynx
 6. The phrenic nerve may be injured during various surgical procedures that include:
 - a. Open heart surgery
 - b. Abdominal surgery
 - c. First rib removal (thoracic outlet surgery)
 - d. Cancer surgery of the neck
 - e. The right phrenic nerve may be injured by the vena cava clamp during liver transplantation

Differential Diagnosis of Neuromuscular Diseases That May Present with Subacute Respiratory Failure

1. Manifest as dyspnea and exercise intolerance:
 - a. Motor neuron disease
 - b. Myasthenia gravis
 - c. Lambert-Eaton syndrome
 - d. Polymyositis/dermatomyositis
 - e. Acid maltase
 - f. Mitochondrial myopathy
 - g. AIDP
 - h. All processes that affect the neuromuscular junction

Subscapular Nerves

General Characteristics

1. The upper and lower subscapular nerves arise from the posterior cord in the axilla
2. The subscapularis muscle fills the subscapular fossa and inserts into the lesser tubercle of the humerus, anterior to the capsule of the shoulder joint

3. Its major function is to rotate the head of the humerus medially when the arm is raised; it also pulls the humerus forward and downward
4. It is the most powerful muscle of the rotator cuff and stabilizes the glenohumeral joint
5. The lower subscapular nerves supply the teres major

Clinical Manifestations

1. There are multiple variations in the origin of the lower subscapular nerve, which is important for surgical procedure in the axilla:
 - a. It may take origin from the axillary nerve in 40–50% of patients
2. Injuries to the subscapular nerves occur in:
 - a. Surgical procedures of the axilla
 - b. Scapular fractures
 - c. Shoulder dislocations
 - d. Infraclavicular brachial plexus blocks

Thoracodorsal Nerve

General Characteristics

1. The thoracodorsal nerve takes origin from the posterior cord to innervate the latissimus dorsi muscle
2. Anatomic variations include origins from the radial or axillary nerves
3. The major spinal nerve is C7 with contributions from C5 and C6

Clinical Manifestations

1. The latissimus dorsi muscle is a functional component for:
 - a. Extension adduction and transverse extension (horizontal adduction)
 - b. Flexion from an extended position
 - c. Internal rotation of the shoulder joint
 - d. It has a synergistic role in extension and lateral flexion of the lumbar spine
2. The nerve may be injured by:
 - a. High-velocity trauma such as motor vehicle accidents (MVA), including motorcycle accidents
 - b. Brachial plexus pathologies
 - c. Rotator cuff surgery

Medial Cutaneous Nerve of the Arm

General Characteristics

1. It arises from the medial cord of the brachial plexus
2. It is composed of spinal nerves C8 and T1
3. It traverses the axilla, behind and then medial to the axillary vein
4. It communicates with the intercostobrachial nerve

Clinical Manifestations

1. The nerve provides sensation to the medial upper arm above the elbow
2. The nerve is injured:

- a. During axillary dissection for lymph nodes
- b. Mastectomy
- c. Brachial plexus injury
- d. Maybe injured in concert with injuries to the intercostobrachial nerve

Medial Cutaneous Nerve of the Forearm

General Characteristics

1. Usually, arises from the medial cord; a variation is its origin from the medial cutaneous nerve of the arm
2. It is derived from the 8th cervical and first thoracic nerves medial to the axillary artery
3. It gives off a branch near the axilla that supplies the integument that covers the biceps brachii
4. Divides into a volar and ulnar branch
5. Supplies sensation from the medial forearm to the wrist
6. Injuries of the nerve:
 - a. Steroid injection for epicondylitis
 - b. Venipuncture
 - c. Open fracture fixation
 - d. Tumor excision
 - e. Elbow arthroscopy
 - f. Rare subcutaneous lipoma

Musculocutaneous Nerve

General Characteristics

1. The musculocutaneous nerve arises from the lateral cord of the brachial plexus
2. It is derived from spinal nerves C5, C6, C7
3. Its usual course is through the coracobrachialis muscles to the biceps brachiale and the brachialis; it pierces the deep fascia lateral to the tendon of the biceps brachii. It continues into the forearm as the lateral cutaneous nerve of the forearm
4. Variations:
 - a. May not penetrate the coracobrachialis
 - b. The median nerve may project to join the nerve
 - c. May pass through the biceps brachii
 - d. May project a filament to the pronator teres
 - e. May supply the dorsal surface of the thumb when the superficial branch of the radial nerve is absent
 - f. In approximately 5% of the population, the nerve originates from the anterior division of the upper trunk; in this situation, the lateral component to the median nerve takes origin from the middle trunk
5. The nerve innervates:
 - a. The coracobrachialis
 - b. Biceps brachii
 - c. Brachialis
 - d. Terminals of the lateral cutaneous nerve of the forearm form sensory innervation of the lateral aspect of the forearm from the elbow to the wrist

Clinical Manifestations

1. Weakness of elbow flexion and supination of the forearm

2. Decreased sensation on the lateral side of the forearm
3. Decreased biceps and brachioradialis reflexes

Neuropathology

- a. The nerve is usually injured in association with upper brachial plexus injuries
- b. Entrapment due to hypertrophy or compression between the biceps aponeurosis and the brachialis fascia
- c. Neuropractic injury during surgery
- d. It is injured at the coracobrachialis level due to stretch or from repetitive movements above the horizontal
- e. Distal to the coracobrachialis:
 - i. Injuries may be due to weight lifting
 - ii. Benign humeral exostosis

Axillary Nerve

General Characteristics

1. Arises from the posterior cord, and is derived from spinal nerves C5 and C6
2. It lies behind the axillary artery and in front of the subscapularis muscle in company with the posterior humeral circumflex artery to traverse the quadrilateral space
3. The quadrilateral space:
 - a. Is bounded above by the subscapularis muscle, below by the teres major muscle, medially by the long head of the triceps brachii muscle, and laterally by the neck of the humerus beneath the deltoid muscle. It divides into:
 - i. The anterior branch:
 1. Innervates the deltoid muscle
 2. Cutaneous branches to supply the skin overlying the deltoid muscle
 - ii. Posterior branch:
 1. Innervates the teres minor and posterior fascicles of the deltoid muscle
 2. Continues as the superior (upper) lateral cutaneous nerve of the arm to supply the skin over the lower 2/3 of the muscle and the long head of the triceps brachii
 - iii. A motor branch to the long head of the triceps
 - iv. The trunk of the axillary nerve gives off an articular collateral branch to the shoulder joint

Clinical Manifestations

1. Weakness of abduction (15–90 degrees) and external rotation of the shoulder
2. Slight weakness of shoulder extension
3. Paralysis of the deltoid and teres minor muscles results in a flat shoulder deformity
4. Quadrilateral space syndrome:
 - a. Compression of the axillary artery and at times the posterior circumflex humeral artery (PCHA)
 - i. Caused by fibrous bands between the teres major and the long head of the triceps tendon

Clinical Manifestations of Quadrilateral Space Syndrome

1. Point tenderness in the quadrilateral space
2. Poorly localized posterior shoulder pain and paresthesia that are exacerbated by humeral abduction and external rotation; patients present with pain from performing overhead tasks
3. The pain can also radiate in a non-dermatomal pattern and may be associated with teres minor and deltoid muscle atrophy

Pathogenesis of Injuries to the Radial Nerves

1. Dislocation and fracture of the shoulder
2. Fracture of the humerus
3. Surgical positioning
4. Entrapment in the quadrilateral space

Laboratory Evaluation

1. EMG:
 - a. Denervation of the deltoid and teres minor
2. MRI:
 - a. Suspected quadrilateral space patients
 - i. Selective fatty infiltration of the teres minor with atrophy; atrophy of the deltoid muscle
 - ii. Increased signal intensity on T2-weighted images of the axillary nerve
3. MRA to evaluate compression of the posterior circumflex humeral artery
4. Ultrasound guided technique for a diagnostic quadrilateral space block

Differential Diagnosis

1. Orthopedic shoulder conditions
2. C5–C6 radiculopathy
3. Brachial plexus traction injury
4. Neuralgia amyotrophica
5. Suprascapular neuropathy

Radial Nerve

General Characteristics

1. The primary spinal nerves that comprise the radial nerve are C5–C8; in approximately 10% of people, there is a contribution from T1
2. It is the continuation of the posterior cord
3. Its branches innervate the dorsal arm muscles (the triceps brachii and the anconeus) as well as the extrinsic extensors of the wrist and hand
4. It provides most of the cutaneous innervations to the back of the hand. It is most often damaged in the upper arm and axilla but is the least involved of the nerves of the arm
5. In the axilla, it gives off the posterior cutaneous nerve that innervates the posterior aspect of the upper arm to the elbow
6. In the proximal upper arm, it descends medial to the humerus through the triangular space between the medial and long heads of the triceps muscles along the spiral groove of the humerus

7. In the upper arm, it innervates the long medial and lateral heads of the triceps brachii and the anconeus muscle
8. After exiting the spiral groove it innervates:
 - a. Brachioradialis
 - b. Extensor carpi radialis longus
 - c. Brachialis
 - d. Supinator
9. Four centimeters proximal to the lateral epicondyle, the nerve bifurcates into the superficial sensory nerve and the posterior interosseous nerve
 - a. The superficial radial sensory nerve supplies the dorso-lateral hand, the lateral part of the thumb, and the proximal phalanges of the index, middle, and ring fingers; it lies under the brachioradialis
 - b. The superficial radial nerve traverses the upper forearm on the underside of the brachioradialis muscle and the side of the radial tunnel. In the mid forearm, it lies superficially. Once past the wrist it innervates sensation for:
 - i. Extensor surface of the hand and fingers except for the distal finger tips (supplied by the median and ulnar nerves); and the dorsum of the medial aspect of the hand and medial fingers that are supplied by the dorsal ulnar cutaneous nerve
 - c. The posterior interosseous nerve is purely motor and innervates:
 - i. Extensor carpi radialis
 - ii. Extensor carpi ulnaris
 - iii. Extensor communis
 - iv. Abductor pollicis longus
 - v. Extensor digitorum communis (EDC)
 - vi. Extensor pollicis longus and brevis
 - vii. Extensor indicis proprius
 - viii. Supinator
 - d. The posterior interosseous nerve traverses the radial tunnel that is bounded by:
 - i. The radius
 - ii. The capsule of the radiocapitular joint
 - iii. The medial wall is formed by the tendons of the brachialis and the biceps brachii tendons
 - iv. The lateral and anterior walls are formed by the brachioradialis, extensor carpi radialis, and the extensor carpi ulnaris muscles
 - v. The radial tunnel terminates at the fibrous band around the superficial head of the supinator muscle known as the Arcade of Frohse
 - e. The posterior interosseous nerve descends under the Arcade of Frohse after traversing the radial tunnel
 - f. The posterior interosseous nerve innervates the interosseous membrane and joint between the radius and ulna

Radial Nerve Injury in the Axilla

General Characteristics

1. Often from compression

Clinical Manifestations

1. Wrist and finger drop
2. Weakness of supination
3. Loss of wrist and finger extension
4. Weakness of arm extension
5. Loss of sensation in the lateral arm, posterior forearm, lateral 1/2 of the dorsal aspect of 3 1/2 digits (excluding the tips of the fingers)
 - a. There is normal deltoid and thoracodorsal nerve function, which rules out a posterior cord lesion of the brachial plexus

Pathogenesis of the Injury

1. Crutch injury (long arm crutches)
2. Axillary surgery (hyperabduction; lymph node dissection)
3. Lymphoma or metastatic tumor
4. Transaxillary first rib resection for thoracic outlet syndrome

Laboratory Evaluation

1. EMG:
 - a. Focal slowing of the radial nerve in the upper arm (motor and sensory NCVs)
 - b. Denervation of radial nerve innervated muscles in the forearm
 - c. The triceps may be spared if the lesion is beyond the axilla

Radial Nerve Injury at the Spinal Groove

General Characteristics

1. Abuts the spinal groove in the mid-shaft of the humerus

Clinical Manifestations

1. Wrist and finger drop
2. Mild weakness of supination (loss of supinator muscle)
3. Slight weakness of elbow flexion (brachioradialis)
4. Spared elbow extension (C7 innervated muscles (triceps) comes off more proximally)
5. Loss of sensation in the posterior forearm; radial half of the dorsum of the hand and the dorsal 3 1/2 digits excluding the fingertips (superficial radial sensory nerve)

Pathogenesis of Nerve Injury

1. Fracture of the mid-shaft of the humerus (2 to 16% occur through the spiral groove)
2. Compression (Saturday night palsy)
3. Vasculitic infarction
4. Strenuous repetitive exercise
5. Multifocal neuropathy with conduction block
6. Compression by the lateral head of the triceps or by a fibrous band

Posterior Interosseous Nerve

General Characteristics

1. Pathology most often occurs just distal to the elbow

2. Injury to the deep branch of the radial nerve that pierces the radial head
3. There is no sensory loss; pain emanates from the innervations of the interosseous ligament

Clinical Manifestations

1. Following injury, patients complain of pain in the elbow and proximal forearm for a few days
2. Pain can be elicited by compression of the nerve distal to the radial head (extensor carpi radialis brevis)
3. Wrist extensor weakness with radial deviation; the extensor carpi ulnaris is weaker than the extensor carpi radialis
4. No extension of the fingers at the MCPs (metacarpal-phalangeal joints)
5. Loss of thumb extension at the MCP joint; no radial thumb abduction; weak extension of the thumb
6. Interphalangeal joints (IP joints) of the intrinsic hand muscles are innervated by the median and ulnar nerves
7. If there is partial paralysis of the nerve:
 - a. There is decreased extension of the MCP joint at digits IV and V; intact extension of the proximal interphalangeal digits (PID) and the distal interphalangeal digits (DIP) because they are innervated by the median ulnar nerves
8. Rare patterns of partial posterior interosseous nerve injury:
 - a. Weakness of MCP extension of the thumb
 - b. Weakness of extension of V

Pathogenesis of Nerve Injury

1. Fracture of neck of the brachialis
2. Elbow dislocation or fracture
3. Tight cast
4. Rheumatoid nodules
5. Injections for tennis elbow
6. Injury of the deep branch of the radial nerve that pierces the radial head (causes the posterior interosseous syndrome)
7. Ganglion cyst
8. Nerve sheath tumors
9. Entrapment under the Arcade of Frohse
10. Open reduction of the fractures at the proximal radius with plating
11. Tenderness band in the supinator muscles

Laboratory Evaluation

1. EMG:
 - a. Focal slowing of motor NCV across the Arcade of Frohse
 - b. Prolonged distal latency from the elbow to the FDC
 - c. The supinator muscle and the extensor carpi radialis are normal (supplied by more proximal components of the nerve)
 - d. Cutaneous branches of the superficial radial nerve are normal

Radial Tunnel Syndrome

General Characteristics

1. The true neurogenic syndrome requires weakness of posterior interosseous innervated muscles

Clinical Manifestations

1. Lateral elbow pain
2. Dull ache deep on extension of the muscle mass of the forearm
3. Night pain with distal and proximal radiations
4. Increased pain with resisted active supination of the forearm
5. Weakness of all posterior interosseus innervated muscles

Pathogenesis of the Nerve Injury

1. Fibrous, tendinous band at the Arcade of Frohse
2. Recurrent fan of aberrant muscles
3. Compression by the tendon of the extensor carpi radialis

Laboratory Evaluation

1. EMG:
 - a. Denervation of the EDC
 - b. ECR should be spared

Superficial Radial Nerve Injury

General Characteristics

1. In the past, this injury has been called Wartenberg's syndrome
2. Entrapment of the superficial radial nerve beneath the tendinous insertion of the brachioradialis muscle

Clinical Manifestations

1. The sensory deficits depend on the lateral antebrachial cutaneous nerve
2. Numbness, tingling and paresthesia in the radial half of the dorsum of the hand and the dorsal radial 3½ digits excluding the distal digits
3. There are no motor deficits
4. In Wartenberg's syndrome patients have wrist pain that is often confused with De Quervain's tenosynovitis (in which Finkelstein's test is often positive)

Pathogenesis of the Nerve Injury

1. Compression by handcuffs, bandages, and watch bands
2. Wartenberg's syndrome:
 - a. Compression beneath the tendinous insertion of the brachioradialis muscle
 - b. Surgical procedures for De Quervain syndrome
 - c. Tight casts
 - d. Joint degenerative arthritis
 - e. Scaphoid fracture
 - f. Accessory brachioradialis muscle compression

Differential Diagnosis of Radial Neuropathy

1. Most patients present with a wrist drop

2. A radiculopathy at C7:
 - a. This is the major spinal nerve that innervates the muscles of extension of the wrist and fingers; C5–C6 roots make major contributions and therefore the loss of extension with this root injury is never as severe as with a radial nerve injury
 - b. The sensory loss from C7 is in the third finger
3. Brachial neuropathy from injury at the spiral groove or axilla: Involves the brachioradialis muscle (C5–C6 spinal nerves) which is not affected by a C7 spinal nerve lesion; the triceps is spared but would be affected by a C7 spinal nerve injury
4. If the C7 spinal nerve is damaged, the pronator teres and radial nerve innervated muscles are weak
5. A posterior cord brachial plexus lesion would involve the subscapular thoracodorsal and the axillary nerve, as well as other radial nerve innervated muscles
6. An embolus from the internal carotid artery (central sulcal branch of the superior division of the middle cerebral artery) to the motor cortex may present with a wrist drop (pseudoradial palsy). Finger flexion is involved, and rarely individual fingers may be affected
8. In the mid forearm, the anterior interosseous nerve branches from the nerve. It is a pure motor nerve and innervates:
 - a. Flexor digitorum profundus 1+2
 - b. Flexor pollicis longus
 - c. Pronator quadratus
9. At the wrist:
 - a. Prior to entering the carpal tunnel, the median nerve gives off the palmar cutaneous branch which innervates the thenar eminence
 - b. The carpal tunnel is bounded by the carpal bones medially and laterally with the transverse ligament superiorly. The median nerve is accompanied in the carpal tunnel by the flexor tendons to the fingers
 - c. Either within or just distal to the carpal tunnel, the median nerve gives origin to the recurrent branch that innervates:
 - i. Abductor pollicis brevis
 - ii. The superficial head of the flexor pollicis brevis
 - iii. Opponens pollicis
 - d. The terminal branches of the median nerve supply:
 - i. The first and second lumbrical muscles
10. Digital branches are the sensory innervations of the volar aspects (and the nail beds) of the thumb, index, and middle fingers

The Median Nerve

General Characteristics

1. The median nerve is composed of components of the lateral and medial cords of the brachial plexus
2. Its contributions are from the ventral roots of C5, C6 and C7 (lateral cord) and C8 and T1 of the medial cord
3. The nerve enters the arm from the axilla at the inferior margin of the teres major muscle and courses with the brachial artery on the medial side of the arm. It lies between the biceps brachii and the brachialis muscles and lies anterior to the elbow joint. In the cubital fossa, it is medial to the brachial artery, anterior to the insertion of the brachialis, and deep to the biceps. Immediately proximal to the elbow joint it may give off a branch to the pronator teres muscle
4. Motor fibers to the nerves arise from spinal nerves C6–T1 while sensory innervation is from C6–C7 spinal segments. Rarely the C5 spinal nerve is a component of the median nerve
5. Sensory fibers traverse the upper and middle trunks to the lateral cord. Motor fibers access all trunks and the medial and lateral cords
6. Distal to the elbow, the nerve traverses through the two heads of the pronator teres muscle, and then between the flexor digitorum superficialis and profundus muscles to the wrist
7. While in the forearm the median nerve innervates:
 - a. Pronator teres
 - b. Flexor carpi radialis
 - c. Palmaris longus
 - d. Flexor digitorum superficialis muscles

High Median Nerve Compression in the Region of the Shoulder or Proximal Humerus

General Characteristics

1. Lesions involving the nerve at this level are uncommon and usually traumatic

Clinical Manifestations

1. Deficit of forearm pronation from paralysis of the pronator teres and pronator quadratus
2. Weak wrist flexion with ulnar hand deviation due to weakness of the flexor carpi radialis
3. Paralysis of:
 - a. Flexor pollicis longus
 - b. Flexor digitorum superficialis of the digits (therefore, absence of flexion of the distal interphalangeal joints and proximal interphalangeal joint of the index finger)
 - c. Weakness of grip of the 3th and 5th digits (flexor digitorum superficialis)
 - d. Slight weakness of the flexor digitorum profundus with consequent weakness of distal interphalangeal flexion
4. Paralysis of the thenar muscles
5. Decreased sensation to the thenar eminence and median nerve innervated digits

Pathogenesis of Median Nerve Injury

1. Anterior dislocation of the shoulder
2. Compression in the axilla from long arm crutches
3. Hanging the arm over hard objects
4. Aneurysms of the brachial or axillary arteries
5. Trauma to the upper arm

*Median Nerve Injury in the Forearm***General Characteristics**

1. In approximately 0.7 to 2.7% of the population there is a supracondylar process that arises five centimeters above the medial epicondyle. There is a fibrous band that passes from this supracondylar process that attaches to the medial epicondyle of the elbow. The median nerve and brachial artery and vein course under the ligament of Struthers
2. In the antecubital fossa the median nerve courses adjacent to the brachial artery and then in the forearm continues below a thick fibrous band known as the lacertus fibrosus (originates from the biceps tendon and attaches to the forearm flexor musculature)
3. The median nerve gives off two branches in the forearm:
 - a. The anterior osseous nerve:
 - i. Courses with the anterior interosseous artery
 - ii. Innervates the deep group of muscles of the anterior compartment except the medial half of the flexor digitorum profundus and the flexor carpi ulnaris (supplied by the ulnar nerve; this branch ends with innervations of the pronator quadratus muscle)
 - iii. The distal median forearm nerve passes deep to the flexor digitorum sublimis muscle and its aponeurotic tendinous edge, known as the sublimis bridge
 - a. Lacertus fibrosus site:
 - i. Forced supination and elbow flexion
 - b. Pronator teres:
 - i. Forced pronation and elbow flexion
 - c. Sublimis bridge:
 - i. Flexion of the proximal interphalangeal joint of the middle finger
2. All three sites of entrapment cause:
 - a. Weakness of FPL and the APB; rarely the FDP
 - b. Paresthesias of the median nerve innervated digits
 - c. Aching of the proximal forearm
 - d. Tenderness over the pronator teres muscle
 - e. Clumsiness and weakness of the hand
3. At the level of the lacertus fibrosus, the median nerve passes through a tunnel; the bottom is the medial trochlea of the humerus; the lateral wall is the brachialis muscle; the medial wall is the pronator muscle and the roof is the lacertus fibrosus
4. The organization of the median nerve in this proximal location is important for surgical considerations:
 - a. At the lacertus tunnel level; the branches to the pronator teres and the FCR are anterior and those to the FPL and FDP are medial
 - b. At the level of the superficialis arcade, the anterior and superficial branches innervate the FDS and sensation to the hand

Pathogenesis of Median Nerve Injury in the Forearm

1. Trauma: casting, direct injury, venipuncture, tumor or hematoma
2. Neuralgia amyotrophica
3. Neuropathy with sensitivity to pressure palsy (chromosome 17)
4. Dislocation of the elbow
5. Persistent median artery

*Ligament of Struthers Compression***Clinical Manifestations**

1. Pain in the volar forearm
2. Paresthesias in the median nerve innervated digits
3. The sensory symptoms are exacerbated by forearm supination and extension at the elbows
4. Palpation of the distal spur on the medial humerus (approximately 5.5 cm proximal to the medial epicondyle)
5. Weakness of the pronator teres is greater than other median nerve innervated muscles

*The Pronator Syndrome***General Characteristics**

1. The pronator syndrome or proximal median nerve entrapment at the level of the elbow occurs at three sites:
 - a. Lacertus fibrosus site
 - b. Pronator teres muscle
 - c. Sublimis bridge

Clinical Manifestations

1. Evocative maneuvers:

Laboratory Evaluation

1. EMG:
 - a. The electrodiagnostic evaluation is abnormal in a minority of patients
 - b. Focal motor nerve conduction at the elbow
 - c. Denervation of median nerve forearm and hand muscles
2. Imaging by MR neurography and high resolution ultrasound
 - a. MRI:
 - i. Ability to sample nerve T2 signal over large areas allows the detection of individual nerve fascicles
 - ii. Diffusion tensor MR neurography provides quantitative estimates of fiber structure which correlates with focal entrapment
 - b. High resolution ultrasound provides localization of symptomatic nerve entrapment:
 - i. Fascicular hypoechogenicity is the ultrasound correlate of nerve T2 signal lesions

Differential Diagnosis of the Pronator Teres Syndrome

1. Entrapment in the carpal tunnel
2. Cervical radiculopathy:
 - a. C6 or C7 spinal nerve injury may cause vague forearm pain
 - b. There may be sensory loss in the thumb, index and 3rd finger
 - c. There may be a positive Spurling's sign at the nerve root exit; foraminal pressure causes mechano-allodynia

- elicited from the spinal nerve; lateral rotation of the neck causes paresthesias in the thumb and index finger as well as pain down the spinous processes of the neck
- d. There is weakness of the biceps (C6) and the triceps muscle (C7)
- e. Decreased biceps reflex (due to injury of C5–C6 spinal nerves) and the triceps reflex is decreased from involvement of the spinal nerves at C7
- 3. Brachial plexus neuropractic injury (upper trunk and lateral cord)
- 4. Musculoskeletal disease at the elbow that includes:
 - a. Sprains of the flexor and pronator muscles
 - b. Vascular anomalies:
 - i. Aneurysm of the median artery
 - c. AV shunt placement for renal dialysis
 - d. Fistula due to trauma (knife > bullet)
 - e. Minimum or no sensory loss

Anterior Interosseous Nerve

General Characteristics

1. The nerve arises from the median nerve 5 to 8 cm distal to the lateral epicondyle
2. Innervates the flexor pollicis longus, flexor digitorum profundus to the index and long finger and the pronator quadratus
3. There are no surface cutaneous innervations; there are proprioceptive and pain afferents to the wrist joint
4. Anomalous innervations:
 - a. The anterior interosseous nerve may supply all of the flexor digitorum profundus (patient would be unable to flex any distal joints); and all median hand
 - b. The flexor digitorum profundus to the index or long finger may be spared (innervated by the ulnar nerve)
 - c. 50% of Martin-Gruber anastomosis arise from the anterior interosseous nerve

Clinical Manifestations

1. Inability to flex the distal phalanx of the thumb and index finger; weak forearm pronation (pronator quadratus)

Pathogenesis of the Nerve Injury

1. Trauma from casting
2. Repetitive elbow flexion and pronation
3. Open reduction of forearm fractures
4. Anatomic anomalies:
 - a. Tendinous origin of the deep head of the pronator teres muscle
 - b. Tendinous compression of the flexor digitorum superficialis of the 3rd finger

Laboratory Evaluation

1. EMG:
 - a. Decreased distal motor latencies from the elbow to the pronator quadratus

- b. Denervation of the flexor digitorum profundus, FPL and pronator quadratus
- c. Fascicular/partial nerve lesions in spontaneous neuropathies have been difficult to delineate with electrodiagnostic methods
- 2. Magnetic resonance neurography (MRN)
 - a. Fascicular lesions with a strict somatotopic organization can be identified in the upper arm median nerve trunks in patients with AIN (anterior interosseous nerve) in non-traumatic instances which supports:
 - i. AIN is a multifocal mononeuropathy that selectively involves the motor fascicles of the median nerve

Differential Diagnosis of Anterior Interosseous Nerve Lesions

1. Paralytic brachial neuritis with concomitant AIN involvement (associated other components of the brachial plexus are involved and pain may last for days or weeks)
2. Vascular anomaly of the lateral cord of the brachial plexus (may have no motor involvement, which is predominant with AIN)
3. Rheumatoid arthritis which may cause rupture of the FPL and FDT tendons
4. Cervical radiculopathy (there is sensory loss with biceps, triceps weakness and loss of motor stretch reflexes)

Median Nerve Injury at the Wrist

General Characteristics

1. Injury at this level is traumatic

Clinical Manifestations

1. Weakness of flexion of the index, long finger and thumb
2. Loss of abduction and opposition of the thumb
3. A simian hand deformity at rest due to hyperextension of the index finger and thumb with thumb adduction
4. Benediction sign when attempting to form a fist due to flexion weakness of the thumb index and long finger
5. Loss of sensation in the first 3½ digits (splits the 4th finger; ulnar side of the finger is insensate; the thenar eminence and the nail beds are affected)

Pathogenesis of the Nerve Injury

1. Laceration
2. Industrial accidents

Carpal Tunnel Syndrome

General Characteristics

1. The carpal bones comprise the floor and side of the carpal tunnel; the transverse carpal ligament forms the roof
2. Proximal to the wrist and the carpal tunnel, the palmar cutaneous branch arises from the median nerve to innervate the thenar eminence
3. In the palm the motor branch arises to innervate the thumb and first and second digits; the recurrent thenar motor

branch supplies the opponens pollicis, APB (abductor pollicis brevis), the superficial head of the flexor pollicis brevis

4. A sensory branch innervates the medial thumb, index, long finger and the radial side of the 4th finger

Clinical Manifestations

1. Numbness of the thumb, index, middle finger and radial side of the 4th finger; a large percentage of patients complain of paresthesia of all fingers (suggested that there may be compression concomitantly of the ulnar nerve)
2. Nocturnal paresthesias that may awaken the patient from sleep; the hand may be held in a dependent posture as a position of comfort
3. Activities that elicit pain or paresthesias:
 - a. Writing
 - b. Computer keyboards
 - c. Driving
 - d. Holding a phone or book
4. Pain is often felt in the hand and forearm:
 - a. Very rarely radiates to the antecubital fossa, but has been reported in the shoulder
 - b. Wrist flexion exacerbates distal and proximal pain radiations (Phalen's sign; usually flexion needs to be maintained for 1 to 2 minutes to elicit pain)
 - c. Tinel's sign (mechanically induced hypersensitivity of the nerve) may be elicited over the carpal tunnel (not specific as it may be elicited in normal people)
5. Weakness or tiredness of the hand during writing; spontaneous dropping of objects
6. Weakness of flexion of the index, 3rd and a component of the 4th finger; weakness of abduction and opposition of the thumb
7. Hyperesthesia in the median nerve distribution (3½ digits including the nail beds) but excluding the thenar eminence which is supplied by the palmar cutaneous branch; unlike the sensory loss that occurs with laceration of the nerve at the wrist, there is no sensory loss of the central palm (palmar cutaneous branch courses above the flexor retinaculum). The tip of the index finger is the earliest and most severe area of sensory loss. Two-point discrimination is affected prior to pin prick and temperature loss. The radial split of the 4th finger is characteristic
8. Raynaud's phenomenon and autonomic dysregulation of the hand may occur (the median nerve supplies the bulk of the sympathetic innervations to the hand)

Pathogenesis of Carpal Tunnel Syndrome

1. A congenitally narrow carpal tunnel
2. Most common in middle-aged women 3:1 female to male incidence; often bilateral; the dominant hand is most often more severely affected
3. Fibrosis of the transverse carpal ligament
4. Repetitive flexion and extension of the wrist
5. Diabetes mellitus

6. Scleroderma
7. Rheumatoid arthritis
8. Acromegaly
9. Amyloidosis
10. Lyme's disease
11. Sarcoid
12. Colles fracture
13. Pregnancy
14. Hemodialysis
15. Anomalous flexor tendons
16. Flexor tendon synovitis (rare)
17. Gout
18. Double crush: associated with cervical spine or brachial plexus pathologies (controversial)

Laboratory Evaluation

1. EMG:
 - a. Median sensory or mixed nerve conduction study
 - b. Median motor conduction study
 - c. Needle examination of the APB
 - d. Ulnar and/or radial motor and sensory NCS (to exclude a peripheral neuropathy)
 - e. Needle EMG of muscles innervated by C5 to T1 roots (to exclude a cervical radiculopathy)

Supplementary Tests Include

1. Comparison of the median motor nerve distal latency (second lumbrical) to the ulnar motor nerve distal latency
2. Inching
3. Median motor terminal latency index
4. Median nerve conduction between the wrist and the palm
5. MRI: neurography
6. High resolution ultrasound

Differential Diagnosis of Carpal Tunnel Syndrome

1. Generalized neuropathy
2. Brachial plexopathy (lateral cord)
3. Cervical radiculopathy ("double crush")
4. Median neuropathy at the elbow:
 - a. Sensory loss of the thenar eminence, which is not found with Carpal Tunnel syndrome (CTS)
 - b. Weakness of distal thumb flexion and arm pronation

Ulnar Nerve

General Characteristics

1. Second most common nerve entrapment of the arm (less than CTS)
2. The major spinal nerves contributing to the ulnar nerve are C8 and T1; C7 fibers may contribute in from 43 to 93% of patients
 - a. The C7 component of the nerve derives from the lateral cord and innervates the flexor carpi ulnaris muscle
3. Proximally the nerve is anterior to the teres major and latissimus dorsi muscles and descends in the posterior

compartment of the upper arm to the ulnar groove at the elbow

4. The ulnar groove at the elbow is formed by the medial epicondyle of the humerus and the olecranon process of the ulna; the ulnar collateral ligament is the floor
5. 1–2.5 cm distal to the ulnar groove the nerve courses under a fibrous aponeurosis arch; the ulnar groove and this arch form the cubital tunnel. The ulnar nerve gives off no branches proximal to the elbow. It enters the forearm between the humeral and ulnar heads and lies under the aponeurosis of the flexor carpi ulnaris next to the ulna. It descends between the flexor carpi ulnaris and flexor digitorum profundus to the wrist. In the forearm it innervates:
 - a. Flexor carpi ulnaris
 - b. Flexor digitorum profundus III and IV muscles
 - c. The dorsal ulnar cutaneous nerve (innervates the dorsum of the medial hand and the 4th and 5th fingers)

Guyon's Canal

Prior to entering Guyon's canal at the wrist, the nerve gives branches to the hypothenar eminence (palmar branch) and innervates the palmaris brevis muscle.

1. Guyon's canal at the wrist is formed by:
 - a. Radially by the hook of the hamate bone
 - b. The pisiform bone on the ulnar side
 - c. The pisohamate ligament is the floor
 - d. The transverse carpal ligament is the roof
2. Either in Guyon's canal or slightly distal to it, it gives off a superficial sensory terminal branch that innervates the palmar aspect of the 5th finger; it also provides sensation dorsally to these digits

The deep motor branch (given off in Guyon's canal or slightly distal to it) innervates:

1. The muscles of the hypothenar eminence:
 - a. Opponens digiti minimi
 - b. Abductor digiti minimi
 - c. Flexor digiti minimi brevis
2. In the hand it innervates:
 - a. The 3rd and 4th lumbrical muscles
 - b. Dorsal interossei
 - c. Palmar interossei
 - d. The deep head of the flexor pollicis brevis
 - e. Adductor pollicis
3. The ulnar nerve is the most commonly injured nerve at the elbow

Clinical Manifestations

1. Injury from the axilla to the upper elbow:
 - a. As there are no branches of the ulnar nerve in the upper arm, proximal lesions cause deficits similar to those that occur from lesions at the elbow

Pathogenesis of Proximal Ulnar Neuropathy

1. Trauma
2. Compression (sleep, operative positioning, coma)

3. Soft tissue or peripheral nerve tumors
4. AV fistula
5. Vasculitis
6. Multifocal motor neuropathy
7. Multifocal acquired demyelinating motor and sensory neuropathy

Laboratory Evaluation

1. EMG:
 - a. Reduced ulnar and dorsal ulnar nerve SNAPs amplitude
 - b. The lateral antebrachial cutaneous SNAP is normal
 - c. Ulnar CMAP demonstrates reduced amplitude without focal slowing or conduction block across the elbow
 - d. Denervation of ulnar innervated muscles of the hand and forearm
 - e. Demonstration of a focal conduction block or slowing of CV of the ulnar CMAP between the axilla and above the elbow areas
2. High resolution ultrasound
3. MRI neurography

Ulnar Neuropathy at the Elbow

General Characteristics

1. Anatomical variant of the cubital tunnel (dense fibrous band)
2. Epitrochleoanconeus muscle may occur between the medial epicondyle and the olecranon process in the ulnar groove
 - a. Tardy ulnar palsy is defined as a neuropathy that occurs following bone injuries at the elbow

Clinical Manifestations

1. Motor deficits include:
 - a. Weakness of flexion of the hand at the wrist
 - b. Loss of flexion of the 4th and 5th digits
 - c. Loss of spreading of the fingers and their opposition (interossei)
 - d. Loss of grip strength
 - e. Weakness of flexion of the little finger at the distal interphalangeal joint is the most sensitive test of forearm muscle weakness
 - f. Patients may present with intrinsic hand muscle atrophy; lateral displacement and loss of control of the 5th finger
 - g. Claw hand deformity (late manifestation)
2. Sensory deficits:
 - a. Initially, there is intermittent hyperesthesia in the ulnar nerve distributions that is exacerbated by elbow flexion; symptoms abate with elbow extension; rarely symptoms may be restricted to the hand
 - b. Decreased sensation of the ulnar aspect of the palm, the volar surface of the 5th digit and the ulnar side of the 4th digit. The dorsal sensory branch supplies the dorsal $\frac{1}{2}$ of the 4th finger and the entire 5th digit

- i. Tactile deficit is greater than that to pinprick loss; both may be lost over the distal two phalanges of the 5th finger
3. Ulnar nerve innervation stops at the skin crease of the wrist (it may extend above the wrist in a small triangular area)
 - a. Proximally the innervation of the forearm is from the antebrachial cutaneous nerve of the forearm and not the ulnar nerve
4. Pathogenesis of ulnar neuropathy at the elbow:
 - a. Tardy ulnar palsy:
 - i. Deformities of the elbow (not allowing full extension or changing the angle of extension) that are related to old fractures of the humerus or trauma to the joint
 - ii. Bone spur at the distal end of the humerus
 - iii. Malalignment after supracondylar fracture of the humerus with valgus deformity
 - iv. Subluxation of the ulnar nerve:
 1. 10 to 20% are asymptomatic
 2. Congenital laxity of the aponeurosis
 3. Direct trauma
 4. Repetitive flexion and extension of the elbow
 5. Controversial:
 - a. That repeated subluxation may cause a clinically significant ulnar palsy
 - v. Compression by the arcade of Struthers (medial intramuscular symptoms)
 - vi. Compression by an aponeurotic band between the heads of the flexor carpi ulnaris
 - vii. Compression by a retrocondylar ligament or fibrous band
 - viii. Soft tissue tumor
 - ix. Leprosy
 - x. Associated with diabetes mellitus
 - xi. Lesions within the cubital tunnel:
 1. Osteophytes from an old fracture or arthritis
 2. Synovitis associated with rheumatoid arthritis
 3. Tumors of the elbow joint
 4. Epitrochleoanconeus ligament
 5. Chondromatosis
 6. Ganglion of the ulnar nerve sulcus

Laboratory Evaluation

1. EMG:
 - a. Ulnar and dorsal ulnar cutaneous SNAP amplitude reduction
 - b. Slow CV between above and below the elbow; conduction block may be demonstrated
 - c. Inching method to determine the site of pathology (the nerve is stimulated every 1–2 cm from 5 cm below to 5 cm above the elbow)
 - d. In neuropraxia or demyelinating lesions, there may be just reduced recruitment of MUAPs
 - e. Short segment nerve conduction studies (SSNCS)
 - f. Conduction slowing and conduction block

2. High resolution ultrasound:
 - a. Changes increase sectional area (CSA) and swelling ratio measurements are equally sensitive
3. MRI neurography

Ulnar Neuropathy at the Wrist/Hand

General Characteristics

1. Guyon's canal:
 - a. The proximal border is the pisiform bone; distally, the hook of the hamate bone
 - b. Floor of the canal:
 - i. Transverse carpal ligament; hamate triquetral bones
 - c. Roof:
 - i. The pisohamate ligament that extends from the hook of the hamate to the pisiform bone
2. Sites of Damage
 - a. Guyon's canal (or slightly proximal to it)

Clinical Manifestations

1. There is damage to the superficial sensory and deep motor branches of the distal ulnar nerve:
 - a. Weakness of all ulnar innervated hand muscles with consequent loss of flexion of the 4th and 5th digits; deficient abduction and adduction of the digits (interossei); particularly noticeable atrophy of the first dorsal interosseous muscle; loss of flexion of the metacarpal phalangeal joint of the 4th and 5th digit)
 - b. Loss of function of the hypothenar muscles
 - c. Sensory loss of the volar aspect of the medial 4th finger and the entire 5th finger; more proximal lesions spare the dorsal ulnar cutaneous nerve that supplies the dorsum of the hand
 - d. There is normal strength of the flexor carpi ulnaris and flexor digitorum profundus III and IV

Pathogenesis of Nerve Injury in Guyon's Canal

1. Ganglion of the triquetral hamate joint
2. Fracture of the metacarpal bones
3. Lipoma
4. Pisohamate arthritis
5. Dislocation of the pisiform bone
6. Dislocation of the distal ulnar bone
7. Degenerative arthritis
8. Rheumatoid arthritis
9. Diabetes mellitus

Laboratory Evaluation

1. EMG:
 - a. The ulnar SNAP may demonstrate a prolonged distal latency or reduced amplitude; the dorsal ulnar cutaneous SNAP is normal (branches off prior to the canal)
 - b. Reduced CMAPs of the abductor digiti minimi and the first dorsal interosseous
 - c. Denervation of the first dorsal interosseous and abductor digiti minimi with normal flexi carpi ulnaris and flexor digitorum profundus III and IV

*Compression Just Proximal to Guyon's Canal***Clinical Manifestations**

1. The superficial branch of the ulnar nerve is affected with:
 - a. Loss of sensation in the ulnar $\frac{1}{2}$ of the palm and half of the 4th finger and the entire 5th finger; dorsal hand is moved
 - b. Motor function is normal
2. Pathogenesis of the nerve injury
 - a. Laceration

Laboratory Evaluation

1. EMG:
 - a. Decreased amplitude and prolonged latency of the ulnar SNAP

Compression in the Hand*Clinical Manifestations*

1. Injury is distal to the branching of the superficial sensory branch
2. Sensation is spared
3. Partial damage to the ulnar innervated intrinsic hand muscles

Pathogenesis of the Nerve Injury

1. Prolonged pressure in the palm of the hand (bike riding, industrial tools)
2. Trauma
3. Laceration

Laboratory Evaluation

1. EMG:
 - a. The ulnar SNAPS are normal
 - b. The CMAPs of the first dorsal interosseous and the digiti minimi are decreased in amplitude and the muscles are denervated

Compression Distal to the Branch Innervating the Hypothenar Eminence*Clinical Manifestations*

1. The interossei and adductor pollicis muscle are affected; a more distal lesion can separately affect the adductor pollicis or the first dorsal interosseous muscle

Pathogenesis of the Nerve Injury

1. Sustained palmar pressure
2. Laceration
3. Trauma

Laboratory Evaluation

1. EMG:
 - a. Ulnar SNAPS and CMAPs of the abductor digiti minimi are normal; the CMAP from the dorsal interosseous muscle would be abnormal
 - b. Denervation of the dorsal interossei and adductor pollicis muscles
2. High resolution ultrasound
3. MRI neurography

Digital Nerve Entrapment in the Hand*General Characteristics*

1. Compression neuropathy in the palm and digits is much less common than proximal compression

Clinical Manifestations

1. Hyperesthesia in the finger or fingers is the most common symptom
2. The proper digital nerve innervates the lateral and medial side of each digit; rarely pain rather than paresthesia is the presenting symptom
3. May be associated with digital Raynaud's syndrome
4. Positive Tinel's sign over the entrapped nerve
5. Digital nerve involvement in the palmar causes numbness in the adjacent side of the digit

Pathogenesis of Nerve Injury

1. Acute external blunt trauma to the palm or digit
2. Dislocation or fracture
3. Bowler's thumb; pain on the ulnar side of the base of the thumb
4. Neuroma-in-continuity associated with perineural and intraneural fibrosis:
 - a. Tinel's sign with lancinating digital pain
5. Cysts of the flexor tendon sheath (proximal flexion crease)
 - a. Volar and lateral extension is painful
6. Degenerative arthritis of the digit
7. Tumors:
 - a. Periosteal chondroma
 - b. Lipoma (from the flexor tenosynovium)
 - c. Schwannoma of the digital nerve
 - d. Fibrosarcoma
8. Rheumatoid flexor tenosynovitis (may compress the common or proper digital nerve within the lumbrical canal)
9. Dupuytren's contracture

Entrapment Neuropathies of the Lower Extremity**Sciatic Nerve***General Characteristics*

1. Originates from the L4–S3 spinal segments; the L4–L5 segments join the nerve from the lumbosacral trunk
2. The nerve is formed by the merger of the superior and inferior gluteal nerves; its lateral division is the peroneal nerve, and the medial division is the tibial nerve
3. The peroneal nerve has minimal innervations from S3 whereas there is minimal L4 contribution of the tibial nerve
4. Prior to the formation of the sciatic nerve, there are two major branches that arise from the upper sacral spinal nerves:
 - a. The pudendal nerve:
 - i. Arises from S2–S4 spinal nerves

- ii. The posterior cutaneous nerve of the thigh from S1–3 spinal nerves
 - iii. The merger of S1–S3 segments and the lumbosacral trunk is the beginning of the sciatic nerve which occurs lateral and anterior to the sacrum
5. The two major sciatic nerve branches in the pelvis are the superior and inferior gluteal nerves:
 - a. The superior gluteal nerve originates from L4–S1 roots
 - b. The inferior gluteal nerve originates from L5–S1 roots
6. The superior gluteal nerve:
 - a. Exits the sciatic notch above the piriformis muscle (originates from the front of the ramus, the gluteal surface of the ilium and the anterior capsule of the sacroiliac joint; it inserts on the greater trochanter)
 - b. Innervates:
 - i. Gluteus medius and minimus
 - ii. Tensor fascia lata
 - c. Abducts the thigh at the hip and internally rotates the thigh:
 - i. Gluteus minimus (small contribution to thigh flexion)
 - ii. Posterior component of the gluteus medius contributes to external rotation of the thigh
7. The inferior gluteal nerve:
 - a. Innervates the gluteus maximus
 - i. The primary thigh extensor
 - ii. Contribution to external thigh rotation
8. There is no sensory component to either the superior or inferior gluteal nerves

The Pudendal Nerve

General Characteristics

1. Originates from spinal segments S2–S4
2. Leaves the pelvis in the caudal component of the sciatic notch proximate to the sacrococcygeal junction
3. The three branches of the pudendal nerve are:
 - a. Inferior rectal
 - b. Perineal
 - c. Dorsal nerve of the penis/clitoris
4. Inferior rectal branch:
 - a. Innervates the external and internal sphincter
 - b. Provides sensation to the distal anal canal and perineal areas
5. The perineal nerve:
 - a. Innervates the muscles of the pelvic floor, the external urethral sphincter and the erectile tissue of the corpus cavernosa of the penis
 - b. It's sensory territory includes the perineum ventral to the rectum, the scrotum, and labia. The dorsal nerve of the penis is a purely sensory branch that supplies sensation to the penis and/or labia and clitoris

The Posterior Cutaneous Nerve of Thigh

1. Origin is spinal segment S1–S3
2. Leaves the pelvis through the lower sciatic notch

3. Lies beneath the gluteus maximus
4. It gives off clinical branches at the level of the gluteal crease that innervates the inferior buttock
5. Its perineal branches innervate:
 - a. Skin and fascia of the lateral perineum
 - b. The proximal medial thigh
 - c. Posterior areas of the scrotum/labia and root of the penis/clitoris
 - d. The terminal branch innervates:
 - i. The posterior thigh and in some individuals the proximal portion of the posterior calf

At the Sciatic Notch

General Characteristics

1. The sciatic nerve passes under the piriformis muscle in approximately 70% of individuals. There is variation in whether the peroneal nerve passes along, through or above the muscle. Rarely the entire nerve passes through the muscle
2. In general, the sciatic nerve divides into the common peroneal and tibial nerve in the upper angle of the popliteal fossa. It may divide in the back of the thigh or, rarely, in the pelvis. The nerve has been described as dividing into its two major divisions at various levels from the sacral plexus to the lower thigh. The nerve descends lateral to the Ischial tuberosity and medial to the greater trochanter of the proximal femur
3. The tibial component of the sciatic nerve (medial trunk) innervates:
 - a. The semitendinosus muscle
 - b. The semimembranosus muscle
 - c. The long head of the biceps femoris
 - d. Sends a branch to the adductor magnus muscle
4. Lesions of the sciatic nerve proximal to the knee cause loss of sensation to the entire foot and the distal half of the lateral surface of the leg. The medial lower leg sensory supply is from the saphenous nerve that derives from the L4 spinal segment
5. The blood supply to the sciatic nerve derives from the inferior gluteal artery and popliteal arteries. This creates a watershed between the two arteries at the mid-thigh level that is significant in atherosclerosis and vasculitic processes
6. In the leg:
 - a. The common peroneal nerve bifurcates into the deep and superficial divisions below the fibular head
 - b. The deep peroneal nerve:
 - i. Innervates the anterior compartment of the lower leg, which includes the following muscles:
 1. Tibialis anterior
 2. Extensor hallucis longus
 3. Extensor digitorum longus
 - ii. In the foot it innervates the extensor digitorum brevis (EDB)
 - iii. The function of the muscles innervated by the deep peroneal nerve is to dorsiflex the foot at the ankle and the toes at the metatarsal-phalangeal joints

- c. The superficial peroneal nerve:
 - i. Innervates the lateral compartment of the leg, which includes the following muscles:
 - 1. Peroneus longus muscle
 - 2. Peroneus brevis muscle
 - ii. The function of these muscles is to evert the foot at the ankle
 - iii. The sensory innervation of the deep peroneal nerve is the interdigital space between the first and second digits; the superficial peroneal nerve supplies cutaneous sensation to the dorsum of the foot and the distal lateral leg
- d. The tibial nerve:
 - i. Arises from L5–S3 nerve roots and is the continuation of the medial cord of the sciatic nerve
 - ii. After dividing from the peroneal nerve in the distal thigh:
 - 1. It transverse the popliteal fossa and enters the leg anterior to the heads of the gastrocnemius muscle
 - 2. In the thigh it innervates:
 - a. Semitendinosus
 - b. Semimembranosus
 - c. Long head of the biceps femoris
 - 3. In the leg it innervates:
 - a. The posterior compartment
 - b. Both heads of the gastrocnemius muscle
 - c. Soleus
 - d. Tibialis posterior
 - e. Flexor digitorum longus
 - f. Flexor hallucis longus
 - 4. In the foot it innervates:
 - a. All intrinsic foot muscles except the EDB (superficial peroneal nerve)
 - 5. Functions of the muscle supplied by the posterior tibial nerve:
 - a. Flexes the leg at the knee
 - b. Plantar flexes and inverts the foot at the ankle
 - c. Flexes, abducts and adducts the toes
 - 6. The three cutaneous components of the tibial nerve branch at the medial malleolus and include:
 - a. The medial and lateral plantar nerves:
 - i. Supply the medial and lateral plantar surfaces of the anterior 2/3 of the sole
 - b. Calcaneal nerve
 - i. Supplies the heel
 - 7. The sural nerve:
 - a. Arises from the common peroneal and tibial nerves in the popliteal fossa
 - b. Its origin is primarily the S1 spinal root
 - c. It has two branches:
 - i. Medial cutaneous branch, which arises from the tibial nerve
 - ii. Lateral cutaneous from the common fibular nerve

- d. Courses down the posterior lateral side of the leg and enters the foot posterior to the lateral malleolus below the fibularis tendon sheath
- e. Provides sensation to the posterior lateral portion of the distal leg and the lateral foot as well as the fifth digit

Clinical Manifestations

- 1. Paresthesias, pain and sensory loss in its cutaneous distributions

Pathogenesis of Nerve Injury

- 1. Entrapment due to fascial thickening
- 2. Ganglion
- 3. Lipoma
- 4. Heel straps
- 5. Repetitive ankle sprains
- 6. Ankle fractures
- 7. Gastrocnemius muscle injury

Laboratory Evaluation

- 1. EMG:
 - a. Increased distal latency and decreased SNAP of the nerve
- 2. High resolution ultrasonography
- 3. MRI neurography

Piriformis Syndrome

General Characteristics

- 1. Controversial; it is suggested that the sciatic nerve can be compressed at the pelvic outlet by the piriformis muscle
- 2. There are anomalous relationships between the sciatic nerve and the piriformis muscle which often do not correlate clinically
- 3. Some patients (women > men) demonstrate an anomalous band or vessel in the sciatic notch in proximity to the sciatic nerve

Clinical Manifestations

- 1. Buttock pain and tenderness without sciatic nerve pain radiations
- 2. Sciatic notch point tenderness
- 3. The pain is exacerbated by sitting and rarely by bending at the waist
- 4. Pain may also be produced by maneuvers that require hip adduction and internal rotation; the pain may be relieved by standing and walking
- 5. Positive Trendelenburg sign
- 6. No weakness, reflex change or hand sensory loss
- 7. Leg may be slightly externally rotated with walking
- 8. Rarely, positive Freiberg, Pace and Beatty tests:
 - a. Pain on adduction, internal rotation and flexion of the thigh
- 9. Rarely mild wasting of the gluteus maximus

Pathogenesis of Nerve Injury

1. Myofascial band between the bicep femoris and the adductor magnus (compresses the nerve)
 - a. Distal thigh pain above the posterior popliteal fossa
2. Muscle spasm with piriformis compression of the nerve caused by rheumatic disease, bursitis or trochanteric disease at its insertion
3. Minimal trauma to the buttock
4. Sciatic nerve compression from muscle fibrosis (pentazocine infections)

Laboratory Evaluation

1. EMG:
 - a. NCVs are usually normal
 - b. Denervation in both peroneal and tibial divisions; peroneal branch usually is more affected
 - c. The short head of the biceps is less affected than other hamstring muscles
 - d. Flexor digitorum longus and medial and lateral gastrocnemius muscles may show fibrillation potentials
2. Botulinum toxin injection into the muscle:
 - a. Relieves spasm
 - b. Blocks pain afferents
3. MRI neurography
4. Diagnostic and therapeutic analgesic block of the muscle
 - a. Percutaneous lidocaine and depomedrol injection under fluoroscopic guidance

Sciatic Nerve Injury at the Hip or Thigh**General Characteristics**

1. The lateral greater than the medial division of the nerve is affected due to the difference of the fasciculi pattern of the nerve and its course in the epineurium

Clinical Manifestations

1. Foot drop; the peroneal component of the nerve is more affected than the tibial
2. Slight weakness of the hamstrings, gastrocnemius, and posterior tibial muscles
3. Rarely, a high sciatic lesion may manifest as a pure peroneal palsy
4. Depressed or absent ankle jerk
5. Decreased sensation on the side and lateral foot; sensation is spared around the medial malleolus (saphenous nerve cutaneous territory)
6. Instability of the foot
7. The gait is impaired due to knee and ankle instability

Pathology of the Nerve Injury at the Hip and Thigh Level

1. Sciatic mononeuropathy is uncommon; most diseases affect the L4–S3 nerve roots; these processes usually compromise only one or two roots and include:
 - a. Disc disease
 - b. Lumbar spondylosis

- c. Spondylolisthesis
- d. Intervertebral osteophytes in the nerve exit foramina
- e. Metastatic disease
2. Hip replacement surgery:
 - a. 1 to 3% of patients injure the nerve during hip joint replacement surgery (much higher percentage by EMG criteria)
 - b. Higher incidence of sciatic nerve damage in:
 - i. Total hip revisions
 - ii. Surgery requiring limb lengthening
 - iii. Congenital dysplasia or dislocation:
 1. Usually noted following surgery
 2. Most often a neuropraxic (stretch) injury
3. Rarer causes of surgical injury:
 - a. Methylmethacrylate leakage
 - b. Traction dislocation
 - c. Migrating traction wire
 - d. Hemorrhage
 - e. Prosthetic dislocation
4. Hip fracture and femur fracture
 - a. Injury occurs during internal fixation or closed reduction
5. External compression of the nerve:
 - a. Coma
 - b. Poor positioning during anesthesia:
 - i. Gluteal or posterior thigh compartment syndrome
 - ii. "Toilet seat" compression
 - iii. Lotus position (yoga)
 - iv. Operative sitting procedures
 - c. Malignant or benign tumors
 - d. Heterotopic ossification following trauma
 - e. Enlargement of the lesser trochanter
 - f. Persistent sciatic artery
 - g. Severe direct trauma; gunshot or stab wounds
 - h. Improper injections (often only the peroneal component is affected)
 - i. May be delayed due to fibrosis
 - i. Hemorrhage within the gluteal compartment:
 - i. Anticoagulation
 - ii. Hemophilia (rare; usually bleeding is into joints)
 - iii. Following hip surgery
 - iv. Rupture of an iliac artery aneurysm
 - j. Endometriosis:
 - i. Catamenial sciatica
 - ii. Starts prior to menstruation and ceases with its end
 - k. Ischemic Nerve Injury
 - i. Watershed between the descending inferior gluteal artery and the ascending popliteal artery in the mid-thigh
 1. Inflammation and occlusion of the vasa vasorum (autoimmune vasculitis)
 2. Atherosclerosis
 3. Iliac or femoral artery occlusion
 4. Prolonged catheter in the femoral artery for interventional procedures
- l. Congenital Lesions

- m. Hereditary neuropathy with liability to pressure palsies (HNPP) deletion on chromosome 17

Differential Diagnosis of Sciatic Nerve Injury

1. Peroneal nerve lesion at the fibular neck:
 - a. Tinel's sign over the nerve at the fibular neck
 - b. Foot pain is rare
 - c. No back pain or L4–S3 radiations
 - d. Negative stretch maneuvers (straight leg raising test)
 - e. Normal ankle jerk
 - f. Intact inversion, plantar and toe flexion
 - g. Sensory loss between the great toe and first digit
2. Herniated Lumbar Disc:
 - a. Usually long standing back pain (may be acute)
 - b. Position of comfort is flexed knee in recumbency
 - c. Cough, sneezing, laughing are all painful as are all valsalva maneuvers (extrude the disc dorsolaterally into the exit foraminal canal)
 - d. Monoradicular symptoms: S1 > L5 > L4 radiations
 - e. Proximal pain is primarily in the buttocks or posterior thigh
 - f. Often bilateral asymmetric symptoms (loss of maintenance of the foraminal exit canal and foramina on the involved and uninvolved side)
3. Spinal stenosis:
 - a. L4–L5 > L5–S1 levels; may involve mid-lumbar to mid-sacral levels; primarily epidural compression; common in elderly patients with degenerative osteoarthritis
 - b. Progressive calf and foot pain induced by walking and relieved by rest (usually patients are able to walk further than patients suffering from arterial intermittent claudication)
 - c. Frequent calf neurogenic cramps (often misdiagnosed as vascular claudication)
4. Vascular monomelic neuropathy:
 - a. Primarily occurs in diabetic or those with severe atherosclerosis
 - b. Often has an acute onset (over several days)
 - c. Leg muscle wasting may be prominent
 - d. No back pain; the pain in the calf is more burning (protons activating acid sensors on C-fibers; rather than the deep "charlie horse" pain of neurogenic cramps)
 - e. Sciatic symptoms are mixed with those of the femoral or saphenous nerves
 - f. Prior history of leg ischemia
 - g. The sensory loss is "stocking"; with sciatic lesions, the saphenous territory is spared
5. Malignancy of the Spinal Cord
 - a. Intraspinal tumor:
 - i. The gastrocnemius is more severely involved than the anterior tibialis or extensor hallucis longus
 - b. Lymphoma:
 - i. The tumor has a tendency to incase the lumbosacral cord and roots (by MRI)

- ii. Often involves the lower sacral roots
- c. Myeloma:
 - i. There may be root compression by fracture and displacement of vertebral bones
 - ii. Loss of marrow signal at multiple spinal levels on MRI

The Peroneal Nerve

General Characteristics

1. A motor branch exits near the gluteal fold to innervate the short head of the biceps femoris
2. In the popliteal fossa:
 - a. Exit of the lateral cutaneous nerve of the calf (upper 1/3 of the lateral leg)
 - b. Gives off a branch to join a branch from the tibial nerve to form the sural nerve
3. The common peroneal nerve passes through the fibular tunnel (tendon of the peroneus longus muscle and the fibula) and then divides into deep and superficial branches:
 - a. Anterior peroneal nerve (the deep peroneal branch)
 - i. Courses in the anterior compartment of the leg and innervates:
 1. Tibialis anterior
 2. Extensor hallucis longus
 3. Extensor digitorum longus
 4. Peroneus tertius
 - b. Under the extensor retinaculum nerve the nerve divides into:
 - i. The lateral motor branch that innervates the extensor digitorum brevis (EDB)
 - ii. A medial sensory branch that supplies cutaneous sensation to the web spaces between the great and second toe

Clinical Manifestations

1. Foot drop with steppage gait
2. Weakness of the tibialis anterior, extensor hallucis longus and extensor digitorum longus
3. Sensory loss of the web space between the great and second toe
4. Distal deep peroneal lesions (traction injuries from an ankle sprain) cause selective weakness of the toe extensors with normal ankle dorsiflexion

Pathology of the Nerve Injury

1. Fracture and sprains of the lower leg
2. Prolonged squatting
3. Pneumatic compression
4. Knee arthroplasty
5. High tibial osteotomy
6. Synovial cysts
7. Schwannoma and other tumors (particularly nerve sheath tumors)
8. Distal tibial osteochondroma
9. Femoral distal extension osteotomy

Laboratory Evaluation

1. EMG:
 - a. Reduced CMAPs amplitudes in the tibialis anterior extensor digitorum longus, and extensor digitorum brevis
 - b. Normal superficial peroneal SNAP
2. High resolution ultrasound
3. MRI neurography

Superficial Peroneal Nerve*General Characteristics*

1. Innervates the peroneus longus and brevis muscles of the lateral compartment
2. In the distal leg, it becomes the superficial peroneal sensory nerve:
 - a. It is subcutaneous 40 cm proximal to the lateral malleolus
 - b. Its intermediate and medial cutaneous branches innervate this skin of the lower 2/3 of the leg and the dorsum of the foot except for the web space between the first and second toe
3. Accessory or deep peroneal nerve:
 - a. Occurs in approximately 20% of people and arises as a continuation of the muscular branch of the superficial peroneal nerve and innervates the peroneus brevis muscle proximally
 - b. Distally it innervates part of the extensor digitorum brevis (EDB), the ankle joint and its ligament

Clinical Manifestations

1. Weak eversion of the foot
2. Sensory loss of the lower lateral leg and dorsum of the foot that is exacerbated with walking or running
3. Tinel's sign at 10 cm proximal to the lateral malleolus (where the nerve becomes subcutaneous)
4. Pain in the distal anterolateral leg
5. Ankle pain with or without numbness over the dorsum of the foot if the nerve is affected at the ankle; increased pain with plantarflexion or inversion

Pathogenesis of Nerve Injury

1. Iatrogenic causes:
 - a. Arthroscopy
 - b. Local anesthetic block
 - c. Surgical approach to the fibula
 - d. Open reduction and internal fixation of lateral malleolar fractures
 - e. Application of external fixators
 - f. Elevation of a fasciocutaneous or fibular flaps for grafting
 - g. Surgical decompression of neurovascular structures:
 - i. Blunt trauma
 - ii. Lipoma
 - iii. Boot or shoe straps
 - iv. Neuroma

Laboratory Evaluation

1. EMG:

- a. Decreased amplitude, prolonged latency or absence of superficial peroneal SNAPs

Common Peroneal Nerve at the Fibular Neck*General Characteristics*

1. It courses between the tendon of the biceps femoris and lateral head of the gastrocnemius muscle and then passes around the neck of the fibula between the peroneus longus and the bone; it divides into its superficial and deep branches beneath the muscle
2. It gives off articular branches, which course with the superior and inferior genicular arteries to the knee
3. The recurrent articular branch is given off at the division of the nerve; it ascends with the anterior tibial artery through the tibialis anterior muscle to supply sensation to the front of the knee
4. It innervates the short head of the biceps close to the gluteal cleft
5. Men are affected more than women 3:1
6. Right side and left are affected equally; it is bilaterally affected in 10% of patients

Clinical Manifestations

1. The symptoms and signs occur from the pathology of its branches
2. If the superficial branch is more affected:
 - a. Weakness of foot eversion; the invertors of the foot and toe and foot plantar flexion are spared
 - b. Sensory loss is noted in the lower 2/3 of the lateral leg
3. Rarely Tinel's sign is positive at the fibular neck
4. The ankle jerk is intact

Pathogenesis of Nerve Injury

1. Bed rest of long duration
2. Hyperflexion of the knee
3. Pressure in obstetrical stirrups
4. Compression from habitual leg crossing
5. Blunt trauma

Laboratory Evaluation

1. EMG
2. High resolution ultrasonography
3. MRI neurography

Acute Peroneal Palsy at the Fibular Neck*General Characteristics*

1. Few or no sensory symptoms

Clinical Manifestations

1. Foot drop; loss of function of the deep peroneal branch is more often seen than that of the superficial branch

Pathogenesis of the Nerve Injury

1. Compression:
 - a. Poor positioning during anesthesia

2. Coma
3. Habitual leg crossing
4. Weight loss
5. Positional (yoga; childbirth)
6. Casts
7. Lithotomy position with stirrups
8. Pneumatic compression devices
9. Trauma:
 - a. Blunt and direct trauma
 - b. Tibial plateau fracture
 - c. Dislocation of the knee
 - d. Knee joint ligament rupture
 - e. Arthroscopic knee surgery
 - f. Knee joint replacement

Differential Diagnosis of Deep Peroneal Neuropathy at the Fibular Neck

1. L5 radiculopathy
 - a. There is normal ankle inversion and toe flexion in peroneal palsy; it is weakened in L5 radiculopathy
2. Anterior compartment syndrome:
 - a. Follows contusion or fracture; hemolytic toxin snake envenomation
 - b. Strenuous exercise
 - c. The anterior compartment contains:
 - i. Anterior tibialis
 - ii. Extensor digitorum longus
 - iii. The extensor digitorum brevis is outside the compartment
 - iv. All muscles of the compartment are weakened; the EDB may be denervated when the peroneal nerve is involved
 - d. Differential points favoring an anterior compartment syndrome versus deep peroneal nerve palsy:
 - i. Severe pain (peaks 1–3 days in anterior compartment syndrome after the inciting event)
 - ii. Exacerbation of pain on toe and planar flexion of the ankle
 - iii. Swelling and heat over the compartment
 - iv. Tissue pressure above 60 mm Hg is diagnostic at the ankle (in compartment syndrome)
3. Forcible inversion of the foot may cause hemorrhage into the nerve trunk
4. Prolonged squatting position (the tendon of the posterior border of the peroneus longus at the fibular head or the tendon of the biceps femoris of the distal thigh may compress the nerve)
5. Rarely the nerve may be compressed between the fibular and the tendinous edge of the peroneus longus muscle

Mass Lesions That Compress the Deep Peroneal Nerve

1. Ganglia from the superior tibia-fibular joint (originate from the synovial membrane)
2. Baker's cyst
3. Osteochondroma
4. Giant cell tumor
5. Pseudoaneurysm (genicular artery)

Laboratory Evaluation

1. EMG:
 - a. Denervation of the anterior tibialis, extensor hallucis longus (EHL), extensor digitorum longus, extensor digitorum brevis, and the extensor hallucis brevis
 - b. Need to rule out proximal common peroneal mononeuropathy by demonstrating no denervation of the short head of the biceps femoris and normal conduction studies of the common peroneal nerve
2. High resolution ultrasonography
3. MRI neurography

Sciatic Mononeuropathy Affecting the Lateral Division (Peroneal Component)

General Characteristics

1. In high- or mid-sciatic nerve injury, the lateral (peroneal division) is affected more frequently than the medial (tibial division)
2. The peroneal division has fewer and larger nerve fascicles with less supportive tissue
3. The peroneal nerve is fixed at the sciatic notch and fibular neck (more taut than the tibial nerve)

Clinical Manifestations

1. Similar to a lesion at the fibular neck, but with subtle tibial nerve (medial division) involvement that includes:
 - a. Slight weakness of the anterior tibialis muscle
 - b. Weak ankle inversion
 - c. Sensory loss in the upper lateral third of the leg (territory of the lateral cutaneous nerve of the calf that takes origin from the common peroneal nerve proximal to the fibular neck)

Pathogenesis of the Nerve Injury at the Sciatic Level

1. Hip trauma
 - a. Fracture/dislocation (femur)
 - b. Hip joint replacement
 - c. Abnormal positioning
2. Gluteal injection (penicillin; iron)
3. Gluteal compartment syndrome

Laboratory Evaluation

1. Denervation of the short head of the bicep femoris (the only hamstring muscle innervated by the peroneal nerve)
2. High resolution ultrasound
3. MRI neurography

Deep Peroneal Neuropathy at the Ankle (Anterior Tarsal Tunnel Syndrome)

General Characteristics

1. The floor is the fascia overlying the talus and tarsal bones; the roof is the inferior extensor retinaculum
2. The entrapment is of the distal segment of the deep peroneal nerve

Clinical Manifestations

1. May be unilateral or bilateral
2. More common in women than men
3. Numbness and paresthesias in the deep peroneal sensory distribution (web space between the great and second toe)
4. Wasting of the EDB
5. Ankle and foot pain is often worse at night

Pathogenesis of the Nerve Injury

1. Pressure from straps, shoe rims
2. Ganglion cysts
3. Pes cavus
4. Osteophytes of the talonavicular bones
5. Plantar flexion of the foot with extension of the toes (high heels)
6. Extreme inversion of the foot as occurs in dystonia or spasticity

Laboratory Evaluation

1. EMG:
 - a. Neurogenic MUAP of the distal segment of the peroneal nerve
 - b. Prolonged latency of the distal peroneal branch to EDB
 - c. Denervation of EDB
2. High resolution ultrasonography
3. MRI neuropathy

Differential Diagnosis of Unilateral Foot Drop

1. Hereditary sensory motor neuropathy/Charcot-Marie-Tooth
 - a. Pes cavus; usually atrophy of all muscles below the knee
 - b. Approximately 10% of patients have a flat foot ("rocker bottom")
 - c. There is foot and ankle weakness in all fields of movement
 - d. Weakness of ankle and toe dorsiflexion with intact plantar flexion is a true foot drop
 - e. HSMN/CMT are overwhelmingly bilateral
2. Deep peroneal neuropathy
3. Common peroneal palsy at the fibular neck
4. L4 and L5 radiculopathy (usually not as severe as with the nerve injury)
5. Poliomyelitis
6. Post-polio syndrome:
 - a. Often associated with pain
 - b. Occurs after a period of stability
7. Cerebrovascular disease:
 - a. Anterior cerebral artery infarction:
 - i. The shoulder is often involved
 - ii. All muscles of the foot are involved
 - iii. Dense sensory loss of cortical pattern in the lower leg and foot
 - iv. Loss of ankle jerk acutely

- b. Lacunar infarction of the corona radiata (penetrating medullary artery)
 - c. Lacunar infarction of the ventral pons (lateral area)
8. ALS:
 - a. Painless foot drop may be a common presentation
 - b. Fasciculations in diffuse muscles
 - c. Hyperactive reflexes
 9. Anterior compartment syndrome:
 - a. Severe swelling and pain
 - b. All muscles of the compartment are involved
 - c. In the face of excessive repetitive movements, snake envenomation, rhabdomyolysis
 10. Lumbosacral plexopathy:
 - a. Weak toe and weak plantarflexion
 11. Hereditary neuropathy with sensitivity to pressure palsy (deletion of chromosome 17):
 - a. Concomitant involvement of other nerves or past involvement of other nerves with recovery
 12. Mononeuritis multiplex:
 - a. Setting of autoimmune disease
 13. Multifocal motor neuropathy with conduction block:
 - a. GM1 ganglioside antibodies
 - b. Usually, the upper extremities are affected first
 14. Parasagittal meningioma:
 - a. Usually, presents with a seizure
 15. L5 radiculopathy
 - a. Greater weakness of EHL than the anterior tibialis muscle
 - b. Ankle jerk is intact as it is primarily innervated by the S1 root
 - c. The usual cause of L5 radiculopathy is a herniated nucleus pulposus with pain radiations that include:
 - i. Lower back and posterior thigh; hip pain, great toe, and dorsum of the foot
 16. Posterior tibial nerve neuropathy:
 - a. Inversion weakness of the foot

Differential Diagnosis of Bilateral Foot Drop

1. Neuropathies:
 - a. GBS (subacute; usually with numbness)
 - b. CIDP (depressed reflexes throughout)
 - c. MMNCB (GM1 antibody, asymmetric; upper extremity often affected first)
 - d. Bilateral peroneal lesions (autoimmune pathologies)
 - e. Bilateral sciatic compressive lesions
 - f. Bilateral lumbosacral plexopathies (metastasis, lymphoma, retroperitoneal hemorrhage)
2. Anterior horn cell:
 - a. ALS (usually unilateral; weakness at onset; associated upper motor neuron signs and symptoms)
 - b. Spinomuscular atrophy (SMA)
 - c. Poliomyelitis
 - d. Leukemia and lymphoma
 - e. Radiculopathies:
 - i. Cauda equina syndrome (disc; spondylolisthesis)

- ii. Conus medullaris (the bowel and bladder symptomatology is predominant over motor loss; cancer; glioma; syrinx)
- iii. If the S1 root is more involved than the L5 root, the process is more suggestive of an intraspinal lesion
- f. Myopathies:
 - i. Myotonic dystrophy (concomitant masseter, neck and distal extremity weakness)
 - ii. Facioscapulohumeral muscular dystrophy (severe facial involvement)
 - iii. Scapuloperoneal dystrophy (upper shoulder girdle is concomitantly involved)
 - iv. Distal congenital myopathies:
 - 1. Welander
 - 2. Markesbery-Griggs
 - 3. Nonaka
 - 4. Laing

Tibial Nerve

General Characteristics

1. Innervates all of the hamstring muscles except the short head of the biceps femoris (innervated by the common peroneal nerve)
2. The sural branch is given off in the upper popliteal fossa
 - a. In 80% of the population, the common peroneal nerve gives off a medial branch that joins the sural nerve
3. In the upper calf the tibial nerve lies under the tendinous arch of the soleus muscle to innervate the flexor digitorum pollicis (FDP), the flexor hallucis longus (FHL), gastrocnemius, soleus and tibialis posterior muscles
4. At the ankle, it passes posterior to the medial malleolus in the tarsal tunnel
5. Its terminal branches are:
 - a. A calcaneal branch
 - b. Medial plantar nerve
 - c. Lateral plantar nerve
6. Interdigital branches arise from the medial and lateral plantar nerves on the soles of the foot

Clinical Manifestations

1. High tibial nerve injury:
 - a. Foot pain and numbness; increased by dorsi and plantar flexion of the foot
 - b. Tenderness and positive Tinel's sign in the posterior popliteal fossa
 - c. Weakness of plantar and toe flexion and inversion of the foot
 - d. Absent ankle muscle stretch reflex

Pathogenesis of the Nerve Injury

1. Most often the nerve is injured at or near the popliteal fossa
2. Synovial cyst or superior tibial-fibular ganglion cyst
3. Fibrous band or aponeurotic arch of the soleus muscle
4. Knee surgery
5. Schwannoma and neurofibromas

Laboratory Evaluation

1. EMG:
 - a. Low amplitude or absent MUAP of the abductor hallucis and abductor digiti minimus
 - b. Sural nerve SNAP amplitude is decreased or absent depending on the location of the origin of the nerve in the popliteal fossa
2. MRI neurography
3. High resolution ultrasonography

Tibial Nerve Injury at the Ankle: The Tarsal Tunnel Syndrome

General Characteristics

1. Usually an insidious onset
2. Women have a greater incidence than men
3. In 10 to 20% of patients it is bilateral
4. Anatomy:
 - a. The roof is the laciniate ligament that extends between the medial malleolus and the calcaneum. The floor of the tunnel is the fascia overlying the navicular bones
5. The medial calcaneal nerve branches from the posterior aspect of the posterior tibial nerve in 75% of individuals and from the lateral plantar nerve in 25%
6. The medial calcaneal nerve terminates as a single branch in 80% of individuals and in numerous terminal brands in the remainder
7. There are three well defined tough fascial septae in the sole of the foot that may entrap individual branches of the nerve
8. The tunnel also contains the posterior tibial artery and the tendons of the tibialis posterior, FDL and FHL muscles

Pathogenesis of the Nerve Injury

1. Repetitive movement injures the nerves in runners and dancers
2. Rheumatoid arthritis
3. Diabetes mellitus
4. Acromegaly
5. SLE
6. Hyperlipidemia
7. Hypothyroidism
8. Ganglion cyst
9. Lipoma
10. Schwannoma
11. Varicose veins
12. Varus and valgus deformities
13. Hypertrophic or anomalous abductor hallucis muscles
14. Mobile pes planus

Clinical Manifestations

1. Burning pain and numbness on the sole of the foot and heel; the pain may radiate to the calf
2. Nocturnal pain
3. Increases with rest after activity

4. May be exacerbated by walking and jogging
5. Tinel's sign is positive over the tunnel; a component of the triple compression test (compression of the tarsal tunnel while flexing and inverting the foot)
6. In approximately 40% of patients, the calcaneal branch may be spared as it may arise proximal to the retinaculum
7. 25% of patients have the sensory loss only in the medial branch; 10% are affected only in the lateral branch
8. There may be weakness of the flexor hallucis brevis (FHB), flexor digitorum brevis (medial plantar nerve), quadratus plantae; interossei (lateral plantar nerve); these deficits impair the pushing off phase of walking and plantar flexion of the lateral toes

Laboratory Evaluation

1. EMG:
 - a. Decreased motor nerve conduction of the posterior tibial nerve; prolonged distal latency
 - b. Decreased SNAPs amplitudes and slowed NCVs of the medial and lateral plantar nerves
 - c. Rare denervation of the abductor hallucis and abductor digiti quinti
2. Ultrasonography
3. MRI neurography

Differential Diagnosis of the Tarsal Tunnel Syndrome

1. Plantar fasciitis (the entire sole is equally involved)
2. Stress fractures (lateral metatarsals, particularly the Vth)
3. Bursitis (insertion of the posterior tibial muscle)
4. Chronic regional pain syndrome type two (CRPS II); (severe allodynia, mechanical hyperalgesia, impaired foot movement and autonomic dysregulation)
5. Rheumatoid arthritis (severe joint deformities)
6. Proximal tibial mononeuropathy (compression by the tendinous arch of the soleus muscle); plantar foot flexion weakness; decreased ankle muscle stretch reflex
7. Tibial component nerve sheath tumor
8. S1 and S2 radiculopathy (concomitant weakness of the roots innervated by these muscles; associated back pain)
9. Peripheral neuropathy (usually bilateral)
10. Entrapment of the medial plantar nerve (area of the insertion of the posterior tibial nerve which originates from the calcaneus; or in the fascial canal of the sole of the foot)
11. Burning in the sole and aching in the arch of the foot; compression of the medial plantar nerve against the tuberosity of the navicular bone

Differential Diagnosis of Injury to the Medial Plantar Nerve

1. Bunion surgery
2. Pes cavus
3. Synovial cyst of the first metatarsal phalangeal joint
4. Schwannoma
5. Running and dancing
6. Prolonged standing
7. Entrapment in the sole of the foot

Differential Diagnosis of Lateral Plantar Nerve Injury

1. Trauma (particularly the Vth metatarsal fractures)
2. Schwannoma
3. Entrapment in the sole of the foot (fascial septae)

Joplin's Neuroma

General Characteristics

1. Compression neuropathy of the plantar proper digital nerve to the hallux

Clinical Manifestations

1. Pain primarily on the medial aspect of the great toe
2. Tinel's sign at the first metatarsophalangeal joint

Pathogenesis of Nerve Injury

1. Bunion surgery
2. Ill-fitting shoes
3. Trauma

Laboratory Evaluation

1. EMG
2. Ultrasonography
3. MRI neurography

Morton's Neuroma

General Characteristics

1. Anatomy:
 - a. Metatarsal tunnels are between the deep and transverse metatarsal superficial ligaments that connect the metatarsal heads
 - b. A Morton's neuroma generally refers to an interdigital neuropathy between the 3rd and 4th toes but may occur between the web space of all toes
 - c. The medial plantar nerve branches, arteries, and veins traverse the metatarsal tunnels of the first, second, third toes
 - d. The lateral plantar nerve branches supply the IVth and Vth toes
 - e. Chronic compression of the interdigital nerve between the metatarsal head or hyperextension of the metatarsal joint exacerbates the angulation of the nerve

Clinical Manifestations

1. Lancing electric-like pain in the territory of the involved interdigital nerve
2. The pain is triggered by pressure between the III and IVth metatarsal head (classic)
3. Hypoesthesia in the distribution of the involved digital nerve
4. Arch pain
5. Exacerbated by standing and walking
6. Web space compression test is positive

Pathogenesis of Nerve Injury

1. Distortion of the metatarsophalangeal joints

2. Repetitive trauma (high heels)
3. Fractures
4. Subluxation of the joint
5. Rheumatic inflammatory disease
6. Synovial cysts
7. Hyperextension of the toes narrows the canals and compresses the nerves
8. Flexion contraction of the hip and knees causes toe hyperextension
9. Dystonia and spasticity

Laboratory Evaluation

1. EMG:
 - a. Decreased sensory NCV's of the interdigital nerves
 - b. High resolution ultrasound demonstrates an ovoid hypoechoic lesion non-parallel to the long axis of the metatarsal bone
 - c. MRI neurography

Sural Nerve

General Characteristics

1. A branch of the distal sciatic nerve from both of its divisions that forms in the posterior popliteal fossa
2. The formation and topography of the nerve is anatomically variable. In approximately 30% of patients, it is formed in the distal leg

Clinical Manifestations

1. Pain and paresthesias in the lateral ankle and foot as well as the distal lateral leg
2. Tinel's sign over its emergence 20 to 25 cm above the foot
3. Normal ankle muscle stretch reflex and gastrocnemius strength differentiate it from an S1 radiculopathy

Pathogenesis of Nerve Injury

1. Entrapment of the sural nerve may occur from compression and fixation caused by fascial thickening
2. Sural neuralgia may occur in 5% of patients after surgical procedures and biopsy (neuroma formation)
3. Ganglion
4. Lipoma
5. Positioning
6. Heel straps
7. Repetitive ankle sprains
8. Fractures of the ankle (Vth metatarsal)
9. The "superficial sural" aponeurosis may be thickened which forms a fibrous tunnel at the fascial opening in the leg at the site of entrapment
10. Vein stripping
11. Vasculitis
12. Arthroscopy
13. Baker's cyst

Laboratory Evaluation

1. EMG

- a. Low amplitude or absent SNAP
2. Ultrasound
3. MRI neuropathy

Femoral Nerve

General Characteristics

1. Formed by the posterior division of the ventral rami of L2, L3, L4
2. Innervates the psoas muscle
 - a. Passes between the psoas and iliacus muscle where it is covered by the iliacus fascia (roof of the iliacus compartment)
3. Passes under the inguinal ligament and innervates the iliacus muscle (4–5 cm proximal to the ligament)
4. After the ligament it innervates:
 - a. Four heads of the quadriceps muscle and the sartorius muscle
 - b. Gives rise to the medial and the intermediate cutaneous nerve of the thigh (innervates the anterior thigh) and the saphenous nerve
 - c. The saphenous nerve is posteromedial in the femoral triangle and passes through the adductor canal:
 - i. It is the origin of the infrapatellar branch that innervates the skin of the anterior patella
 - ii. The saphenous nerve becomes subcutaneous 10 cm proximal and medial to the knee (pierces the fascia between the sartorius and gracile muscles); crosses the pes anserinus bursa at the upper medial tibia
 - iii. In the lower 1/3 of the leg, it divides into the two terminal branches that innervate the medial surface of the knee, leg, medial malleolus and the medial arch of the foot

Clinical Manifestations

1. Usually, the nerve is injured unilaterally
 - a. The exception is the lithotomy position with concomitant pressure on the adductor canal (during delivery or GYN surgery)
2. Acute thigh weakness
3. Weakness and atrophy of the quadriceps muscle
4. Sensory loss over the anterior thigh and the medial lower leg
5. Hip flexor weakness (L1–L3) suggests lumbar plexus involvement
6. An unstable leg:
 - a. The knee buckles when partially flexed
 - b. The patients suffer frequent falls
7. Acute groin and thigh pain; later deep thigh pain
8. Femoral nerve involvement from retroperitoneal hematoma is associated with severe back, abdominal, groin, buttock and anterior thigh pain
 - a. The position of comfort is lying in bed with a flexed thigh
9. Hip flexion weakness (iliopsoas involvement with an intrapelvic lesion); is spared if the lesion is at the inguinal ligament (lithotomy position)

10. A positive reverse straight leg raising test (particularly with proximal lesions)
11. Depressed or absent knee muscle stretch reflex

Pathogenesis of Nerve Injury

1. The nerve is most often injured during surgical or diagnostic procedures
 - a. Retractors compress the nerve against the pelvic wall
2. Pelvic injury:
 - a. Abdominal hysterectomy
 - b. Prostatectomy
 - c. Renal transplantation
 - d. Colectomy
 - e. Inguinal herniorrhaphy
 - f. Lumbar sympathectomy
 - g. Tubal ligation
 - h. Aortic aneurysm surgery
3. Retroperitoneal bleeding:
 - a. Pressure under the fascia; blood is trapped over the iliopsoas muscle beneath the femoral triangle and under the fascia
 - b. Renal transplantation (bleeding)
 - c. Hemophilia
 - d. Anticoagulation
 - e. Coagulopathy
 - f. Ruptured abdominal aneurysm
 - g. Femoral artery catheterization
 - i. Approximately 0.5% of femoral artery catheterization for coronary artery disease bleed; often there is concomitant use of anticoagulation; approximately 1/3 of these patients have a lumbar plexopathy or femoral nerve injury
 - h. Large hemorrhages extend into the psoas muscle and the retroperitoneal space which compromises the lumbosacral plexus
4. Compression at the inguinal ligament:
 - a. Prolonged lithotomy position (hip flexion with external leg rotation):
 - i. Associated with vaginal delivery
 - ii. Vaginal hysterectomy, prostatectomy and laparoscopy
 - iii. Inguinal hematoma
5. Total hip replacement:
 - a. Nerve injury may occur in up to 2–3% of patients
 - b. Anterior acetabular retraction compresses the nerve
 - c. The most common setting for injury occurs with revisions and complicated reconstruction of the hip
6. Lymphadenopathy at the inguinal area
7. Pelvic mass lesions:
 - a. Lymphoma
 - b. Metastatic tumor (ovary, prostate, colon)
 - c. Abscess
 - d. Aortic or iliac aneurysm
8. Neuropraxia (stretch injury)
9. Radiation therapy

10. Laceration (blood drawing and catheterization)
11. Diabetic femoral neuropathy or as a nerve involved with autoimmune mononeuritis multiplex
12. Femoral nerve tumors (neurofibroma, schwannoma and neurogenic sarcoma)

Laboratory Evaluation

1. EMG:
 - a. Slowing of motor nerve conduction at the inguinal ligament
 - b. Decrease SNAP amplitude of the saphenous nerve
 - c. Denervation of femoral nerve innervated muscles
2. High resolution ultrasound
3. MRI neurography

Differential Diagnosis

1. L2, L3, L4 radiculopathy (rare disc disease)
2. Lumbar plexopathy; if the thigh adductors are denervated the lesion is proximal to the femoral nerve (obturator nerve)
3. Weakness of ankle dorsiflexion (L4 and L5) from the peroneal nerve suggests an L4 radiculopathy or lumbar plexopathy; back buttock and leg pain with a positive straight leg raising test favors radiculopathy

Lateral Femoral Cutaneous Nerve

General Characteristics

1. Arises from the sensory fibers of the dorsal rami of the L2 and L3 spinal roots
2. The nerve passes within or under the inguinal ligament anterior or medial to its insertion at the anterior superior iliac spine. There are significant anatomical variations of its passage
3. It pierces the tensor fascia lata to innervate the lateral thigh

Clinical Manifestations

1. Numbness and paresthesias in the lateral thigh (often a burning sensation); never below the knee
2. Hyperesthesia as well as dynamic and static mechanallodynia may occur
3. The abnormal sensation may be exacerbated by standing, walking or turning and may be relieved by hip flexion
4. The “wind-up” phenomenon may be demonstrated; increased dysesthesia with temporal summation

Pathogenesis of Nerve Injury

1. Entrapment of the LFCN as it passes through or under the inguinal ligament:
 - a. Diabetes mellitus
 - b. Pregnancy
 - c. Obesity
 - d. Constricting belts
2. Direct injury:
 - a. Iliac bone graft

- b. Injections
- c. Renal transplantation
- d. Gastric bypass surgery
- e. Herniorrhaphy
- f. Intrapelvic retraction injury
- g. Abnormal positioning (hip flexion)
- h. Blunt trauma (seat belt; avulsion of the anterior superior iliac spine)
- i. Metastasis to the iliac crest
- j. Abdominal aortic aneurysm

Laboratory Evaluation

1. EMG:
 - a. Decreased amplitude of the SNAP and nerve conduction velocity
2. High-frequency ultrasound:
 - a. The LCFN is most easily identified if the intermuscular space between the tensor fascia lata muscle and the sartorius is the initial sonographic landmark
3. MRI neurography

Differential Diagnosis of Lateral Femoral Cutaneous Nerve Injury

1. Lumbar radiculopathy:
 - a. Not as well circumscribed sensory loss with radiculopathy
 - b. Associated back and often groin pain (S1 root)
2. Femoral neuropathy:
 - a. Numbness involves the anterior thigh; may extend medially and to the leg
3. Lumbar plexopathy:
 - a. Anterior thigh pain
 - b. Weakness of the quadriceps and often the iliopsoas
 - c. Loss of knee muscle stretch reflex
4. Lumbar spinal stenosis:
 - a. “Simian” forward flexed posture when walking
 - b. Weakness is primarily in the L4–S1 distributions
 - c. Loss of AJ at times; others have increased knee jerks and ankle jerks due to concomitant cervical stenosis
5. Tensor fascia lata bursitis:
 - a. Lateral thigh pain often with specific point tenderness (usually after compression during recovery from surgical procedure)

Saphenous Nerve

General Characteristics

1. Courses through the adductor canal; penetrates the fascia above the knee
2. Supplies the cutaneous sensation to the medial calf, medial malleolus and medial arch of the foot

Clinical Manifestations

1. Pain or numbness in the distribution of the nerve; the medial calf is most noticeable

2. Tinel’s sign over the site of entrapment
3. Entrapment often occurs at the exit from Hunter’s canal (10 cm above the medial femoral condyle)
4. Knee pain is common
5. Infrapatellar branch entrapment causes anterior anteromedial or anterolateral knee pain; this branch involvement is also a common cause of chronic regional pain syndrome (CRPS II)

Pathogenesis of Nerve Injury

1. Stripping of the long saphenous vein as well as harvesting the vein for coronary bypass surgery
2. Superficial femoral thromboendarterectomy
3. Meniscectomies (knee joint)
4. Arthroscopic procedures (knee)
5. The infrapatellar branch may be entrapped behind the sartorius tendon
6. Medial knee trauma

Laboratory Evaluation

1. EMG:
 - a. Low amplitude or absent SNAP of the nerve
 - b. High resolution ultrasound
 - c. MRI neurography

Ilioinguinal Nerve

General Characteristics

1. The ilioinguinal nerve is a branch of the first lumbar nerve (L1):
 - a. There may be a contribution from T12
 - b. The nerve separates from the first lumbar in association with the iliohypogastric nerve
2. It has both motor and sensory components
 - a. The muscular branches innervate the lowest portions of the transverse abdominal muscle and the internal oblique muscle and fascia
3. After emerging from the lateral border of the psoas major inferior to the iliohypogastric nerve:
 - a. It courses obliquely across the quadratus lumborum and the iliacus muscles, perforates the transverse abdominis muscle near the anterior iliac crest, and associates with the iliohypogastric nerve
 - b. It pierces and innervates the internal oblique muscle and courses with the spermatic cord through the superficial inguinal ring
 - c. It innervates the upper and medial thigh as well as:
 - i. In males (“anterior scrotal nerve”) innervates the root of the penis and upper scrotum
 - ii. In females it innervates (“anterior labial nerve”) the mons pubis and labium majora
 - iii. It does not enter the deep inguinal ring and thus passes through a part of the inguinal canal
 - iv. Entrapment occurs slightly medial to the anterior iliac spine

Clinical Manifestations

1. Burning pain in the lower abdomen; inner portion of the upper thigh; base of the scrotum; labia majora
2. Bulging of the lower abdominal wall from weakness of the internal oblique and transversalis muscles
3. Pain is exacerbated with extension of the thigh or hip; position of comfort is a flexed hip
4. Tinel's sign may be elicited medial to the anterior iliac spine (if this is the point of entrapment)

Pathogenesis of Nerve Injury

1. Laparoscopy
2. Hernia repair
3. Appendectomy
4. Bladder suspension
5. Pfannenstiel incision
6. Blunt trauma
7. Entrapment
8. Parturition
9. Bone harvesting from the iliac crest
10. Nephrectomy

Laboratory Evaluation

1. EMG:
 - a. Denervation of lower abdominal muscles
2. High resolution ultrasound
3. MRI neurography

Differential Diagnosis of Ilioinguinal Nerve Injury

1. High lumbar radiculopathy (L1 or L2)
2. Genitofemoral neuropathy

Iliohypogastric Nerve*General Characteristics*

1. Originates most commonly from L1 with a contribution from the T12 spinal segment
2. It crosses the psoas and quadratus lumborum muscles, passes through and innervates the transverse abdominis and internal oblique muscles
3. The nerve has two terminal cutaneous branches that innervate a portion of the lateral buttock (lateral branch) and the anterior branch that innervates a high portion of the pubis

Clinical Manifestations

1. Pain and sensory loss above the symphysis pubis
2. Rarely weakness of the lower abdominal wall
3. A strip of numbness in the lateral buttock

Pathogenesis of Nerve Injury

1. The nerve is frequently injured in association with the ilioinguinal nerve
2. Surgical procedures:
 - a. Lower quadrant, abdominal surgery that includes:
 - i. Appendectomy

- ii. Nephrectomy
- iii. Retroperitoneal tumors
- iv. Hernia repair
- v. Pfannenstiel incision
- vi. Abdominoplasty

Laboratory Evaluation

1. EMG:
 - a. Denervation of the lower abdominal muscles
 - b. Anesthesia; ultrasound guided iliohypogastric nerve block
 - c. MRI neurography

Differential Diagnosis of Iliohypogastric Nerve Injury

1. Ilioinguinal neuropathy
2. Genitofemoral neuropathy
3. L1 and L2 radiculopathy

Genitofemoral Nerve*General Characteristics*

1. The nerve originates from the L1 and L2 spinal roots and passes through the psoas muscle; it divides into the femoral and genital branches at the inguinal ligament
2. The femoral branch innervates a small area of the anterior thigh; the genital branch innervates the scrotum and labia majora
3. It innervates the cremasteric muscle

Clinical Manifestations

1. Pain in the medial inguinal area, scrotum or labia majora
2. The sensory loss may overlap with that of the ilioinguinal nerve
3. Absent cremasteric reflex

Pathogenesis of Nerve Injury

1. Psoas abscess
2. Appendectomy
3. Inguinal herniorrhaphy
4. Nephrectomy
5. Cesarean section
6. Abdominal trauma
7. Adhesion and scarring from abdominal surgeries (delayed presentation)
8. Concomitant genital branch and ilioinguinal nerve injury that occurs at the inguinal ligament

Laboratory Evaluation

1. EMG:
 - a. No NCS have been reported from this nerve
 - b. Ultrasound guided diagnostic nerve block
 - c. MRI neurography

Differential Diagnosis of Genitofemoral Nerve Injury

1. L1–L2 radiculopathy
2. Ilioinguinal neuropathy
 - a. No anterior femoral distribution

Posterior Cutaneous Nerve of the Thigh*General Characteristics*

1. Its origin is the S1–S3 spinal roots
2. Exits the pelvis with the inferior gluteal nerve through the sciatic notch under the piriformis muscles
3. It supplies cutaneous innervations of the lower buttock, posterior thigh, popliteal fossa and at times the proximal 1/3 of the calf; it has perineal, scrotal and labia majora branches
4. The nerve may be injured with the sciatic and inferior gluteal nerves

Clinical Manifestations

1. Paresthesias of the lower buttock and posterior thigh; exacerbated by sitting or the supine posture

Pathogenesis of Nerve Injury

1. Gunshot and laceration wounds
2. Colorectal tumors
3. Venous malformations
4. Bicycle riding; specific compressions
5. Intramuscular injections

Laboratory Evaluation

1. EMG:
 - a. Decreased or absent SNAP of the nerve
2. Ultrasound guided anesthetic block
3. MRI neurography

Differential Diagnosis of PCNT Injury

1. S1 or S2 radiculopathy (rarely purely sensory)
2. Sacral plexopathy:
 - a. The above root lesions would be accompanied by a depressed or absent ankle jerk; sciatic nerve lesions would have concomitant hamstring or gastrocnemius muscle weakness

Obturator Nerve*General Characteristics*

1. The nerve originates from the ventral divisions of the second, third and fourth lumbar nerves of the lumbar plexus
2. It descends through the psoas muscle and emerges from its medial border at the brim of the pelvis
 - a. It traverses behind the common iliac arteries and progresses along the lateral wall of the pelvis to the upper portion of the obturator foramen
3. It enters the thigh through the obturator canal and divides into an anterior and posterior branch
4. Its sensory innervation is the medial thigh
5. Its motor innervation includes:
 - a. Adductor muscles of the lower extremity:
 - i. External obturator
 - ii. Adductor longus
 - iii. Adductor magnus
 - iv. Gracilis
 - v. Pectineus

Clinical Manifestations

1. The initial symptom is usual pain in the groin, anterior or medial thigh (often in athletes or associated with an obturator hernia)
2. Adductor muscle weakness may cause destabilization of the hip joint; difficulty with walking; wide-based gait
3. Pain may radiate to the medial calf and is exacerbated by extension or lateral leg movement

Pathogenesis of Nerve Injury

1. Lumbar plexopathy
2. Pelvic trauma (fractures)
3. Hip surgery:
 - a. Retractor blade
 - b. Cement extrusion
 - c. Fixation screws
4. Aortofemoral bypass
5. Oophorectomy
6. Laparoscopic lymphadenectomy
7. Vaginal delivery (forceps)
8. Obturator hernia
9. Endometriosis
10. Pelvic malignancy
11. Entrapment under the adductor fascia
12. Schwannoma
13. Sacroiliac lesion may impinge on the nerve
14. Tumors:
 - a. Transitional cell cancer of the bladder
 - b. Cervical carcinoma
 - c. Lymphoma
 - d. Prostatic cancer
 - e. Sarcoma
15. Parturition
16. Surgical tourniquets
17. Myositis ossificans

Laboratory Evaluation

1. EMG:
 - a. Adductor muscle denervation
 - b. Large MUAP and fibrillation potentials in muscles that are innervated by the nerve
 - c. Ultrasonographically guided nerve block
 - d. MRI microneurography

Differential Diagnosis of Obturator Nerve Injury

1. L3–L4 radiculopathy
2. Lumbar plexopathy:
 - a. Diabetes mellitus
 - b. Infection
 - c. Malignancy
 - d. Collagen vascular disease

The above are ruled out by iliopsoas, quadriceps weakness, loss of the knee jerk and ankle reflex. Medial thigh sensory loss is seminal. Symphysis pubis lesions may radiate pain to the medial thigh.

Inferior Gluteal Nerve*General Characteristics*

1. The inferior gluteal nerve arises from the dorsal branches of the ventral rami of L5, S1, and S2 nerves
2. The sacral plexus forms anterior to the piriformis muscle and is the origin of:
 - a. Sciatic nerve
 - b. The superior and inferior gluteal nerves
 - c. Pudendal nerves
 - d. Posterior femoral cutaneous nerve
3. The inferior gluteal nerves exits the pelvis through the greater sciatic foramen:
 - a. It courses inferior to the piriformis muscle
 - b. It divides into muscular branches that innervate the gluteus maximus muscle
 - c. It is superficial to the sciatic nerve and at the lower border of the piriformis muscle it divides into upper and downward diverging branches
 - d. Rarely, it may give origin to a branch of the posterior femoral cutaneous nerve
 - e. The nerve enters the deep surface of the gluteus maximus approximately 5 cm from the tip of the greater trochanter of the femur
4. The inferior gluteal nerve courses with the inferior gluteal artery which is a branch of the anterior trunk of the internal iliac artery
5. Is bounded by:
 - a. The superior edge of the piriformis muscle
 - b. The lower edge of the gluteus medius muscle
 - c. The ischium of the sciatic notch
 - d. The piriformis muscle divides the sciatic notch into a superior and inferior foramen
 - i. L5, S1, and S2 roots exit through the infra-piriformis foramen

Clinical Manifestations

1. Difficulty climbing stairs
2. Decreased extension of the flexed thigh
3. It is active in lateral rotation and abduction of the thigh
4. Stabilizes the femur on the tibia when the knee extensors are relaxed
5. Difficulty running and standing up
6. Atrophy of the buttock
7. Pain in the gluteus muscle that radiates into the posterior thigh
8. Pathogenesis of inferior gluteal nerve injury

Pathogenesis of Nerve Injury

1. Hip replacement:
 - a. Possibly most common with the posterior approach
2. The inferior gluteal nerve is injured by intrapelvic mass lesions that include:
 - a. Lymphoma
 - b. Colorectal cancer
 - c. Iliac artery aneurysms

3. The nerve may be compressed by the sciatic nerve
4. Pelvic fractures
5. Prolonged traction during hip replacement

Laboratory Evaluation

1. EMG:
 - a. Denervation of the gluteus maximus muscle
2. High resolution ultrasound
3. MRI neurography

Differential Diagnosis of Inferior Gluteal Neuropathy

1. Diseases of the hip joint
2. L5 and S1 radiculopathy

Superior Gluteal Nerve*General Characteristics*

1. The superior gluteal nerve arises from dorsal division of L4, L5, and S1
2. It exits the pelvis through the greater sciatic foramen above the piriformis muscle associated with the superior gluteal artery and vein
3. It terminates in the gluteus minimus and tensor fascia lata muscle
4. In the suprapiriformis, it is in juxtaposition with the sciatic and posterior femoral nerve
5. It innervates the gluteus medius, minimus, and tensor fascia lata muscles

Clinical Manifestations

1. Injury to the nerve causes a pelvic tilt to the opposite side during walking or standing on the affected leg (Trendelenburg sign)
2. There is destabilization of the pelvis in the coronal plane; there is weakness of hip abduction
3. Bilateral loss of the muscles causes a waddling gait

Pathogenesis of Nerve Injury

1. Pelvic fracture
2. Damaged during hip replacement
3. Rarely entrapped by the piriformis muscle
4. Misplaced injections

Laboratory Evaluation

1. EMG:
 - a. Fibrillation potentials and decreased amplitudes of the CMAP in the tensor fascia lata muscle and gluteus medius muscle
2. High resolution ultrasound
3. MRI neurography

Unusual Entrapments Neuropathies**Lumbosacral Tunnel Syndrome***General Characteristics*

1. The L5 roots are entrapped across the ala of the sacrum or under the lumbosacral ligament

2. The lumbosacral ligament:
 - a. A fibrous ligament that originates from the fifth lumbar vertebra and inserts on the upper border of the ala of the sacrum
3. The L5 spinal nerve courses under the ligament with the iliolumbar artery and vein

Clinical Manifestations

1. Sensor loss and pain in the L5 dermatomal distribution with minimal or no objective findings

Pathogenesis of Nerve Injury

1. Thickening of the ligament
2. Bony osteophytes
3. Tumor
4. Iliolumbar artery aneurysm

Laboratory Evaluation

1. EMG:
 - a. Evaluation of the L5 root
2. MRI neurography
 - a. Both CT and MRI to evaluate alternate areas of involvement (CT better for bony anomalies)
3. 3-dimensional computed tomographic imaging to diagnose extraforaminal stenosis at the lumbosacral junction:
 - a. The minimum cross-sectional area of the bony tunnel was less than 0.8 cm² in symptomatic patients

Non-Vasculitic Ischemic Nerve Injury

Compartment Syndromes

General Characteristics

1. Increased pressure within a closed muscular space
2. Nerves are injured by compromise of the vasa nervorum which decreases their capillary perfusion
3. Normal compartment pressure is usually 0–8 mm Hg
4. Acute compartment syndromes:
 - a. Anterior compartment of the leg is most common
 - b. The volar forearm compartment is most common in the upper extremity
5. Chronic compartment syndrome:
 - a. Overuse and exercise
 - i. Often the anterior and posterior leg compartments are involved

Acute Compartment Syndrome

Clinical Manifestations

1. May occur hours after the inciting event
2. Pain in the involved compartment
3. Swelling tenderness and edematous skin
4. They may be incipient as they develop; full blown after they are established
5. Dysfunction of the nerves that are located in the compartment (anesthesia and paralysis)
6. The distal circulation is spared

Pathogenesis of Nerve Injury

1. The causes of ACS are either an increase in the volume of a compartment or a decreased ability of the compartment sheath to expand
2. Decreased compartment size:
 - a. Tight dressings
 - b. Bandages
 - c. Casts
 - d. Lying on a limb (during coma)
 - e. Following operations that require unnatural positioning (lithotomy position)
 - f. Circumferential burns (develop an inelastic eschar)
3. Increased volume of the compartment:
 - a. Fractures are the most common cause of ACS (possibly 70% of cases):
 - i. Tibial shaft fractures are the most common > distal radius and ulnar fractures
 1. Tissue swelling and hematoma formation are possible mechanisms of raising intracompartmental pressure
 2. ACS may occur with open fractures; formerly they were thought to decompress naturally
 3. Crush injury:
 - a. Multiple compartments are involved, and large muscle may be crushed (gluteus maximus)
 - b. Systemic manifestations of crush injuries include:
 - i. Rhabdomyolysis with myoglobinuria
 - ii. Increased serum K⁺ with cardiac arrhythmia
 - iii. Renal failure
 - iv. Shock
 - c. Causes of compartment syndrome:
 - i. Exercise
 - ii. Fluid infusion
 - iii. Ruptured ganglion cyst
 - iv. Snake envenomations
 - v. Viral myositis
 - vi. Osteomyelitis
 - vii. Rhabdomyolysis
 - viii. Hematoma

Laboratory Evaluation

1. The pressure of a normal myofascial compartment is usually less than 10 mm Hg:
 - a. Intracompartmental pressure of 30 mm Hg for 6–8 hours causes irreversible muscle damage
 - b. Fasciotomy is usually recommended between 30 mm Hg and 45 mm Hg
2. Non-invasive imaging techniques include:
 - a. Near infrared spectroscopy (NIRS)
 - b. Laser Doppler Flowmetry
3. Biomarkers:
 - a. White cell count, creatine kinase (CK) and myoglobin are not specific

Chronic Compartment Syndrome

General Characteristics

1. The pathology of chronic exertional compartment syndrome:
 - a. Related to a marked increase in tissue pressure within a closed fascial space during exercise
 - b. Muscle volume can increase up to 20% of its resting volume during exercise; most feel that increased compartment pressure causes impaired muscle perfusion
 - c. Recent SPECT scan studies demonstrate no significant difference in relative perfusion of those with chronic compartment syndrome; other theories postulate that pain is caused by stimulation of the sensory fibers of the fascia

Clinical Manifestations

1. Pain in the compartment (usually the leg) at the same time or intensity as caused by exercise
2. The pain increases in intensity as the patient continues to exercise. It is relieved by rest
3. The pain is usually burning, aching, or pressure like. It may be bilateral in the same compartment in a significant number of patients
4. Patients may not be able to achieve the same parameters of the exercise they did before the symptoms were noted
5. Muscle tenderness
6. Paresthesia and muscle weakness of the affected nerve located within the compartment
7. Pain may be evoked with passive stretching of the muscle and firmness of the involved compartment
8. Muscle herniation through defects in the fascia may be palpated in between 40 to 60% of patients (usually over the anterior tibia in lower extremity anterior compartment syndrome)
9. Fascial defects occur at the peroneal exit area from the lateral compartment

Pathogenesis of Nerve Injury

1. Exertion and overuse

Laboratory Evaluation

1. EMG:
 - a. Assesses for peroneal nerve entrapment
 - b. Bone scan to rule out stress fractures
 - c. Measurement of intracompartmental pressure:
 1. A resting pressure of greater than 15 mm Hg and 5 minutes post-exercise pressure greater than 20 mm Hg are diagnostic
- d. MRI:
 - i. An MRI suggestive of chronic compartment syndrome demonstrates increased T2-weighted signal intensity within the involved muscles
 - ii. A decrease of T1-weighted sequences intensity suggests fibrosis and muscle atrophy

Differential Diagnosis of Chronic Exertional Leg Pain

1. Medial tibial stress syndrome:
 - a. Also known as shin splints
 - b. A periostitis of the posteromedial border of the tibia
 - c. Symptoms are pain with activity that is relieved with rest; examination reveals diffuse tenderness of the posteromedial border of the tibia
2. Stress fracture:
 - a. Presents as pain over the tibia and fibula exacerbated by activity and relieved by rest
 - b. Examination reveals point tenderness over the tibia or fibula that is exacerbated by mechanical stimuli
3. Fascial defects:
 - a. Fascial defects by themselves are asymptomatic
 - b. Defects are most frequent over the medial and lateral compartments of the lower leg
 - c. Pain results from muscle herniation through the fascia with concomitant nerve compression
 - d. Pain radiates to the dorsum of the foot
 - e. Muscle bulging may be evident
4. Peroneal nerve entrapment:
 - a. Occurs at the point where the nerve pierces the deep fascia on the lateral leg
 - b. Pain is evoked in the lateral leg by dorsiflexion and eversion of the ankle
 - c. Positive Tinel's sign at the site of penetration of the nerve
5. Popliteal artery entrapment syndrome (PAES):
 - a. The artery is compressed in the compartment following chronic exercise
 - b. Exertional calf pain
 - c. Examination reveals a diminished dorsalis pedis pulse with plantar flexion and dorsiflexion
6. Vascular claudication:
 - a. Pain with exercise (usually burning and in the calf) which is relieved with leg elevation; in some patients with recumbency

Ischemic Monomelic Neuropathy

General Characteristics

1. Distal nerve damage in an extremity due to proximal compromise of the arterial supply:
 - a. Compression of the vessel
 - b. Diversion of blood
2. Occurs in both the upper and lower extremities
3. There is often a distal to proximal gradient of both clinical and EMG deficits
4. At any limb level different peripheral nerves are affected uniformly

Clinical Manifestations

1. Deep burning pain in the hand or foot
2. Coexisting paresthesias (different nerve distributions)
3. The upper extremity has greater distal sensory deficits than the lower extremity

4. Weakness and wasting of intrinsic hand and foot muscles; distal > proximal
5. Symptoms appear acutely and reach maximum intensity within days
6. Impairment of all sensory modalities distal > proximal in the extremities
7. Rarely there are signs of vascular insufficiency in the affected extremity

Pathogenesis of Nerve Injury

1. A–V shunts in the antecubital fossa or the proximal arm for dialysis
2. Lower extremity arterial compromise:
 - a. Superficial femoral artery
 - i. Cardiopulmonary bypass communication
 - ii. Intra-aortic balloon pump
 - iii. Bifemoral thrombosis
 - iv. Aortoiliac embolus
 - v. Ergotamine poisoning; methylsurgicide
3. Neuropathology
 - a. Axonal neuropathy

Laboratory Evaluation

1. Decreased motor and sensory NCV
2. Decreased amplitude or absent SNAPs or CMAP
3. Fibrillation potentials in intrinsic hand or foot muscles
4. No concomitant myopathic changes
5. Immediate closure of the A–V access leads to partial or full recovery

Differential Diagnosis of Ischemic Monomelic Neuropathy

1. Compression (anesthetic positioning)
2. Radiculopathy (L4, L5)
3. Intermittent claudication
4. Plexopathy from axillary block
5. Steal syndrome:
 - a. A–V shunt; reversal of distal arterial flow
 - i. Non-healing wounds; tissue loss
 - ii. Neurologic dysfunction with no ischemic damage

Acute Ischemic Mononeuropathy and Plexopathy

General Characteristics

1. Vasculitis and acute compartment syndrome are the most common causes
2. Large vessel atherosclerotic occlusion:
 - a. The vessel is injured during its repair
 - b. The lower extremity nerves and the lumbosacral plexus may be involved concomitantly

Clinical Manifestations

1. Abrupt weakness and sensory loss after the reconstructive procedures
2. Concomitant signs of vascular insufficiency overshadow neural dysfunction prior to surgery

3. Neurogenic claudication:
 - a. Exercise-induced paresthesias of the buttocks and legs (or pain)
 - b. Weakness of leg muscles with exercises
 - c. Impotence

Neuropathology

1. The usually atherosclerotic vessels are:
 - a. The distal aorta (Leriche's syndrome)
 - b. Internal > external iliac artery
 - c. Common iliac artery
2. Cauda equina and sacral plexus
 - a. Receives its blood supply from the internal iliac artery, the ilioinguinal internal iliac artery, the ilioinguinal artery and the great radicular artery of Adamkiewicz whose origin is T12–L1, L2
3. Femoral nerve and the lumbosacral plexus are most frequently ischemic
4. Surgical causes of ischemia of the lower extremity nerves and the lumbosacral plexus include:
 - a. Abdominal aortic-iliac surgery:
 - i. Aneurysms (abdominal aortic)
 - ii. Infected grafts and graft failure
 - b. Atherosclerotic distal aorta or iliac artery stenosis
 - c. Pelvic radiation
 - d. Aortic balloon pumps
 - e. Intra-arterial injections of the iliac or gluteal arteries
5. Rarely the sciatic and common peroneal nerves are affected concomitantly:
 - a. Ischemia of the common iliac artery
6. Ischemia of the nerves and plexus during procedures occurs from:
 - a. Prolonged hypotension
 - b. Embolus to the vasa nervorum
 - c. Inadequate heparinization
 - d. Cross clamping the aorta or major vessels

Laboratory Evaluation

1. EMG:
 - a. Similar findings as those of ischemia monomelic neuropathy
 - b. Arteriography to evaluate the operated artery
 - c. Laser Doppler flowmetry

Differential Diagnosis of Acute Ischemic Mononeuropathy/Plexopathy

1. Cauda equina lesions
2. Conus medullaris lesions (bowel/bladder are involved; no pain)
3. Ischemic femoral neuropathy:
 - a. Psoas and iliacus anterior compartment syndrome; the quadriceps is almost universally involved
4. Sciatic neuropathy:
 - a. Incomplete cauda equina lesion
 - b. Sacral plexopathy
 - c. Ischemic monomelic neuropathy

Differential Features of the Entities

1. Lumbosacral plexopathy:
 - a. Unilateral
 - b. Bladder involvement occurs
 - c. Motor and sensory loss is in the distribution of more than one nerve
 - d. Buttock pain occurs first with ischemic lumbosacral plexopathy
2. Ischemic femoral neuropathy:
 - a. Quadriceps weakness
 - b. Saphenous nerve involvement (sensory loss or paresthesias of the medial lower leg)
 - c. Femoral nerve sensory loss (quadriceps)
 - d. Depressed or absent knee jerk
3. Iliacus acute compartment syndrome:
 - a. Groin mass
 - b. Severe pain with hip flexion
4. Ischemic sciatic neuropathy:
 - a. Presents in the distribution of the common peroneal and tibial nerves
 - b. Weakness and sensory loss below the knee
 - c. Hamstring, paraspinal and glutei muscles are spared

Frostbite*General Characteristics*

1. Tissue injury from temperature below the freezing point on intact skin
2. Men are affected more than women 10:1
3. It is most prevalent in adult men 30 to 49 years of age
4. There is a high incidence in psychiatric and homeless patients
5. The feet are involved in more than 90% of patients; less often the ears, nose, cheeks and penis

Clinical Manifestations

1. Exposure occurs in:
 - a. Outdoor activities in extremely cold weather
 - b. Psychiatric illness
 - c. Trauma
 - d. Homeless patients
2. Pre-freeze stage:
 - a. Loss of light touch, pain and temperature perception
 - b. Edema
 - c. Poor coordination of hands and feet
3. Freezing stage:
 - a. Direct injury of frostbite occurs
 - b. Superficial frostbite:
 - i. Minimal, if any, tissue loss
 - ii. Supple painful skin
 - iii. Large blisters with fluid after thawing
 - iv. Sensation may be intact
 - c. Deep frostbite:
 - i. Significant tissue loss
 - ii. Anesthetic tissue

- iii. Blue-gray discoloration of the tissue
 - iv. Hemorrhagic blisters occur with thawing
 - v. Edematous and suffused tissue
4. Residual signs and symptoms:
 - a. Burning pain
 - b. Hyperhidrosis
 - c. Autonomic dysregulation of the affected part
 - d. Sensory loss of all modalities
 - e. Cold intolerance
 - f. Hyperpigmented and atrophic skin

Neuropathology

1. Direct injury phase (prior to freezing):
 - a. Skin temperature is less than 10°C
 - b. Microvascular vasoconstriction with endothelial damage
2. Freezing phase:
 - a. Skin temperature is usually below 2°C
 - b. Ice crystals that form in the extracellular fluid causes increased osmotic pressure
 - c. Intracellular shrinkage; disruption of membrane lipid complexes
 - d. Cells die an osmotic death when they lose 1/3 of their volume
3. Indirect phase during thawing:
 - a. Vascular stasis with progressive ischemia
 - b. Tissue destruction occurs during this phase (the first few hours)
 - c. Microvascular destruction: affects venules prior to arterioles
 - d. Release of proinflammatory mediators such as prostaglandin F₂ and thromboxane A₂

Laboratory Evaluation

1. Triple phase bone scan
2. Angiography in patients considered for thrombolysis
3. MRI/MRA:
 - a. Direct visualization of occluded vessels and surrounding tissue; may demonstrate demarcation of ischemic tissue

Hand Arm Vibration Syndrome (HAVS)*General Characteristics*

1. Vibrating tools are causative: pneumatic drills, electric grinders, polishers, and gasoline-powered chain saws
2. Occurs after approximately 1000 hours of exposure

Clinical Manifestations

1. Secondary Raynaud's phenomenon
2. Numbness and decreased sensitivity of the affected extremity; tips of the fingers are affected first
3. The palms are not involved
4. Specific vasospastic attacks last 1 to 160 minutes; they occur more commonly in the morning
5. Continued exposure increases the numbers and duration of attacks

6. Attacks may be aborted by warmth; pain and hyperemia occur during warming
7. Intrinsic hand muscle atrophy
8. Vibration at less than 40 Hz causes wrist and elbow osteoarthritis

Neuropathology

1. Osteoarthritic changes of distal phalangeal bones
2. Caustic small bone lesions
3. Local osteoporosis
4. Impaired vascular regulation

Laboratory Evaluation

1. X-ray defined osteoporosis
2. Osteoarthritis of the elbow and shoulder
3. Laser Doppler imaging of skin blood flow before, during, and after cold water immersion
4. Skeletal x-rays of the hands
5. Infrared thermometry

Differential Diagnosis of Neuropathy

Axonal Neuropathies

1. Acute onset:
 - a. Acute demyelinating axonal neuropathy (AIDP)
 - b. Acute intermittent porphyria
 - c. Variegate porphyria
 - d. Coproporphyria
 - e. Tick paralysis
2. Acute intoxications (axonal destruction):
 - a. Heavy metals
 - i. Lead (Pb)
 - ii. Arsenic
 - iii. Mercury
 - iv. Thallium
 - v. Gold
 - vi. Antimony
 - vii. Zinc
 - viii. Bismuth
 - b. Organic solvents:
 - i. N-hexane
 - ii. N-butyl-ketone
3. Subacute toxic neuropathies:
 - a. Misonidazole
 - b. Metronidazole
 - c. Chloroquine and hydroxychloroquine
 - d. Amiodarone
 - e. Colchicine
 - f. Podophyllin
 - g. Thalidomide
 - h. Disulfiram
 - i. Dapsone
 - j. Leflunomide (possible)
 - k. Nitrofurantoin
 - l. Pyridoxine (vitamin B6)
 - m. Isoniazid
 - n. Ethambutol
 - o. Anti-nucleosides
 - p. Phenytoin
 - q. Lithium
 - r. Acrylamide
 - s. Carbon disulfide
 - t. Ethylene oxide
 - u. Organophosphates
 - v. Hexacarbons
4. Subacute and chronic axonal neuropathies associated with systemic disease:
 - a. Diabetes mellitus (mixed neuropathies that have an axonal component):
 - i. Distal symmetric sensory and sensorimotor neuropathy
 - ii. Autonomic neuropathy
 - iii. Neuropathic cachexia
 - iv. Radiculoplexus neuropathy
 - v. Mononeuropathies
 - b. Hypoglycemia
 - c. Insulinoma
 - d. Acromegaly
 - e. Hypothyroidism
 - f. Liver failure
 - g. Chronic obstructive lung disease
 - h. Celiac disease
 - i. Crohn's disease
 - j. Ulcerative colitis
 - k. Pancreatitis
 - l. Uremia
 - m. Sarcoid
 - n. Congestive heart failure
 - o. Primary biliary cirrhosis
 - p. Amyloidosis:
 - i. TTR-met30
 - ii. Familial forms
 - q. Hyperoxaluria
 - r. Scleroderma
 - s. Sjögren's
 - t. Rheumatoid arthritis
5. Axonal neuropathies associated with chemotherapeutic agents (axonal damage may be just a component, as these neuropathies affect dorsal root ganglion cells and are also demyelinating)
 - a. Vinca alkaloids:
 - i. Vincristine
 - ii. Vinblastine
 - iii. Vindesine
 - iv. Vinorelbine
 - b. Cisplatin
 - c. Taxanes (paclitaxel; docetaxel)
 - d. Suramin
 - e. ARA-C

- f. Etoposide (UP-16); possibly pathology is in the DRG
- g. Bortezomib (possible axonal component)
- 6. Axonal neuropathies associated with malignancies; these diseases often have demyelinating features and direct invasion of malignant cells:
 - a. Lymphoma
 - b. Multiple myeloma
 - c. Osteosclerotic myeloma (POEMS syndrome)
 - d. Castleman's disease
 - e. Waldenström's (overwhelmingly a demyelinating process)
 - f. MGUS (primarily demyelinating)
- 7. Infections associated with axonal neuropathy:
 - a. HIV
 - b. Diphtheritic (segmental demyelination and axonal degeneration)
 - c. Lyme's disease (also associated with perivascular infiltration of plasma cells)
 - d. Human T-lymphocyte Type I infection
 - e. Herpes varicella zoster

Hereditary Neuropathies

CMT1

- 1. CMT1A
 - a. AD; chromosome 17p11.2
 - b. PMP22
- 2. CMT1B
 - a. AD; chromosome 1q21-23
 - b. MPZ
- 3. CMT1C
 - a. AD; chromosome 16p12.3-13.1
 - b. LITAF
- 4. CMT1D
 - a. AD; chromosome 10q21.1-22.1
 - b. ERG2
- 5. CMT1E (with deafness)
 - a. AD; chromosome 17p11.1
 - b. Point mutations in the PMP22 gene
- 6. CMT1F
 - a. AD; chromosome 8p13-21
 - b. Neurofilament light chain
- 7. CMT1X
 - a. X-linked dominant; Xq13
 - b. Connexin-32
- 8. HNPP
 - a. AD; 17p11.2; 1q21-23
 - b. MPZ

CMT2

- 1. CMT2A1
 - a. AD; chromosome 1p36.2
 - b. Microtubule motor kinesin-like protein
- 2. CMT2A2
 - a. Allelic to HMSNVI with optic atrophy

- b. AD; chromosome 1p36.2
- c. MFN2
- 3. CMT2B
 - a. AD; chromosome 3q13-3q22
 - b. RAB7
- 4. CMT2B1
 - a. Allelic to LGMD1B
 - b. AR; chromosome 1q21.2
 - c. Lamin A/C
- 5. CMT2B2
 - a. AD; chromosome 19q13
- 6. CMT2C (with vocal cord and diaphragm involvement)
 - a. AD; chromosome 12q23-24
- 7. CMT2D
 - a. Allelic to distal SMA5
 - b. AD; chromosome 7p14
 - c. Glycine tRNA synthetase
- 8. CMT2E
 - a. Allelic to CMT1F
 - b. AD; chromosome 8p21
 - c. Neurofilament light chain
- 9. CMT2F
 - a. AD; chromosome 7q11-q21
 - b. Heat-shock 27-kDa protein-1
- 10. CMT2G
 - a. May be allelic to CMT4H
 - b. AD; chromosome 12q12q13
 - c. Possibly frabin
- 11. CMT2H
 - a. AD; chromosome 8q21.3
 - b. Possibly GDAP1 (ganglioside-induced differentiation-associated protein-1)
- 12. CMT2K1
 - a. Allelic to CMT1B
 - b. AD; chromosome 1q22
 - c. MPZ (myelin protein zero protein)
- 13. CMT2K
 - a. Allelic to CMT4A
 - b. AD; chromosome 8q13-q21
 - c. GDAP1
- 14. CMT2L
 - a. Allelic to distal hereditary motor neuropathy type 2
 - b. AD; chromosome 12q24
 - c. Heat-shock protein 8
- 15. CMT2N
 - a. Mutations in the alanyl-tRNA synthetase gene
- 16. CMT2O
 - a. Mutation in the DYN C1H1 gene
- 17. CMT2P
 - a. Mutation in the LRSAM1 gene
- 18. CMT2S
 - a. Mutation in the IGHMBP2 gene
- 19. CMT2T
 - a. Mutation in the DNAJB2 gene
- 20. CMT2U
 - a. Mutation in the MARS gene

Dominant Intermediate CMT Disease

1. DI-CMTA
 - a. AD; chromosome 10q24.1-q25.1
2. DI-CMTB
 - a. AD; chromosome 19p12-p13.2
 - b. Dynamin-2
3. DI-CMTC
 - a. AD; chromosome 1p34-p35
 - b. Tyrosyl-RNA synthetase

CMT3 (Dejerine-Sottas Disease, Congenital Hypomyelinating Neuropathy)

1. AD; chromosome 17p11.2
 - a. PMP22
2. AD; chromosome 1q21-23
 - a. PO
3. AR; 10q 21.1-22.1
 - a. ERG2 (early growth response-2 protein)
4. AR; chromosome 19q13
5. Periaxin

CMT4

1. CMT4A
 - a. AR; chromosome 8q13-21.1
 - b. GDAP1
2. CMT4B1
 - a. AR; chromosome 11q23
 - b. MTMR2 (myotubularin-related protein-2)
3. CMT4B2
 - a. AR; chromosome 11p15
 - b. MTMR13 (myotubularin-related protein 13)
4. CMT4C
 - a. Autosomal recessive; chromosome 5q23-33
 - b. SH3TC2 (SH3 domain and tetratricopeptide-repeats-2)
5. CMT4D (HSMN-Lom)
 - a. AR; chromosome 8q24
 - b. NDRG1 (N-myc-downstream-regulated gene)
6. CMT4E (congenital hypomyelinating neuropathy)
 - a. AR
 - b. PMP22, MPZ and ERG-2
7. CMT4F
 - a. AR; 19q 13.1-13.3
 - b. Periaxin
8. CMT4G
 - a. AR; 10q23.2
9. CMT4H
 - a. AR; chromosome 12q12-13
 - b. Frabin

Other Hereditary Neuropathies

1. HNA (Hereditary neuralgic amyotrophy)
 - a. AD; chromosome 17q24
 - b. SEPT9 (septin 9)
2. HMSN-P (hereditary motor and sensory neuropathy-proximal)
 - a. AD; chromosome 3q13-q14

Classification of Hereditary Motor and Sensory Neuropathies

1. HMSN I
 - a. CMT-type 1
2. HMSN II
 - a. CMT-type 2
3. HMSN III
 - a. CMT-type 3
4. HMSN IV
 - a. Refsum's disease
5. HMSN V
 - a. CMT with pyramidal features
6. HMSN VI
 - a. CMT-type 6 with optic atrophy
7. HMSN VII
 - a. With retinitis pigmentosa

*Hereditary Motor and Sensory Neuropathy with Proximal Dominance**General Characteristics*

1. AD; 3q13-q14
2. Clinical heterogeneities exist between Japanese and Korean patients
3. Mutation of the TFG gene (demonstrated in Korean patients and Japanese patients)

Clinical Manifestations

1. In Japanese patients, the disease starts in the 40s and is steadily progressive; it has a faster progression in Korean patients
2. In Japanese patients:
 - a. Involuntary and spontaneous muscle contractions
 - b. Asthenia
 - c. Atrophy with distal sensory involvement; the sensory loss is a late development in the disease progression
 - d. Urinary disturbance
 - e. Dry cough
3. Tremor is seen in Korean patients

Neuropathology

1. Hyperlipidemia is associated in Korean patients
2. Mutation in the TRK-fused gene (TFG) is causative
 - a. TFG/ubiquitin and TDP-43-immunopositive cytoplasmic inclusion in motor neurons (experimental)
 - b. The gene appears to be prominent in the protein secretion pathways
 - c. Endoneurial blood vessel narrowing with swollen vesicular endothelial cells

Laboratory Evaluation

1. EMG:
 - a. SNAPs of the sural nerve are lost earlier in Korean than in Japanese patients
2. Hyperlipidemia in Korean patients
3. MRI:

- a. Lower extremity examination reveals a distinct proximal dominant and sequential pattern that is different from CMT1A

Inherited Axonal Neuropathies

1. HMSN Type II
 - a. CMT 2
2. HMSN Type IV
 - a. Optic atrophy
3. HMSN Type VI
 - a. Optic nerve and spastic paraparesis
4. Hereditary sensory autonomic neuropathy:
 - a. Type I – AD
 - b. Type II – AR
 - c. Type III – Riley-Day
 - d. Type IV
5. Leigh's disease
6. NARP (neuropathy, ataxia, retinitis pigmentosa)
7. Acute intermittent and variegate porphyria
8. Coproporphyrinuria
9. Ataxia telangiectasia
10. Giant axonal neuropathy
11. Spinocerebellar ataxia 3
12. Amyloidosis:
 - a. TTR-met 30
 - b. Familial amyloidosis
13. MNGIE (myelopathy, neurogastrointestinal encephalopathy)
14. Fabry's disease

Hereditary Demyelinating Neuropathies

1. HMSN I, III, IV
2. Krabbe's globoid leukodystrophy
3. Tangier's disease
4. Adrenomyeloneuropathy
5. Metachromatic leukodystrophy
6. Cockayne syndrome

Segmental Demyelinating Neuropathies

1. AIDP
2. CIDP
3. Arsenic
4. Lymphoma
5. HNPN-chromosome 17
6. Hypothyroidism
7. Ulcerative colitis
8. Amiodarone
9. Perhexiline
10. Ara-C
11. Waldenström's macroglobulinemia
12. MGUS (IgM, IgG, IgA)
13. Diphtheria
14. Leprosy
15. Diabetes
16. HIV
17. Lyme's disease

18. SLE
19. Cryoglobulinemia
20. Osteosclerotic myeloma

Asymmetric Single or Multiple Neuropathies

1. Diabetic proximal asymmetric neuropathy
2. Polyarteritis
3. Vasculitis
4. Compression neuropathies
5. Traumatic neuropathy
6. Autoimmune (upper extremity > lower)

Acute Demyelinating Neuropathy

1. AIDP
2. HIV
3. Diphtheria
4. Lyme's disease

Chronic Demyelinating Neuropathy

1. Hypomyelinating neuropathy (CHN)
2. HMSN I and III
3. HMSN IV (Refsum's disease)
4. Metachromatic leukodystrophy
5. HNPP (Deletion chromosome 17)
6. Hypothyroidism
7. Diabetes
8. Uremia (axonal > demyelinating)
9. Perhexiline
10. Sodium cyanide
11. Allergic vasculitis
12. HIV (autoimmune form)
13. Paraproteinemias
14. CIP/CIDP/multifocal
15. Waldenström's macroglobulinemia
16. Osteosclerotic myeloma
17. MGUS
18. SLE
19. Melanoma (immunotherapy)
20. Plasma cell dyscrasia
21. Inflammatory bowel disease
22. MAG epitope
23. SGPG-autoimmune epitopes
24. SICCA complex
25. CID-codon 200
26. Mitochondrial DNA neuropathy 3243

Sensory Neuropathies

Autoimmune Epitopes

1. MAG
2. SGPG (small fiber)
3. Anti-Hu (primarily small fiber)
4. Anti-sulfatide (small fiber)
5. Gd1b (Miller-Fisher variant)
6. GD3
7. Gal (B1–B2) Gal Nac

8. GTD1A
9. GALOP
10. GQ1b

Demyelinating Sensory Neuropathy

1. MAG
2. SGPG
3. CM Fisher variant of GBS (primarily ophthalmoplegia and ataxia)
4. CIDP (sensory variant)

Inherited Sensory Neuropathy

1. HSAN (I–V)
2. Bassen-Kornzweig disease (beta hypolipoproteinemia)
3. Fabry's disease (alpha-galactosidase)
4. SANDO
 - a. Sensory ataxia
 - b. Dysarthria
 - c. Ophthalmoplegia
5. Perrault's syndrome (ovarian dysgenesis/VIIIth nerve dysfunction)
6. Neuropathy with spinocerebellar degenerations:
 - a. SCA5
 - b. Friedreich's ataxia (large fiber)

Toxic Metabolic Sensory Neuropathy

1. Vitamin B6 excess (pyridoxine); burning neuropathy
2. Methylmercury
3. Docetaxel/paclitaxel (large and intermediate fibers)
4. Vitamin E deficiency (alpha-tocopherol transporter I deficit)
5. Vitamin B12 deficiency (primarily large fiber modalities; dorsal column degeneration)
6. INH (decreased vitamin B6)
7. Ciguatera poisoning (paradoxical channelopathy; primarily burning pain)
8. Adriamycin (dorsal ganglionopathy)

Infectious Causes of Sensory Neuropathy

1. HIV (distal symmetric painful sensory neuropathy)
2. Tabes dorsalis (posterior column deficits)
3. Herpes zoster (dermatomal)
4. Herpes simplex (regional)
5. HTLV-1 (primarily small fiber)
6. Leprosy (small and large fiber deficits depending on the autoimmune status of the patient)
7. CMV

Sensory Neuropathy Associated with Systemic Disease

1. Diabetes (burning feet syndrome)
2. Uremia (small fiber)
3. Paraneoplastic (dorsal root ganglia with sensory ataxia; "burning" from small fiber component)
4. Sjögren's (large fiber; posterior column deficits; small fiber component)

5. Hypothyroidism (CTS, tarsal tunnel syndrome; mucopolysaccharide involvement of the Vth nerve; generalized neuropathy with all sensory modality involvement)
6. Sensory perineuritis (autoimmune; primarily around the ankles)
7. Ischemic neuropathy (painful; all modalities are involved)
8. Malabsorption syndromes (primarily B12; large fiber)

Ataxic Sensory Polyneuropathy (Large Fiber)

1. Immune-mediated:
 - a. Carcinomatous sensory neuropathy
 - b. Sensory ganglionitis neuropathy
 - c. Sjögren's syndrome
 - d. Miller-Fisher variant of GBS
 - e. MAG
 - f. Sensory CIDP
 - g. Immunoglobulin associated paraproteinemias
 - h. Idiopathic sensory neuropathy
 - i. Paraneoplastic

Inherited Small Fiber Sensory Neuropathy

1. Fabry's disease
2. Tangier's disease
3. Familial amyloid polyneuropathy (FAP)
4. Hereditary sensory neuropathies II and IV (small component)
5. HSAN I–V
6. Hereditary thermosensitive neuropathy (AD)

Sensory Neuropathy Associated with Systemic Illness

1. Amyloid (secondary)
2. Diabetes
3. Primary biliary cirrhosis
4. Sjögren's syndrome
5. Rheumatoid arthritis

Sensory Neuropathy Associated with Drugs and Toxins

1. Ciguatera toxin
2. Metronidazole
3. Misonidazole
4. Kepone
5. Vacor rodenticide
6. Vincristine (erythromelalgia)
7. Chronic ergotamine

Associated with Trauma

1. Chronic regional pain syndrome I and II
2. Triple cold syndrome
3. Angry back firing C nociceptor syndrome (ABC syndrome; transmodality sensitization)

Chronic Painful Neuropathies

1. Diabetes mellitus
2. Alcohol
3. Pantothenic acid deficiency

4. Pyridoxine B6 (excess or deficiency)
5. CRPS I/II (causalgia)
6. Amyloidosis (primary or secondary)
7. Paraneoplastic (sensory neuropathy ganglionopathy)
8. TTR-met 30 (amyloidosis)
9. Anti sulfatide epitopes
10. Uremia
11. Arsenic
12. Fabry's disease
13. Hereditary (Na 1.7 erythromelalgia)
14. ABC syndrome
15. Triple cold syndrome
16. Hypertriglyceridemia
17. Niacin deficiency
18. Thiamine deficiency

Motor Neuropathies

1. Acute intermittent porphyria
2. Variegated porphyria
3. Coproporphyrinuria
4. Lead
5. Vinca alkaloids
6. Diphtheria
7. Diabetes (amyotrophy and radiculoplexus)
8. Acute inflammatory demyelinating polyneuropathy (AIDP)
9. Rabies
10. Thallium
11. Phenytoin
12. HIV
13. Insulinoma/hypoglycemia
14. Osteoclastic multiple myeloma
15. GM1 ganglioside antibody
16. MMNCB (multifocal motor neuropathy with conduction block)
17. Dapsone
18. MAG

Acute Ascending Motor Paralysis with Minimal Sensory Dysfunction

1. AIDP:
 - a. Hepatitis B virus
 - b. EBV (Epstein-Barr virus)
 - c. Mumps
 - d. HIV
 - e. Lymphoma (Hodgkin's or non-Hodgkin's)
 - f. Post vaccination (influenza, typhoid, hepatitis, rabies)
 - g. Following surgery
 - h. *Campylobacter jejuni*
2. Tick paralysis (usually accompanied by severe ataxia)
3. Lyme's disease
4. Porphyria (AIP/variegate)
5. Thallium
6. Ethylene Oxide
7. Triorthocresyl phosphate
8. Diphtheria

Neuropathies with Prominent Autonomic Features

1. Diabetes (gastroparesis; sexual dysfunction)
2. Amyloidosis:
 - a. Transthyretin-related FAP (familial amyloid polyneuropathy)
 - b. Apolipoprotein A-1 related FAP
 - c. Gelsolin-related FAP
3. Paraneoplastic syndrome
4. SICCA complex
5. Acquired generalized amyloidosis
6. Porphyria (AIP, variegate)
7. B12 deficiency
8. Uremia
9. HSAN (I–V)
10. Fabry's disease
11. Pandysautonomia (paraneoplastic/acute infections)
12. EBV (Epstein-Barr virus)
13. Holmes-Adie syndrome
14. Harlequin syndrome
15. Vacor rodenticide intoxication
16. Chronic relapsing autonomic neuropathy
17. Familial sensory autonomic neuropathy (Navajo Indian ancestry)

Hypertrophic Neuropathies

1. HMSN I, III, IV
2. CIDP
3. Longstanding diabetes (minimal)
4. Hypothyroidism
5. Mucopolysaccharidosis (Scheie variant)
6. Amyloidosis
7. Multifocal hypertrophic neuropathy
8. Leprosy
9. Acromegaly

Infectious Causes of Peripheral Neuropathy

1. HIV
2. Syphilis
3. Leprosy
4. Lyme's disease
5. CMV
6. EBV
7. Brucellosis (L5 root involvement)
8. *Campylobacter jejuni*
9. GBS (specific and most often unidentified virus)
10. Mumps
11. Tick paralysis
12. Whipple's disease
13. Mycoplasma
14. Sepsis syndrome
15. Infective endocarditis
16. Herpes simplex
17. Herpes zoster

Intermittent Neuropathies

1. CIDP

2. Vasculitides
3. Myelin-associated glycoprotein (MG) antibody neuropathy
4. SGPG antibody
5. Gal (B1–3) Gal Nac antibody
6. Asido GMI antibody
7. Anti-sulfatide
8. Gd1B antibody
9. GQ1B antibody
10. Acute relapsing axonal GBS
11. Acute intermittent porphyria
12. Variegate porphyria
13. Coproporphyrinuria
14. Refsum's disease (HMSN-IV)
15. Tangier's disease
16. Hereditary heat sensitive neuropathy
17. Fabry's disease
18. Hereditary sensitivity to pressure palsy (HNPP)
19. Chronic relapsing autonomic neuropathy
20. Hereditary neuralgic amyotrophy
4. Thoracic outlet syndrome
5. Rib-band syndrome (C8–T1)
6. Cleido-clavicular syndrome
7. Cubital tunnel (ulnar nerve)
8. Arcade of Frohse (posterior interosseous and radial sensory nerve)
9. Struthers' ligament (medial nerve)
10. Guyon's canal (ulnar)
11. Entrapment of the medial antebrachial cutaneous nerve
12. Dorsal scapular nerve
13. Suprascapular nerve (suprascapular notch)
14. Musculocutaneous nerve
15. Intercostobrachial nerve (from the medial cord of the brachial plexus)
16. Radial nerve (radial groove of the humerus)
17. Anterior/posterior interosseous nerves
18. Recurrent nerve of Kuntz (T1–T4 sympathetic nerve)
19. Lumbosacral syndrome (pelvic entrapment of L5)
20. Ilioinguinal nerve
21. Genitofemoral nerve
22. Sciatic nerve (sciatic notch; piriformis)
23. Piriformis syndrome
24. Posterior popliteal fossa syndrome
25. Peroneal (common; superficial and deep entrapments)
26. Intercostal nerves
27. Rectus abdominis syndrome
28. Sural nerve (usually when it penetrates the deep fascia of the lower leg)
29. Obturator nerve (canal compression)
30. Femoral nerve (under the inguinal ligament)
31. Lateral femoral cutaneous nerve (under the inguinal or through the ligament)
32. Anterior femoral cutaneous nerve
33. Intermediate femoral cutaneous nerve
34. Recurrent nerve of Gonyea (branch of the tibial nerve)
35. Recurrent nerve of Spurling (innervates the dura of L5; radiates to the anterior thigh)
36. Medial plantar nerve (tarsal tunnel)
37. Calcaneal branch of the plantar nerve (posterior tibial nerve)
38. Entrapment of the plantar nerve within septae in the sole of the foot
39. Gluteal nerve
40. Iliohypogastric nerve
41. Posterior tibial nerve
42. Anterior tarsal tunnel syndrome
43. Digital nerves
44. Metatarsal tunnels (entrap the digital nerves)
45. Lumbrical canal entrapment of the metacarpophalangeal digital nerves

Neuropathy from Traumatic/Physical Agents

1. Overuse syndromes (tunnel entrapments, particularly of the upper extremity)
2. Brachial plexus fixation with secondary peripheral nerve tunnel syndromes
3. Compartment syndromes
4. Perioperative neuropathies (compression during malplacement under anesthesia)
5. Prolonged lithotomy position
6. Diaphragmatic neuropathy:
 - a. Trauma
 - b. Thoracic outlet surgery
 - c. Neck surgery
 - d. Spinal cord injury (stabilization procedures)
7. Direct trauma to peripheral nerves:
 - a. Motor vehicle accidents
 - b. Falls
 - c. Contact sports
8. X-RT (ischemia of the vasa vasorum)
9. Bone marrow transplantation (perineural and intraneural hemorrhage)
10. Heat
11. Cold (frostbite)
12. Snake bite envenomation (hemolytic toxins; compartment syndromes)
13. Entrapment syndromes
14. Double and triple crush syndromes (C5–C6 spondylosis, osteophytes with concomitant carpal tunnel syndrome)

Entrapment Syndrome

1. Long neck sloping shoulder syndrome
2. Roos congenital bands (12 bands; entrap various components of the brachial plexus)
3. Cervical rib syndrome

Mononeuropathy Multiplex

1. Vasculitis
2. Vasculopathy
3. Rheumatoid arthritis

4. Connective tissue diseases
5. Systemic necrotizing vasculitides
6. Polyarteritis nodosa
7. Allergic granulomatous angiitis (Churg-Strauss)
8. Hypersensitivity angiitis
9. Wegener's granulomatosis
10. "Overlap" connective disease syndromes
11. Non-systemic vasculitis (isolated vasculitic neuropathy)
12. Mixed cryoglobulinemia
13. Diabetes
14. Amphetamine abuse
15. Sarcoidosis
16. Leprosy
17. Cytomegalovirus (in HIV patients with AIDS)
18. Neurofibromatosis

Multiple Mononeuropathies

1. Immune-mediated neuropathies
2. Entrapments
3. Pressure palsies (including HNPN)
4. Electrical injury
5. Immunization
6. Herpes zoster
7. Carcinomatous infiltration
8. Lymphoma
9. Diphtheritic wound infection (local toxin production)
10. Diabetes
11. All collagen vascular diseases
12. Monomelic sensory neuropathy

Bilateral Carpal/Tarsal Tunnel Syndrome

1. Occupational overuse syndromes
2. Rheumatoid arthritis
3. Double crush syndrome (CTS and brachial plexus traction injury)
4. Scleroderma
5. Mucopolysaccharidosis
6. Acromegaly
7. Ganglion cysts
8. Diabetes mellitus

Neuropathies Involving the Diaphragm

1. Thiamine deficiency
2. Pyridoxine deficiency
3. Trauma (cervical fractures)
4. Following or during brachial plexus decompression (often injured with either first rib removal or medial scalenectomy surgery)
5. Chiropractic manipulation
6. Critical illness neuropathy
7. CMT2C
8. CMT1 (4C)
9. AIDP
10. CIDP
11. AIP

12. Paraneoplastic neuropathy
13. Viral (acute)
14. Hereditary (brachial plexopathies)
15. Neuralgia amyotrophic (hereditary and acute)

Chapter 8

The Neuromuscular Junction

Overview

The neuromuscular junction is anatomically divided into:

1. The presynaptic region
2. The synaptic cleft
3. The postsynaptic area

Diseases of the neuromuscular junction are due to abnormalities in each of these compartments. Presynaptic defects occur from reduced release of normal amounts of acetylcholine (ACh) from:

1. Impaired terminal calcium entry
2. Defective synthesis or packaging of ACh into synaptic vesicles
3. Diminished ACh release into the synaptic cleft

Synaptic neuromuscular transmission (NMT) defects occur primarily with congenital myasthenic syndromes in which there are mutations in the gene for acetylcholinesterase, which decreases its amount or its kinetics. Continuous depolarization leads to structural changes in the functional folds of the ACh receptors (AChR) as well as its desensitization. Postsynaptic neuromuscular transmission defects occur from loss of AChR due to antibodies, complement fixation, and cross-linking. In congenital myasthenic syndromes, there are mutations in the genes that encode AChR subunits that change the kinetics of the receptor (post and slow channel myasthenia). In either mechanism, there is a reduced excitatory postsynaptic (EPSP) amplitude that fails to produce depolarization of the innervated somatic muscle fibers.

Synaptic vesicles are clustered in membrane dense areas called active zones. ACh vesicle release is dependent on calcium entry into the presynaptic terminal. The presynaptic L and P/Q calcium channels are pivotal to the process and are located in the active zones where vesicle fusion occurs in the presynaptic membrane. Calcium entry through L and P/Q channels initiates vesicle fusion and exocytotic release of vesicles containing ACh (quanta) into the synaptic cleft. It takes approximately 75 to 100 microseconds from the arrival of the terminal action potential to vesicle release. An average nerve terminal contains between 200 to 400 thousand vesicles: approximately 20% of which are in the active zone that are positioned for immediate release. Each vesicle contains approximately 5 to 10 thousand ACh molecules. The reserve pool of vesicles is estimated to contain 300,000 vesicles that can be rapidly transported to active zones. After vesicle fusion and with the presynaptic membrane and exocytosis acetylcholine is degraded by acetylcholinesterase in the synaptic cleft and also diffuses away. Reuptake mechanisms recycle choline into the presynaptic terminal (acetylcholine transferase) for resynthesis and repackaging. Under normal

physiologic conditions, the rate of resynthesis and ACh release are equal.

The synaptic processes that maintain neuromuscular transmission are extremely complex and include:

1. ACh synthesis and resynthesis
2. Clustering of synaptic vesicles at the active zone
3. Docking of synaptic vesicles at the active zone
4. Fusion pore opening and exocytotic release of ACh into the synaptic cleft initiated by calcium entry into the presynaptic terminal
5. Endocytosis, refilling, and packaging of vesicles in the presynaptic site with further distribution to either the active or reserve vesicle pool

Three major proteins associated with this extremely complicated process are:

1. Synaptobrevin (vesicle-associated membrane protein)
2. Syntaxin
3. SNAP-25

These soluble N-Ethylmaleimide-sensitive factor (NSF) attachment proteins (SNARE) are pivotal for vesicle binding and fusion and creation of the fusion pore. The SNARE complex is also dependent on other proteins that include Munc18-1 and the synaptophysins that interact with synaptobrevin which is pivotal for vesicle fusion and exocytotic release. Synaptotagmin is a calcium sensor in the presynaptic terminal.

The primary synaptic cleft, between the nerve terminal and muscle membrane, has multiple secondary clefts that are composed of postfunctional folds that extend into the postsynaptic area. These secondary folds greatly increase the postfunctional membrane area that increases the density of ACh receptor channels. The synaptic cleft is 50 nm in width between the presynaptic terminal membrane and the convexity of the synaptic folds. The primary and secondary synaptic clefts communicate. The basement membrane of the lateral synaptic space communicates with the extracellular space, and there is also communication between the muscle transverse tubular system and the secondary synaptic clefts. The synaptic cleft contains acetylcholinesterase (AChE) which is attached to the basement membrane by its collagen tail (ColQ) and hydrolyses acetylcholine into acetate and choline. The density of AChRs is 5 to 10 X greater than the molecular density of AChE such that under normal physiologic conditions 50 to 75% of released presynaptic quanta interact with AChRs. AChE exists in two primary isoforms. The cis-form terminates ACh ligand interaction with its receptor. The R isomer lacks an anchoring tail and is soluble. It limits access of ACh to its receptor and may be a regulator of ACh and AChR interaction.

Postfunctional folds develop with age and are perpendicular to the orientation of the synaptic cleft and the afferent presynaptic terminal. Fast twitch muscles have more extreme functional folds than slow twitch muscles. The convexities of the functional folds contain the great proportion of ACh receptors (10,000 particles/mm²).

ACh receptors are anchored to the sarcolemma and are clustered by the protein rapsyn (in conjunction with other proteins) that is located in the immediate subsarcolemmal area. Rapsyn is bound to the transmembrane protein B dystroglycan that is linked to the intracellular cytoskeleton by the protein utrophin. This AChR-utrophin-glycol-protein complex is linked to the extracellular matrix by the protein agrin (also important in AChR aggregation). MuSK (muscle-specific kinase) is also important for AChR and colocalizes with agrin in the sarcolemmal membrane.

AChRs are transmembrane complexes that consist of four different glycoprotein subunits (A, B, G and E). The adult AChR consists of 5 subunits, two alpha (A), one beta (B), one gamma (G), and one epsilon (E). Fetal receptors contain gamma rather than E-subunits on some oculomotor and bulbar muscles. In denervation and some congenital myasthenic syndromes, a gamma subunit may replace the E-subunit.

A nerve action potential causes a muscle non-propagating endplate potential of >50 mV which exceeds the muscle action potential threshold (by approximately fourfold). Voltage-gated sodium channels, primarily located in the depths of the synaptic folds, facilitate the excitatory endplate potential that is generated by ACh receptor openings. Temperature affects neuromuscular transmission. The duration and amplitude of the nerve action potential at the presynaptic terminal increases with cooling. This may be affected by prolongation of calcium channel open states that augments ACh release. The hydrolytic kinetics of the acetylcholinesterase decreases at temperatures below 34°C , which increases the probability of ligand ACh binding with its receptors. Lower temperatures also decrease the resting membranes' potential (bring it closer to the threshold) of the resting muscle membrane. Jitter may improve with reducing muscle fiber temperature.

The excitatory postsynaptic potential (EPSP) is a graded response different from the all-or-none response action potential it initiates. It is decreased by repetitive stimulation at very high frequencies due to depletion of the ACh vesicles in the active zone. After the fourth or fifth stimulus, the EPSP increases due to augmentation of vesicles from the reserve pool. Repetitive stimulation at high frequencies may augment the EPSP due to post-tetonic facilitation from enhanced ACh release which is due to increased calcium within the presynaptic terminals. This response declines in approximately 1 minute due to depletion of ACh vesicles (post-tetonic exhaustion). The loss of the EPSP safety margin is the basis of many neuromuscular function disorders.

Neuromuscular Junction Disorders

General Characteristics

1. Peripheral Neuropathy with Anhidrosis
 - a. Pure autonomic failure
 - b. Diabetes

- c. Amyloidosis
- d. Fabry's disease
- e. Acute autonomic neuropathy (autoimmune/viral)
- f. AIDS
- g. HSAN (I–V)
- h. Tangier's disease
- i. Sjögren's disease
- j. Ross syndrome
- k. Holmes-Adie syndrome
2. Dermatological Causes of Anhidrosis
 - a. Local
 - i. Thermal
 - ii. X-RT
 - iii. Scarring
 - iv. Inflammation
 - b. Anhidrotic ectodermal dysplasia
 - c. Psoriasis
 - d. Exfoliative dermatitis
 - e. Lichen sclerosus atrophicus
 - f. Ichthyosis
 - g. Miliaria
 - h. Incontinentia pigmenti
 - i. Dermatomal distribution fillings

Neuropathy of Connective Tissue Disease

1. SLE
2. Rheumatoid arthritis
3. Mixed connective tissue disease
4. SICCA complex
5. Relapsing polychondritis

Neuropathy with Systemic Necrotizing Vasculitis (Small- and Medium-Sized Arteries)

1. Polyarteritis nodosa (PAN)
2. Allergic anguitin granulomatosis (Churg-Strauss)
3. Wegener's granulomatosis
4. Vasculitis of connective tissue disease
5. Polyangitis over cap syndrome
6. Isolated peripheral nerve vasculitis (PAN)

Neuropathy with Hypersensitivity Vasculitis (Small Vessel, Capillaries, Arterioles, and Venules)

1. Henoch-Schönlein purpura
2. Vasculitis with infectious disease
3. In association with drug reactions
4. Connective tissue disease
5. Neoplasm

Neuropathy with Vasculitis and Malignancy

1. More common in myelo- and lymphoproliferative disease
2. Rare in association with solid tumors
3. Prominent in hairy cell leukemia
4. Chédiak-Higashi disease

5. Unusual Vasculitis of Peripheral Nerves in Association with:
 - a. Cryoglobulinemia
 - b. Sjögren's disease
 - c. Relapsing polychondritis
 - d. Reiter's disease
 - e. Hypereosinophilic syndrome

Differential Diagnosis of CIDP

1. Osteoclastic myeloma
2. Plasma cell dyscrasia
3. HIV
4. SLE
5. Malignant melanoma
6. Monoclonal gammopathy
7. Hepatitis B
8. Inflammatory bowel disease

Differential Diagnosis of Dorsal Root Ganglionopathy

1. Herpes zoster
2. Syphilis (dorsal root entry zone)
3. Paraneoplastic syndromes (sensory variants)
4. GD1b (epitopes)
5. Sjögren's disease
6. Anti-sulfatide epitopes
7. SICCA complex
8. Autoimmune disease

Axonal Restless Leg Syndrome

1. Diabetes
2. Chronic obstructive lung disease
3. Primary amyloid
4. Anemia
5. Cancer
6. Iron deficiency anemia

Neuropathy Primarily of the Upper Extremity

1. Gen I
2. Lead
3. Amyloid
4. Porphyria
5. Multiple myeloma
6. Hypoglycemia (Insulinoma)
7. Hypothyroidism

Neuropathy Associated with Lymphoma/Leukemia/Blood Dyscrasias

1. Polycythemia vera
2. Chronic lymphocytic leukemia
3. Direct lymphomatous infiltration of nerves
4. Bone marrow transplant (interperineural hemorrhage)
5. Acute leukemia (bleeding into nerves)

6. Chédiak–Higashi disease
7. Hypereosinophilic syndrome (idiopathic; tryptophan impurity induced)
8. Paraprotein associated
9. Waldenström's macroglobulinemia

Myasthenia Gravis (MG)

Overview

The most common neuromuscular junction disorder encountered in clinical practice is acquired myasthenia gravis. It is physiologically characterized by decreased endplate potentials that fail to generate an action potential. Its primary cause is the reduction and blockade of acetylcholine receptors (AChR) at the postjunctional membrane from antibodies directed primarily at the alpha subunit. Recently other antigenic targets have been identified. The neuromuscular junction disorders are the clinical representation of deficits in:

1. Quantal release of acetylcholine
2. Postsynaptic membrane architecture alteration (destruction)
3. AChR conduction parameter (kinetic) dysfunction
4. Density of ACh receptors at the neuromuscular junction
5. Acetylcholinesterase activity
6. Calcium-induced releasing factors at the motor nerve terminal. The difference between the membrane potential and the threshold for initiating an action potential in these disorders is the safety factor for neuromuscular transmission

Different physiological mechanisms for failure of neuromuscular transmission are operative in each disorder of neuromuscular function. Specific muscular functions that are affected, the associated diseases and components of the CNS/PNS that are involved differentiate the entities. In general, patients with neuromuscular diseases have no sensory loss (unless peripheral nerves are affected concomitantly) and have intermittent symptoms particularly with exercise. Diaphragmatic and thoracic paralysis lead to hypercarbia that manifests as lethargy, asterixis, dilated retinal and cerebral veins and rarely papilledema (young patients). All forms of NMJ disease lead to muscle weakness. The pupils and reflexes are variably involved, as is the autonomic nervous system.

General Characteristics

1. The incidence of MG is 1–9 per million persons; prevalence is between 25–142/million persons
2. The incidence is greater in women than men
3. The age of onset is bimodal for both sexes:
4. In women the peak incidence is:
 - a. 20–24 years
 - b. 70–75 years
5. The peak incidence in men is:

- a. 30–34 years
 - b. 70–74 years
6. The gender ratio in early disease is women 7:3; in late disease it is 1:1

Clinical Manifestations

1. Most often the onset is subacute
2. Ptosis of one eyelid is the most common early sign
3. Symptoms and signs vary over time
4. Proximal weakness particularly of the lower extremities is greater than distal weakness and is a common pattern
5. In approximately 10% of patients the weakness may be restricted to distal limb muscles; foot or finger drop may be the initial manifestation
6. Head drop may be a presenting feature
7. Ventilatory failure may also occur initially in a small group of patients
8. There is fatigue with exercise of specific muscle groups (chewing, swallowing, and holding the head up)
9. Clinical involvement may be purely ocular in 15% of patients
10. Aggravating features for weakness include:
 - a. Exercise
 - b. Heat
 - c. Menses
 - d. Infection
 - e. Pregnancy
 - f. Stress
 - g. Hypokalemia
 - h. Thyroid dysfunction
11. 40 to 50% of patients present with ptosis or diplopia; mild ocular deviation often causes blurred vision (non-foveation)
12. 20 to 30% of patients have combined ocular complaints and muscle weakness
13. Bulbar complaints at initial presentation occur in approximately 20% of patients

Clinical Examination

1. Ptosis (usually is asymmetric); lifting the ptotic lid may exacerbate droop of the other lid
2. Normal pupil (with a magnifying glass there may be slight slowness of contraction to light)
3. Cranial nerves III, IV or VIth nerve weakness; the IIIrd nerve is the most commonly affected
4. A pseudo intranuclear ophthalmoplegia may be demonstrated
5. Cogan's twitch sign (overactivation of coinnervated yoked muscles; overstimulation or stimulation of the levator palpebrae after fatigue of the inferior oblique and superior rectus muscles)
6. Lower facial muscle weakness (transverse smile); prominent jaw weakness; patients may hold them closed with their hand

7. Neck flexor and extensor muscle weakness to a similar degree (flexor are weak with myopathy and extensor are weak with motor neuron disease)
8. Triple furrowed tongue (differential weakness of intrinsic tongue muscle contraction)
9. Peek-a-boo sign (slight opening of the eyelids occurs after forced eyelid closure due to weakness of the orbicularis oculi)
10. Sluggish gag reflex, difficulty swallowing liquids and nasal speech
11. Weakness increases with repetitive use
12. Reflexes are normal to increased (spread of acetylcholine sensitivity of the sarcolemmal membrane to mechanical stimuli)
13. Respiratory weakness may appear as an isolated sign
14. Patients may suffer isolated distal limb weakness and neck extensor weakness
15. Difficulty in weaning from a respirator following a surgical procedure
16. Rarely isolated bulbar weakness
17. No sensory loss
18. No autonomic dysregulation

Osserman Scale for Disease Severity

1. Group 1
 - a. Ocular
 - b. 15–20%
 - c. Extraocular muscle involvement
2. Group 2A
 - a. Mild generalized disease
 - b. 30%
 - c. Oculo bulbar and limb muscle
 - d. Minimal ventilator embarrassment
 - e. Respond well to anticholinesterase medication
3. Group 2B
 - a. Moderately severe generalized disease
 - b. 20%
 - c. Severe brainstem signs that include:
 - i. Ptosis
 - ii. Diplopia
 - iii. Dysarthria
 - iv. Dysphagia
 - v. Fatigue with exercise
4. Group 3
 - a. Severe generalized weakness with rapid progression over 6–8 months
 - b. Ventilatory difficulties
5. Group 4
 - a. Initially have mild disease that plateaus over approximately 2 years
 - b. Progresses to severe disease

Clinical Manifestations of Patients with MuSK Antibodies

1. Higher female to male ratio
2. Disease onset in the third or fourth decade

3. Ocular bulbar weakness with dysarthria
4. In long-standing disease patients may develop face and tongue atrophy
5. Drooped head, shoulder and respiratory muscle weakness
6. Myasthenic crises may be more frequent than in patients with AChR disease

Clinical Manifestations of Patients with Antibodies to KV 1.4 Voltage-Gated Potassium Channels

1. Bulbar involvement
2. Thymoma
3. Myocarditis
4. Long QT interval

Clinical Manifestations of Juvenile Myasthenia Gravis

1. Approximately 10% of acquired disease
2. Onset is prior to age 18
 - a. Most prior to puberty
 - b. Mean age is between 7–14 years
3. Majority of patients present with ocular signs and symptoms
4. Similar signs and symptoms to adult MG

Clinical Manifestations of Neonatal MG

1. Transient neonatal MG occurs in approximately 10% of infants born to affected mothers
2. Onset is usually within the first 3 days of life
3. Failure to suck and feed properly
4. Facial muscle weakness
5. Duration of the illness is approximately 3 weeks

Associated Medical Illnesses

1. Rheumatoid arthritis
2. Systemic lupus erythematosus
3. Sjögren's syndrome
4. Red blood cell aplasia
5. Ulcerative colitis
6. Sarcoid
7. Addison's disease
8. Hyper- and hypothyroidism
9. Diabetes mellitus
10. Platelet abnormalities (ITP)
11. B12 deficiency

Associated Neuromuscular Diseases

1. Thymomas increase the number of other associated concomitant autoimmune mediated neurological diseases
2. Acute and chronic inflammatory demyelinating polyneuropathy
3. Severe autoimmune neuropathy (may be associated with encephalopathy; concomitant with MG and thymoma)
4. Rare combination of MG and Lambert-Eaton syndrome
5. Approximately 5% of patients with MG suffer an associated inflammatory myopathy (often with thymoma and myocarditis)

6. Myasthenia and thymoma may be associated with:
 - a. Acquired neuromyotonia
 - b. Rippling muscle disease
 - c. Stiff person syndrome
 - d. Granulomatous myositis
 - e. Cerebellitis
 - f. Autonomic neuropathy

Neuropathology

1. The thymus gland is pivotal in the pathogenesis of MG with AChR autoantibodies
2. Almost all MG patients have thymic alterations; approximately 50% have thymic hyperplasia
3. 10–15% have a thymic tumor
4. Hyperplastic thymus glands contain:
 - a. T-cells
 - b. B-cells
 - c. Plasma cells
 - d. Muscle-like myoid cells that express AChR
5. The components for an immune response to AChR
6. Thymocytes in culture spontaneously secrete anti-AChR antibodies
7. Suggested that there is an intrathymic source for the initiation of the anti-AChR immune response with the productions of AChR antibodies in MG patients with thymic hyperplasia

Thymoma

1. A neoplasm of thymic epithelial cells
2. Express self-antigens that include:
 - a. AChR
 - b. Titin
 - c. Ryanodine receptor-like epitopes
3. There is no autoantibody production within thymomas; sensitized autoreactive lymphocytes proliferate and exit the tumor to activate B-cells that produce autoantibodies
4. The thymus gland is a primary site for immune regulation; in MG there may be a defect in immune suppression of autoreactive lymphocytes
5. ACh-specific CD4+ T-cells are present in the serum of MG patients concomitantly with antibodies and are also expressed in the thymus, which suggests that the thymus is the site of T-cell sensitization
6. There may be deficiency of the autoimmune regulator gene and a selective loss of regulatory T-cells in the disease process

Muscle Biopsy

1. Type 1 fiber predominance; mild fiber type grouping
2. Type 2 fiber atrophy
3. Focal interstitial inflammatory infiltrates (lymphorrhagias) may be seen at endplates
4. Electron microscopy:
 - a. Postsynaptic membrane:

- i. IgG and complement precipitation on the membrane
- b. Increased synaptic space
- c. Reduced postsynaptic membrane complexity with diminished post-junctional folds
- d. Decreased AChR; those that remain may be cross-linked with IgG antibodies
- e. Presynaptic terminals are normal
- f. MuSK antibody disease:
 - i. Has normal density and distribution of AChR
 - ii. No structural changes of the NMJ
 - iii. No complement deposition

Laboratory Evaluation

1. EMG:
 - a. Normal motor and sensory conduction velocities
 - b. Fibrillation potentials and positive sharp waves are rare but have been noted in paraspinal, bulbar and proximal muscles
 - c. Short duration and low amplitude MUAP with early recruitment can occur (due to neuromuscular blockade within a specific motor unit)
 - d. Unstable MUAP variability
 - e. Decremental response to slow repetitive stimulation
 - i. A Jolly response is positive in 85% of patients with generalized MG
 - ii. At least a 10% decrement between the first and fourth compound muscle action potential (CMAP) at 2–3 Hz
 - iii. 30–40% will have a negative repetitive stimulation test in pure ocular MG
 - iv. In the face of a decremental response:
 1. Maximal contraction of the tested muscle for 30–60 seconds abolishes the discriminant for 120 seconds after exercise (post-tetanic potentiation)
 2. The decrement is increased (post-tetanic exhaustion) for 120–240 seconds following further vigorous exercise
 - v. Single-fiber electromyography
 1. Jitter (latency variability between single muscle fiber potentials innervated by the same axon) is increased in MG
 2. Blocking (absence of the second muscle fiber potential) may be noted
 3. Single-fiber EMG is abnormal in 95–100% of MG patients
2. Serological evaluation
 - a. AChR antibodies are detected in the great majority of patients
 - b. There are 3 types of antibodies that include:
 - i. AChR binding antibodies
 - ii. AChR modulation antibodies
 - iii. AChR blocking antibodies
 - c. An elevation of one or more of these antibodies occurs in 80–90% of patients with MG:

- i. In patients with ocular myasthenia the sensitivity is 70–80%
- ii. In generalized MG it is usually >90% sensitive
- iii. There is no phenotype difference between seronegative or positive patients
- d. Most patients demonstrate both binding and modulation antibodies
- e. Approximately 75% of patients with a thymoma have modulating antibodies
- f. AChR blocking antibodies occur in 30% of patients with restricted ocular myasthenia and in 50% of patients with generalized disease
- g. AChR binding antibodies are found in:
 - i. Autoimmune liver disease
 - ii. LEMS (approximately 13%)
 - iii. Cancer (in the absence of neuromuscular disorder)
- h. The serum level of antibodies does not correlate with the severity of disease

MuSK Antibodies

1. Muscle-specific kinase (MuSK) antibodies are found in 40% of MG patients who do not have AChR antibodies
 - a. It is a NMF (neuromuscular function) protein that is specifically expressed at the postsynaptic membrane:
 - i. Colocalized with the AChR
 - b. Has a pivotal role in the maintenance of the NMF by mediating clustering of the AChRs; inhibition of MuSK synthesis causes AChR dispersion and endplate disruption
 - c. MuSK and low-density lipoprotein receptor-related protein 4 (LRP4 is a receptor for neural agrin – a nerve-derived extracellular protein)
 - i. MuSK antibodies bind to the N-terminal half of the extracellular domain of MuSK that inhibits agrin-induced AChR clustering
 - ii. Anti-MuSK antibodies in human MG are of the IgG4 subclass and do not activate complement
 - d. Approximately 7 to 8% with MG are double seronegative and have neither anti-AChR nor anti-MuSK antigens:
 - i. Approximately 60% of these patients have “low affinity” AChR antibodies as opposed to the “high affinity” antibodies of detached autoantibodies to AChR and MuSK
 - ii. These antibodies activate complement

Striated Muscle Antibodies

1. These are antibodies directed against components of skeletal muscles and include:
 - a. Titin
 - b. Ryanodine
 - c. Myosin
 - d. L-actin
2. These antibodies are detected in:
 - a. 30% of MG patients without thymoma

- b. 24% of patients with thymoma and without MG
- c. 70 to 80% of patients that have a thymoma with MG
- d. They may be detected in patients without MG or thymoma
- 3. Antibodies against KV.1 subunit of the voltage-gated potassium channels:
 - a. Do not occur in patients with thymoma-induced inflammatory myopathy

Pulmonary Function Tests

- 1. Are positive or abnormal in 85 to 90% of patients with generalized MG
- 2. Pulmonary function tests:
 - a. Abnormal spirometry
 - b. Decreased mean ventilatory volume:
 - i. Fatigue
 - ii. Restrictive pattern
 - c. CT scan of the chest:
 - i. Evaluation for thymoma
 - d. Blood evaluation to rule out associated autoimmune disease

Differential Diagnosis of Ocular Myasthenia Gravis

- 1. Brainstem lesions that affect the IIIrd cranial nerve (in this instance the pupil is often involved)
 - a. Pseudo intermuscular ophthalmoplegia from MG (convergence is often affected)
 - b. Central Horner's syndrome (pupil is meiotic)
 - c. Painless and alternating ptosis over several days favors MG
 - d. Graves (thyroid) ophthalmopathy:
 - i. All ocular muscles enlarge
 - ii. Forced ductions demonstrate decreased motility
 - iii. Pathologic retraction of the globe
- 2. Kearns-Sayre syndrome:
 - a. Associated heart block
 - b. Usually ophthalmoplegia involves several extraocular muscles
- 3. Progressive external ophthalmoplegia (PEO):
 - a. Symmetric ptosis
 - b. Associated cardiomyopathy, peripheral neuropathy and proximal muscle weakness
 - c. Slow saccades are associated with PEO; MG demonstrates rapid saccades within the limits of EOM weakness
- 4. Aneurysm:
 - a. Retro-orbital pain
 - b. Pupillary involvement; it is often oval along with decreased response to light
- 5. Diabetic IIIrd nerve palsy:
 - a. Sudden onset of dysfunction
 - b. No pupillary involvement (most often)
- 6. Autoimmune thyroid disease:
 - a. Commonly exists with MG
 - b. Periorbital pain

Differential Diagnosis of Generalized MG Paralysis from Central Disorders

- 1. Brainstem lesions (have associated long tract signs)
- 2. Basilar meningitis (fever, stiff neck)
- 3. Demyelinating disease (sensory loss; cerebellar signs; optic nerve involvement)

Differential Diagnosis from Other Neuromuscular Disorders

- 1. ALS (bulbar presentation):
 - a. Extraocular muscle (EOM): extremely rare – involvement with ALS
 - b. Fibrillation in affected muscles
- 2. Diphtheria
 - a. Pupils are involved
- 3. Polymyositis:
 - a. Swallowing may be involved
 - b. Painful muscles with proximal weakness
- 4. Inclusion body myositis:
 - a. Swallowing may be involved
 - b. Contractions and atrophy of forearm flexor muscles
- 5. Granulomatous myopathy (sarcoid):
 - a. VIIth nerve involvement
 - b. More symmetric muscle involvement than with MG
- 6. Lambert-Eaton syndrome:
 - a. Autonomic involvement (dry mouth)
 - b. "Load in the pants" gait
 - c. Minimal ptosis (less cranial nerve involvement)
 - d. Exercise-induced increase in strength
- 7. CM Fisher syndrome:
 - a. May have severe ophthalmoplegia
 - b. Loss of reflexes (does not occur in MG)
- 8. Botulism:
 - a. Symmetrical pupillary involvement
 - b. Pharyngeal dysfunction
 - c. Autonomic alterations

Congenital Myasthenic Syndromes

Overview

The congenital myasthenic syndromes are a heterogeneous group of disorders in which specific mechanisms involved in neuromuscular transmission fail.

These include:

- 1. The syntheses and packaging of acetylcholine (ACh) quanta into synaptic vesicles
 - 2. The Ca^{2+} -dependent release of ACh from the afferent nerve terminal
 - 3. The effectiveness of the released quanta in depolarizing the postsynaptic membrane
- The ability of the released ACh quanta to depolarize the postsynaptic membrane in turn depends upon:
- 1. Endplate geometry
 - 2. The density and effectiveness of acetylcholinesterase (AChE) in the synaptic cleft
 - 3. The kinetic parameters of the acetylcholine receptor (AChR)

Presynaptic Congenital Myasthenic Syndromes

1. A defect in the transfer of an acetyl group from acetyl – CoA to choline in cholinergic neurons

Clinical Manifestations

1. Patients may present with hypotonia, bulbar weakness and apneustic episodes at birth
2. A subgroup of patients is normal at birth but suffer apneic attacks during infancy and childhood. Rare respiratory insufficiency may last a long time following an apneic attack. The attacks may be precipitated by infection or emotional upset
3. Apneic attacks may require ventilatory support and have been associated with cerebral hypoxemia and cerebral atrophy. A few are paralyzed since birth
4. The patients that improve with age have variable ptosis, ophthalmoplegia, weakness with exercise and recurrent cyanotic episodes. The signs and symptoms are aggravated by cold

Neuropathology

1. Pathologic mutations may alter expressions of the enzyme, diminish its catalytic efficiency or structural stability
2. Repetitive firing is associated with a decreased rate of ACh resynthesis, which depletes ACh content of synaptic vesicles
3. Electron microscopy:
 - a. Synaptic vesicles are smaller
 - b. Postsynaptic structures are normal

Laboratory Evaluation

1. Physiology:
 - a. Amplitude of the miniature EP potential (MEPP) decreases with repetitive stimulation

*Paucity of Synaptic Vesicles and Reduced Quantal Release**General Characteristics*

1. The number of acetylcholine quanta released by nerve impulses is decreased

Clinical Manifestations

1. Ptosis
2. Ophthalmoparesis
3. Facial weakness
4. Fatigable muscle weakness

Neuropathology

1. Decreased store of quanta
2. Decreased density of synaptic vesicles in the release zone of the presynaptic terminal

Laboratory Evaluation

1. EMG
 - a. Amplitude of the MEPP decreases with repetitive stimulations

Congenital Lambert-Eaton-Like Syndrome*General Characteristics*

1. The number of quanta released by the afferent impulse is decreased

Clinical Manifestations

1. Hypotonia and decreased reflexes
2. No ocular or facial signs
3. No response to 3,4-DAP:
 - a. Enhances quantal release in the acquired forms of Lambert-Eaton syndrome

Neuropathology

1. Decreased probability of quantal release
2. Normal endplate ultrastructure

Laboratory Evaluation

1. Repetitive nerve stimulation demonstrates marked facilitation of the compound action potential at physiological stimulation rates

Synaptic Basal-Lamina-Associated CMS*General Characteristics*

1. The components of the endplate form of the AChE enzyme is encoded by two genes:
 - a. AChE
 - b. Encodes the catalytic subunit
2. COLQ
 - a. Encodes the collagen structural subunit
 - b. COLQ protein anchors the complex in the synaptic basal lamina
3. ACh time in the synaptic cleft is increased

Clinical Manifestations

1. Most patients present in infancy and are severely disabled; the clinical course, however, is variable depending on the specificity of the mutation
 - a. The patients with a severe course have mutations in the N-terminal or rod domain of COLQ
 - b. Abolishes the expression of AChE in the synaptic cleft
2. Patients with missense mutations that don't affect the triple helical assembly of COLQ or do not inhibit the insertion of COLQ into the synaptic basal lamina present later in children and have a less severe clinical course
3. Mild slowness of the pupillary light reflex
4. Adult patients:
 - a. Reduced muscle bulk
 - b. Axial weakness
 - c. Hyperlordosis and kyphoscoliosis

Neuropathology

1. The cation overload at the endplate causes degeneration of the functional folds and loss of AChRs
2. Altered endplate geometry

3. Reduction in the size of the nerve terminals that fail to cover the endplate
4. Atrophy of presynaptic terminals
5. Decreased number of secondary ending postsynaptic clefts
6. Presence of fetal AChR that contain the G-subunit rather than the E-subunit
7. Muscle biopsy:
 - a. Normal tissue
 - b. Type 1 fiber predominance
8. Mutations of the COLQ gene on chromosome 3p24.2 have been well described

Laboratory Evaluation

1. Electrophysiology
 - a. The decrease of acetylcholinesterase within the synaptic cleft increases the half-life of acetylcholine
 - i. The EPP is prolonged; if it exceeds the refractory period of the muscle fiber there may be multiple depolarizations (discharges) from a single nerve action potential
 - ii. AChR desensitization

CMS Associated with B2-Lamina Deficiency

General Characteristics

1. B2 laminin is encoded by LAMB2 gene that maps to chromosome 6 of 22, 33
2. The protein is the basal lamina component of many tissues and is highly expressed in the kidney, eye, and NMJ
3. Synaptic B2-laminin aligns the axon terminal with the postsynaptic region
4. Pivotal for trophic interactions

Clinical Manifestations

1. The patient suffered Pierson syndrome with ocular and kidney dysfunction
2. Patients had heteroallelic missense and frameshift mutations in the LAMB2 gene
3. One patient suffered ocular, respiratory and limb-girdle weakness

Neuropathology

1. Electron microscopy:
 - a. Abnormally small endplates that are often encased by Schwann cells
2. Decreased quantal release
3. A widened synaptic space with simplified functional folds
4. Electrophysiological evaluation:
 - a. Reduced MEPP amplitude

Postsynaptic CMS – Primary AChR Deficiency

General Characteristics

1. The endplate deficiency is caused by AR homozygous or heterozygous mutations of the E-subunit of the AChR
2. There are other mutations in the E-subunit promoter region, the signal peptide region or in areas important for

subunit assembly (usually in an N-glycosylation site, in CYs128, the canonical CYN loop and in the long cytoplasmic loop of the subunit)

3. Homozygous subunit mutations occur in Mediterranean and Near Eastern ethnicities

Clinical Manifestations

1. Bulbar and severe extraocular muscle weakness
2. Weakness of both proximal and distal muscles
3. Incomplete response to AChE inhibitors; same response to 3,4-DAP and recently to albuterol

Neuropathology

1. An increased number of small endplate regions with an increased area of the muscle fiber
2. Attenuated and patchy distribution of the AChR's on the functional folds
3. The endplates in some areas demonstrate less complex functional folds although in general their structural integrity is intact
4. Type 1 fiber predominance
5. Fetal AChRs with the G-subunit rather than the E-subunit

Laboratory Evaluation

1. Reduced synaptic response to acetylcholine

Slow Channel Syndromes

General Characteristics

1. Most patients have gain of function
2. The mutation either enhances receptor affinity for ACh or increases its gating efficiency due to an accelerated rate of channel opening or may have a slow rate of channel closing

Clinical Manifestations

1. There is a variable phenotype that usually has a progressive course
2. Weakness in adult patients involves the cervical, wrist and finger extensor muscles
3. Mild ophthalmoparesis
4. Infant may be ventilator dependent

Neuropathology

1. Muscle biopsy:
 - a. Type 1 fiber predominance with type grouping of atrophic type I or II fibers
 - b. Fiber size variation
 - c. Tubular aggregates
 - d. Fiber splitting and endomysial fibrosis
 - e. Vascularization near the NMJ
2. Electron microscopy:
 - a. Endplate functional fold degeneration
 - b. Apoptotic nuclei
 - c. Degenerating organelles
 - d. An abnormal distribution of endplates over a large region of the muscle fiber

Laboratory Evaluation

1. Electrophysiology:
 - a. EPPs are prolonged; if the EPP (endplate potential) exceeds the absolute refracting period of the muscle fiber there may be repetitive CMAP; the repetitive response is accentuated with edrophonium – the opposite of AChE deficiency
2. At physiological rate of stimulation:
 - a. A depolarizing block may occur
3. Mutant channels may open in the absence of ACh which causes a leak into the postsynaptic area
4. The safety margin of neuromuscular transmission is decreased by:
 - a. Progressive depolarization block
 - b. Endplate myopathy (see neuropathology)
 - c. Desensitization of a proportion of mutant receptors
5. The syndromes (slow channel) are exacerbated by cholinergic agonists and improved by open-channel blocks of the AChR that include:
 - a. Quinine or quinidine
 - b. Fluoxetine

Fast Channel Syndrome*General Characteristics*

1. Recessively inherited
2. They have a decreased affinity for ACh, reduced gating efficiency, destabilization of channel kinetics or a combination of these mechanisms
3. Each mechanistic dysfunction causes an abnormally brief channel opening

Clinical Manifestations

1. Often have severe weakness
2. Muscle weakness involves limb, trunk, bulbar, respiratory, facial and extraocular muscles
3. Severe respiratory crisis in infancy and childhood
4. Patients respond to 3,4-DAP and anticholinesterase medications

Neuropathology

1. There are no neuropathological abnormalities

Laboratory Evaluation

1. Electrophysiology
 - a. There is an abnormally rapid decay of the EP potential and current

Prenatal Syndromes Caused by Mutation in AChR Subunits and Other Endplate Specific Proteins*General Characteristics*

1. AChR with the fetal gamma V subunit are demonstrated in myotubes in the ninth week of development; they cluster at early NMJ at the sixteenth week
2. The gamma-subunit is replaced by the E-subunit at the 31st week

Clinical Manifestations

1. Pathogenic mutations of the gamma-subunit cause:
 - a. Hypomotility in utero (16–31 weeks)
 - b. At birth, there are multiple joint contractions
 - c. Decreased muscle bulk
 - d. Multiple pterygia (webbing of the neck, axilla, fingers, elbows and popliteal fossa)
 - e. Camptodactyly (fixed flexion contraction of the fingers)
 - f. Facial dysmorphism (mild ptosis, small mouth with downturned corners)
 - g. Rocker-bottom feet (flat arches)
2. Myasthenic symptoms are absent after birth (there is normal expression of the E-subunit)
3. Lethal fetal akinesia occurs from biallelic null mutations in the AChR that affect:
 - a. Alpha, beta, and gamma (G) subunits
 - b. Rapsyn
 - c. Dok-7

Defects of Rapsyn That Cause CMS*General Characteristics*

1. Rapsyn along with agrin, LRP4, MuSK and Dok-7 clusters AChR in the postsynaptic membrane
2. Links it to the cytoskeleton through dystoglycans
3. Mutations have been demonstrated in the entire open reading frame and promoter regions
4. Mutations cause:
 - a. Decreased rapsyn colocalization with AChR
 - b. Decreased agrin-induced AChR clusters
 - c. Decreased rapsyn self-association
 - d. Decreased rapsyn expression
 - e. Indo-European ethnicity patients often have common N88K mutation

Clinical Manifestations

1. In most patients symptoms and signs are present at birth; rarely they present in the second or third decade
2. Arthrogryposis and other congenital anomalies occur in approximately 1/3 of patients
3. Increased weakness and respiratory crises occur with febrile illnesses and may be associated with anoxic encephalopathy
4. Open reading frame mutations may cause a phenotype that resembles autoimmune MG except that ophthalmoparesis is rare
5. Ptosis, facial and bulbar weakness is common and is associated with neck muscle weakness
6. Proximal muscle weakness is greater than distal
7. Severe weakness of foot dorsiflexor muscle is characteristic of the late onset patients
8. Patients may respond to 3,4 DAP AChE inhibitors

Neuropathology

1. Small cholinesterase reactive EP (endplate regions) are dispersed over an extended area of the muscle fiber

2. The synaptic contacts have altered geometry from the compact pretzel-shaped synaptic contacts at normal endplates

Laboratory Evaluation

1. May require single-fiber EMG to demonstrate defects in neuromuscular transmission

Defects in Plectin That Cause CMS

General Characteristics

1. Plectin is encoded by the PLEC gene that maps to chromosome 8q 24.3
2. It is an ubiquitously expressed intermediate neurofilament linking protein
3. It is a versatile link of cytoskeletal components to target organelles
4. It is found primarily at the site of mechanical stress that includes:
 - a. Postsynaptic membrane lining junctional folds
 - b. Sarcolemma
 - c. Z-disks in skeletal muscles
 - d. Hemidesmosomes in skin
 - e. Intercalated discs of cardiac muscle
5. Due to tissue and organelle-specific transcript isoforms it is a versatile linker of cytoskeletal components to specific organelles in different tissues

Clinical Manifestations

1. Plectin deficiencies in muscle cause progressive muscular dystrophy
2. Deficiency of plectin in skin causes epidermolysis bullosa simplex (EBS)
3. Epidermolysis bullosa simplex (EBS) – MD with a myasthenic syndrome has been documented
4. Clinical signs and symptoms in two patients:
 - a. Patient 1:
 - i. Had EBS as an infant; myasthenic symptoms and signs emerged at nine years of age
 - ii. She suffered dysphagia dyspnea on slight exertion with generalized weakness
 - b. Patient 2:
 - i. Infantile onset with poor suck which gradually improved
 - ii. At age 15:
 1. Reduced muscle bulk
 2. Bilateral ptosis
 3. Weakness of extraocular muscles
 4. Facial weakness
 5. Diffuse cervical and limb muscle weakness
 6. Ankle jerks were intact, but otherwise, he was areflexic
 7. Wheelchair-bound by age 18 and respirator dependent by age 26

Neuropathology

1. Study of 2 patients:

- a. Dislocated and degenerating muscle fiber organelles
- b. Plasma membrane defects with Ca^{2+} overload of the muscle fiber
- c. Degeneration of junctional folds (lack of skeletal support)

Laboratory Evaluation

1. Electrophysiology:
 - a. Normal conduction studies
 - b. Repetitive stimulation at 2 Hz demonstrated a decremental response (corrected by endophonium chlorite)
 - c. Reduction of the mean miniature endplate potential to 50% of normal
 - d. Quantal content of the EPP is low normal

Non-Channel Myasthenia

General Characteristics

1. Mutation in the SCN4A gene that encodes the Nav1.4 channel was found causative in a well-studied patient

Clinical Manifestations

1. Abrupt attacks of respiratory and bulbar paralysis since birth which lasted 3 to 30 minutes
2. Similar to attacks characteristic of CHAT deficiency

Laboratory Evaluation

1. Supra threshold EPP failed to generate a muscle action potential
2. The mutation caused:
 - a. Enhancement of fast inactivation to close the resting membrane potential
 - b. Use-dependent inactivation at high-frequency stimulation
 - c. A large fraction of the Nav1.4 channels is inexcitable

Defects in Endplate Development and Maintenance

Defect in Agrin That Causes a CMS

General Characteristics

- a. Agrin is encoded by AGRN gene that maps to 1p36.33
 - i. It is a multi-domain proteoglycan
 - ii. Secreted into the synaptic basal lamina by the afferent nerve terminal
 - iii. Agrin phosphorylates and activates MuSK in association with its LRP4 receptor

Clinical Manifestations

1. Eyelid ptosis with normal ocular ductions
2. Mild weakness of facial and hip-girdle muscles

Neuropathology

1. Endplates demonstrate misshaped synaptic gutters; filled by nerve endings and formation of new endplate areas
2. Normal postsynaptic regions
3. AChR and agrin expression at the endplate are normal

Laboratory Evaluation

1. Electrophysiology
 - a. Decrease of the amplitude of miniature endplate potentials (autoimmune agrin deficiency)

Defects in MuSK in CMS*General Characteristics*

1. MuSK (muscle-specific receptor tyrosine kinase) is controlled by agrin that is mediated by LRP4 (concomitant with Dok-7)
 - a. Is pivotal in the maturation and maintenance of the endplate and directs rapsyn to cluster AChR into the post-synaptic membrane
2. Both mutations and autoimmune processes are responsible for MuSK defects

Clinical Manifestations

1. Dependent on specific mutations which include:
 - a. Phenotype consistent with AChR deficiency
 - b. Severe congenital myasthenic syndrome with dropped head, prenatal onset, and severe bulbar symptomatology
 - c. A subset with a relatively mild course

Neuropathology

1. Specific ultrastructural features that are dependent upon mutation and include:
 - a. Decreased AChR aggregation
 - b. Endplates consist of multiple small areas linked by nerve sprouts
 - c. AChR expression of less than 45% of normal
 - d. Simplified postsynaptic areas with few secondary synaptic clefts

Laboratory Evaluation

1. Electrophysiology (dependent on the mutation)
 - a. Reduction of MEPP and MEPC amplitudes (approximately 30% of normal)
 - b. Decreased EPP quantal content

Dok-7 CMS*General Characteristics*

1. Dok-7 is a muscle intrinsic activator of MuSK
2. Expressed in postsynaptic areas of skeletal muscle and the heart

Clinical Manifestations

1. Typically patients have a limb-girdle distribution of weakness
2. Some patients have mild ptosis and facial weakness
3. Severe bulbar symptoms are rare; laryngeal stridor may occur in infants
4. One mutation causes hypomotility in utero and infancy

5. The course varies from mild static weakness of the limb-girdle muscles to severe generalized progressive weakness with muscle atrophy
6. All patients have fatigability with exercise
7. May have episodes of exacerbation that last for days to weeks

Neuropathology

1. Muscle biopsy:
 - a. Type 1 fiber predominance and Type 2 fiber atrophy
 - b. Decreased oxidative enzyme activity
 - c. Synaptic contacts are small relative to fiber size
 - d. Endplates may lack the usual pretzel shape
2. Ultrastructure:
 - a. Destruction and regeneration of endplates
 - b. Loss of junctional folds; absence of nerve terminals; degeneration of subsynaptic organelles

Laboratory Evaluation

1. Electrophysiology (14 patients)
 - a. The mean MEPP and MEPC amplitudes were reduced to 2/3 of normal
 - b. Some patients demonstrated decreased quantal content of EPP

Centronuclear Myopathy with a Myasthenic Syndrome*General Characteristics*

1. Centronuclear myopathies:
 - a. Clinically and genetically heterogeneous
 - b. The anatomical alteration is abnormal centralization of the muscle fiber nucleus
 - c. Involved genes include:
 - i. Myotubularin (MTM1)
 - ii. Dynamin 2 (DNM2)
 - iii. Amphiphysin 2 (BIN1)
 - iv. Ryandine receptor (RYR1)

Clinical Manifestations

1. Associated myasthenic features in some patients with centronuclear myopathy include:
 - a. Ptosis
 - b. Ophthalmoparesis
 - c. Muscle fatigue
 - d. Weakness

Neuropathology

1. Muscle biopsy consistent with centronuclear myopathy
2. EM studies in one patient demonstrated simplified postsynaptic structure with decreased ADCH deficiency

Laboratory Evaluation

1. EMG: (one patient)
 - a. 35% decremental response partially corrected with pyridostigmine
2. Electrophysiology: (one patient)
 - a. Decreased MEPP amplitude (60% of normal); decreased quantal release to 40% of normal

CMS Associated with Alteration of the Hexosamine Biosynthetic Pathway

General Characteristics

1. Mutation of the GFPT1 gene (glutamine-fructose-6 phosphate transaminase 1) gene is causative of this CMS; it maps to chromosome 2p13
2. It controls the entry of glucose into the hexosamine pathway
3. Mutations decrease the availability of precursors for the N- and O-linked glycosylation of proteins

Clinical Manifestations

1. Multiple kinships demonstrated a limb-girdle CMS syndrome that was associated with tubular aggregates in which this mutation of GFPT1 was demonstrated
2. Presents in the first decade of life
3. Some patients had distal and proximal weakness
4. Ptosis and respiratory weakness are rare

Neuropathology

1. Muscle biopsy:
 - a. Immunoblot arrays demonstrated decreased expression of O- N- acetyl glucosamine residues on muscle proteins
 - b. One patient demonstrated a decreased number of AChR endplates

Laboratory Evaluation

1. Approximately 25% of patients showed elevated CK levels
2. Neurotransmission defects have not been demonstrated in detail

Recent discovery of genes that code for extraconjunctional molecules have demonstrated that abnormalities in the post-translational modification of proteins cause neurotransmission defects that expand both the clinical and physiological spectrum of congenital myasthenic syndromes.

Recently described mutations in genes that cause CMS include:

1. N-glycosylation pathway
2. Several proteases
3. Lipoprotein-like receptor
4. Splicing mutations of non-functional exon of CHRNA1

Familial Limb-Girdle Myasthenia

General Characteristics

1. Primarily an AR disease; two new mutations have recently been described that cause this phenotype
2. Genomic deletion affecting exons 2–3 of MuSK
3. DPAGT1:
 - a. Encodes dolichyl-phosphate (UDP-N-acetylglucosamine) N-acetyl glucosamine phosphotransferase 1
 - b. The enzyme is involved in the asparagine-linked glycosylation pathway
 - c. Impaired glycosylation of the muscle acetylcholine receptor in pathogenesis
 - d. GFPT1 mutation may have a similar phenotype

Clinical Manifestations

1. Onset is in childhood
2. Patients may have myasthenic features associated with tubular aggregates
3. Fatigable muscle weakness
4. Proximal muscles are involved
5. No ocular or facial muscle involvement
6. Marked fluctuations in muscle weakness
7. Muscle cramps (also noted with Dok-7 CMS)
8. There may be hand weakness in some patients
9. Loss of reflexes in some patients
10. Mutations in DPAGT1 may also cause glycosylation defect type 1J (CDG-type 1J)
 - a. Defects in formation or processing of glycoproteins or glycolipids that may cause disorder characterized by:
 - i. Intractable seizures
 - ii. Congenital cataracts
 - iii. Mental retardation
 - iv. Developmental delay
 - v. Microcephaly
 - vi. Fetal hypoplasia (death in infancy or early childhood)

Neuropathology

1. Impairment of subunit glycosylation may decrease assembly and transport of AChRs to the postsynaptic membrane
2. Muscle biopsy:
 - a. Decreased number of muscle fibers replaced with fat
 - b. Some fibers with central nuclei
 - c. No tubular aggregates

Laboratory Evaluation

1. EMG:
 - a. Decremental response in some muscles (intrinsic hand muscles)
 - b. Myopathic change in proximal muscles

Lambert-Eaton Myasthenic Syndrome (LEMS)

General Characteristics

1. LEMS is possibly the second most common neuromuscular disorder
2. It is an autoimmune disorder with antibodies primarily directed against voltage-gated calcium channels
3. In approximately two-thirds of patients:
 - a. It is paraneoplastic
 - b. Underlying malignancies include:
 - i. Small cell carcinoma of the lung
 - ii. Lymphoproliferative disease
 - iii. Breast, pancreatic and ovarian cancer
4. LEMS may precede diagnosis of the tumor
5. Greater than 80% of patients are older than forty years of age
6. There is no difference clinically between seronegative or positive patients

7. Approximately one-third of patients with LEMS have no underlying malignancy and occur most commonly in young females with other autoimmune diseases that include:
 - a. Rheumatoid arthritis
 - b. SLE
 - c. Inflammatory bowel disease
 - d. Primary biliary cirrhosis

Clinical Manifestations

1. Weakness and easy fatigability with muscular exercise
2. The majority of patients present with proximal and lower extremity weakness although 80% develop upper extremity proximal weakness during the course of the disease
3. Approximately 1/3 of patients have muscle aches and stiffness during or following exercise
4. Hot weather or any form of heat exacerbates weakness in approximately 20% of patients
5. Ocular muscle weakness other than ptosis is less common than in myasthenia gravis. Bulbar symptoms are also less common, but both may be presenting symptoms
6. Neck flexor, extensor, and facial weakness may also be seen in patients with cranial nerve involvement
7. Cholinergic dysautonomia manifests as:
 - a. Xerostomia and xerophthalmia
 - b. Blurred vision
 - c. Constipation
 - d. Decreased sweating
 - e. Impotence
8. Ventilatory embarrassment is rare although it is documented
9. There are complaints of numbness and paresthesias in the extremities
10. Muscle potentiation occurs:
 - a. In hip- and shoulder-girdle muscles
 - b. Dissipates after several minutes
 - c. Exercise may improve ptosis (opposite of MG); observed by sustained voluntary lid elevation
 - d. Muscle atrophy occurs in advanced stages
 - e. Sluggish pupillary light reflex, decreased sweating and salivation
 - f. Reflexes may be diminished but improve with sustained contraction of the affected muscles
 - g. LEMs associated with anti-Hu antibodies is associated with:
 - i. Small cell cancer of the lung
 - ii. Sensory neuropathy
 - iii. Cerebellar ataxia
 - iv. Limbic encephalitis
 - h. A small percentage of patients have an MG/LEMS overlap syndrome

Neuropathology

1. The acquired autoimmune disorder is due to:

- a. Antibodies against P/Q type voltage-gated calcium channels primarily, with some directed towards N-type voltage-gated calcium channels and synaptotagmin
- b. The antibody attack occurs on and in presynaptic motor terminals
- c. The mechanism suggested is “molecular mimicry” due to cross-reaction of embryonic type calcium channels or their component proteins on tumor cells with neuronal calcium channels
- d. Cross-linking of antibodies with neighboring calcium channels induces their internalization and degradation; complement does not appear to be involved
- e. The major physiological mechanics for the syndrome is decreased quantal release of ACh although the vesicles are normal histologically
- f. Muscle biopsy:
 - i. Type 2 fiber atrophy is occasionally demonstrated
- g. Electron microscopy:
 - i. Nerve terminals are normal in size and numbers of synaptic vesicles
 - ii. The postsynaptic membrane has an increase in the size of the postsynaptic fold
 - iii. Freeze-fracture analysis demonstrates a decrease of intramembranous proteinaceous particles that are thought to be P/Q voltage channels

Laboratory Evaluation

1. EMG:
 - a. CMAP amplitude is increased (the electrodiagnostic characteristic that distinguishes presynaptic from postsynaptic processes)
 - b. Preserved SNAPs
 - c. In the majority of patients with LEMS brief exercise causes an incremental response of 100%; patients with endstage disease may not demonstrate an incremental response
 - d. Low rates of repetitive stimulations (2–3 Hz) may yield a decremental response similar to MG; a brief maximal period of exercise (10 seconds) may block the decremental response, and this post-exercise facilitation may last for 20–30 seconds
 - e. Post-exercise exhaustion may last for up to 20 minutes
 - f. Insertional activity is normal and usually there is no positive sharp waves or fibrillation in potentials
 - g. Abnormalities of MuAP morphology may occur
 - h. Single-fiber EMG reveals:
 - i. Increased jitter values
 - ii. Blocking is more prevalent and severe than in MG
 - iii. Increased stimulation rates (2–15 Hz) decreases blocking
 - i. Decreasing temperature increases:
 - i. CMAP amplitude at rest
 - ii. Decreases decremental response at low rates of stimulation
 - iii. Prolongs the duration of postactivation facilitation

- j. Autonomic evaluation in LEMs is altered and demonstrates deficits in:
 - i. Sudomotor function
 - ii. Cardiovagagal reflexes
 - iii. Salivation (decreased)
 - iv. Adrenergic function

Botulism

General Characteristics

1. The neurotoxin is derived from the bacterium (*Clostridium botulinum*)
 - a. It is an anaerobic and requires alkaline conditions for growth
 - b. The spores are heat resistant; temperatures of 120°C are required for sterilization
 - c. High-altitude cooking is a risk factor (because water boils at lower temperatures and does not inactivate spores; there may also be inadequate sterilization of canned goods)
 - d. There are eight antigenic types of botulinum toxins: A, B, C1, C2, D, E, F, G; they are zinc-dependent endopeptidases
 - e. Human disease is caused primarily by types A, B, E; a fatal dose is between .05–1 mg
 - f. There are approximately 250 cases of botulism/year in the USA
 - i. Type A: Western USA
 - ii. Type B: Eastern USA and Europe
 - iii. Type E: from fish; more prevalent in Japan (approximately 20% of USA patients)
 - iv. Ingested toxin from food (USA)
 - a. Vegetables ~60%
 - b. Fruit ~12%
 - c. Fish ~15%
 - v. Infantile form of the toxin is produced by organisms in the GI tract
 - vi. Wound infection as a source of primary botulism is rare but that from I.V. drug abuse is increasing

Clinical Manifestations

1. Adult disease:
 - a. The clinical presentation is similar irrespective of the sources of the toxin
 - b. Foodborne and infantile varieties are the most common forms of the illness
 - c. Neurologic signs and symptoms:
 - i. Dysphagia, xerostomia, diplopia and dysarthria begin acutely and progress over 12–36 hours
 - ii. Anxiety may be severe
 - iii. The course is dependent on the amount of toxin exposure
 - iv. In foodborne illness:
 - a. Nausea, vomiting, and diarrhea may occur prior to or concomitantly with neurologic symptoms

- v. Abdominal cramps, constipation, dizziness, fatigue occur with other signs and symptoms
- vi. Dyspnea may occur prior to extremity weakness
- vii. Usually, there are no sensory complaints; a few patients complain of paresthesia of the face or extremities
- viii. Cranial nerve involvement causes:
 - a. Ptosis
 - b. Decreased gag reflex
 - c. Dysphagia
 - d. Dysarthria
 - e. Facial weakness
 - f. Tongue weakness
 - g. Nystagmus (Rare)
- ix. Diminution to absent muscle stretch reflexes
- x. Respiratory muscles are affected with between 31–81% of patients requiring mechanical ventilation
- xi. Forced vital capacity is reduced in most patients
- xii. Autonomic alterations include:
 - a. Decreased vagal cardiac responses
 - b. Hypothermia
 - c. Urinary retention
 - d. Ileus
 - e. Hypotension without tachycardia
 - f. Decreased pupillary light reflex
 - g. Decreased vasomotor response to postural stress

Clinical Manifestations of Wound Botulism

1. A traumatic event may not be elicitable in the patient (particularly in patients with drug abuse)
2. Gastrointestinal complaints are less severe than in patients who have food-borne illness
3. Incubation period is usually 4–14 days as compared to 6 hours in toxin or spore disease

Clinical Manifestations of Infantile Botulism

1. Variable phenotype from mild symptoms to sudden death:
 - a. Constipation is common and may be the sole manifestation in mild disease
 - b. Listlessness and diminished spontaneous movements are noted
 - c. Diminished suck
 - d. In severe forms, the infant may be hypotonic and “floppy”
 - e. Excessive drooling and a weak cry; ptosis and loss of facial movement
 - f. Fatigue of the pupillary light reflex
 - g. Deep tendon reflexes may be diminished to absent
 - h. Approximately 50% of infants require mechanically assisted ventilation
 - i. Botulism toxin A may produce a more severe course than toxin B (similar to adults)

Adverse Events Associated with Therapeutic and Cosmetic Use of Botulinum Toxin

1. Serious adverse events include:
 - a. Dysphagia
 - b. Respiratory compromise
 - c. Generalized muscle weakness
 - d. Marked ptosis
 - e. Pseudoaneurysm of the frontal branch of the temporal artery
 - f. Necrotizing fasciitis

Neuropathology

1. The majority of strains produce one type of BTX which is released after the infected cell undergoes lysis
2. All of the BTXs are composed of a heavy chain and a light chain linked end to end; a proteolytic enzyme within the bacterium or the involved host is required to cleave the bond between the chains to activate the molecule
3. After ingestion, the toxin is absorbed and hematogenously transported
4. The toxin is active at:
 - a. Cholinergic presynaptic terminals
 - b. NMJs
 - c. Autonomic ganglia
 - d. Post-ganglionic parasympathetic and sympathetic nerves
 - e. Adrenal glands
5. The toxin is internalized by receptor-mediated endocytosis
6. Toxic intracellular activity is mediated by zinc-dependent specific proteases
7. BTX B, D, F and G
 - a. Cleave vesicle-associated membrane protein (VAMP/synaptobrevin)
8. BTX A, D, and E
 - a. Hydrolyze SNAP-25 (synaptosomal-associated protein)
9. BTX C
 - a. Cleaves syntaxin (only animals are affected)
10. BTX D and F
 - a. Cleaves cellubrevin
11. Types A, B and E cause food poisoning
12. Denervation atrophy has been demonstrated in muscle biopsy

Laboratory Evaluation

1. EMG:
 - a. CMAP amplitude reduction (documented in 85% of patients)
 - b. Most often NCV, F-wave or H-reflex latencies are normal
 - c. CMAP amplitude decrease at baseline, incremental response to brief exercise or "fast" repetitive stimulation and decremental response to "slow" repetitive stimulation may not be seen in early illness

- d. The incremental response is usually <100% and more prevalent in proximal muscles
- e. Facilitation is common
- f. Abnormalities may be seen in specific muscles, in particular those that are weak
- g. Early in the course of the illness there is usually normal insertional and spontaneous activity; several affected patients may demonstrate positive sharp waves and fibrillation potentials
- h. MuAPs may demonstrate a low amplitude, short duration morphology with early recruitment
- i. Single-fiber EMG:
 - i. Increased filter values
 - ii. Blocking
 - iii. May be seen in 40–50% of patients early in the course of illness
2. CSF evaluation:
 - a. An increased protein in some patients
3. Culture of serum gastric contents, stool and wound aspirate; food for toxin and organisms
4. BTX assay (indirect bioassay utilizing mice) is positive
5. Toxin test evaluation:
 - a. A positive yield in only 1/3 of patients
 - b. Higher in blood and stool than gastric contents
6. Positive culture occurs in 50–70% of patients (anaerobic culture)

Differential Diagnosis of Botulism vs GQIb GBS

1. GBS (CM Fisher variant) GQIb has absent reflexes
2. Pharyngeal cervical brachial variant of GBS; GT1a (antibody)
3. Lambert-Eaton syndrome (increased reflexes and strength with exercise)
4. MG (normal pupillary responses; weakness with exercise)
5. Tick paralysis (ataxia with weakness)
6. Toxic shellfish (pain at the site of envenomation)
7. Diphtheritic neuropathy (sore throat); eschar or membrane

Summary of Specific Botulism

Infant Botulism

General Characteristics

1. Spores are ingested and germinate in the infant GI tract
2. Honey consumption is a risk factor; Type B > A organisms

Clinical Manifestations

1. Affects infants less than six months old
2. Weakness of bulbar and limb muscles; hypotonia with loss of head control; decrease of spontaneous movements
3. Parasympathetic signs and symptoms

Wound Botulism

General Characteristics

1. Primarily in IV drug abuse patients (abscesses)
2. Sinusitis in cocaine users

Clinical Manifestations

1. Approximate incubation period of 4–14 days
2. Most often a clear wound
3. Bulbar signs and descending paralysis

Hidden Botulism**General Characteristics**

1. No obvious source of toxin
2. Abnormality of the GI tract may be a risk factor which includes:
 - a. Achlorhydria
 - b. Surgery
 - c. Crohn's disease
 - d. Recent antibiotic treatment

Clinical Manifestations

1. Similar to the chronic form
2. *C. botulinum* has been cultured from the stool of an adult patient

Iatrogenic Botulism**General Characteristics**

1. Toxin injected for movement disorder or cosmetic indications

Clinical Manifestations

1. Signs and symptoms in the somatic, motor, sympathetic and parasympathetic systems
2. May develop distant and generalized weakness

Tetanus**General Characteristics**

1. Approximately one million cases occur annually worldwide
2. Twenty-five percent (approximately) from occupational injury
3. *Clostridium tetani*:
 - a. Obligate anaerobe
 - b. Requires extrachromosomal DNA (plasmid for production of tetanospasmin)
 - c. Inhibits release of ACh from the presynaptic terminals
 - d. Retrogradely transported to enter the CNS
 - e. Blocks release of glycine and GABA-b from presynaptic terminals
 - f. Toxin transported to both the sensory neurons of the dorsal root ganglia and archenteric neurons

Clinical Manifestation

1. Generalized tetanus:
 - a. Rigid masseters ("lock-jaw") at presentation
 - b. Generalized spasms with opisthotonus; no loss of consciousness
 - c. Painful muscles with increased reflexes
2. Localized tetanus

- a. May progress to generalized disease
3. Cephalic form:
 - a. Involves the lower cranial nerves
 - b. Facial weakness, dysphagia, and rarely ophthalmoplegia
 - c. Source is chronic middle ear infection
 4. Neonatal variety
 - a. 50% of tetanus infection with an approximate 90% mortality
 - b. Infection of the umbilical stump
 - c. Weakness and inability to suck during the second week of life
 5. Mechanisms of death are:
 - a. Respiratory
 - b. Autonomic dysregulation

Laboratory Evaluation

1. EMG:
 - a. Continuous and excessive motor unit activity
 - b. Normal nerve conduction studies
 - c. Absent silent period from affected muscles

Tick Paralysis**General Characteristics**

1. There are three major families of ticks:
 - a. Ixodidae (hard body ticks)
 - b. Argasidae (soft body ticks)
 - c. Nuttalliellidae
2. The saliva of Ixodidae and Argasidae cause human disease
3. In North America, the wood tick, *Dermacentor andersoni* most often causes the disease; the second most common tick that causes illness is the dog tick *Dermacentor variabilis*; very rarely *Amblyomma americanum* and *Amblyomma maculatum* have been implicated; in Australia, *Ixodes holocyclus* (Australian marsupial tick) causes very severe disease
4. The site of the tick attachment is often the scalp, neck and perineum
5. In North America the illness is seen most frequently in states west of the Rocky Mountains
6. The peak occurrence of disease is during the spring and summer; gravid female ticks feed longer (days) and are thought to be the most common vector; their attachment is most often painless

Clinical Manifestations

1. Children are affected three times more frequently than adults
2. Patients present with an ascending weakness that evolves over hours to days which may cause flaccid paralysis
3. Cranial nerve involvement includes;
 - a. Internal and external ophthalmoplegia
 - b. Facial weakness
 - c. Dysarthria

- d. Respiratory and muscle weakness
- e. Dysphagia
- 4. Sensory symptoms include:
 - a. Paresthesias
 - b. Burning and itching
 - c. Pain
 - d. Numbness
- 5. Sensory complaints may be out of proportion to the objective findings
- 6. Some patients develop sensory ataxia
- 7. There are decreased or absent muscle stretch reflexes
- 8. The onset may be more abrupt and the course more rapid than GBS
- 9. Symptom onset usually occurs after 4–7 days of tick feeding; resolution of symptoms usually occurs within 24 hours of the tick's removal

Neuropathology

- 1. The Australian tick *Ixodes holocyclus* injects a toxin that:
 - a. Decreases ACh release at presynaptic terminals
 - b. North American cases of tick paralysis may be caused by the released toxins block of sodium channels at the nodes of Ranvier and distal motor nerve terminals

Laboratory Evaluation

- 1. EMG:
 - a. Mild reduction of motor conduction velocities
 - b. Mild decrease of SNAP in paretic extremities
 - c. Sensory nerve conduction parameters may increase with resolution of the illness suggesting that there is a mild sensory neuropathy
 - d. In most patients, repetitive nerve stimulation shows no decremental or incremental responses
 - e. There are no positive sharp waves or fibrillation potentials
- 2. CSF protein is normal

Drugs/Toxins That Alter Neuromuscular Transmission

Toxins

General Characteristics

- 1. The best descriptions have been from ingestion of Fungi or Puffer fish; it is found in species of the order Tetraodontidae
- 2. May be found in certain mollusks, the horseshoe crab, California newt and the blue ringed octopus

Clinical Manifestations

- 1. The severity and delay of symptoms onset depends on the quantity of the toxin ingested
- 2. Paresthesias may be the first symptom reported and initially involves the lips, tongue and mouth
- 3. Gastrointestinal symptoms include nausea and vomiting

- 4. An ascending flaccid paralysis can occur with large ingestions
- 5. Other manifestations may include:
 - a. Dilated pupils
 - b. Seizures
 - c. Sweating
 - d. Pleuritic chest pain

Neuropathology

- 1. Blocks sodium channels

Laboratory Evaluation

- 1. High performance liquid chromatography with tandem mass spectrometry identifies the toxin in urine and blood samples

Saxitoxin

General Characteristics

- 1. Saxitoxin and its derivatives are collectively referred to as paralytic shellfish toxins
- 2. They are unique neurotoxins as they are found in both marine and fresh water environments; prokaryotic cyanobacteria are responsible for the toxin in fresh water while eukaryotic dinoflagellates produce the toxin in marine water
- 3. The organisms have a world-wide distribution

Clinical Manifestations

- 1. Ascending paralysis with respiratory failure

Neuropathology

- 1. Inhibition of voltage gated sodium channels

Laboratory Evaluation

- 1. Molecular sensor binding methodologies are used for detection

Ciguatoxin

General Characteristics

- 1. Caused by the ingestion of fish that have been bioaccumulated ciguatoxins of the photosynthetic dinoflagellate gambierdiscus toxins
- 2. Ciguatoxins accumulate in all fish tissues; they are heat stable polyether toxins

Clinical Manifestations

- 1. The presenting signs are primarily neurotoxic in greater than 80% of patients; these include:
 - a. Paresthesias and dysesthesias
 - b. Paradoxical cross modality sensitization (a cold object may feel hot)
 - c. Metallic taste
 - d. Arthralgias and myalgias
 - e. Dental pain
- 2. Rarely ataxia and weakness
- 3. Autonomic dysfunction with hypotension bradycardia
- 4. Mild cases have primarily GI symptomology

Neuropathology

1. They are potent lipophilic sodium channels activators which bind to the voltage sensitive (site 5) of the sodium channel on cell membranes of all excitable tissue

Laboratory Evaluation

1. Mouse bioassay; detected with high performance liquid chromatography
2. Other toxins that cause nerve sodium channel overactivation include:
 - a. Sea anemone (*Anemonia sulcata*)
 - b. The Brazilian scorpion (*Tityus serulatus*)
 - c. The spider (*Phoneutria nigriventer*) that causes:
 - i. Spastic paralysis
 - ii. Muscle pain
 - iii. Abdominal cramps
 - iv. Seizure
 - v. Cardiovascular dysfunction
 - vi. Nerve terminal sodium channel activation

Black and Green Mamba Envenomation*General Characteristics*

1. African snakes; there are four species of mamba that inhabit equatorial and southern Africa
2. Black mamba (*Dendroaspes polylepis*)

Clinical Manifestations

1. Paralysis, cranial nerve dysfunction and respiratory failure
2. Cramps and fasciculations

Neuropathology

1. Blockade of nerve terminal potassium channels that cause prolongation of the action potential with an increased ACh release
2. Envenomation causes an increase of EPP amplitude and repetitive EPP
3. Similar clinical and physiological effects can be seen with envenomation from the scorpion (*Pandinus imperator*)
4. The Australian Tiger snake
 - i. Toxin (notexin) blocks potassium channels and decreases the release of ACh

Calcium Channel Inhibitor*General Characteristics*

1. Myasthenia gravis patients may be affected by drugs that inhibit the calcium channel. These include:
 - a. Verapamil
 - b. Diltiazem
 - c. Aminoglycosides
 - d. Neomycin and polymyxin B
 - e. Clindamycin
 - f. Oxytetracycline

Clinical Manifestations

1. Exacerbation of myasthenia muscle weakness

Neuropathology

1. Verapamil (block L type Ca^{++} channels)
2. Diltiazem
 - a. Non-dihydropyridine (non-DHP) calcium channel blocker
3. Aminoglycosides
 - a. Block presynaptic voltage calcium channels
 - b. Presynaptic Ca^{++} sensor receptor enhanced activation with decreased terminal excitability rather than direct inhibition of voltage activated calcium channels
4. Clindamycin
 - a. Less severe depression of voltage dependent calcium entry into nerve terminals

Magnesium Salts*General Characteristics*

1. Primarily administered for pre-eclampsia and eclampsia; may be significant in myasthenia gravis patients
2. A possible central mechanism of action may occur at low concentrations

Clinical Manifestations

1. Serum levels $> 5 \text{ mg/L}$ may abolish deep tendon reflexes
2. Levels > 9 to 10 mg/L are associated with generalized weakness and loss of reflexes

Neuropathology

1. Competitive inhibition of calcium entry into the nerve terminal

Laboratory Evaluation

1. EMG:
 - a. Similar to conditions with presynaptic defects of neuromuscular transmission
 - b. Low amplitude CMAP
 - c. Facilitation with exercise "fast" repetitive stimulation

Conotoxins*General Characteristics*

1. Conopeptides are a diverse group of recently evolved venom peptides
2. Each species of cone snail produces greater than 1000 conopeptides that target a wide spectrum of membrane proteins with high potency or specificity
3. Two toxins secreted by the marine snail (*Conus geographus*) affect neuromuscular transmission

Clinical Manifestations

1. The snail has a dart-like proboscis that injects the toxin
2. Severe local pain
3. Within 30 minutes, there is a generalized weakness
4. Respiratory failure occurs within 1 to 2 hours
5. Approximately 60% of envenomations are fatal

Neuropathology

1. Omega-conotoxin: binds to presynaptic voltage-dependent calcium channels, which prevents calcium entry into the nerve terminals and consequent decrease of ACh release

Drugs That Affect Neuromuscular Transmission**Corticosteroids**

1. Directly affect the nerve terminal membrane by inducing depolarization which causes:
 - a. Depletion of ACh
 - b. Alteration of MEPPs
 - c. Decreases intratubular potassium homeostasis

Azathioprine, Theophylline, and Papaverine

1. Inhibit phosphodiesterase and thereby increases intracellular cyclic AMP (as phosphodiesterase hydrolyze)
2. Increased intracellular cyclic AMP potentiates ACh release
3. Imidazole decreases ACh release by increasing phosphodiesterase and thereby lowering intra-nerve terminal cyclic AMP

Snake Envenomation*General Characteristics*

1. Major species:
 - a. Viperidae (pit vipers)
 - b. Crotalinae (rattlesnakes and pit vipers)
 - c. Elapidae (coral snakes, mambas, kraits, and cobras)
 - d. Hydrophiidae (sea snakes)
 - e. Neuromuscular blockade occurs with:
 - i. Elapidae
 - ii. Hydrophiidae
 - iii. Crotalinae (South American rattlesnakes)

Clinical Manifestations

1. Pit viper or cobra:
 - a. Local pain
 - b. No pain with other elapidae and hydrophiidae
2. Swelling and necrosis within one hour of bite from viperidae and crotalinae
 - a. No swelling from mamba, krait or coral snake bite
3. Preparalytic stage (viperidae and crotalinae):
 - a. Headache
 - b. Loss of consciousness
 - c. Paresthesia
 - d. Hematuria and hemoptysis
 - e. These manifestations are rarely seen with cobra or mamba envenomation
4. Neuromuscular toxicity:

- a. Usual time from envenomation to paralysis
 - i. 1/2 hour to 19 hours
 - ii. Mamba envenomation as short as 10 minutes
 - iii. Location of the bite and direct venous access are determining features, as is the variant of injected toxin
- b. Sequence of clinical signs:
 - i. Ptosis and ophthalmoptosis
 - ii. Facial and bulbar weakness
 - iii. Extremity, diaphragm and intercostal weakness
 1. May progress over a 2 to 3 day period
 - iv. No sensory abnormalities except at the site of envenomation
 - v. Cardiovascular collapse, seizure, and coma are terminal events
5. Hemotoxic effects (Viperidae/Crotalinae)
 - a. Cerebral hemorrhage
 - b. Subarachnoid hemorrhage (SAH)
 - c. Intracerebral hemorrhage (ICH)
 - i. The leading cause of viperidae death
 - d. Crotalinae (rattlesnakes)
 - i. Persistent fasciculations long after clinical recovery of the affected muscles

Neuropathology

1. Presynaptic toxins:
 - a. Hemorrhage; a phospholipase constituent from the multi-banded krait (*Bungarus multicinctus*)
 - b. Brazilian rattlesnake (*Crotalis durissus*)
 - i. Initially, increases and then decreases the amount of ACh released from the nerve terminal
 - c. Taipan:
 - i. Initial augmented release of ACh
 - ii. Late depletion of the neurotransmitter
 - iii. Presynaptic toxins are often more potent than postsynaptic toxins
2. Postsynaptic toxins:
 - a. Alpha-neurotoxins
 - b. Cause a non-depolarizing neuromuscular block
 - c. Most toxins are mixtures of pre- and postsynaptic compounds
 - d. Sea snakes inject less toxin; it is more potent than other snake toxins
3. Alpha-neurotoxins
 - a. Bind the nicotine ACh receptor of muscles
 - b. More potent than curare
 - c. Slower onset of action and longer duration than presynaptic toxins

Beta-Neurotoxins

1. Contain phospholipase
2. All suppress release of presynaptic ACh
3. Taipan (Australia) has an additional myotoxin (causes rapid muscle necrosis)

Arthropod Envenomation – Black and Brown Widow Spiders

General Characteristics

1. The most common envenomations in the USA are from the black widow spider (*Latrodectus mactans*, *L. hesperus*, and *L. variolus*) and the brown widow (*Latrodectus geometricus*)
2. The toxin alpha-latrotoxin is the most extensively studied

Clinical Manifestations

1. Female black widow spiders have an hour-glass pattern that is red or orange on their black abdomen; they are 2 to 2 1/2 times more poisonous than males
2. Approximately 15% of their bites are non-envenomating
3. Onset of clinical signs occurs during the first 8 hours post-envenomation and include:
 - a. Pain at the site of the bite
 - b. Pain in the extremity that migrates to other muscle groups
 - c. Muscle cramps and severe abdominal rigidity
 - d. Priapism (described in children)
 - e. Hypertension may supervene within 2–4 hours
 - f. Mild cardiac arrhythmia may occur; fulminant myocarditis has been reported
 - g. Opisthotonus may occur in severe envenomation
 - h. Autonomic instability
 - i. Recovery may be prolonged

Neuropathology

1. Electron microscopy:
 - a. Swollen nerve terminals without synaptic vesicles
2. Acetylcholine, noradrenalin, dopamine, glutamate and enkephalin systems are affected
3. Alpha-latrotoxin causes an initial surge of spontaneous MEPP frequency which then decreases and disappears over the next 30 minutes (depolarizing block)

Funnel-Web Spider

General Characteristics

1. The Australian funnel-web spiders are the most lethal spiders worldwide
2. The Sydney funnel-web spider (*Atrax robustus*) caused approximately 14 deaths per year until the introduction of antivenom in 1980
3. Hexatoxin, a 42-residue peptide, is the major toxin in this spider venom causing neuromuscular transmission defects

Clinical Manifestations

1. Male spiders' toxins have greater potency than that from females
2. Nausea, vomiting, and dizziness are the initial symptoms
3. Fasciculation and paralysis of striated muscle and the diaphragm supervene
4. Death occurs by asphyxia and concomitant cardiac arrest

Neuropathology

1. Hexatoxin delays the inactivation of voltage-gated sodium channels
 - a. Massive ACh release
 - b. Both somatic and autonomic nerve endings are affected
 - c. Repetitive firing and prolongation of action potentials

Scorpion Envenomation

General Characteristics

1. Scorpion envenomation is a potential threat to 2 billion people worldwide
2. Annual envenomations are estimated at one million; the lethality rate is 27%
3. Most stings are reported from North Africa, South India, Latin America and the Middle East:
 - a. *Hottentotta tumulus* (India)
 - b. *Leiurus quinquestriatus* and *Androctonus crassicauda* of North Africa and the Middle East
 - c. *Tityus serrulatus* (Brazil)
 - d. *Centruroides suffusus* of Mexico
4. The severity of scorpion envenomation varies with species, size, and age and is much more severe in children

Clinical Manifestations

1. Primary signs and symptoms reflect overstimulation of the sympathetic and parasympathetic nervous system, and include:
 - a. Local pain and paresthesia
 - b. Agitation, dizziness, and disorientation
 - c. Vomiting and abdominal pain
 - d. Salivation and diaphoresis
 - e. Muscle rigidity and fasciculation
 - f. Pupillary abnormalities
 - g. Priapism
 - h. Tremor and ataxia
2. Systemic symptoms:
 - a. Bradycardia and tachycardia
 - b. Hypertension > hypotension
 - c. Cardiac failure
 - d. Shock
3. *Tityus obscurus* (Brazilian Amazon, northern Brazil)
 - a. Clinical manifestations:
 - i. Acute onset of signs within a minute of envenomation
 - ii. Ataxia
 - iii. Nausea and vomiting
 - iv. Myoclonus
 - v. Fasciculations
 - vi. Paresthesias, burning and radiating from bite site

Neuropathology

1. Some toxins increase ACh release
2. Most affect sodium and potassium channel function

Laboratory Evaluation

1. Hyperglycemia
2. Pleocytosis
3. Elevation of cardiac and pancreatic enzymes
4. Ischemic EKG changes
5. Cardiac dysfunction on ECHO cardiography

Drugs That Interfere with Neuromuscular Transmission**Botulinum Toxin***General Characteristics*

1. Primarily used in specific neuromuscular disorders (dystonia, spasticity, spasms)
2. Cosmetic
3. Migraine

Clinical Manifestations

1. Decreases pain (migraine)
2. Paralysis of specific musculature (dystonia, spasticity, cosmetics)

Neuropathology

1. Botulinum toxins A, B and E cleave SNARE proteins which prevent the fusing of vesicles with the inner surfaces of the plasma membrane at release sites, which blocks the release of neurotransmitter (ACh)

Aminopyridine*General Characteristics*

1. 4-aminopyridine is one of three isomeric amines of pyridine

Clinical Manifestations

1. Primarily utilized to improve gait in demyelinating disease
2. Major adverse effect is seizure
3. Experimentally has been shown to reverse saxitoxin and tetrodotoxin

Neuropathology

1. 4-AP is a voltage-gated potassium channel blocker:
 - a. Delays egress of potassium from the nerve terminal, which prolongs action potential duration, which allows a greater concentration of calcium to enter the nerve terminal
 - b. Increases quantal ACh release

Guanethidine*General Characteristics*

1. A nitrogenous analog of carbonic acid

Clinical Manifestations

1. Has been used as an adjuvant in the treatment of botulism (guanidine hydrochloride)

Neuropathology

1. Inhibits calcium egress from the postsynaptic terminal
2. Increases vesicle fusion and thereby quantal ACh release

Hemicholinium-3*General Characteristics*

1. Has no clinical use

Clinical Manifestations

1. Inhibition is noted only with increased firing rates of a neuron

Neuropathology

1. Blocks the reuptake of choline by the high-affinity choline transporter (ChT) in the presynaptic terminal
2. Reduces ACh resynthesis

Anticholinesterases*General Characteristics*

1. Anticholinesterases bind with the enzyme and decrease the hydrolysis of ACh in the synaptic cleft

Clinical Manifestations

1. Increases muscle strength in MG
2. Affects ACh synapse of the autonomic nervous system to induce gastrointestinal effects as well as hypotension (some autonomic conditions)
3. At high doses produces severe dizziness and convulsions

Neuropathology

1. Augments ACh-ACh receptor interactions
2. Increase EPP and thus the depolarization of the postsynaptic membrane

Organophosphates*General Characteristics*

1. Organophosphates:
 - a. Highly effective acetylcholinesterase inhibitors that are primarily used as multipurpose insecticides
 - b. They are also used as chemical weapons, and use the active core of G-series and V-series chemical warfare agents that include:
 - i. Tabun
 - ii. Sarin
 - iii. Soman
 - iv. Cyclosarin
 - v. VX

Clinical Manifestations

1. Intoxication is usually from accidental or dermal exposure. The latter is prominent in agricultural workers (insecticide sprayings)
2. Initial signs and symptoms:

- a. Miosis
- b. Bronchoconstriction and increased secretions
- c. Diaphoresis
- d. If ingested:
 - i. Abdominal cramping
 - ii. Nausea, vomiting, and defecation
 - iii. Increased salivation
 - iv. Urinary incontinence
 - v. Bradycardia and hypotension
- 3. Neuromuscular signs and symptoms:
 - a. Muscle paralysis that may include respiratory failure
 - b. Fasciculations
 - c. Patients with chronic organophosphate exposure (agricultural workers) may develop a length-dependent axonal motor sensory neuropathy that may not completely resolve

Neuropathology

- 1. Increased EPP and prolonged depolarization of postsynaptic membranes of ACh neurons
- 2. The enzyme may be reactivated with an oxime antidote (2-PAM C.1), which is administered with atropine

Neuromuscular Blocking Drugs

General Characteristics

- 1. Neuromuscular blocking agents are primarily used for intubation and during surgical procedures for muscle relaxation
- 2. All agents interact with the acetylcholine receptor, by effecting competitive antagonism against acetylcholine or by continuous activations of the receptor
- 3. Several nerve agents have additional physiological actions

Clinical Manifestations

- 1. Compounds related to curare, used in anesthesia for neuromuscular blockade that maintains muscle relaxation, are:
 - a. Pancuronium
 - b. Vecuronium
 - c. Atracurium and gallamine
- 2. Acetylcholine blocking agents are the major depolarizing muscle relaxants in clinical use
- 3. Critical illness paralysis:
 - a. Occurs after the prolonged administration of the short acting blocking drug vecuronium or atracurium, often in conjunction with corticosteroids (severe asthma attacks)
 - b. The clinical features of critical illness paralysis include effects on peripheral nerves, muscles, and the neuromuscular junction in various combinations
 - c. It masks latent myasthenia gravis (poor recovery from anesthesia)
 - d. Succinylcholine causes early muscular overactivity (fasciculations) with later flaccid paralysis

Neuropathology

- 1. Curare-like compounds bind to ACh receptors (which enlist neuromuscular transmission) by competitive blockades
- 2. Succinylcholine and decamethonium have high affinity and persistently bind to the ACh receptor, maintaining depolarization of the postsynaptic membrane
- 3. Vecuronium may suppress activity of the A(3)B(2) subunit of the AChR in the presynaptic membrane and enhance quantal release:
 - a. Vecuronium also blocks L-type calcium channels, which may decrease calcium influx into the presynaptic terminals
 - b. Vecuronium may decrease neuromuscular transmission in both a pre- and postsynaptic manner

Drugs That Act Primarily Postsynaptically

- 1. Polymyxin B, polymyxin E, netilmicin and colistin
 - a. Act primarily postsynaptically
- 2. Tetracycline, oxytetracycline, and rolitetracycline
 - a. Act primarily postsynaptically but less severely than the polymyxins or colistin
- 3. Lincomycin and clindamycin
 - a. Act primarily postsynaptically in lower concentrations, but at higher dosages can decrease ACh release
- 4. Aminoglycosides
 - a. May act pre- and postsynaptically
 - b. Can precipitate abrupt onset of weakness (particularly in myasthenia gravis)
 - c. Blockage of presynaptic voltage-activated calcium channels; has a relatively low affinity for voltage-activated calcium channels
 - d. An alternative mechanism recently described is aminoglycoside activation of a presynaptic Ca^{2+} sensing receptor that modulates synaptic transmission
 - e. Aminoglycoside-induced weakness may be primarily due to increased activation of a channel that decreases terminal excitability
 - f. Presynaptic mechanisms of decreased neurotransmission with aminoglycosides are operative at lower concentrations
 - g. Activation of the CaSR channel inhibits the NSCC current, which shortens action potential duration that reduces the time for Ca^{2+} entry, which in turn decreases the probability of neurotransmitter release
 - h. Aminoglycosides may inhibit voltage-gated calcium channels at high concentrations
- 5. Procainamide:
 - a. May exacerbate weakness in patients with NMJ disease
 - b. Both pre- and postsynaptic mechanisms that are not completely established
- 6. Penicillamine and alpha-interferon:
 - a. General characteristics:

- i. Both of these drugs can initiate an autoimmune disease that has the clinical, serological and electrophysiological characteristics of myasthenia gravis
- b. Clinical manifestations:
 - i. The onset of the illness is within days to months of drug use; some rare cases have developed years after exposure
 - ii. The syndrome usually resolves within 2–6 months after cessation of drug use
- c. Laboratory evaluation
 - i. Serologic and electromyographic features are similar to MG
7. Myasthenic syndromes have been precipitated by:
 - a. Beta-interferon
 - b. Riluzole
 - c. Chloroquine
 - d. Trimethadione
 - e. Ritonavir
 - f. Statins
8. Analgesics:
 - a. Morphine and its derivatives do not depress neuromuscular transmission.
 - i. Depress respiration (clinically)
 - ii. Are potentiated by anticholinesterases
9. General anesthetics:
 - a. Potentiate neuromuscular blocking agents in MG patients
 - b. Ethrane and nitrous oxide do not cause neuromuscular blockade
10. Local anesthetics:
 - a. Lidocaine, procaine, and mexiletine potentiate neuromuscular blockade when administered intravenously
 - b. Mechanism may include:
 - i. Reduction of ACh release
 - ii. Possible decreased sensitivity of the postsynaptic ACh receptor
11. DL-carnitine:
 - a. NMJ block may occur during dialysis
 - b. Presynaptic block similar to that produced by hemicholinium
 - c. Postsynaptic block possibly due to the accumulation of acylcarnitine esters
12. Psychotropic drugs:
 - a. Chlorpromazine and promazine
 - b. Postsynaptic block
 - c. Prolongs the effects of succinylcholine
13. Lithium:
 - a. Possible decrease of the quantal release of ACh
 - b. Decreases the synthesis of ACh
 - c. Possible induction of an increased rate of receptor degradation
2. The painless weakness can be focal or diffuse:
 - a. Motor neuron disease
 - b. Myopathy
 - c. Motor neuropathies
 - d. Rarely, diabetic radiculoplexus neuropathy or brachial plexopathy are primarily motor
3. Disorders of oculomotor and brainstem receptors:
 - a. Miller-Fisher syndrome (no reflex loss in acquired MG)
 - b. Fazio-Londe and other motor neuron diseases of childhood
 - c. In adult patients:
 - i. Bulbar ALS (rare ocular involvement)
 - ii. Kennedy's disease (fasciculation of the face rather than ocular involvement)
 - iii. In general, ptosis and ophthalmoparesis exclude acquired or hereditary myopathy:
 1. Hereditary myopathies that involve the oculomotor system and bulbar functioning include:
 - a. Oculopharyngeal muscular dystrophy (symmetric ptosis and progressive course; genetic)
 - b. Mitochondrial myopathies (short stature, hearing loss, diabetes mellitus, cardiac involvement; PEO in adults may start with asymmetric ptosis and EOM weakness)
 - c. Myotonic muscular dystrophy (abnormal facies, cataracts, some patients with cognitive impairment)
 - d. Adult onset of some congenital myopathies (dysmorphic features, non-fluctuating course)
 - e. Rarely:
 - i. Subacute autoimmune paraneoplastic syndrome (anti-Ri antibody disease; some with opsoclonus myoclonus)
 - ii. Carcinomatosis of the meninges (usually cognitive impairments, rarely only one cranial nerve involved; progressive course)
 - iii. Rare infection processes may involve the oculomotor and brainstem early in their course. This includes:
 1. Listeria monocytogenes (dorsal pontine lesion in pregnant patients)
 2. Mucormycosis (immuno-suppressed patients, diabetic ketoacidosis; ophthalmoparesis; severely ill patients)
 - f. Herpes zoster (ophthalmicus) the overwhelming number of patients have characteristic rash; third nerve involvement; may have a concomitant headache
 - g. Rhombencephalitis (presentation of several viruses)
 - h. Chronic tuberculous meningitis (usually the VIth and VIIIth nerves are involved; associated headache and cognitive impairment)

Differential Diagnosis of Neuromuscular Transmission Diseases

1. Overwhelmingly motor signs and symptoms

- i. Syphilis (most often Argyll-Robertson pupillary abnormalities; rare EOM involvement; often VIIIth nerve is affected)
- j. Lyme's disease (VIIIth nerve involvement)

Differential Diagnosis of Congenital Myasthenic Syndromes

1. The "floppy infant" which includes myopathy, anterior horn cell disease, and arthrogryposis multiplex
2. Most floppy infants have corticospinal disorders and dysmorphisms
 - a. Floppy infants with neuromuscular disorders that are primary include:
 - i. Spinal muscular atrophy
 - ii. Congenital hypomyelinating neuropathy
 - iii. Neonatal myasthenia
 - iv. Congenital myotonic dystrophy
 - v. Congenital Duchenne and Becker muscular dystrophy
 - vi. Congenital myopathies:
 1. Lipid
 2. Mitochondrial
 3. Glycogen

Differential Diagnosis of Congenital Ptosis

1. Muscle diseases:
 - a. Congenital myotonic dystrophy
 - b. Central nuclear myopathy
 - c. Nemaline myopathy
2. NMJ disorders:
 - a. LEMS (Lambert-Eaton myasthenic syndrome)
 - i. Less cranial nerve involvement than MG increased strength with exercise, autonomic involvement (dry mouth); "load in the pants" gait and some sensory symptoms
 - ii. Diseases that could be confused with LEMS include:
 1. Subacute myopathy (no increase of strength with exercise, no autonomic symptomatology)
 2. Pure motor forms of CIDP (no autonomic symptomatology, rare cranial EOM involvement, no increase of strength with exercise)

Differential Diagnosis of Fulminant Myasthenia (Severe General Weakness and Cranial Nerve Involvement)

1. Botulism (involvement of pupils, bulbar and the autonomic nervous system, and loss of reflexes)
2. Tick paralysis (ataxia and sensory loss; motor weakness)
3. Guillain-Barré (particularly Miller-Fisher variants; loss of reflexes is prominent)
4. Brainstem stroke (cognitive impairment; sensory loss, may have flaccid asymmetric weakness; rarely isolated IIIrd or VIth nerve palsy)

Differential Diagnosis of Neuromuscular Transmission at the Neuromuscular Junction

1. Presynaptic:
 - a. Lambert-Eaton myasthenic syndrome
 - b. Botulism (acquired and iatrogenic)
 - c. Botulism A, C and E cleave SNAP-25; type B, D, F and G cleave synaptobrevin; all cleave SNARE proteins required for the synaptic fusion complex
 - d. Congenital myasthenic syndrome:
 - i. Choline acetyltransferase deficiency
 - ii. Paucity of synaptic vesicles and reduced quantal release
 - iii. Congenital Lambert-Eaton syndrome
2. Drugs:
 - a. Hypermagnesemia (blockade starts at approximately 75 mg/L)
 - b. Antibiotics:
 - i. Aminoglycosides:
 1. Decrease the nerve terminal entry of calcium with consequent reduction of quantal acetylcholine release
 - ii. Primary aminoglycosides
 1. Amikacin
 2. Tobramycin
 3. Kanamycin
 4. Paromycin (paromomycin)
 5. Gentamicin
 6. Streptomycin
 7. Neomycin
 8. Other antibiotics (lesser effects on voltage-dependent calcium entry):
 - a. Clindamycin
 - b. Oxytetracycline
 - iii. Calcium channel blockers:
 1. Verapamil (L-type Ca^{2+} channels)
 2. Diltiazem
 - iv. Corticosteroid (affects the nerve terminal membrane; depolarization causing depletion of ACh)
 - v. Amidopyridines:
 1. Primarily 4-AP (utilized in demyelinating disease)
 2. Voltage-gated potassium blocking drugs
 3. Delay the egress of potassium from the nerve terminal, which prolongs the duration of the action potential, increasing calcium in the presynaptic terminal and thus increasing ACh quantal release

Differential Diagnosis of Toxins

1. Black and green mamba snakes:
 - a. Dendrotoxin
 - b. Blockade of nerve terminal potassium channels that prolongs the action potential allowing more calcium entry and increased ACh release

2. Scorpion (*Pandinus imperator*):
 - a. Blockade of nerve terminal potassium channels
3. Australian tiger snake:
 - a. Notexin
 - b. Blockade potassium channels that decrease the release of ACh
4. *Conus* marine snail (*C. geographus*):
 - a. Omega-conotoxin
 - b. Binds presynaptic calcium channels, preventing calcium entry and ACh release
5. Multi-banded krait:
 - a. Beta-bungarotoxin
 - b. Alpha-phospholipase
 - c. Presynaptic specific site-directed phospholipase A2-induced permeabilization of the plasma membrane
 - d. Impairs ACh release
6. Brazilian rattlesnake (*Crotalus durissus*)
 - a. Crotoxin
 - b. Initially, increases and then reduces the quantal release of ACh at presynaptic terminals
7. Black widow spider (*Latrodectus mactans*) and the brown widow spider (*Latrodectus geometricus*)
 - a. Produced alpha-latrotoxin
 - b. Affects motor nerve endings and endocrine cells
 - c. The toxin forms pores in the lipid membranes, inducing calcium entry
 - i. A dramatic early surge of spontaneous MEPP frequency which dissipates over 30 minutes
 - ii. Neuromuscular blockade occurs due to depletion of synaptic vesicle contents

Differential Diagnosis of Synaptic Structural Disorders

1. Synaptic basal-lamina-associated congenital myasthenic syndrome
 - a. Endplate acetylcholinesterase deficiency
 - i. Mutations in the gene encoding the anchoring and the catalytic component of AChE in the synaptic basal lamina complex
 - ii. Acetylcholine is prolonged in the synaptic cleft with prolonged duration of MEPP and EPP and degeneration of the junctional folds and loss of ACh receptors
 - b. B2-laminin deficiency:
 - i. Mutation in LAMB2 gene
 - ii. Widened synaptic space
 - iii. Decreased quantal release
 - iv. Simplified MEPP
2. Drugs that act in the synaptic cleft:
 - a. Acetylcholinesterase inhibitors
 - i. Edrophonium
 - ii. Pyridostigmine
 - iii. Neostigmine
 - b. Organophosphates
 - i. Increased EPP and prolonged depolarization of postsynaptic membranes

Differential Diagnosis of Postsynaptic Disorders

1. Myasthenia gravis
 - a. Neonatal
2. Primary AChR deficiency:
 - a. Mutations in AChR genes concentrated in the E-subunit
 - b. Fewer receptors and less folding of the junctional folds
3. Slow-channel syndrome:
 - a. Gain of function mutations
 - b. Enhances receptor affinity or increases its gating efficiency
 - c. Prolonged endplate currents
4. Fast-channel syndromes:
 - a. Recessively inherited
 - b. Decreased affinity for AChR and reduced gating kinetics
 - c. Abnormal short channel opening time
5. Prenatal myasthenic syndrome:
 - a. Mutation of the subunit (gamma)
6. Rapsyn mutations:
 - a. Mutations in the open reading frame and promoter region of Rapsyn
 - b. Less concentrations of AChR in the postsynaptic membrane
7. Plectin mutations:
 - a. Heteroallelic, nonsense, frame-shift and splice-site mutations
 - b. Low amplitude of MEPPs
 - c. Lack of cytoskeletal support from defects of the intermediate filament-linking protein
8. Non-channel myasthenia:
 - a. Mutation in SCN4A that encodes Na_v1.4
 - b. Enhanced fast inactivation of the sodium channels
 - c. Na_v1.4 are inexcitable in the resting state
9. MuSK (muscle-specific receptor tyrosine kinase):
 - a. In conjunction with agrin, Lrp4, and Dok-7, is involved in the maturation and maintenance of the endplate and in concentration of AChR in the postsynaptic membrane
 - b. Specific mutations in frame-shift and missense that are heteroallelic result in specific electrophysiological and structural deficits
 - c. MEPP amplitude may be reduced: a decreased EPP quantal content was detected in one kinship
10. Dok-7 mutations:
 - a. A muscle-intrinsic activator of MuSK
 - b. Multiple mutations in Dok-7
 - c. MEPP and MEPC amplitudes are reduced; some patients have decreased quantal content of ACh vesicles
 - d. There are both pre- and postsynaptic structural defects of the neuromuscular junction

Myasthenic Syndromes Associated with Centronuclear Myopathy

1. Centronuclear Myopathy (CNM) is a heterogeneous congenital myopathy whose defined genes are:
 - a. Myotubularin (MTM)
 - b. Dynamin 2 (DNM2)
 - c. Amphiphysin (BIN1)
 - d. Ryanodine receptor (RYR)
2. A decremental EMG response has been documented in CNM with myasthenic features

CMS in Defect of the Hexosamine Pathway

1. Mutation in the GEPT1 gene that encodes glutamine-fructose-6-phosphate transaminase 1
2. The enzyme controls glucose entry into the hexosamine pathway and ultimately N-O-linked glycosylation of protein
3. Limb-girdle weakness
4. Electrodiagnostic features have not been determined

Differential Diagnosis of Drugs and Toxins That Block the NMJ

1. D-tubocurarine
2. Vecuronium
3. Non-depolarizing agents
4. Depolarizing agents
 - a. Succinylcholine

Envenomations

1. Elapid species (cobras and kraits)
2. Conus marine snails

Drugs That May Cause Myasthenia Gravis

1. D-penicillamine
2. Alpha-interferon
3. Rarely reported (case reports):
 - a. Trimethadione
 - b. Riluzole
 - c. Ritonavir
 - d. Chloroquine
 - e. Statins
 - f. Beta-interferons

Drugs That Exacerbate Myasthenia Gravis

General Characteristics

1. Patients may develop cranial nerve dysfunction, generalized weakness and respiratory failure abruptly
2. Failing to awaken with full strength after anesthesia (often precipitated by the stress of surgery, neuromuscular blocking agents, and antibiotics administered during the procedure)
3. Myasthenic signs and symptoms are unmasked with specific drug administration due to concomitant electrolyte disorders or an increased concentration of the drug due to drug interaction, failure of metabolism or excretion (liver or renal dysfunction)

Calcium Channel Blockers That Exacerbate Myasthenia Gravis

1. May affect neurotransmission both pre- and postsynaptically by blockade of L-type calcium channels
 - a. Verapamil:
 - i. Blockade of L-type postsynaptic channels
 - ii. Decreases potassium efflux at the motor endplate
 - iii. Decreases intracellular ionized calcium levels
 - b. Nimodipine and nifedipine
 - i. Have caused dysphagia, ptosis and weakness after 18 months to 12 years of use
 - ii. Decremental response on EMG
 - iii. Nifedipine has been shown to exacerbate myasthenia
 - iv. Both oral verapamil and amlodipine taken for three months in normal subjects may cause abnormal single-fiber EMG
2. Antiarrhythmic agents
 - a. Procaine amide:
 - i. May both induce and exacerbate MG
 - ii. Decreases the release of ACh quanta
 - iii. Raises the threshold of action potential generation of the postsynaptic membrane
 - iv. Procaine amide and propafenone block sodium channels
 - v. The duration of use to NMJ dysfunction varies from hours to 8 months
 - b. Quinidine:
 - i. Blocks fast sodium channels
 - ii. Its concentration may be increased if it is used with dextromethorphan in the treatment of "pseudo bulbar palsy"; dextromethorphan blocks its metabolism
 - c. Lidocaine:
 - i. Blocks sodium channels
3. Antimicrobial agents:
 - a. Aminoglycosides
 - i. Streptomycin
 - a. Prevents release of presynaptic ACh quanta
 - b. Streptomycin acts primarily by blocking the receptor
 - i. Some blocking effects at the postsynaptic receptor
 - ii. Neomycin
 - a. Reduces the quantal release of acetylcholine by competitive antagonism with calcium for a common presynaptic site required for transmitter release
 - b. May block acetylcholine channels in their open configuration
 - iii. Clindamycin affects neuromuscular transmission less severely; it interacts with the open state of the AChR
 - iv. Lincomycin also has less severe neuromuscular blocking effects
 - v. Gentamicin, tobramycin and amikacin
 - a. Decrease presynaptic release of ACh quanta

- vi. Polymyxin B, polymyxin E (colistin), and netilmicin
 - a. Postsynaptic effects
- b. Macrolides:
 - i. Erythromycin:
 - a. Worsens myasthenia in patients with postsynaptic defects
 - b. Decreases presynaptic release of ACh quanta
 - c. Telithromycin and azithromycin may also exacerbate myasthenia by a similar mechanism
- c. Fluoroquinolones, including:
 - i. Ciprofloxacin
 - a. Blocks voltage-gated potassium channels that affect presynaptic calcium channels affecting ACh release mechanisms
 - ii. Gemifloxacin
 - iii. Levofloxacin
 - iv. Norfloxacin
 - v. Ofloxacin
 - vi. Profloxacin (ciprofloxacin)
 - vii. All may cause neuromuscular transmission defects, but the mechanisms have not been completely established

Other Drugs That May Worsen Myasthenia

1. Other antibiotics that may worsen myasthenia:
 - a. Ampicillin and other penicillins
 - b. Bacitracin
 - c. Tetracycline, oxytetracycline, chlortetracycline:
 - i. Postsynaptic blockade
 - ii. Less severe clinical effects than other antibiotics
 - d. Imipenem/cilastatin
2. Quinolone derivatives:
 - a. Quinine, quinidine, and chloroquine
 - b. Decreased acetylcholine quantal release due to blockade of voltage-dependent sodium channels (located deep in the secondary synaptic cleft)
 - c. Postsynaptic potentiation of depolarization
 - d. Antibodies have been detected in some patients to ACh receptors
3. Beta blockers:
 - a. Propanolol
 - b. Practolol
 - c. Oxprenolol
 - d. Atenolol
 - e. Sotalol
 - f. Nadolol
 - g. Ophthalmic timolol:
 - i. May interfere with presynaptic ACh quantal release or work at the level of the muscle membrane
4. Corticosteroids:
 - a. Affect the nerve terminal membranes that causes continual depolarization
 - b. Depletes presynaptic ACh vesicles (decreased MEPP amplitude)

- c. Alters intracellular potassium concentration
- 5. H₂ receptor antagonists
 - a. Cimetidine, ranitidine, and roxatidine:
 - i. Pre- and postsynaptic interactions
 - ii. Inhibition of acetylcholinesterase
- 6. Depolarizing neuromuscular blocking agents:
 - a. Succinylcholine and decamethonium
 - b. Prolonged binding to the AChR with persistent depolarization of the postsynaptic membrane
- 7. Non-depolarizing blocking agents:
 - a. Vecuronium
 - b. Atracurium
 - c. Mivacurium
 - d. Doxacurium
 - e. Cisatracurium
 - f. Pancuronium
 - g. Rocuronium
- 8. Chloroquine:
 - a. Decreased ACh quantal release
 - b. Competitive post-junctional blockade
 - c. Decreased excitability of the sarcolemmal membrane
- 9. Magnesium:
 - a. >5 meq/L; severe deficit at 10 meq/L
 - b. Decreased release of ACh-containing vesicle
- 10. Drugs with potential NMJ blocking properties in myasthenia patients
 - a. Anesthetics:
 - i. Diazepam (chloride channel)
 - ii. Ketamine (primarily NMDA receptor)
 - iii. Propanediol ether
 - iv. Proparacaine
 - b. Anticonvulsants:
 - i. Phenytoin (sodium channel blockers)
 - ii. Carbamazepine (sodium channels)
 - iii. Ethosuximide (calcium channels)
 - iv. Gabapentin (alpha2delta subunit of calcium channel)
- 11. Drugs of abuse with possible NMJ blocking effects
 - a. Cocaine
- 12. Miscellaneous drugs:
 - a. DL-carnitine
 - b. Tropicamide
 - c. Iodinated radiographic contrast
 - d. Trihexyphenidyl
 - e. Echothiopate
 - f. Phenothiazine
 - g. Lithium

Chapter 9

Muscle Diseases

Overview of Muscular Dystrophies

The estimated prevalence rate of the most common muscular dystrophies are 1 in 5,000 live births for Duchenne dystrophy, 1 in 7,000 for facioscapulohumeral muscular dystrophy and 1 in 20,000 live births for myotonic muscular dystrophy. The muscular dystrophies are caused by mutations in over 30 genes that cause myofiber degeneration and atrophy. Similar or identical mutations in a single gene can produce different phenotypes. A more accurate classification of these illnesses is by both their muscular deficits and their phenotype dystroglycanopathies, laminopathies or ion channelopathies. The dystrophies demonstrate mechanisms of genetic disease: 1. Duchenne muscular dystrophy is a single gene loss of function disorder; 2. Facioscapulohumeral muscular dystrophy is due to epigenetic dysfunction; 3. myotonic dystrophy is a toxic gain of function illness from a tandem gene repeat.

The different muscular dystrophies are the results of mutations in genes that encode proteins pivotal to the:

1. Sarcolemma
2. Myonuclei
3. Basement membrane
4. The muscle extracellular matrix
5. The sarcomere
6. Non-structural enzymatic proteins

The major proteins affected in the dystrophies and their mechanism of action will be briefly discussed.

Dystrophin-Glycoprotein Complex and Related Proteins

Dystrophin

Dystrophin is the abnormal gene product in Duchenne and Becker muscular dystrophy. It is located on the cytoplasmic face of skeletal and cardiac muscular membrane. It is a large rod-shaped molecule composed of four domains. It is a 427 KDa submembrane cytoskeletal protein that is incorporated into a large macromolecular complex of proteins known as the dystrophin associated protein complex (DAPC). The DAPC is composed of dystroglycans, sarcoglycans, sarcospan, dystrobrevins and syntrophins. The dystrophin glycoprotein complex (DGC) is localized to a lattice-like structure in the muscle fiber that transmits force radially from the Z-disc to neighboring muscle fibers. Dystrophin has four domains, two globular domains and its N- and C-termini that are connected by a large rod domain. The rod domain consists of 24 spectrin-like repeats that includes four interspersed hinge regions. The C-Terminal domain binds the cytoplasmic tail of beta-dystroglycan. Dystrophin interacts with actin filaments

at two sites: 1. ABD1 at its N-terminus, a tandem calponin homology domain and 2. ABD2 site within the spectrin-like repeats 11–17 which interact with actin filaments by electrostatic attraction. These two binding sites anchor the sarcolemma to the muscle actin cytoskeleton that stabilizes the membrane against the mechanical forces of contraction. The dystrophin cysteine rich domain and the first half of the carboxy terminal domain link dystrophin to beta-dystroglycan and other glycoproteins that span the sarcolemma. Recent studies have demonstrated that phosphorylation within the cysteine rich region of dystrophin augments its interaction with beta-dystroglycan.

Dystrophin Associated Protein/Glycoproteins

The dystrophin glycoprotein complex consists of oligomeric proteins tightly bound to dystrophin. Mutations of the genes that code for the proteins of this complex cause many of the muscular dystrophies.

Other proteins that compose the dystrophin associated protein complex (DAPC) are: 1. dystroglycan; 2. sarcoglycans; 3. sarcospan; 4. dystrobrevins and syntrophin. The DAPC is a scaffold for various signaling and channel proteins as well as anchoring a variety of signaling molecules near their sites of action. The DAPC may be a component in the transduction of extracellular mediated signals to the muscle cytoskeleton. Recent work has demonstrated that beta-dystroglycan is involved in MAPK and Rac1 (small GTP-ase) signaling although it has been suggested to serve as a cell surface receptor for extracellular matrix proteins.

The syntrophins are a family of cytoplasmic membrane associated adaptor proteins that are characterized by a unique domain organization that is composed of a C-terminal syntrophin unique domain (SU) and an N-terminal Pleckstrin homology (PH) domain that is split by a PDZ domain. There are several isoforms B1, B2, and U2 that are encoded by different genes. A-Syntrophin is the primary isoform expressed in striated and cardiac muscle in the sarcolemma. MNI B1-syntrophin also localizes similarly while B2- and U2-syntrophin localize to the NMF. A-syntrophin interacts with dystrobrevin at the Ur3 domain. Syntrophin coordinates the assembly of 1. nitric oxide synthase, 2. stress activated protein kinase; 3. Grb2 and 4. calmodulin to the DAPC. Nitric oxide synthase generates NO from L-arginine that regulates focal blood flow in contracting skeletal muscle by antagonizing sympathetic induced vasoconstriction. Decreased vasodilation from decreased expression of nNOS is a feature of many muscular dystrophies. Transient receptor potential channels (TRPCs) also associate with syntrophin and are anchored to the DAPC. Emerging evidence suggests that they are a signaling complex for cations and regulate calcium homeostasis in skeletal muscle that is pivotal for muscle contraction, metabolism, and gene expression. The DAPC can bind as many as four syntrophins through binding domains or both dystrophin and dystrobrevin that allows the

scaffolding of multiple signaling proteins to be in close proximity. The multiple interactions of the Pleckstrin domain and PDZ domains of syntrophin form a signal plexus that enables regulated signal transduction and ion transport. The syntrophins also serve as a link between the extracellular matrix and downstream intracellular targets that include the cell cytoskeleton through their interactions with F-actin.

The mammalian dystrobrevin protein family consists of A- and B-dystrobrevin that are encoded by the genes DTNA and DTNB on chromosome 2p22. They are cytoplasmic proteins that bind to the syntrophin complex and to the C-terminus of dystrophin in striated muscle. In striated muscle dystrobrevin is localized to the cytoplasmic face of the sarcolemma. B-dystrobrevin is also expressed in non-muscle tissue.

Dystrobrevin is comprised of four major domains. Its two EF-hand motifs are thought to bind calcium, a 2Z domain, a helical coiled-coil domain that contains a dystrophin binding site and a tyrosine kinase substrate domain. Dystrobrevin is subject to extensive splicing regulation that generates three major dystrobrevin isoforms: 1. dystrobrevin 1; 2. dystrobrevin 2 and dystrobrevin 3. Dystrobrevin is associated with dystrophin by interaction at its coiled-coil domain and with the sarcoglycan complex through its N-terminal half. Additional dystrobrevin-binding proteins are syncoilin, B-synemin and dysbindin. Syncoilin and B-synemin are intermediate filament proteins. The interfilaments are an important part of the cell cytoskeleton by providing mechanical stability to the cell. Intermediate filaments include the two lines of each myofibril that connects all adjacent myofibrils and links the 2-lines of the peripheral layer of myofibrils to the sarcolemma.

Syncoilin, an intermediate filament protein, is highly expressed in striated muscle and colocalizes with dystrobrevin at the NMJ and the sarcolemma. It organizes and directs desmin filaments to the Z-line and provides further linkage of the DAPC and the cytoskeleton. This linkage may also be important for force transduction during muscle contraction. Syncoilin has been found to be increased in the sarcolemma of immature regenerating fibers. Thus syncoilin and dystrobrevin may play a role in muscle regeneration.

B-Synemin is a large heteropolymeric intermediate filament protein that interacts and colocalizes with dystrobrevin at NMJs and myotendinous junctions (MTJs). B-synemin dystrobrevin interacts with plectin, a linker protein of intermediate filaments to Z-discs, which interacts directly with dystrobrevin.

Dysbindin is a coiled-coil containing protein that is located in the sarcolemma. It binds to dystrobrevin and interacts with myospryn and other muscle-specific proteins localized to the sarcolemma. Myospryn may be a docking platform for structural and signaling molecules.

A recently described catenin/ninutin-related molecule, alpha-catulin has been shown to be another binding partner of dystrobrevin 1. It colocalizes with alpha-dystrobrevin at nerve bundles and blood vessels to regulate $\alpha 1D$ -adrenergic receptor signal transduction.

The sarcoglycan complex is a component of the major dystrophin complex and is a transmembrane protein. The sarcoglycans are transmembrane proteins that mature in the endoplasmic reticulum to reach their normal conformation by the activity of a quality control system. Misfolded proteins are identified and retrotranslocated to the cytosol where they undergo proteasomal degradation by the ER-associated protein degradation (ERAD) pathway. Defects in each sarcoglycan destabilize the entire sarcoglycan complex.

The sarcoglycan complex is composed of four membrane spanning proteins: 1. Sarcoglycan; 2. B-sarcoglycan; 3. U-sarcoglycan; 4. I-sarcoglycan. The sarcoglycan complex interacts with the cystein-rich domain or the first half of the carboxy terminal of dystrophin via the dystroglycan complex. Pathogenic mechanisms that effect sarcoglycans are: 1. the processing of defective sarcoglycan subunits; 2. failure of complete sarcoglycan complex assembly; 3. targeting of a dysfunctional sarcoglycan complex to the sarcolemmal membrane; 4. inadequate N- and O-glycosylation.

Sarcospan is a transmembrane protein that colocalizes with the sarcoglycan complex. The functions of sarcospan include:

1. Increased expression of the dystrophin and glycoprotein complexes
2. Increased expression of the 7B1 integrin
3. Interactions between integrin and sarcospan are pivotal for maintenance of the dystrophin-glycoprotein complex
4. Is a regulation of AKt signaling pathways that are important for muscle regeneration
5. Regulates glycosylation of some dystroglycans, the laminins-binding receptors for dystrophin and utrophin at the neuromuscular junction
6. Mutations of sarcoglycan genes are responsible for limb girdle muscular dystrophies (LGMDs) 2S, 2D, 2E and 2F

Laminin/Merosin

Laminins are large heterotrimeric proteins composed of three different homologous β -beta and γ -gamma chains held together by disulfide binds. There are five different α -alpha chains, three β -beta chains and two γ -gamma chains. The trimeric proteins intersect to form a lattice-like structure that binds other cell membranes and extracellular molecules. Laminin-2, composed of $\alpha 2$, $\beta 1$, and $\gamma 1$ chains is the major isoform of laminin heavy chains in muscle. Muscle also has a component of laminin 4 that is composed of $\alpha 2$, $\beta 2$ and $\gamma 1$ subunits. Greater than 15 laminin trimers have been identified. Merosin refers to laminins that have a common $\alpha 2$ chain. Basement membranes also are composed of type I and IV collagen, heparan sulfate, proteoglycans, fibronectin and laminin. They attach to cell membranes through integrin receptors and other molecules in the plasma membrane that include the dystroglycan complex. Laminin is a component of the basal lamina that surrounds each muscle fibril and is closely adherent to the sarcolemma. Alpha-dystroglycan binds to lamin-2. The sarcoglycan complex may associate with laminin 4. Merosin is a ligand in the Schwann cell

dystroglycan complex and binds alpha-dystroglycan. Mutations of the merosin gene are a cause of congenital muscular dystrophy and may also be associated with dysmyelination in the peripheral and central nervous system. LAMA2-gene mutations cause an autosomal recessive severe early-onset congenital muscular dystrophy as well as a limb-girdle muscular dystrophy (LGMD2).

Integrins

Integrins are transmembrane heterodimeric receptors composed of α and β chains. They are pivotal for cell-cell and ECM (extracellular matrix) interactions. After activation, they initiate signal transduction that induces the chemical composition and mechanical status of the ECM. They work in concert with cadherins, selectins, syndecans and the immunoglobulin super family cell adhesion molecules. They are also important for cell adhesion, proliferation, migration, and cytoskeletal organization. The major integrin expressed in the sarcolemma of skeletal muscle is $\alpha 7 \beta 1$ D. Ligands for integrins include fibronectin, collagen and laminins. $\alpha 7 \beta 1$ D integrin binds to merosin in skeletal muscle which links α -dystroglycan to merosin which augments sarcolemmal structural stability. Muscle fibers attach to lamin in the myofibril basal lamina by the dystrophin glycoprotein complex and the $\alpha 7 \beta 1$ integrin. Defects in these linkage mechanisms cause Duchenne muscular dystrophy, $\alpha 2$ laminin congenital muscular dystrophy, sarcoglycan-related muscular dystrophy and $\alpha 7$ integrin congenital muscular dystrophy.

Sarcolemmal Proteins Dysferlin

Dysferlin is a member of a family of proteins that are composed of multiple Ca^{2+} sensitive domains. They are important for vesicle fusion, trafficking, and membrane repair. There are seven domains in the dysferlin protein with different affinities for calcium and phospholipids that regulate its association with multiple protein complexes. Emerging evidence indicates association of dysferlin with the (t)-tubule membrane, where it is postulated to maintain Ca^{2+} homeostasis, during mechanical stress. Experimental studies in cultured muscle cells that demonstrated translocation from internal structures as well as its binding partners (tubulin, annexins, coneolin 3, BIN1) suggests its role in membrane repair. The most recent model of dysferlin function supports its role as a Ca^{2+} sensitive signaling scaffold protein that is localized to the t-tubule membrane. Its major function is postulated to involve the maintenance of t-tubules structure and function. Mutations of the gene that encodes dysferlin cause LGMD2B and Miyoshi distal myopathy.

Caveolae

Caveolae are specialized lipid rafts that form flask-shaped invaginations in the sarcolemmal membrane. They are 10–100 nm invaginations of approximately 14–16 caveolin-3

monomers that form a scaffolding complex of protein and lipids. Caveolin-1 is the major protein essential for their formation. Emerging evidence indicates that other caveolae-associated proteins, the cavin proteins are required for their formation and organization. The cavin proteins work in concert with caveolins for caveolae biogenesis. The N-terminal domain of the cavin HR1, is required for their homo- and hetero-oligomerization that form distinct subcomplexes on caveolae. Caveolae interact with dysferlin and caveolae-3 may have a function in the formation of (t) tubules and the organization of signaling complexes (dihydropyridine and ryanidine receptors and sodium channels). Caveolae interact with membrane associated signaling molecules that are important for cholesterol incorporation, macromolecular transport and permeability. Caveolin-3 gene mutations cause LGMD1C, rippling muscle disease and some forms of hyper-CK-emia.

Sarcomere Proteins

The cyclic interactions between the contractile proteins myosin and actin driven by the turnover of adenosine triphosphate (ATP) produce muscle contraction. In striated skeletal muscle actin and myosin in conjunction with accessory proteins are organized into sets of interdigitating thin and thick filaments which are connected in series with each other to form 1 μm wide myofibrils that run the entire length of the muscle cell. A thick filament is a polymer of myosin that is composed of approximately 300 myosin molecules. Muscle contraction occurs when globular myosin motor domains (“heads”) which extend from the thick filaments to interact with actin-binding sites to form “cross-bridges.” This anatomical arrangement produces effective summation of length changes by sarcomeres that are arranged in series. A structural working stroke in the myosin head pulls the thin actin filament towards the center of the sarcomere by 11 nm. Molecular motors are classified depending on whether they require several steps or only one step along their track prior to their detachment. The myosin II motor of muscle (the head on the thick filament) requires only one step along an actin filament before detaching (non-processive movement). The production of force and displacement by this actin-myosins mechanism is the result of cyclic interactions of billions of myosin motor domains with actin filaments. The force generating interaction cycles between actin and myosin is provided by the turnover of ATP. The “cross-bridge” globular head has two flexible hinges one at the head and the other at the arm filament interface. The myosin filament is coiled around a central axis that allows the cross-bridges 360° of longitudinal and circumferential extension. The globular heavy chain myosin head contains actin-binding sites and functions as an ATPase. The three major myosin heavy chain (MyHC) isoforms are expressed in different fiber types:

1. Type I expresses MYH7 in type I fibers
2. Type IIa expresses MYH2 in 2A fibers
3. Type IIx expresses MYH1 in 2B fibers

Mutations in the genes that encode the various MyHC isoforms cause both myopathies and cardiomyopathies.

Three subcomponents composed of actin, tropomyosin and troponin comprise the thin filament. G-actin has a globular structure that consists of two lobes separated by a cleft which is the "ATPase fold". This fold is the enzymatic center of catalysis which binds ATP and Mg^{2+} and hydrolyses it to ADP and phosphate. G-actin is only functional with ATP or ADP in its cleft. F-actin has a filamentous structure that is a single-stranded levorotatory helix. F-actin has a structural polarity in that all of its subunits are oriented to the same end. The helical F-actin filament of striated muscle contains a tropomyosin molecule, a 40 nanometer long protein that wraps around the F-actin helix. At rest, the tropomyosin covers the actin active sites that blocks actin-myosin contraction coupling. Troponins are the third subcomponent of the actin thin filament. Troponin I binds to actin, troponin T binds to tropomyosin and troponin C has high affinity for calcium. The troponin complex links tropomyosin to actin to form the complete thin filament. One end of an actin filament is anchored to the Z-disc that extends from myofibril to myofibril across the diameter of the muscle fiber while its other end is interspersed between myosin filaments. The Z-discs defines the lateral borders of sarcomeres whose core consists of actin filaments from adjacent sarcomeres that are cross-linked by α -actinin in myosin. They (Z-discs) are composed of hundreds of proteins and are an extremely complex macromolecular structure. The disc size varies in different types of muscle. F-actin filaments, the large protein titin, the nebulin/nebulette complex directly attach to Z-discs. In addition to its function in the mechanical stability of the sarcomere it has a role in signaling and mechanosensation. The Z-disc also communicates with the t-tubular system, the sarcoplasmic reticulum and E3 ubiquitin ligases.

Other major proteins of the Z-disc include:

1. Nebulin, a giant 500–900 KDa filamentous protein that courses alongside actin filaments and is attached to α -actinin at the Z-disc. The giant muscle proteins (titin, nebulin and obsurin) have major roles in muscle elasticity, stretch response and sarcomeric organization. Nebulin consists of multiple tandem structural domains arranged in a modular pattern that span 500 KDa. Each thin filament has two nebulin molecules. Nebulin is also found in cardiac muscle. Mutations in the nebulin gene (NEB) causes nemaline myopathy
2. Desmin is an intermediate filament protein (along with vimentin and lamin A/C) and is essential for the structure of the extra-sarcomeric cytoskeleton in muscle cells. It has a three-dimensional filamentous frame work. It has a central alpha helical rod and globular domain in its amino-terminal and carboxyl terminal ends. Desmin interacts with several proteins and may be the sensor of deformation in cellular structures. There is evidence that it is linked to mechano sensation and is associated with the intracellular cytoskeletal network. It also links the Z-disc to the sarcolemma myonuclei and neighboring myofibrils

3. Alpha-B crystalline and HSPB7 alpha crystalline. Alpha crystalline (alpha A) is restricted to the lens. Alpha-B crystalline interacts with desmin, vimentin and actin and is localized to the Z-disc. It is a member of the small heat shock protein family. They have some molecular chaperone functions but they do not renature proteins. They hold proteins in soluble aggregates. They have autokinase activity and AB-crystalline functions with desmin to assemble and stabilize the Z-disc. Syncoilin and plectin may also augment the link of desmin filaments to the Z-disc
4. ZASP (Z-band alternatively spliced PDZ motif containing protein) functions to bind α -actinin and crosslink thin filaments of adjacent sarcomeres. Mutations in ZASP cause one form of myofibrillar myopathy
5. Titin. Titin is encoded by the TTN gene, is a giant protein greater than 1 μ m in length and connects the Z line to the M line in the sarcomere. It has been suggested to serve as a "molecular ruler" that determines the spacing of sarcomeres. It has Ig and fibronectin domains. The protein contributes to force transmission at the Z line as well as resting tension in the I-band. It contributes to sarcomere stabilization, the prevention of overstretching and the return to normal length after muscle contraction. Its semi-rigid rod-like A-band region has been suggested to act as a scaffold in the formation of thick filaments during muscle development. Titin is the third most abundant protein in muscle. It has a length of 27,00–33,000 amino acids (due to splice variant isoforms which makes it the largest protein). Its gene contains 363 exons
6. Titin interaction with other sarcomeric proteins include:
 - a. Telethonin and alpha-actinin at the Z-line region
 - b. Calpain-3 and obscurin at the I-band region
 - c. Myosin-binding protein C, calmodulin I, CAPN3 and MURF1 at the M line region

Titin Mutations Cause:

1. Myopathy with early respiratory failure
2. Early-onset myopathy with fatal cardiomyopathy
3. Core myopathy with heart disease
4. Centronuclear myopathy
5. Limb-girdle muscular dystrophy type 2J
6. Familial dilated cardiomyopathy 9
7. Hypertrophic cardiomyopathy and tibial muscular dystrophy
8. Scleroderma has autoantibodies to titin
9. Telethonin: Telethonin is a 167 amino acid protein that is striated muscle-specific with a B-sheet structure. It binds to the Z1–Z2 domains of the titin protein and attaches the N-terminals of two adjacent titin molecules at the Z-disc and along thick filaments. Telethonin interacts with multiple other proteins, is linked with myotitin that interacts with α -actinin and actin. Nonsense mutations in the telethonin gene cause limb-girdle muscular dystrophy type 2G (LGMD2G), while heterozygous missense mutations cause dilated and hypertrophic forms of cardiomyopathy

10. **Myofilin:** Myofilin is a 5 KDa cytoskeletal protein localized to the sarcomeric Z-disc and augments the stability of thin filaments during muscle contraction. Its functions include: 1. the binding of F-actin, 2. cross-linking actin filaments and 3. preventing latrunculin A induced filament disassembly
11. **Filamin-C:** Filamin-C is encoded by the FLNC gene and is primarily expressed in cardiac and striated skeletal muscles. It functions at Z-discs and subsarcolemmal areas. It has an N-terminal filamentous actin-binding domain and a long C-terminal self association domain that contains immunoglobulin-like domains as well as a membrane glycoprotein-binding domain. Filamin is a component of a focal adhesion protein. Filamin-C interacts with specific proteins in different parts of the sarcomere:
 - a. It interacts with γ -sarcoglycan and IL sarcoglycan at the sarcolemma
 - b. Myotilin and FATZ/calsarcin/myozenin at Z lines
 - c. LL5beta is a phosphatidylinositol (3,4,5)-trisphosphate sensor that binds the cytoskeletal adaptor, gamma-filamin
 - d. Filamin-C interacts with INPPL1, KCND2 and MAP2K4

Filamin-C:

1. Binds actin
2. Is involved in Z-disc formation
3. Binds γ -gamma and L sarcoglycan at the sarcolemma
4. Is involved in signaling pathways from the sarcolemma to the myofibril

Summary of Z-Disc Proteins

1. Core Z-disc proteins:
 - a. α -actinin
 - b. Stabilization of the sarcomere during contraction (mechanical function)
2. Partial Z-disc proteins:
 - a. Titin, nebulin and actin
 - b. Functions:
 - i. Stabilization of the sarcomere during contraction
 - ii. Signal transduction
 - iii. Relaxation
 - iv. Contractibility
 - v. Passive elasticity
3. Peripheral Z-disc proteins:
 - a. Telethonin, calcineurin, calcarcin and MLP (muscle LIM protein)
 - b. Function:
 - i. Signaling
 - ii. Survival
4. Mutations in Z-disc genes give rise to Z-discopathies that include:
 - a. Cardiomyopathies:
 - i. DCM (dilate cardiomyopathy)
 - ii. HCM (hypertrophic cardiomyopathy)
 - iii. ARVC (autosomal recessive ventricular compaction)
 - b. Myopathies:

- i. Titinopathy
- ii. Zasopathy
- iii. Myotitinopathies
- iv. Myofibrillar myopathy
- v. LGMD
- vi. XMPMA (X-linked myopathy with postural muscle atrophy)

Sarcoplasm

Sarcoplasm is the intracellular fluid that surrounds myofibrils. It contains mitochondria and a variety of organelles that includes the sarcoplasmic reticulum. The intracellular calcium concentration determines skeletal muscle force that is regulated by the uptake and release of calcium from the sarcoplasmic reticulum. The sarcoplasmic reticulum is an intrinsic series of channels that terminate in cisternae at either end of the sarcomere. The ryanodine receptor (RyR) is the calcium release channel in the sarcoplasmic reticulum. The free calcium in the sarcoplasmic reticulum regulates its own excitability by activating Ca^{2+} release channels in its membrane that involves Ca^{2+} sensing mechanisms on both the luminal and cytoplasmic sides of the ryanodine receptor. Inositol 1, 4, 5-trisphosphate receptors (IP3R) are also Ca^{2+} release channels on the endo/sarcoplasmic reticulum. T-tubules are closely associated with terminal SR cisternae. Two terminal cisternae associated with one T-tubule form a triad that conducts the action potential into both the cisternae and the interior of the muscle fiber. Calcium release from intracellular stores plays an essential role in excitation-contraction coupling. Ryanodine (RyR) and inositol 1, 4, 5-trisphosphate receptors (IP3Rs) are the major release channels of the endo/sarcoplasmic reticulum. The sarco (endo) plasmic reticulum Ca^{2+} ATPase (SERCA) are the uptake channels. Calsequestrin is the major calcium buffer in the sarcoplasmic reticulum. Calsequestrin both inhibits and activates muscle RyR1 depending on its binding status that may be direct or through anchoring proteins. Its phosphorylation status influences its Ca^{2+} -binding capacity, the regulation of the RyR1 receptor and its interaction with the anchoring protein junction 5. The calcium reuptake channel also located in the sarcoplasmic reticulum is the calcium ATPase (SERCA1) receptor. Mutations in the genes that encode these channels cause hypokalemic periodic paralysis, central core disease, and malignant hyperthermia. Mutations in the gene encoding the SERCA1 receptor causes Brody disease in which there is impaired relaxation of muscle.

Nuclear Proteins

The nuclear envelope is made of two lipid bilayers. The outer nuclear membrane is contiguous with the endoplasmic reticulum and the inner nuclear membrane. The inner nuclear membrane contains a variety of integral membrane proteins that include LAP2, Emerin and MAN1. Emerin is a LEM domain nuclear protein. The LEM domain mediates binding to

BAF (chromatin-associated protein barrier to autointegration factor), which is essential for higher order chromatin structure, nuclear assembly and gene regulation. The binding of LEM proteins to chromatin bound BAF recruits chromatin to the nuclear envelope. In addition to LEM proteins there are between 80–100 integral inner nuclear membrane proteins. Emerin is a serine rich nuclear membrane protein and belongs to the nuclear lamin-associated protein family. It is located on the inner nuclear membrane of skeletal, cardiac and smooth muscle.

The nuclear lamina consists of lamins and nuclear lamin-associated membrane proteins. The lamins are type V intermediate filaments that are either type A (lamin B1, B2). Type V intermediate filaments have arm extended rod domains, a nuclear localization signal at their C-terminus and typical tertiary structures. The nuclear lamina is a multimeric matrix composed of lamins A, B and C that are associated with the nucleoplasmic surface of the inner nuclear membrane.

The nuclear lamin associated membrane proteins are either integral or peripheral membrane proteins, the most important are:

1. Lamin associated polypeptide 1 and 2 (LAP, LAPa)
2. Emerin
3. Lamin B-receptor (LBR)
4. Otefin and MAN1

The assembly of the nuclear lamina is accomplished by the interactions of two lamin polypeptides. Their α -helical regions are intertwined to form a coiled-coil structure that is followed by a head to tail linkage of these dimers. The elongated linear polymer has side-to-side polymers that give it a 2D structure that forms the nuclear envelope. The functions of the nuclear envelope include:

1. Mechanical stability of the nucleus
2. Chromatin organization
3. Cell cycle regulation
4. DNA replication
5. Cell differentiation and apoptosis
6. Binds nuclear pore complexes

Emerin attaches to the inner nuclear membrane by its carboxyl terminal tail. Lamins bind to emerin, other LAPs, and specific lamin receptors on the inner nuclear membrane. This protein complex is essential for the structural integrity and organization of the nuclear membrane as well as signal transduction between the nucleus and the sarcoplasm. Mutations in the gene that codes for emerin causes Emery-Dreifuss muscular dystrophy. Lamins A and C are caused by alternate splicing while mutations in the LMNA gene is responsible for autosomal dominant limb-girdle muscular dystrophy Type 1B.

Valosin containing protein (VCP) is encoded by the valosin-containing protein gene that has been mapped to chromosomal region 9p13.3-12. It is a type II member of the AAA⁺-ATPase family and localizes to nuclei around nucleoli. It serves a variety of functions that include:

1. A ubiquitin segregase that remodels multimeric protein complexes by extracting polyubiquitinated proteins that are subsequently recycled or degraded by the proteasome

2. Mitochondrial quality control
3. Autophagy
4. Vesicle transport and fusion
5. 26S proteasome activity
6. Proteasome assembly
7. It is associated with calthrin, heat shock protein Hsc 70 in a complex
8. Valosin is a component of cellular events that are regulated during mitosis which include:
 - a. Membrane fusion
 - b. Spindle pole body physiology
 - c. Ubiquitin dependent degradation
9. Mutation in the VCP gene cause inclusion body myopathy associated with Paget's disease of bone and frontotemporal dementia. Mutations in the VCP1 gene are also responsible for amyotrophic lateral sclerosis, in 10–15% of patients with hereditary inclusion body myopathy as well 2–3% of isolated familial amyotrophic lateral sclerosis

Poly(ADP-ribose) binding nuclear protein 1 (PABNP1) is encoded by the PABN1 gene that is located in chromosome 14q11.1. Mutations in the gene cause short (GCG) (8–13 expansion that lengthens an N-terminal polyalanine domain). The mutation mechanisms have been postulated to cause slippage and unequal recombination. Under normal circumstances, the encoded protein polymerizes poly (A) tails on the 3' ends of eukaryotic genes and controls the size of the poly (A) tail to approximately 250 nt. The major function of PABNP1 is to polyadenylate mRNA and shuttle it from the nucleus to the cytoplasm. Mutation of the PABNP1 gene causes oculopharyngeal dystrophy. The GCG expansion is stable in subsequent generations and is translated into a polyalanine tract. The pathologic hallmark of the disease is intranuclear inclusions that contain the aberrant protein that may interfere with normal RNA function.

Enzymatic Proteins in Muscle

Calpain-3 is a heterodimer that consists of a large and small subunit. It is a major intracellular cysteine protease. In addition to its enzymatic activity recent research supports that, its phosphorylation is involved in the pathology of LGMD2A through defects in the structure of myofibrils and their signaling pathways rather than its function as a protease. It is found in both the nucleus and cytoplasm of myofibrils. It may activate other enzymes involved in muscle metabolism.

Tripartite motif-containing protein 32 (TRIM32) is encoded by the TRIM32 gene on chromosome 9. The TRIM motif includes three zinc-binding domains, A Ring, a B-box type 1 and type 2 and a coiled region. It is localized to cytoplasmic bodies and the nucleus. It has two mechanisms of action:

1. Acting through the N-terminal RING finger as an E3 ubiquitin ligase it attaches ubiquitin molecules to lysine residues of target proteins, which marks them for proteasome degradation. It ubiquitinates multiple proteins that include:

- a. C-Myc
 - b. Dysbindin
 - c. Actin
 - d. Abl-interactor 2
2. It activates microRNAs by binding proteins to the c-terminal repeat
 3. Recent evidence signaling that causes muscle atrophy supports evidence that mutation in TRIM-2 gene causes LGMD2H

Fukutin is a glycosyl transferase encoded by the FCMD gene located on chromosome 9q31. Mutation of the gene causes abnormal glycosylation of alpha-dystroglycan that causes congenital muscular dystrophy and LGMD2L. Mutations in fukutin related protein cause congenital muscular dystrophy with normal merosin as well as LGMD2I. Glycosylation defects of alpha-dystroglycan also cause muscle-eye-brain disease and Walker-Warburg syndrome.

The muscle-eye brain (MEB) gene encodes a protein O-mannase b-1, 2-N acetyl glucosaminyl transferase (POMGnT1) which also causes LGMD2M. Walker-Warburg syndrome is caused by mutations in O-mannosyl transferase (POMT1) and the recently described GTDC2 genes. Presently there are 7 gene mutations defined in WWS that explain approximately 50–60% of patients. GTDC2 is predicted to encode a glycosyltransferase. Mutations in the DAG1 gene cause the loss of both α -alpha and β -beta dystroglycan and have been shown to cause WWS. LGMD2K is also seen with POMT1 mutations.

Mutations in the LARGE gene, another member of the N-acetylglucosaminyl transferase gene family, is a golgi protein. Mutations of the gene cause congenital muscular dystrophy 1D that is characterized by severe mental retardation. Abnormal glycosylation of alpha-dystroglycan and possibly defective synthesis of glycoprotein and glycosphingolipid are reported with this mutation LARGE may also function in tumor specific genomic rearrangements.

Mutations in the GNE gene in chromosome 9 which encodes UDP-N-acetylglucosamine 2-epimerase/n acetylmanosamine cause an autosomal recessive inclusion body myopathy from defects of post-translational glycosylation.

Sarcomere Structure

A sarcomere is the segment of a myofibril between two Z-lines. The I-band is the zone of thin filaments that is not superimposed by thick filaments and surrounds the Z-line. Next to the I-band is the A-band (anisotropic under a polarizing microscope). It contains the entire length of a single thick filament. The A-band contains the H-band that is a zone of thick filaments that is not superimposed by thin filaments. The H-zone contains the thin M-line that is formed by cross connecting elements of the cytoskeleton. Actin thin filaments extend into the A-band and are the major component of the I-band. Myosin thick filaments extend throughout the A-band and are cross-linked at their center by the M-band. Titin extends from the Z-line where it is attached to the thick filament

system to the M-band where it interacts with myosin. Nebulin extends along the thin filaments and the entire I-band. The M-band proteins myomesin and C-protein cross link myosin and the M-band component of Titin. The thin filaments are anchored in the Z-disc and the thick filaments (myosin) in the M-band. The alignment and linkage of actin and myosin filaments depends on the accessory proteins α -actinin, myomesin, M-protein, titin, desmin and the myosin-binding proteins (MYBP)-C and H. Alpha actinin is the major protein of the Z-line and cross links and fixes actin filaments in a lattice at the Z-disc. Myomesin and M-protein connect titin and myosin. Myomesin may also be essential in the integration or the assembly of sarcomeres. Titin courses parallel to the filament array and is a continuous filament system in myofibrils.

Desmin is a major intermediate filament protein that is essential for maintaining the structural integrity and alignment of myofibrils. Myosin-binding protein C runs parallel to the M-band and interacts with both the thick and titin filaments for their linkage and alignment in the A-band. Other functions of myosin-binding proteins include:

1. MyBP-C:
 - a. Reduces the critical concentration for myosin polymerization that forms longer filaments that are more uniform in length
 - b. Both MyBP-C and H are involved in the assembly of thick filaments into their precise lengths
 - c. MyBP-C and H may be a regulator of muscle contraction

The Structure of Myosin

Myosin is a hexameric protein composed of two myosin heavy chain (MyHC) subunits and two pairs of non-identical light chain (MyLC) subunits. The lobular domain of myosin binds the MyLC and forms the cross-bridges that contain the binding sites for actin and ATP. The rod domain is an elongated alpha-helical coiled-coil carboxyl-terminal with filament-forming characteristics. Proteolytic enzyme cleavage of MyHC produces two subfragments: 1. heavy meromyosin (HMM) that contains the head region (subfragment 1-S1) and a part of the coiled-coil-forming sequences (subfragment 2-S2) which connects the myosin head to the thick filament. The light meromyosin (LMM) is the C-terminal portion of the rod that is adjacent to the thick filament. The myosin motor domain is complicated and is formed by three domains connected by flexible linkers. An amino-terminal nucleotide-binding domain that is connected to the upper subdomain that in turn is connected to the lower domain. The third domain is the converter region from which extends a long helix that is the binding site for MyLCs. The essential light chains (ELC) are closest to the converter domain and the regulatory light chains (RLC) attach at the second site. The elongated neck region in S1 functions as a lever arm that amplifies small configured changes of the motor domain into greater displacements of actin. The six striated muscle MyHCs:

1. Are encoded by a cluster of genes on chromosome 17
2. The genes are arranged in the following sequence: MyH3, MyH2, MyH1, MyH8, MyH13 and MyH4
3. There are three major MyHC isoforms in adult limb muscles:
 - a. MyHC1 is encoded by MyH7 and is expressed in type I slow fibers and the heart ventricles
 - b. MyHC 11a is encoded by MyH2 is expressed in fast contracting type 2A muscle fibers
 - c. MyHC IIX is encoded by MyH1 and expressed in fast type 2B muscle fibers
 - d. There are special MyHC isoforms expressed in specific muscles (extraocular muscles)
 - e. Specific MyHC isoforms are expressed in developing and regenerating muscles

The Structure of Actin

Actin is the major protein component of sarcomeric thin filaments. F-actin is the backbone of the thin filament that is a two-stranded helical structure.

TM is an actin-binding protein that forms a rod-shaped coiled-coil dimer from its two alpha-helical chains. It is encoded by four TM genes (TPM1, TPM2, TPM3 and TPM4). It is localized along the length of the actin filament. Transmission from Ca^{2+} dependent movement of the Tn complex, TM blocks or opens myosin-binding sites on actin. TM has three homologous isoforms in striated muscle: 1. α -TM (fast); 2. β -TM and 3. VTM (slow). TM is encoded by the TPM1 gene and is present in fast type 2 and cardiac muscle. β -TM is encoded by the TPM2 gene and is predominantly expressed in slow type 1 muscle and to a lesser extent in cardiac and fast muscle fibers. VTM is encoded by the TPM3 gene and is expressed in slow muscle fibers and the heart.

Tn is a complex of three component proteins: 1. troponin C (TnC), 2. troponin I (TnI) and 3. troponin T (TnT). These three proteins are regulators of muscle contraction:

1. TnC is the Ca^{2+} -binding subunit
2. TnI binds to actin and inhibits actomyosin ATPase
3. TnT links the Tn complex to TM

There are isoforms of TnI, TnC and TnT expressed by different genes. Nebulin is a giant filamentous protein that spans the length of the thin filament. It functions as a length-regulating template of the sarcomeric actin filament.

An Overview of Muscle Contraction

During rest, the myosin head is bound to an ATP molecule and is unable to access cross-bridge binding sites of actin. Muscle afferents release acetylcholine that initiates a postsynaptic action potential that propagates along the transverse Tubules to the sarcoplasmic reticulum that activates voltage gated L-type calcium channels of the plasma membrane. L-type calcium channels are in close proximity to the ryanodine receptors on the sarcoplasmic reticulum. The increased

calcium concentration mediated by L-type calcium channels activate ryanodine receptors that release calcium from the sarcoplasmic reticulum known as calcium-induced calcium release. Calcium ions bind with troponin-C molecules that are on tropomyosin that alters its structure and uncovers the cross-bridge binding sites on actin. In a muscle at rest, the myosin head is bound to an ATP molecule in a low energy configuration and is unable to bind with actin because the binding sites are blocked by tropomyosin. Myosin head actin site binding hydrolyzes ATP into adenosine diphosphate and an inorganic phosphate ion. The energy of the reaction changes the shape of the myosin head placing it into a high-energy configuration. As a consequence of binding with actin the myosin head ADP and the inorganic phosphate ion are released. Myosin remains attached to actin until it is bound by another ATP molecule that dissociates actin from its cross-bridge binding site. Hydrolysis of the ATP associated myosin reaches the sarcomere for another cycle of contraction.

The sarcoplasmic reticulum controls the concentration of calcium within muscle cells. Muscle contraction terminates when calcium ions are pumped back into the sarcoplasmic reticulum.

The structure of the sarcomere determines the length-tension curve. Sarcomere force output decreases when the muscle is stretched which decreases the number of cross-bridges that can be formed. During muscle contraction, actin filaments interact with each other. Sarcomere length affects both force and velocity. A longer sarcomere has more cross-bridges and more force but this is counteracted by a reduced range of shortening.

Dystrophinopathies

Duchenne Muscular Dystrophy (DMD)

General Characteristics

1. DMD is an X-linked recessive disorder with an estimated prevalence of 1 in 5,000 live births
2. The disease is a consequence of the loss of functional dystrophin protein that is essential in linking the muscle cytoskeleton to the extracellular matrix, but also has a role in signaling and regulating muscle response to oxidative stress

Clinical Manifestations

1. Most male children appear normal at birth although some demonstrate slightly hypertrophied and firm gastrocnemius muscles
2. Minimal or no delay in reaching the milestones of sitting or standing; a few patients are hypotonic and weak at birth
3. Between the ages of 2–6 it is clear that the child has a waddling gait, difficulty in running and jumping, may walk on his toes, has calf hypertrophy and suffers falls; Gower's sign is noted when the child rises to a standing position

4. Weakness is greater proximally and is more severe in the lower extremities; by 6–12 the upper extremity and axial muscles are affected
5. Most patients are wheelchair bound by age 12
6. The weakness is progressive and is accompanied by kyphoscoliosis and contractures
7. Reflexes diminish and by age 10, approximately 50% of patients have lost the biceps, triceps and quadriceps reflexes. The ankle jerks tend to be less affected
8. Postural changes are exacerbated by ankle and hip contractures
9. Respiratory muscles are affected and in addition to cardiac involvement cause death in the early 20's
10. Smooth muscle may be involved and a subset of patients develops gastroparesis and intestinal pseudo obstruction
11. The average IQ of patients is usually one standard deviation less than normal children

Neuropathology

1. Muscle biopsy:
 - a. Variability in fiber size
 - b. Increased endomysial and perimysial connective tissue
 - c. Some small rounded regenerating fibers
 - d. Central nuclei and fiber splitting
 - e. Scattered “glassy” and necrotic fibers
 - f. Increasing replacement of necrotic muscle tissue with fat and connective tissue
 - g. Cytotoxic T-lymphocytes and macrophages phagocytise necrotic muscle fibers; there is a variable degree of endomysial inflammation
 - h. A few non-necrotic fibers that express major histocompatibility antigen are attacked by cytotoxic T-cells
 - i. Reduced or absent dystrophin on the sarcolemma
 - j. Utrophin (normally restricted to the NMJ) is overexpressed
 - k. Approximately 0–3% of dystrophin may be demonstrated but is truncated

Laboratory Evaluation

1. The serum creatine kinase is elevated to 50–100 times normal at birth, peaks at around three years of age and declines at approximately a rate of 20% per year
 - a. Electrodiagnostic testing:
2. EMG:
 - a. Needle evaluation reveals increased insertional activity, positive sharp waves and fibrillation potentials
 - b. The amplitude of nonpolyphasic MuAP are decreased; an admixture with large amplitude polyphasic potentials. Short and long MuAPs occur in individual muscles
 - c. Early recruitment is noted
3. EKG:
 - a. EKG abnormalities are seen in approximately 90% of patients and include:
 - i. Sinustachycardia

- ii. Tall right precordial R waves
- iii. Deep narrow Q waves in this left precordial leads
4. ECHO:
 - a. Dilatation and hypokinesis of ventricular walls with a decreased ejection fraction
5. Genetic testing:
 - a. Exon skipping which utilizes antisense oligonucleotides to initiate alternating splicing in an attempt to restore the open reading frame of dystrophin mRNA is being tested
 - b. The product of this experimental approach is an altered, but functional dystrophin molecule
 - c. Genetic testing for mutations in the dystrophin gene on the X-chromosome for definitive diagnosis

Becker's Muscular Dystrophy (BMD)

General Characteristics

1. The incidence of Becker's muscular dystrophy is approximately five patients per 100,000 people
2. Approximately 10% of patients occur from spontaneous mutations

Clinical Manifestations

1. BMD has a slower rate of progression than DMD
2. A family history of X-linked recessive inheritance
3. Ambulation is maintained after 15 years of age
4. Limb girdle pattern of muscle weakness
5. Calf pseudohypertrophy
6. A subgroup of patients have predominant involvement of the quadriceps muscles
7. Spectrum of clinical phenotypes include:
 - a. Approximately 50% of patients cannot walk by the 4th decade
 - b. A subgroup of patients only demonstrate:
 - i. Myalgias
 - ii. Myoglobinuria
 - iii. Cardiomyopathy
 - iv. Asymptomatic hyperCKemia
8. Cardiac function is similar but not as severe as in DMD
9. A borderline or slightly impaired IQ has been demonstrated in some patients

Neuropathology

1. In general, the same pathology as that seen with DMD
2. Immunostaining demonstrates dystrophin in muscle membranes although the staining pattern is often reduced and can vary both between and within fibers. There is decreased quantity and size of dystrophin
3. The dystrophin gene is located on chromosome p21
 - a. It is composed of 2.4 megabases of genomic DNA
 - b. Includes 79 exons which code for the 14-kb transcript
 - c. Large deletions that range from several kilobases to over one million base pairs have been demonstrated in 2/3rd of patients
 - d. Approximately 5–10% of DMD mutations are point mutations that cause premature stop codons; duplications occur in 5% of patients

- e. Hot spots for mutations are in the gene center (80%) as those near the amino terminal are 20%
- f. Mutations in the translational reading frame lead to severe loss of dystrophin (DMD); inframe mutations cause translation of a semifunctional dystrophin of abnormal size or quantity that is seen in BMD or outlier patients

Laboratory Evaluation

1. Serum CK are greatly elevated in most patients; those patients only manifesting exertional myalgias may have minimally elevated CK levels
2. EMG:
 - a. Similar characteristics as DMD in weak muscles
3. Skeletal MRI:
 - a. Fatty infiltration of affected muscles

Female Carriers of BMD

General Characteristics

1. The daughters of men with BMD and the mothers of affected children who have a family history of DMD or BMD are obligate carriers of the mutated dystrophin gene on the X-chromosome
2. Other at risk females are the mothers and sisters of isolated patients
3. Males born to carrier females have a 50% chance of inheriting the defective X-chromosome; 50% of daughters will become carriers

Clinical Manifestations

1. Most women carriers are asymptomatic; a few develop proximal muscle weakness
2. If symptomatic, it is postulated that skewed inactivation of the normal X-chromosome has occurred (the Lyon hypothesis) and there is increased transcription by the mutated dystrophin gene
3. Rarely some carriers develop severe weakness

Neuropathology

1. Histologic features are similar to BMD (Less severe)
2. Immunostaining for dystrophin reveals its absence, reduced or mosaic pattern. Some patients may have normal staining

Laboratory Evaluation

1. Serum CK elevations can occur early in life but is an insensitive marker of carrier status. In general, elevated CK levels are demonstrated in less than 50% of carriers; a normal CK level does not rule out carrier status
2. Genetic testing is the most reliable method of determining carrier status. The detection of dystrophin gene mutations in affected male relatives determines the at-risk females. Sporadic mutations in a DMD affected patient may occur from a germline mosaicism. In this situation, the mutation

will involve only a percentage of the oocytes (germ cells). The recurrence rate in germline carriers is dependent on the number of affected oocytes has been estimated to be approximately 14%

3. An X-linked contiguous gene syndrome involving congenital adrenal hypoplasia, glycerol kinase deficiency, muscular Duchenne dystrophy and intellectual disability has been described

IL1RAPL (X-Linked Interleukin-1 Receptor Accessory Protein-Like 1)

General Characteristics

1. Contiguous gene syndromes are illnesses caused by deletions of adjacent genes
2. Glycerol kinase deficiency is caused by a partial deletion of p21
3. The gene order for the contiguous loci is pter-AHC-GKD-DMD-centromere
4. Microdeletions can span these contiguous genes that produces a different phenotype from that produced by mutations in the individual genes (DMD, GK, AHC)

Clinical Manifestations

1. Children with combined DMD and GKD suffer:
 - a. Muscular weakness
 - b. Episodic nausea, vomiting and stupor (GKD deficient)
 - c. If there are mutations in the DAX1 gene (causing congenital adrenal hypoplasia) there may be associated life threatening adrenal insufficiency. These mutations also cause:
 - i. Addisonian hyperpigmentation
 - ii. Hypogonadotropic hypogonadism/cryptorchidism
 - iii. Hyperkalemia
 - iv. Hyponatremia
 - v. Hypoglycemia

Neuropathology

1. Defects in glycerol kinase cause defects in glycolysis, gluconeogenesis and triglyceride metabolism
2. Defects in DAX1 (dosage-sensitive sex reversal AHC, X-chromosome gene 1)
 - a. A member of the nuclear hormone receptor superfamily
 - b. Regulates the transcription of genes that are essential for development of the adrenal glands
3. Mutations in the 3' portion of the dystrophin gene involve the glycerol kinase locus. Most of these patients have DMD although BMD can occur

Laboratory Evaluation

1. GKD causes elevation of serum triglycerides
2. AHC:
 - a. Decreased serum gonadotrophin level
 - b. Poor response of serum cortisol levels to ACTH stimulation
 - c. The patients with either DMD or BMD phenotypes:
 - i. Diagnosis of X-chromosome can be accomplished by DNA amplification through PCR

Outliers of DMD and BMD*General Characteristics*

1. This is a term for the clinical phenotype of children who manifest signs and symptoms between DMD and BMD

Clinical Manifestations

1. Are able to walk after the age of 12, but are wheelchair bound by age 15
2. In early childhood they can lift their head against gravity
3. They may develop a cardiomyopathy
4. Slight cognitive impairment in some patients

Neuropathology

1. Some dystrophin is present which is smaller in size

Laboratory Evaluation

1. Similar to BMD

LGMD (Limb Girdle Muscular Dystrophies)**Overview**

Limb girdle muscular dystrophies comprise Mendelian disorders that manifest progressive weakness and deterioration of proximal girdle muscles. Frequently these may be heart, respiratory and other muscle involvement. The clinical course and the phenotypic expression are variable. There are forms with a rapid onset and progression to very mild forms with minimal proximal weakness that allow for normal activities and life span. At present, there are 31 loci that have been characterized (8 autosomal dominant and 23 autosomal recessive). The use of next generation sequencing technology will accelerate the discovery of new LGMD genes.

Autosomal Dominant LGMD**Overview**

In general, the autosomal dominant forms of LGMD have an adult onset and are less severe than autosomal recessive forms. They account for less than 10% of LGMD patients. The phenotype may be present with mutations in genes that cause other disorders such as myotilin, lamin A/C or caveolin muscle disease.

LGMD1A*General Characteristics*

1. LGMD1A is caused by mutations in the myotilin (MYOT) gene located in chromosome 5q22.3-31.3. The DNA involved is a 2.2 kb and contains 10 exons

Clinical Manifestations

1. It may present in early or late adult life

2. Early involvement of scapular, humeral and pelvic muscles; rarely distal leg and arm weakness can be more profound than girdle proximal weakness
3. Affected muscles are atrophic
4. Contractures of the elbows and heel cords may occur early
5. Some patients develop nasal and dysarthric speech
6. Calf hypertrophy is rare in distinction from dystrophinopathies and sarcoglycanopathies
7. Patients may develop cardiomyopathy

Neuropathology

1. LGMD1A is caused by mutations in the myotilin gene; spontaneous mutations are common and therefore there may be a negative family history of muscle disease
2. Muscle biopsy:
 - a. Rimmed vacuoles with or without inclusions (nemaline rods)
3. Electron microscopy:
 - a. Prominent Z-line streaming
4. Histologic features may be similar to autosomal dominant hereditary inclusion body myopathy and myofibrillar myopathy

Laboratory Evaluation

1. Serum CK is normal or minimally elevated
2. EMG:
 - a. Myopathic pattern

LGMD1B*General Characteristics*

1. LGMD1B is caused by mutations in lamina A/C (LMNA) gene located in chromosome 1q11-21
2. There is overlap between LGMD1B and Emery-Dreifuss muscular dystrophy (EDMD); the severe forms of EDMD, those with childhood onset, have missense mutations while LGMD1B is associated with truncating mutations (haploin sufficiency)

Clinical Manifestations

1. The usual presentation is hip and shoulder girdle weakness; some patients may have a predilection for humeral peroneal muscle involvement
2. A severe cardiomyopathy is associated that causes:
 - a. Atrioventricular defects that have been associated with sudden death and may require a pacemaker
 - b. Dilated cardiomyopathy
3. Some patients may only have the cardiomyopathy

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Increased endomysial connective tissue
 - c. Occasional rimmed vacuoles
2. Electron microscopy:

- a. Myonuclei demonstrate loss of peripheral heterochromatin
- b. Detachment of the heterochromatin from the nuclear envelope, altered interchromatic structure and a decreased number of nuclear pores
- 3. Immunocytochemistry:
 - a. Normal emerin and lamin A/C in the nuclear membrane
 - b. Normal dystrophin, sarcoglycan and emerin

Laboratory Evaluation

- 1. Serum CK may be normal or greatly elevated
- 2. EMG:
 - a. Myopathic pattern

LGMD1C

General Characteristics

- 1. LGMD1C is caused by mutations in the caveolin-3 gene in chromosome 3p25; spontaneous mutations occur

Clinical Manifestations

- 1. A variable phenotype
- 2. The illness may present in childhood or in adult life
- 3. Proximal girdle weakness
- 4. A subgroup has only exertional myalgias
- 5. Calf hypertrophy
- 6. Unusual signs and symptoms include:
 - a. Rippling muscle disease
 - b. Distal weakness of the anterior tibialis or gastrocnemius muscles
 - c. Asymptomatic hyperCKemia

Neuropathology

- 1. Muscle biopsy:
 - a. Non-specific myopathic features
 - b. Caveolin-3 is a muscle-specific protein and the major component of caveolae membrane in muscle cells; there may be reduced quantity of caveolin in the sarcolemma. The caveolins are essential in the formation of caveolar membranes. Caveolar membranes may function:
 - i. As scaffolding proteins that organize and concentrate caveolin interacting lipids and proteins
 - ii. A component of the organization of signaling complexes and interaction with sodium channels (possibly related to the demonstration of rippling muscles)
- 2. Normal quantities of dystrophin, sarcoglycan and merosin

Laboratory Evaluation

- 1. Serum CK is increased 3 to 25 times normal
- 2. EMG:
 - a. Rippling muscle disease
 - b. Myopathic pattern

LGMD1D

General Characteristics

- 1. LGMD1D has been mapped to chromosome 7q36.3; it is caused by a heterozygous missense mutation in the DNAJB6 gene (desmin). The DNAJ family is characterized by an amino acid stretch called the "J-domain"
- 2. The encoded protein functions as a molecular chaperone in a variety of cellular processes that include protein folding and oligomeric protein complex assembly
 - a. DNAJB6 heterozygous mutations are located in the GLY/Phe domain and cause decreased clearance of misfolded protein
- 3. The phenotype may overlap with myofibrillar myopathy

Clinical Manifestations

- 1. The lower limbs are more severely affected predominantly in the soleus, adductor magnus, semimembranosus, and biceps femoris. The rectus femoris gracilis and sartorius muscles as well as the muscles of the anterolateral lower leg are relatively spared
- 2. Onset is from 25–50 years of age
- 3. No cardiac or respiratory involvement
- 4. Patients may be able to walk throughout life
- 5. Symptoms in the upper limbs manifest late
- 6. DNAJB6 mutations may also cause a distally predominant myopathy

Neuropathology

- 1. The DNAJB6 protein is located in the Z-line and interacts with BAG3
- 2. Muscle biopsy:
 - a. Autophagic vacuoles and protein aggregation are demonstrated
 - b. The protein aggregates contain:
 - i. DNAJB6 protein with its ligands MLF1 and HSAP1
 - ii. Desmin
 - iii. AB-crystallin, myotilin and filamin C. These proteins also aggregate in myofibrillar myopathy

Laboratory Evaluation

- 1. Mildly elevated serum CK levels
- 2. EMG:
 - a. Myopathic pattern

LGMD1E

General Characteristics

- 1. Originally linked to chromosome 6q23; it may be considered a form of autosomal dominant desminopathy or myofibrillar myopathy
- 2. Also known as dilated cardiomyopathy type 1F (CMD1F)

Clinical Manifestations

- 1. Onset is the second or third decade
- 2. There may be a family history of sudden death
- 3. Progressive proximal muscle weakness
- 4. Dilated cardiomyopathy with conduction defects
- 5. A childhood onset family has been described

Neuropathology

1. Dystrophic changes
2. Perinuclear or subsarcolemmal granulofilamentous inclusions. Congophilic inclusions have been noted in some childhood patients

Laboratory Evaluation

1. Normal or slightly elevated serum CK levels
2. EMG:
 - a. Myopathic pattern

LGMD1F*General Characteristics*

1. LGMD1F is caused by a frame shift mutation in the transportin 3 (TNPO3) gene on chromosome 7q32.1-82.2. The frame-shifted TNPO3 protein is located around the nucleus

Clinical Manifestations

1. Patients with an early onset have a more severe phenotype with a rapid progressive course
2. Adult onset patients:
 - a. Slower progression of weakness
 - b. Lower limb muscles are atrophied with predominant involvement of the vastus lateralis and iliopsoas muscles
 - c. Other features include:
 - i. Dysphagia
 - ii. Arachnodactyly
 - iii. Respiratory insufficiency
 - iv. No cardiac involvement

Neuropathology

1. Muscle biopsy:
 - a. Increased fiber size variability, fiber atrophy, and acid phosphatase positive vacuoles
 - b. Immunofluorescence showed accumulation of myofibrils, ubiquitin-binding protein aggregates and autophagosomes
 - c. Electron microscopy:
 - i. Autophagosome vacuoles
 - ii. Disarray of myofibrillar components due to rod-like granular structures
 - iii. Findings are felt to demonstrate disarrangement of the cytoskeletal network

Laboratory Evaluation

1. Serum CK is 1–3x normal
2. EMG:
 - a. Myopathic pattern

LGMD1G*General Characteristics*

1. LGMD1G has been mapped in Brazilian and Uruguayan families to chromosome 4p21

2. The gene is HNRPDL that encodes the ANRPDL protein that is involved in RNA processing of proteins. The ribonucleoprotein is involved in mRNA biogenesis and metabolism

Clinical Manifestations

1. Late onset
2. Proximal limb girdle weakness
3. Progressive finger and toe flexion limitations

Neuropathology

1. Muscle biopsy (one patient)
 - a. Myopathic pattern
 - b. Rimmed vacuoles

LGMD1H*General Characteristics*

1. The LGMD1H locus has been mapped to chromosome 3p23-25.1 in a 4-generation Italian family

Clinical Manifestations

1. Onset is during the fourth-fifth decade with variable expressivity as to age and severity
2. Slowly progressive proximal weakness of both upper and lower extremities
3. An earlier onset is noted in a group of patients with calf hypertrophy

Neuropathology

1. Muscle biopsy:
 - a. Subsarcolemmal accumulation of mitochondria
 - b. Multiple mitochondrial DNA deletions

Laboratory Evaluation

1. A subgroup of patients had high CK and serum lactate levels
2. EMG:
 - a. Myopathic pattern

Autosomal Recessive LGMD**Overview**

The autosomal recessive limb girdle muscular dystrophies are much more common than the autosomal dominant forms. Their cumulative prevalence is 1:15,000 of the population. There are regional differences that depend on the degree of consanguinity and carrier distribution. The recessive genes in which there is loss of function mutations in both alleles cause LGMD2 (LGMD 2A-2H) and LGMD2L. Some other genes have mutations that are associated with LGMD or a complex disorder. Some variations in ordinary LGLMD gene mutations are associated with phenotypic forms of LGMD such as LGMD2A-2U.

LGMD2A*General Characteristics*

1. Has a worldwide distribution. It is the most common LGMD in those of eastern European, Spanish, and Italian ancestry and in Brazil
2. LGMD2A is caused by mutations in the Calpain 3 gene (CAPN3). The gene spans 53 kb of genomic sequence and is located at chromosome 15q15.2
3. There are heterozygotes (1:100) with varying CAPN3 mutations
4. Calpains are non-lysosomal cysteine proteases modulated by the concentration of calcium ions. They consist of a large and small subunit. One gene encodes the small subunit while there are several that encode the large subunit. Calpains target proteins and modify their function

Clinical Manifestations

1. The onset is variable and can occur from early childhood to mid-adult-life
2. Pelvic girdle muscles are usually affected initially and include:
 - a. Gluteus maximus
 - b. Thigh adductors
 - c. Hamstrings
 - d. Gluteus medius
 - e. Psoas (less severely)
3. Approximately 2–5 years after the onset of lower extremity weakness, the latissimus dorsi, serratus anterior, rhomboids, pectoralis major and the biceps brachii are affected
4. Muscles that are relatively spared include:
 - a. Deltoid and brachioradialis
 - b. Neck muscles
 - c. Distal leg muscles
 - d. Supra- and infraspinatus
 - e. Brachialis
 - f. Forearm muscles
5. Facial muscles extraocular and pharyngeal muscles are spared
6. Axial muscles may be weak and are associated with slight scoliosis
7. Abdominal muscles are weaker than paraspinal muscles
8. Contractures occur early at the elbows and calves (may be similar to EDMD)
9. Calf hypertrophy is rare, which is a strong differential point from dystrophinopathies, sarcoglycanopathies, and LGMD2I
10. Reflexes are markedly decreased or absent
11. Progression is variable among different kinships but is usually steadily progressive
12. Earlier onset correlates with faster progression of symptoms and signs
13. Approximately 50% of patients are unable to walk by age 20 although some are ambulatory in late life
14. Respiratory function is minimally involved, there is no cardiomyopathy and no cognitive loss

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size with an increase of endomysial connective tissue
 - b. Lobulated muscle fibers on NADH histochemistry (not specific)
 - c. Western blot reveals reduced calpain-3 (20% of biopsies may be normal)
 - i. Secondary deficiency in calpain-3 may be demonstrated in dysferlinopathies and titinopathies
 - d. An eosinophilic infiltrate has been noted in some biopsies

Laboratory Evaluation

1. Serum CK levels may be 20x normal in children but decrease with disease progression
2. Children may demonstrate peripheral eosinophilia
3. EMG:
 - a. Myopathic pattern
4. Skeletal muscle MRI:
 - a. Predilection for severe involvement of posterior thigh muscles
 - b. Fat and connective tissue replaces normal muscles

Limb Girdle LGMD2B*General Characteristics*

1. LGMD2B is caused by missense or null alleles of the dysferlin gene (DYSF) located on chromosome 2p13.2
2. The protein is involved in calcium mediated sarcolemma resealing
3. LGMD2B is the second most frequent LGMD2 in many countries; accounting for 15–25% of patients
4. Mutations of the dysferlin gene cause:
 - a. Miyoshi myopathy
 - b. LGMD2B
 - c. Some distal myopathies with anterior tibial muscle weakness

Clinical Manifestations

1. Onset is in the late teens or early twenties although it has been reported to occur in middle age
2. Has a variable phenotype:
 - a. Proximal limb girdle weakness
 - b. Early involvement of the posterior calf muscles (Miyoshi myopathy)
 - c. Anterior tibial muscle weakness
 - d. Combinations of the various patterns
3. The most common initial pattern is the Miyoshi phenotype that demonstrates atrophy and weakness of the gastrocnemius and soleus muscles. The involvement of calf muscles may be asymmetric
4. Unusual presentation is with paraspinal involvement that causes rigid spine syndrome or a lax spine with hyperlordosis or kyphosis

5. A typical pattern of muscle weakness is gastrocnemius/soleus and subsequently gluteal and hamstring muscles and finally distal arm muscles. Less commonly proximal hip girdle then shoulder girdle weakens. A subgroup of patients has early anterior tibial muscle involvement. There may be atrophy and weakness of the gastrocnemius and soleus muscles in both the “limb girdle” and “anterior tibial” phenotypes. A helpful differential point in the dysferlinopathies is loss of the Achilles reflex early that is often the most preserved reflex in other LGMDs. In general, the progression of illness is slow but there is variability both intra- and interfamilially. A few patients have had a rapid onset and progression of the disease

Neuropathology

1. Muscle biopsy:
 - a. Variable fiber size, scattered necrotic and regenerating fibers and increased endomysial fibers
 - b. Immunostaining reveals decreased sarcolemmal dysferlin
 - c. Western blot on either muscle or white cells determine a primary dysferlin deficiency
 - d. There may be a mononuclear infiltrate in the endomysial connective tissue and around blood vessels. The inflammatory cells do not invade non-necrotic fibers that are in contrast to polymyositis
 - e. Deposition of membrane attack complexes on the sarcolemma of non-necrotic fibers that occurs in dysferlinopathies that demonstrate inflammation
 - f. Electron microscopy:
 - i. Reduplication of the basal lamina
 - ii. Disruption of the sarcolemma
 - iii. Invaginations or papillary defects of the muscle membrane
 - iv. Subsarcolemmal vesicles
 - v. Recent studies demonstrate:
 1. Dysferlin has an association with calcium (Ca^{2+}) signaling proteins in the transverse (T) tubular system
 2. It may also function besides its role in repair of the sarcolemma as a t-tubule protein that stabilizes stress-induced Ca^{2+} signaling

Laboratory Evaluation

1. Serum CK levels are often 25–200 times the normal value
2. Western blot analysis of white blood cells may demonstrate dysferlin
3. EMG:
 - a. Myopathic pattern

Sarcoglycan Mutations

Overview

The sarcoglycans are N-glycosylated transmembrane proteins that have a short intracellular domain, a single transmembrane region, and a large extracellular domain that contains a clus-

ter of cysteines. Mutations of the four genes that encode alpha, beta, gamma and delta sarcoglycans cause LGMD2D, 2E, 2C, and 2F, respectively. They form a tetrameric complex that is part of the dystrophin-associated proteins. The sarcoglycan complex (SGC) is a subcomplex within the dystrophin glycoprotein complex (DGC) that is essential for connecting the cytoskeleton to the extracellular matrix and protecting damage to the sarcolemma membrane from shearing forces generated with muscle contraction. In general, they have a childhood onset, a phenotype similar to the intermediate form of Duchenne/Becker dystrophinopathies and may involve both cardiac and respiratory musculature in some forms.

The sarcoglycanopathies are approximately 10% of the LGMDs. The frequency of occurrence is alpha sarcoglycan 6.6%, B sarcoglycan 3.1%, gamma sarcoglycan 1.5%, and delta J (SM) sarcoglycan at less than 1%.

LGMD2C, LGMD2D, LGMD2E and LGMD2F

General Characteristics

1. LGMD2C
 - a. Mutation in the gamma-sarcoglycan gene; located in chromosome 13q12.12
 - b. Common in the Maghreb and India
 - c. Patients may have absence of gamma-sarcoglycan with small amounts of the other non-mutated sarcoglycans
2. LGMD2D
 - a. Mutations of the alpha-sarcoglycan gene cause LGMD2D
 - b. The gene has 10 exons and is located at chromosome 17q21.33
 - c. The gene has a “dystroglycan type” cadherin-like domain
3. LGMD2E
 - a. The beta-sarcoglycan gene is located on chromosome 4q11
4. LGMD2F
 - a. The delta-sarcoglycan gene is the largest LGMD gene and one of the largest in the human genome. Mutations cause LGMD2F

Clinical Manifestations

1. In general, the clinical manifestations of these sarcoglycan mutations manifest the same clinical features as the intermediate dystrophinopathies:
 - a. Some children have an early onset with a severe phenotype that resembles DMD. A subgroup has a later onset with a slower progression suggestive of BMD
 - b. A proximal “limb-girdle” phenotype is seen early
 - c. Cardiomyopathy may occur

Neuropathology

1. Muscle biopsy:
 - a. There is normal dystrophin

2. The proteins of the sarcoglycan complex function as a unit. A mutation of any of the sarcoglycans destabilizes the complex and decreases the expression level of the other proteins
3. The clinical severity of the illness is determined by the type of mutation and the level of functional protein expression

LGMD2H

General Characteristics

1. LGMD2H and sarcotubular myopathy are allelic disorders
2. Mutations have been described in Manitoba Hutterite and Italian families
3. The disease is caused by mutations in the tripartite-motif containing gene 32 (TRIM32) located on chromosome 9q31-q33
4. The gene codes for a ubiquitous E3 ubiquitin ligase that localizes to cytoplasmic bodies

Clinical Manifestations

1. Onset is between 8–27 years of age
2. Slow progressive proximal muscle weakness and atrophy
3. Walking is preserved into the fourth decade
4. The D487N mutation in TRIM32 causes sarcotubular Myopathy

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic features
 - b. Some type 2 fibers contain small vacuoles that are positive for sarcoplasmic reticulum associated ATPase. The vacuoles are adjacent to T-tubules and are membrane bound

Laboratory Evaluation

1. Serum CK levels are five to 50 times normal
2. EKG and ECHO changes have been described

LGMD2I

General Characteristics

1. LGMD2I is caused by mutations in the fukutin-related protein gene located in chromosome 19q13.32
2. Mutations in the FKRP gene also cause:
 - a. Congenital muscular dystrophy MDC1C which demonstrates:
 - i. Secondary laminin alpha 2 deficiency
 - ii. Abnormal glycosylation of alpha-dystroglycan
3. The mutation in the fukutin-related protein gene causes defects in the extracellular part of the dystrophin-utrophin associated complex
4. FKRP is located in rough endoplasmic reticulum
5. The mutation that causes CMGIC:
 - a. Produces mislocalization of the protein and alpha-dystroglycan is not processed

- b. The mutation that causes LGMD2I either affects the active site of the protein or its Golgi site localization
6. Fukutin (in chromosome 9q31) and FKRP:
 - a. Are involved in O-manno-sylglycan synthesis of alpha-dystroglycan. FKRP is involved in the initial step of its synthesis
 - b. It is possible that the mutant protein derived from FKRP gene mutation is retained in the ER (endoplasmic reticulum)

Clinical Manifestations

1. LGMD2I has a worldwide distribution and is the most common LGMD in England, Netherlands and Northern Europe
2. Onset may be in infancy (MDC1C to the fourth decade)
3. Patterns of weakness and the cause are variable
4. Some patients have predominant pelvic girdle weakness while others have proximal arm and neck flexor weakness
5. There may be calf hypertrophy
6. Fifty percent of patients develop a dilated cardiomyopathy and respiratory muscle weakness

Neuropathology

1. Muscle biopsy:
 - a. Non-specific dystrophic changes are noted
 - b. Immunostaining:
 - i. Normal dystrophin and sarcoglycan
 - ii. Decreased alpha-dystroglycan and rarely merosin

Laboratory Evaluation

1. In some younger patients the CK may be 10–30 times the normal value but may be normal in older patients
2. EMG:
 - a. Myopathic patterns

LGMD2J

General Characteristics

1. The titin gene (TTN) is very complex and encodes the largest protein of the human genome
2. It is located in chromosome 2q31 and has 363 exons. The protein encoded has 38, 138 amino acids and a length of 2 microns
3. Titin is a giant sarcomeric protein that comprises a continuous filament system in myoblasts. It spans from the sarcomere 2 disc to the M-band
4. Various mutations in TTN cause:
 - a. LGMD2J
 - i. A homozygous mutation in the TTN gene
 - ii. 11-6p mutation in the last titin exon causes tibial muscular dystrophy
 - iii. 2-bp insertion in exon 32.6 causes autosomal dominant dilated cardiomyopathy
 - b. Other titinopathies include:
 - i. Tibial muscular atrophy (TMD)

- ii. UDD myopathy
- iii. Early onset myopathy with fatal cardiomyopathy
- c. A French nonsense mutation in titin located in Mex6 has a milder phenotype than the usual FIN mutation that causes LGMD2J

Clinical Manifestations

1. Most patients manifest with autosomal dominant UDD type distal myopathy
2. Heterozygous mutations in the gene cause late adulthood weakness of the anterior tibial muscles
3. Some patients have a childhood onset of limb girdle weakness
4. A subgroup of patients have predominant biceps forearm and hand involvement
5. Patients have been described with weakness of the posterior calf compartment without anterior tibial muscle involvement
6. Truncating TTN mutations have been identified in 5 patients with the phenotype of congenital centronuclear myopathy

Neuropathology

1. Dependent on the specific phenotypic variant

Laboratory Evaluation

1. Dependent on the specific variant

LGMD2K

General Characteristic

1. LGMD2K is caused by mutations in the POMT1 gene
2. The gene is located in chromosome 9q34

Clinical Manifestations

1. Specific missense mutations in the POMT1 gene cause congenital muscular dystrophies
2. Mutations with residual enzyme activity cause the LGMD phenotype

Neuropathology

1. Decreased with congenital muscular dystrophies (Walker-Warburg phenotype); dystroglycan glycosylation

Laboratory Evaluation

1. Discussed with Walker-Warburg congenital muscular dystrophy (MDDGC1)

LGMD2L

General Characteristics

1. LGMD2L is caused by mutations in the anoctamin-5 gene (ANO5) located in chromosome 11p14.3
2. Anoctamins are calcium activated chloride channels
3. The disease is most frequent in Northern Europe and accounts for 10–20% of LGMD in this region

4. Penetrance is thought to be incomplete as females are less often affected than males
5. LGMD2L is allelic with:
 - a. AD gnathodiaphyseal dysplasia
 - b. AR distal Myopathy

Clinical Manifestations

1. Onset is in adulthood
2. There is asymmetric muscle involvement with prominent quadriceps atrophy
3. Pain occurs following exercise
4. There is no contracture, cardiomyopathy or respiratory involvement
5. Macular dystrophy has been described in two siblings
6. Patients usually maintain the ability to walk for several decades
7. Upper extremity strength is minimally affected (biceps brachii)
8. Miyoshi pattern of muscle weakness occurs in some patients
9. Recessive mutations in Anoctemin-5 have been found in three French Canadian LGMD2L families and one Finnish and one Dutch non-dysferlin family

Neuropathology

1. Muscle biopsy:
 - a. Myopathic pattern with variations in fiber size, central nuclei, fiber splitting, and degeneration of muscle fibers
 - b. An increase of intrafascicular and interfascicular connective tissue
 - c. In 2–40% of fibers regeneration was detected
 - d. 31% of biopsies demonstrated inflammatory changes
 - e. Approximately 10% of patients demonstrated rimmed vacuoles
2. Muscle wasting is predominant in quadriceps, hamstrings, and medial gastrocnemius muscles

Laboratory Evaluation

1. EMG:
 - a. Myopathic pattern
2. Serum CK levels are 300–10,000 normal values
3. Muscle MRI:
 - a. Asymmetric variable fatty replacement of the posterior compartment with involvement also of the adductor magnus. Semimembranosus and semitendinosus
 - b. Moderate to severe atrophy of the medial gastrocnemius and soleus muscles

LGMD2M

General Characteristics

1. LGMD2M is caused by mutations in the fukutin gene (FKTN) located at chromosome 9q31.2
2. One missense mutation causes the limb girdle phenotype; mutations in both alleles is associated with Walker-Warburg syndrome, muscle-eye-brain disease (MEB) or congenital muscular dystrophies

Clinical Manifestations

1. Onset is early childhood
2. Patients are hypotonic
3. Symmetric and diffuse muscle involvement that may be exacerbated by febrile illness
4. The CNS is not involved and patients have normal intelligence
5. They have spinal rigidity
6. Contractures
7. Respiratory muscle weakness

Neuropathology

1. Dystrophic features on muscle biopsy
2. WWS, FCMD, MEB disease have severe migrational and developmental alterations in the brain

Laboratory Evaluation

1. Serum CK levels are 5–20 times normal
2. EMG:
 - a. Myopathic pattern

LGMD2N*General Characteristics*

1. LGMD2N is caused by mutations in the POMT2 gene that is located on chromosome 14q24
2. POMT2 is a second O-mannosyltransferase that overlaps with POMT1 expression
3. O-mannosyltransferase 1 (POMT1) a glycosyltransferase, is complexed with POMT2, another O-mannosyltransferase, that catalyzes the first step in O-mannosylation. N-acetylglucosamine is transferred to the O-mannose of glycoproteins by the enzyme O-mannose B-1, 2-N-acetylglucosaminyl transferase (POMGnT1) in the post-translational glycosylation of α -dystroglycans
4. Glycosylation of α -dystroglycan is essential for its binding to merosin
5. In addition to a pivotal role in skeletal muscle, abnormal glycosylation of α -dystroglycan causes defects in neuronal migration that one found in Fukuyama type muscular dystrophy (FCMD), WWS, MEB disease, MDC1C and MDC1D

Clinical Manifestations

1. POMT2 mutations usually cause WWS or MEB disease
2. The phenotype of LGMD2N is that of LGMD without brain involvement

Neuropathology

1. Muscle biopsy
 - a. Dystrophic pattern

Laboratory Evaluation

1. High serum CK levels
2. Myopathic EMG pattern

LGMD2O*General Characteristics*

1. LGMD2O is caused by mutations in the POMGnT1 gene located on chromosome 1p32

Clinical Manifestations

1. The usual mutations in the POMGnT1 cause WWS or MEB disease
2. The milder mutations are associated with LGMD phenotype without brain involvement

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic features

Laboratory Evaluation

1. High serum CK
 - a. EMG:
 - i. Myopathic pattern

LGMD2P*General Characteristics*

1. LGMD2P is caused by alterations of the dystroglycan gene (DAG1) which is located in chromosome 3p21.31
2. In general, the dystroglycanopathies are caused by mutations in the genes associated with the glycosylation of α -dystroglycan. In this instance the gene itself is mutated

Clinical Manifestations

1. Usual phenotype is that of LGMDs
2. A missense mutation in the gene has been reported to cause cognitive impairment
3. One patient with compound heterozygous missense mutations presented with hyperCKemia and mild proximal weakness

Neuropathology

1. Muscle biopsy:
