Differential Diagnosis in Neurology

Revised Second Edition

Robert J. Schwartzman

IOS
Press

The purpose of an exercise in differential diagnosis is to establish crosslinks between medical facts stored in different sections of our memory.

This book, *Differential Diagnosis in Neurology*, is the unified perspective of an eminent physician with decades of clinical experience and teaching; one of the most skilled clinical neurologists of modern times and a seasoned researcher who was the primary investigator for many clinical trials, and who published numerous clinical and basic research papers. The “real world” aspects of the book are based on morning reports with neurology residents and students conducted over 40 years. The differential diagnosis generated by subspecialty division chiefs supplemented those proposed in morning reports.

The book is conceived as a guide that will give the clinician a concise snapshot or skeleton with a general background of the disease at hand. Other disease aspects included in this book are molecular genetics, physiology, and biochemistry that will elucidate mechanisms and assist in discovering new entities. Each chapter includes an extensive list of suggestions for further reading.

It is the art of crosslinking between medical facts that distinguishes Dr. Schwartzman from other teachers of Neurology and that makes this book uniquely valuable.

“The essence of a differential diagnosis is ‘splitting’ rather than ‘lumping’: it requires bringing knowledge to the table and then adding experience.”
- R.J. Schwartzman

Foreword

Dr. Robert Schwartzman's book entitled *Differential Diagnosis in Neurology* is unique in many ways. It is written by one of the most skilled clinical neurologists of modern times; someone who devoted his entire career to teaching the art of Neurology to generations of residents and students; someone who shaped the field of Neurology to become an independent specialty but never stopped teaching it in the greater context of Internal Medicine.

Dr. Schwartzman's unique way of teaching Neurology is reflected in this book. Every day as a Neurology resident in his program started with Morning Report – an hour of case review, differential diagnosis, discussion of diagnostic studies and treatment combined with quizzing the residents on pertinent literature, new and historical alike. It is here where the foundation was laid to taking the best possible care of our patients throughout the rest of the day. One of the most valuable experiences in morning report was the exercise in differential diagnosis, an aspect of clinical medicine that in the times of ever-increasing sub-specialization and reliance on “handheld” knowledge is at great risk of becoming extinct.

Writing a book on differential diagnosis is probably one of the most difficult tasks in academic medicine. By nature, these writings ought to be monographs as they reflect an individual style. The purpose of an exercise in differential diagnosis is to establish crosslinks between medical facts stored in different sections of our memory – sections that unless accessed through the same channel we learned them are irretrievable. It is the art of crosslinking that distinguishes Dr. Schwartzman from other Neurology teachers and that makes this book uniquely valuable. It helps you see the forest in spite of all the trees, the bigger picture, the bird's eye view.

Admittedly, I'm biased. I can truly say that my career has been shaped by Dr. Schwartzman and his way of teaching Neurology. Without him, I would have become a different Neurologist or maybe not a Neurologist at all. *Differential Diagnosis in Neurology* makes accessible his way of thinking, analyzing, and teaching to a much broader audience.

The book is organized by neuroanatomical structures. A separate chapter is devoted to epilepsy. For each level within the hierarchy of the nervous system and the vascular tree, neurologic syndromes are listed and their differential diagnosis is outlined. The depth and breadth with which these syndromes and differential diagnoses are described is one of a kind. In addition, the reader is provided with an unprecedented plethora of clinical tricks and secrets. The mostly tabular form of the book is the only way to fit such an abundance of information in a single book. While the book does not contain citations, most of the facts can be easily tracked in the literature. By not providing citations, Dr. Schwartzman honors some of his core principles in neurologic education: teaching by stimulating and challenging, avoiding the “Nuernberger Trichter” (Nuremberg funnel) method, using the competitive interplay between teacher and student.

The student and junior resident have to study this book, not read it. It does not prepare you for the board exam in the most efficient way but for life as a Neurologist. More experienced neurologists will find it to be a valuable when confronted with a difficult patient. Take on the challenge! It will be a transforming experience.

Joachim M. Baehring, MD
Associate Professor of Medicine (Medical Oncology), Neurology, and Neurosurgery

New Haven
Clinical Program Leader, Brain Tumor Program
Smilow Cancer Hospital at Yale-New Haven
New Haven

Preface

The concept for Differential Diagnosis in Neurology was formed from my training in internal medicine and neurology.

Dr. Eugene A. Stead, chairman of Medicine at Duke for many years, taught me the importance of the fine points of the history and the significant details of the examination that separate one disease from another. "Let's sharpen the data," he would say, as he would elicit a small pearl from the history that would lead to the diagnosis.

Dr. Milton Shy was a master diagnostician whose great depth of knowledge for neurological diseases allowed him to meld each disease with its scientific basis.

Dr. W.K. Engel demonstrated just how adept one could become in an area of neurology. He described many new neuromuscular disorders by uncovering a seminal feature of the history or the examination.

It was a great privilege rounding with these physicians, I hope a trace of their medical knowledge, and scholarship comes through in these pages.

The "real world" aspects of the book are derived from giving morning report with neurology residents and students for over 40 years. Difficult patients were presented and examined in grand rounds. The differential diagnosis generated by subspecialty division chiefs supplemented those proposed in morning report. The discussion was always lively and new components of the examination or history were added.

The essence of a differential diagnosis is "splitting" rather than "lumping": it requires bringing knowledge to the table and then adding experience.

This book is meant to be a guide that will give the clinician a concise snapshot or skeleton with a general background of the disease at hand. Other disease aspects included in this book are molecular genetics, physiology, and biochemistry that will elucidate mechanisms and assist in discovering new entities.

Each chapter includes an extensive list of suggestions for further reading.

It is hoped that the clinician will use the volume as a workbook in which new diseases are added or older classifications revised on a molecular basis.

A strength of this work is that this is the unified perspective of one physician with decades of clinical experience and teaching; a seasoned researcher who has been the primary investigator for many clinical trials as well as publishing numerous clinical and basic research papers. The limitation of a work such as this is that obviously, one person can't know everything for the depth of information needed to be comprehensive for each topic.

Robert J. Schwartzman

Contents

Foreword	v
Preface	vi

CHAPTER 1. VASCULAR DISEASE

Ischemic Stroke	1
The Neurovascular Unit: Outline of Some Mechanisms Common to Stroke	4
Risk Factors for Ischemic Stroke	7
Risk Factors That Predict Stroke	9
Atherosclerosis	10
The Arterial Wall and Aneurysms	15
Collateral Circulation	16
Evolving Evaluation of Biomarkers in Acute Cerebrovascular Disease	17
The Natural History of Extracranial and Intracranial Atherosclerosis	21
Localization of Ischemic Lesions	22
Transient Ischemic Attacks (TIA)	24
Stroke Mimics	28
Differential Diagnosis of Stroke Mimics	29
Arterial Localization – (Arterial Topology/Stroke Localization)	33
Posterior Circulation Major Artery Strokes (Long Circumferential Arteries)	60
Border Zone Infarction	66
Multiple Infarctions	69
Lacunar Stroke	72
Small Vessel Disease	76
Lacunar Stroke	90
Retinal, Vestibular Small Vessel Diseases of the Brain	96
Venous Stroke	102
Medical Causes of Stroke	107
Autoimmune Disease and Stroke	153
Infectious Disease and Stroke	168
Stroke in Association with Named Vascular Syndromes	179
Vasculopathy	209
Vasoconstriction Syndromes and Stroke	212
Vascular Wall and Vasculopathy	218
Emboli and Valvular Disease	231
Ischemic Encephalopathy	251
Dilatative Arteriopathy	258
Stroke and Substance Abuse	261
Hemorrhagic Vascular Disease	263
Further Reading	313

CHAPTER 2. EPILEPSY

Overview of Epilepsy	367
Voltage-Gated Channel Integration	368
SCN1A Mutations	368
Potassium Channel Mutations	368
Calcium Channel Mutations	369
Epilepsy Mechanisms	369
Electrophysiology	369
Immune Seizures	370

Secondarily Generalized Tonic-Clonic Seizures (SPECT Imaging) Mechanisms	371
Cortical and Subcortical Network Analysis	371
Malformations of Cortical Development	371
Introduction to Epileptic Seizures	372
Differential Diagnosis of Causes of GTCS	375
Tonic Seizures	384
Localization Related Epilepsy	386
Temporal Lobe Epilepsy	390
Differential Diagnosis in Epilepsy	415
Further Reading	419

CHAPTER 3. ANTERIOR HORN CELL DISEASE

Introduction	438
Adult Spinal Muscular Atrophies Linked to Chromosome 5q11.12-13.3	438
The Spinal Muscular Atrophies	438
Outline of dSMA (Hereditary Distal Motor Neuropathies)	444
Summary of Manifestations of Distal SMA	445
Differential Diagnosis of the Spinal Muscular Atrophies	445
Differential Diagnosis of Proximal Symmetric Weakness of Childhood to Early Adulthood Versus SMA (II, III, IV)	445
Diagnostic Features for SMA	446
Diagnostic Features of Kennedy's Disease	446
ALS	446
Differential Diagnosis of the Spinal Muscular Atrophy	447
Differential Diagnosis of Kennedy's Disease	447
Differential Diagnosis of Hirayama Disease	447
Differential Diagnosis of Scapuloperoneal Syndrome	447
Differential Diagnosis of Distal SMAs	447
Differential Diagnosis of Fazio-Londe and Brown-Vialetto-Van Laere Syndrome	448
Amyotrophic Lateral Sclerosis	448
Further Reading	467

CHAPTER 4. SPINAL CORD

Overview of Spinal Cord Anatomy	476
Spinal Cord Disease	479
Congenital Spinal Defects	490
Hereditary Spastic Paraplegias	492
Congenital Bony Defects That Compromise the Spinal Cord or Root Exit Foramina	493
Trauma to the Vertebral Column with Spinal Cord Injury	494
Arterial Spinal Cord Infarction Syndromes	499
Hemorrhagic Disease of the Spinal Cord	500
Rare Vascular Spinal Cord Malformations	501
Epidural Cavernous Hemangioma	502
Spinal Cord Venous Occlusion	507
Hereditary Spastic Paraplegia	507
Differential Diagnosis of Hereditary Forms of Spastic Paraplegia	515
Metabolic Disorders Affecting the Spinal Cord	518
Selected Toxins That Affect the Spinal Cord	520
Autoimmune Causes of Spinal Cord Dysfunction	521
Infections of the Spinal Cord	526
Myelitis from Bacteria, Fungal and Parasitic Diseases	533
Differential Diagnosis of Granulomatous Spinal Cord Disease	534
Meningomyelitis Caused by Fungi, Rare Organisms, and Major Parasites	535

Syphilis	537
Autoimmune Spinal Cord Inflammation	538
Vitamin Deficiencies with Spinal Cord Involvement	544
Spinal Cord Tumors	545
Primary Tumors of the Vertebral Column with Secondary Epidural Compression	547
Intradural Extramedullary Tumors	548
Metastatic Spinal Cord Tumors	555
Differential Diagnosis of Intrinsic Disc Disease with Spinal Cord Involvement	560
Further Reading	567

CHAPTER 5. RADICULOPATHY

Overview of Pain	578
General Features of Radicular Pain	582
Differential Diagnosis of Lumbar Radicular Pain	584
Differential Diagnosis of Pathologic Fractures	585
Disc Disease (Lumbar)	585
Cervical Disc Disease	589
Thoracic Root Disease	597
Lumbosacral Root Disease L1–L5; S1–S5	599
Epidural and Vertebral Metastasis	609
Differential Diagnosis of Radiculopathy	612
Further Reading	615

CHAPTER 6. PLEXUS

Cervical Plexus	620
The Brachial Plexus	622
Lumbosacral Plexus Lesions	642
Further Reading	650

CHAPTER 7. PERIPHERAL NEUROPATHY

Overview	656
Hereditary Peripheral Neuropathies Charcot-Marie-Tooth Disease (CMT)	657
Clinical Variants of CMT	658
Hereditary Neuropathy with Liability to Pressure Palsies (HNPP)	660
CMT2 Autosomal Dominant Axonal Neuropathies	661
Seminal Manifestations of the Clinical Variants of CMT2	661
Dominant Intermediate CMT	664
X-Linked CMT Disease	668
Impaired Mitochondrial Physiology	671
Other Hereditary Motor and Sensory Neuropathies	671
Hereditary Sensory and Autonomic Neuropathies	672
Rare Hereditary Neuropathies	675
Hereditary Ataxias with Neuropathy	679
Disorders of Defective DNA Repair	681
Other Hereditary Neuropathies	682
Guillain-Barré Syndrome and Its Variants	684
GBS Variants	689
The Differential Diagnosis of AIDP	692
Acute Peripheral Neuropathies	692
Chronic Inflammatory Demyelinating Polyneuropathy and Related Autoimmune Neuropathies	695

Systemic Vasculitis That Affect Large and Medium-Sized Vessels	700
Secondary Systemic Vasculitides	703
Differential Diagnosis of Vasculitic Neuropathy by Signs and Symptoms	705
Neuropathies of Systemic Disease	707
Neuropathies Associated with Infections	719
Toxic Neuropathies	726
Neuropathies Associated with Cancer	736
Tumor Infiltration of Peripheral Nerve	738
Infiltrating Tumors	739
Secondary Non-Infiltrative Peripheral Neuropathies Associated with Lymphoproliferative Disorders and Plasmacytomas	741
Chemotherapy-Induced Peripheral Neuropathy (CIPN)	746
Endocrinopathies Associated with Neuropathy	751
Differential Diagnosis of DNC	753
Nutritional Deficiencies and Neuropathy	757
Tumors of Peripheral Nerves	762
Malignant Peripheral Nerve Sheath Tumors (MPNST)	767
Traumatic and Compressive Neuropathies	767
Entrapment Neuropathies of the Lower Extremity	781
Unusual Entrapments Neuropathies	796
Non-Vasculitic Ischemic Nerve Injury	797
Differential Diagnosis of Neuropathy	801
Further Reading	808

CHAPTER 8. THE NEUROMUSCULAR JUNCTION

Overview	834
Neuromuscular Junction Disorders	835
Myasthenia Gravis (MG)	836
Defects in Endplate Development and Maintenance	844
Drugs/Toxins That Alter Neuromuscular Transmission	851
Drugs That Affect Neuromuscular Transmission	853
Drugs That Interfere with Neuromuscular Transmission	855
Further Reading	861

CHAPTER 9. MUSCLE DISEASES

Overview of Muscular Dystrophies	875
Dystrophin-Glycoprotein Complex and Related Proteins	875
An Overview of Muscle Contraction	882
Dystrophinopathies	882
LGMD (Limb Girdle Muscular Dystrophies)	885
Autosomal Dominant LGMD	885
Autosomal Recessive LGMD	887
Sarcoglycan Mutations	889
Congenital Muscular Dystrophy	895
Dystroglycanopathies	897
Rare Congenital Muscular Dystrophies	901
Regional Muscular Dystrophies	904
Distal Myopathy (Muscular Dystrophies)	909
Congenital Myopathies	920
Metabolic Myopathies	928
Disorders of Muscle Carbohydrate Metabolism	928
Lysosomal Glycogen Storage Myopathies	934
Disorders of Purine Nucleotide Metabolism	935

Lipid Metabolic Disorders	936
Mitochondrial Myopathies	940
Muscle Channelopathies, Non-Dystrophic Myotonias and Periodic Paralysis	951
Chloride Channelopathies	952
Sodium Channelopathies	953
Potassium Aggravated Myotonias	954
Additional Calcium Channelopathies	959
Inflammatory Myopathies	960
Rarer Inflammatory Myopathies	968
Viral Infections	971
Bacterial Infection of Muscle	972
Parasitic Infections	973
Differential Diagnosis of Myositis Autoantibodies	974
Myopathies of Systemic Disease	976
Rare Myopathies Associated with Systemic Disease	982
Toxic Myopathies	983
Antimicrotubular Myopathies	987
Drug-Induced Mitochondrial Myopathy	987
Drug-Induced Inflammatory Myopathies	988
Rare Drug-Induced Inflammatory Myopathies	989
Myopathies Due to Impaired Protein Synthesis or Increased Catabolism	990
Multifactorial Toxic Myopathies	991
Myopathies of Drug Abuse	993
Differential Defects of Specific Muscles	994
Congenital Facial Paresis	998
Congenital Diaphragmatic Hernia (CDH)	1000
Congenital Hand Muscle Abnormalities	1001
Axial Musculature	1001
Abdominal Musculature	1002
Rhabdomyolysis and Myoglobinuria	1004
Differential Diagnosis of Genetic Causes of Rhabdomyolysis and Myoglobinuria	1006
Specific Mitochondrial Depletion Syndromes of Adults	1010
Thymidine Kinase Deficiency (Myopathic Type)	1012
Defects of Oxidative Phosphorylation Coupling	1014
Defects of the Mitochondrial Respiratory Chain	1015
Defects of Mitochondrial Substrate Utilization and Gluconeogenesis	1018
Inflammatory Myopathies	1019
Neural Disorders of Skeletal Muscle Overactivity	1022
Metabolic Muscle Disease	1037
Differential Diagnosis of Nondystrophic Myotonia and Periodic Paralysis	1042
Further Reading on Muscle Diseases	1044

CHAPTER 10. BRAINSTEM AND CRANIAL NERVES

The Regulation of Breathing	1058
The Medullary Respiratory Center	1058
The Dorsal Respiratory Group (DRG)	1058
Hereditary Optic Neuropathies	1077
Mitochondrial Protein-Import Disorders	1080
Idiopathic Intracranial Hypertension	1081
The Optic Chiasm	1084
Cranial Nerve III	1089
Cranial Nerve IV	1094
The Vth Cranial Nerve	1095

The Maxillary Division of V (V ₂)	1097
Mandibular Division of V	1097
The VIth Cranial Nerve	1099
Cranial Nerve VII	1102
Cranial Nerve VIII	1107
An Outline of the Anatomy and Physiology of the Vestibular System	1108
Cranial Nerve IX	1117
Cranial Nerve X	1119
The XIth Cranial Nerve	1123
Cranial Nerve XII	1124
Congenital Abnormalities of the Brainstem	1126
Vascular Disease	1131
Demyelinating Disease	1131
Cerebellum Diseases	1135
Vascular Diseases of the Cerebellum	1136
Rare AR Cerebellar Ataxias	1146
X-Linked Disorders That Cause Episodic Ataxia	1169
Intermittent Ataxia from Amino Acidurias	1170
Spastic Ataxias	1172
Cerebellar Dysplasias	1179
Cerebellar Ataxic Syndromes	1180
The Differential Diagnosis of Secondary Cerebellar Disease	1185
Further Reading	1189

CHAPTER 11. BASAL GANGLIA AND MOVEMENT DISORDERS

Overview	1194
Summary	1195
Bradykinetic Disorders	1196
The Differential Diagnosis of Parkinson's Disease	1202
Differential Diagnosis of Parkinson's Disease	1205
Hyperkinetic Disorders	1212
Chorea	1217
Neuroacanthocytosis Syndrome	1218
Dyskinesia	1232
Autosomal Recessive Dystonia	1246
X-Chromosome Recessive Dystonia	1247
Secondary Dystonia	1247
Myoclonus	1250
Myoclonus Classification by Etiology	1253
Further Reading on Basal Ganglia and Movement Disorders	1260

CHAPTER 12. THE CEREBRAL CORTEX

Overview	1271
The Left Frontal Lobe	1271
The Primary Motor Cortex (M1)	1272
The Premotor Cortex (PMC)	1272
The Medial Premotor Cortex (Supplementary Area BA8)	1273
The Major Motor Loops Derived from the Cortex	1273
The Dorsolateral Prefrontal Cortex (DLPFC)	1275
Left Ventrolateral Prefrontal Cortex (VLPFC)	1275
Right Ventrolateral Prefrontal Cortex (VLPFC)	1275
The Right Frontal Lobe	1277

Vascular Disease

Ischemic Stroke

Introduction to General Features of the Differential Diagnosis of Ischemic Stroke, Embolus, and Intracranial Hemorrhage

Cerebral thrombosis occurs most frequently in the early morning hours during sleep. Patients frequently awaken and fall as they are unaware of their deficits. Transient ischemic episodes occur prior to thrombotic stroke in approximately 30% of patients. They are almost always atherosclerotic in origin. Transient ischemic attacks are usually emboli that arise either from the heart or intra-arterial vessels (carotid, arch of the aorta or vertebral arteries to distal smaller branches). They occasionally occur from distal field ischemia due to compromised vessels and decreased cerebral perfusion or vasospasm (migraine). Emboli may cause symptoms at each level of the brain as they progress through the cerebral circulation. They often occur in showers so that a number of vessels may be occluded simultaneously. The symptoms of intra-arterial vessel to vessel emboli are usually less than 2 minutes. Longer transient ischemic attacks suggest a cardiac origin. Transient ischemic attacks may occur only a few times or up to several times a day or on rare occasions in a rapid series (crescendo transient ischemic attacks). They often are stereotypical, but careful examination may reveal a new sign or symptom with each transient ischemic attack. If an infarction follows the first transient ischemic attack, it will be within one month in 20% of patients and within one year in 50%. Anterior transient ischemic attacks involve the cerebral hemisphere and the eye. Visual loss in the ipsilateral eye is usually characterized by transient monocular blindness. A shade may descend over the eye uniformly or more rarely there is a wedge of visual loss, sudden blurring or bright scotoma. (This finding is often noted with concomitant carotid stenosis). The visual deficit clears painlessly and uniformly. Often ocular attacks precede hemispheric attacks. Hollenhorst plaques (yellow, birefringent, cholesterol particles) are rarely noted and occur at branch points of the retinal arterioles. Rarely the pupil is paralyzed from ischemia of the ciliary body. Hemispheric attacks are most often characterized by face and arm weakness with concomitant sensory loss. The face and lips may be involved together or singly, a cheiro-oral presentation. The sensory loss involves the corner of the mouth and usually the C6 to C8 hand sensory root distribution: most hemispheric transient ischemic attacks cause aphasia, heaviness, weakness and numbness of the face and arm (brachiocephalic) or of the arm, face and leg (internal capsule distribution). Rarely dysarthria or leg weakness may predominate. A pseudo radial palsy of the arm suggests ischemia of

the motor “knuckle” of the motor cortex. Simultaneous eye and hand involvement from a carotid embolus is extremely rare. Anterior transient ischemic attacks may cause: dizziness, confusion, both anterior and/or posterior aphasia, higher cortical sensory and cognitive deficits, and neglect to contralateral space with non-dominant hemispheric involvement. Headaches are common and are usually ipsilateral. The usual manifestation of transient ischemic attacks in the posterior circulation (includes the vertebral, basilar and posterior cerebral arteries) are: bilateral visual field loss, dizziness, perioral numbness, ataxia, diplopia, dysphagia, dysarthria and bilateral motor or sensory symptoms. A crural hemisensory deficit (ipsilateral face and contralateral body below the clavicle) is pathognomic of brainstem involvement but is extremely rare. Dizziness alone is rare as a posterior transient ischemic attack symptom but has been described with posterior inferior cerebellar artery involvement.

Unusual signs and symptoms of posterior circulation transient ischemic attacks are: veering to one side (posterior inferior cerebellar artery at the level of the inferior olive); staggering posterior inferior cerebellar artery territory; lateral pulsion (posterior inferior cerebellar artery territory, medial branch); a feeling of crossed-eyedness, bilateral dark vision; noise or pounding in the head or ear; unusual cephalic sensations; and pain in the face or head. Drop attacks, sudden loss of tone with falling may occur and are unaccompanied by loss of consciousness. The patients are stunned or slightly confused. Impaired hearing (sounds are faint or distant); deafness, forced eye deviation, hemiballismus, and a feeling of moving of a part and choreoathetosis have rarely been described. Peduncular hallucinosis has recently been demonstrated to occur from hippocampal formation ischemia. Forced eye deviation is encountered from unilateral para pontine reticular formation ischemia. Basilar artery ischemia may cause alternate hemiparesis. The affected extremities may be simultaneously weak or there is spread of weakness over 10 to 60 seconds which is much longer than expected from seizure activity. A basilar transient ischemic attack may resolve suddenly or gradually. Posterior transient ischemic attacks have a higher incidence of headache than anterior transient ischemic attacks. In general, ipsilateral carotid disease causes face and parietal headache. Vertebral artery involvement refers pain to the retroauricular area whereas basilar artery disease produces occipital and C2 distribution (forehead) pain. Posterior cerebral artery ischemia refers to the lateral eyebrow.

The major risk factors for thrombotic stroke are an important diagnostic feature. Hypertension, diabetes mellitus, cigarette smoking, prior stroke, heart and peripheral vascular disease are most common in older patients. Stroke in the young is embolic from the heart or secondary to dissection, collagen vascular disease, hypercoagulable states, genetic diseases, or associated medical conditions.

Development of neurologic deficits in thrombotic strokes occur in several ways: 1. single attack with the full deficit evolving over hours; 2. stuttering or intermittent progression

that may continue over hours to 1 to 2 days; 3. a partial deficit that may improve and then progress to a completed stroke; 4. fleeting deficits may be followed by a longer episode and then a major stroke that occurs within days.

The deficits may be regional at onset or evolve in a step-like pattern. Intermittent progression is a characteristic of thrombotic stroke. Rarely there is an apparent gradual progression of the deficit over 1 to 2 weeks which is most common in pure motor strokes.

In general, thrombotic strokes of the large conducting vessels of the middle cerebral artery (M1 and M2 components) reach maximum disability in three days which is dependent on consequent edema. Carotid occlusion, particularly if there is a fetal origin of the posterior cerebral artery (from the carotid artery) results in maximum edema and disability within 24 hours. Death is usually from transtentorial herniation at midbrain levels. Posterior fossa strokes, particularly of the vertebral artery, (the most common site of origin of posterior inferior cerebellar artery), may have delayed cerebral edema (4 to 7 days) and produce tonsillar herniation at this time (tonsillar coning).

Particular arteries will thrombose with different diseases. Diabetic patients suffer infarction of posterior inferior cerebellar artery and the thalamogeniculate and thalamoperforate arteries from the posterior cerebral artery to a greater extent than expected. Young hypertensive women on birth control pills infarct posterior inferior cerebellar artery. Lipohyalinosis and focal atheromatous plaques at the origin of penetrating arteries (lacunar strokes) occur most frequently in diabetic hypertensive patients. Dissection of the vertebral or carotid arteries usually causes stroke by emboli from the site of dissection but less commonly by decreased flow. Dissection of the vertebral artery is common in the horizontal component of the artery at C2. This frequently causes neck pain and may be followed by chiropractic manipulation which extends the dissection.

Diabetes accelerates atherosclerosis by approximately 10 years. Radiation therapy in the neck induces a vasculopathy that accelerates atherosclerosis and causes proliferative endarteritis over long segments of the artery. If the brain is involved, small vessels occlude in the cortex with focal deficits and strokes. In the spinal cord, the perforating sulcal arteries are involved which produces a Brown-Séquard syndrome. Polycythemia most often affects the posterior circulation. The vasculopathy of sickle cell disease affects large and small vessels.

The usual sites of atherosclerotic disease are the carotid bifurcation, siphon and the intracavernous portion of the artery. Rarely there may be isolated stenosis of superficial branches as well as the M1 and M2 segments of the middle cerebral artery. In the posterior circulation, the origins of the vertebral arteries, mid and top of the basilar artery, as well as the junction of the vertebral and basilar arteries, are major sites of disease. Stenosis may be seen singly or in tandem.

Anomalies of arteries from their embryological origin may be important in determining the extent of thrombotic stroke. Poor development of the anterior and posterior communicating arteries may isolate one cerebral hemisphere. In general, the right vertebral artery is atretic or smaller than the left. Atherosclerosis of the left vertebral artery may induce severe basilar symptoms because of lack of circulatory support from the right vertebral artery. Occlusion of a vertebral artery may occur with prolonged abnormal head positions during surgical procedures as the artery on the side of the ipsilaterally turned head is occluded. If it is the predominant artery, there is no effective basilar flow. Similarly, a single thalamic peduncle (Percheron's artery) at the top of the basilar may cause bilateral thalamic infarction as it will be the origin of the paired interpeduncular arteries that usually arise separately from the top of the basilar artery. Failure of regression of the four major embryologic connections between the carotid and basilar artery (persistent trigeminal, otic, hypoglossal and proatlantal) may allow an embolus from the anterior circulation to infarct posterior circulation territory or vice versa. A fetal origin of the posterior cerebral artery arising from the carotid may be the cause of complete hemispheric infarction following carotid occlusion.

A lacune is an area of infarction within the territory of a single perforating artery. The basic clinical syndromes associated with these lesions are: pure motor stroke, pure sensory stroke, homolateral ataxia and crural paresis, dysarthria – clumsy hand syndrome, ataxic hemiparesis and sensorimotor stroke. Approximately 80% of lacunes may be clinically silent. The temporal profile of a lacunar infarct may evolve over hours or rarely days in contradistinction to a cortical infarct. Lacunar strokes do not present with loss or impairment of consciousness, headache, seizure or higher cognitive deficits. Approximately 20% have transient ischemic attacks at the time of incipient occlusion and may be embolic. Often several perforating arteries are occluded in the latter circumstance. The capsular warning syndrome describes a crescendo of lacunar transient ischemic attacks prior to completion of internal capsule infarction.

A cerebral embolus strikes suddenly during wakefulness and frequently has a suggestive underlying cause. It may involve superficial surface cortical vessels giving pure cortical symptoms such as aphasia or hemianopia, or it may occlude stem arteries such as the M1 segment of the middle cerebral artery. This location causes deep internal capsular as well as surface hemispheric symptoms. Seizures occur in at least 15% of patients, and a similar number appear stunned and mute (stem middle cerebral artery territory and rarely supplementary motor area). A small percentage of patients lose consciousness. Smaller emboli characteristically are cholesterol-platelet-fibrin in origin and give shorter symptoms (minutes). Larger red emboli from the heart clear more slowly (hours). The deficit following an embolus is most severe at onset and then clears over time. Most emboli occur in the middle cerebral artery territory as this vascular territory receives the most

blood flow. There may be evidence at presentation of prior embolic events in other vascular territories. Approximately 30% of cerebral emboli are associated with blood in the cerebrospinal fluid (100 red blood cells/mm³).

The setting for a cerebral embolus is a cardiac arrhythmia of which atrial fibrillation is by far the most common. A patient with atrial fibrillation that has the onset of an acute isolated Wernicke's aphasia has almost certain embolization to the temporo-occipital branch of the inferior division of the middle cerebral artery. Brady-tachy arrhythmia is the second most common arrhythmia causing cerebral embolus (usually during the tachy phase). A myocardial infarction, subacute bacterial endocarditis, artificial heart valve, perforated foramen ovale (20% of patients), aneurysm of the atrial septum, cardiomyopathy, lower extremity thrombophlebitis (paradoxical emboli) and cancer (non-bacterial thrombotic endocarditis) all suggest an embolus as the cause of stroke. Newer transthoracic echo-cardiographic techniques have demonstrated the importance of the aortic arch as a source of emboli (approximately 15 to 25%).

The brain is the first clinical herald of systemic emboli from the heart in the overwhelming majority of patients. Recent diffusion/perfusion magnetic resonance imaging studies confirm the diagnosis particularly if two circulations are involved.

Arteries to artery emboli are smaller than those from the heart and often involve several territories in the circulation. It is not unusual to have a vertebral artery embolus produce lower brainstem, pontine, midbrain, thalamic and cortical symptoms and signs as it move up the posterior circulation. Carotid artery emboli to ophthalmic and central retinal arteries frequently produce amaurosis fugax, a shade descending in the involved eye that lasts for 1–2 minutes. It is coincident with a Hollenhorst plaque at a retinal artery bifurcation. The embolic deficit from a carotid or vertebral artery dissection may be associated with sympathetic ocular paralysis in the former and lateral neck pain in the latter. The clinical deficits caused from these events are from emboli at the site of dissection rather than cerebral blood flow limitation. Embolic disease both from artery to artery and from the heart may occur as a shower with several circulations affected. Characteristically, emboli may affect the same territory with each event, which is thought to be due to laminar flow characteristics of that circulation. In the vertebrobasilar system, the top of the basilar artery is narrowest and is most often occluded from emboli. Rarely, emboli occur in a stepwise fashion that simulates distal field ischemia. The use of transesophageal echocardiography has demonstrated the root of the aorta as a rich source of emboli (15 to 25% of all emboli). Grade V (pedunculated) atherosclerosed material is most likely to cause a clinical problem. The recent application of transcranial Doppler techniques during carotid endarterectomy and other procedures has demonstrated that emboli may be asymptomatic. Those from high frequency "hits" are smaller platelet fibrin emboli while lower frequency

"hits" favor larger clots in the heart. Lacunar disease of the basal ganglia and subcortical white matter is most often due to lipohyalinosis or atheromatous plaques at the origin of the penetrating vessels. If a group of these small penetrating vessels is occluded simultaneously emboli are the most likely cause. Persistent embryological arteries (trigeminal, otic, and hypoglossal) may allow an anterior embolus to infarct the posterior circulation or vice-versa.

Hemorrhagic vascular disease can easily be divided by location, age of the patient, underlying medical disease, iatrogenic factors and clinical features.

In general, hemorrhagic vascular disease occurs when the patient is awake and active. The exceptions may be aneurysms and cavernous hemangiomas that may rupture while the patient is asleep. The usual pattern of cerebral hemorrhage is the apoplectic onset of severe neurologic deficits with gradual headaches. Occasionally, the headache is severe, the patient vomits once (pressure on the floor of the fourth ventricle followed by compensating mechanisms), and there are focal neurologic deficits and loss of consciousness. Specific clinical points allow differentiation of the location and the most likely pathogenesis of the hemorrhage. Hypertensive hemorrhages occur in the setting of sustained hypertension. The most common locations for hypertensive hemorrhages are the basal ganglia (40%), the thalamus (20%), the cerebellum 10%, lobar 10%, the pons 5%, and infrequently the medulla 1%. Hemorrhages in the white matter of the centrum semiovale suggest platelet and clotting disorders. Several areas of hemorrhage in different lobes that have mixed magnetic resonance imaging signals (old and new blood surrounded by a dark hemosiderin ring) are suggestive of cavernous hemangioma. Blood in the suprachiasmatic cistern is often noted with posterior communicating artery, carotid and anterior communicating artery aneurysms. Blood tracking anteriorly between the hemispheric fissures is most characteristic of anterior communicating artery aneurysms. Blood in the Sylvian fissure on one side suggests middle cerebral artery aneurysm. Perimesencephalic prepontine blood in a patient with little or no focal abnormality is probably venous although a small arteriovenous malformation or causative has been reported. Cavernous sinus aneurysms decompress into the sinus and are associated with cranial nerve abnormalities (IIIrd, IVth, VIth). Approximately 50% of aneurysms have a short episode of loss of consciousness at the ictus. A small percentage of patients have seizures. Almost all have electrocardiogram changes. The neck is stiff, and Brudzinski's and Kernig's signs are positive. Frequently hydrocephalus is noted on the initial computed tomography scan. Dural irritation from blood may be associated with tender eyes, a retinal hemorrhage on the side of the lesion (Torsten's syndrome) and sore neck and shoulder muscles (meningeal irritation). Rarely, pain in the lower back is the major manifestation. Irritation of lower back meninges without headache should always raise the suspicion of a spinal arteriovenous malformation. Each aneurysm has its own clinical profile.

Posterior communicating arteries are associated with a pupil involving IIIrd cranial nerve palsy. Anterior communicating artery aneurysms show little focal neurological deficit (weak leg) but prominent personality defects. Middle cerebral artery aneurysms may have a prominent hemiparesis. Carotid aneurysms may be associated with a contralateral hemiparesis and IIIrd cranial nerve palsy. Ophthalmic artery aneurysms cause unilateral visual loss.

Parenchymal vascular malformations most often present with seizures rather than overt bleeding. These emanate from abnormal glial and neuronal tissue within the malformation. Migraine-like headaches are also common. Hemorrhage clearly can present with focal neurologic signs depending on the affected lobe. Arteriovenous malformations are associated with phakomatoses such as Von Hippel-Lindau, Cobb's, Sturge-Weber, Wyburn-Mason, Klippel-Feil-Trenaunay syndromes. There are genetic chromosomal defects with arteriovenous malformations and cavernous hemangiomas (Krit1 gene).

Elderly patients presenting with single or multiple lobar hemorrhages suffer congophilic angiopathy. Gradient Echo magnetic resonance imaging sequences demonstrate prior bleeds because this technique is very sensitive to hemosiderin deposition. Traumatic hemorrhages may be associated with blood in the subarachnoid space, a coup contra coup location (frontal lobe coup and contra coup in occipital lobe) with contusion of the crown of the gyrus. They may be delayed for four to seven days after the injury. If severe, the hemorrhage may be associated with loss of autoregulation, severe cerebral edema and "commotio retinae" (an increased light streak from the retinal blood vessels).

Venous hemorrhages occur in association with sinus thrombosis (particularly the superior sagittal sinus). They present with seizures, headache and focal deficits. They are accompanied by bilateral basal ganglia or thalamic hemorrhages. If cortical, they also are frequently seen in the middle cerebral artery territory. In the setting of pre or post-partum, they frequently present with seizures in a lower extremity that generalizes, associated with bloody spinal fluid. Venous malformations are linear and often connect to a ventricle. They seldom bleed spontaneously but will cause infarction and hemorrhage into the drained territory if they are clipped.

The use of tissue plasminogen activator will cause approximately 6% of hemorrhage into the occluded territory. Hyperextension, the size of the infarcted area and age are risk factors. Transformed hemorrhage which occurs in a previously infarcted area often is petechial but may be massive. Hemorrhage from anticoagulants usually is nonhomogeneous on magnetic resonance imaging scan (swirling effect). Arteriograms following infarction may appear to be hemorrhages.

Twenty percent of patients that have suffered a cerebral hemorrhage from cocaine abuse have an underlying vascular malformation. Rarely, propane ethanolamine and Dexedrine (Dextroamphetamine) may cause cerebral hemorrhage from hypertensive mechanisms.

Hereditary congophilic superficial hemorrhages are noted in Dutch, Swedish and Icelandic patients. Cavernous hemangiomas may be most common in Mexican Americans. The history and physical examination should localize vascular disease. The medical setting and this localization generates the differential diagnosis. Imaging proves the diagnosis, uncovers unsuspected pathology and allows insight into the basic mechanisms that are involved. There is no substitute for the history, physical examination, interpretation of the imaging studies and clinical judgment. The rapid advance of interventional radiological techniques, thrombolytic and possibly neuroprotective agents has made stroke neurology very therapeutic.

The Neurovascular Unit: Outline of Some Mechanisms Common to Stroke

The concept of a neurovascular unit composed of endothelial cells, a basal lamina, pericytes, a cellular matrix and neurons acting in concert to maintain central nervous system's homeostasis in health and disease are now well established. Clinical differential diagnosis is buttressed by a mechanistic approach which is rapidly evolving to an understanding of genetic, immune and molecular causes of pathology within the neurovascular unit. Major aspects of these mechanisms will be referenced as the diseases and their differential diagnoses are discussed.

Neurovascular Unit

The neurovascular unit is classically composed of endothelial cells, astrocytes, pericytes, the basal lamina and the extracellular matrix that surrounds the cerebral microvasculature. It was originally thought to primarily couple local cerebral glucose metabolism (increased by neural activity) to local cerebral blood flow. More recently it has been studied in regard to its role in brain homeostasis and physiology by its regulation of the blood-brain barrier. Recent anatomical and experimental studies support the existence of an extended neurovascular unit that includes pericytes, microglia and a specialized cellular compartment, the endothelial glycocalyx.

The glycocalyx has the following features:

1. It is located on luminal surfaces of endothelial cells of cerebral arteries, veins and cerebral capillaries
2. It is composed of proteoglycans, glycoproteins and glycolipids in a negatively charged network (platelets are also negatively charged)
3. It is an irregularly shaped layer of 50–100 nm thick that coats the vascular lumen
4. It contains enzymes and proteins that are involved in plasma and vessel wall integrity and homeostasis

The enzymes and proteins contained are:

1. Growth factors
2. Chemokines

3. Apolipoproteins
4. Lipoprotein lipase
5. Extracellular superoxide dismutase
6. Angiotensin converting enzyme
7. Antithrombin III
8. Endothelial nitric oxide synthase

The major functions of the glycocalyx are:

1. Cell – cell recognition
2. Modulation of red cell volume in capillaries
3. A permeability barrier that:
 - a. Decreases leukocyte adhesion which is pivotal in blood-brain barrier penetration
 - b. Inhibits coagulation
4. Protects vascular walls from the direct effects of blood flow (shear stress) by regulating local nitric oxide release
5. Modulates the filtration of interstitial fluid from capillaries into the interstitial space

Disruption of the glycocalyx causes:

1. Atherosclerosis
2. Vascular wall inflammation
3. Increase in vascular permeability
4. Inability to protect against fluid shear stress

Blood-Brain Barrier

A major function of the neurovascular unit important in ischemic/hypoxic injury from stroke is its regulation of the passage of proteins and cellular elements from the intravascular space into the brain parenchyma through the blood-brain barrier. This function is dependent on the integrity of tight junction proteins between endothelial cells and the functional interaction between these endothelial cells, their basal lamina and perivascular astrocytes. Adherens junctions are primarily formed by vascular endothelial – cadherin proteins that couple with catenin proteins which effects cell – cell adhesion by their connection to the actin cytoskeleton. The transmembrane components of tight junctions contain junctional adhesion molecule (JAM-1), occludin and claudin proteins that are linked by the zonula occludin (ZO-1 and ZO-2) proteins to the cytoskeleton. The tight junctions primarily determine blood-brain barrier permeability and the high electrical resistance of the endothelium. The basement membrane separates endothelial cells from the end feet of astrocytes, pericytes and neurons. Pericytes are opposed to endothelial cells opposite to tight junctions where they secrete trophic substances (paracrine function) in conjunction with perivascular astrocytes that strengthen and help to maintain the blood-brain barrier. Pericyte processes cover a significant portion of the capillary wall. Their location allows them to phagocytize red blood cells that may extrude from disrupted tight junctions during pathological states.

The basement membrane is composed of extracellular matrix proteins that include laminar, collagen IV, fibronectin and perlecan. Approximately 95% of the basal lamina of cerebral capillaries is encased by astrocytic end-feet processes

that also contain the osmoreceptor aquaporin 4 and inwardly rectifying potassium channels (K_{IR}). Their proximal poles are in contact with dendritic synapses of neurons. There is accumulating evidence that boutons from neuronal axons containing vasoactive neuropeptides are also in close contact with astrocytic end-feet and the basal lamina.

The adhesion of endothelial cells and astrocytes to the basal lamina depends on integrins and their ligands on the matrix. Integrins also activate cellular signaling pathways under pathologic conditions and are a component of endothelial cell and perivascular astrocyte regulation. Astrocytic secreted factors are important for: 1. the attachment of end-feet to the basement membrane; 2. the distribution and maintenance of interendothelial tight junction proteins. The integrin subunit $\beta 1$ is located in both endothelial cells and astrocytes whereas the $\alpha 2 \beta 4$ subunits are on astrocytic end-feet processes and interact with lamin-1 and -5 of the basal lamina. The interaction of perivascular astrocytes and the basal lamina is also important in determining the permeability of the blood-brain barrier. Disruption of the astrocytic end-feet processes from the basal lamina decreases transendothelial electrical resistance of the neurovascular unit and increases the permeability of the blood-brain barrier.

Immune Components of the Neurovascular Unit

The importance of the immune system in the neuropathology of ischemic stroke is evident at many levels. It orchestrates the inflammatory response, permeability of the blood-brain barrier, blood flow in the microcirculation and aspects of recovery. Immune surveillance is accomplished by circulating T- and B-cells in the glycocalyx as well as perivascular macrophages and the microglia. The cytokine tumor necrosis factor-like weak inducer of apoptosis (TWEAK) and its receptor fibroblast growth factor-inducible 14 (Fn14) are pivotal in the regulation of the endothelial cell – basement membrane – astrocyte interface. This component of the neurovascular unit is a major component of physiologic response of the blood-brain barrier in the ischemic hypoxic injury of stroke. TWEAK binding to Fn14 receptor activates intracellular NF κ B (nuclear factor kappa-light-chain-enhancer of activated B-cells), extracellular signal-regulated kinases and c-JUN N-terminal kinases (JNKs) signal transduction pathways that directly affect the composition of the basal lamina and the function of astrocytic end-feet processes and the basement membrane.

The functional adaptations of the neurovascular unit are effected by 1. cell – cell communication; 2. cell – extracellular matrix interaction; and 3. paracrine cell – cell communication.

The principal functions of the neurovascular unit:

1. Couples local cerebral blood flow to neuronal metabolic rate of glucose utilization (neuronal activity)
2. Blood-brain barrier permeability
3. Transport processes
4. Neuroimmune functions

5. Astrocytic interface between endothelial cells and neurons
The microvascular changes and neuronal injury evolve simultaneously and that suggests there is a coordinated response to ischemia.

Neurovascular Unit Pathology During Hypoxia and Ischemia

1. Early changes after ischemia/hypoxic injury within the neurovascular unit:
 - a. Lack of glucose and oxygen to the affected territory leads to:
 - i. Failure of the sodium/potassium ATPase membrane pumps on cellular elements in the ischemic territory (reflected by bright images on diffusion-weighted magnetic resonance imaging sequences)
 - b. Within 2 hours of experimental middle cerebral artery ischemia, neurons that are most distant from a proximate microvessel (about 30 μm radius) are heterogeneously affected and demonstrate DNA damage
 - c. Down regulation and loss of $\beta 1$ -integrin subunits $\alpha 1$, $\alpha 3$, $\alpha 6$ from endothelial cells; $\alpha 6\beta 4$ subunits from astrocytes and $\alpha \beta$ -dystroglycan from astrocyte end-feet occur most intensely in the ischemic core
 - d. In hypoxic tissue, immediate early response genes are induced that encode:
 - i. Secreted proinflammatory cytokines/chemokines
 - ii. Cytoplasmic enzymes – the pivotal inducible cyclooxygenase-2
 - iii. Inducible transcription factors
 - iv. Hypoxia-inducible factor HIF-1 α
 1. A specific transcription factor specifically activated by hypoxia that upregulates genes important for cell survival under hypoxic conditions that includes:
 - a. Oxygen dependency
 - b. Erythropoietin
 - c. Transferrin
 - d. Heme oxygenase
 2. Glucose transport
 - a. Glucose transporter-1
 3. Glycolysis
 - a. Lactate dehydrogenase A
 4. Angiogenesis:
 - a. Vascular endothelial growth factor
 - b. Inducible nitric oxide synthase
 - c. Angiopoietin-2
 - d. Fibroblast growth factor
 - v. HIF-1 α induces four major families of proteases in ischemic tissue (experimental studies) that are expressed on microvessels and neurons:
 1. Latent matrix metalloproteinase (pro-MMP)-2 and MMP-9:
 - a. MMP-2 associated with neuronal injury
 - b. MMP-9 associated with hemorrhagic transformation
 2. Cathepsin L (a cysteine protease) involved with degradation of perlecan and laminin of the microvessel basement membrane
 3. Heparanase
 4. Urokinase plasminogen activator binds to its receptor. These proteases degrade laminin collagen IV, cellular fibronectin and perlecan that are a component of matrix-adhesion receptors and also have major effects on basement membrane integrity
 5. In reperfusion injury, the early opening of the blood-brain barrier is effected by HIF-1 α -induction of the furin gene which induces furin convertase. This converts the constitutive enzymes pro-MT-MM2 (metalloproteinase) to its active form, MMP-2, which increases the permeability of the blood-brain barrier. This occurs during the first 12 to 24 hours post injury. At 24 to 48 hours, the permeability of the blood brain barrier is irreversibly due to the induction of MMP-3 and MMP-9 during the inflammatory responses. The induction of COX-2 (cyclooxygenase-2) is also important in the late irreversible changes of the blood-brain barrier during late reperfusion injury
 - vi. HIF-1 α and inflammation:
 1. An initial trigger of inflammatory gene transcription that produces:
 - a. Proinflammatory cytokines
 - b. Chemokines
 - c. Eicosanoids from endothelial cells, pericytes, astrocytes and perivascular macrophages
 2. Recruitment of peripheral inflammatory cells
 3. Recruited activated leukocytes releases free radicals, metalloproteinases and eicosanoids which damage the endothelium and disrupt the blood-brain barrier
 4. Local cerebral blood flow adaptation to local metabolic rate of glucose utilization:
 - a. Early studies demonstrated that the production of protons from neurologic activity dilated capillaries and arterioles by ligand binding to acid sensing receptors
 - b. Recent studies suggest that projections from basal forebrain neurons to cortical microvessels and surrounding astrocytes are important. These projections release vasoactive neuropeptides onto microvascular endothelial cells, smooth muscles cells and astrocytes that correlate local cerebral blood flow to neuronal activity
 - c. Intracellular Ca^{2+} concentration in astrocytes, through Ca^{2+} sensitive phospholipase

A₂ activated receptors initiate vasoconstriction or dilatation by activation of arachidonic pathways regulated by nitric oxide. Smooth muscle cells in arterioles and pericytes in capillaries effect constriction or dilatation in response to vasoactive mediators

5. Cortical spreading depolarization

- a. Is a slowly propagation wave of neuronal and glial depolarization that occurs in tissue affected by ischemia. It can be produced by endothelin-1 (a vasoconstrictor) or potassium ion applied to the cortex. Its exact mechanism is not entirely clear but in ischemia there may be an imbalance between vasoconstriction and dilatation (greater vasoconstriction) that causes spreading depolarization. In stroke there is little spread beyond ischemic tissue which differs from migraine. Under normal circumstances the neurovascular unit responds to increased neuronal activity by reactive hyperemia while during ischemia there may be vasoconstriction (inverse neurovascular coupling) with consequent neuronal injury

6. Metabolic and electrical processes during ischemia:

- a. Generation of free radicals
- b. Spreading depolarization
- c. Calcium mediated cell death
- d. Impaired mitochondrial function
- e. Decreased protein phosphorylation, synthesis and increased proteolysis
- f. Activation of lipolytic pathways

Late Neurovascular Unit Processes in Ischemia

1. Occlusion of nutrient microvessels occurs heterogeneously in ischemic territories which is dependent upon fibrin formation, platelet activation and endothelial cell adhesion of polymorpholeukocytes
2. Hemorrhagic transformation develops following degradation of the microvasculature basal lamina matrix from induced proteases
3. Dysfunction of the blood-brain barrier causes:
 - a. Changes of the brain extracellular milieu which causes an increase in potassium concentration and decrease in calcium and magnesium concentrations that increase neural and network excitability
 - b. A parenchymal influx of large size molecules (serum proteins) that cause water influx and edema. Albumin may be selectively transported into astrocytes to trigger transcriptional changes that also increase neuronal hyperexcitability
 - c. Astrocytic signaling from serum protein exposure triggers transcriptional changes that cause down regulation of inward rectifying potassium channels (K_{ir}4),

aquaporin 4 water channels, gap junction proteins and glutamate transporters. Inability of astrocytes to buffer potassium and glutamate leads to N-methyl-D-aspartate activation and neuronal depolarization that leads to neuronal death from excitotoxicity. Entrance of thrombin into the brain from a dysfunctional blood-brain barrier also increases neuronal excitability

- d. Angiogenesis and remodeling orchestrated by vascular endothelial growth factor is initiated by loss of microvascular integrity and the degradation of the vessel lamina matrix. The dysfunctions of angiogenesis and remodeling of the neurovascular unit after ischemic stroke are:
 - i. Increased blood-brain barrier permeability
 - ii. Dysfunctional neurovascular coupling
 - iii. Immune dysfunction with leukocyte adhesion and parenchymal infiltration
 - iv. Thrombosis in the microvasculature
- e. Liquefaction and cavitation of infarcted tissue

Components of the physiology and neuropathology of the neurovascular unit are evident in all ischemic and oxygen derived brain tissues. As understanding of the molecular basis of these events accrues, there will be advances in stroke therapy.

Risk Factors for Ischemic Stroke

Introduction to Modifiable Risk Factors

The Framingham study illustrated the first epidemiological evidence that identified specific risk factors associated with cardiovascular disease. It found a correlation between hypertension, deficient glucose tolerance, obesity, cigarette smoking and atrial fibrillation. The Northern Manhattan Stroke Study and the Honolulu Heart study corroborated these findings and added alcohol and inflammation as added risk factors. The treatment of risk factors prevents the first and subsequent strokes and is responsible for the decline in incidence of strokes in Western countries.

Non-Modifiable Risk Factors for Stroke

The primary non-modifiable risk factors are male sex, age, low birth weight, ethnicity and family history.

General Characteristics

1. The combined risk of fatal and non-fatal stroke increases by:
 - a. Men: 9%/year
 - b. Women: 10%/year
2. Incidence of ICH increases with age from <45 to >85
3. The Framingham Heart Study
 - a. The lifetime risk for stroke is 1 out of 6 for middle aged adults

Low Birth Weight

1. Low birth weight is associated with stroke in later life:
 - a. Stroke mortality rates among adults in England and Wales have been shown to be higher in adults with low birth weights
 - b. An odd ratio of 2.16 ($p < .001$) for low birth weight babies for the risk of stroke, MI or heart disease by 50 years of age
2. The association of low birth weight has not been proven to be causal
 - a. There are geographical differences in this epidemiology
 - b. Mothers may have been socially and economically disadvantaged

Race/Ethnicity

1. There are epidemiologic studies that support racial and ethnic differences in the risk of stroke
 - a. Hispanic/Latin Americans (some) and Black patients have higher incidence of all stroke types than Caucasians
 - b. Younger and middle-aged Blacks have a higher risk of SAH and ICH than Caucasians of similar age
 - c. Blacks had an incidence of all stroke type 38% higher than Caucasians (ARIC study)
 - d. Black patients have a higher prevalence of prehypertension, obesity and diabetes mellitus
 - e. Stroke risk may also have contributions from:
 - i. Social determinants
 - ii. Geography
 - iii. Language
 - iv. Access to healthcare
 - v. Nativity
 - vi. Neighborhood characteristics

Genetic Determinants

1. A positive family history increases the risk of stroke approximately 30%
2. A stroke prior to 65 years of age is associated with a three times increase in risk of stroke in children (Framingham study)
3. Monozygotic twins have a 1.65 higher risk of stroke than dizygotic twins
4. Genome-wide common variant single nucleotide polymorphisms (SNP) data heritability:
 - a. Cardioembolic (32.6%)
 - b. Large vessel disease (40.3%)
 - c. Small vessel disease (16.1%)
5. Chromosomal variants:
 - a. Variant on 9p21:
 - i. Adjacent to tumor suppressor genes CDKN2A and CDKN2B are associated with large vessel stroke and MI
 - b. Variants on 4p25 and 16q22:

- i. Are adjacent to genes involved in cardiac development:
 1. PITX2
 2. ZFHX3
- ii. May be associated with atrial fibrillation and ischemic stroke (primarily cardioembolic)
- c. Patients with European ancestry:
 - i. Large vessel stroke association:
 1. Locus in 6p21.1 and 7q21
 2. Near HDAC9 gene that encodes a protein in histone deacetylation
- d. Small vessel stroke in Asians:
 - i. Associated with PRKCH gene:
 1. Encodes a protein kinase

Defined Genes and Stroke

1. CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy)
 - a. NOTCH 3 gene
2. CARASIL (Cerebral Autosomal Recessive Arteriopathy with Subcortical Infarction and Leukoencephalopathy)
 - a. Autosomal recessive
3. Retinal vasculopathy with cerebral leukodystrophy
 - a. TREX1 gene
4. Collagen type IV (COL4A1 and A2) gene
 - a. Ischemic or hemorrhagic stroke
 - b. HANAC (Hereditary Angiopathy with Nephropathy, Aneurysms, and muscle Cramps)
5. Fabry's disease
 - a. Lysosomal α -galactosidase A deficiency
6. Autosomal dominant coagulopathies:
 - a. Protein C deficiency
 - b. Protein S deficiency
 - c. Factor V Leiden mutation
 - d. Prothrombin mutations
7. Lupus anticoagulant and anticardiolipin antibody
 - a. Familial in approximately 10% of patients
8. Autosomal recessive mutations in
 - a. V,VII,X,XI and XIIIth cranial nerves
9. A familial component of approximately 10 to 20% is seen in:
 - a. Moyamoya syndrome
 - b. Fibromuscular dysplasia
10. Autosomal dominant polycystic kidney disease
 - a. Intracranial aneurysm occur in approximately 8% of patients
11. Ehlers-Danlos syndrome (type IV):
 - a. Dissection of extracranial arteries
 - b. Dolichoectasia
12. Marfan's syndrome:
 - a. Fibrillin gene mutations
 - b. Dissection of extracranial arteries
 - c. Dolichoectasia
13. Cerebral cavernous malformations:
 - a. KRIT (CCM1)

- b. Malscavernin (CCM2)
- c. PDCD10 (CCM3)
- 14. Inherited cerebral angiopathy
- 15. Amyloid precursor protein gene:
 - a. Cystatin C
 - b. Gelsolin
 - c. BR12
 - d. D

Risk Factors That Predict Stroke

Independent Factors for Stroke Risk Prediction

1. Age
2. Systolic blood pressure
3. Hypertension
4. Cardiovascular disease
5. Myocardial infarction
6. Angina or coronary insufficiency
7. Congestive heart failure
8. Intermittent claudication
9. Atrial fibrillation
10. Left ventricular hypertrophy on ECG

Atrial Fibrillation (AF)

AF causes substantial morbidity. After adjustment for age, hypertension, smoking, diabetes, congestive heart failure, valvular heart disease, stroke and TIA, the risk of death was 1.5 times greater in men and 1.8 times greater in women with AF. In patients without valvular heart disease and pre-existing heart disease AF confers twice the mortality in both sexes.

The thrombogenic effects of AF are: 1. stasis in the left atrium; 2. abnormalities of vessel walls; 3. changes in clotting factors. AF accounts for approximately 15% of strokes. Anticoagulation is recommended for all AF patients with moderate or high risk for ischemic stroke or TIA that have no contraindications. The CHADS₂ scoring system helps to determine moderate to high risk persons that would benefit from anticoagulation therapy. One point is assigned for "C" congestive heart failure, "H" for hypertension; "A" for age >75 years and "D" for diabetes. Two points are assigned for a history of stroke or TIA. Patients that have a score of > or equal to 2 are at a high risk of stroke (1.9–7.65) per year. Refinements were made in the scoring system (CHA₂DS₂ – VAS_C) to evaluate patients from 0–1. Invasive fibrillation ablation procedures, Cox maze and catheter based ablation reduce recurrence approximately 70%. Newer anticoagulants are being investigated. The Framingham Heart Study score to predict 5 year risk of stroke alone or stroke or death in patients with recent onset of AF scores advancing age, female gender, and systolic blood pressure prior to stroke/TIA, diabetes and smoking. Stroke rates in low risk groups were 1.1 (14% of low risk cohort) and 1.5 (30% of cohort) per 100 person years. Warfarin has demonstrated a 64% stroke risk reduction relative to 22% for antiplatelet therapy.

Secondary Factors for Stroke Risk Prediction

Hypertension

Lowering of systolic blood pressure (BP) by 10 mm Hg may decrease stroke risk by 30–40%. Recent studies have drawn attention to blood pressure variability as an additional risk factor beyond mean or usual BP. Blood pressure is circadian and decreases 10–20% during sleep. An abnormal BP decline during sleep ("extreme dipping") or a rise in nocturnal BP ("reverse dipping") have been correlated with silent infarctions and clinical ischemia. Orthostatic hypotension also causes stroke. It has also been suggested that reduction in blood pressure variability is important in hypertensive control to decrease stroke risk.

Diabetes Mellitus

Approximately one third of patients with ischemic stroke have diabetes and insulin resistance is seen in 50% of patients with TIA or ischemic stroke. The combination of diabetes and hypertension doubles stroke risk. There is no strong data that treatment of hyperglycemia or management to a specific glycosylated hemoglobin level reduces stroke risk.

Dyslipidemia

The correlation of total cholesterol or low-density lipoprotein cholesterol (LDL-C) to ischemic stroke is not entirely clear. High serum cholesterol appears to be correlated with ischemic stroke and inversely correlated with hemorrhagic stroke. Strong evidence in favor of the deleterious effects of high LDL-C is the effect of lipid lowering agents. Statin treatment decreases non-fatal first ischemic strokes, a 21% decrease per 1.0 mmol/dL (39 mg/dL) of LDL-C. The evidence is equivocal that statin use increases the incidence of hemorrhagic stroke.

Smoking

Cigarette smoking is a major modifiable risk factor. It is associated with progression of atherosclerosis, endothelial dysfunction, hypercoagulability and an inflammatory state. Smokers have a 2-fold risk of ischemic stroke and subarachnoid hemorrhage which is dose-responsive and declines with cessation. The process evolves over 20 years (decreased risk at least in women).

Alcohol

There is a dose-response relationship between intracerebral and subarachnoid hemorrhage to alcohol consumption. There is a "J" shaped association for ischemic stroke. The benefits of mild alcohol consumption are: 1. decrease of fasting insulin levels; 2. increased insulin sensitivity and improved lipid profile; and 3. increased adiponectin plasma levels.

Diet

Hypertension is reduced by weight loss, decreased sodium and increased potassium intake. The Dietary Approaches to

Stop Hypertension (DASH) which is low in saturated and total fats and rich in fruits, vegetables and low-fat dairy products decreases hypertension and reduces components of the metabolic syndrome. This diet also improves the lipid profile, lowers LDL-C and improves insulin sensitivity and may reduce stroke risk. There is evidence that a Mediterranean diet maybe beneficial in stroke is but it is less clear. Consumption of fish in older patients has been correlated with a lower prevalence of subclinical infarcts and MRI white matter hyperintense lesions.

Physical Activity

Physical activity may reduce the risk of both ischemic and hemorrhagic strokes. The beneficial effects of aerobic exercise are blood pressure reduction, weight loss and improvement of the metabolic syndrome.

Obesity

The body mass index (BMI) defines obesity. A BMI (body weight (kg) divided by the square of height (m²) between 18.5–24.9 (kg/m²) is normal. The risk of stroke-related mortality increases linearly when the BMI is greater than 25 kg/m². There is an obesity paradox where an increased BMI has been protective for both ischemic stroke and intracranial hemorrhage. Weight control has been associated with lowered blood pressure and increased insulin sensitivity which reduce the risk of stroke.

Probable Secondary Factors for Stroke Risk Prediction

The Metabolic Syndrome

The metabolic syndrome consists of abdominal obesity, insulin resistance, hypertriglyceridemia, low levels of HDL-C and hypertension. The criteria for the syndrome have been associated with an independent risk factor for ischemic stroke.

Sleep Disordered Breathing

Obstructive sleep apnea, which affects 5–15% of the general population, is the most common form of sleep disordered breathing seen in stroke patients. Cheyne-Stokes respiration and central sleep apnea are also frequently encountered. Sleep disordered breathing maybe associated with stroke because of associated obesity, hypertension and intermittent hypoxemia from obstructive sleep apnea. It also is associated with pulmonary vasoconstriction and consequent increased pulmonary artery pressure, diastolic cardiac dysfunction and atrial fibrillation. Obstructive sleep apnea patients have a higher recurrence rate of AF following cardioversion. CPAP therapy has been shown to decrease the incidence and mortality of stroke. Oxygen and mechanical ventilation have been utilized for central sleep apnea and central hypoventilation.

Lipoprotein (a)

Lipoprotein (a) is composed of a LDL-like particle and apolipoprotein (a). Its plasma concentration is primarily con-

trolled by the apolipoprotein gene on chromosome 6q26-27.

Apo(a) is synthesized by the liver. Its structure is similar to plasminogen and tissue plasminogen activator (tPA). It stimulates secretion of PA inhibitor-1 and competes with plasminogen for its binding site – both of which decrease fibrinolysis. It may also predict a risk of early atherosclerosis. There is an independent association of lipoprotein (a) with stroke and carotid atherosclerosis. It is not clear if lowering lipoprotein (a) levels independently lowers stroke risk.

Hyperhomocysteinemia

High homocysteine levels have been associated with myocardial infarction, atherosclerosis and stroke. Homocysteine levels are determined by genetic background, cystathionine β -synthase and methylenetetrahydrofolate reductase allelic variants, diet, folic acid, vitamin B level and renal function. Homocysteine increases thrombosis and is associated with venous thromboembolism. It is less clearly associated with atherosclerosis as demonstrated by studies of carotid intima-media thickness.

Clotting Disorder

Hereditary clotting defects such as prothrombin 20210 mutation, protein C and S dysfunction, factor V Leiden and antithrombin deficiency cause venous thrombosis rather than arterial stroke. There is evidence that they are relevant in young stroke patients. Immune-mediated clotting disorders include anticardiolipin antibodies, lupus anticoagulant and anti- β_2 glyco-protein-1 antibody. The antiphospholipid syndrome has multiple manifestations due to venous arterial and small vessel thrombosis. Antiphospholipid antibodies activate endothelial cells, monocytes and platelets with overproduction of tissue factor and thromboxane A₂. Lupus anticoagulant may be the strongest predictor of the ensuing APL syndrome. There is conflicting evidence in regard to anticardiolipin antibody elevation and ischemic stroke. Risk of subsequent stroke or a differential response to aspirin or warfarin has not been correlated with anticardiolipin antibodies. Lupus anticoagulant may be significant in young women.

Atherosclerosis

Atherosclerosis is the major mechanism underlying both thrombotic and embolic stroke. It is a pathologic process that affects arteries and is characterized by: the formation of plaques that consist of modified lipids, inflamed smooth muscle cells, endothelial cells, leukocytes and foam cells. An atherosclerotic plaque has a necrotic core and a fibrin cap. Regions of involved arteries calcify. Low-density lipoprotein (LDL) is a major kinetic and metabolic component of the process. Immune and inflammatory mechanisms have been shown to be increasingly important in both initiation and progression of atherosclerosis. Endothelial dysfunction, lipid

metabolism and lipid retention as well as reactivity to self-antigens are pivotal. Atherosclerosis is a chronic inflammatory condition.

Definition of Factors That Affect the Vascular Wall

Wall Shear Stress

1. Shear stress is the component of stress coplanar with a material cross section
2. Arises from the force vector component parallel to the cross section. Normal stress arises from the force vector perpendicular to the material cross section
3. Important for adaptation of endothelial cells, the initiation of atherosclerotic lesions and the induction and growth of aneurysms

Turbulent Flow

1. Turbulent flow is a flow regime characterized by chaotic property changes
2. Laminar flow loses kinetic injury due to the action of fluid molecular velocity
3. Import function for endothelial cell, adherences molecules and remodeling of arterial walls

Lipid Core

1. Core region of atherosclerotic plaques
2. Composed of lipid deposition with absence of cells and matrix proteins
3. Arises early in plaque formation after the induction of a fatty streak
4. A major detrimental development in ischemic vascular disease and emboli

Fibrous Cap

1. A layer of fibrous connective tissue which is thicker and less cellular than the normal intima
2. Surrounds the lipid core of atherosclerotic plaques
3. Composed of collagen and elastin, macrophages, smooth muscle cells, foam cells and lymphocytes
4. With expansion of the lipid core it ulcerates and ruptures causing at site thrombosis and distal embolization

Vascular Smooth Muscle Cells

1. Primary function is contraction and relaxation
2. They expresses contractile proteins, ion channels and signaling molecules that regulate contraction
3. Contraction:
 - a. Initiated by Ca^{2+} calmodulin phosphorylation of the light chain of myosin
 - b. Removal of Ca^{2+} from the cytosol and stimulation of myosin phosphatase initiates relaxation
4. α_1 receptors bind norepinephrine and cause vasoconstriction; α_2 receptor stimulation cause vasoconstriction. β_2 receptor agonism causes vaso-dilatation

Macrophage

1. Precursors are monocytes
2. Engulf apoptotic cells and pathogens as well as secreting effector molecules
3. They exhibit plasticity and adopt pro or anti-inflammatory phenotype dependent on environmental signals. Different subsets contribute to tissue homeostasis or disease pathogenesis

Glycoprotein

1. Proteins that contain oligosaccharide chains that are covalently attached to polypeptide side-chains
2. Glycosylation is the process that attaches the carbohydrate to the protein
3. Secreted extracellular proteins and their extracellular segments are often glycosylated
4. They are important integral membrane proteins which are important in cell-cell interactions
5. Functions include:
 - a. As transport molecules
 - b. Immunology
 - c. Cell attachment recognition sites
 - d. Receptor
 - e. Affect protein folding
 - f. Hemostasis and thrombosis

Oxidized Low Density Lipoprotein Cholesterol

1. Oxidative modification of low density lipoproteins are important for foam cell formation and possibly the initiation or acceleration of atherosclerosis
2. Increased plasma low-density lipoprotein levels cause an increased rate of entry of low density lipoprotein into the intima. Low density lipoprotein undergoes oxidative modification by endothelial, smooth muscle cells or macrophages
3. Oxidized low density lipoproteins are recognized by scavenger receptors and can give rise to foam cells
4. Effects of oxidized low density lipoprotein:
 - a. Cytotoxic to endothelial cells in culture
 - b. Inhibit vasodilation by nitric oxide
 - c. Mitrogenic for smooth muscle cells and macrophages
 - d. Immunogenic

Endothelial Cell Adhesion Molecules (CAMs)

1. Cell adhesion molecules are located on the cell surface and bind with other cells such as the extracellular matrix
2. They are trans-membrane proteins with three domains:
 - a. An intracellular domain that interacts with the cytoskeleton
 - b. Transmembrane domain
 - c. Extracellular domain that interacts with cell adhesion molecules of the same kind (homophilic binding or with other endothelial cell adhesion molecules, heterophilic binding) as with the extracellular matrix

d. The important endothelial cell adhesion molecules for vascular disease are calcium-dependent:

i. Integrins:

1. A major class of receptor within the extracellular matrix
2. Mediate cell-extracellular matrix interactions with collagen, fibrinogen, fibronectin and vitronectin
3. Essential links between the extracellular environment and intracellular signaling pathways

ii. Cadherins:

1. Homophilic Ca^{2+} dependent glycoproteins
2. Concentrated at intermediate cell junctions
3. Link to the actin filament network through linking proteins (catenins)
4. Their extracellular domains are important for cell adhesion

iii. Selectins:

1. Heterophilic endothelial cell adhesion molecules
2. Bindmycins
3. E-selectin (endothelial); L-selectin (leukocyte); P-selectin (platelet)
4. Pivotal in transmigration of inflammatory cells through cerebral blood vessels into brain parenchyma

Monocytes

1. Circulating blood leukocytes that are pivotal in the inflammatory response as part of the innate immune response
2. Functions include:
 - a. Replenishment of resident macrophages
 - b. Respond to chemokines from the site of inflammation and then differentiate/divide into macrophage and dendritic cells as part of the immune response
 - c. Produced in the bone marrow from hematopoietic stem cells
 - d. In tissue, mature into different type of macrophages. Approximately 50% are held in reserve in the spleen

Foam Cell (Lipid Laden Cells)

1. Lipoprotein aggregate within the intima of blood vessels
2. Macrophages and endothelial cells generate free radicals that oxidize lipoproteins
3. Macrophages engulf the oxidized low-density lipoproteins by endocytosis utilizing scavenger receptors
4. Oxidized low density lipoproteins in macrophages and other phagocytic cells become foam cells which form the fatty streaks of the atheroma in the tunica intima during the atherosclerotic process

Internal Elastic Lamina

1. Thicker in arteries than arterioles and very thin in veins
2. Separates the intima and media of an artery wall
3. A restrictive barrier to macromolecular permeability

4. Holes within the internal elastic lamina allow for permeability of diffusible vasoactive molecules and the interface of endothelial cell projections with the smooth muscle of the vascular wall

5. Smooth muscle cells secrete elastin that forms sheets or lamellae which increase with age and form the internal elastic lamina

External Elastic Lamina

1. Found in the tunica adventia
2. The lamina is composed of collagen fibers secreted by fibroblasts
3. The external elastic lamina in at the inner boundary of the tunica adventia

Cholesterol Crystallization (Transformation)

1. Cholesterol crystallizes as it accumulates in the vascular wall
2. Transforms from a liquid to a solid state and expands
3. Expansion of the crystals is a mechanism of vulnerable plaque disruption
4. Cholesterol crystals induce inflammation in the arterial wall

Cholesterol Crystals

1. Trigger for inflammation in blood vessel walls
2. Activate "inflammasome" complex within immune cells that release inflammatory mediators (chemokines and cytokines)
3. Activates the innate immune system

Cholesterol Crystal Embolization

1. Refers to embolization of the contents of a ruptured atherosclerotic plaque from a more proximal larger-caliber artery to distal small to medium-sized arteries
2. End organ damage is both by ischemia and the induced inflammatory response
3. Systemic vessel embolization (cholesterol embolization syndrome) is characterized by showers of microemboli over time
4. Arterio-arterial thromboembolism is usually characterized by an abrupt release of emboli
5. Cholesterol emboli in the central nervous system often manifest as amaurosis fugax (fleeting blindness from retinal arterial occlusion by a Hollenhorst plaque) or an ischemic lesion in the cerebral circulation
6. Usual size of emboli 100–200 μm

Arterial Spasm (Cerebral)

1. Diffuse or focal narrowing of cerebral blood vessels
2. The pathophysiology is complex and not fully understood but includes molecular mechanism that involve smooth muscle contraction, endothelial dysfunction, and inflammatory changes

Plaque Histology

1. Type I
 - a. An increase of macrophages with scattered foam cells
2. Type II
 - a. Layers of macrophage foam cells and lipid-laden smooth muscle cells that constitute fatty streaks on the artery luminal surface
3. Type III
 - a. Lipid laden cells with scattered extracellular lipid droplets
 - b. Disruption of smooth muscle cells
 - c. Extracellular lipid
 - d. Intermediate stage between type II and type IV lesions
4. Type V
 - a. Contains a lipid core and layers of fibrous connective tissue
 - b. Calcification of a type V lesion is classified as Type V
5. Type VI
 - a. Contains a lipid core with a fissure, hematoma and thrombosis with minimal lipid as calcium

Adaptive (Blood Vessel Wall)

1. In vitro studies demonstrate:
 - a. Stretch may affect cell proliferation
2. Smooth muscle cells and endothelial cells also demonstrate proliferation
3. There may be a phenotypic switch in smooth muscle cells from contractile cells to synthetic cells
4. Vascular remodeling is an adaptive response to variations in wall shear stress and hemodynamic factors
5. A redistribution of the structural components of the ECM has been shown experimentally that involves up-regulation of metalloproteinase-2 and its enzymatic activity

Type I and Type III Collagen

1. Type I collagen is the most abundant collagen:
 - a. Alpha-1 type, collagen is a protein encoded by the COL1A1 gene
 - b. Component of the tunica media of cerebral vessel walls and the internal and external elastic lamina
 - c. Mutations in the COL1A1 gene are associated with Ehlers-Danlos syndrome, osteogenesis imperfecta and osteoporosis
2. Collagen Type III:
 - a. Encoded by COL3A1 gene on chromosome 2
 - b. Distributed in extensible connective tissues, skin, lungs and the vascular system
 - c. It is a fibrous scleroprotein
 - d. Mutation are associated with Ehlers-Danlos type IV and aortic and arterial aneurysms

Caspase

1. Cysteine dependent aspartate-directed proteases are a family of cysteine proteases
2. Major functions:

- a. Programmed cell death (apoptotic caspases)
 - i. Initiate caspases that cleave inactive proforms of effector caspases (CASP2, CASP8, CASP9, CASP10)
 - ii. Effector caspases (CASP3, CASP6, CAS7) that cleave other protein substrate within the cell as a component of the apoptotic process
 - iii. Maturation of red blood cells and myoblasts
 - iv. Maturation of lymphocytes

NLRP3

1. A cyto cytosolic protein complex important for early inflammatory responses
2. Processes interleukin-1 β (IL-1 β) to its active form
3. Activates Caspase-1 pathway

Interleukin-1 β

1. A cytokine protein that is cleaved by Caspase-1 to activate the protein
2. Produced by activated macrophages
3. Functions:
 - a. Mediator of the inflammatory response
 - b. Apoptosis
 - c. Cell proliferation
 - d. Induces cyclooxygenase-2 in the CNS

Mechanism of Factors That Affect the Vascular Wall*Lipoprotein Accumulation in the Artery Wall*

1. LDL is rapidly transported across an intact endothelium and is trapped by fibers and fibrins secreted by artery wall cells. LDLs are associated with the extracellular matrix of the sub-endothelial space. Early lesions develop at specific sites possibly due to wall shear stress and hemodynamic factors
2. The cells of the arterial wall secrete oxidation products that initiate lipid oxidation of the LDL that are trapped in the sub-endothelial space. The first stage of oxidative modification occurs prior to the recruitment of monocytes with little modification of Apolipoprotein B monocytes that are recruited to the lesion site, convert to macrophages and further oxidize the lipids. During this process the LDL receptor is modified such that there is LDL uptake by scavenger receptors or oxidized LDL receptors. These receptors are not regulated by the cholesterol content of the cell, accumulate cholesterol in their cytoplasm and are known as foam cells. They are the basis of the fatty streak of the arterial wall
3. Oxidation of LDL and the induction of arterial wall inflammation. Mildly oxidized lipids induce monocytes to bind to the endothelial cell surface by the usual mechanisms of binding, tethering, attachment and activation. The chemokine for monocytes MCP-1 has been found in atherosclerotic lesions. Mildly oxidized LDLs induce endothelial cells to secrete MCP-1 and monocyte stimulating

factor. Mildly oxidized LDL induces gene transcription for monocyte adherence, but not for lymphocyte or neutrophil adherence. The mildly oxidized LDL induces cAMP by a G-protein-mediated process that decreases the expression of ELAM-1 (endothelial-leukocyte adhesion molecule-1), the receptor for neutrophils. There is some experimental evidence that HDL may protect against LDL oxidation.

4. Lesion Progression

Arterial endothelial cells interact with monocytes by a complicated process that involves gap junction protein connexin 43, increased production of matrix molecules, interleukin-1 and interleukin-6. Monocytes and macrophages which have been attracted to the lesion site secrete smooth muscle growth factor and plate-derived growth factor which is a mechanism for the migration of smooth muscles into the lesion. Oxidized lipids stimulate the release of interleukin one (IL-1) from macrophages which is also a growth factor for smooth muscles.

LDL oxidation produces lysophosphatidylcholine that has several important functions in the cause of atherogenesis that include: a. chemo attraction for monocytes and T-lymphocytes; b. induction of vascular adhesion molecule-1 (VCAM-1) and intercellular adhesion molecule-1 (ICAM-1); c. increased levels of platelet derived growth factor 1 and heparin-binding epidermal growth factor in endothelial and smooth muscle cells. Highly oxidized LDL inhibits endothelial cell migration, impairs the repair of ulcerated plaques and is toxic to macrophages all of which amplify the inflammatory process. The atherosclerotic lesion expands toward the adventitia through the media until a critical point is reached which starts to narrow the lumen. The lesions grow by: a. the entrance of mononuclear cells; b. the proliferation of monocytes, macrophages and smooth muscle cells; c. the production of increased extracellular matrix and d. the accumulation of extracellular lipid in a necrotic core.

5. Calcification of the Arterial Wall

Experimental evidence suggests that a soft plaque with an area of weakness due to inflammation when superimposed on calcified arterial wall causes: a. a difference in physical properties of the tissue interface; b. rupture from the pulsatile forces of arterial blood pressure. Recent observations suggest that a cell with characteristics of a pericyte is found in large and medium-sized arteries and is responsible for vascular calcification. These calcifying vascular cells express similar genes to those that are expressed during bone formation. They are induced by transforming growth factor- β (TGF- β) and oxysterol which are present in the fatty streak and atherosclerotic lesions. The calcific changes in the arterial wall change its physical properties and are a factor in plaque ruptures. Rupture most often occurs in the shoulder region of the lesion.

6. Differential Biologic Effects from the Degree of Oxidation of LDLs

Mildly oxidized lipids from LDLs induce the expression of tissue factor from vascular endothelial cells. Highly oxidized LDLs are cytotoxic and mildly oxidized LDLs are not. Specific oxidized lipids (possibly oxidized phospholipids) activate the NF κ B like transcription factor (pivotal for inflammation) and the genes induced by mildly oxidized LDLs.

Immune Mechanisms in Atherosclerosis

1. There is a great expansion of dendritic cells (antigen presenting) and lymphocytes in the adventitia of atherosclerotic arteries. Inflammatory cells, macrophages, dendritic cells, foam cells and lymphocytes are found in the intima of atherosclerotic lesions. Underneath these lesions there are clusters of adventitial leukocytes that resemble tertiary lymphocytic tissue.
2. During the progression of the atherosclerotic lesion endothelial nitric oxide production is decreased and there is an increase of reactive oxygen species and advanced glycation end products (AGE). The latter are formed by non-enzymatic modification of proteins by reducing sugars. This alteration in glucose and lipid metabolism leads to the increased production of aldehydes and the formation of AGEs. AGEs are important in the cross-linking of proteins of the extracellular matrix. AGE receptors (RAGE), a member of the immunoglobulin superfamily are expressed on endothelial cells, smooth muscle cells, monocytes and lymphocytes. Activation of the RAGE receptor causes: a. oxidative stress; b. endothelial dysfunction; c. increases proinflammatory cytokines and tissue factor; d. up regulates expression of adhesion molecules all of which accelerate atherosclerosis.
3. Reactive Oxygen Species

Production of reactive oxygen species occurs throughout the course of atherogenesis. They induce activation of the vascular endothelium and components of the immune system. Reactive oxygen species from vascular endothelial cells are generated from: a. nicotinamides adenine dinucleotide phosphate (NADPH); b. mitochondrial respiratory chain dysfunction; c. xanthine oxidase; d. lipoxygenase; e. nitric oxide synthases. Pivotal is superoxide generation from monocytes/macrophages and vascular endothelial cells.

Superoxide activates smooth muscle mutagenic signaling pathways while NADPH-induced superoxide causes enhanced availability of released ADP and increased recruitment of platelets. Reactive oxygen species production may overwhelm antioxidant systems that include superoxide dismutase, catalase, glutathione peroxidase and glutathione reductase. This produces oxidative stress that damages nucleic acids, lipids, proteins and membranes.

The role of the complement system, heat shock proteins and toll-like receptors in the generation of atherosclerosis is being actively pursued. The immune response in atherogenesis is predominantly Th1.

Summary of the Mechanisms in the Development of Atherosclerosis

1. Occurs in large arteries and is characterized by local lipid accumulation. It is partially determined by vessel geometry flow and oscillatory wall shear stress that induces a chronic inflammatory state
2. Low density lipoproteins are transported into the subendothelial arterial space and are differentially oxidized by vascular cells
3. Oxidized LDLs trigger overexpression of adhesion molecules, chemokines, cytokines and growth factors that induce chronic arterial wall inflammation, cell proliferation and apoptosis
4. Many of the biological effects of mildly oxidized LDLs are mediated by transcription factors (NF κ B-like) and subsequent proinflammatory gene expression
5. Oxidized LDLs exert a biphasic effect on the redox-sensitive transcription factor NF κ B. It's up regulation activates proinflammatory gene expression but at high concentration may have an immunosuppressive effect
6. Inflammatory mechanisms regulate all phases of atherosclerosis that include immune cell function, activation of the vascular epithelium and alteration of metabolic parameters

The Arterial Wall and Aneurysms

Overview

The arterial blood vessel wall is composed of the tunica intima that is lined by endothelium, the media and the adventitia. The tunica media consists of smooth muscle cells and the extracellular matrix proteins, collagen, elastin and glycosaminoglycans. The adventitia is made of connective tissue, nerve fibers and the vasa vasorum. The internal elastic membrane separates the tunica intima from the tunica media. There is no external elastic lamina in cerebral blood vessel walls.

Vessel wall inflammation may occur from several different mechanisms. The proinflammatory cytokine tumor necrosis factor- α (TNF- α) is pivotal in many pathologic conditions. It damages structural components of the vessel wall that include the endothelium, smooth muscle cells and the internal elastic membrane. It induces inflammatory processes in the vessel wall that include migration of monocytes as well as inhibiting cell proliferation that inhibits cell repair. It also activates matrix metalloproteinases that degrade elastin and collagen which are major structural components of the arterial wall.

Vessel wall inflammation may also be induced by carbon monoxide. Carbon monoxide has a higher affinity for hemoglobin than oxygen which decreases the oxygen carrying capacity of blood that in turn causes hypoxemia induced inflammation. The putative pivotal cause of inflammation of the vessel wall is hemodynamic stress (parameters of shear

vessel stress that lead to degradation of the extracellular matrix and apoptosis of smooth muscle cells (the primary origin of the proteins of the extracellular matrix). Tissue infiltration of monocytes and macrophages release proinflammatory cytokines and chemokines (MCP-1) that amplify and recruit inflammatory cells as well as release matrix metalloproteins. Macrophages are found in a high percentage of surgical aneurysms. M1 (proinflammatory macrophages) predominate in ruptured aneurysms.

In early stages of aneurysm formation, smooth muscle cells migrate into the intimal layer and proliferate which then forms myointimal hyperplasia. Over time they undergo phenotypic differentiation from contracting cells to proinflammatory cells. In the process they change morphologically from compact bands to spider-like cells. They secrete less collagen and are a cause of a thinned media. There is evidence that the phenotypic switch noted in aneurysmal smooth muscle cells (SMCs) is induced by TNF- α which induces genes for MCP-1, MMPs, vascular cell adhesion molecule 1 and IL-1 β . Mast cells are detected in aneurysm walls and contribute to arterial wall inflammation during aneurysm formation by the release of proinflammatory mediators.

Cytokine mechanisms in arterial wall inflammation are:

1. TNF- α :
 - a. SMC phenotype modulation
 - b. Activation of metalloproteinases (MMPs)
 - c. Decreased expression of tissue inhibitor metalloproteinase-1
 - d. Proapoptotic effects through FAS
2. IL-1 β :
 - a. Induced in early stages of aneurysm formation
 - b. Causes SMC apoptosis

Both chemokines (MCP-1 and others) as well as complement are involved in the inflammatory wall mechanisms of aneurysm formation. Reactive oxygen species are being studied in regard to their role in direct endothelial cell injury, SMC phenotype switch of SMC and the up-regulation of genes that control chemotactic cytokines, adhesion molecules and activation of metalloproteinases (MMPs).

Hemodynamic Stress

Hemodynamic stress is a major initiating factor for the arterial wall structural modulation that occurs with aneurysm formation. Hemodynamic stress is greater at arterial junctions, bifurcations or at areas of vascular angulation. Hypertension, loss of autoregulation and increased blood viscosity may also be synergistic with other factors that cause hemodynamic stress. It has been postulated that hypertension may compromise the vasa vasorum which supply the tunica media of the vascular wall. The effects of wall shear stress (WSS) are complicated and while there is evidence that high WSS may be important in the initiation of aneurysm formation, low WSS may be involved in aneurysm rupture by inducing apoptosis of endothelial cells and structural remodeling of the arterial wall. It has also been suggested that low WSS triggers

the growth and rupture of large atherosclerotic aneurysms by an inflammatory mechanism while high WSS induces MMP activation, smooth muscle cell apoptosis and medial thinning in small aneurysms. There is accumulating evidence that endothelial dysfunction and vessel wall remodeling and inflammation are induced by WSS.

The Effects of Wall Shear Stress

1. Occurs at bifurcation, junctions and areas of acute vessel angulation
2. Induction of inducible nitric oxygen synthase (iNOS) produces peroxynitrate that is cytotoxic
3. Stimulation of endothelial production of matrix metalloproteinase
4. Smooth muscle cell injury in the tunica media from increased transmural flow gradients
5. WSS induced injuries are a component of:
 - a. Endothelial cell damage
 - b. Degradation of the internal elastic membrane
 - c. Thinning and phenotypic change of SMC in the tunica media

Collateral Circulation

Overview

The collateral circulation is a major determinant of the functional outcome following a stroke. It is a major factor in preserving cerebral perfusion by recruiting blood flow to the ischemic territory. The anatomical features of the collateral circulation are also an important determinant if the stroke will be territorial or border-zone. Cerebral arterial autoregulation is the primary mechanism that maintains CBF at 50 ml/100 grams/minute. Approximately 90% of blood is in the gray matter. Autoregulation in general is maintained between 50 and 150 mm Hg. There is some autoregulatory control by means of the locus coeruleus and the adrenergic system. There appears to be less sympathetic innervation of the posterior cerebral arteries that perfuse the occipital lobe.

Cerebral blood flow is determined by vascular resistance, perfusion pressure and autoregulation. Cerebral perfusion pressure is the difference between the mean arterial pressure minus the sum of the CSF pressure (intracranial pressure) and jugular venous pressure. Blood pressure, metabolic activity and neurogenic factors may modify autoregulation. The effectiveness of the collateral circulation for compensation of ischemia of an arterial territory depends on: 1. anatomical variation; 2. systemic arterial pressure; 3. age; 4. rate of development of occlusive disease. During large artery occlusion the Circle of Willis is the main effector of the collateral circulation. Following occlusion of the carotid artery the drop of perfusion pressure distally generates a pressure gradient between neighboring arterial territories that change the rate and fraction of blood flow which may occur in a matter of seconds. Trans cranial doppler (TCD) monitoring during carotid

endarterectomy has demonstrated an increase in contralateral anterior cerebral artery blood flow velocity within a few heart beats. In small cortical arterioles of 50–250 microns, the rapid decrease in intraluminal pressure relaxes smooth muscle which causes vasodilation and a fall of vascular resistance. A component of the cerebral collateral arterial network is in the pial leptomeninges. The extent of this pial circulation varies among individuals and impacts upon the severity of stroke.

Cerebral Collateral Circulation

The importance of the collateral circulation is underscored by: 1. collateral cerebral blood flow may have a greater impact on ultimate infarct volume than time from ictus to thrombolytic treatment; 2. pretreatment collateral status is correlated with infarct growth; 3. collateral status may predict the extent and location of cerebral infarcts.

Internal Arterial Connections

1. Internal arterial connections are internal carotid artery to basilar and posterior communicating arteries
2. Circle of Willis anterior cerebral arteries connected by the anterior communicating artery
3. Anastomosis between the internal carotid artery and the vertebral and basilar artery from embryonic vessels include:
 - a. Persistent trigeminal (.1–1%)
 - b. Persistent otic (rare occurrence)
 - c. Persistent hypoglossal (.1–.25%)
 - d. Proatlantal artery (rare occurrence)
4. Posterior cerebral and superior cerebellar artery anastomosis with the tectal rami (tectal plexus)
 - a. Connect supra and infratentorial arteries
5. Anastomosis between the terminal branches within and between the arterial territories of the ACA/MCA and the MCA/PCA
6. Leptomeningeal anastomosis:
 - a. Pia plexus-adjacent arterioles from same or adjacent arteries (branches of major cerebral arteries)
 - b. Cerebral and meningeal arteries
7. Extranial Anastomoses
 - a. Orbital plexus – connections of the ophthalmic and middle meningeal, maxillary and ethmoidal arteries
8. Rete mirabile caroticum – anastomosis between the internal and external carotid arteries

Anatomical Variants of the Circle of Willis

1. Absent posterior communicating arteries bilaterally
2. Absent A1 segment of anterior cerebral artery
3. Bilateral fetal origin of the posterior cerebral arteries (carotid artery to PCA)
4. Absent anterior or posterior communicating arteries

*Anatomic Variants of the Major Intracranial Arteries***Anterior Cerebral Artery (ACA)**

1. Azygos ACA (unpaired ACA: 0–5%)
2. Medial ACA (3–22%)
3. Bihemispheric ACA (2–7%)
4. Persistent POA (rare occurrence)

Middle Cerebral Artery

1. Duplicated (.7–2.9%)

Posterior Cerebral Artery (PCA)

1. Fetal PCA (20–30%)

Evolving Evaluation of Biomarkers in Acute Cerebrovascular Disease

At present there is no single or panel of biomarkers that is sensitive or specific enough for the diagnosis, stratification or usefulness in management of acute ischemic stroke. They reflect different components of the ischemic cascade. They do hold promise for 1. identifying patients at high risk for vertebral ischemic vascular disease; 2. stratifying the risk of reperfusion hemorrhage; 3. predicting the volume of penumbra tissue (salvageable); 4. prognosis of the ictus; 5. serve as a quantifiable surrogate measurement in clinical trials.

Markers of the Ischemic Cascade

The measurement of protein blood biomarkers released from neurons and glia following ischemic stroke is due to the breakdown of the blood-brain barrier. The early processes underlying the ischemic cascade are: failure of ion pumps; cortical spreading depression; glial activation; excitotoxicity of glutamate; neuronal injury and death; oxidative stress and release of inflammatory mediators.

1. Neuronal markers of cell death include:
 - a. Neuron specific enolase
 - b. Heart fatty acid binding protein
 - c. NMDA receptor antibodies
 - d. Virus-like protein
2. Specific glial activation markers include:
 - a. S100B:
 - i. Calcium-binding protein expressed by astrocytes and oligodendrocytes
 - ii. Predicts risk for hemorrhagic transformation after tissue plasminogen activator (tPa), successful clot lysis, infarct volume and prognosis
 - iii. Delayed time course and lack of specificity decrease its utility
 - b. Glial fibrillary acidic protein:
 - i. Intermediate filament
 - ii. Primarily expressed by astrocytes
 - iii. Differentiates ICH versus ischemic stroke
 - c. Myelin basic protein:

- i. Myelin sheath protein
 - ii. Diagnosis of early stroke
3. Lipid Peroxidation Markers:
 - a. Oxidized low density lipoprotein
 - b. Malondialdehyde
4. Markers of Hemostasis and Endothelial Dysfunction:
 - a. Thrombomodulin
 - b. D-dimer
 - c. Fibrinogen
 - d. Fibronectin
 - e. Von Willebrand factor
 - f. Asymmetric dimethylarginine
5. Markers of Inflammation:
 - a. C-reactive protein
 - b. Matrix metalloproteinase
 - c. IL-6
 - d. TNF-alpha
 - e. Cell adhesion molecules
 - f. PARK-7
6. Astrocytic Markers:
 - a. S-100B
 - b. Glial fibrillary acidic protein

Non-Specific Markers of Inflammation

1. C-reactive protein:
 - a. An acute phase protein
 - b. Prognosis of ischemic stroke
 - c. Risk of recurrent stroke
2. Matrix metalloproteinase 9:
 - a. A zinc-binding proteolytic enzyme
 - b. Affects BBB integrity and possible risk of HT
3. IL-6 and TNF- α :
 - a. Released from invading leukocytes, activated microglia and monocytes
 - b. Inflammatory cytokine
 - c. May initiate apoptosis
4. Adhesion molecules (VCAM, sICAM):
 - a. Immunoglobulin super family
 - b. Diagnosis, stratification, prognosis
 - c. Poor specificity
5. Oxidative Stress Markers:
 - a. PARK-7:
 - i. Redox-sensitive molecular chaperone
 - ii. Diagnosis of ischemic stroke
 - b. Oxidized low density lipoprotein:
 - i. Lipid peroxidation product
 1. Stroke prognosis
 - c. Malondialdehyde:
 - i. Lipid peroxidation product
 - ii. Diagnosis and prognosis of stroke
 - d. F₄-neuroprostane:
 - i. Derived from free radical-induced oxidation of docosahexaenoic acid (fatty acid highly concentrated in brain)

Markers of Neuronal Injury and Death

1. Neuron specific enolase (NSE):
 - a. An intracytoplasmic dimer glycolytic enzyme
 - b. Reflects infarct volume and prognosis
2. Heart fatty acid binding protein:
 - a. Cytosolic protein component of intracellular fatty acid transport
 - i. Early diagnosis of ischemic stroke
 - b. Released following neuronal injury
3. N-methyl-D-aspartate (NMDA) receptor antibodies:
 - a. Relatively neuron specific
 - b. Is an excitotoxic glutamate receptor
 - c. Decreased utility due to time course of the ischemic cascade

Endothelial and Hemostatic Markers

1. Components of the ischemic cascade:
 - a. Hypoxic endothelial cells up-regulate cell adhesion molecules
 - b. Subendothelial matrix proteins are exposed to the blood stream
 - c. Platelet surface receptor bind to endothelial von Willebrand factor
 - d. Platelets adhere to collagen which causes decreased blood flow and are a component of delayed ischemia
2. Following ischemia there is an increase of soluble glycoprotein VI which facilitates platelet adhesion and thrombus formation
3. D-dimer:
 - a. Fibrin degradation product
 - b. Predicts early recurrent ischemic lesions and prognosis
4. Plasminogen activator inhibitor-1:
 - a. Encoded by the SERPINE 1 gene on chromosome 7q21.3-q22
 - b. A serine protease inhibitor (serpin)
 - c. Produced by endothelial cells and also by adipose tissue
 - d. Inhibits matrix metalloproteinases
 - e. The principal inhibitor of tissue plasminogen activator (tPA) and urokinase (uPA), the activators of plasminogen and fibrinolysis
 - f. Predicts HT after tPA
5. Thrombomodulin:
 - a. CD141; endothelial glycoprotein
 - b. An integral membrane protein expressed on the surface of endothelial cells
 - c. Cofactor for thrombin's activation of Protein C
 - d. May be a procoagulant by inhibiting fibrinolysis by cleaving thrombin-activatable fibrinolysis inhibitor
 - e. Predicts ischemia prognosis
6. Fibronectin:
 - a. A glycoprotein of the extracellular matrix
 - b. Binds membrane spanning proteins similar to integrins
 - c. Binds collagen, fibrin and heparin sulfate (proteoglycans)

- d. Major role in cell adhesion
- e. Deposited at the site of injury; component of the blood clot
- f. Predicts HT after tPA
7. Fibrinogen:
 - a. Plasma glycoprotein that the serine protease thrombin cleaves to insoluble fibrin strands:
 - i. Factor XIII crosslinks fibrin strands
 - ii. Factor XIIIa stabilizes the fibrin further by incorporating into the clot:
 1. Thrombin activator fibrinolysis inhibitor
 2. α -2-antiplasmin
 - b. Leukocyte – endothelium interaction
 - c. Platelet aggregation
 - d. Predicts ischemia prognosis
8. von Willebrand Factor:
 - a. Glycoprotein
 - b. Synthesized in vascular endothelium, megakaryocyte, subendothelial connective tissue
 - c. Domains that bind to factor VIII and the GP16 platelet receptor and A3 domain of collagen
 - d. Thrombin cleaves vWB from factor VIII stress (fast flowing blood)
 - e. Increased in atrial fibrillation
9. Thrombin activatable fibrinolysis inhibitor (TAFI):
 - a. A carboxypeptidase that hydrolyzes C-terminal peptide bonds
 - b. Decreases clot lysis
 - c. Predicts HT after tPA

Biomarkers Predictive of Hemorrhage

1. After tPA:
 - a. Plasminogen activator inhibitor-1 (PAI-1)
 - b. D-dimer
 - c. Thrombin-activatable fibrinolysis inhibitor
 - d. Combination of admission PAI-1 <21.4 ng/mL and TAFI >180% had a sensibility of 75% and a specificity of 98%
 - e. Biomarkers predictive of hemorrhagic transformation following tPA treatment
 - i. Elevated baseline vascular adhesion protein-1

Possible Future Markers of Ischemia and Hemorrhage

1. Asymmetrical dimethyl arginine (ADMA):
 - a. A metabolic by-product of protein modification and related to L-arginine
 - b. Interferes with L-arginine in the production of nitric oxide
 - c. Its concentration is increased by oxidized LDL-C
 - d. Increased ADMA levels cause decreased nitric oxide production and decreased vasodilation
 - e. A marker of endothelial dysfunction
 - f. Possible marker of subclinical ischemic injury

2. Atrial Natriuretic Peptides (ANP) and brain natriuretic peptides (BNP):
 - a. Vasoactive polypeptide hormones primarily secreted by cardiomyocytes
 - b. Primary function is homeostatic control of water sodium and potassium
 - c. Released in response to atrial stretch and stimulation of β -adrenoreceptors
 - d. ANP released after stroke: source could be heart or brain; elevated after stroke; may predict stroke mortality
 - e. BNP is elevated after ischemic stroke and SAH
3. Lipoprotein associated phospholipase-A₂ (platelet-activating factor acetyl hydrolase PAF-AH):
 - a. PLA2G7 gene
 - b. Travels with LDL-C
 - c. Produced by inflammatory cells
 - d. Hydrolyzes oxidized phospholipids in LDL-C
 - i. Catalyzes the degradation of PAF
 - e. Both brought to plaque by LDL-C and synthesized de novo in the plaque by T-cells, mast cells and macrophages
 - f. Associated with coronary heart disease and stroke
 - g. Predicts first and recurrent stroke following TIA
4. Free hemoglobin:
 - a. Serum free hemoglobin which contain peaks of α and β chains
 - b. Associated with stroke but not its severity
5. Calcium levels:
 - a. Are elevated between 3 and 4 days following stroke
 - b. Failure of calcium antagonists to alter functional recovery
 - c. Predictive of outcome of ischemic stroke at 3 months
6. Nucleoside diphosphate kinase A:
 - a. Protein kinase
 - b. Catalyzes the exchange of phosphate groups between different nucleoside diphosphates
 - c. Increases in the CSF following ischemic stroke
7. Adiponectin:
 - a. Fat derived protein
 - b. Low levels noted in obese patients
 - c. Anti-inflammatory and antiatherogenic
 - d. Predicts ischemic stroke mortality but not stroke
8. Copeptin:
 - a. A component of pro-vasopressin which consists of neurophysin II and copeptin
 - b. Arginine vasopressin (AVP) release:
 - i. An early physiological response to cerebral ischemia
 - ii. May correlate with stroke severity
 - c. Copeptin released in an equimolar ratio to AVP and is easier to measure and more stable
 - d. An independent predictor of functional outcome and mortality. Improves the prognostic accuracy of the NIHSS
 - e. Copeptin mirrors stress better than cortisol

Differential Diagnosis of Ischemic Stroke Subtypes with Plasma Biomarkers

1. Embolic or thrombotic occlusion of large arteries is the major cause of stroke. Less usual causes include:
 - a. Obstruction of small perforating vessels (diabetes, hypertension, dyslipidemia)
 - b. Arterial dissection
 - c. Arteritis (immune)
 - d. Infection
 - e. Venous disease
 - f. Hyperviscosity
 - g. Anemia
2. Approximately 35% remain cryptogenic after extensive evaluation

The Combined Biomarkers Brain Natriuretic Peptide (BNP) and D-Dimer (DD) Are Predictors of Cardiac Embolic Stroke

1. BNP concentrations are increased with systolic and diastolic dysfunction. The left atrium is the main source of BNP in atrial fibrillation
2. Patients with atrial fibrillation and clinical evidence of stroke have higher levels of BNP than AF alone
3. High levels of DD are an independent predictor of cardioembolic stroke
4. The combination of biomarkers and clinical findings had a sensitivity of 66.5% and a specificity of 91.3% for cardioembolism

Biomarker Panels for Ischemic Stroke

1. Astroglial protein S100
2. β -type neurotrophic growth factor
3. von Willebrand factor (vWB)
4. Matrix metalloproteinase-9 (MMP-9)
5. Monocyte chemotactic protein-1:
 - a. Test sensitivity of 91% and specificity of 97% in:
 - i. 223 stroke patients (ischemic stroke, subarachnoid hemorrhage and ICH)
 - ii. Sample taken within 12 hours
6. Panel consisting of BNP, S100b, C-reactive protein and D-dimer:
 - a. Sample taken from 30 patients with acute deficits within 6 hours
 - i. Sensitivity of 81% and a specificity of 70% for the diagnosis of ischemic stroke
7. Prospective multicenter trial utilizing: D-dimer, BNP, MMP-9 and S100B:
 - a. 1100 patients enrolled for probable stroke within a 3 year period
 - b. Only moderate ability to differentiate between ischemic stroke, ICH and mimics
 - i. Sensitivity of 86% and specificity of 37% in separating stroke patients from mimics

Biomarkers for the Differentiation of ICH from Ischemic Stroke

1. 6 hours after onset:
 - a. GFAP was detectable in 81% of ICH patients and 5% with IS
 - b. 2.9 ng/L of GFAP provided a sensitivity of 79% and a specificity of 98% for ICH
2. A study of 776 patients with IS and 139 with ICH studies at 6 hours post ictus:
 - a. S100B and RAGE (receptor for advanced glycation end products)
 - i. Differentiated ICH from IS acutely
3. ICH had significantly lower ApoC-I and ApoC-III lipoproteins than IS (n of 15 and 16 respectively)
 - a. ApoC-III had a sensitivity of 94% and a specificity of 87% in differentiating ICH from IS

Markers for Hemorrhagic Transformation After Thrombolysis

Disruption of the blood-brain barrier (BBB) is a major determinant of hemorrhagic transformation (HT) after thrombolysis. Molecular components of the blood-brain barrier (MMP-9 and fibronectin) in addition to astroglial and coagulation proteins are pivotal. MMP-9 plasma levels prior to thrombolytic therapy predict hemorrhagic transformation in a graded manner. Fibronectins form cell to cell to matrix adhesive interactions. It is synthesized by endothelial cells and high circulation levels suggest endothelial damage and consequent hemorrhagic transformation: a cut-off value of pretreatment levels of c-Fn of 3.6 $\mu\text{g/ml}$ and MMP-9 at 140 ng/ml was predictive of hemorrhagic transformation.

Foerch demonstrated S100B to be elevated early after stroke onset (within 6 hours) which was found to be an independent predictor of hemorrhagic transformation. The combination of admission PAI-1 at <21.4 ng/ml and TAFI >180% conferred a sensitivity of 75% and a specificity of 98% for the prediction of parenchymal hemorrhagic transformation.

Malignant Infarction

Malignant infarction causes severe cerebral edema with consequent increased intracranial pressure and herniation. In general it occurs from occlusion of a major artery in the anterior circulation (usually the MCA) or the posterior inferior cerebellar artery in the posterior fossa. Biomarkers that correlate infarct volume (S100b) or degradation of the blood-brain barrier (c-Fn, MMP-9) have been evaluated to predict this complication. At 12 hours, an S100B value of >.35 $\mu\text{g/L}$ predicted a malignant infarction with 75% sensitivity and 80% specificity. A c-Fn (fibronectin) concentration of >16.6 $\mu\text{g/mL}$ had a sensitivity of 90% and a specificity of 100% for the prediction of malignant infarction.

Potential Biomarkers of Cell Death That Activate the Immune Response

1. Alarmins:

- a. Endogenous molecules released from necrotic cells injured by infection, trauma and ischemia
- b. They are not released by apoptotic cell death
- c. Produced by several cell types including immune cells and are released by the ER-Golgi secretory pathway
- d. Activate innate immune cells and recruit and activate antigen-presenting cells
- e. Activated by pattern recognition receptors (Toll-like receptors). The high-mobility group protein B1 (HMGB1), is a well characterized alarmin, that initiates components of the inflammatory cascade during ischemic brain injury. It also upregulates MMP-9 in astrocytes and neurons in all phases of ischemic injury. In one study, elevated HMGB/elevation in ICH correlated with severity scores and elevation of inflammatory cytokines. Circulating DNA may correlate with stroke severity and possible morbidity and mortality in hemorrhagic stroke

Microparticles

Microparticles are small vesicles released from dead cells. They are composed of a plasma membrane that surrounds a small amount of cytoplasm. Membranes of endothelial cell microparticles contain receptors and cell surface molecules that identify their endothelial origin. Arrays of cell surface molecules may reflect the state of endothelial dysfunction prior to their release into the circulation. They are being evaluated to determine stroke etiology and lesion volume. They may be of value in differentiating intra versus extracranial stenosis but not between stroke and mimics.

Summary of Biomarker Utility

1. Hemorrhagic transformation after thrombolysis
 - a. MMP-9 elevation (measured 3–24 hours)
 - b. Prior PAI-TAFI decreased levels
 - c. Elevated fibronectin
2. Malignant edema
 - a. Elevated S100B
3. In hospital deterioration
 - a. D-Dimer elevation
4. Elevated levels of BNP and D-Dimer predict cardioembolic stroke
5. Elevated levels of inflammatory cytokines IL-6, IL- β and TNF- α correlate with cardioembolic stroke
6. NMDAR antibodies signify possible stroke etiology
7. Heart fatty acid-binding protein; possible correlation with severity of stroke deficit and infarct volume
8. D-dimer elevation: possible correlation with poor functional outcome, recurrent ischemia, progressive ischemic stroke
9. Elevated fibrinogen after stroke: possible correlation with mortality
10. Elevated CRP levels have been correlated with an increased risk of ischemic stroke and poor prognosis

11. Decreased adiponectin correlates with neurological outcome
12. Infarct size severity and functional outcome correlate with serum levels of vWF, MDA and IL-6
13. Copeptin levels correlate with functional outcome, mortality are recurrent TIA

The Natural History of Extracranial and Intracranial Atherosclerosis

Extracranial Arterial Atherosclerosis

A discussion of plaque induction and evaluation is found in the section on atherosclerosis (see Plaque Histology). This process occurs on the luminal surface as well as between the internal and external elastic membranes. There is concomitant remodeling of extracranial and intracranial vessels during the process of atherosclerosis. A recent evaluation of participants from the Atherosclerosis Risk Communities (ARIC) study cohort involved a prospective biracial observational study with a cohort of 15,702 subjects between 45–64 years of age. Subjects were selected from four disparate communities. Arteries were evaluated over 9 years. Intima-media thickness was measured with B-mode ultrasound and MRI. The sample evaluation consisted of 3348 common carotid arteries and 1064 internal carotid arteries. The mean age of the population evaluated was 70.3 years. Only 1.3% of the subjects had carotid stenosis of at least 50%. The internal carotid artery (ICA) lumen was constant for wall thickness less than 1.5 mm but decreased when wall thickness increased above this level. Common carotid lumen size was smaller than that of the ICA at every wall thickness. Above a maximum wall thickness was associated with a smaller luminal area. Each 1 mm increase of wall thickness corresponded to an approximate 20% reduction of luminal area. At the 1.38 mm thickness of threshold, 62% of the total vessel area was composed of the vessel wall. There is less accommodation in the ICA versus the CCA as regards preservation of the lumen. Studies of remodeling of the common carotid artery are conflicting. Some studies have demonstrated paradoxically that lumen size increases with increased intima-media thickness. The relevance of extracranial atherosclerosis is multiple: 1. association with silent infarcts and white matter disease; 2. plaque rupture and 3. hypoperfusion of deep subcortical watershed circulation. Outward remodeling of the CCA may be associated with circumferential wall tension which has been associated with large artery stroke.

Intracranial Arterial Atherosclerosis (ICAD)

Overview

The epidemiology of intracranial arterial atherosclerosis reveals that it causes 30–50% of strokes in Asians and 8–10% of strokes in North American Caucasians. Intracranial arterial atherosclerosis, that preferentially affects Asians, Hispanic and blacks, is more prevalent than that which affects

the carotid bifurcation. There is some evidence that race and genetic background are responsible for differences in sites of cranial atherosclerosis possibly working through stroke suppressor genes. The risk factors associated with ICAD are: 1. ethnicity; 2. females greater than males; 3. hypertension; 4. smoking; and 5. lipid disorders. Compared to extracranial vascular disease some studies have demonstrated no association between male sex and hypercholesterolemia that is usually seen with coronary artery and peripheral vascular disease. The metabolic syndrome is an independent risk factor for intracranial versus extracranial atherosclerosis. More recent analysis suggests that the severity of intracranial stenosis may depend on diabetes and the metabolic syndrome.

Heritability for all ischemic strokes is approximately 38% and varies by subtype: 1. 40% for large vessel disease; 2. 33% for cardiac embolism; and 3. 16% for small vessel disease. Three loci from related gene wide association studies are significant for stroke: 1. PHACTRI for large vessel disease; 2. PTX2 and ZFHX3 for cardioembolic stroke. No candidate gene was significant for stroke.

General Characteristics

1. Prevalence of 20–40/100,000 persons worldwide; higher in African Americans and Hispanic than Caucasian patients
2. Intracranial atherosclerotic disease cause 33–37% of ischemic strokes in the Chinese population
3. Severe ICA affects 43% of subjects 65 years and older, 65% in those 60–69 years old and 80% of those 70–79 years old

Intracranial Arterial Disease Risk Factors

1. Non-modifiable:
 - a. Age
 - b. Men (younger age and in the basilar artery)
 - c. Hispanic subjects
 - d. Chinese subjects
 - e. Angiotensin converting enzyme polymorphisms
 - f. African American subjects
 - g. Plasma endostatin vascular endothelial growth factor ratio
 - h. Glutamine S-transferase. Omega-1 gene polymorphism
 - i. Plasma homocysteine levels
2. Modifiable Risk Factors:
 - a. Hypertension
 - b. Serum beta lipoprotein
 - c. Total serum cholesterol
 - d. Serum LDL-cholesterol
 - e. Serum Apolipoprotein
 - f. Serum HDL-cholesterol
 - g. Sickle cell disease
 - h. Meningitis
 - i. Extracranial carotid stenosis
3. Possibly Modifiable Risk Factors:
 - a. Diabetes mellitus

- b. Metabolic syndrome
- c. Alzheimer's disease
- d. Aortic Plaques
- e. X-RT (radiotherapy)
- f. Tuberculosis and cryptococcal meningitis
- g. Family history of stroke
- 4. Asymptomatic stenosis (50–99%) of other arteries in a proportion of patients
- 5. Patients with symptomatic intracranial arterial disease
 - a. Ischemic stroke, ICH or vascular death (not caused by ischemic stroke) occurred in 22% (WASD trial)
 - b. Ischemic stroke occurred in the territory of the symptomatic artery (14%); other vascular territories (19%)
 - c. One year risk of stroke in the territory of a symptomatic stenosis artery (greater than 70%) was 19%

Clinical Manifestations

- 1. TIA
- 2. Stroke
- 3. Recurrent stroke: highest risk within two weeks
- 4. Rate of recurrence of ischemic events is high regardless of antiplatelet or anticoagulation therapy

Neuropathology

- 1. Increased deposition of fibrinogen and LDL-cholesterol in the sub endothelial space
- 2. Inflammation in the walls of affected arteries

Neuroimaging

- 1. Spin-echo MRI with contrast demonstrates arterial wall enhancement
- 2. Intravascular ultrasonography
 - a. Provides real-time dynamic measurements and histology maps of the plaques

Localization of Ischemic Lesions

Motor Signs and Symptoms of Ischemic Lesions

Overview

The topographical pattern of motor deficits is extremely helpful in determining both the size and distribution of the arterial territory involved as well as the etiology of the stroke. Approximately 75% of patients with ischemic lesions demonstrate uniform weakness of the hand, foot and hip. In general, extensor musculature is more affected than flexor. A faciobrachial motor pattern is characteristic of conducting vessel deficits of the frontal branch of the superior division of the MCA (often embolic). This territory is adjacent to the frontal eye fields (FEF), supplied by the frontal branch of the superior division and Broca's area (BA44). Smaller cortical branches may give weakness of the distal arm and hand (the motor knuckle) which is frequently caused by embolic material from the carotid artery. Rarely individual fingers may

be involved. Often immediately following the ictus, reflexes may be increased which is never the case with internal capsule lesions. Large MCA artery disease does not involve the leg nearly as much as the arm (unless MI is involved which affects the internal capsule) as the homunculus for the leg on the cortical surface is supplied by the ACA. The leg may be more involved in cortical MCA infarction as edema progresses. Monoparesis may occur as noted from small lesions of the homunculus, the corona radiata and the centrum semiovale. Anterior lesions may affect the arm and face while posterior lesions affect the leg. Medial lesions of the pons may differentially affect the legs (pontine sludge on MRI-penetrating basilar artery arterioles) while more lateral lesions the arms. The anatomy of the internal capsule is complex and will be discussed in more detail with brainstem stroke. In general, corticospinal fibers in the capsule are somatotopically organized with arm fibers ventromedially and leg fibers dorso-laterally. More proximal extremity weakness suggests pontine involvement (weak shoulder but intact fractionated individual finger movement). Fractionated finger movement and particularly loss of thumb dexterity is almost invariant with MCA cortical involvement. MCA M1 involvement affects leg fibers in the internal capsule such that arm, face and leg may be equally involved (associated with depressed reflexes). Proximal limb paresis is most often infratentorial while distal involvement is supratentorial. Rarely faciobrachial predominant motor weakness is caused by anterior cerebral artery, basal ganglia and brainstem involvement.

Pure motor hemiparesis occurs in approximately 9 to 24% of patients with stroke. It most commonly occurs from lesions in the internal capsule and basis pontis (basilar artery). Extremely rarely it can occur from medullary pyramid involvement. In this instance, the face should be spared but it has been suggested that there are aberrant descending facial fibers that may be lesioned and give a slight central facial involvement. Rarely the P1 and P2 components of the posterior cerebral artery can be infarcted which affect the arm and leg solely (involved in the cerebral peduncle). Severe shoulder and upper arm weakness may be seen with watershed infarction between the MCA and ACA territories ("man in the barrel" syndrome). Isolated toe paralysis has been described from cortical homunculus infarction. The face may be singularly involved with corona radiata and genu capsular (usually dysarthria is present) lesions. Severe isolated facial palsy that may mimic a peripheral rather than central cause (upper face involvement) occurs with pontine lesions.

If pure motor signs are associated with corresponding sensory loss in an awake patient then the lesion is in the internal capsule (associated with decreased or absent reflexes). A lethargic patient with arm, face and leg involvement and hyperactive reflexes suggests subdural hematoma. The ipsilesional pupil may be slightly dilated, slower to react to light and assumes an oval or "tadpole" appearance. The patient will have a headache and the ipsilesional scalp is often sensitive

to mechanical stimulation. Patients with ataxia out of proportion to weakness (ataxic hemiparesis) usually have a lesion of pontine crossing fibers that comprise the middle cerebellar peduncle. It has been described with both cortical and corona radiata lesions (usually frontal lobe infarction). Infarctions of the ACA may cause severe distal leg weakness in approximately 25% of patients. Depending on the blood supply from the Circle of Willis (a single peduncle from which A2 arises, the medial frontal lobe can be infarcted with consequent upper extremity weakness and incoordination). There are multiple movement disorders that occur with stroke that include:

1. Lower body Parkinsonism – basal ganglia involvement; lacunar states
2. Hemichorea – thalamoperforate artery infarction; often seen in diabetic and hypertensive patients
3. Dystonia – thalamic stroke; thalamoperforate artery
4. Hemiballism – at least two-thirds involvement of the STN (corpus Luysii); interpeduncular or thalamoperforate artery infarction
5. Asterixis – reported from cortical and reticular formation lesions
6. Ataxic Syndromes:
 - a. Posterior inferior cerebellar artery PICA – leg ataxia more than arm; gait affected (inferior cerebellar peduncle affected)
 - b. Anterior inferior cerebellar artery AICA – arm is more affected than the leg; infarction of the middle cerebellar peduncle; unilateral hearing loss occurs if the internal auditory artery is affected
 - c. Superior cerebellar artery – upper and lower extremity ataxia; speech involvement; often from the top of the basilar embolic stroke
 - d. Interpeduncular artery infarction – total body ataxia; infarction of the decussation of the superior cerebellar peduncle (top of the basilar embolus; atherosclerosis; aneurysm)
 - e. Bruns' Ataxia – Involvement of frontopontine crossing fibers: the cerebellar proprioceptive zone (globose and emboliform nuclei); the thalamic cerebellar area (component of VL); Brodmann's area BA 3,1,2 which then projects back to BA4
 - i. Frontal component:
 1. Ataxia of the extremities out of proportion to weakness
 2. Pontine crossing fibers (origin is the pontine nuclei of the basis pontis) similar clinically to cortical involvement; basilar artery penetrating arteries are involved
 3. Cerebellar proprioceptive zone; extremely rare from stroke
 4. Thalamic involvement noted for ataxia of stance (thalamoperforate artery)
 - f. Anterior cerebellar infarction:
 - i. Gait ataxia; "Martinet gait"; an increase of extensor tone primarily of the legs and trunk

g. Hemispheric cerebellar infarction:

- i. Complete cerebellar syndrome of the affected extremities that includes dysmetria, hypotonia, hyporeflexia, dysdiadocho-kinesia

General Features of Sensory Signs Following Ischemic Lesions

Sensory signs may be apparent in 80% of stroke patients. Most stroke patients demonstrate several somatosensory deficits that include primary modalities of pain, temperature, vibration, proprioception and higher cortical function. A significant number of patients diagnosed with pure motor stroke have sensory dysfunction. The pattern and primary modality and higher cortical sensory deficits (stereognosis, graphesthesia; 2-point discrimination, posture copy, extinction to double simultaneous stimulation) are extremely helpful in topographical diagnosis in ischemic stroke. Studies reveal that between 53 and 64% of stroke patients have impairment of primary modalities after stroke. Impaired proprioception occurs at the same frequency and decreased stereognosis (tactual object recognition) is the most frequent sensory deficit after stroke. Pure somatosensory syndromes are frequent with lacunar stroke of the thalamus, internal capsule, brainstem, and parietal cortex.

Patterns of Brainstem Sensory Stroke

The usual brainstem sensory syndromes are the result of small infarcts or hemorrhages in the pons and medulla. The rostral mid pons (contain the nucleus and descending tract of V) and innervates the mid face. The lateral caudal pons (containing the N and descending tract of V) innervates the peripheral face. The more lateral pons contains sympathetic fibers that are frequently involved with lateral lesions. Trigeminal fifth cranial nerve dorsal root entry zone lesions are involved in syphilis and denervate the midface. In lateral medullary and pontine strokes, the ipsilateral face and contralateral body lose pain and temperature sensation. Circumoral bilateral sensory deficits suggest a pontine lesion while midface versus lateral face (concomitant central Horner's) is more characteristic of the pons. The spinothalamic tract fibers (pain and temperature) decussate at the segmental level of entry and therefore an ipsilateral lesion will give a contralateral deficit. These fibers are segregated such that the sacrum, leg and trunk representation is the most lateral. Hemianesthesia of the tongue suggests a medullary lesion and bilateral intraoral numbness most often occurs following a posterior ventromedial thalamic nuclear lesion.

The Stopford classification is helpful in organizing brainstem sensory loss:

1. Type I: ipsilateral face and contralateral leg (most lateral brainstem)
2. Type II: upper part of the body – a mediolateral infarction
3. Type III: larger infarction involving medial and lateral area and can cause a combination of crossed and unilateral deficits

Paramedian infarctions (penetrating arterioles from the basilar artery) affect vibration and proprioception (lemniscal afferents) and may show a cheiro-oral and leg weakness pattern (leg fibers are medial and arm fibers are supplied by short circumferential arteries). These infarctions causes gait ataxia (pontine crossing fibers that make up the middle cerebellar peduncle) and dizziness (vestibular fiber involvement).

Thalamic infarction (thalamogeniculate artery from P1) or more commonly lacunar infarction affects the VPL nucleus. Face, arm and leg are involved. The most common symptoms are numbness or paresthesia but some patients report “formication” (insects crawling on the skin), burning and pain. Pain may occur with the stroke, 2 to 15 days later or after months. This form of central pain is referred to as Dejerine’s syndrome. Characteristic of thalamic sensory loss is strict mid-line topology (occasionally bilateral sensory loss periumbilically), loss of vibration sensation (including the forehead) and bilateral intraoral numbness if VPM is involved.

Parietal sensory loss is characterized by deficits in higher cortical sensory function such as graphesthesia, 2-point discrimination, the ability to copy posture and identify textures. It often spares the trunk. Left parietal lesions may cause anomia, aphasia, deficits with reading, transcortical conduction aphasia with involvement of the supramarginal gyrus, Brodmann areas 41, 42 and the arcuate fasciculus. Right-sided lesions cause visuoconstructive and spatial deficits. Denial of individual body parts (asomatognosia), of illness (anosognosia) and neglect may be seen. The patient often will be lying asymmetrically in bed with both head and eyes turned to the side of the lesion. A parietal drift of the arm (updrift with polyminiomyoclonus) is common. If the patient has neglect but an extremity is in a peculiar position, the thalamus or parietal afferents may be involved. Higher cortical sensory loss with preserved vibration is characteristic of a parietal sensory lesion. The gait is hesitant and it appears that the patient explores space with the left foot. Motor function is frequently involved as there are dense projections from the superior parietal lobe through the superior longitudinal fasciculus to M1 for hand-eye coordination. The parietal cortical syndromes usually arise from infarction of the anterior and posterior parietal branches of the superior division of the MCA. Infarction of the central sulcal branch of the MCA causes M1 and S1 damage which affects primary modalities except vibration. Most patients report heaviness (S1 – 3a, 3b) or numbness of the affected areas. The posterior insular cortex encodes interoception, affect and intensity of pain. A lesion of the inferior anterior parietal cortex affecting the parietal operculum and the posterior insula is difficult to distinguish from a thalamo-sensory syndrome (pseudo-thalamic syndrome). Discriminative rather than affectual pain deficits are rare with cortical lesions although SI has recently been shown to encode pain and SII receives pain afferents. Recent electrophysiological studies, primarily trans-cortical magnetic stimulation, are furthering our understanding of the role of the cortex in pain. Somatosensory

deficits are more severe with right-sided lesions and there is a 17% incidence of ipsilateral sensory loss following unilateral stroke.

Transient Ischemic Attacks (TIA)

Overview/General Characteristics

The great majority of TIAs are atherothrombotic. They can involve any cerebral artery in either the anterior or posterior circulation. By definition, a TIA is a brief episode of ischemia that terminates within 24 hours without a clinical or imaging deficit. They present with focal neurologic deficits which may precede or rarely follow a stroke or they can occur without evolving into a stroke. The exact time limit for the neurologic deficit is controversial but most accept that it should be less than 24 hours. Longer TIAs suggest larger fibrin platelet emboli (red) while those lasting minutes are most often artery-to-artery cholesterol particles from atherosclerotic lesions.

TIAs may be separated into a single episode or recurrent stereotyped deficits. Prolonged fluctuating TIAs have a high proclivity for vascular occlusion. Approximately 20 to 30% of TIAs are followed by a stroke within one month and 50% by one year. A predictive tool to determine the likelihood of stroke within 1 week is the ABCD score and its variants. Unilateral weakness and deficits lasting longer than 1 hour are solid clinical signs of impending stroke. There is a strong correlation with carotid TIA and myocardial infarction. A significant number of TIAs may be diffusion weighted MRI sequence image negative.

Transient monocular blindness, also known as amaurosis fugax is a transient ischemic episode of the eye. Most of the episodes are short lived between 5 to 30 seconds.

Many patients describe the attack as if a shade comes down (or rarely rising) over the eye. The episode is painless but the eye may be completely blind. Vision returns slowly and uniformly. The variants of transient monocular blindness include a wedge or visual loss, generalized blurred vision or a bright scintillating light that obscures vision. The attacks of transient monocular blindness are more stereotyped than hemispheric TIAs and are markedly less correlated with stroke. Rarely a Hollenhorst cholesterol embolus may be seen as a “birefringence” yellow embolus occluding a retinal artery bifurcation. Progression of the embolus through the bifurcation coincides with visual clearing.

Lacunar transient ischemic attacks may be “stuttering” at onset but are difficult to distinguish from a large vessel TIA.

Clinical Manifestations

1. Transient monocular blindness (TMB)
2. Capsular warning syndrome
3. Aphasia
4. Hemiparesis
5. Hemisensory deficits (numbness or tingling)

6. Perioral numbness
7. Ataxia
8. Dysarthria
9. Diplopia
10. Dizziness
11. Visual field deficits
12. Alteration in consciousness

Neuropathology

The atherosclerotic plaque is pivotal in the mechanism of artery-to-artery embolism and flow limiting stenosis.

The arterial wall of the plaque is thickened and there is endothelial compromise with an accumulation of cholesterol. A chronic inflammatory response occurs in the walls of arteries in part caused by the accumulation of macrophages and leukocytes whose migration is induced by low-density lipoprotein oxidation and decreased removal of fat and cholesterol from macrophages by functional high-density lipoproteins (HDL). The site of plaque formation is due in part to the effects of wall shear stress and turbulent flow.

The core of atherosclerotic plaque is composed of lipid deposits with absence of cells and matrix proteins. Plaque formation starts after the induction of a fatty streak.

Oxidative modification of low-density lipoprotein (LDL) is important for foam cell formation and possibly the initiation or acceleration of atherosclerosis. Increased levels of plasma low-density lipoproteins cause an increased rate of low-density lipoprotein entry into the intima. Low-density lipoproteins undergo oxidative modification by endothelial smooth muscle cells or macrophages. The oxidized low density lipoproteins are recognized by scavenger receptors which give rise to foam cells. The effects of oxidized low-density lipoproteins are:

1. Cytotoxicity to endothelial cells (demonstrated in cell culture)
2. Inhibit vasodilation by nitric oxide
3. Stimulates mitogen-activated protein kinases in smooth muscle cells (SMC) and macrophages
4. Immunogenic

Foam cells are lipoprotein aggregates within the intima of blood vessels. Macrophages and endothelial cells generate free radicals that oxidize lipoprotein. The macrophages engulf the oxidized low-density lipoproteins by endocytosis utilizing scavenger receptors (SCAs). Oxidized low-density lipoproteins in macrophages and other phagocytic cells become foam cells which form the fatty streaks of the atheroma in the tunica intima during the atherosclerotic process.

The internal elastic lamina is thicker in arteries than arterioles and is very thin in veins. It separates the intima from the media of the arterial wall. It is a restrictive barrier to macromolecular permeability. Holes within the internal elastic lamina allow for permeability of diffusible vasoactive molecules and are the interface of endothelial cell projections with the

smooth muscle of the vascular wall. Smooth muscle cells secrete elastin that forms sheets or lamellae which increase with age and form the internal elastic lamina.

Cholesterol crystallizes as it accumulates in the vascular wall. It transforms from a liquid to a solid state and expands which is a mechanism of vulnerable plaque disruption. Cholesterol crystals induce inflammation in the arterial wall. Cholesterol crystals activate the "inflammasome" complex within immune cells that release inflammatory mediators (chemokines and cytokines). Cholesterol crystal embolization is the release of contents of a ruptured atherosclerotic plaque from a more proximal larger caliber artery to distally small to medium-sized arteries. Arterio-arterial thromboembolism is usually characterized by an abrupt release of emboli. The size of a cholesterol embolus is 100 to 200 μm and cause end organ damage both by ischemia and an induced inflammatory response.

Vascular remodeling is an adaptive response to variations in wall shear stress and hemodynamic factors. Experimental evidence supports the concept that wall stretch induces smooth muscle and endothelial cell proliferation as well as phenotypic switch in SMC from contractile to synthetic cells. Pericytes, vascular mural cells located within the albuminal vascular basal laminae regulate vascular development, stability, angiogenesis and remodeling. Extracellular membrane proteins (ECMs) drive angiogenesis by means of integrin receptors. The $\beta 1$ class unregulated fibronectin which is an important component of the vascular wall. Vascular remodeling is also promoted by several growth factors which include:

1. VEGF
2. bFGF
3. PDGF-BB
4. Cytokine TGF- β
5. Cytokine TNF- α

These growth factors and cytokines modulate ECM-integrin interactions. An important mechanism that effects change in the blood vessel wall during plaque formation is a TNF- α dependent switch from $\alpha 1$ to $\alpha 2$ that stimulate pericyte proliferation, migration and modulation of cerebral blood vessel collagen. The remodeling process can be summarized by the evolution of plaque formation.

Plaque Histology

1. Type I
 - a. An increase of macrophages with scattered foam cells
2. Type II
 - a. Layers of macrophage foam cells and lipid-laden smooth muscle cells that constitute fatty streaks on the artery luminal surface
3. Type III:
 - a. Lipid laden cells with scattered extracellular lipid droplets
 - b. Disruption of smooth muscle cells
 - c. Extracellular lipid
 - d. Intermediate stage between type II and type IV lesions

4. Type V:
 - a. Contains a lipid core and layers of fibrous connective tissue
 - b. Calcification of a type V lesion is classified as Type V
 5. Type VI:
 - a. Contains a lipid core with a fissure, hematoma and thrombosis with minimal lipid as calcium
- The identification of unstable plaques is of great clinical interest.

Neuroimaging

Ultrasound

1. A juxtaluminal black area of $>8 \text{ mm}^2$ in a plaque (which indicates a thrombus or a thin or absent fibrous cap)
2. Presence of discrete white areas in a hypoechoic plaque
3. TCD demonstration of reduced cerebral flow reserve

MRI

1. Intraplaque hemorrhage
2. Necrotic core size
3. Plaque volume
4. Silent embolic infarcts

Neuropathology

Mechanism of Plaque Growth and Rupture

Inflammation in a plaque is manifest by activated macrophages, mast cells and T-lymphocytes. The initiation of the process is the LDL-C particles into the arterial wall subintimal space. The particles are trapped by their high affinity for glycoprotein molecules at vulnerable sites (determined by wall shear stress and turbulent flow). If LDL-C is oxidized there is activation of endothelial surface adhesion molecules that attract monocytes to clear these oxidized lipid particles. The process initiates local inflammation and attracts smooth muscle cells. Monocytes differentiate into macrophages that engulf this lipid and transform into foam cells. When these macrophages die, lipid and free cholesterol is released into the extracellular space. Macrophages are attracted by chemokines secreted by inflammatory cells to form a necrotic core between the internal and external elastic membranes. The core is composed of cellular debris and free cholesterol which crystallizes; the sharp edges of the crystals disrupt fibrinous tissue. It appears that cholesterol expands during transformation from a liquid to a crystalline state and that this is what disrupts the overlying plaque's fibrinous cap. Statins decrease cholesterol crystallization and blunt sharp tipped crystal structures. The cholesterol crystals that pierce the arterial plaque and intima also trigger local and systemic inflammation.

The disruption of the fibrinous cap leads to thrombosis and distal embolization. Crystals in distal arteries can injure the endothelium leading to arterial spasm. Plaque instability persists after a TIA and then decreased with time after a stroke. Symptomatic carotid plaques remodel over time and become

more stabilized which has been associated with decreased expression of IL-6, caspase 3 and fewer macrophages. Plaques morphology as studies from carotid endarterectomy specimens revealed that younger patients had a greater inflammatory cell infiltrate while older patients had a larger lipid core and calcification. There was no linear progression of plaque instability with age. In asymptomatic patients with greater than 50% stenosis, plaques in men had:

1. Increased features that predict rupture
2. Thinner fibrous caps
3. Larger lipid cores (LRNC) for the same degree of stenosis than women

There is some evidence that larger LRNC causes plaque rupture while smaller LRNCs erode.

Alternative Mechanisms of TIA

1. Exercise and postural TIA
 - a. Suggestive of stenosis of aortic branch arteries
 - i. Takayasu's disease
 1. Amaurosis with walking or change of head position
2. TIA induced by hyperventilation
 - a. Moyamoya disease
3. Rheological causes of TIA include:
 - a. Polycythemia vera
 - b. Thrombocythemia
 - c. Hyperlipidemia
 - d. Macroglobulinemia
 - e. Sickle cell disease
 - f. Antiphospholipid antibodies
 - i. Emboli primarily from heart valves
4. Post thrombus TIA
 - a. Embolic material dislodged from the distal end of the thrombus (particularly in basilar artery stenosis)
 - b. Bypass the thrombus and enter vascular territory by collateral blood vessel
5. Hemodynamic alternations in brain circulation occur
 - a. Lumen in the carotid artery is decreased to 2.0 mm (normal is 5 to 10 mm)
 - b. A reduction of cross-sectional area of the vessel of $>95\%$
6. The clinical features most suggestive of cardioembolism are:
 - a. Sudden onset with maximum deficit at ictus
 - b. Decreased level of consciousness at onset
 - c. Sudden mutism (stunned appearance)
 - d. Sudden Wernicke's aphasia (temporo-parietal-occipital branch of the inferior division of MCA) in a setting of atrial fibrillation
 - e. Global aphasia without hemiparesis (top of the carotid; break-up of stem MCA embolus)
 - f. Valsalva maneuver at time of ictus (possible PFO)
 - g. Co-occurrence of cerebral and systemic emboli
 - h. The appropriate clinical setting

Lacunar presentations and especially multiple lacunar infarcts suggest small vessel disease. Bilateral cerebellar infarctions (territory of the posterior inferior cerebellar artery; dorsomedial thalamic lesion) suggest embolism to the top of the basilar artery often from a burst plaque in the vertebral artery.

Distal Field Ischemia

Another major cause of transient ischemic episodes is those from distal field ischemia that may lead to deep or superficial watershed hypoperfusion. The most frequent cause occurs in a setting of hypotension. A cerebral conducting vessel or a deep penetrating arteriole may be compromised from atherosclerosis and in the face of systemic hypotension cannot perfuse its usual territory after an embolus (poor washout). The M1 and P2 segments of the middle and posterior cerebral arteries as well as superficial branches of the cortical circulation are also often involved. Clinically, changing the position of a patient from the supine to the erect position may induce symptoms. Symptoms clear with position change and restoration of perfusion pressure. The major cortical areas of involvement are between the anterior cerebral/middle cerebral arteries and middle cerebral/posterior arteries. In the deep circulation of the carotid territory the watershed is between ascending lenticulostriate vessel from the MCA and descending cortical medullary arteries. MRI T2-weighted sequences demonstrate a rosary-like pattern of white matter hyper-intensities approximately 1 cm from the ventricle. Another possible mechanism is micro emboli dislodgement from a thrombus in a partially blocked arterial lumen.

Differential Diagnosis of Transient Ischemic Attacks

Overview

The differential diagnosis of transient ischemic attacks (TIA) is best thought of by mechanism. As noted above, most TIA's are embolic; either burst plaques (artery to artery) or fibrin/platelet clots from the heart. TIAs that are widely separated in time may arise from a large artery that is undergoing gradual occlusion. This process frequently occurs at the carotid bifurcation with shedding of cholesterol crystals and platelet/fibrin clots from the area of ulceration. The small cholesterol crystals may enter the ophthalmic and retinal arteries (Hollenhorst plaques) to cause amaurosis fugax. As an artery reaches a critical flow limiting state (usually greater than 70% occlusion) TIAs may occur sequentially from a combination of distal field ischemia or artery-to-artery emboli: They have been reported up to several hundred per day. They are known as crescendo TIAs and most often present as multiple episodes of amaurosis fugax. Tight stenosis of intracranial proximal conducting vessels occurs at characteristic locations (M1 of the MCA and A1 and P1 of the anterior and posterior circulations). This stenosis combined with lower systemic pressure and decreased cerebral pressure perfusion compromise cerebral blood flow in the distal field of the affected artery. MRI scans frequently demonstrate high

signal T2-weighted lesions periventricularly (rosary-lesions) that constitute the ischemic perivascular stripe (about 1/2 cm from the lateral ventricle). Tandem lesions of the carotid siphon and M1 segment cause neurological deficits that occur with fluctuations of blood pressure. Specific stenotic lesions cause stereotypical neurological symptoms as opposed to emboli that are slightly different from attack to attack, but often lodge in the same or adjacent vessels due to laminar flow characteristics.

Embolic TIAs, particularly from the heart cause specific neurologic deficits. Some are pathognomonic such as a pure receptive aphasia (in the setting of atrial fibrillation) which is characteristic of occlusion of the temporo-parietal-occipital branch of the inferior division of the MCA. Top of the basilar lodgment of emboli are also common and cause deficits depending on the course and lodgment of embolic material (midbrain, thalamus, parietal or occipital lobe). Patients suffering a dilated cardiomyopathy (ejection fraction less than 20–30%) invariably embolize over time.

Emboli overwhelmingly occur during wakefulness and during activities of daily living. Occasionally they occur when a patient gets up to urinate at night or during a valsalva maneuver (suggestive of a patent foramen ovale).

The characteristic clinical features of an embolus are: 1. a maximum deficit at ictus; 2. partial or complete recovery over hours to days; 3. pure Wernicke's aphasia (TPO branch of the inferior division of the MCA); 4. top of the basilar syndrome (signs dependent on cerebellar, midbrain, thalamic parietal or occipital vessel occlusion). Emboli may not cause catastrophic symptoms. A sudden headache or dizziness rather than hemiparesis, hemisensory loss or aphasia may be the only symptoms. Silent visual loss in superior quadrants suggests an embolus to the lower banks of the calcarine cortex in the setting of atrial fibrillation. Headache occurs if the dura is involved. There is often a small amount of blood in the CSF (about 100 RBCs/mm³). Seizures occur at onset in approximately 20–30% of patients.

Emboli are common with atrial fibrillation and the time required for EKG monitoring to rule out cryptogenic paroxysmal AF is being determined. The embolic material is often larger than that from artery to artery burst plaque material, the occlusion is more severe and the deficit longer lasting. Cardiomyopathies with ejection fractions of less than 20–30%, dyskinetic ventricular wall segments following myocardial infarction and rheumatically involved heart valves are common cardiac settings. Non-bacterial thrombotic emboli occur in 10% of cancer patients. Patent foramen ovale with atrial septal aneurysm as well as other congenital heart defects with right to left shunts have a significant risk of embolization. Sub-acute bacterial endocarditis is frequently announced by an embolus to the middle cerebral artery territory (mitral greater than aortic valve). Atrial myxomas are noted for small embolic strokes but the clinical picture may be clouded by fever or a remittent course from an immunological response to the myxomatous material. A peripheral cerebral vessel aneurysm suggests atrial myxoma or SBE.

Mobile plaques of the arch of the aorta and associated atherosclerotic detritus account for 30% of emboli to the posterior circulation and can now be evaluated with transesophageal echocardiography (TEE). Patent foramen ovale with or without atrial septal aneurysms or tunnel emboli account for a large number of formerly cryptogenic emboli in younger patients. Symptoms from extracranial arterial dissections are usually from emboli rather than limitation of flow.

Rarer causes of emboli are myxomatous degeneration of valves noted in mitral valve prolapse, verrucous endocarditis of SLE and air, fat, and calcium.

The only common condition that causes vasospasm and TIA is migraine. The differential points for migraine versus embolism or ischemia as a cause of neurological dysfunction are clear. Migraine is noted for positive visual symptoms of scintillating or fortification scotoma a gradual evolution over 20 minutes, one somatosensory complaint gradually merging with the next (visual symptoms merging with parietal sensory loss) and a headache after the neurological symptoms. Embolic or ischemic events are characterized by for the occurrence of all deficits simultaneously with primarily negative symptomatology (heaviness, visual loss and weakness). Family history and risk factors are different. However, CADASIL (cerebral AD arteriopathy with subcortical infarction and leukoencephalopathy) as well as mitochondrial disease are noted for concomitant migraine headaches. SLE and other connective tissues have a high incidence of associated migraine.

Emboli may occlude deep penetrating blood vessels that mimic lacunar disease (10–12 perforators from M1 or M2) that infarct the internal capsule or basal ganglia. Congophilic angiopathy patients may suffer repeated small bleeds that mimic emboli.

Imaging studies are extremely helpful. CT scan may demonstrate older lesions in two circulations or a dense MCA sign at the site of embolic occlusion. Diffusion weighted MRI demonstrates areas of acute ischemia and in tandem with perfusion studies, demonstrates the ischemic penumbra. Occasionally, one sees lesions not only in different circulation, but also with different intensities that suggest earlier events.

Transcranial Doppler studies, particularly during carotid surgery, have shown that most emboli are asymptomatic (similar to the lung). The frequency characteristics suggest size of the embolic material. Carotid Doppler characteristics suggest qualities and morphology of the ulcerated plaque or dissection. As Dr. Caplan has pointed out, it is most important to discover the type of bird that has left the nest (the nature of the embolic material).

Stroke Mimics

General Characteristics

Definitions

1. Stroke mimic:

- a. Acute neurologic symptoms that have other causes that simulate ischemic stroke
 - b. In many large series stroke mimics account for 10–20% of emergency room apparent strokes
2. Stroke chameleon:
 - a. Neurologic signs that present as other conditions that in fact are stroke
 - b. Thrombolytic therapy administered to stroke mimics has not resulted in symptomatic intracranial hemorrhage
 - i. Approximately less than 1% of symptomatic ICH after thrombolytic use for myocardial infarction

Neuroimaging

1. Neuroimaging negative cerebral ischemia:
 - a. The patient has had a stroke, but it is not documented on diffusion weighted MRI sequences (DWI):
 - i. The affected artery may have recanalized prior to loss of sodium/potassium membrane pump failure
 - ii. DWI resolution with 1.5 and 3 Tesla magnets may not detect microinfarcts (<2 mm)
 - iii. Transient ischemic attack or aborted stroke
2. Stroke mimics with neuroimaging negative cerebral ischemia (NNCI) have shorter hospital stays, a greatly improved NIHSS and good functional recovery

Differential Diagnosis of Stroke Mimics

1. Seizures with Todd's paralysis
2. Complicated migraine
3. Psychiatric conditions (somatization)
4. Tumors (with or without bleeding)
5. Metabolic dysfunction:
 - a. Hypoglycemia
 - b. Liver failure
6. Phenobarbital overdose
7. Mitochondrial disease (MELAS)
8. Methotrexate leukoencephalopathy
9. Demyelinating disease
10. Cervical epidural blood or infection

Differential Diagnosis of a Chameleon

1. Syncope
2. Altered mental status
3. Deterioration of a compensated stroke from sepsis or metabolic dysfunction
4. Acute coronary syndrome (PICA may cause chest pain)
5. Hypertensive emergency
6. Systemic infection

Differential Points Between Acute Ischemic Strokes Versus Stroke Mimics

1. Acute ischemic stroke patients are older than stroke mimics

2. Increased chance of having atrial fibrillation and dyslipidemia (stroke)
3. No pure sensory signs or symptoms (mimics)
4. Stroke mimics have a higher incidence in females than males; females have lower admission NIHSS
5. Stroke mimics tend to have loss of function that is not consistent with a vascular territory
6. The onset of symptoms in stroke mimics is often not apoplectic
7. A blood pressure of less than 55 mm Hg (diastolic) is against stroke

Differential Diagnosis of Restricted Diffusion

1. Acute ischemia
2. Bacterial abscess
3. Epidermoid tumors
4. Central portions of some primary and secondary brain tumors that have outgrown their blood supply
5. Demyelinating diseases and other inflammatory conditions

Differential Diagnosis of Cortically Restricted Diffusion

1. Ischemia
2. Venous infarction
3. Viral encephalitis
4. Meningitis
5. Creutzfeldt-Jakob disease
6. Mitochondrial cytopathies
7. Post-ictal stroke

Differential Diagnosis of Stroke Mimics

Seizure

Overview

A history of loss of consciousness, Jacksonian march and post-ictal state are most helpful. The pattern of seizure activity if involving the motor strip is determined by innervation density of the body part and depolarization threshold of the affected neurons. In general, if the motor strip is the elliptical zone, the corner of the mouth and thumb twitch first which is progressively followed by the arm and then the distal leg. The shoulder and hip are often spared. Most patients who have lost consciousness awaken confused, have a dull throbbing headache and are perspiring. They require minutes to hours to return to normal. They frequently complain of subscapular and quadriceps pain. If there is an underlying structural lesion they may suffer a Todd's paralysis. Todd's paralysis from a focal seizure usually lasts less than one hour but may persist for one week to 10 days, particularly if the seizures emanate from speech areas. Extremely rarely, a seizure emanating from the suppressor strip of the motor cortex (area 6) may cause contralateral paralysis of the face and arm. A shaking TIA from carotid stenosis and hemispheric ischemia (distal field ischemia) occurs from decreased cerebral blood flow.

The movements are brief, arrhythmic, flailing or jerking of the arm or leg. There is no loss of consciousness, aura, incontinence or Jacksonian march. The symptoms are initiated by maneuvers that may decrease hemispheric perfusion such as arising from a supine position or getting out of a chair. Rarely does it occur from hyperextension of the neck or hyperventilation (decreasing pCO₂ and consequent cerebral vasospasm). These features also differentiate a shaking unilateral TIA from hemiballism, dystonia and focal myoclonus which may occur on an ischemic basis. Bilateral shaking of the upper extremities and lower extremities may occur with internal capsule or cerebral peduncle ischemia (top of the basilar distal field ischemia).

Atrial Fibrillation

General Characteristics

1. The normal regular impulse generated by the atrial node is overwhelmed by rapid depolarization originating in the atria and adjacent parts of the pulmonary veins
2. The source of these depolarizations are autonomous foci (pulmonary veins) or a left atrial reentrant electrical spiral waves (rotors) or repetitive focal beats

Clinical Manifestations

1. AF may be asymptomatic as the atria account for about 15% of the cardiac ejection fraction
2. Frequent micturition
3. Awareness of the abnormal rhythm by the patient

Neurologic Manifestations

1. There is a 5X risk of cardioembolic stroke
2. Classic sudden onset of Wernicke's aphasia without hemiparesis
3. Emboli most often go to the MCA vascular territory
4. Usually long TIA as fibrin platelet clots (red) are large
5. A putative cause of cryptogenic stroke

Neuropathology

1. Progressive fibrosis of the atria due to atrial dilatation. There are genetic, endocrine (thyroid) and inflammatory pathologies (sarcoid). Inflammation occurs with sarcoid
2. Autoimmune disorders demonstrate antibodies against myosin heavy chains
3. Mutation of the Lamin A/C gene causes fibrosis of the atria with fibrillation
4. Molecular events leading to fibrosis:
 - a. Activation of the renin aldosterone angiotensin system that induce metalloproteinases and disintegrins. These process leads to remodeling and fibrosis if it extends to the sinus node and atrioventricular node, it correlates with sick sinus syndrome
5. Lower atrial wall motility
6. Large left atrium

Laboratory Evaluation

1. Fibrillary conduction occurs due to heterogeneous atrial recovery from excitations
2. Depolarization electrical waves generated by AF sources undergo repetitive, spatially distributed break-ups and fragmentation ("fibrillatory conduction")
3. Absent P waves
4. Rhythm is irregularly irregular and may be rapid or slow
5. No difference in plasma levels of hemostatic markers in patients with atrial flutter and those with normal sinus rhythm

Atrial Flutter*General Characteristics*

1. Caused by a reentrant rhythm from the right or left atrium. It is due to differences in the refractory periods of atrial tissue. This causes depolarization of atrial tissue that moves in a self-perpetuating loop
2. The AV node blocks atrial impulses at about 180 beats/minute due to its longer refractory period. The block is dependent on the patient's age

Clinical Manifestations

1. If the patient is cardiovascularly compromised the rapid heart rate may cause shortness of breath, chest pain, dizziness and occasionally feelings of impending doom (ischemia of the medial temporal lobes)
2. Rate related hypotension due to poor ventricular filling and a decreased ejection fraction
3. Type I atrial flutter has an atrial rate of 240–340 beats/minute. The reentrant loop traverses a fibrous band in the lower atrium between the inferior vena cavae and the tricuspid valve
4. Embolism
5. Sudden Death

Neuropathology

1. Thrombus formation in the atrial appendages
2. The reentrant electrical loop traverses a fibrous band in the lower atrium between the inferior vena cavae and the tricuspid valve

Laboratory Evaluation

1. Atrial flutter is an organized electrical conduction usually in the right atrium. EKG reveals:
 - a. Characteristic: saw-toothed P-waves of constant amplitude and frequency

Mechanism of Embolism in Atrial Fibrillation and Atrial Flutter

The traditional concept is that atrial thrombosis forms after greater than two days of AF or flutter and embolizes due to shear forces. In the setting of AF, the thrombus organizes

over 14 days. Left atrial thrombus may form before the onset of AF in the face of sinus arrhythmia. Conversion to sinus rhythm may increase the thrombogenic milieu of the left atrium. An atrial thrombus may form in the acute phase of AF. Atrial flutter, which is characterized by a rate of greater than 240 beats/minute in the absence of an isoelectric baseline between deflections, occurs secondary to atrial dilatation. It may occur in patients with a pre-existing accessory conduction pathway (bundle of Kent in Wolff-Parkinson-White syndrome). Extremely high ventricular rate may degenerate into ventricular fibrillation with hemodynamic collapse.

Hypoglycemia*Overview*

The usual neurological symptom of hypoglycemia include: 1. altered level of consciousness; 2. personality change; 3. seizure; 4. hemiplegia; 5. coma. The most common cause is inadvertent overdose of insulin or hypoglycemic agents. Systemic causes include renal or hepatic failure, Addison's disease, severe sepsis and rarely an insulin secreting tumor. Lesions can be seen on DWI MRI within 45 minutes after symptom onset and are present at 12 hours on T2-weighted imaging. Patients with good clinical recovery have clearing of lesions within 6 hours. Acute hypoglycemia may mimic acute stroke or brain imaging in 20% of patients. CT generally reveals unilateral cortical and adjacent subcortical hypodensities and swelling to a greater degree than cortical or lacunar stroke. Less severe episodes cause hemiparesis and smaller corticospinal tract lesions. Rapid response to glucose is diagnostic. A parasympathetic response (hyper salivation), slightly low temperature 97°F are helpful. The imaged lesions may not strictly conform to a vascular pattern.

Multiple Sclerosis (MS)*Overview*

Clinically isolated neurologic signs and symptoms are frequent in MS. The most usual of these are optic neuritis, paresthesia, and intranuclear ophthalmoplegia. The MRI findings of Dawson's fingers (callosal lesions), optic nerve involvement, and multiple white matter intensities on T2-weighted MRI secure the diagnosis. The short symptoms of MS, those that last for a few minutes are thought to occur from the Uhthoff phenomena (failure of partially demyelinated axons to conduct if their temperature is raised) or block from ion blocking antibodies. Focal motor and sensory deficits often occur with MS. However optic nerve involvement, cognitive dysfunction, ataxia and bilateral hyperreflexia that persist differentiate it from TIA. Spinal cord signs predominate.

Migraine*Overview*

Complex, familial and Bickerstaff's migraine may all be confused with transient cerebral ischemia. In general, various

forms of migraine can be differentiated from transient cerebral ischemia by triggering factors, age and hereditary patterns. Most migraine symptoms are positive and the progression is from one modality to the next serially. Thus, visual loss or scotoma slowly melds with parietal sensory loss and then weakness. The spreading cortical depression usually occurs over twenty minutes and is then followed by a unilateral or bifrontal throbbing headache. Though patients with ischemia suffer deficits in several modalities simultaneously, in general these are negative and include loss of vision, numbness and weakness. The headache is usually concomitant with the deficits occur most frequently from posterior rather than anterior circulation ischemia. Bickerstaff migraine affects the vertebrobasilar circulation and is associated with parenthesis of the hands, perioral numbness, bilateral visual disturbance (visual field deficits, scintillating scotoma, and teichopsia), dysarthria, ataxia and loss of consciousness. It may be confused with a brainstem stroke. Complicated migraine (that with neurological signs) and hemiplegic migraine may also be confused with TIA. Hemiplegic migraine usually affects the same side of affected family members and is less likely to cause permanent deficits than the sporadic form. The usual deficit (hemiplegia) lasts for 2–3 days.

Systemic Infection

Overview

1. Chest most common source
2. Acute illness exacerbates an old ischemic lesion (breakdown of prior compensatory mechanisms)
3. Activation of immune aspects of atherosclerotic lesions

Hypotension

Overview

1. Unusual in ischemic disease and TIA; blood pressure of less than 120/80 occurs at presentation in 7.1% of stroke patients
2. May occur if the stroke or ischemia impairs the vasomotor centers of the dorsolateral medulla or pons (severe vertebral or basilar atherosclerosis)

Dural Arteriovenous Fistula

Overview

1. Clinical history of a brief focal neurologic deficit
2. Imaging evidence of a perfusion deficit in the appropriate location
3. Increase of mean transit time (MTT) and regional cerebral blood volume (rCBV); a measure of venous congestion
4. In rare instances, transient neurological deficits may be due to venous congestion

Central Nervous System Vasculitis

Overview

1. Primary angiitis of the CNS (PACNS)

2. Systemic vasculitis (the CNS is involved in 20% of patients)
3. Usual presenting symptoms of PACNS are headache and cognitive impairment
4. Affects small and medium-sized vessels of the brain parenchyma, spinal cord and leptomeninges
5. PACNS is most common in males in the fourth and fifth decades and represents 1.2% of vasculitis involving the CNS
6. In PACNS, transient ischemic attacks occur later in the course of the illness and is seen in approximately 28% of patients

Cerebral Amyloid Angiopathy (CAA)

Overview

1. Usual presentation is cognitive decline or lobar symptomatic intracerebral hemorrhage
2. Some attacks similar to migraine with aura
3. Patients that experience prolonged stereotyped sensory symptoms: may predate ICH

Focal Subarachnoid Hemorrhage (FSH)

Overview

1. FSH presented in 4 patients with transient migraine auras
 - a. No prior migraine history in these elderly patients
 - b. FSH of contralateral cortical sulcus
 - c. Mechanism is possible cortical spreading depression; possible underlying CAA

Mitochondrial Disease (MELAS)

Overview

1. Migraine like headaches
2. Painful myoclonic jerks
3. Visual complaints
4. Rapid resolving stroke-like picture in parietal, temporal and occipital lobes
5. Non-vascular territory involvement
6. Usually presents in childhood or adolescence but may occur for the first time in the elderly
7. Headaches, muscle cramps, blurred vision, cardiac conduction deficits, hearing loss, psychiatric disorders, seizures and gastrointestinal symptoms may occur concomitantly
8. MRI predominantly reveals gray matter lesions not confined to vascular territories

Intracranial Tumors That Mimic Transient Cerebral Ischemia

Overview

1. Underlying features associated with tumor are:
 - a. Focal seizure-like activity
 - b. Pure sensory symptoms
 - c. Loss of consciousness
 - d. Isolated aphasia or speech arrest

Subdural Hematoma (SDH)

Overview

1. Direct bleeding into the subdural space from head trauma
2. Vessels in the leptomeninges rebleed that may produce intermittent symptoms
3. Usually spasticity of the afferent extremities
4. Third cranial nerve signs
5. Ruptured intracranial aneurysm
6. Ruptured cortical artery
7. Neoplasm
8. Hematological disorders
9. Anticoagulant/thrombolytic therapy
10. Cerebral Amyloid Angiopathy
11. Dural arteriovenous fistula
12. Acquired immune deficiency syndrome

Temperature Dependent Disease

Overview

1. Diseases that are exacerbated by heat may demonstrate the onset of focal symptoms:
 - a. Demyelinating disease (Uhthoff phenomena)
 - b. Myasthenia Gravis
 - c. Lambert-Eaton syndrome
 - d. Fabry's disease
2. The neuromuscular junction diseases have cranial nerve involvement; fluctuating weakness and maintained reflexes
3. Lambert-Eaton patients lose reflexes but gain strength with exercise
4. Myasthenic patients weaken with exercise but may have increased reflexes (spread of sarcolemma acetylcholine sensitivity)

Subclavian Steal

Overview

1. Rarely is clinically significant
2. In general, the process is exacerbated when the patient vigorously exercises the left arm overhead (which further lowers the pressure in the arm by dilating muscular vessels)
3. The subclavian artery is stenosed prior to the origin of the vertebral artery (decreases arm blood pressure)
4. Blood flows from the ipsilateral vertebral artery into the exercising arm
5. Patients demonstrate brainstem signs and symptoms which include vertigo, drop attacks, arm claudication (rare occurrence), ataxia presyncope, hearing loss
6. Linear correlation between increasing arm blood pressure difference and symptoms
7. Symptomatic patients may have concurrent cerebrovascular disease

Syncope (Discussed in Chapter on Convulsions)

Overview

1. Reflex (neurally – mediated):

- a. Emotional distress (a major trigger)
- b. Reflex causes: cough, gastrointestinal, micturition, post-exercise, post prandial and stretch
- c. Specific functions (weight lifting, laughing, wind instrument)
- d. Carotid sinus pressure
- e. Atypical (no specific triggers)
2. Orthostatic syncope:
 - a. Primary autonomic failure (genetic mutations)
 - b. Secondary autonomic failure (processes that destroy autonomic nerves or central nuclei and pathways)
 - c. Volume depletion
3. Cardiac syncope:
 - a. Arrhythmia
 - i. Bradyarrhythmia
 - ii. Tachyarrhythmia
 - iii. Drug-induced
 - iv. Brugada syndrome
 - v. Long QT syndrome
 - b. Structural cardiovascular disease
 - c. Miscellaneous:
 - i. Pulmonary embolus (spasm of blood vessels and cardiac arrhythmia)
 - ii. Aortic dissection (hypotension, cardiac tamponade, hemispheric or spinal lesions)
 - iii. Pulmonary hypertension (cerebra; hypoxia)

Cryptogenic Stroke

General Characteristics

1. The TOAST classification (Trial of ORG 10172 in Acute Stroke Treatment): a brain infarction that is not attributable to a source of definite cardioembolism (CE), large artery atherosclerosis (LAA) or small artery disease (SAD)
2. Risk factors include:
 - a. Left ventricular thrombi (often infarction)
 - b. Aortic plaques
 - c. Hypercoagulable states
 - d. Patent foramen ovale/atrial septal aneurysm and atrial septal defects
 - e. Inflammation and infection
 - f. DM, homocysteinemia, hypertension, family history, hyperlipidemia are possible causes
 - g. Prior TIA
 - h. Smoking
 - i. Race and ethnicity

Clinical Manifestations

1. Superficial hemispheric infarction in 75% of patients
2. Lacunar infarcts are rare: less than 5%
3. Severity at presentation: less than cardioembolic stroke but greater than lacunar stroke
4. A significant proportion of cryptogenic strokes respect embolic infarct topography

5. The same incidence of parenchymal hemorrhage as cardioembolic stroke
6. Large subcortical strokes greater than 15 mm suggest cardioembolism or are cryptogenic
7. Abnormalities detected by transthoracic echocardiography include:
 - a. Enlarged left atrium
 - b. Thrombus in an atrium
 - c. Spontaneous echo contrast ("smoke" poor quality of the stroke ejection fraction)
 - d. Patent foramen ovale
 - e. Atrial septal aneurysm
 - f. Aortic plaques
 - g. Mitral valve prolapse
8. Possibly a better prognosis with lower recurrence rate than identifies strokes

Arterial Localization – (Arterial Topology/Stroke Localization)

Clinical Symptoms and Signs of Major Vessel Stroke

Carotid Occlusion Overview

A patient that has suffered a complete carotid occlusion is not infrequently asymptomatic if the process has been insidious and has been accompanied by extensive collateralization. Patients have been described with slowly developing complete carotid and vertebral occlusion that are relatively asymptomatic. In the face of acute occlusion without sufficient collateralization patients suffer weakness or paralysis of the contralateral arm, face and leg, the head and eyes are deviated to the side of the lesion (may not be dolled across the midline to the opposite side for 12–24 hrs) and may have a contralateral hemisensory deficit to all modalities. Cerebral edema supervenes within the first 12–24 hours and is manifest by lethargy, Cheyne–Stokes respiration exacerbated (if cardiac or pulmonary disease is present) and slight downward deviation of the eyes (5° below the horizontal). The arm on the contralateral side is pronated and the leg externally rotated. If the infarction is in the dominant hemisphere (90% of dextral and sinistrals are dominant in the left hemisphere) expressive and receptive aphasia is evident. If the occluded carotid affects the non-dominant hemisphere (NDH) hemineglect may be associated with unnoticed weakness of the contralateral leg and consequent falling when walking or standing. Similarly contralateral coarse shaking or involuntary movements may be seen in the extremities opposite the stenotic carotid artery precipitated by standing, walking, or head hyperextension due to ischemia of the ipsilateral corticospinal pathways (shaking TIA).

Severe Preocclusive Carotid Disease

Severe preocclusive carotid disease may present with recurrent TIA's, a stepwise onset, or a pseudotumoral slowly progressive form. Ischemic orbital pain may awaken the patient

from sleep and is described as severe, deep and boring. Ischemic oculopathy with a swollen disc, and neovascularization may occur in conjunction with engorgement of conjunctival and episcleral vessels. The intraocular pressure may be extremely low. Optic atrophy on the ischemic side is rare. High-grade stenosis may be associated with a unilateral loss of vision in bright light which may persist for seconds to hours and is related to delayed regeneration of visual pigments in the retinal pigment epithelial layer. These phenomena may occur bilaterally if both carotids are severely stenotic. Monocular visual loss may also be described as dimming or blurring of vision or seeing through a fog. The attacks are short, from 1–2 minutes, but occasionally last for 20 to 30 minutes. They are not positionally related.

Bruits are frequently associated with severe stenosis but frequently disappear when the occlusion reaches approximately 90% of the arterial diameter. A diastolic component of the bruit is very significant. A bruit may be heard contralaterally in a minimally affected carotid due to augmented blood flow through the less diseased artery.

Acute Carotid Occlusion

Carotid occlusion at or below the bifurcation may cause a complete Horner's syndrome with ptosis meiosis, facial anhidrosis and apparent enophthalmos. If only the internal carotid is occluded past the branching of the external carotid there, will be no facial anhidrosis. The sympathetics surround the internal carotid artery to innervate the iris whereas the external carotid carries sympathetic innervation to the face. In a few patients, the pupil on the affected side will be dilated (less than 10%) and unresponsive to light due to iris ischemia. Pupillary cortical representation may lie in the motor sensory cortex or the prefrontal eye fields so that unilateral infarction may cause unilateral or bilateral ptosis (cortical innervation to the central caudal nucleus which innervates the levator palpebrae) and ipsilateral meiosis. This constellation is known as a cortical baby Horner's syndrome. If severe carotid stenosis has preceded acute occlusion, the arcus senilis may be less apparent on the affected side. A major motor seizure may occur in a small proportion of patients concomitant with the occlusion. Waxing and waning of consciousness occurs during the first few days and Cheyne–Stokes respiration is common. The anterior 2/3 of the hemisphere is most severely affected. Rarely the affected side demonstrates hyperhidrosis (involvement of the anterior hypothalamus supplied by the meningo-hypophyseal trunk of the cavernous carotid).

The hemisphere may be more severely involved if it is isolated due to hypoplasia of the anterior or posterior communicating arteries or if there is a fetal origin of the posterior cerebral artery from the carotid (concomitant hypoplastic ipsilateral posterior communicating artery). The stenotic or emboli lesions may extend to occlude the origin of the anterior cerebral artery with its consequent occlusion or in the case of a fetal origin of the posterior cerebral artery it may be occluded along with the middle cerebral artery.

The size of the ICA occlusion may be minimized by collateral circulation through the Circle of Willis, cortical leptomeningeal vessels and those from the external carotid (internal maxillary, superficial temporal artery to meningeal vessels, ophthalmic and external carotid vessels to middle cerebral artery branches).

Clinical Correlate of the Acute Carotid Occlusion

1. Lethargy, fluctuating level of consciousness, rare seizures
2. Horner's syndrome (ipsilateral)
3. 10% dilated unresponsive pupil (iris ischemia)
4. Periodic respiratory breathing pattern
5. Head and eyes deviated ipsilaterally (frontal eye fields are 8 and 10)
6. Hemisensory deficit to all modalities (contralaterally); vibration spared
7. Broca's aphasia > Wernicke's (DH)
8. Hemineglect contralateral side (NDH)
9. Pronated arm, externally rotated leg (contralaterally)
10. Depressed reflexes (contralaterally) acutely
11. Babinski sign (contralaterally)

Features of Intracranial Internal Carotid Occlusive Disease

Atherosclerosis of the Carotid Siphon

Calcification of the siphon is common and is coexistent with extracranial disease. There is a high death rate from coronary artery disease and disease in this location is more common in Afro-Americans than Caucasians. There are frequent concordant lesions in the origins of the internal carotid and vertebral arteries. Tandem ICA and siphon disease is common. There is a higher ratio of stroke to TIA in carotid siphon disease than cervical carotid disease. The major clinical differential points of siphon versus internal carotid diseases are:

1. Few episodes of amaurosis fugax
2. No ocular retinal pathology
3. Retrograde extension of the siphon clot may cause delayed optic ischemia
4. Leg is more affected than the arm
5. Associated scattered ACA and MCA infarcts are noted. These may involve the foot and face, sparing the arm
6. Slowly progressive symptoms
7. Worse prognosis than ICA origin disease
8. There are no collaterals through the external carotid artery

Occlusion of the Top of the Carotid (T Portion)

A block at the top of the carotid causes infarction of both the anterior cerebral and the internal carotid artery. It is most common with sickle cell disease and with circulating anticoagulants.

The Anterior Choroidal Artery (ACHA) Syndrome

The anterior choroidal artery is the second branch of the internal carotid artery. It partially supplies the caudal 2/3 of

the posterior limb of the internal capsule, the posterior optic tract, the uncus of the temporal lobe, medial GP₁, cerebral peduncle, lateral geniculate body and portions of the thalamus. AchA does not supply the corona radiata or the ventricular wall. Its most consistent branches are to the optic tract, cerebral peduncle and choroid plexus. There are variable anastomosis with branches of the MCA, PCA and posterior communicating artery. This artery supplies territories in both anterior and posterior circulations.

Most Consistent Clinical Presentation

1. Hemiparesis, hemisensory loss, hemianopsia
 - a. Pure motor hemiplegia (face, arm and leg affected)
 - b. Bilateral AchA infarcts:
 - i. Pseudo bulbar palsy
 - ii. Mutism
 - iii. Quadriparesis
 - c. Hemisensory symptoms: incomplete or temporary and comprise all modalities

Unusual Sensory Manifestations

1. Hemisensory deficit with spared proprioception
2. Painful thalamic-type syndrome
 - a. Formication (crawling paresthesias)
 - b. Feeling of limb swelling
 - c. Pain in the arms and legs
3. Hemiataxia with the sensory symptoms
4. Temporary sensory loss

Clinical Manifestations

1. Motor Deficits:
 - a. Face, arm and leg affected
 - b. Ataxic hemiparesis (thalamic)
 - c. Hypesthetic ataxic hemiparesis
2. Visual field deficits and eye movement abnormalities:
 - a. Congruent homonymous visual field deficit sparing the central sector
 - i. Lateral geniculate body infarcted
 - ii. Known as a quadruple sectoranopic defect
 - b. Homonymous congruent superior quadrantanopia
 - i. With or without macular sparing
 - c. Congruent homonymous hemianopia
 - d. Ipsilateral conjugate eye deviation

Higher Cortical Deficits with AchA Infarction (Unusual)

1. Non-dominant hemisphere
 - a. Visual neglect
 - b. Constructional apraxia
 - c. Short term visual memory loss
 - d. Anosognosia
 - e. Motor impersistence
2. Dominant hemisphere infarction
 - a. Decreased fluency
 - b. Semantic paraphasia

- c. Perseveration
- d. Deficits in language processing
- e. Poor understanding of word associations
- f. Poor comprehension
- g. Short term verbal memory loss

AchA Infarction of Lateral Thalamus and Posterior Limb of the Internal Capsule

1. Dysarthria
2. Language processing defects
3. Short term verbal memory loss

Bilateral AchA Infarction

1. Urinary incontinence without dementia
2. Dysarthria
3. Dysphagia
4. Dysphonia
5. Palatal paralysis – (may occur with unilateral stroke)
6. Pseudobulbar affect
7. Depression
8. Blunted affect
9. Mutism
10. Lethargy

Anatomic Variants of AchA

1. Anastomosis with:
 - a. MCA
 - b. Posterior communicating artery
2. Paraventricular areas
 - a. Watershed between the deep MCA perforators and lateral lenticulostriate arteries
 - b. Watershed between the posterior choroidal arteries (near the superior portion of the internal capsule)
3. May supply the temporo-occipital lobe (PCA territory)

Pathogenesis of AchA Occlusion

1. Surgical manipulation
 - a. Aneurysm (spasm)
 - b. Seizure surgery
2. Hyperviscosity states
3. Decreased perfusion
4. Embolism
 - a. Cardiac
 - b. Often with concomitant MCA embolism
5. Thrombosis
 - a. Intracranial atherosclerosis

Anterior Cerebral Artery

Overview

The anterior cerebral artery arises from the internal carotid artery at the level of the anterior clinoid process to supply the medial surfaces of the frontal and parietal lobes as well as the anterior 4/5 of the corpus callosum, the ventrobasilar frontal cortex (substantia innominata, septal nuclei, and

nuclei of the diagonal band) and the anterior thalamus. The A1 segment from the carotid joins the anterior communicating artery AcoA in the interhemispheric fissure. There are approximately 8 perforating branches from the A1 segment. Proximal A1 branches perfuse the genu, contiguous areas of the posterior limb of the internal capsule, the anterior hypothalamus, anteroventral putamen and pallidum. Distal A1 segment branches perfuse the optic nerve, chiasm and tract. The perforating branches of the AcoA perfuse the most anterior aspects of the hypothalamus, the basal forebrain, and the medial anterior commissure, fornix and lamina terminalis, corpus callosum and anterior cingulum. A2 branches, part of the ascending segment, perfuse the gyrus rectus, the inferior frontal cortex, the anterior thalamus and the rostrum of the corpus callosum. The recurrent artery of Heubner takes origin near the AcoA and travels backward along the A1 segment to penetrate the brain at the lateral anterior perforating substance, Sylvian fissure or orbitofrontal cortex to supply the head of the caudate and anterior limb of the internal capsule.

The distal A2–A5 segments comprise the pericallosal and callosomarginal arteries. If the callosomarginal artery is absent, all cortical branches originate from the pericallosal artery (18–60%) of patients. The ascending orbitofrontal and the frontopolar arteries arise from the A2 segment and supply the inferior, medial and lateral surfaces of the frontal pole. The superior frontal gyrus is supplied rostrocaudally by A2–A4 segments of the pericallosal artery. The paracentral artery, the superior parietal artery may arise from either the callosal marginal or the A4–A5 segment of the pericallosal artery to supply the superior precuneus while the posterior inferior cuneus is supplied by A5 branches of the inferior parietal artery from the pericallosal artery. There are a great number of normal variations of the anterior cerebral artery and anterior portion of the Circle of Willis.

The usual etiology of ACA-territory infarction is a cardioembolic stroke particularly if there is increased blood flow through the artery due to a contralateral ICA occlusion or a congenital defect of the anterior Circle of Willis. In situ thrombosis of the artery is more common in Asian patients. Extension of thrombus from the ipsilateral carotid is the usual atherosclerotic mechanism. Occlusion by transtentorial herniation, vasospasm from ruptured ACOA aneurysm or embolisms from these aneurysms are particular causes of infarction peculiar to this artery. Bilateral occlusion is rare but has been reported. Approximately 25% of these patients have had an azygous or unilateral supply of both ACAs from one carotid artery, the others having suffered probable emboli from atrial fibrillation or recent myocardial infarction. Bilateral infarction of the ACA causes akinetic mutism with poor recovery. The artery may be infarcted by the angitis of collagen vascular disease, prothrombotic states, lacunar infarction, rare emboli (fat, air, and atrial myxoma), dissection or fibromuscular dysplasia.

Anterior Cerebral Artery (ACA) Stroke: Clinical Signs and Symptoms

The clinical signs and symptoms of ACA are distinct. The artery is involved primarily following vasospasm secondary to anterior communicating aneurysm rupture, damage from neurosurgical procedures, propagation from ICA occlusion and artery-to-artery embolism from more proximal atherosclerotic occlusive disease.

Cortical branch occlusion causes severe weakness of the distal foot and leg, the proximal arm with sparing of the face and tongue. The patient can frequently perform fractional movement of the hand and thumb. Muscle tone is flaccid early and then becomes spastic. The paracentral lobule, upper motor cortex and subcortical fibers from these areas that project into the corona radiata are affected. A few patients may only suffer a crural monoplegia (contralateral weakness of the leg). The pattern of weakness may vary considerably with some patients suffering arm and leg weakness to the same degree, others with hemiparesis and brachial predominance. Distal occlusion of the ACA may also cause pure motor hemiparesis and homolateral ataxia and crural paresis.

Patterns of ACA Weakness

1. Paresis of foot and leg > arm; face and tongue spared
2. Crural monoplegia (contralateral paralysis of leg and foot)
3. Contralateral arm and leg involved equally
4. Contralateral hemiparesis with brachial facial predominance
5. Homolateral ataxia with crural paresis
6. Pure motor hemiparesis

Infarction of the recurrent artery of Heubner from the A1 segments affects the head of the caudate, the putamen and the anterior limb of the internal capsule. This lesion may cause faciobrachial predominance in the observed hemiparesis. The proximal perforators from A1 may also supply the genu and anterior internal capsule. Right-sided > left-sided medial frontal infarction that includes the SMA may cause contralateral motor neglect.

Sensory deficits are most severe in the foot and leg contralaterally. They are most often in discriminative touch but may be severe to all modalities.

Psychomotor Dysfunction

The anterior cerebral artery supplies regions of the limbic system and basal ganglia essential for integration of emotional aspects of movement and frontal lobe function. Transient loss of consciousness may occur with ACA infarction. Bilateral damage to the anterior cingulate gyrus or head of the caudate nucleus may cause akinetic mutism. These patients do not initiate speech or movement and have no emotional expression. They do not respond to sensory stimuli but may follow the examiner with their eyes. Transient abulia may be seen with a unilateral lesion of the caudate head and cingulate gyrus and is characterized by decreased spontaneous speech and delayed response to questions, minimal spontaneous activity

and impersistence. These patients may speak almost normally on the telephone.

Infarction of projections from the caudate nucleus to the orbital and dorsolateral prefrontal cortex causes agitation hyperactivity and delirium. If they occur on the dominant side and disrupt connections into the thalamus, aphasia may be noted. Medial frontal lobe infarction causes euphoria, lability of affect and pathological jocularity. Antegrade amnesia may occur from damage to the paramedian basal forebrain during aneurysm surgery that damages perforators from the ACOA. If concomitant mesial frontal damage occurs confabulation may occur with the amnesia.

Aphasia and Language Disorders

Damage to the left supplementary motor area (SMA) may cause decreased spontaneous speech, normal articulation, repetition and comprehension. Transcortical motor or mixed transcortical aphasia has been documented with SMA lesions. Mirror writing can develop with right SMA lesions. Acquired stuttering may occur with anterior callosal or bifrontal lesions. Occlusion of either the right or left anterior cerebral artery may cause muteness.

Anterior Cerebral Artery Speech Disorders

1. Muteness
2. Transcortical motor aphasia
3. Transcortical sensory aphasia
4. Acquired stuttering
5. Whispered speech
6. Reduced spontaneous speech
7. Normal comprehension
8. Normal articulation

Urinary and Fecal Incontinence

Unilateral or bilateral ACA infarction may cause urinary and fecal incontinence by damaging the midportion of the superolateral and medial superior frontal gyrus and the anterior cingulate gyrus. Damage to the paracentral lobule may induce precipitate micturition that cause patients to urinate uninhibitedly when their bladder is partially full.

The Grasp Reaction of ACA Infarction

The grasp reflex is caused by a contralateral basal ganglia or frontal lesion. This response is flexion and adduction of the hand when an object is gently moved from the palmar hypothenar eminence through the palmar index finger and thumb. This is an involuntary response. The instinctive grasp reaction is elicited by a stationary touch in the same areas of the hand and consists of: 1. several grasping movements directed toward the object; 2. a true grasp is one grasp in response to an object; 3. the traction response follows stretching of the patient's flexed fingers that he cannot release; 4. in a magnetic response in which the patient shadows the movements of the examiner's hand. A contralateral lesion of the mesial superior frontal and cingulate gyrus or rarely the basal ganglia causes a grasp reflex.

Callosal Disconnection Syndromes Following ACA Infarction

In right-handed patients, a left handed ideomotor apraxia may occur following ACA infarction. The patient is unable to perform a simple command with the left hand such as a military salute. This is due to disconnection of Wernicke's area and the premotor cortex from the premotor and primary motor cortex of the right hemisphere. It may also occur after infarction of the left premotor area (8), the anterior corpus callosum or the right premotor cortex. The patient may have impaired ability to imitate the examiner's movements with the left hand.

Left-hand agraphia may be seen with ACA infarction. Patients are unable to write readable letters, utilize correct words and often demonstrate substitutions or perseverations both to dictation and with spontaneous writing. No linguistic mistakes are made with the right hand. They are able to write or copy correctly but cannot type or use block letters. In general, ideomotor apraxia and agraphia occur concomitantly with callosal lesions but may be dissociated. The callosal fibers for praxis cross the midline in the rostral portion of the posterior body of the corpus callosum.

Unilateral tactile anomia occurs in the left hand. The patient can manipulate the objects correctly with either hand. He has an associated unilateral left agraphia that is caused by a lesion of the posterior part of the body of the corpus callosum. Right handed constructional dysfunction and crossed pseudoneglect to both visual and tactile stimuli. Line dissection tasks have been noted with callosal posterior body infarction. A crossed visuomotor apraxia results from damage to the dorsal aspect of the posterior callosum. A crossed avoiding reaction (patient unable to move the left hand when an object is placed in the right hemisphere) has been seen with a lesion of the genu and body of the corpus callosum.

The alien hand syndrome denotes a patient who has a feeling that the left hand does not belong to him and notes that one hand works at cross purposes with the other. In general, these patients have suffered a mesial frontal lobe and corpus callosum lesion. The patient cannot voluntarily suppress motor perseveration in which the he or she compulsively repeats stereotyped movements. These movements are usually associated with a grasp reflex and instinctive grasp reaction. Compulsive manipulation of tools placed in front of the patient is a release of praxis from damage of the left mesial frontal lobe, cingulate gyrus and genu of the corpus callosum. The syndrome occurs with a concomitant grasp reflex and instinctive grasp reaction but no disconnection syndrome. The utilization behavior of Lhermitte differs from compulsive manipulation of tools because it is bilateral and lacks the compulsive quality noted in the compulsive manipulation of tools. Diagnostic dyspraxia is a dissociative movement in which the left hand undoes the actions of the right. Usually the left hand works at cross-purposes to the right. Damage to the body of the corpus callosum is required for this behavior. Damage to the contralateral mesial frontal lobe and genu of the corpus callosum may cause purposeless movements of the contralateral hand such as an updrift, tucking the hand in the axilla or grasping the throat.

Alien Hand Phenomena and Variants

1. Le signe de la main étagée "strange hand"
2. Intermanual conflict
3. Motor perseveration
4. Compulsive manipulation of tools
5. Diagnostic dyspraxia
6. Updrift, hand in the axilla, grasping the throat

Callosal Disconnection Syndromes

1. Ideomotor apraxia – left hand
2. Agraphia – left hand
3. Tactile anomia – left hand

Pathologic Grasp Phenomena

1. Grasp reflexes
 - a. True grasp
 - b. Instinctive groping
 - c. Traction response
 - d. Magnetic response

The Middle Cerebral Artery

Overview

The middle cerebral artery is most commonly affected in ischemic cerebral vascular disease. African-American or Asian patients have a higher incidence of infarction of this artery than white patients.

The TIAs of MCA disease are less frequent than those stemming from carotid disease and occur over a shorter time period. White patients present with TIAs of the MCA more frequently than with stroke; cigarette smoking is a strong risk factor for all groups that suffer MCA infarction.

Major differential points of MCA occlusive disease from that of the ICA are: 1. deficits on awakening; 2. fluctuation or progression of symptoms; over the following 1–7 days; 3. probable low flow mechanism. Carotid disease is more suggestive of an embolic mechanism. There are no ocular symptoms with MCA disease.

Approximately 2/3 of all first brain infarcts are in the MCA territory. Approximately 1/3 affects the deep MCA territory and 10% occlude both deep and superficial territories. Approximately 50% of MCA infarctions are restricted to the superficial pial arteries.

Anatomy of the MCA and Its Patterns

1. Pial branches supply:
 - a. Almost the entire convex surface of the brain
 - b. Lateral frontal, parietal and temporal lobes
 - c. Insula, claustrum and extreme capsule
2. MCA emerges from the ICA for 1.8–2.6 cm as a single trunk
 - a. Proximal M1/M2 segments give rise to medial and lateral lenticulostriate arteries
3. The stem divides into three patterns:
 - a. Bifurcation pattern
 - i. Superior and inferior division – 79%

- b. Trifurcation pattern:
 - i. Superior, middle, inferior division – 12%
- c. Four or more trunks – 10%

Bifurcation Pattern (Superior/Inferior Division)

1. Superior division (pial branches):
 - a. Ascending orbitofrontal branch
 - b. Prefrontal branches
 - c. Precentral branches
 - d. Central or central sulcal branches
 - e. 2–3 anterior parietal branches
 - f. 1–3 angular branches
2. Inferior division (pial branches):
 - a. Ascending temporopolar branch
 - b. Anterior temporal branch
 - c. Middle temporal branch
 - d. Posterior temporal branch

Trifurcation Pattern

1. Superior division:
 - a. Ascending orbitofrontal branch
 - b. Prefrontal branches
 - c. Precentral branches
2. Middle division:
 - a. Central/central sulcal branches
 - b. Variable origin of:
 - i. Precentral/anterior and posterior parietal branches
 - ii. Angular/temporo-occipital branches
3. Inferior division (pial branches):
 - a. Ascending temporopolar
 - b. Anterior temporal branches
 - c. Middle temporal branches
 - d. Posterior temporal branches
 - e. Variable origin of (posterior parietal/angular/temporo-occipital arteries):
 - i. In both bifurcation and trifurcation patterns superficial branches may come from the stem of the MCA prior to its division:
 1. Ascending temporopolar branches
 2. Anterior and middle temporal branches

Anomalies of the Middle Cerebral Artery

1. Rare: occur in 3% of individuals
2. Duplication of the MCA:
 - a. A second vessel arises from the ICA which supplies the anterior and middle temporal territories
3. Variable patterns of ACA and PCA pial terminal anastomosis at hemispheric border zones
4. If the main MCA trunk is short the lenticulostriate arteries may arise from the superior division

General Features of Superficial Middle Cerebral Artery Territory Infarction

Patients frequently develop distal MCA trunk occlusions that spare the deep penetrators from the M1 and M2 segments of

the proximal MCA. The pathogenesis is most often thrombosis in situ rather than embolic. Complete infarction of the superficial MCA territory of the dominant hemisphere causes head and eye deviation to the side of the lesion, lethargy, global aphasia (often early mutism) and perseveration. The hemiparesis and hemisensory loss is brachiocephalic predominant with an invariant contralateral homonymous hemianopia. Non-dominant hemisphere infarction in addition to similar motor and eye signs demonstrate contralateral neglect, constructional apraxia, alloesthesia, anosognosia and multiple non-dominant (ND) parietal lobe symptomatology.

Superior division dominant (D) hemisphere infarction causes brachiofacial predominant motor and sensory symptoms, no visual field deficits, but gaze preference or eye deviation (Brodmann's 8 and 10) to the affected side. Broca's aphasia, ipsilateral ideomotor or limb kinetic apraxia and oral buccal lingual apraxia may be seen. Non-dominant infarcts have similar motor and sensory deficits with hemispatial neglect and emotional aprosody. Inferior division territory infarction causes minimal weakness but usually an up drift can be appreciated acutely. Astereognosis, difficulty with dynamic and static parietal copy and point localization is noted after the ictus. The most common visual field deficit is a contralateral superior quadrantanopsia if Meyer's loop is involved, although a contralateral non-congruent homonymous hemianopsia may also be seen (optic tract). Dominant hemisphere lesions cause a Wernicke's aphasia with an occasional patient demonstrating acute agitation. Characteristics of non-dominant lesions are a contralateral predominant sensory hemineglect, anosognosia, constructional apraxia and an agitated confusional state.

Superior Division of the Middle Cerebral Artery (Pial Branches)

Ascending Orbital Frontal Artery

This artery perfuses the orbital portion of the middle and inferior frontal gyrus and the inferior pars orbitalis. Its infarction (emboli or arteritis) causes behavioral disinhibition and a contralateral grasp sign.

Prefrontal Arteries

The territory perfused by these arteries is the middle frontal gyrus, pars triangularis, anterior pars opercularis and superior pars orbitalis. The clinical symptomatology includes apathy, abulia, poor ability to change motor sets, perseveration (DH), impersistence (NDH), poor judgment and abstraction, imitation and utilization behavior, and poor retrieval of short term semantic material. A transcortical motor aphasia may be noted with (DH) lesions and motor neglect with non-dominant hemisphere infarction.

Precentral Arteries

This group of arteries supplies the posterior middle frontal gyrus, the posterior pars opercularis and the anterior and mid-portion of the precentral gyrus. The clinical features of infarction of this branch or branches are proximal upper extremity

weakness or distal brachiofacial weakness. Dominant hemisphere lesions may have a concomitant transcortical motor aphasia. Due to infarction of area 8, patients may have bilateral upper extremity ideomotor apraxia. If the infarction involves the posterior left middle frontal gyrus (Exner's area) they may have agraphia out of proportion to hand weakness.

Central Sulcal Artery

The central artery group supplies the posterior bank of the precentral gyrus and the anterior half of the post central gyrus. A pathognomic clinical sign of infarction of this territory is monoparesis of the upper extremity (pseudoradial palsy) although brachiofacial weakness is the most common pattern. Infarction of the motor knuckle anteriorly causes selective weakness of muscles innervated by C5 and C6. Posterior infarction causes C8–T1 innervated muscle weakness. Sensory loss is noted in the same distribution. Rarely a pure motor stroke affecting arm, face, and leg occurs. Infarction of the parietal operculum may cause a cheiro-oral sensory loss (corner of the mouth and hand). Dominant hemisphere infarctions cause Broca's aphasia or dysarthria and dysprosody. Non-dominant hemisphere infarction usually causes less severe dysarthria.

Anterior Parietal Artery

This artery or group of arteries supplies the post central gyrus, parasagittal portion of the central sulcus, and the anterior inferior portions of both the inferior and superior parietal lobules.

Anterior parietal branch occlusions may cause a contralateral updrift of the arm with abnormal proprioceptive finger movements (mini myoclonus). Loss of touch and position sense is common in the arm and face distribution. Vibration is usually spared. The distal upper extremity may be most severely affected. Incoordination of the affected hand may be noted. Dominant hemisphere infarction may cause conduction aphasia while non-dominant lesions are associated with visual-spatial deficit.

Posterior Parietal Artery

Infarction of this territory involves the posterior portions of the superior and inferior parietal lobules and the supramarginal gyrus. Discriminative sensations such as two point localization, stereognosis and graphesthesia are predominantly involved. Patients may demonstrate an inferior quadrantanopsia or non-congruent homonymous hemianopsia. Dominant hemisphere lesions may cause anomia (aphasia (SMG), agraphia, and alexia (areas 39, 40, 41). Ideational and bilateral representational ideomotor apraxia as well as a posterior alien hand syndrome may occur. Left right confusion, finger agnosia, dyscalculia, inability to cross the midline and dysgraphia (Von Gerstmann's syndrome) may be seen singularly or concurrently. Non-dominant hemisphere infarction causes contralateral sensory spatial neglect, constructional apraxia and visuospatial deficits.

Differential Diagnosis of Parietal Sensory Loss

In general, parietal sensory symptoms from infarction have a regional pattern. Dramatic involvement of 1/2 of the body is characteristic of thalamic disease. Other thalamic signs are the upper extremity is more severely affected and often the trunk is spared. The deficit may be limited to the fingertips (ventral posterior inferior nucleus) and primarily involves the discriminative aspects of sensation. Vibration loss is a thalamic or dorsal column nuclear deficit. Motor dysfunction with these sensory symptoms occurs in a large majority of patients. This motor deficit first described by Foerster as an afferent paresis or tactile paresis (loathness to move). Partial pseudosegmental, pseudoradicular, cheiro-oral (posterior parietal operculum) pseudospinal patterns may be seen with parietal lesions. The usual pseudoradicular pattern is C6 or C8–T1. A pseudothalamic pattern (SI area) consists of deficits of elementary modalities of sensation with faciobrachial predominance (syndrome of Roussy and Foix). Spinothalamic type of sensory loss (Brodmann's area 43, part of SMG and the posterior insula) may be seen. Patients may demonstrate asymbolia for pain, if SII is infarcted (adjacent to the lower extent of SI). Portions of the cortical sensory syndrome with loss of discriminative touch, position sense, astereognosis, ability to copy posture, sensory hemineglect (NDH) with preserved vibration sense may be seen with both anterior and posterior parietal branch infarctions. Corona radiata and occasionally SI infarction may cause a feeling of heaviness in the contralateral extremities and are associated with difficulty initiating and sustaining movement (disconnection of deep SI, 3b and area 4) in the depths of the central fissure.

Angular Artery Branch

This artery supplies the posterior portion of the superior temporal gyrus, parts of the supramarginal and angular gyri and the superior lateral occipital gyri. The major features of infarction of this branch are the angular gyrus syndrome (Von Gerstmann). Frequently associated is anomia or transcortical aphasia, alexia without agraphia, an inability to cross the midline and constructional apraxia. Non-dominant lesions are associated with: 1. contralateral spatial neglect; 2. visuospatial and constructional deficit; 3. loss of opticokinetic nystagmus (eyes remain; toward the ipsilateral side); 4. hemianopia or inferior quadrantanopsia; 5. anosognosia (denial of illness); 6. asomatognosia (denial of a limb); and 7. alloesthesia (perception of sensation on the normal side when the affected side is stimulated are seen).

If there is a short mainstem MCA, the lenticulostriate arteries may originate from the superior trunk. Infarction in this circumstance would involve the basal ganglia and the internal capsule.

Inferior Division of Middle Cerebral Artery

The general characteristics of an inferior division MCA infarction are:

1. Wernicke's aphasia (DH)

2. Contralateral superior quadrantic VF deficit
3. Poor drawing and copying (NDH)
4. Agitation (NDH)

Ascending Temporopolar/Anterior Temporal/Middle Temporal Branch Occlusion

The anterior temporal artery supplies the anterior portion of the superior, middle, and inferior temporal gyri. The temporopolar artery complex supplies the anterior pole of the superior middle and inferior temporal gyri. The middle temporal group of arteries supplies the superior gyrus below the pars triangularis and pars opercularis as well as the middle portion of the middle temporal gyrus and posterior portion of the inferior temporal gyrus.

The clinical features of infarction of the anterior temporal branches are a contralateral homonymous superior quadrantanopsia. If on the dominant side, the visual field deficit may be associated with an anomic aphasia with category-predominant naming deficits. Non-dominant infarction may cause hemispatial neglect and an acute confusional syndrome.

Temporo-Occipital/Posterior Temporal Branch Occlusion

These arteries supply the posterior half of the superior temporal gyrus and the posterior portions of the middle and inferior temporal gyri and the inferior portion of the lateral occipital gyri. These occlusions cause a contralateral superior quadrantanopsia or hemianopsia. Dominant hemisphere infarction of the posterior superior temporal gyrus causes Wernicke's aphasia. This infarction is frequently embolic and if pure (no other neurologic symptoms) is often caused by atrial fibrillation or another cardiac source. Non-dominant hemisphere infarction produces an acute confusional state, contralateral hemispatial neglect and constructional apraxia.

Other Common MCA Occlusions of the Superficial Territory Insular Branch Occlusion

The insula is supplied by the MCA trunk or proximal portions of its division and is rarely infarcted in isolation. Bilateral infarctions from serial strokes cause the Foix-Marie-Chavany syndrome which consists of severe apraxia for all of the muscles of branchial origin. Patients have difficulty swallowing, moving the face and tongue, buccal movements and initiating and articulating speech. This is a cause of aphemia which is a dramatic dysarthria that renders speech unintelligible. It may occasionally occur from unilateral insular branch occlusion.

Long Penetrating Medullary Artery Occlusion

Infarction of a group of long-penetrating arteries causes large infarcts in the centrum semiovale. Their origin is in the MCA pial branches and they usually cause a contralateral motor and sensory deficit as well as a non-congruent hemianopsia. If in the dominant hemisphere, patients are dysphasic while

NDH lesions are associated with hemineglect and visuospatial deficits.

Infarcts of less than 1.5 cm in diameter cause pure motor or sensory strokes, ataxic hemiparesis without cognitive impairment or isolated involvement of face, arm or leg (fibers are widely separated). This fractionation is less common than with deep subcortical infarcts. Severe ipsilateral carotid disease produces the lesions by distal field ischemia or embolic disease.

Deep Territory MCA Infarction

The deep territory is composed of penetrating branches from the M1 and M2 proximal segments of the MCA which are known as the lenticulostriate arteries. If these arteries are infarcted, the process is usually embolic and occlusion of many perforators occurs simultaneously. This type of infarction is a striatocapsular infarction rather than a lacunar infarction in which only one lenticulostriate perforator is occluded. In general, striatocapsular infarction involves the head of the caudate, the putamen, and the lateral internal and external capsule and may extend into the corona radiata. The insular cortex and the thalamus is spared. Striatocapsular infarcts may involve the territory of Heubner's artery (recurrent branch from A1) or the anterior choroidal artery. In general, the area infarcted is in the range of 2–7 cm, is wedge or comma shaped, and is not ovoid as are the smaller lacunar infarctions. Cortical symptoms are rare and if present resolve quickly. The cortex is not infarcted due to leptomeningeal anastomoses. In situ thrombosis or cranial arteritis involving a segment of M1 that occludes multiple perforators is rare.

Acutely, patients present with predominantly motor or sensory motor hemiparesis with or without dysarthria. Hemiparesis results from damage to the posterior limb (mid 1/3) of the internal capsule (motor cortex corticospinal fibers) or if only the frontal part of the internal capsule is involved (the lateral premotor cortex corticospinal fibers or those from the SMA cortex in the genu) are involved.

The differential diagnosis of striatocapsular infarcts are: 1. lacunar syndromes; 2. pure sensory stroke; 3. strokes in the basis pontis; 4. ICH of the striatum. If the leptomeningeal anastomosis fails patients may suffer cortical deficits which add to the underlying deficit and rule out lacunar stroke.

In striatocapsular stroke, cortical deficits such as aphasia or neglect resolve in the face of persistent motor or sensory deficits. In a moderate or large territorial or MCA branch occlusion the cortical deficits are more severe and long lasting. Extended striatocapsular stroke is most often associated with Wernicke's aphasia (involvement of insular or superior temporal gyrus). Rarely focal dystonia, contralateral choreoathetosis, or hemiballismus has been noted. Bilateral striatocapsular infarction may cause tetraplegia and akinetic mutism.

Striatocapsular Stroke

1. Predominant motor or sensorimotor hemiparesis

2. Minimal cortical signs and symptoms that resolve
3. 2 to 7 cm in size
4. Wedge or comma shaped
5. Involves caudate, putamen, anterior or posterior limb of the internal capsule
6. Rare contralateral movement disorder
7. Rare tetraplegia with akinetic mutism (if bilateral)

Distal field infarction (or low flow state in the periventricular white matter) between the penetrating cortical branches and the ascending lenticulostriate branches that does not infarct the basal ganglia or internal capsule may mimic some of these findings.

If the head of the caudate nucleus, the putamen and the anterior portion of the internal capsule are infarcted the pattern represents that of occlusion of the recurrent artery of Heubner whose origin is the A1 segment of the ACA aberrant (medial lenticulostriate artery). The resultant hemiparesis has brachiocephalic predominance with tongue involvement. A similar infarction can occur from occlusion of the perforating branches of the most proximal portion of the A1 segment of the ACA artery. If the caudate head and the anterior limb of the internal capsule are involved, the eyes may be deviated ipsilaterally and the face and arm are more severely affected than the leg. Caudate infarction interrupts fibers that project to the frontal and dorsolateral prefrontal cortex and may be associated with an acute confusional, agitated or an abulic state. If the infarction extends anteriorly and destroys fibers that project to the medial dorsal and anteroventral thalamic nuclei, patients may have an expressive aphasia. Rarely with infarctions in this area patients demonstrate a hemisensory defect that affects the face and hand more severely than the leg. Dysarthria is more severe with left-sided than right-sided capsular lesions (corticobulbar projections to cranial nerves VII, X and XII). A non-congruent homonymous hemianopsias results from optic tract infarction. This may also be accompanied by a Behr's pupil (larger, poorly reactive pupil on the ipsilateral side).

The lateral lenticulostriate group of perforators takes origin from the M2 proximal middle cerebral artery segment and supplies the putamen, claustrum, external and extreme capsule and the insular cortex. Putaminal infarction causes brachiocephalic predominant weakness with increased tone and hyperreflexia but no sensory loss. Rarely putaminal infarction causes contralateral dystonia, choreoathetosis, and abnormal contralateral hand posture. Bilateral insular cortex infarction (insular branches of the MCA) produces the Foix–Chavany–Marie syndrome which causes apraxia of all branchial derived musculature and disrupts speech and swallowing. The dysarthria may be so severe that speech is unintelligible (usually requires bilateral infarction).

The Capsular Warning Syndrome

These are TIA's restricted to the face, arm and leg and are not often seen with severe carotid stenosis accompanied by a low flow state. The major clinical features are:

1. Simultaneous sensorimotor involvement of face, arm and leg
2. No neglect, dysphasia or dyspraxia
3. Three or more clinical events within 24 hours
4. Onset over seconds
5. Pure motor hemiparesis is most common
6. Sensory symptoms clear prior to motor signs
7. Capsular infarction follows in approximately 40% of patients

As noted above, the capsule may be predominately involved in specific areas.

Capsular Genu Syndrome

1. Contralateral facial, lingual and brachial weakness
2. With or without ipsilateral horizontal conjugate eye deviation
3. Rare thalamic aphasia

Midpoint Infarction of the Upper Capsule with Lower Corona Radiata Extension (Anterior 1/3 of the Posterior Limb)

Clinical Signs and Symptoms

1. Dysarthria
2. Contralateral clumsy hand
3. Faciolingual weakness
4. Blood supply is from the lenticulostriate arteries that concomitantly supply the upper ventricular wall (anastomosis with ependymal vessels)
5. Posterior 1/3 limb of internal capsule infarction:
 - a. Middle third
 - i. Face < arm < leg weakness
 - ii. Purely motor
 - b. Posterior 1/3:
 - i. Pure sensory
 - ii. Arm, face, and leg involved
 - c. Arterial supply (lenticulostriate)
6. Rare behavioral signs and symptoms of striatocapsular stroke are:
 - a. Fluctuating alertness
 - b. Inattention
 - c. Memory loss
 - d. Apathy
 - e. Frontal lobe deficits
7. These deficits are caused by infarction of:
 - a. Inferior and anterior thalamic peduncles
 - b. Anterior limb of internal capsule

The Differential Diagnosis of Striatocapsular Infarctions

1. Lacunar infarcts (1–2 perforating vessels)
 2. Pure sensory stroke (thalamic infarction)
 3. Infarction of the basis points (penetrating basilar branches)
 4. Small striatal or intracranial hemorrhage
- If leptomeningeal anastomoses fail, or there is a concomitant shower of emboli, patients may suffer cortical deficits. As noted earlier, lack of cortical dysfunction is characteristic of lacunar stroke.

Clinical Differential Diagnosis of Capsular Infarction

1. The first of frequent hemiplegic events is more likely capsular than pontine
2. Premonitory events are characteristics of anterior choroidal artery ischemia
3. Capsular ischemia: patients are aware of its onset; it resolves over seconds to minutes
4. Incipient occlusion of the ICA often is accompanied by repetitive events with cortical dysfunction
5. Hemodynamic events are posturally influenced and are shorter than embolic events
6. Artery-to-artery embolic events are more widely separated in time

Rare Patterns of Stroke in the MCA Territory

Central sulcal branch artery infarction may cause a right pseudothalamic sensory loss (primary sensory modality involvement), ideational apraxia and conduction aphasia. Wernicke's aphasia and hemianopsia often follows embolic occlusion of the temporooccipital branch of the inferior MCA division particularly in the setting of atrial fibrillation. Precentral branch occlusion may cause transcortical motor aphasia, proximal weakness of the arm and ideomotor apraxia.

The anatomical variants of the middle cerebral artery, specifically the origin of the angular artery may determine unusual stroke symptoms following infarction in the MCA territory. Stenosis of the M1 segment of the MCA in conjunction with hypertension may cause periventricular longitudinal infarction.

Double infarcts are those that involve two components of one arterial territory. Aphasia without hemiparesis occurs when Broca's and Wernicke's area are infarcted leaving the motor strip intact. Hemiplegia with visual field deficits occur when the superior division (central sulcal branches) are occluded concomitantly with temporo/occipital branches (inferior division) thus sparing the primary sensory cortex. Conduction aphasia with hemiparesis has been noted with motor cortex and supramarginal gyrus lesions. Fragmentation of emboli at the MCA bifurcation or serial strokes are the most likely mechanisms.

Complete MCA Infarction (Superficial and Deep Territory)

Panhemispheric MCA occlusion is often embolic particularly if sudden. If it occurs with a slower or stuttering onset it is most likely due to carotid occlusion. These patients have cerebral swelling usually within 12 hours of infarction that impairs consciousness. Their head and eyes are deviated ipsilaterally, they demonstrate periodic or Cheyne-Stokes respiration, a flaccid contralateral hemiparesis and hemisensory deficit, homonymous hemianopsia and global aphasia (DH), or severe contralateral sensory neglect (NDH). The eyes are usually congruently deviated slightly below the horizontal due to pressure on the center for upgaze (the rostral interstitial nucleus of the medial longitudinal fasciculus (riMLF)) that is ventral to the superior colliculus. In stem MCA infarction,

edema is most severe at 3 days. Prior to herniation, patients may demonstrate an ipsilateral sluggish and oval pupil (pressure on the III nerve) as well as ipsilateral or bilateral ptosis (frontal eye field compromise).

Clinical Summary of Complete Superficial Territory Infarction

1. Hemiparesis faciobrachial > leg
2. Hemineglect for space and motor activity (NDH)
3. Anosognosia (NDH)
4. Asomatognosia (NDH)
5. Spatial disorientation (internal/external/geographical) NDH
6. Disorientation NDH > DH hemisphere
7. Depressed reflexes contralaterally (acutely); rarely increased (cortical disinhibition)
8. Babinski sign contralaterally (ipsi or bilaterally if there is increased ICP)
9. Angular gyrus syndrome (DH)
10. Supra marginal gyrus syndrome (DH)
11. Wernicke's aphasia (DH)
12. Broca's aphasia (DH)
13. Conduction aphasia (motor DH)
14. Conduction aphasia (sensory DH)
15. Alexia without agraphia (DH)
16. Ideomotor/limb-kinetic apraxia D > NDH
17. Ideational apraxia (DH)
18. Alien hand syndrome (DH > NDH)
19. Sympathetic apraxia or callosal apraxia (DH)

Superior Division MCA Occlusion (Bifurcation Pattern)

1. Broca's aphasia (DH)
2. Exner's area (severe inability to write) DH; Brodmann's area 45
3. Parietal hand (updraft; loathness to move)
4. Dysarthria
5. Motor conduction aphasia (DH)
6. Limb kinetic/ideomotor apraxia (DH)
7. Alien hand syndrome (area6/DH)
8. Brachiofacial pattern of weakness > leg weakness
9. Depressed reflexes contralaterally
10. Head and eye deviation (ipsilaterally)
11. Babinski sign contralaterally
12. Frontal behavioral syndrome
13. Apathy and abulia
14. Brachiofacial crural weakness (rare)
15. Phonemic paraphasia
16. Rare cheiro oral sensory loss

Inferior Division MCA Occlusion (Bifurcation Pattern)

1. Wernicke's aphasia (DH)
2. Sensory conduction aphasia (DH)
3. Supramarginal gyrus syndrome (DH)
4. Angular gyrus syndrome (DH)
5. Hemineglect for space (NDH)

6. Depressed optokinetic nystagmus (ipsilateral hemisphere)
7. Depressed optic scanning (contralateral space)
8. Constructional apraxia (NDH)

Prosopagnosia (NDH)

1. Loss of higher cortical sensory function (contralateral)
2. Ideational apraxia
3. Posterior type alien hand

Dominant Hemisphere

1. Wernicke's aphasia (DH)
2. Sensory conduction aphasia (DH)
3. Supramarginal gyrus syndrome (DH)
4. Angular gyrus syndrome (DH)

Summary of MCA Infarctions

1. 2/3 of first brain infarcts involve the MCA
2. 1/3 of MCA infarction involves the deep MCA territory
3. 1/10 of MCA infarction involves both superficial and deep territory
4. 50% are branch occlusions

Large Middle Cerebral Artery and Pan Hemispheric Stroke

General Characteristics

1. Definitions:
 - a. The cortical and deep territory supplied by the MCA
 - b. Territory supplied by MCA and ACA
 - c. Territory supplied by the MCA and PCA
 - d. Combination infarction of all three territories including the anterior choroid artery
2. These infarctions often cause severe edema, increased intracranial pressure and cerebral herniation and are termed malignant infarctions
3. Hemispheric stroke accounts for approximately 10% of supratentorial strokes
4. Higher incidence in:
 - a. Women
 - b. Younger patients
 - c. Involvement of the anterior choroidal artery
5. Usual arteries affected are the internal carotid and the proximal MCA (M1)
6. Predisposing features:
 - a. Hypoplasia and rotation of components of the circle of Willis
 - b. Decreased caliber and number of collateral vessels

Clinical Manifestations

1. M1 stem occlusions of the dominant hemisphere cause muteness
2. Initial loss of consciousness is unusual with MCA or hemispheric infarction. The exception is seizure activity
 - a. Deteriorating level of consciousness begins on the third or fourth day concomitant with cerebral edema and herniation

b. Transtentorial herniation in association with:

- i. Central neurogenic hyper ventilation
- ii. Small 2–3 mm pupils that are reactive
- iii. Decorticate to decerebrate posture:
 1. Decerebrate posture contralateral to the lesion and decorticate posture ipsilaterally to the lesion
- iv. Head and eyes to the side of the lesion (frontal eye field involvement) and contralateral severe hemiparesis and hemisensory defect.
- v. Homonymous hemianopia (contralateral to the lesion)
 1. Maybe hard to determine due to level of consciousness
 - a. Secondary to involvement of the optic tract from the stroke
 - b. Compression and infarction of the PCA under the tentorium
- vi. Prior to death, blood pressure falls, the pulse is thready and rapid, Doll's maneuvers fail to move, the eyes, the pupils dilate (and maybe oval) and respiration becomes agonal
- vii. Lateral temporal lobe herniation
 1. Much rarer than diencephalic herniation
 2. IIIrd nerve with pupillary involvement is early; concomitant contralateral decorticate then decerebrate posture
 - a. Rare compression of the contralateral cerebral peduncle against the tentorium producing Kernohan's notch syndrome (ipsilateral hemiparesis due to compression of the CST in the cerebral peduncle; the pyramidal decussation is at C1–C2)

Neuropathology

1. Usually greater than 2/3 of MCA territory is infarcted
 - a. Devastating effect of M1 stem infarction derives from the infarction of the internal capsule
2. If fetal carotid (the PCA takes origin from the ICA) the MCA and PCA are infarcted
3. If there is atherosclerotic involvement of the carotid siphon (T embolus) the anterior cerebral artery may be involved

Neuroimaging

1. 2/3 of MCA territory includes its cortical territory and basal ganglia structures (head of the caudate, insular stripe, and cortical effacement)
2. Cerebral edema with swelling; pineal or interhemispheric dural displacement (anteriorly)
3. ACA or PCA involvement
4. Midline shift of greater than 5–7 mm

Intracranial Atherosclerotic Disease (ICA)

General Characteristics

1. Prevalence of 20–40/100,000 persons worldwide; higher in African Americans and Hispanic than Caucasian patients
2. Intracranial atherosclerotic disease cause 33–37% of ischemic strokes in the Chinese population
3. Severe ICA affects 43% of subjects 65 years and older, 65% in those 60–69 years old and 80% of those 70–79 years old
4. Intracranial arterial disease risk factors:
 - a. Non-modifiable:
 - i. Age
 - ii. Men (younger age and in the basilar artery)
 - iii. Hispanic subjects
 - iv. Chinese subjects
 - v. Angiotensin converting enzyme polymorphism
 - vi. African American subjects
 - vii. Plasma endostatin vascular endothelial growth factor ratio
 - viii. Glutamine S-transferase. Omega-1 gene polymorphism
 - ix. Plasma homocysteine levels
5. Modifiable Risk Factors:
 - a. Hypertension
 - b. Serum beta lipoprotein
 - c. Total serum cholesterol
 - d. Serum LDL-cholesterol
 - e. Serum Apolipoprotein
 - f. Serum HDL-cholesterol
 - g. Sickle cell disease
 - h. Meningitis
 - i. Extracranial carotid stenosis
6. Possibly Modifiable Risk Factors:
 - a. Diabetes mellitus
 - b. Metabolic syndrome
 - c. Alzheimer's disease
 - d. Aortic Plaques
 - e. X-RT (radiotherapy)
 - f. Tuberculosis and cryptococcal meningitis
 - g. Family history of stroke
7. Asymptomatic stenosis (50–99%) of other arteries in a proportion of patients
8. Patients with symptomatic intracranial arterial disease
9. Ischemic stroke, ICH or vascular death (not caused by ischemic stroke) occurred in 22% (WASD trial)
10. Ischemic stroke occurred in the territory of the symptomatic artery (14%); other vascular territories (19%)
11. One year risk of stroke in the territory of a symptomatic stenosis artery (greater than 70%) was 19%

Clinical Manifestations

1. TIA
2. Stroke

3. Recurrent stroke: highest risk within two weeks
4. Rate of recurrence of ischemic events is high regardless of antiplatelet or anticoagulation therapy

Neuropathology

1. Increased insinuation of fibrinogen and LDL-cholesterol in the sub endothelial space
2. Inflammation in the walls of affected arteries

Neuroimaging

1. Spin-echo MRI with contrast demonstrates arterial wall enhancement
2. Intravascular ultrasonography
 - a. Provides real-time dynamic measurements and histology maps of the plaques

Sentinel Differential Diagnostic Features of Large Vessel Stroke of the Anterior Circulation

The hallmark of carotid disease is retinal involvement either embolic from burst plaques or artery to artery. Hollenhorst plaque material at a bifurcation of a retinal artery is pathognomonic. Horner's syndrome associated with a brachycephalic predominant lesion points to the internal carotid artery. Due to the circle of Willis collaterals may save a great deal of the hemisphere. Carotid siphon disease has no ocular pathology, but the anterior cerebral artery may be involved concomitantly with the middle cerebral artery. Emboli from the siphon may occlude the anterior cerebral artery and the inferior branch of the dominant middle cerebral artery sparing the major portions of the motor sensory cortex. This causes a Wernicke's aphasia with shoulder and leg weakness.

The anterior choroidal artery supplies aspects of both anterior and posterior circulations. The hallmark of its infarction is a quadruple sectoranopic defect that spares the central sector. The defect arises from infarction of the lateral geniculate body. Infarction of the uncus and components of its thalamic supply cause a deficit in short term memory and language processing. Hyperesthetic hemiparesis (thalamic) and hyperesthetic ataxic hemiparesis are patterns of infarction.

The usual pattern of anterior cerebral artery infarction is severe weakness and sensory loss of the foot, minimal involvement of the shoulder and face with excellent preservation of hand movement. The patient may be able to wiggle the thumb, but not the arm if the A1 section is involved. If the recurrent artery of Heubner is infarcted, the patient demonstrates facio brachial predominant weakness. Involvement of the supplementary motor area (distal ACA) causes transcortical motor aphasia, mirror writing acquired stuttering and muteness. Muteness is often seen as well with sudden occlusion of the stem of the MCA. Medial frontal lobe infarction often causes euphoria, lability and jocularity. Anterior callosal involvement causes sympathetic apraxia (inability to follow commands with the left hand) and the anterior alien hand syndrome (intermanual conflict).

The major differential distinction of middle cerebral artery disease is that from internal carotid artery occlusion. TIAs in the middle cerebral artery distribution occur on awakening, are less frequent than carotid TIAs and once initiated occur over a shorter time period. They frequently fluctuate or progress over 1–7 days. The mechanism often is distal field ischemia so symptoms often vary with posture. There are no monocular symptoms. Characteristic of superficial territory involvement is hemiparesis and hemisensory deficit with brachycephalic predominance. The frontal eye fields are frequently involved (FEF) with no corresponding visual field deficit. Severe motor neglect and parietal visuospatial deficits are noted if the non-dominant parietal lobe is involved. The angular artery syndrome of Von Gerstmann localizes the lesion to posterior parietal territory if the DH is involved. The pre and frontal superficial branches of the superior division supply Broca's area (Brodman's area 44). The dorsolateral prefrontal cortex (DLPC) is also frequently involved and causes memory retrieval difficulties. Characteristic of inferior division infarction of the superficial territory is Wernicke's aphasia (pathognomonic of embolus if isolated and concomitant with atrial fibrillation) and agitation.

Deep territory middle cerebral artery territory infarction is characterized by internal capsule and basal ganglia infarction. The important differential point from superficial territory and carotid infarction is involvement of the leg, absence of eye deviation and the transient nature of any cortical deficits. This infarction causes a striatocapsular stroke with persistent motor sensory signs. The medial and lateral lenticulostriate group of arteries from the M1 and M2 segments of the MCA of the lateral group is involved. The putamen may be affected causing motor weakness, increased tone and reflexes without sensory loss. The capsular warning and genu syndromes may be seen prior to stroke.

Differential Diagnosis of Posterior Circulation Stroke

The posterior circulation can be considered the arch of the aorta, the innominate and subclavian arteries and vertebral, basilar, posterior cerebral and their derivative arteries.

The arch of the aorta is a rich source of embolic material to the posterior circulation. Its prominence in this regard has recently been accentuated by transesophageal echo cardiography. A mobile grade V plaque is extremely dangerous as a source of embolus. Approximately 30% of emboli to the posterior circulations arise from this source. Emboli to both anterior and posterior circulations arise from the heart or the arch of the aorta in the great majority of cases. The embryologic connections from the carotid to the basilar artery are rare sources of emboli. These include the persistent trigeminal artery, the otic, hypoglossal and proatlantal arteries. The most significant of these arteries is the persistent trigeminal which connects this top of the basilar to the carotid artery just below the siphon.

The vertebrobasilar system can be divided into diagnostic thirds. Each major artery has sentinel features that can guide

diagnosis. Characteristic of a subclavian stenosis proximal to the origin of the vertebral artery is the subclavian steal syndrome. The patient uses the affected arm (left greater than right) which further lowers pressure in the arm (lower than that in the vertebrobasilar system) and blood flows to the arm from the vertebral supply. Most patients have a clear difference in blood pressure between the two arms and a significant decrease of pulse volume and clear lag of the pulse in the affected side. The syndrome usually causes more claudication in the arm than brainstem symptoms. It is rarely significant clinically.

A rare syndrome of ischemia of the brachial plexus and posterior circulation can occur from ischemia of the vertebral and axillary artery (feeds the plexus) that occurs simultaneously. Patients may complain of arm pain in the lateral or medial cord distribution, hand weakness concomitantly with lower brainstem, and cranial nerve symptoms.

Atheromatous occlusion with or without emboli may cause simultaneous carotid and vertebral artery symptoms on the right side. In general, the left carotid takes origin from the aorta and this will not occur on this side.

The common congenital anomaly of the posterior cerebral artery taking origin from the carotid may cause complete hemispheric infarction if that carotid is occluded. The patency of the posterior communicating arteries may determine upper basilar perfusion if there is occlusion of the mid basilar or vertebral arteries.

Proximal vertebral artery disease is most common at the origin from the subclavian artery which is accessible to stenting and angioplasty. The most prominent clinical symptoms are dizziness, diplopia (VIth nerve), dysphagia, oscillopsia, bilateral leg weakness and sensory loss on the trunk. Isolated dizziness especially points to the labyrinth rather than the brainstem. The origin of the posterior inferior cerebellar artery is from the vertebral. It is most commonly involved due to occlusion of the parent artery. The sentinel features of its involvement are dysphagia, nausea and vomiting (out of proportion to dizziness), hoarseness, lateral pulsion to the side of the lesion. These patients have a great deal of difficulty walking which is out of proportion to their ipsilateral ataxia. Seventh nerve weakness (ipsilateral) may occur due to recurrent medullary pyramidal fibers. Ipsilateral facial pain "salt and pepper" in the Vth nerve distribution is characteristic.

Medial medullary infarction is suggested by contralateral flaccid paralysis of the arm and leg (infarction above C2) or ipsilateral flaccid hemiparesis if ischemia involves the cervical medullary junction. Spasticity evolves within days to weeks and causes flexion of the upper extremity and extension of the lower extremities. The motor deficit is more severe distally in the upper extremity which is also typical for pontine infarction. Infarction of the pyramidal decussation may cause a crural paresis. The sensory loss is lemniscal, the face may be involved alone and rarely there is dissociation of position sense and vibratory loss. Upbeat nystagmus

implies pontomedullary junction infarction. Respiratory dysfunction (Ondine's curse), mild ptosis with hypohidrosis and XIIth nerve involvement may occur.

Bilateral medial medullary infarction is manifest by flaccid quadriplegia, paralysis of the tongue, loss of lemniscal sensation, and cardiorespiratory failure.

Combined medial and lateral medullary infarction is suggested by ipsilateral involvement of IX, X, XI, XII a Horner's syndrome, contralateral lemniscal and spinothalamic sensory loss and hemiparesis. Ipsilateral ataxia is apparent if the patient is hemiparetic.

The most common infarction of the pons is ventral and occurs due to occlusion of the anteromedial or anterolateral branches from the basilar artery. These infarctions are suggested by the constellation of facio-branchial crural hemiparesis, brachio-cranial ataxia (homolateral to the motor deficit), ataxic hemiparesis and the dysarthria clumsy hand syndrome. Ataxic hemiparesis and dysarthria clumsy hand occur more often in the middle and upper pons or at the ventro- tegmental junction. Pontine hemiparesis is greater in the distal upper extremity than the lower extremity.

Pontine tegmental involvement is suggested by cranial nerve involvement (Vth, VIth) a depressed level of consciousness and an intranuclear ophthalmoplegia or one-and-a-half syndrome.

Tegmental pontine syndrome from occlusion of short circumferential vessels is heralded by mild motor deficit, cranial nerve involvement Vth–VIIth, and lemniscal (medial) or spinothalamic sensory loss.

The major circumferential artery of the lower pons is the anterior inferior cerebellar artery. Infarction of this artery characteristically causes sudden ipsilateral hearing loss, ipsilateral ataxia arm greater than leg (the reverse of PICA), dizziness, ipsilateral VIIth nerve palsy (small artery to the facial nerve peripherally in the CPA angle) and contralateral loss of pain and temperature of the limbs and trunk.

Mid basilar branch disease is suggested by the motor deficits with a fluctuating and progressive course, the ocular signs of horizontal gaze dysfunction, ataxic hemiparesis (level of the MCP) the clumsy hand dysarthria syndrome and classic lacunar syndromes.

Basilar artery thrombosis may have dizziness as the most frequent early symptom, a herald hemiparesis, alternating levels of consciousness to stupor or coma. Dysarthria, pseudobulbar symptoms, tongue paralysis are common. Pin point pupils and ocular bobbing are diagnostic. The locked in syndrome with maintained consciousness is pathognomonic of ventral pontine infarction.

The top of the basilar (distal 1/3) is commonly involved from embolic disease. The superior cerebellar artery and specific components of the posterior cerebral artery are involved and determine the specific symptoms and signs of the infarction.

The superior cerebellar artery brainstem territory is most often infarcted in conjunction with the posterior cerebral

artery. Severe dysarthria with various degrees of appendicular ataxia are characteristic. The associated components of the posterior cerebral artery often suggest the diagnosis.

The posterior cerebral artery supplies the medial temporal lobe, the midbrain (paramedian branches), the medial and lateral motor sensory thalamus, medial parietal lobe and the occipital cortex. Hippocampal formation ischemia from proximal PCA branch occlusion causes transient global amnesia. A similar amnesic syndrome, much longer lasting may also occur from dorsal medial thalamic ischemia from occlusion of the interpeduncular artery from the top of the basilar artery. Midbrain involvement from paramedian ischemia causes crossed syndromes involving the third nerve. Crossed hemiparesis is Webers syndrome, crossed movement disorder is Benedict's, and Claude's is cerebellar ataxia. Disorders of vertical gaze such as one-and-a-half syndrome, dissociation of vertical and horizontal opticokinetic nystagmus and pupillary abnormalities are characteristic. A peduncular hemiparesis from cerebral peduncle infarction may simulate MCA infarction. The IIIrd nerve is not involved and the face may be spared. Rarely a nuclear IIIrd nerve syndrome is noted with bilateral ptosis, pupillary dilatation and failure of upgaze. Nystagmus retractorius may occur from vascular lesions of the periaqueductal area but is more characteristic of dorsal midbrain pressure. Posterior cerebral artery thalamic involvement is characterized by striking sensory involvement. The patient is aware of a midline split of the sensory deficit. The leg may be involved first (VPL). The fingertip involvement of one hand is diagnostic of thalamic VPI nuclear involvement. Bilateral involvement of intraoral sensation is characteristic of VPM ischemia. Thalamic sensory loss includes vibration. This modality is rarely lost with a cortical lesion, but may be seen with dorsal column nuclear lesions. Thalamic motor involvement may be suspected from a characteristic thumb in the palm drift. Proprioceptive deficits combined with weakness and ataxia of stance is characteristic of thalamic lesions that affect zones of proprioceptive and cerebellar input that converges in VL. Rarely dystonic postures are seen after VA/VL thalamic motor lesions.

Occipital lobe posterior cerebral artery involvement should always be suspected in the face of a dense congruent VF deficit of which the patient is aware. If there is visual neglect the patient has parietal lobe involvement. Deficits in optic scanning and visual gaze coordinative hand function and ocular fixation comprise Bálint's syndrome that overlaps parietal and occipital posterior cerebral artery territories. Anton's syndrome of cortical blindness is manifest by visual confabulation, euphoria and normal pupillary function. Specific field deficits such as a checkerboard field, quadrantic altitudinal deficits, macular sparing and temporal crescent of spared vision all point to PCA occipital lobe branch occlusions.

Lateral posterior choroidal artery infarction is suggested clinically by a homonymous quadrantanopsia. If the lateral geniculate body is involved, patients demonstrate a homonymous horizontal sectoranopia. There may be a concomitant

transcortical aphasia and hemisensory deficit. This infarction is suggested by pulvinar involvement on MRI or CT.

Medial posterior choroidal artery infarction is less common than lateral PchA infarction and is suggested by nystagmus retractorius and a central Horner's syndrome. A mild hemiparesis and lemniscal sensory deficit may occur. CT or MRI of medial pulvinar involvement suggests this arterial territory.

The following is a detailed differential analysis of posterior circulation vascular infarctions.

Posterior Circulation

Occlusion or Severe Stenosis of the Subclavian and Innominate Arteries

Extracranial Vertebral Arteries (ECVA)

1. Arise from the proximal subclavian arteries
2. Subclavian steal syndrome:
 - a. Obstruction of proximal subclavian artery (prior to the origin of the vertebral artery):
 - i. Low pressure system within the ipsilateral vertebral artery
 - ii. Blood supply of the ipsilateral arm is deficient. During exercise these blood vessels dilate which further lowers vascular resistance in the exercised arm
 - iii. Higher pressure system:
 1. Contralateral vertebral artery
 2. Blood flows retrogradely down the ipsilateral VA into the arm (brainstem becomes ischemic)

Clinical Manifestations

1. Most patients are asymptomatic in the face of arterial demonstration of a steal
2. Complaints relate primarily to arm ischemia:
 - a. Fatigue, achiness with exercise, autonomic dysregulation (coolness)
3. Neurologic symptoms are more common with concomitant carotid disease
4. 75% of patients are asymptomatic (demonstrated in Takayasu's disease)
5. Rare neurologic symptoms (usually brief) occur:
 - a. Arm is used repetitively and often overhead
 - b. Blurred vision
 - c. Oscillopsia
 - d. Diplopia
 - e. Vertigo/spinning
 - f. Incoordination and imbalance

Clinical Signs

1. Delayed antecubital and wrist pulse on the stenotic side
2. Smaller pulse volume
3. Supraclavicular bruit (rare)
4. Inflation of blood pressure cuff on the ipsilateral side:
 - a. If the bruit is generated from ECVA the bruit increases as more blood flows through the stenosis (less reversal)

- b. If the bruit is generated from the subclavian stenosis the bruit decreases (increased pressure of ipsilateral system because there is no arm "run-off")
5. Clinical sequelae:
 - a. Stroke is rare with subclavian steal
 - b. Clots can form in a subclavian occlusion
 - i. Embolization to vertebral artery territory
 - c. Raynaud's phenomenon and autonomic dysregulation of the affected extremity may occur

Innominate Stenosis on the Right Side

1. Decrease of carotid flow
2. Exacerbated by cigarette smoking
3. Women > men
4. Associated with other large vessel occlusive disease
5. Right subclavian steal < frequent than left
6. Clot may spread from the innominate into the carotid arteries
 - a. Recurrent arm and brain ischemia
 - b. Floating thrombi within the innominate artery

Differential Diagnosis of Subclavian Artery Disease

1. Takayasu's disease
2. Severe atherosclerosis
3. Aortic arch syndrome
4. Syphilis (chronic aortitis)
5. Cervical rib
6. Giant cell arteritis
7. Athletics that utilize a constant throwing motion

In Takayasu's disease, there is major inflammation and occlusion of the aortic arch vessels. Intermittent claudication of the arm is the most common symptom. Loss of vision with head position (precarious arterial supply to the optic nerve head from posterior ciliary arteries and central retinal artery compromise) and trophic loss of integument of the face and cataracts are common. Most patients with Takayasu's disease are asymptomatic in the face of an arteriographic steal.

Giant cell arteritis may compromise the great vessels at the arch with occlusion and stroke of the carotid artery. A cervical rib most frequently compresses the lower trunk of the brachial plexus with atrophy and weakness of the intrinsic hand muscles.

Vertebrobasilar Infarction

General Characteristics of Lateral Medullary Territory Infarction

Three Major Medullary Divisions

1. Anterior
 - a. Primarily the corticospinal tract that crosses at C2
 - b. Corticobulbar fibers cross at the level of the cranial nerve
2. The tegmentum comprising:
 - a. The respiratory complex
 - b. Cranial nerve nuclei VIII–X; descending VIII–X

- c. Components of the reticular formation
- d. Ascending and descending sensory systems (lemniscal (descending)/spinothalamic (ascending); diffuse nociceptive inhibitory controls DNIC (inhibitory for pain); descending tract and nucleus of V)
- 3. Posterior portion:
 - a. Lemniscal pathways to dorsal column nuclei
 - b. Merges into extension of spinal cord anatomy

Arterial Supply of the Medulla

1. Rostral-paramedian branches of the vertebral arteries (medial)
2. Caudal-paramedian branches of the anterior spinal arteries (vertebral artery origin); medial
3. The anterior lateral medulla is supplied by the circumferential branches of the vertebral arteries
4. Posterior medulla – supplied laterally by the posterior inferior cerebellar artery
5. The posterior dorsal medulla is supplied by branches of PICA (two posterior medullary arteries)

Proximal Vertebral Artery Disease

General Characteristics

1. Most frequent location of extra axial vertebral artery disease (ECVA) is at the origin from the subclavian artery (accessible to stenting and angioplasty)
2. ICA and ECVA stenosis frequently are affected concomitantly
3. Occurs in Caucasians > Asian and African Americans

Clinical Manifestations

1. Most common symptom is dizziness
 - a. Extremely rare for this symptom to be solitary
 - b. TIAs are not precipitated by arm movement as is the case with subclavian-steal syndrome (on rare occasions)
2. Diplopia
3. Dysphagia
4. Oscillopsia (environment moving from nystagmus)
5. Hemiparesis
6. Bilateral leg weakness
7. Sensory loss on the trunk
8. Hypoplastic congenital vertebral and basilar arteries coexist:
 - a. Patient suffers posterior circulation ischemia
 - b. Left vertebral artery 80% of the time dominant over right
 - c. Complete atresia of a vertebral artery is rare

Lateral Medullary Territory (Posterior Inferior Cerebellar Artery)

General Characteristics

1. Direct penetrators from the distal vertebral supply the lateral medulla and cerebellum

2. Posterior inferior cerebellar artery (PICA) supplies the lateral medulla and inferior cerebellum including the floccular nodular lobe
3. Posterior inferior cerebellar artery (PICA) frequently overlaps AICA territory or forms an AICA/PICA artery that supplies both territories
4. Variable: PICA/AICA supply to the lateral medulla or portions of the pons
5. Lateral medullary syndrome: most often occurs from occlusion of the distal perforators of the vertebral artery (VA)
6. If coexisting, AICA involved: middle cerebellar peduncle involved (core territory)
7. If coexisting, PICA involved: lower cerebellum infarcted
8. Dorsal medulla supplied by branches of PICA (two posterior medullary arteries)

Clinical Manifestations

1. General:
 - a. 40% are sudden (ictal)
 - b. 60% a gradual or stepwise pattern over 24–48 hours
 - c. 25% of patients have had a preceding TIA in the same arterial territory
2. Cranial Nerve Abnormalities:
 - a. Dysphagia (rostral nucleus ambiguus)
 - b. Hoarseness (caudal N. ambiguus)
 - c. Crowing cough (N. ambiguus)
 - d. Nausea and vomiting:
 - i. Vestibular nuclei
 - ii. N. tractus solitarius (NTS)
 - iii. Vomiting out of proportion to dizziness
 - e. Ipsilateral Horner's syndrome:
 - i. Descending central sympathetic fibers
 - f. Hiccoughing (singultus; NTS)
 - g. Ipsilateral VII nerve dysfunction:
 - i. Occurs in 33–50% of patients. This is due to two groups of recurrent VII nerve fibers
 - ii. In the upper medulla an origin that recurs through the lateral medulla
 - iii. Fibers that leave the pyramidal tract (at the decussation in the medial medulla and course rostrally to the contralateral tegmentum)
 - h. Lateral medullary infarction lateral recurrent fibers of VII are infarcted
 - i. Dysarthria caused by faciopalatal-glossal dysfunction and cerebellopetal pathways
3. Visual signs and symptoms:
 - a. Blurred vision
 - b. Oscillopsia (with acute infarction)
 - i. Environment appears to move with patient's nystagmus (usually horizontal)
 - c. Vertical, horizontal or oblique diplopia:
 - i. Disruption of the ocular tilt reaction (OTR)
 - d. Incyclotropia:
 - i. Cyclorotation abnormalities (clockwise or counter-clockwise eye rotation)

- ii. Disruption of the vestibulo-ocular response (VOR)
- e. Horizontal and rotary nystagmus is most prominent to the ipsilateral side
- f. Skew deviation-ipsilateral eye down (otic-oculomotor pathways)
- g. Hypermetric saccades to the ipsilateral side (flocculonodular lobe of the cerebellum); hypoactive saccades to the contralateral side
- h. Deviation of the subjective visual vertical (SVV) to the ipsilateral side (internal concept of the body's vertical position)
- 4. Motor signs:
 - a. Ipsilateral hemiparesis (Opalski's syndrome)
 - i. If the pyramidal fibers below the decussation at C2 are involved
 - b. Contralateral hemiplegia occurs with the combined lateral and medial medullary syndrome; no weakness with pure PICA infarction
 - c. Most often there is ataxia without weakness
- 5. Sensory signs and symptoms:
 - a. Ipsilateral facial pain and sensory loss:
 - i. Touch, temperature, pain, cold decreased (ipsilateral descending spinothalamic tract of V)
 - ii. Loss of ipsilateral corneal reflex (V)
 - iii. "Salt and pepper" facial paresthesia and pain (ipsilesional)
 - b. Far lateral medullary infarction of the spinothalamic tract (STT)
 - i. Crossed hemisensory loss to pinprick and temperature on the contralateral body below the clavicle
 - c. More medial infarction of the lateral medullary STT
 - i. Contralateral loss of pinprick and temperature of the face, trunk, and upper limb (the ipsilateral STT from the arm, trunk and leg and the crossed ventroreticulospinal ascending fibers that cross medially in the medulla that subserve the contralateral face)
 - d. Medial medullary infarction of the SST:
 - i. Bilateral facial hypalgesia with variable contralateral sensory loss (dog's nose pattern)
 - ii. "Onion skin" facial sensory loss
 - 1. Nose involved
 - 2. Pre-auricular area spared
 - 3. Maybe seen as well with V nerve entry zone lesions
- 6. Headache:
 - a. Occipital
 - b. Unilateral
 - c. Non-throbbing
 - d. Vth nerve origin of trigeminal pain afferents to the dura, proximal blood vessels and sinuses (somatic visceral convergence)
- 7. Brainstem dysfunction:
 - a. Autonomic dysregulation
 - i. Cardiac arrhythmia
 - ii. Blood pressure variability

- 1. Lateral medullary vasomotor center
 - 2. Most often postural hypotension
- b. Respiration
 - i. Sleep apnea
 - ii. Sleep disordered breathing
- iii. Failure of automatic breathing Ondine's curse
 - 1. Disruption of oscillations of lateral and medial respiratory neurons (Boettinger complex)
 - 2. Afferent disruption of IX and X pulmonary afferents (Hering-Breuer reflex) may be carried centrally in STT
- 8. Cerebellar syndrome:
 - a. Gait and ipsilateral limb ataxia; leg more than arm
 - b. Axial lateropulsion (if restiform body involved from concomitant medial branch infarction); patient is pushed to the side of the lesion

Unilateral Medial Medullary Infarction (Dejerine's Syndrome)

General Characteristics

- 1. Less than 1% of posterior circulation strokes
- 2. Branch occlusion from the VA

Clinical Manifestations

Motor Signs and Symptoms

- 1. Flaccid hemiparesis:
 - a. Contralateral if above C2
 - b. Ipsilateral if the infarction spreads to the cervical medullary junction
- 2. Spasticity within days to weeks:
 - a. Flexion of upper extremities
 - b. Extension of the lower extremities
- 3. Rarely weakness can be minimal or absent
- 4. Rarely upper limb monoparesis:
 - a. Fibers after decussation may be lateral
- 5. Motor deficit is more severe distally in the upper extremity
- 6. Patterns of weakness at the level of the pyramidal decussation:
 - a. Leg fibers may cross anteriorly and then remain lateral to arm fibers
 - b. Some studies – arm fibers decussate anteriorly to leg fibers
 - c. Crural paresis:
 - i. Proximal portion of the limbs affected with finger and toe movements preserved
 - ii. Hemiplegia cruciata:
 - 1. Arm involved ipsilaterally with contralateral leg weakness
- d. Pontine recurrent VIIth nerve pathway may be infarcted with facial weakness

Sensory Signs and Symptoms

- 1. Contralateral lemniscal type sensory loss of the hemibody with or without the face

2. More marked distally
3. May involve the face only
4. Pseudospinal dropped sensory level on the trunk
5. Dissociation between vibration and position loss
 - a. Vibration may be involved with more lateral extension
6. Pain sensation
 - a. Occasionally decreased with preserved temperature, sensation, and mild hypesthesia

Cognitive Dysfunction

1. Medial reticular formation involvement:
 - a. Apathy
 - b. Somnolence
 - c. Hallucinations
 - d. Delirium
2. Differential diagnosis of pathologic laughing and crying that occurs with infarction of:
 - a. Internal capsule
 - b. Pons
 - c. Pyramidal tract (usually bilateral)
 - d. Bilateral temporal lobe (usually trauma)
 - e. Medial frontal lobe (laughing)

Ophthalmologic Signs

1. Upbeat nystagmus:
 - a. Dorsolateral medulla or pontomedullary junction infarction that spares the medial medulla
 - b. Ipsilateral MLF or perihypoglossal nuclei are involved in upgaze
 - c. Horizontal nystagmus (ipsilateral) or multiple directional nystagmus related to vestibular nuclear involvement or their connections to the cerebellum in the lateral medulla
 - d. Rare – ocular bobbing (usually a pontine lesion)

Lateral Pulsion

1. Contralateral lateral pulsion:
 - a. Dorsolateral medulla and cerebellum are not involved
 - b. Patient feels as if he is pushed to the side
 - c. Lesion at the level of the restiform body or olivary nuclei

Respiratory Dysfunction

1. Cluster breathing
2. Decrease of voluntary control of breathing secondary to corticospinal destruction and lack of intercostal muscle control
3. Loss of automatic breathing (Ondine's curse)

Autonomic Dysregulation

1. Mild ptosis with hypohidrosis
 - a. Severe miosis (0.5 mm pupil) with pontine infarction
 - b. Dissociation of ptosis and pupillary sympathetic fibers is due to a somatotopic arrangement of sympathetic fibers around the N. ambiguus
2. Bladder retention or inhibited contractions only occur with bilateral MMI

Cranial Nerve XII

1. Isolated contralateral XII nerve
2. More common with hemorrhage than infarction

Isolated Drop Attacks

1. May progress to stroke over several days
2. Ischemia of:
 - a. Medullary or pontine corticospinal fibers
 - b. Medial reticular formation involvement (loss of tone)

Differential Diagnosis of Vascular Etiologies of Unilateral Medial Medullary Infarction

1. Branch occlusion from VA (upper medulla)
2. Dolichoectasia of vertebrobasilar system
3. Embolus
4. Syphilis
5. Branch occlusion from the anterior spinal artery (lower medulla) secondary to atheroma of the VA or anterior spinal artery

Underlying Associated Conditions

1. Diabetes mellitus
2. Birth control pills
3. Dissection of VA
4. Thrombosis of VA
5. Embolus in 1/4 of patients

Bilateral MMI Infarction

Clinical Manifestations

1. Quadriplegia (flaccid)
2. Associated loss of lemniscal sensation
3. Paralysis of the tongue
4. May have step wise progression
5. Bladder retention or uninhibited contractions
6. Death by cardiorespiratory failure

Differential Diagnosis

1. Anomalous anterior spinal artery from one vertebral artery
2. Occlusion of the ASA after it forms a single vessel

Medial and Lateral Medullary Syndrome (Babinski–Nageotte)

Clinical Manifestations

1. Clinical features of combined LMI and MMI:
 - a. IX, X, XI, XII ipsilaterally
 - b. Horner's ipsilaterally
 - c. V ipsilateral (most often STT modalities)
 - d. Ocular findings (LMI and MMI)
 - e. Contralateral hemiparesis; may be ipsilateral (depending on infarction below decussation at C2)
 - f. Lemniscal and STT sensory loss (contralateral)
 - g. Ipsilateral ataxia
 - h. Reinhold's syndrome

Hemimedullary Syndrome (Reinhold's Syndrome)*General Characteristics*

1. Usually vertebral artery occlusion
2. Combination of both medial and lateral medullary syndromes
3. Hemiparesis may be ipsi- or contralateral

Cestan-Chenoi Syndrome*General Characteristics*

1. Intermediolateral medullary infarction
2. Vertebral artery, PICA, and anterior cerebral artery are involved

Clinical Manifestations

1. Contralateral hemiplegia
2. Paralysis of the larynx and soft palate
3. Horner's syndrome

Neuroimaging

A recent evaluation of 142 patients with medullary infarction (from a total of 3833 patients) demonstrated by diffusion-weighted magnetic resonance imaging revealed:

1. Bilateral medullary infarction in 8.2%
2. Upper medulla sustained infarcts in the anterior medial or lateral territories
3. Lateral infarctions more common in the middle and lower territories
4. 50% stenosis or occlusion of the VA was noted in 52% of patients
5. Large artery atherosclerosis – 34.5%
6. Lacunes and cardioembolism comprised 3.5% and 4.2% respectively
7. Lacunar infarction involved the anterior and anterolateral territories
8. Cardiac emboli involved lateral or posterior territories

In a second study of 77 patients, large artery disease was the most common etiology for both LMI and MMI.

1. LMI – arterial dissection greater than small vessel disease and cardioembolism
2. MMI – more prevalent in younger patients
3. Patients with large artery disease and dissection had positive DWI
4. Patients with large artery disease and dissection had positive DWI

Pontine Infarction*General Characteristics*

1. Most often pontine infarction is associated with atherosclerotic cerebrovascular disease
2. There may be restricted pontine lesions from atheromatous ostial lesions or lipohyalinosis
3. The anteromedial and anterolateral territories are most commonly involved

4. Atheromatous ostial occlusion the most common etiology (> 15 mm lesion on 3 slices); lipohyalinosis (less evidence; smaller lesion)
5. Pontine lesions are 12–27% of posterior circulation strokes

Clinical Manifestations

1. Pontine TIAs are seen in 1/3 of patients. Often preceding stroke onset:
 - a. Pathologic laughter: spontaneous laughing and crying spells – “Fourier prodromique”
 - b. Pontine warning syndrome
 - c. Yawning
 - d. “Salt and pepper” face pain (trigeminal nucleus)
 - e. Herald hemiparesis
2. 5 specific arterial territories

Anteromedial Infarcts (Paramedian)*General Characteristics*

1. Approximately 2/3 of pontine infarcts
2. Arterial territories involved:
 - a. Medial basis pontis – includes the corticospinal tracts, supplied from short midline perforators from the basilar artery
 - b. Long midline perforators from BA supply:
 - i. Medial medial lemniscus
 - ii. IIIth cranial nerve
 - iii. MLF
 - c. Para pontine reticular formation (PPRF) – the center for horizontal gaze
 - d. Infarction may extend to the ventral surface
 - e. Ischemic changes are seen commonly:
 - i. In the midline affecting the legs (gait disturbance)
 - ii. Seen in T2-weighted images as high intensity lesions (pontine sludge)

Clinical Manifestations

1. Pure Motor Hemiplegia
 - a. Arms greater than legs
 - b. Distal greater than proximal muscles
 - c. Seen in 50% (some evidence that arm fibers more lateral than leg fibers)
 - d. Infarcts in middle or caudal pons
2. XIIth nerve; central and lateral palatal muscles – lingual – laryngeal paresis
3. Isolated dysarthria: rare
4. Upper pontine paramedian infarcts dysarthria associated with:
 - a. Hemiparesis
 - b. Brachial monoparesis
 - c. Supranuclear VIIth nerve palsy and hemiataxia
5. Paramedian lesions associated with transitory tegmental signs that include:
 - a. Decreased proprioception and vibration
 - b. Cheiro-oral crural or facial hypoesthesia (rostral pons – central face; caudal pons, pre-audicular area)

6. Neuro-ophthalmological signs:
 - a. One-and-a-half syndrome; PPRF involvement in association with posterior MLF lesion; 8^{1/2} syndrome (VII nerve involved)
 - b. Ocular bobbing (eyes driven down and float up; ocular dipping)
 - c. Primary position downbeating nystagmus
 - d. Skew deviation (down eyeside of the lesion)
 - e. Horner's syndrome (lateral extension)
 - f. VIth nerve palsy (isolated or with contralateral hemiparesis)
7. Ventroregmental junction infarction:
 - a. In middle or upper pons are associated with:
 - i. Dysarthria – clumsy hand syndrome
 - ii. Ataxic hemiparesis (crossing fibers from pontine nuclei to middle proprioceptive zone)
8. Etiology most commonly basilar branch disease from ostial atheromatous plaque

Anterolateral Territory Infarction

General Characteristics

1. Arterial supply – short circumferential arteries from the basilar artery
2. Supplies lateral corticospinal tract and components of the medial lemniscus

Clinical Manifestations

1. Facio-brachial-crural weakness
2. Dysarthria clumsy hand syndrome
3. Ataxic hemiparesis
4. Homolateral gaze paralysis
5. Saccadic substitution for smooth pursuit
6. Horner's syndrome
7. One-and-a-half syndrome
8. Skew deviation
9. Horizontal nystagmus
10. Isolated VIth nerve
11. Etiology is most often basilar atheromatous disease in 50% and lipohyalinosis in 20%

Lateral Territory Infarction

General Characteristics

1. Accounts for 12–30% of pontine infarctions
2. The superior cerebellar arterial branches irrigate the lateral upper pontine structures that include:
 - a. Pontine nuclei
 - b. Dorsolateral corticospinal tract
 - c. Medial lemniscus
 - d. Ventral trigeminothalamic tract
 - e. Middle cerebellar peduncle

Clinical Manifestations

1. Facio-brachial-crural hemiparesis
2. Crural monoparesis (more commonly at upper levels)
3. Contralateral lemniscal or spinothalamic sensory deficits that include the following distributions:
 - a. Brachial crural
 - b. Facio-brachial-crural
 - c. Arm, face and leg hypoesthesia
 - d. Rarely, trigeminal weakness with hypoesthesia
4. Neuro-ophthalmologic signs similar to those seen with medial infarcts and are associated with:
 - a. Contralateral motor and sensory deficits
 - b. Ataxia
5. Lateral dorsal infarcts associated with:
 - a. Fascicular VIth nerve or nuclear VII nerve palsy
 - b. Painful ipsilateral Vth nerve palsy (descending tract and nucleus of V)
6. Caudolateral infarction associated with:
 - a. No oculomotor signs
 - b. May have isolated vertigo that suggests an acute peripheral vestibulopathy
 - i. A cause of contralateral lateral pulsion
7. Small artery disease is the primary etiology

Dorsomedial Pontine Infarction

General Characteristics

1. The arterial territory is supplied by long circumferential arteries from the superior cerebellar artery or AICA

Clinical Manifestations

1. Infarcts often associated with strokes of the cerebellum or brainstem infarction from basilar artery disease
2. Rarely, homolateral cranial nerve palsy

Bilateral Infarction

General Characteristics

1. Associated with extensive brainstem ischemia or extension of prior infarcts
2. Approximately 10% of pontine infarcts

Clinical Manifestations

1. Bilateral motor deficits with tegmental signs
2. Associated neuro-ophthalmological cranial nerves and sensory deficits
3. Ventral infarcts at the middle and caudal level:
 - a. Depressed level of consciousness
 - b. Locked-in syndrome:
 - i. Patients are conscious
 - ii. Unable to move
 - iii. Vertical gaze and eye closure are maintained
 - iv. Variant partial forms are seen
 - c. Motor deficits include:
 - i. Tetraplegia
 - ii. Triparesis

- iii. Paraplegia
- iv. Ataxic tetraparesis
- 4. Acute pseudobulbar palsy

Anteromedial and Anterolateral Infarction

- 1. Large infarcts
 - a. Severe hemiparesis and dysarthria
- 2. Small infarcts
 - a. Dysarthria clumsy hand syndrome
 - b. Ataxic hemiparesis
 - c. Pure motor hemiparesis
- 3. Anterolateral and dorsolateral infarcts
 - a. Crural monoparesis

Summary of Pontine Infarction

Patterns of Weakness in Pontine Hemiparesis

- 1. Greater in the distal upper extremity than lower extremity
- 2. Less commonly the leg has distal weakness greater than the arm
- 3. Crural or brachiorural paresis with preservation of finger and toe movement
- 4. Arm fibers – disrupted by more dorsal lateral lesions
- 5. Ventral tegmental lesions – leg weakness and gait ataxia
- 6. Leg fibers – disrupted by more lateral lesions
- 7. Facial palsy associated with palato-glossal weakness – involvement of pontomedullary bundle
- 8. Severe dysarthria
- 9. Isolated dysarthria and facial weakness are rare
- 10. Some correlation of severity of motor deficits and contralateral ataxia

Rare Signs of Paramedian Infarction

- 1. Pure VI or VII nerve paralysis
- 2. Contralateral hyperhidrosis alone or associated with hemiparesis
 - a. Destruction of inhibitory fibers for thermal sweating
 - i. Lesion noted in middle pons
- 3. Variants of the one-and-a-half syndrome
 - a. Absent horizontal gaze to the side of the lesion; abducting nystagmus of the contralateral eye (MFL lesion); if convergence is intact, the lesion is caudal near the PPRF
 - b. The nine syndrome:
 - i. “Eight-and-a-half” syndrome (cranial nerve VII and one-and-a-half syndrome) plus contralateral hemiplegia and hemihypesthesia
 - c. Non-paralytic pontine exotropia
 - d. WEBINO syndrome (wall eyed bilateral INO)
 - e. Sixteen and one half syndrome associated with ipsilateral supranuclear VII palsy
 - f. Upbeat nystagmus associated with ataxia, INO and hemiparesis
 - g. Millard–Gubler syndrome:
 - i. Ipsilateral VI, VII palsy

- ii. Contralateral hemiparesis
- h. Foville’s syndrome:
 - i. Ipsilateral cranial VI and VII
 - ii. Infarction of the ipsilateral PPRF (ipsilateral horizontal gaze paralysis)
 - iii. Contralateral hemiparesis
- i. REM sleep behavior disorder:
 - i. Periodic limb muscle movements during sleep
 - ii. Contralateral lateral pulsion

Rare Signs of Posterior Pontine Territory Infarction

- 1. Marie-Foix syndrome
- 2. Homolateral cranial nerve palsies
- 3. Central Horner’s syndrome (ipsilesional)
- 4. Hemiataxia (ipsilesional)
- 5. Uveula-palato-pharyngeal myoclonus (ipsilesional)
- 6. Contralateral pain and temperature deficit

Rare Manifestations of Combined Anteromedial and Anterolateral Syndrome

- 1. Raymond-Cestan syndrome:
 - a. Ipsilateral I&O
 - b. Contralateral hemiparesis
 - c. Contralateral hemihypesthesia

Rare Manifestations of Bilateral Infarcts

- 1. Peduncular hallucinations:
 - a. Paramedian rostral pontine infarct
- 2. Freezing of gait and gait ignition deficits
 - a. Disruption of pedunculo-pontine input to the nucleus cuneiformis
- 3. Bilateral horizontal gaze palsy associated with nuclear VII nerve palsy
- 4. Perioral hypesthesia, hypesthesia of the hands and distal arms
 - a. Bilateral tegmental infarcts at the caudal pons

Vertebral and Basilar Artery Stroke

General Characteristics

Posterior circulation strokes are 20% of all ischemic cerebral vascular disease.

- 1. Infarcts are frequently multiple
- 2. Basilar artery irrigates:
 - a. Most of the brainstem
 - b. Occipital lobes (through PCAs)
 - c. Cerebellum (AICA; SCA artery)
 - d. Thalamus (PCA-thalamogeniculate and thalamoperforate arteries)
 - e. Midbrain (top of the basilar interpeduncular arteries)

Neuropathology

Pathogenesis of Vertebrobasilar Disease

- 1. Atherothrombosis is the most common cause of vertebrobasilar disease

2. Emboli occur from:

- a. Cardiac source or arch of the aorta
- b. Artery-to-artery (vertebral to basilar; basilar to P1 and P2 (PCA) or midbrain from interpeduncular artery (arises from top of the basilar))
- c. Middle basilar artery infarction is usually atherothrombotic
- d. Top of the basilar (distal) or proximal basilar are occluded by emboli
- e. Atherothrombotic lesion of the vertebral artery:
 - i. Present in the intracranial portion of the artery and are often occlusive and bilateral
 - ii. There are often concomitant atherosclerotic lesions in the anterior circulation
 - iii. Multiple risk factors are present (particularly HCVD, diabetes mellitus and cardiac insufficiencies)
 - iv. Collateralization is from the posterior communicationings leptomeningeal and anterior spinal arteries
 - v. Dissection most frequently occurs in the vertebral artery (occasionally extending to the basilar artery)
 1. VA dissection occurs with an annual incidence of 97/100,000 patients
- vi. Clinical signs and symptoms are variable due to:
 1. Variation of the arterial supply
 2. Number and extent of lesions in both vessels (VA and BA)
 3. 50% of patients with acute VB stroke have had TIA in the same vascular territory whose characteristics are:
 - a. Waxing and waning pattern due to:
 - i. Distal field ischemia
 - ii. Hemodynamic changes (decreased BP)
 - iii. Head position (occlusion of the contralateral vertebral artery in the trans-cervical canal)
 - iv. Usual symptoms reflect:
 1. Cranial nerve deficits
 2. Vestibulocerebellar dysfunction
 3. Motor deficits
 - vii. Premonitory and progressive signs and symptoms suggest atherothrombosis. Ictal signs and symptoms suggest emboli (particularly with top of the basilar topography). Less frequently proximal vertebral or mid basilar topography of sudden stroke suggests an embolism from a unilateral VA
 - viii. Most vulnerable VA territories:
 1. Lateral medulla supplied by perforating arteries from the intracranial VA
 2. PICA (cerebellar perfuses area)
 - ix. The vestibular nuclei and connections to the vermis:
 1. Supplied by the intracranial VA
 2. Common signs of hypoperfusion are vertigo and ataxia

Clinical Manifestations

Major Clinical Patterns of VB Ischemia (New England Medical Center Classification)

1. Lower territory:
 - a. Medulla and PICA fed by intracranial vertebral arteries and their branches
2. Middle territories irrigated by the BA and its branches:
 - a. Pons
 - b. Lower midbrain
 - c. Aica (arterial territory)
3. Distal territory irrigated by the distal BA; superior cerebral artery branches:
 - a. Upper midbrain
 - b. Thalamus
 - c. SCA arterial territory
 - d. Temporal, medial and occipital lobes
4. Multiple infarcts in VB territory are due to:
 1. Bilateral VA atherosclerotic narrowing or occlusion
 2. Proximal BA stenosis or occlusion
 3. BA branch occlusion including the posterior cerebral arteries

Clinical Sign and Symptoms of Basilar Artery Thrombosis

1. May be acute, a progressive stroke or preceded by prodromal symptoms
2. Vertigo and nausea (54–73%)
3. Facial weakness and hemiparesis (40–67%)
4. Dysarthria (30–63%)
5. Headache (40–42%) – basi-occipital
6. Diplopia (21–33%); VI cranial nerve; I & O
7. Confusion, changes in consciousness (17–33%) may alternate and may progress to stupor
8. Pseudo bulbar symptoms
9. Ocular bobbing and dipping, dysfunction of the ocular tilt reaction, skew deviation
10. Bilateral hearing loss
11. Pathologic laughter
12. Pontine warning syndrome

Differential Diagnostic Points Between Basilar Artery vs Vertebral Artery Stroke

1. BA at any location tends to have motor and oculo-motor signs and symptoms particularly in the face of altered consciousness
2. Vertigo and cerebellar symptomology suggest VA disease

Midbrain Infarction*General Characteristics*

Midbrain infarctions are 2% of all cerebral infarcts and 8% of those that occur in the posterior circulation. The midbrain is usually infarcted in association with the thalamus and pons or the superior cerebellum and temporal occipital cortex. There are four major vascular territories. The most commonly involved is the paramedian (anteromedial) followed by the anterolateral which supply the middle and upper midbrain. The major consequence of infarction in this territory is abnormalities of vertical gaze.

Paramedian (Anteromedial) Territory

1. This territory is supplied by:
 - a. Perforators from the top of the basilar (the interpeduncular artery)
 - b. Superior cerebellar perforating arteries
 - c. The thalamo-subthalamic paramedian artery from the P1 segment of the posterior cerebral artery (origin is medial to the posterior communication artery)
2. The major oculomotor structures affected and involved with vertical gaze are:
 - a. The rostromedial nucleus of the medial longitudinal fasciculus (riMLF), the posterior commissure and the periaqueductal area

Clinical Manifestations

1. Occur from both bilateral and unilateral infarction of the upper midbrain
2. Oculomotor deficits are rarely isolated
3. Unilateral or bilateral thalamic infarcts cause vertical eye movement dysfunction with associated deficits that include:
 - a. Down and in eyes
 - b. Decreased levels of consciousness (waxing and waning)
 - c. Short term memory loss and aphasia
4. Complete bilateral ophthalmoplegia with:
 - a. Bilateral ptosis
 - b. Bilateral infarction at the mesodiencephalic junction
5. Supranuclear conjugate gaze palsies from infarction of the paramedian rostral midbrain:
 - a. Vertical palsies that can be either up or down
 - b. Complete ophthalmoplegia with ptosis
 - c. Dorsal midbrain syndrome (Parinaud's syndrome)
 - i. Failure of upgaze
 - ii. Associated with impaired hearing (if the inferior colliculus is involved)
 - iii. Dissociated optokinetic nystagmus (loss of vertical component)
 - iv. Bilateral ptosis (central caudal nucleus)
 - v. Bilateral mydriasis (Edinger – Westphal nucleus; mid-dilated pupil)
 - vi. Skew deviation (vertical diplopia)
 - vii. Accommodation spasm on attempted upgaze
 - viii. Pupillary light-near dissociation
 - ix. Spasm of convergence
 - d. Convergence-retraction nystagmus
 - e. See-saw nystagmus
 - f. Pseudoabducens palsy (slower movement of the abducting eye than the adducting eye during horizontal saccades)
 - g. Bilateral down-gaze palsies (dorsomedial to the red nucleus; rostral interstitial nucleus of the medial longitudinal fasciculus (riMLF)); supranuclear disconjugate gaze palsies:

- i. Double elevator palsy (weakness of the superior rectus and inferior oblique; contralateral pretectal supranuclear fibers that subserve the superior rectus subnucleus of the IIIrd nerve complex)
- ii. Vertical one-and-a-half syndrome (supranuclear down gaze paralysis with monocular elevation palsy)
 1. Bilateral infarction at the thalamo-mesencephalic junction; region of the upper medial red nucleus
 - a. Efferent tracts of the riMLF are affected bilaterally
 - b. Lesion of the premotor fibers to the contralateral superior rectus subnucleus and ipsilateral inferior oblique sub-nucleus (pre or post decussation in the posterior commissure)
 - c. Skew deviation (down eye opposite the infarction)
 - d. Prenuclear syndrome of the oculomotor nucleus

Non Neuro-Ophthalmologic Signs of Midbrain Rostral Infarcts

1. Pure motor hemiparesis:
 - a. Simulating MCA infarction (perforating arteries from the PCA; no facial involvement; infarction of medial 3/5 of the cerebral peduncle)
 - b. Isolated gait ataxia
 - c. Body lateral pulsion (falls to the side of the lesion; involvement of the ascending fibers of the crossed dentatorubrothalamic tract near the red nucleus)

Paramedian Middle Midbrain Infarction

1. Nuclear III (with hemiparesis or ataxia):
 - a. Ipsilateral IIIrd nerve with central SR palsy (failure of upgaze)
 - b. Bilateral ptosis (central caudal nucleus that innervate the levator palpebrae)
 - c. Bilateral mid-brain mydriasis (Edinger-Westphal nucleus)

Unusual Middle Midbrain Signs

1. Dysarthria is found in approximately 50% of patients with pure midbrain infarction usually with other signs and symptoms
 - a. Isolated dysarthria from a medial ventral substantia nigral lesion
2. Acquired stuttering
3. Isolated IIIrd, IVth nerve palsy may be caused by giant cell arteritis, neoplasm or pituitary apoplexy (IIIrd and IVth with pituitary apoplexy)
4. Divergence paralysis:
 - a. Lesion is in the vicinity of the PAG; possible medial reticular formation
5. Plus-minus eyelid syndrome with ataxia:

- a. Ptosis on one side and eyelid retraction on the other
 - i. IIIrd nerve infarction ipsilaterally
- b. Nucleus of the posterior commissure (inhibits the levator palpebrae)

Anterolateral Territory Infarction

General Characteristics

1. Subservd by P2 branch mesencephalic arteries

Clinical Manifestations

1. Peripheral type of IIIrd most usual (more severe ptosis than with aneurysm of P-COM)
2. IIIrd nerve palsy with hemiparesis (Weber's syndrome)
 - a. Patients are awake; hypotonic, hyporeflexic
 - b. Subdural hematoma patients: lethargic; spastic hemiplegic
3. IIIrd nerve palsy plus cerebellar signs:
 - a. Claude's syndrome:
 - i. Involvement of dentatohalamic fibers
 - b. Benedict's syndrome:
 - i. IIIrd nerve palsy and contralateral movement disorder
 - ii. Tremor (rubral, large amplitude at right angle to the line of movement); chorea from infarction of the red nucleus and dentatohalamic fibers. In general, the closer the infarction is to the red nucleus, the greater the tremor and failure of proximal extremity fixation
 - c. Ataxic hemiparesis or hypesthetic ataxic hemiparesis
 - d. Rarely – hemiparkinsonism particularly of the lower extremities
 - i. Substantia nigra pars compacta (SNPc) involvement
 - e. Unilateral or bilateral infarction of the SNPc may cause peduncular hallucinosis

Paramedian Caudal Midbrain Infarction

General Characteristics

1. Unilateral or bilateral INO (MLF involvement associated with limb and gait ataxia, dysarthria and rubral tremor (Wernekinck's commissure which is the decussation of the superior cerebellar peduncle))
2. Bilateral INO
3. Rarely – pathologic laughter may be premonitory. This sign is most often associated with dysarthria and hemiparesis
 - a. Interruption of basal ganglia projections to the forebrain

Lateral Territory Infarction

General Characteristics

1. The rostral level of the caudal territory is supplied by the posterior choroidal artery
2. The caudal 2/3 of the laterodorsal region is perfused by short circumferential branches of the SCA

Clinical Manifestations

1. The clinical signs derive primarily from involvement of the medial and trigeminal lemniscus and include:
 - a. Cheiro-oral and cheiro-oral pedal large fiber sensory loss associated with hemiataxia and hemiparesis

Dorsal Territory Infarction

General Characteristics

1. Often infarction due to concomitant involvement of SCA territory

Clinical Manifestations

1. Clinical signs include:
 - a. Isolated IVth nerve
 - b. Ipsilateral Horner's syndrome
 - c. Contralateral ataxia
 - d. Isolated hemihypesthesia

Unusual Patterns of Midbrain Infarction

1. Bilateral infarction of upper paramedian territories:
 - a. Associated ischemic thalamic involvement
2. Vertical gaze dysfunction:
 - a. Plus-minus syndrome with ataxia
 - b. Divergence Paralysis
3. Locked-in syndrome:
 - a. Bilateral cerebral peduncle infarction

Neuropathology

Mechanism of Midbrain Infarction

1. In a 74 patients with pure mesencephalic infarction:
 - a. Basilar artery stenosis or occlusion was most common (43%)
 - b. Small artery disease (30%)
 - c. Cardiac embolism (11%)
 - d. Not determined (15%)
 - e. An embolic source is suspected if ischemia involves the thalamus, superior cerebellum and temporo-occipital cortex
 - i. Artery-to-artery (VA > BA)
 - ii. Cardiac source

Rare Stroke Syndromes from Midbrain Infarction

1. Subthalamic small deep infarcts:
 - a. Abnormal movements and asterixis
 - b. Unilateral or bilateral ballistic movements (>2/3 of the corpus Luysi; STN has to be infarcted)
 - c. Blepharospasm
2. Cerebellar syndromes:
 - a. Rostral and lateral red nucleus area infarcts with rubral tremor
 - b. Unilateral ataxia with superior cerebellar infarct (SCA) with rostral midbrain signs
 - c. Superior cerebellar decussation syndrome (ataxia of all extremities) at the level of the IVth nerve at the inferior colliculus

3. Masugi's syndrome:
 - a. Ipsilateral IIIrd and IVth nerves
 - b. Ipsilateral ataxia (SCP)
 - c. Contralateral hemiparesis
 - d. Contralateral sensory defect
 - e. Caused by infarction of the superior cerebellar artery or branches of the lateral and medial posterior choroidal arteries

Summary of Midbrain Infarction

1. Paramedian arteries:
 - a. Isolated third nerve palsy
 - b. Nuclear third nerve: bilateral ptosis; bilateral pupillary dysfunction (large); bilateral failure of upgaze (superior rectus palsy and inferior oblique)
2. IIIrd nerve and contralateral hemiplegia (Weber's syndrome):
 - a. Supranuclear gaze palsy; mydriatic or miotic pupil depending on sympathetic involvement; occasional sensory dysfunction: P1 segment of the PCA is infarcted (medial 3/5 of the cerebral peduncle infarcted); patients are awake; hemiparesis may spare the face
 - b. Concomitant thalamic and occipital lobe involvement may occur
3. IIIrd nerve plus cerebellar signs:
 - a. IIIrd nerve palsy and contralateral cerebellar dysfunction is Claude's syndrome. Basilar paramedian artery (dentatothalamic projections are involved)
 - b. IIIrd nerve palsy plus contralateral abnormal movements (Benedict's syndrome). Tremor (rubral, large amplitude at right angle to the line of movement); chorea (paramedian artery; infarction of the red nucleus, dentatothalamic fibers often with third nerve paralysis)
 - c. The closer the infarction is to the red nucleus, the greater the tremor and failure of extremity postural fixation
4. Supranuclear conjugate vertical gaze palsy:
 - a. Median or paramedian infarction of the upper midbrain
 - b. Superior cerebellar artery: infarction; destruction of:
 - i. Periaqueductal gray matter
 - ii. Posterior commissure
 - c. Single trunk (paramedian thalamic mesencephalic artery of Percheron) infarcts involves the medial and subthalamic (STN) areas bilaterally as well as the upper midbrain
 - d. Upgaze paralysis:
 - i. Posterior commissure, riMLF (rostral interstitial nucleus of the MLF); PAG
 - e. Down-gaze palsy:
 - i. Bilateral upper midbrain infarction; more caudal than upgaze palsy (above the red nucleus; Pasik's syndrome)
 - f. Combined up and down gaze palsy:
 - i. Bilateral or unilateral midbrain infarcts

- ii. Unilateral lesion of the riMLF may decrease conjugate vertical gaze
- g. Supranuclear disconjugate vertical gaze palsies:
 - i. Monocular elevation palsy
 - ii. Vertical one-and-a-half syndrome
- iii. Infarction of paramedian upper midbrain

Unusual Neuro-Ophthalmological Deficits

1. Skew deviation (lesion is on the side of the down eye)
2. Tonic ocular-tilt reaction (incyclotropia or excyclotropia dysfunction)
3. Intermittent corectopia (pupillary size changes)
4. Upper lid retraction (Collier signs; increased upper lid retraction on down gaze; central caudal nucleus of the IIIrd nerve involved)
5. Ptosis with intranuclear ophthalmoplegia
6. Convergence retraction nystagmus (PAG; and involvement of the periaqueductal gray area)
7. Dissociated vertical gaze palsies

Associated Clinical Midbrain Signs

1. Gaze palsies with:
 - a. Coma and hypersomnia
 - b. Akinetic mutism
 - c. Disorientation to time and place
 - d. Antegrade amnesia
 - e. Motor and multimodal neglect
 - f. Faciobrachial hypesthesia
 - g. Transcortical motor aphasia
 - h. Delayed athetoid or clonic movements

Specific Midbrain Stroke Syndromes

1. Classic lacunar syndromes from midbrain infarcts
 - a. Weber's
 - b. Claude's
 - c. Benedict's
 - d. Masugi's
2. Lateral midbrain involvement of the cerebral peduncle (P1-PCA) pure motor stroke
3. Dorsolateral midbrain:
 - a. Hemiparesis
 - b. Hypesthesia
 - c. Ataxia
4. Eye movement deficit

Midbrain Locked-In Syndrome

1. Bilateral lateral midbrain infarction
2. Midbrain hematoma-pure sensory stroke (rare)

Hemiplegia with Posterior Cerebral Artery Occlusion

1. Proximal P2 infarction:
 - a. Hemiplegia
 - b. Visual disturbance
 - c. Neuropsychological abnormalities
 - d. Mimics MCA occlusion

Rare Stroke Syndromes from Midbrain Infarction

1. Subthalamic small deep infarcts
 - a. Abnormal movements and asterixis
 - b. Unilateral or bilateral ballistic movements
 - c. Blepharospasm
2. Cerebellar syndromes
 - a. Rostral and lateral red nucleus infarcts with cerebellar syndromes
 - b. Unilateral ataxia with superior cerebellar infarct (SCA) with rostral midbrain signs
 - c. Superior cerebellar decussation syndrome (ataxia of all extremities); infarction of the decussation of the brachium conjunctivum (Windekink's commissure; level of the IVth nerve at the inferior colliculus)
3. Masugi's syndrome
 - a. Ipsilateral IIIrd, IVth nerve
 - b. Ipsilateral ataxia (SCP)
 - c. Contralateral hemiparesis
 - d. Contralateral hemisensory defect
 - e. Infarction of the superior cerebella artery or branches of lateral and medial posterior choroidal arteries
4. Peduncular Hallucinoses
 - a. Vivid visual hallucinations; objects moving (kaleidoscopic); peculiar dress
 - b. Rarely auditory hallucinations
 - c. Often occurs at sundown

Thalamic Stroke*Overview*

The thalamus is a major relay to the cerebral cortex and is pivotal for: 1. arousal and consciousness; 2. sensory functions both spinothalamic and lemniscal; 3. cognitive function and 4. oculomotor function. It can be conveniently thought of as an egg (anatomically) with an anterior, medial, lateral, and posterior arterial supply. It is frequently involved from embolic stroke as it receives a great deal of its blood supply from the top of the basilar artery (particularly the paramedian territory).

*Infarcts in the Territory of the Tuberothalamic Artery***General Characteristics**

1. Origin is the middle third of the posterior communicating artery

Clinical Manifestations

1. Left hemisphere lesions cause
 - a. Deficits in retrieval or acquisition of visual or verbal memory
 - b. Disorientation for time (DM lesion)
 - c. Acalculia and thalamic aphasia
2. Amnesic syndrome lesions caused by:
 - a. Lesions of the mammillothalamic tract and the amygdala thalamic projections
 - i. Disconnects the anterior nuclei from the amygdala and hippocampal formation

- ii. Thalamic aphasia (not completely defined) consists of:

1. Amnesia (dichotomy between visual or auditory presentation)
2. Decreased fluency
3. Impaired comprehension
4. Fluent paraphasias
5. Oral reading relatively preserved
6. Decreased reading comprehension
7. Retained ability to repeat

- iii. Non-dominant hemisphere lesions cause:

1. Visual memory deficits
2. Mild cognitive impairment
3. Apathy, abulia, anosognosia

3. Bilateral infarctions cause:

- a. Severe abulia and memory deficits

*Infarction of the Paramedian Territory (Interpeduncular Artery)***General Characteristics**

1. Interpeduncular artery arises from the top of the basilar (P1)

Clinical Manifestations

1. Acute infarction causes decreased and fluctuating levels of consciousness (similar to subdural hematoma)
2. May evolve to agitation, confusion, aggression or apathy which may become permanent
3. Disturbances in arousal and vigilance caused by lesions of the intralaminar nuclei and rostral midbrain reticular formation
4. Oculomotor dysfunction:
 - a. Up and down gaze palsy: often the patient is looking at the tip of his nose with one or both eyes
 - b. Skew deviation: down eye is opposite the lesion (brainstem: the down eye is ipsilesional)
 - c. Pure down-gaze paresis (only bilateral lesion)
 - d. Horizontal gaze palsy (rare)
 - e. Rarer ophthalmological signs:
 - i. Bilateral INO
 - ii. Loss of convergence
 - iii. Miosis (2 mm pupils)
 - iv. Acute esotropia
 - v. Pseudo VIth nerve palsy
 - vi. Photophobia
5. Chronic paramedian territory deficits
 - a. Amnesia
 - b. Short term memory/learning deficits
 - c. Abnormal movements (contralateral)
 - i. Uni- or bilateral asterixis
 - ii. Tremors (dentate-rubro-thalamic tract)
 - iii. Dystonia (VL nucleus)
 - iv. Thalamic hand (down drift, flexion of the wrist, adduction of the thumb)
 - v. Blepharospasm

*Bilateral Paramedian Territory Infarction***General Characteristics**

1. A single peduncle supplies both territories from P1 (thalamic peduncle of Percheron) and the rostral mid-brain

Clinical Manifestations

1. "Thalamic dementia"
2. Akinetic mutism
3. Utilization behavior
4. Disinhibition
5. Abulia
6. Personality change

*Inferolateral Territory Artery Infarction***General Characteristics**

1. The thalamogeniculate arteries takes origin from P2 of the PCA (a peduncle of 6 to 12 arteries)

Clinical Manifestations

1. Pure sensory stroke:
 - a. The sensory deficit respects the midline (as if a line were drawn down the middle of the body)
 - b. There is bilateral sensory loss around the umbilicus
 - c. VPM involvement produces bilateral intraoral sensory deficit (numbness)
 - d. In general, thalamic (VPL) sensory loss causes an active deficit. Patients have disturbing paresthesias as if insects were crawling on their skin – formication; burning sensation or in 15% numbness
 - e. All sensory modalities (including vibration) are involved; occasionally touch, temperature and pin-prick are spared)
 - f. Patients may develop decreased touch with pain (anesthetic douloureux)
2. Sensorimotor stroke:
 - a. Infarction of VPL and the posterior limb of the internal capsule:
 - i. Thalamic sensory loss
 - ii. Hemiparesis
 - b. Large inferolateral infarction described by Dejerine and Roussy include:
 - i. Cerebellar outflow tremor
 - ii. Dystonia, chorea, athetosis
 - iii. Thalamic astasia
 1. Lesion of proprioceptive projections to VL nucleus
 - iv. Loss of the sense of the subjective visual vertical (SVV):
 1. Patients tilt to the side of the lesion and push themselves back to the midline
 2. "Pusher syndrome"
 3. Most often seen with posterior thalamic infarction
 - v. Hand jerks associated with hemidystonia, severe sensory loss and ataxia:
 1. Thalamic hand may be seen
 2. Executive dysfunction: rare

3. Auditory illusions

- a. Medial geniculate involvement
- b. Anosognosia with right sided lesions

Infarction of the Lateral Posterior Choroidal Artery (L PchA)*General Characteristics*

1. PchA Arterial Territories Involved:
 - a. Lateral geniculate body (LGD)
 - b. Pulvinar and posterior thalamus
 - c. Hippocampus and parahippocampal gyrus

*Clinical Manifestations***Clinical Syndromes of Lateral PchA Infarction**

1. Homonymous quadrantanopsia
2. With or without hemisensory loss
3. Homonymous horizontal sectoranopia (lateral LGD)
4. Memory loss
5. Delayed movement disorder
6. Transcortical aphasia

Visual Field Deficits

1. PchA – Homonymous horizontal sectoranopia
2. AchA – middle horizontal sector is spared
3. Quadruple sectoranopia is characteristic
 - a. Lower or upper quadrantanopsia
4. Complete homonymous hemianopia
5. Superior quadrantanopsia-may have macular sparing
6. Homonymous hemianopia
 - a. Sparing of the horizontal sector
 - b. Inferior lateral LGD infarction
7. Homonymous superior-quadrantanopsia
 - a. Lateral geniculate infarction
 - b. Infarction of:
 - i. Optic tract
8. Origin of the geniculocalcarine tract
9. Sectoranopia visual field deficits
 - a. Lateral geniculate body infarction

Specific Visual Field Deficits

1. Wedge or tubular homonymous sectoranopia with delayed sectorial optic atrophy
2. Lower or upper quadrantanopsia more common but less specific with LGD infarction
3. Wedge or tubular sectoranopia also possible with AchA, MCA, PCA infarction
4. Visual field deficits with concomitant anatomical lesions of the LGD

Ocular Motility Deficits

1. Impairment of ipsilateral pursuit
2. Poor contralateral saccades

Sensory Symptoms

1. Involvement of thalamic radiations of the internal capsule or damage to ventroposterior nucleus (caudal part)

Motor Symptoms

1. Damage to corticospinal or corticobulbar fibers in the internal capsule (PchA)
2. AchA more severe hemiparesis than PchA

Aphasia and Higher Cortical Deficits

1. Transcortical motor aphasia – pulvinar damage
2. Transient visual and verbal memory disturbance
3. Disorientation for time without confusion or confabulation
 - a. May also be seen following thalamic stereotactic surgery
4. Abulia
5. Non-dominant hemisphere lesion:
 - a. Visual spatial processing deficit with dorsal lesions

Thalamic Stroke with PchA Infarction

1. Neuropsychologic deficits
2. Pulvinar infarction on CT/MRI
3. Paramedian infarction; tuber thalamic artery involvement (concomitant)

Visual Hallucinations

1. Paramedian thalamic infarction

Correlative Anatomy of the Lateral Geniculate Body

1. Anterolateral LGD subserve lower quadrants
2. Anteromedial LGD subserve medial quadrants
3. Posterior LGD subserve the macula
4. Central LGD: supplied by lateral posterior choroidal artery
 - a. VF defect: homonymous horizontal sectoranopia
 - b. Supplied by PchA
5. AchA also supplies the LGD

Unusual Features of Thalamic Infarction

1. Simultaneous ptosis and astasia:
 - a. Anteromedial infarction
2. Emotional synesthesia:
 - a. Specific sensory stimuli are associated with emotional responses
3. Left thalamic infarction:
 - a. Aphasia (anterior ventral nucleus)
 - b. Amnesia; recent memory impairment
 - c. Frontal lobe dysfunction by diaschisis

Medial Posterior Choroidal Artery (MPchA)**General Characteristics**

1. Territory supplied: medial pulvinar; dorsomedial thalamus; anterior thalamic nuclei
2. Less common than lateral PchA infarcts

Clinical Manifestations**Ocular Signs (Midbrain Involvement)**

1. Nystagmus retractorius

2. Upgaze or horizontal gaze paralysis
3. Meiosis
4. Central Horner's syndrome

Sensory Loss (MPchA)

1. Lemniscal or spinothalamic

Motor Symptoms

1. Mild hemiparesis

Neuropathology**Pathogenesis (MPchA)**

1. HCVD and DM
2. Cardiac embolism, large artery disease, migrainous stroke, catheter induced thrombosis

Differential Diagnosis**Differential Diagnosis of MPchA vs PchA vs AchA**

1. M PchA:
 - a. Sensory loss is noted acutely with later onset of pain and abnormal movements
2. Movement disorder:
 - a. Choreoathetotic myoclonic syndrome
 - b. Pseudobulbar tremor
 - c. Dystonic posture of the fingers
 - d. Dystonic thalamic hand worsened by voluntary activity
 - e. Akathisia
3. L PchA infarct
 - a. Sectoranopia VF deficit
4. AchA infarct:
 - a. Quadruple sectoranopia VF deficit
 - b. Greater hemiparesis than L PchA stroke

Posterior Circulation Major Artery Strokes (Long Circumferential Arteries)**Cerebellar Artery Infarction****General Characteristics****General Features of Cerebellar Artery Infarction**

1. Infarction of the cerebellum is approximately 7.5% of all ischemic strokes
2. Major clinical manifestations are: vertigo/dizziness, gait instability, headache, nausea and vomiting. They are non-specific and are often misdiagnosed
3. Serious complications are worsening edema and consequent brainstem compression
4. Superior cerebellar arterial territory:
 - a. Superior cerebellar peduncle
 - b. Tentorial surface
5. Anterior inferior cerebellar artery territory is:
 - a. Middle cerebellar peduncle (core territory)
 - b. Flocculus
 - c. Petrosal surface of the cerebellum
6. Posterior inferior cerebellar artery perfuses:
 - a. Inferior cerebellar peduncle
 - b. Suboccipital surface to the horizontal fissure

Epidemiology (Perugia Hospital-Based Stroke Registry)

1. Cerebellar infarction accounts for about 3.4% of all cerebral infarctions
2. Mean age of 72 years; 3:1 males to females
3. Unilateral in 86%; bilateral in 14%
4. Bilateral infarctions: emboli to the top of the basilar
5. Superior cerebellar artery region – 36%
6. Anterior inferior cerebellar artery region – 12%
7. Posterior inferior cerebellar artery region – 40%
8. Multiple vascular region involvement – 12%
9. Approximately 52% have associated brainstem infarctions

Clinical Manifestations

1. Dizziness/vertigo in approximately 50%:
 - a. Lasts for more than 72 hours
 - b. Moderate to severe imbalance
 - c. Differential is often acute peripheral labyrinthine disease
2. Severe ataxic gait:
 - a. Anterior lobe involvement
 - b. “Martinet gait”:
 - i. Disinhibited anterior lobe projections to lateral vestibular nuclei (increased extensor tone)
3. Lateral pulsion to ipsilesional side:
 - a. Involvement of ascending gravicentric fibers
4. Nausea and vomiting:
 - a. Vomiting more severe than vertigo suggests brainstem ischemia
 - b. Present in 50% of patients
 - c. Ischemia and/or pressure on the vomit center of the floor of the IVth ventricle; involvement of the nucleus solitarius and vestibular connections
5. Headache occurs in approximately 40% of patients:
 - a. Usually homolateral in the basiocciput
 - b. May project to C2 territory (the meninges of the posterior fossa are innervated by C2; C2 projects to the nucleus caudalis of the Vth nerve which may sensitize all the distributions of the nerve)
6. Overshoot and increasing oscillations as the target is approached (cerebellar outflow tremor) may be more prominent than limb ataxia
7. Dysarthria is present in 50% of patients (scanning speech is produced from the inability to coordinate speech and breathing; abnormal prosody)
8. Upbeat nystagmus occurs from lesions of the superior vermis or pontomedullary junction
9. Eye movement abnormalities include:
 - a. Saccadic substitution for smooth pursuit
 - b. Ocular overshoot or undershoot on attempted fixation
 - c. Hypometric saccades

Neuropathology**Pathogenesis of Cerebellar Infarction**

1. Large artery atherosclerosis – 41%
2. Small artery disease – 24%

3. Cardioembolism – 9.8%
4. Varied etiologies occur in 7.3% and include:
 - a. Vertebral artery dissection
 - b. Vasculitis
 - c. Hypercoagulable state
 - d. Drug abuse (cocaine, methamphetamine)
5. Indeterminate etiology – 17%

Superior Cerebellar Artery (SCA) Infarcts**General Characteristics**

1. Rarely involves the brainstem territory of the SCA; usually partial; good outcome; 50–60% of cerebellar infarctions
2. Early and delayed edema (one week); brainstem compression with tonsillar herniation if edema is severe (4–7 days; pseudotumoral presentation)
3. Associated infarction in other territories with complete SCA infarction (usually that of PCA):
 - a. Rostral territory of the basilar artery
 - b. Unilateral or bilateral occipitotemporal lobe infarction
 - c. Thalamic; subthalamic and mesencephalic infarcts
 - d. Rare upper ventral pontine infarction
 - e. 1/3 occur with PICA and AICA infarction
 - f. Partial SCA infarcts most frequently involve the rostral superior cerebellar artery territory
 - g. Some SCA infarcts occur with MCA infarcts due to emboli

Clinical Manifestations**Clinical Features of Superior Cerebellar Artery: 6 Clinical Patterns**

1. Classic SCA:
 - a. Occur in 3% of infarctions
 - b. Involves the brainstem territory of SCA
 - c. Ipsilateral limb dysmetria
 - d. Ipsilateral Horner’s syndrome
 - e. Contralateral IVth nerve involvement
 - f. Contralateral loss of pain and temperature
2. Unusual signs and symptoms of classic SCA infarction:
 - a. Ipsilateral loss of mimetic facial
 - b. Unilateral or bilateral hearing loss (nucleus of lateral lemniscus)
 - c. Sleep disorder (locus coeruleus)
 - d. Ipsilateral choreiform, athetotic or coarse tremor
 - e. Head tremor or unsteadiness of the head
 - f. Palatal myoclonus; may be associated with myoclonus of the tongue, vocal cord, jaw and face
 - g. Cerebellar cognitive affective disorder:
 - i. Visual dyslexia/surface dysgraphia
 - ii. Personality behavioral deficit
3. SCA infarction with top of the basilar artery involvement:
 - a. Vomiting, dizziness, visual field deficits, diplopia, paraesthesia, ataxia, weakness and drowsiness
 - b. Occipitotemporal lobe concomitant involvement:
 - i. Cortical blindness and hemianopsia (Anton’s syndrome)

- ii. Bálint's syndrome
- iii. Memory loss or confusion
- c. Thalamic-mesencephalic infarction:
 - i. Thalamic multimodal sensory loss; latter possibly Dejerine Roussy syndrome (VPL)
 - ii. Contralateral Horner's syndrome
 - iii. Appendicular ataxia (ataxia of stance); involvement of cerebellar thalamic projections
 - iv. Behavioral abnormalities: abulia, contralateral spatial neglect, memory loss, transcortical motor aphasia
- d. Midbrain infarction (concomitant):
 - i. Claude's, Benedict's, Weber's, Nothnagel's Syndromes, Masugi's
 - ii. Parinaud's syndrome
 - iii. Pseudo VIth nerve, gaze paresis or deviation, Collier's sign, pupillary abnormalities (light-near dissociation, inverse Argyll-Robertson pupil, miosis or mydriasis, corectopia)
 - iv. Drowsiness, peduncular hallucinosis, confusion
 - v. Hemiballismus (subthalamic involvement)
- 4. Coma at initial presentation:
 - a. Tetraplegia and IIIrd nerve palsy
 - b. Embolic occlusion of basilar tip
- 5. SCA involvement with ICA infarction:
 - a. Aphasia
 - b. Brachiofacial sensorimotor hemiplegia
 - c. Cardiac embolism; occlusion of innominate artery with embolism to right MCA and vertebral artery with propagation to SCA
- 6. Cerebellar vestibular syndrome:
 - a. Occipital headache and gait ataxia
 - b. Dizziness and vomiting
 - c. Nystagmus (most often horizontal to affected side) or contralaterally; rarely vertical
 - d. Dysarthria-cardinal symptom of SCA infarct
 - e. Hemiparesis in 25%
- 7. Lateral SCA syndrome (anterior rostral territory):
 - a. Arm and leg dysmetria
 - b. Ipsilateral axial lateropulsion
 - c. Dysarthria
 - d. Nystagmus; saccadic overshoot (ipsilaterally)
- 8. Medial SCA syndrome:
 - a. Most medial branch: unsteadiness of gait
 - b. Lingula, culmen, centralis lobules (anterior cerebellar lobe) appendicular ataxia (legs affected > arm), head tilt (ipsilateral)
 - c. Paravermal involvement: dysarthria; left-sided paravermal zone of rostral cerebellum causes consistent dysarthria

Neuropathology

Differential Diagnosis of Causes of Superior Cerebellar Artery Infarction

1. Cardiac embolic source

2. Artery-to-artery embolus:
 - a. Vertebral artery
 - b. Aortic arch
3. Vertebral dissection
4. In young patients:
 - a. SCA dissection
 - b. Fibromuscular dysplasia (FMD)
 - c. Patent foramen ovale (PFO)
 - d. Cocaine and methamphetamine abuse

Anterior Inferior Cerebellar Artery Infarction

General Characteristics

1. Origin: first 1/3 of the basilar artery
2. Brainstem signs at presentation
3. Involved territory: lateral caudal pons; middle cerebellar peduncle (always involved)
4. Supplies the inner ear: internal auditory artery from which derive the anterior vestibular artery; common cochlear artery
5. 70% involve the anterior inferior flocculus
6. AICA and PICA may arise from a common trunk from the vertebral or basilar artery
7. Anastomosis between the AICA and PICA – constant when both arteries have equal dominance
8. AICA dominance on one side; then consequent ipsilateral vertebral PICA hypoplasia
9. Infarction of the inferolateral pons; may extend up to the middle third of the lateral pons or down to the superior part of the lateral medulla
10. AICA infarction: may be associated with PICA and SCA infarction with consequent ventromedial pontine infarction

Clinical Manifestations

1. Prodromal vertigo (minutes); dizziness, dysarthria
 - a. Ipsilateral peripheral VIIth nerve (small artery to facial nerve in CPA angle)
 - b. Hearing loss (sudden) ipsilaterally
 - c. Ipsilateral Vth nerve involvement
 - d. Horner's syndrome (ipsilaterally)
 - e. Ipsilateral appendicular dysmetria (arm > leg)
 - f. Contralateral loss of pain and temperature of the limbs and trunk
 - g. Delayed facial paralysis

Unusual Signs

1. Ipsilateral conjugate or lateral gaze palsy (floccular involvement)
2. Dysphagia (superior part of the lateral medulla)
3. Ipsilateral motor weakness (involvement of the corticospinal tract in the pons or mesencephalon contralaterally)
4. Periodic alternating nystagmus

Coma

1. Tetraplegia (massive ventromedial infarction of the basis pontis)

2. Cerebellar infarction PICA/AICA/SCA distribution
3. Isolated vertigo mimicking labyrinthitis; infarction of the internal auditory artery or its superior vestibular division
4. Isolated cerebellar signs

Differential Diagnosis

Differential Diagnosis of AICA Infarction

1. Atherosclerotic lower basilar artery occlusion (AICA)
2. Occlusion of the vertebral artery above PICA
3. Pure AICA: a basilar branch occlusion; plaque in the basilar artery extends to occlude its origin; microatheromata block the origin of the artery
4. Migraine (Bickerstaff variant)

Vascular Anomalies of the Vertebrobasilar System

1. Persistent trigeminal artery with embolus from carotid system
2. Dolichoectasia of the basilar artery
3. Hypoplastic vertebral artery

Extracranial and Intracranial Vertebrobasilar Dissection

1. Intradural dissection:
 - a. Subadventitial hematoma of the basilar artery causes:
 - i. Subarachnoid hemorrhage
 - ii. Brainstem stroke
 - iii. Pseudoaneurysm
 - iv. May occur silently
2. Extracranial dissection
 - a. Hematoma within the media or intima
 - b. Emboli at the site rather than a blood flow limiting process cause symptoms

Post Operative Cerebellar and Brainstem Stroke

Signs and Symptoms

1. Altered consciousness; stupor, restless agitation
2. Vestibulocerebellar syndrome

Differential Diagnosis

1. Neck positioning during or after surgery
2. Thrombus that embolized from compressed arteries

Hypercoagulability After Surgery

1. Increased thrombin activity
2. Increased fibrinogen
3. Increased factor VIII
4. Decreased fibrinolytic activity
5. Altered platelet function

Posterior Inferior Cerebral Artery – See Lateral Medullary Infarct (PICA)

Posterior Cerebral Artery (PCA) Infarction

General Characteristics

1. Major blood supply of: midbrain, thalamus, occipital lobes, part of the posterior inferior parietal lobe

2. The arterial segment prior to the posterior communicating artery fusion with the basilar artery is the P1 segment:
 - a. 10% of PCAs take origin from the carotid artery (fetal origin). If this occurs, there is a concomitant hypoplastic P1 from the basilar artery
3. 29% of patients have large or (24%) unusually small PCA arteries
4. Accounts for 5–10% of all ischemic strokes

Vascular Territory Supplied by the PCA

1. Vascular supply of the P1 segment (peduncular or precommunal segment; between the tip of the basilar artery and the posterior communicating artery) is:
 - a. Medial midbrain; posteromedial thalamus
 - b. Origin of the paramedian mesencephalic arteries (take off is the top of the basilar)
2. Tuberothalamic (polar arteries)
 - a. Origin is the posterior communicating artery
 - b. Anterior and anterolateral thalamus
 - c. Tuber thalamic artery may be absent. Its territory is then supplied by the thalamic subthalamic artery (thalamoperforating arteries)
3. P2 segment is the origin of the peduncular perforating (PPA); thalamogeniculate arteries (TGA)
 - a. Thalamoperforate artery supplies:
 - i. Lateral midbrain
 - ii. VA and VL of the motor thalamus
 - iii. Part of the internal capsule
 - iv. VPL, VPM of the thalamus
 - b. Thalamogeniculate artery supplies the ventrolateral thalamus: arteries arise from the ambient portion of the PCA
 - c. Anterior temporal artery arises from the ambient portion of the PCA and supplies the medial temporal lobe
 - d. Posterior temporal artery (origin between the tentorium and the medial temporal lobe)
 - e. Parieto-occipital artery: originates from the ambient segment; supplies the occipital and medial inferior parietal lobe); this branch is the origin of the posterior pericallosal artery
 - f. Calcarine artery:
 - i. Usually arises as a single branch of the PCA
 - ii. In 16% of patients the calcarine artery arises from the parieto-occipital artery
 - g. P3 and P4 are the distal segments with their cortical branches
 - i. Infarction of P2 and P2 cause 25% of PCA infarction as does P3 and P4
 - ii. Combined deep and superficial arteries occur in 50% of patients

Clinical Manifestations

Clinical Symptoms and Signs of Unilateral PCA Ischemia and Infarction

1. PCA Stenosis:
 - a. TIA's precede infarction with PCA stenosis is causative
 - b. Usually atherosclerotic narrowing

General Features of PCA Infarction

1. Ambient section is affected most frequently which causes a hemispheric branch occlusion
2. P1 segment – 13% of PCA occlusions
3. PCA with thalamic involvement – 37% of infarctions
4. Occipital, parietal and posterior temporal branch arteries are frequently involved concomitantly
5. Anatomic areas involved: medial midbrain, posteromedial thalamus, lateral thalamus, and posterior hemisphere
6. Penetrating arteries from the top of the basilar artery may arise from one PCA (artery of Percheron) and therefore the thalamic infarction may be bilateral and paramedian:
 - a. Infarctions are usually embolic from the heart, proximal aorta and the proximal vertebral arteries (to the top of the basilar artery)
 - b. Patients that have suffered rostral paramedian tegmental mesencephalic and posteromedial thalamic infarcts are comatose, hyper somnolent and may demonstrate vertical gaze palsies and an amnesic state

The distinguishing features of proximal PCA infarction (P1 precommissural branch) are:

1. Hemiplegia, infarction of the cerebral peduncle (medial 3/5); may spare the face
2. Paramedian mesencephalic and PPA arteries are involved (cognitive deficit; hypersomnolence)
3. Partial or complete IIIrd nerve palsy
4. Nuclear IIIrd nerve signs include:
 - a. Bilateral ptosis (central caudal nucleus)
 - b. Failure of upgaze bilaterally (superior rectus is bilaterally innervated)
 - c. Dilated pupils
 - d. Skew deviation:
 - i. Skew deviation is seen with vertical IIIrd nerve paresis if the nuclei of Cajal and Darkschewitsch are involved with cortico-mesencephalic or mesencephalic tracts themselves are lesioned
5. Midline infarctions: patients are lethargic and abulic
6. Involvement of DM and the wall of the IIIrd ventricle
7. One paramedian artery may supply both medial thalamic territories (the thalamic peduncle of Percheron)
8. Paramedian thalamic clinical triad:
 - a. Hypersomnia and fluctuating levels of consciousness (intralaminar nuclei; Dorsomedial nucleus)
 - b. Cognitive dysfunction:
 - i. Short term memory deficits (DM nucleus)
 - ii. Transcortical motor aphasia (DM nucleus)
 - c. Oculomotor deficits
 - d. Often associated with thalamic signs

Thalamogeniculate Artery Infarction (TGA)*General Characteristics*

1. Infarction of the lateral thalamus and posterior temporal lobe is known as the syndrome of Foix–Hillman
2. Pathogenesis: trunk PCA occlusion (multiple penetrating branches involved) or single atheromatous branch occlusion

Clinical Manifestations

1. Sensory symptoms:
 - a. Leg may be involved most severely; pattern of face, arm and leg
 - b. Conscious perception that the symptoms bisect the body (face, trunk, penis)
 - c. Intraoral involvement (may be bilateral)
 - d. Quality of sensation: tingling, pricking, crawling, burning (active dysesthesias and paraesthesias)
 - e. Loss of pinprick, touch, or thermal sensation. May lose vibration sensibility which is rarely lost with cortical infarction. The other location for vibratory loss is the dorsal column nuclei
 - f. If medial, ventrolateral or thalamoparietal projections are involved:
 - i. Proprioceptive, thermal sensory loss, decreased pain
 - g. Tips of the fingers of the contralateral hand (VPI nucleus); spinothalamic afferents to each finger
2. Slight hemiparesis
3. Clumsiness and ataxia (dentate thalamic projections)
4. Choreiform and ataxic limb movements (contralateral)
5. Thalamic hand posture
6. Clinical symptomatology of thalamic pain:
 - a. Delayed onset (months after VPM/VPL infarction)
 - b. Hyperpathic pain
 - c. Mechanical and thermal hyperalgesia and allodynia of the affected area
 - d. Spontaneous
 - e. If provoked-not stimulus bound
7. Associated infarcts in the temporal and occipital lobes if midbrain and thalamus are involved

Ambient Segment (P2) Infarction (Thalamoperforating Artery)*General Characteristics*

1. Occlusion is proximal to the origin of the thalamogeniculate artery:
 - a. Vascular supply to the motor thalamus
 - i. Ventroanterior, ventrolateral nuclei
 - ii. VOA, VIM, VOP (stereotactic nomenclature, part of VL)
 1. VIM is the target for stereotactic surgery to relieve tremor

Clinical Manifestations

1. Motor symptoms
 - a. Contralateral 4–6 HZ tremor
 - b. Usually sudden onset of choreoathetosis:
 - i. Frequent arterial involvement in diabetic patients
 - c. Rare contralateral dystonia
 - d. Thalamic hand
 - e. More medial lesions in this territory cause thalamic ataxia
 - i. Interrupt cerebellar projections (dentatorubral loop)
 - ii. “Ataxia of stance”

Posterior Cerebral Artery (PCA) Hemispheric Infarction (P3 and P4 Infarction)

General Characteristics

1. The anterior and posterior temporal arteries arise from P3 (rarely from distal P2) and supply the medial temporal lobe
2. The 3 main branches of P3 are:
 - a. Occipitotemporal
 - b. Calcarine
 - c. Occipital parietal

Anatomy of the Visual Radiations

1. The PCA and its branches supply the lower component of the geniculocalcarine radiations; the MCA supplies the upper
2. The more posterior and closer to the cortex, the more congruent the VF deficit

Clinical Manifestations

Visual Field Loss

1. Most common defect – contralateral homonymous dense VF loss
2. Infarction may occur in: lateral geniculate body, optic radiations, or the striate cortex
3. 50% of patients are aware of the deficit
4. If unaware of the deficit there is parietal lobe involvement
5. Acute or with resolution of VF defect:
 - a. Photopsias, colors, and hallucinations in the affected field
6. Usual VF deficits: congruent contralateral hemianopia, inferior or superior quadrantanopsia
 - a. Macular sparing often noted (middle cerebral artery supply compensates)
 - b. Involvement or sparing of the contralateral visual temporal crescent (inferior lip of the calcarine fissure subserves the most peripheral temporal field)
 - c. Homonymous central scotoma (occipital pole infarct)
 - d. “Checker board” deficit (one inferior quadrant with contralateral superior quadrant)
7. Complex visual phenomena

Visual Perseveration

1. Objects seen in sighted field-then noted in the defective hemifield although gaze fixation maintained
2. Object in the sighted field appears in the defective hemifield after gaze is shifted to defective field
3. Palinopsia (perseveration of an object)
4. Motion detection in blind field but no ability to discriminate (Riddoch’s object phenomena)
5. Defects in distance, depth and localization in the defective hemifield
6. Micropsia and macropsia

Sensory Symptoms of PCA Hemispheric Infarction

1. Paresthesia, numbness or loss of pain; thermal or positional sense loss

Higher Cortical Deficits from Hemispheric Infarction

1. Dominant Hemisphere: parieto-occipital and/or temporal branch occlusion:
 - a. P3 and P4 segments
 - b. Alexia without agraphia patients; write, speak, and spell normally. They cannot read words or name colors (damage must include left occipital cortex and splenium of the corpus callosum). Can read letters and numbers. Cannot access Wernicke’s area
 - c. Alexia with agraphia:
 - i. Angular gyrus or white matter of the inferior parietal lobule involved
 - ii. Abnormalities of reading, writing, and spelling
2. Inferior parietal lobule infarction:
 - a. Decreased ability to read letters and paragraphs
 - b. Decreased spelling and writing
 - c. Components of Gerstmann’s syndrome are noted: dyscalculia, finger agnosia, right left confusion, and dysgraphia and conduction aphasia. The latter may be accompanied by paraphasia
 - d. Transcortical sensory aphasia
 - e. Aggressive behavior
3. Paralexia or hemidyslexia:
 - a. Dominant hemisphere: reading errors to the right side of words
 - b. Non-dominant hemisphere: reading errors at beginning of words
4. Visual agnosia:
 - a. Dominant hemisphere
 - b. Concomitantly with alexia and agraphia and decreased color naming
5. Amnesia:
 - a. Involvement of left hippocampus and adjacent white matter
6. Sensory Symptoms:
 - a. Lesions of the thalamic projections to the sensory cortex; concomitant supply from the MCA territory (central sulcal, anterior and posterior parietal branches of the superior division of MCA)

Non-Dominant Hemisphere – PCA Infarction

1. Neglect of contralateral visual field
2. Constructional apraxia (parietal and temporal lesions)
3. Right posterior parietal lesion-disorientation for geographical space
4. Reduplicative paramnesia (two versions of a geographic location)
5. Prosopagnosia (usually bilateral lesions required)
 - a. Inability to recognise faces

Neuropathology

Mechanisms of Unilateral PCA Infarction

1. Embolism: cardiac, proximal vertebral artery, arch of aorta, fetal origin of PCA

2. Emboli arise from the end of atheromatous plaques of recently occluded proximal vertebral artery
3. African Americans and Asians patients: infarction is more frequent in context of stenosis with in situ thrombosis
4. Migraine
5. Coagulopathy
6. Transtentorial herniation – temporal and calcarine branches compressed against the tentorium
7. If 2 PCA branches and the posterior chorioidal artery are affected if there is severe small vessel disease

Bilateral PCA Infarction

General Characteristics

1. Infarcts often restricted to bilateral inferior or superior calcarine branches

Clinical Manifestations

1. Cortical blindness (Anton's syndrome):
 - a. Bilateral infarction of the striate cortex:
 - i. Anton's syndrome:
 1. Denial of blindness
 2. Maneuver around objects (visual crescent remains, bilateral hemianopsias or scotoma)
 3. Visual confabulation
 4. Normal pupillary reaction to light
 5. Euphoria
2. Bálint's syndrome (superior parietal and occipital lobe involvement):
 - a. Simultagnosia (patients see objects piecemeal); cannot describe the entire object)
 - b. Optic ataxia (lack of coordination of hand eye movements; usually under reaching the object)
 - c. Apraxia of gaze (inability to look at an object on command)
 - d. Difficulty in breaking fixation of gaze
 - e. Poor visual scanning of areas of interest
 - f. May be limited to one visual field
3. Amnesia:
 - a. Bilateral infarction of the temporal lobe
 - b. Amnesia occurs concomitantly with visual sensory loss and acute depression of level of consciousness
4. Emboli and infarction (below calcarine fissure):
 - a. Upper quadrant altitudinal defect
 - b. Abnormal color perception
 - c. Difficulty in recognizing faces (prosopagnosia)
 - d. Inability to revisualize the form of an object; able to revisualize direction and place relationships of objects
 - e. Agitated delirium (involvement of the lingual and fusiform gyri, inferior temporal lobe)
 - f. Central achromatopsia (may perform adequately on Ishihara plates) unable to match hues or colors
 - g. Agitated delirium (left posterior inferior temporal lobe)
 - h. Emboli to tip of the basilar artery have predilection for inferior calcarine branches

5. Bilateral superior bank infarction
 - a. Severe hypotension (MCA/PCA border zone) is the usual mechanism
 - b. Less common than lower bank infarcts
 - c. Disorientation to place, difficulty in revisualization of locations (where people and places are topographically)

Neuropathology

Pathogenesis of Bilateral PCA Infarction

1. Serial infarction; stenosis of arteries from atherosclerosis
2. Simultaneous; embolus to top of the basilar artery or from thrombus in the basilar artery
3. Capillary-leak syndrome (primarily white matter) of the occipital lobe
 - a. Hypertensive encephalopathy
 - b. Cyclosporine and FK 506 (tacrolimus)
 - c. Uremia
 - d. Eclampsia
 - e. Dissection of distal basilar artery
 - f. PRES

Clinical Manifestations of PCA Progressive Occlusion

1. Progressive stenosis of PCA following anterior augmentation surgery for Moyamoya disease:
 - a. Often is delayed following original revascularization surgery
2. Vertebral artery calcification:
 - a. Associated with distal PCA segment stroke
3. Transneuronal retrograde degeneration of the optic nerve following PCA occipital lobe lesions
4. Posterior cerebral laterality is favorable sign for recovery in middle cerebral artery occlusion
5. Occlusion of the artery of Percheron causes bilateral thalamic infarction:
 - a. Single artery arises from one cerebral artery to perfuse the paramedian thalamic territory (usually arises from the top of the basilar artery)

Border Zone Infarction

Overview

Border zone infarctions occur between two or three arterial territories during prolonged periods of hypotension or cardiac arrest. The infarction may occur between pial conducting vessels or internally between ascending vessels that are feeding deep nuclear structures and descending penetrating vessels. They tend to be symmetric and occur in characteristic areas. There are internal laminar infarctions between the capillaries that are the functional metabolic columns of the brain. An O₂ molecule diffuses approximately 10 μ from the hemoglobin of its 7 μ RBC. These 10 μ constitute the functional intercapillary metabolic zones of the brain. Patients less than 40 years

of age have infarctions in the anterior circulation while older patients tend to infarct the border zones of the posterior circulation. Specific syndromes have been described for many of these infarctions. The “man in the barrel” suggests an anterior cerebral/middle or cerebral artery border zone infarction. The shoulder on upper arm components of the homunculus are involved. These patients have preserved intrinsic hand muscle function. Posterior MCA/PCA infarction may cause Bálint’s syndrome of infarction of the superior parietal lobule. These patients have a simultagnosia, poor optic scanning, failure to break fixation and optic ataxia. Ascending lenticulostriate and penetrating medullary vessels from pial conducting vessels cause the periventricular vascular stripe. Leg fibers may be preferentially affected. Isolation of the speech area suggests cortical hypoxia, carbon monoxide poisoning or hypotension. Ischemia of the optic nerve head from poor perfusion of the central retinal artery and posterior ciliary artery with giant cell arteritis and prolonged hypotension. Border zone infarcts of the brainstem do not demonstrate clear patterns of anatomical localization as those of the anterior circulation.

The following discussion is of the differential diagnosis and characterization of border zone infarcts.

General Characteristics

The major cerebral arteries have superficial pial branches that anastomose at the junction of their territories and perforating centripetal vessels. The deep ascending branches of the major vessels supply the parenchyma and do not anastomose. The territories between a superficial vessel and its ascending deep perforators define border zone areas of the deep circulation. These areas are known as the distal fields of the particular vascular territory and may suffer decreased:

1. Cerebral blood flow
2. Perfusion pressure
3. Increased oxygen extraction

These areas are susceptible to hemodynamic changes principally hypotension. It has also been postulated that microemboli from the heart, aorta or vessels from vessel atherosclerotic plaque debris preferentially lodge in these boundary areas. Hemodynamic parameters in border zone areas decrease the washout of embolic material and increase the susceptibility to infarction. Infarction between two or three arterial territories are defined as border zone (termino-terminal) if there is no arterial collateral circulation between the two arterial territories. There are two types of border zone infarct:

1. Cortical – between major arteries of the cerebral cortex or cerebellar cortex (possible microembolic mechanism)
2. Internal border zone infarction:
 - a. Occurs in deep cerebral or cerebellar white matter or the brain stem
 - b. Probable hemodynamic mechanism

Cerebral Border Zone Infarction

1. Territory between the ACA/MCA:
 - a. Frontal parasagittal cortex from the anterior horn of the lateral ventricle to the frontal cortex
2. Territory between the MCA and PCA:
 - a. Cortex between the posterior horn of the lateral ventricle to the parieto-occipital cortex

Cerebral Internal Border Zone Infarction

1. Localized between the superficial (long medullary perforators from MCA branches and the lenticulostriate arteries)
 - a. Affects the corona radiata
2. Junctional territories between perforators of the ACA/MCA
 - a. Affects the centrum semiovale
 - b. Arm area anteriorly; leg posteriorly and the bladder fibers next to the ventricle
3. Junctional territory between the lenticulostriate (carotid branches), paramedian territory and the inferior lateral thalamic territory (thalamogeniculate artery)

Cerebellar Border Zone Infarction

General Characteristics

1. Superficial territories between the PICA and superior cerebellar arteries:
 - a. Affects the cerebellar hemispheres
2. Internal border zone infarction:
 - a. Affects deep cerebellar white matter

Brainstem Internal Watershed

1. Junctional arterial territories between the paramedian perforators of the basilar arteries and the lateral perforators of the short circumferential branches of the cerebellar arterial supply

Clinical Manifestations

1. Precipitating features if the mechanism is hemodynamic:
 - a. Arising from a supine position
 - b. Physical exercise
 - c. Post prandial
 - d. Valsalva maneuvers (decreased CBF)
 - e. Coughing (decreased CBF)
 - f. Systemic hypotension (often after change in antihypertensive medications)
 - g. Anesthesia
 - h. Cardiac or other prolonged surgery
 - i. Hypervolemia (bleeding or anemia)
2. Symptoms and MRI findings are often bilateral and symmetrical
3. Concomitant carotid or vertebral artery partial occlusion are often present:
 - a. Concomitant carotid stenosis in a high percentage of patients

4. Loss of consciousness at the onset of border zone stroke more frequent than in thromboembolic disease
5. Early onset of seizures (if there is cortical ischemia)

Specific Syndromes of Border Zone Infarction

1. Carotid hypoperfusion
 - a. Unilateral shaking TIA (bilateral if in VB circulation)
 - i. Hemodynamic precipitants
 - b. Optico-cerebral syndrome
 - i. Rare
 - ii. Amaurosis fugax ipsilesionally with contralateral hemiparesis
 - c. Retinal claudication
 - i. Monocular transitory loss of vision when exposed to bright light
 1. Failure of retinal pigment regeneration due to ischemia
 - d. Mild cognitive impairment
 - i. Particularly with bilateral disease
 - ii. Chronic hypoperfusion

ACA/MCA Border Zone Stroke

1. Contralateral hemiparesis
2. Facial sparing
3. If cortical, arm involvement is greater than leg involvement
4. The wrist and hand can be preferentially involved as can the shoulder
5. Bilateral involvement causes:
 - a. "Man in the barrel" syndrome
 - b. Bilateral arm weakness (proximal greater than distal)
 - c. Patient can walk
 - d. Subcortical lesions:
 - i. Leg greater than arm weakness
 - ii. If bilateral, both legs are involved and can appear as "pseudo-spinal"
 - e. Dominant hemisphere:
 - i. Transcortical motor aphasia
 - ii. Affected area usually above Broca's area
 1. Disconnection of supplementary motor cortex from Broca's area
 - f. Non-dominant hemisphere:
 - i. Transitory mood disturbance
 1. Euphoria or apathy
 2. Apathy can be severe
 - a. Akinetic mutism
 - b. Loss of frontal lobe executive function

Posterior Border Zone MCA/PCA Infarction

1. Optic radiation ischemia (the geniculate body to the calcarine cortex)
 - a. Peripheral visual field constriction
 - b. Homonymous inferior quadrantanopsia (emboli often cause superior quadrantanopsia)
 - c. Hemianopsia

Bilateral Cortical MCA/PCA Border Zone Infarction

1. Anton's syndrome
 - a. Can distinguish light from dark
 - b. Can avoid large objects while walking; possible preservation of peripheral retinal projections
 - c. Normal pupillary reflexes
 - d. Visual confabulation
 - e. Euphoria
2. Bálint's syndrome
 - a. Under reaching (inability to reach a target (superior longitudinal fasciculus damage; connects the superior parietal lobule with frontal eye fields); visual navigation deficit)
 - b. Simultanagnosia – inability to see objects as a whole (can identify pieces of a face – eyes, nose, mouth but can't perceive these components as a face; superior parietal lobule)
3. Optic apraxia (delayed volitional saccades)
 - a. Poor initial scanning of a visual scene
 - b. Inability to break fixation and follow a moving object
 - c. Optic ataxia (visual navigational deficit)
 - i. Inability to point at a target volitionally
4. Cortical involvement (dominant hemisphere)
 - a. Wernicke's aphasia
 - i. Lesion between Wernicke's area (BA22/BA23) and posterior parietotemporal association areas (BA39, BA40, BA41)
 - ii. Parietal sensory loss and hemihypesthesia
 1. Non-dominant hemisphere: hemineglect and anosognosia
 2. Dissociation of primary sensory area (SI) from primary sensory association areas of the posterior parietal lobe
 - iii. Brachiofacial hemiparesis or no motor loss subcortical
5. Hemispheric internal border zone infarction
 - a. Ischemic territory between deep and cortical perforators of the MCA
 - b. Ischemic zones between internal capsule and thalamus (lenticulostriate and thalamogeniculate and thalamoperforate arteries)
 - c. Clinical manifestations:
 - i. Brachiocephalic paresis
 - ii. Cortical sensory loss
 - iii. Dominant hemisphere aphasia
 - iv. Vascular stripe on MRI
 1. Periventricular (1 cm from the ventricle) increased T2-weighted signal

Border Zone Cerebellar Infarction

General Characteristics

General Features of Arterial Territories

1. Less than 2 cm in diameter
2. Between SCA and PICA boundary zones

3. Between left and right SCAs on the cortex
4. Between SCA and PICA branches in the deep cerebellar white matter

Deep Cerebellar Watershed Territory of Arterial Territories

1. Caudal cerebellum
2. Deep boundary zones of AICA–lateral PICA, medial PICA–lateral SCA and medial SCA territories
3. Appear as round holes above the dentate nucleus

Clinical Manifestations

Clinical Features of Border Zone Cerebellar Infarction

1. Similar to territorial infarcts
2. Rarely: transient loss of consciousness; usually dysequilibrium
3. May represent low flow state of the posterior circulation

Brainstem Border Zone Infarction

General Characteristics

1. Usually prolonged hypotension
2. Arterial territories
 - a. Symmetrical necrosis of the tegmentum:
 - i. Territory involved between pontine penetrating vessels and short and long circumflex arteries

Clinical Manifestations

1. Cranial nerve, oculomotor and brainstem dysfunction
2. Coma

Rare Clinical Border Zone Infarctions

General Characteristics

1. Isolation of the speech areas (Perisylvian):
 - a. Anterior and posterior aphasia
 - b. Can only repeat

Neuropathology

1. Severe cortical hypoxia (cardiac arrest)
2. Carbon monoxide poisoning
3. Prolonged hypotension
4. Isolation of the speech areas from much of the cortex (perisylvian border zone)

Deep Cerebral Infarcts Extending to the Subinsular Region

General Characteristics

1. Involved territory is between the lateral ventricle and subinsular region
2. The paraventricular region in the centrum semiovale is involved and extends for greater than .5 cm
3. The at risk territory of the subinsular cortex is 1/3 of the anterior posterior extent of the insula

Clinical Manifestations

1. Hemiparesis
2. Transcortical conduction aphasia
3. Dysarthria
4. Dysphasia

Neuropathology

1. Stenosis or occlusion of extracranial arteries
2. Initiating factors: bradycardia, high hematocrit, systemic hypotension, drop in cerebral perfusion pressure
3. Systemic hypotension due to:
 - a. Cardiac surgery
 - b. Bilateral symmetrical distributions
 - c. More common in posterior watershed zones (MCA/PCA)
4. Systemic disease
 - a. Artery-to-artery cholesterol microemboli
 - b. Sick cell anemia
 - c. Polycythemia vera

Granular Cortical Atrophy

1. Multiple small foci of cortical infarction in all border-zones
2. Gray matter involvement
3. Pial arteries supplying the cortex
4. Cortical microinfarcts

Multiple Infarctions

Overview

The differential diagnosis of multiple infarctions is usually suggested by the clinical setting. Not surprisingly many patients in the course of their evaluation for their first clinical stroke are found to have had either asymptomatic prior strokes or concomitant strokes in territories other than that suspected by their clinical presentation. The major categories of illness that cause multiple infarctions are:

1. Atherosclerosis
2. Cardiac emboli
3. Angiopathies
4. Hematologic disorders
5. Hypoperfusion and venous infarction

Patients with poorly controlled diabetes, hypertension and similar history have an overwhelming probability of suffering both large and small vessel disease. Lacunes are expected in the basal ganglia, pons, internal capsule, thalamus and centrum semiovale. Accelerated and disseminated large vessel atheroma will be seen at the carotid bifurcation, siphon, and at M1 and M2. Calcified and thick, vertebral, carotid and basilar arteries are expected on CT. Severe hypertension will produce dolicoectasia. In situ thrombosis, flow limiting ischemic stenosis greater than 70% and cholesterol laden plaques will

be seen asymmetrically in both anterior and posterior circulations. Accelerated atherosclerosis will be seen beyond bifurcations of the great vessels and intracranially in the fields of X-ray therapy.

Cardiac emboli from clots formed from an ischemic myocardium, arrhythmias, dilated myocardial failure, valve disease, embolize primarily to the MCA circulation that receives the most CBF. Emboli tend to go to the same territory due to flow and viscosity characteristics. They often occur in showers in which two circulations are involved simultaneously. Emboli from atrial fibrillation often occlude the temporoparietal occipital branch of the inferior division of the MCA. Carotid distribution and superior cerebellar artery concomitant stroke suggest an embolic cardiac origin. Occlusion of the top of the basilar artery is most often embolic often from a cardiac source in which the midbrain, thalamus and posterior cerebral arteries are involved. An embolic event in younger patients in two distinct circulations over a long time course suggests a patent foramen ovale with or without an atrial septal aneurysm. Peripheral aneurysms in two distal circulations suggest atrial myxoma. Rhabdomyosarcoma is to be expected with tuberous sclerosis. A shower of emboli in a cancer patient suggests non-bacterial thrombotic emboli. Severe migraine with visual aura and stroke in two circulations is strong evidence for the anticardiolipin syndrome.

Small strokes in pial conducting vessels of all territories of the cerebral cortex occur with active and severe collagen vascular disease. SLE is the most prominent of these illnesses.

Hematologic illness such as leukemia and lymphoma, particularly when the white cell count approaches $250,000/\text{mm}^3$, is attended by strokes in multiple territories. Polycythemia most frequently occludes the posterior circulation. Disseminated intravascular coagulation may strike large extracranial vessels as well as conducting intracranial vessels. Sickle cell disease affects large and small vessels of both anterior and posterior circulations.

Hypoperfusion causes strokes by distal perfusion failure in affected arteries as well as by circulatory compromise between vascular territories. This complication is to be expected and is routine with cardiac pump surgery and following cardiac arrest.

Venous infarction is immediately suggested in the setting of pregnancy and delivery, dehydration and a hypercoagulable state. Bilateral thalamic infarction easily seen on CT or MRI is characteristic of superior sagittal sinus thrombosis. Severe seizures accompany cortical vein thrombosis.

Multiple infarctions other than that from atherosclerosis suggest internal medical and cardiac disease as the source. The younger the patient the more this is true.

General Characteristics

Concomitant Infarction

1. 33% of patients when diagnosed with first stroke have multiple infarcts in the carotid territory

2. 2% of multiple infarcts are in vertebrobasilar territory
3. 2% of patients at first infarct have had prior strokes in both territories (carotid and vertebrobasilar territories)

Asymptomatic Infarction

1. Occurs in 10–38% of stroke patients
2. Often occurs in non-critical areas and are small
3. Right-sided deep hemisphere and basal ganglia lesions more common than left-sided if non-lacunar
4. Risk is the same in multiple and single lesions

Neuropathology

Atherosclerosis

1. Atherosclerosis: large and medium-sized arteries
2. Small vessel disease:
 - a. Lipohyalinosis (penetrating vessels); HCVD
 - b. Spread of atheromatous plaque to occlude adjacent origins of major vessels
 - c. Atheroma at origin of penetrating vessels
 - d. Emboli: artery to artery; cardiac or arch of the aorta are sources

Cardiac Embolism

1. Nonrheumatic atrial fibrillation (AF) most common source of cardiac embolism
2. AF with emboli 10% per year (if untreated):
 - a. Multiple pial territory infarction suggests cardioembolic source
 - b. Bilateral anterior circulation infarcts are more common in patients with emboligenic heart disease

Angiopathies

1. Isolated angitis of the CNS (cerebrum, cerebellum)
2. Granulomatous vasculitis
3. Herpes zoster
 - a. Affects small and medium-sized vessels
 - b. Infarction more common than hemorrhage
 - c. Localized lesions: cerebrum, cerebellum, brainstem in >75% of patients
 - d. May occur in carotid MCA territory if V1 involved. Occurs 2 weeks after onset of skin lesions or may be delayed

Differential Diagnosis

Differential Diagnosis of Non-Inflammatory Angiopathies with Multiple Strokes

1. Eales disease (arterioles and venules involved)
2. Sneddon's syndrome (livedo reticularis)
3. Moyamoya syndrome (carotid occlusion at siphon with collaterals)
4. MELAS (mt DNA) mitochondrial encephalopathy with lactic acidosis and stroke
5. Cerebral amyloid angiopathy (associated dementia)
6. Intravascular lymphoma (angiotrophic endovascular lymphomatosis); dural involvement
7. Arterial dissection of intracranial and cervical arteries (diseases of collagen)

Hematological Disorders

1. Thrombotic thrombocytopenic purpura (TTP):
 - a. Multiple occlusions of small vessels
 - b. Large artery occlusion
 - c. Hallucinations
 - d. Renal failure
 - e. Focal cortical deficits
 - f. Seizures
2. Polycythemia vera:
 - a. Posterior > anterior circulation stroke
 - b. Megakaryocyte proliferation greater than one million has a high incidence of stroke
 - c. Hemoglobins of 18–22 g/dl
 - d. Rheological abnormalities (dysfunction of laminar flow)
3. Sickle Cell disease (HbSS):
 - a. Stroke occurs in 3–17% of patients
 - b. Ischemic stroke 15%
 - c. Large and small vessels involved
 - d. Strokes <15 years of age; border zone, and subcortical areas
 - e. Hemoglobin C: strokes in pregnancy; aseptic necrosis of the hip
 - f. Severe abdominal and joint pain
4. Disseminated intravascular coagulations (DIC):
 - a. Small and large vessel strokes (often concomitantly)
 - b. Encephalopathy
 - c. Non-bacterial thrombotic emboli (NBTE) frequently associated
 - d. SAH
5. Systemic lupus erythematosus:
 - a. Vasculopathy affecting:
 - i. Small arteries
 - ii. Arterioles
 - iii. Capillaries
 - iv. Pathology is fibrinoid neurosis
 - b. Vasculitis
 - i. Pathologically similar to hypersensitivity vasculitis
 - ii. Approximately 10% of patients
 - c. Microangiopathy:
 - i. 50% of SLE patients
 - ii. Circulating antiphospholipid antibodies (APA's)
 - iii. 2 mm to 3 cm infarction size
 - d. Clinical manifestation of stroke:
 - i. May occur at any time during course of the disease
 - ii. Caused by APA's (antiphospholipid)
 1. Titer may fluctuate and is not tightly correlated with systemic disease activity
 2. Circulating IgG and IgM antibodies associated with the thrombotic events
 3. APA's that bind to the phospholipid on factor V and X
6. Inhibits conversion of prothrombin to thrombin
7. Anticoagulant properties in vitro (lupus anticoagulant; LAC)
8. Some LAC are procoagulant
9. High titers of anticardiolipin antibodies (ACL):
 - a. Greater specificity for thrombotic events
 - b. IgG > association with thrombosis than IgM
 - c. Stroke risk with secondary APA's in SLE is increased with:
 - i. Oral contraceptives
 - ii. Smoking
 - iii. Hypertension
10. Stroke types:
 - a. Branch occlusion most common
 - b. Multiple infarcts
 - c. Centrum semiovale strokes
 - d. Cardioembolic from Libman-Sacks endocarditis
11. Vasculitis in SLE:
 - a. Ischemic and hemorrhagic stroke
 - b. Intracranial hemorrhage
 - i. Parenchymal
 - ii. SAH
 - iii. Most associated with vasculitis
 - c. Most likely cause of stroke if:
 - i. Active systemic disease
 - ii. Normal TEE
12. Associated collagen vascular disease
13. Hyperviscosity syndromes:
 - a. Bing-Neel syndrome (poor cerebral perfusion from high viscosity)
 - b. Bleeding gums
 - c. Myeloproliferative and dysglobulinemia states (IgM particularly severe)
 - d. Multiple occlusions of small blood vessels
 - e. Petechial hemorrhage
 - f. Waldenström's macroglobulinemia
 - i. Petechia below the knee
 - ii. Acrocyanosis

Hypoperfusion

1. Severe hypotension (cerebral perfusion pressure of less than 70 mm systolic)
2. Prolonged hypoxemia
3. Cardiac circulatory failure (no reflow phenomena of specific microcirculations)
4. Symmetrical and asymmetrical watershed infarcts
5. Infarcts in deep and superficial MCA territories
6. Cerebellar watershed infarcts
7. Multiple clinical syndromes depending on involved circulations

Venous Infarction

1. Hemorrhagic
2. Specific circumstance: pregnancy, prothrombotic state, cancer, Behçet's disease
3. Gray matter (basal/thalamus); subcortical white matter

Lacunar Stroke

Overview

Lacunae are small ovoid lesions 1–2 mm in size noted in deep nuclear gray matter of the basal ganglia and thalamus as well as the internal capsules, centrum semiovale and pons. They are found in the setting of poorly controlled diabetes and hypertension. They are caused by fibrinoid necrosis of the endothelium and adventitia of the single perforating arterioles. The infarct is limited to the territory of deep perforators and is caused by in situ infarction. The process may also be caused by atheromatous occlusion of the mouth of these blood vessels. If a series or a group of perforators are involved simultaneously emboli are suspected as causal (this most often occurs in the lenticulostriate territory).

Discrete clinical syndromes are noted with infarctions of these perforators which outline their territory and allow anatomic localization.

Involvement of arm, face, and leg suggests lacunar infarction of the middle 1/3 of the posterior limb of the internal capsule. Genu involvement is suggested by more face than arm involvement and severe dysarthria. The posterior 1/3 of the capsule may be selectively involved with hemisensory numbness. Occasionally, a single extremity may become weak from involvement of the medullary stria arteries that perfuse the centrum semiovale. The motor and sensory fibers are separated in the fiber deep into the brain. The dysarthria clumsy hand syndrome occurs from posterior ventral 1/3 pontine infarction in which the corticobulbar fibers, speech and arm fibers are closely opposed. Ataxic hemiparesis suggests pontine lacunar involvement at the midpontine level.

Lacunar infarctions rarely ever are associated with headache, VF cut or aphasia. Pure motor, pure sensory and mixed deficits are common. There are no cortical sensory or behavioral manifestations which differentiates this from pial artery stroke. Pure motor hemiparesis with III nerve pattern (Weber, Benedict; Claude's and Nothnagel's) places the lesion in the midbrain. Rarely hemiballisms occurs from lacunar infarction of the subthalamic nucleus due to paramedian thalamic involvement. Lacunes of basilar artery territories are suggested by dizziness, diplopia, and intranuclear ophthalmoplegic without weakness.

General Characteristics

1. Lacunes are the result of small vessel disease and are usually ovoid lesions
 - a. No evidence of cerebral cortex involvement
 - b. Imaging evidence of a lesion less than 15 mm
 - c. Often concomitant hypertensive cardiovascular disease or diabetes mellitus
 - d. Overlap both in risk factor profile and clinical symptoms with large artery disease
 - e. Lacunes are defined as occlusions of a single perforating artery:
 - i. Large lacunae are 15–20 mm in diameter
 - ii. Small lacunae are 3–4 mm
 - f. Generally, large lacunes have more symptoms; small lacunes are symptomatic if in a critical location of a sensory or motor tract
2. If a specific clinical syndrome is present there is an 87% chance the patient has suffered a lacunar stroke
3. Some series demonstrate a 40–50% incidence of concomitant ischemic heart disease
4. Predictive value for lacunar stroke:
 - a. Pure sensory stroke 100%
 - b. Highly correlated
 - i. Ataxia, hemiparesis
 - ii. Sensorimotor stroke
5. 25% of lacunes are due to a non-lacunar mechanism
 - a. Atherosclerosis
 - b. Cardiac source of emboli
 - i. 10–15 perforators are occluded
 - ii. Larger size than those from small vessel disease
6. May have stuttering course over 2–3 days
7. No cortical sensory loss
8. May have behavioral changes; minimal cognitive deficits
9. No visual field deficit
10. Involvement of the territory of one single perforating arteriole
11. <1.5 cm lesion on CT or MRI; (ovoid in shape)
12. Infarct is limited to the territory of the deep perforators
13. Caused by in situ small vessel disease
14. Infarcts limited to the territory of deep perforators may occur with:
 - a. Cardiac emboli
 - b. Ipsilateral internal carotid artery stenosis or occlusion
15. Diabetes is a major risk factor for lacunes
16. The most suggestive clinical syndrome for lacunar infarction:
 - a. Pure motor hemiparesis with face, arm and leg involvement
17. Arterial networks that supply subcortical territories:
 - a. Deep perforating branches form the ACA
 - i. Recurrent artery of Huebner (A2)
 - ii. Direct anterior lenticulostriate branches
 - b. Deep perforating branches from the anterior choroidal artery
 - c. Thalamic arteries from P1 and P2 segments
 - i. Interpeduncular (top of the basilar)
 - ii. Thalamoperforate
 - iii. Thalamogeniculate
 - iv. Posterior choroidal artery
 - v. Tuberothalamic artery (from the posterior communicating artery) These arteries are perforators, but have collateral branches and are not terminal branches
 - d. White matter medullary arteries
 - i. Originate from the superficial (pial) branches of the MCA > ACA > PCA

- ii. 2–5 cm long
- iii. Selective territories
- iv. No collaterals
- v. Subserves the centrum semiovale
- vi. Do not anastomose with the deep perforators (lenticulostriate arteries)
- e. Cortical arteries with subcortical territories that supply:
 - i. U-fibers
 - ii. Extreme capsule
 - iii. External capsule
 - iv. Claustrum
- f. Most commonly found:
 - i. Centrum semiovale
 - ii. Basal ganglia
 - iii. Thalamus
 - iv. Midbrain
 - v. Pons
 - vi. Medulla
- g. Infarction in these territories are often not lacunar (i.e., from one perforator) but may be secondary to distal field ischemia (carotid stenosis) or cardiac thromboembolism
- 6. Mesencephalic; decreased upgaze (Nothnagel's syndrome)
- 7. Thalamic dementia (DM, AV nuclei)
- 8. PMH with horizontal gaze palsy – lower 1/3 of pons, PPRF (para pontine reticular formation)
- 9. PMH with III nerve (Weber's syndrome)
- 10. PMH with III nerve and ataxia – Claude's syndrome (midbrain)
- 11. PMH with III and movement disorder (Benedict's) (mid-brain)
- 12. PMH with VI nerve palsy (Ramon's syndrome); pons
- 13. PMH with confusion (brainstem RF; thalamus AV/DM)
- 14. Sensorimotor stroke (thalamic-capsular)
- 15. Hemiballism – (STN; paramedian mesencephalic vessels)
- 16. Lacune of basilar territory (dizzy, diplopia, gaze dysfunction)
- 17. Lateral medullary partial infarction (penetrators from the vertebral artery)
- 18. Lateral pontomedullary territory (partial AICA)
- 19. Loss of memory (DM nuclei of thalamus); paramedian perforator)
- 20. Locked in syndrome (infarction of ventral pons; bilateral cerebral peduncles)
- 21. Unusual lacunar syndromes:
 - a. Weakness in one leg with falling (corona radiata; ventral portion of ventral pons)
 - b. Pure dysarthria – posterior 1/3 of ventral pons
 - c. Acute dystonia (thalamoperforate artery to basal ganglia)
 - d. Lacunar strokes and cognitive deficit
 - i. Late onset of bipolar disease
 - ii. Silent lacunar infarct with:
 - 1. Brain atrophy
 - 2. Multiple subcortical sites
 - 3. Enlarged ventricles
 - iii. Decreased executive function
 - iv. Decreased visuospatial ability

Clinical Features of Lacunar Stroke

Clinical Presentation of Lacunar Stroke

1. Occur more commonly during sleep
2. Arm, face, leg may be affected separately (corona radiata and pons most common areas of infarction)
3. Pure motor, pure sensory or mixed clinical patterns
4. Rare aphasia (a differential point against lacunar stroke)
5. No headache
6. No visual field deficit
7. May have stuttering course over 2–3 days
8. No cortical sensory or behavioral manifestations (strong differential point for lacunar stroke)
9. Cause of multi-infarct dementia (état spongiosus)

Clinical Patterns of Lacunar Stroke

1. Pure sensory stroke (PSS) (primarily thalamus)
2. Pure motor hemiparesis
 - a. Corona radiata
 - b. Middle internal capsule
 - c. Cerebral peduncle (medial 3/5)
 - d. Ventral pons
 - e. Medullary pyramidal
 - i. At decussation with cruciate pattern (ipsilateral arm; contralateral leg)
3. Ataxic hemiparesis (AH) (pontine gray – MCP and descending CST)
4. Dysarthria clumsy hand syndrome (pons)
5. Pure motor hemiparesis sparing the face (farther posterior in the middle 1/3 of the posterior limb of the internal capsule)

Clinical Presentation and Patterns of Pure Motor Hemiparesis (PMH) and Sensory Stroke

1. Motor Cortex
 - a. Hand and arm representation is in the precentral gyrus "motor knuckle"
 - i. C5–C6 roots are represented medially
 - ii. C8–T1 are more lateral
 - b. Infarction frequently appears as a pseudo radial palsy (wrist drop)
 - c. Embolic pathogenesis from the internal carotid artery
 - d. Rare that face is involved in isolation
 - e. Cranial nerve III or VI involved with pure hemiparesis, ataxia or movement disorder
 - f. Medullary pyramid-flaccid hemiparesis that spares the face

Pure Motor Stroke (PMS)

1. The most common lacunar syndrome
 - a. 45–57% in 3 major stroke registries
2. Territories involved:
 - a. Anterior limb of the internal capsule
 - i. Facial brachial pattern of weakness
 - b. Leg weakness – the lesion is more posterior in the internal capsule
 - c. Distal upper limb – pontine infarction
 - d. Medullary pyramid – flaccid hemiparesis that spares the face
3. Mechanism
 - a. Occlusion (atheroma at ostium) of deep perforating end artery
 - b. Lipohyalinosis of perforator: fibroid necrosis of media of the perforating arteriole
 - c. Embolus to a group of perforators
 - d. Basilar artery branch disease in pontine infarction due to atherosclerosis of the basilar artery

Pure Sensory Stroke

1. Lacune in the centrum semiovale (deep penetrating medullary arteries)
 - a. Usual feeling of numbness or heaviness
2. Infarction of ventrobasilar thalamic complex (VPM or VPL):
 - a. Patients may describe numbness, paraesthesias, formication or pain
 - b. Bilateral intraoral loss of sensation (VPM). This is to be differentiated from a vascular brainstem stroke in which patients may feel numbness on one side of the tongue. VPL involvement may present as numbness of the trunk and extremities in 20% of patients. Dysesthetic, paraesthetic and burning occurs more often in the involved territory. Later this territory may be associated with the hyperpathia of Dejerine-Roussy syndrome (thalamic pain). Associated thermal and mechanical allodynia and hyperalgesia are frequently present concomitantly with this syndrome. Thalamic lesions respect the midline and may involve vibration sensibility. Exception is bilateral decreased periumbilical sensation
3. Thalamic-capsular lacunar infarction most often causes sensorimotor stroke. Feeling loss is perceived as numbness and heaviness
4. Involvement of the ventral medial spinothalamic tract (quintothalamic tract) by lacunar infarction at medullary levels causes unilateral or bilateral facial pain or numbness (onion skin distribution)
5. Smallest of the symptomatic deep infarcts
6. Approximately 6% of lacunar strokes
7. Territories involved:
 - a. Posterior limb of the internal capsule
 - b. Thalamus (VPL)
 - c. Anterior thalamic radiations

- d. Rostral pontine tegmentum that involves:
 - i. Medial lemniscus
 - ii. Lateral spinothalamic tracts
- e. 9.5% of pure sensory strokes are not due to lacunar infarction

Ataxic Hemiparesis

1. Ataxic Hemiparesis or Corticobulbar Dysfunction
 - a. Infarction of the descending corticospinal tracts and pontine crossing fibers (comprises the middle cerebellar peduncle)
2. Anatomical locations:
 - a. Internal capsule – 39%
 - b. Thalamus – 13%
 - c. Corona radiata – 13%
 - d. Lentiform nucleus – 8%
 - e. Cerebellum – 4%
 - f. Frontal cortex – 4%

Clinical Features of Ataxic Hemiparesis

1. Hemiparesis or corticospinal signs associated with ipsilateral cerebellar signs:
 - a. Lesion topology
 - i. Lesions in the white matter of the corticospinal (motor cortex to pontine nuclei)
 - ii. Afferents to the middle cerebellar peduncle that project to the cerebella afferent zone for proprioception
 - iii. Thalamic cerebellar nuclei
 - iv. 3a of SI in the sensory cortex that projects back to MI. There are subtle differences with lesions at each level of this pathway
 - b. Partial hemiparesis, nystagmus, dysarthria – suggest an infratentorial lesion
 - c. No facial involvement, dysarthria, sensory loss is more cortical lesion site
 - d. Painful ataxic hemiparesis
 - i. Edema or ischemia of the internal capsule
 - ii. Pain and ataxia
 1. VPL of the thalamus
 2. Cerebellar proprioceptive zone in VL
 - e. Ataxic hemiparesis from:
 - i. Frontal infarction and contralateral cerebellar diaschisis (demonstrated by SPECT scan)
 - f. Ataxic hemiparesis accounts for between 9–18% of lacunar strokes

Dysarthria (Clumsy Hand Syndrome)

1. Corticobulbar fibers to the Xth and XIIth cranial nerves with contralateral ataxia of the hand and arm
2. IIIrd nerve palsy with contralateral ataxia (Claude's syndrome); contralateral movement disorder (Benedict's); failure on upgaze Nothnagel's)

Sensorimotor Stroke Syndrome

1. Territories involved:
 - a. Thalamic capsule component of the corona radiata and putamen
 - b. Ventral posterior lateral thalamus and internal capsule
 - c. Cortical infarction anterior to the Rolandic fissure
 - d. In the Stroke Data Bank Study, lesions were seen:
 - i. Posterior limb of the internal capsule – 3%
 - ii. Corona radiata – 22%
 - iii. Genu of the internal capsule – 7%
 - iv. Thalamus – 9%
 - v. Anterior limb of the internal capsule – 6%

Hemiballism

1. Infarction of at least 2/3 of the corpus Luysi (subthalamic nucleus. Usually thalamoperforate or paramedian thalamic penetrating artery is occluded.)

Tetraplegia (Locked-In Syndrome)

1. Patients are fully awake
2. Quadriplegic
3. Able to blink and look up and down on command
4. Unable to perform lateral eye movements
5. Involvement of the basis pontis (basilar artery) or the cerebral peduncles (bilaterally)
 - a. P1 segment of the PCA's

Unusual Patterns of Lacunar Weakness

1. Weakness in one leg with falling
 - a. Basis pontis (ventral portion of ventral pons)
 - b. Posterior corona radiata fibers
2. Pure dysarthria: corona radiata, internal capsule, cerebral peduncle; basis pontis
 - a. No difference in dysarthria
 - b. Imprecise articulation of labials and glottals
 - c. Monotonous voice
 - d. Slowed rate
 - e. Pontine or medullary areas have more severe dysarthria
 - f. Left paravermian cerebellar lesions
 - i. Coordination of articulation and respiration is disrupted
3. Acute dystonia
 - a. Thalamus (VA, VL or VIM)
 - b. Putamen

Rarer Lacunar States

1. Loss of memory
 - a. Anterior thalamic nuclei
 - b. Anterior limb of internal capsule that involves anterior thalamic efferent fibers
2. Thalamic dementia (dorsal medial nucleus from paramedian infarction)

3. Pure motor hemiparesis sparing the face
4. Multiple lacunar infarctions:
 - a. Primarily in the basal ganglia
 - b. "État" Lacunaire
5. Dysarthria, facial, lingual paresis
 - a. Genu capsular syndrome
6. Cerebellar lacunes
 - a. Unusual small round lesions in the watershed between SCA, PICA, AICA
 - b. One case of giant lacune in the cerebellum
 - c. SCA greater deep territory supply from AICA or PICA
 - d. Large artery occlusion, cardiac embolic, end artery lesion

Differential Diagnosis by Arterial Territory and Anatomical Structure of Pontine Stroke with Lacunar Infarction

1. Paramedian arteries:
 - a. Medial basis pontis
 - b. Ventral tegmentum
 - i. Corticospinal tract
 - ii. VIth cranial nerve fibers as they exit
 - iii. Facial nerve fibers as they exit
 - iv. Rare PPRF (para pontine reticular formation by extension)
2. Short circumferential arteries
 - a. Lateral 3/5 of the pons involved
3. Long circumferential arteries
 - a. Lateral tegmentum
 - b. Tectum:
 - i. Cerebellar projections
 - ii. Vth and VIIIth cranial nerves
 - iii. Part of sensory lemniscus infarcted
4. Large bilateral pontine infarcts
 - a. Basilar artery lesions
 - i. PPRF, one-and-a-half syndrome
 - ii. Ocular bobbing and dipping
 - iii. <0.5 mm pupils
 - iv. Decreased consciousness
 - v. Decerebration
 - vi. Hyperactive reflexes
 - vii. Babinski signs

Differential Diagnosis Between Pontine Hemorrhages vs. Infarction

1. Ischemic:
 - a. Prior TIA
 - b. Stuttering clinical course
2. Hemorrhage:
 - a. Abrupt headache
 - b. Nausea and vomiting
 - c. Meningeal irritation
 - d. Rapid decrease of consciousness

3. Lacunar syndrome may be due to hemorrhage or infarction; isolated small hemorrhage may be associated with:
 - a. Dysarthria clumsy hand syndrome
 - b. Pure sensory stroke
 - c. Ataxic hemiparesis

Small Vessel Disease

Small Vessel Disease Overview

Small vessel disease is a major component of cerebral vascular disease that is manifest by lacunar infarction, microhemorrhages both in the cortex and basal ganglia, dilated Virchow Robin spaces and white matter intensities (identified on T2-weighted MRI) that may be generalized or topographic. There are monogenic conditions that present primarily as small vessel disease such as: retinal vasculopathy with cerebral leukodystrophy (RVCL) that has recently been mapped to chromosome 3p21 and may have 3 variants: 1. Hereditary Retinal Vasculopathy (HRV), 2. Cerebroretinal Vasculopathy (CRV) and Hereditary Endotheliopathy, 3. Retinopathy and Nephropathy (HERNS). An infantile syndrome that is similar but does not map to 3p21 is: Hereditary Infantile Hemiparesis with Arteriolar Retinopathy and Leukoencephalopathy (HI-HARL). Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is well recognized as a genetic cause of small vessel disease. Less recognized in Western populations is the autosomal recessive small vessel disease Cerebral Autosomal Recessive Arteriopathy with Subcortical Infarction and Leukoencephalopathy (CARASIL). There are multiple mutations in the genes encoding type IV collagen (COL4A1 and A2), a major component of basement membrane that cause multi system involvement (eye, brain, kidney) as well as cerebral aneurysms, hemorrhages and severe small vessel disease. Hereditary Angiopathy with Nephropathy, Aneurysms, and muscle Cramps (HANAC) is a specific variant. Fabry's disease is now being increasingly diagnosed as a cause of small vessel disease. It is clear that migraine is common in several monogenic causes of small vessel disease and has been shown in and of itself to be causative of cerebral ischemia (vasospasm or secondary ischemia from spreading cortical depression). Intracranial small vessel disease from atherosclerosis is a major subcategory of small vessel disease. Poorly controlled hypertension, diabetes and dyslipidemia are the most common causes of small vessel disease. White matter hyperintensities (WMH) that are a concomitant of normal aging are associated with cognitive dysfunction and are increased in migraine, some monogenic forms of SVD, hypertension, diabetes and dyslipidemia. They are topographic such that symmetry, density, periventricular and specific lobe involvement suggests a specific leukoencephalopathy, Alexander's disease, frontal variant of adrenar leukodystrophy, metachromatic leukodystrophy (periventricular) that affect the frontal lobe to a greater

degree than hypertension or diabetes. The genetic forms of amyloid angiopathy occur in specific populations (Icelandic, Dutch, Iowa kindred, Volga Germans) while sporadic congophilic angiopathy is a major cause of sporadic small vessel disease in the elderly.

The clinical symptomatology of small vessel disease from all causes is convergent but there are seminal features that help in differential diagnosis.

Clinically, small vessel disease (SVD) is associated with lacunar infarction, microhemorrhages and white matter hyperintensities on T2-weighted MRI sequences. If severe, the multiple small vessel infarctions cause vascular dementia characterized by subcortical type apraxia and slowness of information processing. SVD occurs very frequently in association with Alzheimer's disease so the cognitive decline noted may be multifactorial. Severe disease may cause pseudobulbar palsy gait disorder and spasticity. Uncontrolled diabetes and hypertension are almost universally associated with SVD. There are controversial arguments as to the pathologic relevance of lipohyalinosis atheroma at the origin of penetrating perforators or hyaline degeneration of the arterial media in SVD. Chronic kidney disease clearly exacerbates both large and small vessel disease. Calcifications of larger vessels are common. Less sympathetic control of posterior cerebral artery blood flow may be causative of posterior occipital lobe SVD as noted with eclampsia, reversible vasoconstriction syndrome and hypertensive encephalopathy. Family history may suggest a monogenetic cause of SVD. Migraine in young patients may have scattered white matter hyperintensities while microhemorrhages in the cortex will be seen in elderly patients with CAA. Microhemorrhages in the basilar ganglia are more characteristic of hypertension. An associated lobar hemorrhage supports the diagnosis of CAA if the microhemorrhages are cortical. A single microhemorrhage, either cortical or deep, is significant.

General Characteristics and Definitions for Small Vessel Disease

1. Small Vessel disease causes:
 - a. Lacunar infarcts
 - b. White matter hyperintensities (WHM)
 - c. Microinfarction (smaller than lacunes)
 - d. Dilatation of perivascular spaces
 - e. Microbleeds
2. Small Vessel disease often occurs in association with atherosclerosis and affects large and medium-sized arteries
 - a. By intimal proliferation and accumulation of lipids and cholesterol within the vessel wall
 - b. Plaques form at bifurcations of arteries and in areas of blood flow derived shear stress (stenosis of the lumen)
 - c. Plaques rupture occurs from:
 - i. Local thrombosis (primarily due to endothelial dysfunction)

- ii. Emboli from both cholesterol plaque material and fibrin-platelet clots
3. Vessel wall changes of small artery arteriosclerosis occur in 200–800 μm sized blood vessels
 - a. Similar to atherosclerosis but the vessels do not calcify
4. Lipohyalinosis:
 - a. Occurs in arteries of 30–300 μm size
 - b. Asymmetric fibrosis and hyalinosis associated with foam cells and accumulation of blood derived lipids and proteins within the vessel wall
5. Arteriolosclerosis
 - a. Occurs in arterioles between 50–150 μm in diameter
 - b. A concentric hyaline thickening of the vessel wall with stenosis
6. White matter hyperintensities (most easily seen on MRI) and associated with sporadic and familial SVD:
 - a. Most common in the elderly and may be seen frequently in normal subjects
 - b. White matter changes are characterized by:
 - i. Demyelination axonal loss
 - ii. Astrogliosis
 - iii. Often severe in the deep white matter
 - iv. Spares U-fibers
 - v. Associated with microglial activation
 - c. White matter lesion progression:
 - i. Growth of existing lesions
 - ii. WMH are surrounded by regions of milder injury ('penumbra')
 - iii. Gradual spatial spreading
 - iv. New lesions accrue in approximately 20% of patients in addition to growth of prior lesions
 - d. Study of CADASIL patients (pure SVD) reveals that:
 - i. Lacunes develop at the edge of white matter hyperintensities along the course of perforating vessels
7. Leukoaraiosis
 - a. Age related (as well as disease caused) white matter hyperintensities
 - i. Major risk factors are age and hypertension
 - b. Pathology:
 - i. Demyelination/axonal loss/gliosis/infarcts
 - ii. Fibrohyalinosis of small vessels (30–150 μm) in size
 - iii. Venous collagenosis
8. Microinfarcts:
 - a. Smaller than lacunar infarcts (1 mm or less)
 - b. In SVD occurs in the white matter
 - c. In CAA they occur in the cortex
 - d. Watershed microinfarcts:
 - i. Occur in hyper perfused areas between two vascular territories

Clinical Features

Lacunar Infarction

1. Round, usually 1 mm (maybe up to 3 mm); the territory served by a penetrating arteriole

2. Differentiated from a Virchow-Robin space (surrounding a penetrating arteriole). These spaces (often not ovoid) are increased in number and size by uncontrolled hypertension. They are more frequent in specific locations
3. Most patients have multiple lacunes with SVD
4. Lacunes most frequently involve the centrum semiovale, the, basal ganglia and the pons
5. Multiple penetrating arterioles are involved from both the anterior and posterior circulations. Descending arterioles from cortical conduction vessels cause large lacunar infarctions in the centrum semiovale
6. Large lacunes (>25 mm) may involve multiple perforating arterioles and may be embolic

Extensive Lacunar Infarction

1. Cystic lesions of the basal ganglia, thalamus, anterior and posterior limbs of the internal capsule, brainstem and pons are known as "état lacunaire"
2. Traditional clinical features of "état lacunaire"
 - a. Pseudobulbar palsy:
 - i. Emotional dyscontrol: "laughter without mirth, crying without tears", inappropriate to the social environment (bilateral cortical spinal tract involvement at any level from the internal capsule to the medullary pyramids)
 - ii. Difficulty with swallowing combined with a hyperactive gag reflex (poor fractionated pyramidal control of bulbar musculature for swallowing innervated by cranial nerve V, IX, X and XII)
 - iii. Gait dysfunction
 1. Small (decreased swing phase), unsteady guarded gait (Well's dementia gait)
 - iv. Subcortical dementia (apraxia and decreased processing speed)
 - v. Spasticity (often with bilateral Babinski sign)
 - vi. Mild focal motor and sensory deficits
 - vii. Cortical release reflex (forced grasp, parietal hand, palmomental)

Clinical Features of All Patients with Small Vessel Disease

1. Decreased information processing speed:
 - a. Areas of involvement that correlate with this deficit are the left medial frontal cortex and anterior thalamic radiations
 - b. The medial frontal cortex (MFC):
 - i. Pivotal for a short reaction time
 - ii. Response adjustment
 - iii. Receives projections from the anterior thalamus
 - iv. Microinfarctions in this circuitry is the characteristic pathology which causes retrograde degeneration of the medial frontal cortex
2. Effects of periventricular white matter demyelination
 - a. Frontal cortical thinning
 - b. Decreased executive function

3. Occipital and temporal cortical thinning also noted with SVD
 - a. Exact functional loss has not been determined
4. Role of frontal subcortical circuits is essential for processing speed, praxis, executive function and possibly episodic memory

Gait Disorders with Small Vessel Disease

Clinical Manifestations

1. Lower gait velocity
2. Shorter stride length (swing phase)
3. Broader stride width

Neuroimaging

MRI

1. Lesions that correlate with gait deficiency
 - a. Centrum semiovale lacunes
 - b. Periventricular white matter hyperintensities in the frontal lobe
 - c. Genu of the corpus callosum (lacunes)
 - d. Fibers interconnecting bilateral areas of the prefrontal cortex
2. Utilizing fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), radial diffusivity (RD) and MRI sequences:
 - a. Mobility is correlated with FA and AD of the inferior cerebellar peduncle (ICP) and the superior cerebellar peduncle (SCP)
 - b. Measures of fiber tract integrity of both myelinated and unmyelinated axons are demonstrated
3. T2-weighted and FLAIR sequences on a 3 Tesla magnet are excellent for location and anatomy of lacunar infarction, 7 Tesla magnets are being utilized in major centers which will certainly bring new understanding of lesion correlation with functional deficits in lacunar states
4. Gradient ECHO MRI and Susceptibility Weighted imaging are the present standard for detection of microbleeds and hemorrhages

Functional MRI (fMRI)

1. Functional connectivity and network function:
 - a. Dependent on white matter structural integrity
 - i. Demonstrated with diffusion tensor tractography and functional connectivity within all networks. The major nodes of the default mode network (DMN) are the medial frontal cortex, posterior cingulate gyrus, precuneus, hippocampus and inferior parietal lobule. This network is active during introspection and important for consciousness
2. SVD associated with minimal cognitive impairment (MCI) has deactivation failure or deficient functional connectivity in the default mode network (DMN) associated with cognitive task performance
 - a. Impaired deactivation of the precuneus and posterior cingulate gyrus

3. MCI patients without SVD
 - a. Relative hyper activation during vigilance and hypo activation of the salience network at high working memory load

Monogenetic Causes of Small Vessel Disease

1. CADASIL (central autosomal dominant angiopathy with subcortical infarction and leukoencephalopathy)
 - a. Notch 3 gene
2. CARASIL (cerebral autosomal recessive angiopathy with subcortical infarction and leukoencephalopathy)
 - a. HTRA-1 gene
3. Fabry's disease
 - a. Lysosomal α -galactosidase A deficiency
 - b. X-chromosome
4. COL4A1/A2 (collagen 4a and a2)
 - a. Chromosome 13q34 collagen IV gene
 - b. Hereditary angiopathy with Nephropathy Aneurysm and Muscle cramps (HANAC)
5. Amyloid Angiopathy (Genetic Variants)
 - a. Dutch
 - b. Icelandic
 - c. Kindred variants (founder mutations)
 - d. Specific mutations
 - e. Iowa variant
 - f. Flemish variant
 - g. Italian variant
 - h. Familial British and Danish Dementia
6. Retinal Vasculopathy with Cerebral Leukodystrophy (RVCL)
 - a. TREX 1 gene mutation
7. Chromosome 3p21 causes of retinal vasculopathy with cerebral leukodystrophy
 - a. Cerebroretinal Vasculopathy (CRV)
 - b. Hereditary Vascular Retinopathy (HVR)
 - c. Hereditary Endotheliopathy, Retinopathy and Nephropathy (HERNS)
8. Non-chromosome 3p21 variant
 - a. Hereditary Infantile Hemiparesis with Arteriolar Retinopathy and Leukoencephalopathy (HIHARL)
9. Pontine Autosomal Dominant Microangiopathy and Leukoencephalopathy (PADMAL)
10. Hereditary Angiopathy with Nephropathy, Aneurysm and Muscle Cramps (HANAC)
 - a. Mutations in COL4A1 gene
11. Swedish Hereditary Multi Infarct Dementia (SHMID)
 - a. Hypertension
 - b. Diabetes
 - c. Dyslipidemia

Sporadic and Hereditary Cerebral Amyloid Angiopathies (CAA)

Overview

1. Amyloid fibrils deposit primarily in the walls of arteries and arterioles

2. Veins and capillaries are affected less frequently
 - a. Amyloid- β peptide is the most common amyloid subunit deposited in both sporadic and hereditary CAA
 - b. Other proteins deposited in familial forms of CAA include:
 - i. A Bri and A Dan in British and Danish dementia (BR1₂ gene related dementia)
 - ii. Variant cystatin C (hereditary cerebral hemorrhage with amyloidosis-Icelandic type)
 - iii. Variant transthyretin (meningovascular amyloidosis)
 - iv. Prion associated amyloidosis (premature stop codon mutation)
 - v. Gelsolin mutation (A Gel) in familial amyloidosis Finnish type
2. Perivascular inflammatory response
 - a. Activates microglia and astrocytes cause:
 - i. Seizures, focal neurologic deficits, headaches
3. Cerebral infarction, lobar hemorrhages and diffuse white matter changes occur irrespective of the type of vascular amyloid deposited
4. Cerebral amyloid angiopathy (CAA) is:
 - a. Defined by the deposition of amyloid proteins in the walls of cerebral vessels
 - b. Overproduction or abnormal degradation of circulating precursor proteins is causative
 - c. Tissue or organ affinity is present for each type of amyloid
 - i. Amyloid- β (A β) and cystatin C are most commonly associated with CAA
 - ii. Amyloid A β
 1. 40–43 amino acid proteolytic product of amyloid- β precursor protein (APP)
 2. Several isoforms (derived from alternate splicing); the gene is located on chromosome 21; most prominent in neuronal tissue
 - a. A β deposits are found:
 - i. In the walls of cerebral vessels in patients with sporadic CAA
 - ii. Dutch type hereditary ICH (HCHWA-D)
 - iii. Alzheimer's disease
 - iv. Down syndrome
 - v. Cystatin C colocalizes with:
 1. A β in vessel walls of AD
 2. HCHWA-D
 3. Sporadic CAA
 4. Not in senile plaques

Amyloid Formation

1. Aggregation and polymerization of soluble circulating proteins:
 - a. Conformational change from coiled protein to toxic β sheet configuration
2. Increase of protein conformers to a critical level
3. Protofibrillar intermediate state
4. Formation of amyloid fibrils

Precondition of Amyloid Formation

1. Proteolytic processing of a larger precursor protein:
 - a. β and γ -secretases act on the amyloid precursor protein (APP) in Alzheimer's disease to produce amyloid- β (A β peptide)
 - b. Mutated BRI₃ precursor protein
 - i. Processed by furin enzyme
 - ii. Releases A Bri or A Dan amyloid proteins in familial British and Danish familial dementia

Mechanisms That Destabilize the Secondary Structure of Soluble Native Proteins

1. Genetic and posttranslational modifications that include:
 - a. Missense mutation in gene coding region
 - b. Consequent amino acid substitution in the protein changes the rate of conversion of soluble native protein to a fibrillary conformer
2. Increased concentration of the soluble protein:
 - a. Trisomy of Down's syndrome
 - b. Duplication of the APP gene of early onset AD
3. Amyloid-associated proteins:
 - a. Pathological chaperones
 - b. Binding may facilitate misfolding of the soluble protein

Cerebrovascular Amyloid Deposition

1. A staged process:
 - a. A β first deposited in the tunica media
 - b. Intimal layers are affected
 - c. Amyloid replaces smooth muscle cells
 - d. Degenerative changes in the vessel wall

Sporadic A β CAA

General Characteristics

1. A β CAA is primarily sporadic and found in:
 - a. Normal elderly patients
 - b. Alzheimer's disease and Down syndrome
 - c. Long-standing repeated head injury (dementia pugilistica)
 - d. Post anoxic encephalopathy
2. Annual incidence of lobar hemorrhage in patients greater than 70 years old is 30–40/100,000 persons of which 30% are caused by A β CAA
 - a. Women greater than 80 years have a higher incidence than men and this increases with age
 - b. Alzheimer's Dementia patients (autopsy series) with A β CAA (25%–100%)

Genetics

1. 2/3 of patients demonstrate:
 - a. ApoE ϵ 2/cystatin C has been implicated
 - b. Polymorphisms associated with sporadic CAA or CAA-related ICH include:
 - i. Presenilin-1 (PS1)
 - ii. ApoE
 - iii. α 1-antichymotrypsin (ACT)
 - iv. Neprilysin (NEP)
 - v. Transforming growth factor β 1 (TGF- β 1)

Clinical Manifestations

1. Most sporadic CAA is asymptomatic
2. Cerebral microbleeds associated with lobar hemorrhages:
 - a. Temporal and occipital lobes are affected to a greater degree than the frontal lobe in location; rarely are there cerebellar or pontine bleeds
 - b. May have TIA features with focal deficits prior to the bleed
 - c. Headache, seizures and recurrent bleeds occur
 - d. Cerebral and subarachnoid siderosis are seen:
 - i. Linear streaks in the cortex
 - ii. Adjacent to lobar hemorrhage
3. Cerebral ischemia
 - a. Small cortical infarcts that are silent or associated with focal deficits
4. Dementia
 - a. Associated with infarcts, hemorrhages and generalized leukoencephalopathy
 - b. Concomitant Alzheimer's disease and stroke
 - c. Rapid onset of dementia may be caused by association with angiitis (inflammation)
5. Reversible acute leukoencephalopathy:
 - a. Rapid progression of signs and symptoms followed by rapid clinical and radiologic recovery
 - b. Suggested by MRI; signs of white matter edema and microbleeds (cortical predominant)

Pathology

1. A β CAA involves small and medium-sized arteries and veins in the cortex, leptomeninges and capillaries
 - a. Deposits are in the external layers of the vessels
 - b. Eosinophilia and thickening of vessel walls occurs
 - c. Loss of smooth muscle cells
 - d. Diminution or occlusion of the vascular lumen
 - e. Cystatin may co-localize
 - f. Hippocampal vessels are rarely involved and the spinal cord vessels are spared
2. 2/3 of patients demonstrate:
 - a. Fibrinoid necrosis
 - b. Microaneurysms
 - c. Fibrinoid necrosis, the degree of amyloid deposition and the involvement of white matter vessels are associated with ICH

- d. Vasculitis (chronic inflammation) is seen in some patients which causes loss and de-differentiation of smooth muscle cells
- e. Associated pathologies include:
 - i. Senile plaques, neurofibrillary tangles and dystrophic neurons
- f. Leukoencephalopathy:
 - i. Isolated or associated with ICH
 - ii. Associated with A β 40
 - iii. Associated with lacunar infarction and WMH

Neuroimaging**MRI**

1. MRI in 2/3 of patients demonstrate:
 - a. MRI (gradient-echo or susceptibility weighted images) to detect paramagnetic hemosiderin deposits in macrophages (microhemorrhages)
 - i. Cortical lobar location; deep microhemorrhages are associated with hypertension
 - ii. One or more previous ICHs
 - iii. Temporal and occipital lobe predominance
 - iv. Hemorrhage cluster
 - v. Fibrillary A β is the only amyloid that induces MRI T2 changes

Dutch Variant of Hereditary Cerebral Hemorrhage with Amyloidosis**General Characteristics**

1. Autosomal Dominant
2. Mutation at codon 693 of APP gene that replaces the glutamate (E) by a glutamine (Q); E22Q

Clinical Features

1. An aggressive clinical phenotype
2. Recurrent stroke
3. Valvular dementia in the absence of neurofibrillary plaques
4. Cerebral hemorrhage
5. Dementia may develop in the absence of ICH

Pathology

1. Massive amyloid deposition in leptomeningeal and cortical vessels
2. Parenchymal mature plaques are rare but diffuse preamyloid deposits are common – particularly in young patients
3. High ratio of A β 40 to A β 42

Neuroimaging

1. Cortical microbleeds
2. Cortical ICH
3. Increased superficial siderosis
4. Large centrum semiovale perivascular spaces

Flemish Variant**General Characteristics**

1. Described in one family
2. Mutation is in the APP gene at codon 692; A692G

Clinical Manifestations

1. Early onset Alzheimer's disease
2. Intracranial hemorrhage at young age (approximately 40 years) in the cortex

Pathology

1. A β CAA identified in one autopsied patient; diffuse A β deposits were noted but no neurofibrillary tangles and few senile plaques were seen

Neuroimaging

1. Cortical microhemorrhages
2. Ischemic leukoencephalopathy

Familial CAA with APP Mutations*General Characteristics*

1. Variations in the same gene can occur:
 - a. Rare familial forms
 - b. Common sporadic forms of the same disease
2. There is a rare autosomal dominant pattern
3. Most affected families have:
 - i. β amyloid peptide (A β) coding region mutations in the gene for APP
 - ii. Duplications of chromosomal segments containing APP
4. Familial mutations are generally more severe phenotypically and may have an earlier onset
 - i. Common variants often are less severe phenotypically than rare variants
5. Variants of the APP mutations within the A β sequence include:
 - a. "Italian" variant
 - i. E693K
 - b. "Arctic" variant
 - i. E693G
 - c. "Japanese" variant
 - i. E693 Δ
 - d. "Iowa" variant
 - i. D694N
 - e. L705V mutations

Clinical Manifestations

1. Mixed AD/severe CAA phenotype
2. Pure CAA/cerebral hemorrhage phenotype

Pathology

1. The pathology of these mutations is similar to either Dutch or Flemish APP pathology
 - a. Pure CAA/cerebral hemorrhage phenotype or
 - b. Mixed Alzheimer's disease – CAA/cerebral phenotype
2. Italian APP and APP L705V mutations with predominant CAA phenotype with or without recurrent cerebral hemorrhages
 - a. Also similar to Dutch APP mutations

- i. No neurofibrillary tangles in APP L705V carriers or they were minimal and restricted to the archicortex
3. The Arctic and Iowa variant genotypes are similar to the Flemish APP genotype with a mixed AD/severe CAA phenotype without hemorrhagic strokes. The Arctic genotype also demonstrates parenchymal, ring-like plaques
4. Intragenic A β mutations near the β -secretase and γ -secretase sites of APP, such as APP A713T, cause multiple strokes and progressive dementia. The pathology is consistent with severe Alzheimer's disease, CAA and brain infarcts
5. The APP A673V mutations near the β -secretase site of APP are associated with autosomal recessive inheritance and dementia of the Alzheimer's site

Neuroimaging

1. Leukoaraiosis
2. Cortical microhemorrhages
3. Perivascular space enlargement of the cortex and centrum semiovale
4. Cerebral siderosis

Genes with Familial Early Onset Alzheimer's Disease and CAA*General Characteristics*

1. Presenilin-1 on chromosome 14
2. Presenilin 2 on chromosome 1
3. Duplication of APP locus on chromosome 21
4. Volga German families have PSN gene 2 mutation
5. Finnish family (4 generations):
 - a. No gene determined
 - b. ICH and dementia are the clinical expression

Clinical Features

1. Progressive dementia associated with A β vascular deposition (primarily A β (1-40))

Pathology

1. Increase in the extracellular concentration of A β peptides
2. Ratio of A β (1-42) is increased relative to A β (1-40)
3. A β (1-42) is the principal component of amyloid deposits. It has rapid nucleation and aggregation kinetics

Neuroimaging

1. Leukoaraiosis
2. Cerebral microhemorrhages
3. Enlarged perivascular spaces
4. Voxel based tensor imaging reveals diffusion alterations in gray and white matter areas
5. Earliest clinical stages (memory deficit):
 - a. Deficits in the mesial temporal lobe anterior thalamus and mammillary bodies as well as the posterior cingulate gyrus

Hereditary Cystatin C CAA (Icelandic Type; HCHWA-I)*General Characteristics*

1. AD; chromosome 20
 - a. Glutamine for leucine amino acid substitution at codon 68 of the cystatin C gene
 - b. Cystatin C protein is a type II family cysteine protease inhibitor
 - i. Produced by neurons and other cell types

Clinical Manifestations

1. Early onset of cerebral hemorrhage (20 to 30 years of age) at the corticomedullary junction
2. Condition may stabilize: death before 50
3. Infarcts are rare; vascular dementia occurs

Pathology

1. Cystatin C protein is deposited as vascular amyloid in the leptomeninges, cerebral cortex, basal ganglia, brainstem and cerebellum
2. The deposited protein is an N-terminal degradation product of the mutated cystatin C protein
3. Characteristic feature of HCHWA-I is that in addition to CAA:
 - a. Amyloid deposits are seen in lymphoid organs, skin, salivary glands and testes
4. Extensive ICH that occur at varying time periods and amyloid deposition in leptomeningeal and cerebral vessels
5. Involvement of distal microvasculature including capillaries
6. Demyelination is noted; no Alzheimer's disease pathology

Neuroimaging

1. Recurrent lobar cerebral hemorrhage
2. Rare infarcts
3. Leukoaraiosis

Gelsolin Mutation (A Gel) Amyloidosis (Finnish Type)*General Characteristics*

1. Autosomal Dominant; mutations of the gelsolin gene on chromosome 9q32-34
2. G654A and G654T mutations; the G654A is characteristic of the Finnish population
3. Gelsolin is an actin-binding protein
4. A protein subunit isolated from amyloid fibrils

Clinical Features

1. Dementia
2. Mood disorders
3. Dermatologic (sagging facial skin; cutis laxa)
4. Ophthalmologic (lattice corneal dystrophy)

Pathology

1. Gelsolin deposited:

- a. Gray and white matter vessels of the brain and spinal cord
- b. Basement membranes
- c. Amyloid angiopathy in systemic organs
- d. CNS

Neuroimaging

1. Leukoaraiosis
2. Cortical microhemorrhage
3. Small vessel infarction

CAA Due to Deposition of Variant Transthyretin (TTR)*General Characteristics*

1. Familial amyloid polyneuropathy due to:
2. Multiple mutations of the TTR gene located on chromosome 18; AD
3. Amyloid subunit is composed of 60 known variants of the protein transthyretin
4. Involved in the transport of retinol and thyroid hormone
5. Endemic foci in Japan and Portugal

Clinical Manifestations

1. Hemiplegic migraines
2. Dementia
3. Seizure
4. Stroke
5. Visual loss
6. Familial sensorimotor polyneuropathy with or without ANS involvement
7. Vitreous, meningeal and leptomeningeal involvement in some variants
8. CAA

Pathology

1. Amyloid fibrils may be composed of full length TTR concomitantly with C and N terminal degradation fragments
2. TTR fragment derived from the retinal epithelium or choroid plexus
3. Some variants have vitreous, leptomeningeal and meningeal deposition of amyloid transthyretin

Neuroimaging

1. Leukoaraiosis
2. Small vessel stroke
3. Microhemorrhage

CAA in Human Prion Disease*General Characteristics*

1. Prion protein gene is located on chromosome 20
 - a. Disease associated prions recruit normal cellular prion protein and facilitate its conversion to disease associated prion protein isoform (PrP^{Sc})
 - i. Protease resistant protein causes polymerization and amyloid fibril formation

- ii. In general, PrP^{Sc}-CAA is not a feature of prion diseases that include:
 1. Creutzfeldt-Jakob disease (CJD)
 2. Gerstmann-Sträussler-Scheinker syndrome
 3. Fatal familial insomnia
 4. Kuru
 5. Variant CJD
- iii. Rare hereditary disease forms:
- iv. Premature stop codon mutation of PRPN gene (T to G mutation at codon 145) causes:
 1. Extensive PrP-positive CAA with perivascular PrP deposition
 2. Neurofibrillary tangles
- v. Cerebrovascular amyloid deposition
- 3. Neurofibrillary tangle pathology
- 4. Ability to form ion-channel-like structures in cell membranes may be related to its neurotoxicity
- 5. CAA is extensive and involves blood vessels of the leptomeninges, cerebral cortex, white matter, deep gray nuclei, brainstem, cerebellum and spinal cord
- 6. There is astrocytic, microglial and complement activation in both the classical and alternate pathways in amyloid lesions
- 7. Vascular systemic deposits of ABri are found in peripheral tissues

Neuroimaging

1. White matter ischemic change secondary to CAA is widespread

Clinical Manifestations

1. One patient manifested dementia but possibly symptomatology was due to underlying prion disease

Pathology

1. In a pedigree in which there is a T to G mutation at codon 145 which causes an early stop codon (Y145STOP)
 - a. Extensive PrP-positive CAA with parenchymal perivascular PrP deposition noted along with neurofibrillary tangles
 - b. There is frequent co-deposition of PrP^C in A β amyloid plaques in Alzheimer's disease

Hereditary CAAs in Familial British Dementia (BR12 Gene)

General Characteristics

1. FBD (Familial British Dementia)
 - a. Mutation of the BR12 gene located on chromosome 13; autosomal dominant
 - b. Encodes:
 - i. Type II transmembrane protein that undergoes furin-like proteolysis that releases 23-aa C-terminal peptide
 - ii. Interacts with APP and modifies its processing
 - iii. Possible tumor suppressor and has proapoptotic properties
 - iv. Mutation (T to A) of the normal stop codon of the BR12 gene underlies FBD

Clinical Manifestations

1. Clinical onset in the fifth decade; course approximately 10 years
2. Associated with progressive dementia, spasticity and ataxia
3. Rare: clear clinical stroke

Pathology

1. Parenchymal ABri amyloid and parenchymal plaques
2. Widespread ABri-CAA

Danish Familial Dementia (FDD)

General Characteristics

1. 10-nt duplication insertion mutation between codons 255–256 is causative
2. 34aa long C-terminal peptide cleaved from the mutated precursor protein form amyloid fibrils; toxicity may also occur from production of ion-channel structures in cell membranes
3. Mutation in the BRI2/ITM2B gene
 - a. Loss of Br12 protein
 - b. Inhibits processing of A β PP

Clinical Manifestations

1. Cataracts
2. Deafness
3. Ataxia
4. Dementia

Pathology

1. Anatomical distribution of A Dan deposition is similar to FBD
2. Parenchymal lesions are granular, sparsely fibrillary protein deposits
3. CAA is extensive in blood vessels of the leptomeninges, cerebral cortex, basal ganglia, brainstem and cerebellum
4. Vascular involvement occurs in other organs

Neuroimaging

1. Generalized widespread vascular changes in the white matter similar to ABR12

Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CADASIL)

General Characteristics

Genetics

1. Mutation of the NOTCH 3 gene; chromosome 19
2. Expressed only in arterial smooth muscle cells

3. Mutations are in exon 3 and 4 (70%) which encodes a transmembrane receptor with epidermal growth factor repeats
4. Regulates differentiation and maturation of vascular smooth muscle cells

Clinical Features

1. Migraine with aura starting between 20 to 40 years of age may be the initial presentation
2. Cerebral ischemic events supervene between 4th and 5th decade associated with behavioral changes and cognitive dysfunction
3. Dementia is apparent between age 50 to 60
4. Approximately 50% of patients suffer atypical migraine auras that include basilar hemiplegia or long duration. A few suffer coma
5. 60 to 85% of patients suffer TIAs or strokes. 2/3 of ischemic events are classic lacunar strokes. TIAs and strokes may occur in the absence of classical risk factors
6. 5 to 10% of patients have seizures that may be focal or generalized
7. Apathy is common while aphasia, apraxia or agnosia is rare
8. Dementia is associated with corticospinal tract signs, gait disturbance and urinary incontinence. Pseudobulbar palsy is demonstrated in approximately 50% of patients

Pathology

1. Diffuse hemispheric demyelination with sparing of U-fibers and periventricular and centrum semiovale predominance
2. Lacunar infarction is noted in the thalamus and basal ganglia
3. Deep infarcts and dilated Virchow-Robin spaces are frequent
4. Walls of cerebral and leptomeningeal arterioles are thickened
5. Granular material within the media (glycoproteins) while the endothelium is spared
6. Smooth muscle cells are swollen and degenerated
7. Dense granular osmophilic deposits are seen in the media close to the cell membranes of smooth muscle cells
8. The dense granular osmophilic deposits are seen in the media of arteries in internal organs (spleen, liver, and kidney) as well as skin and muscle

Neuroimaging

1. MRI reveals widespread T2-weighted signal in white matter with focal hyperintensities in the basal ganglia, thalamus and brainstem
2. Younger patients have a periventricular predominance
3. External capsule and anterior temporal lobe lesions are distinctive
4. Corpus callosal lesions occur. Pontine lesions predominate in the brainstem

5. Lacunar lesions and enlarged Virchow-Robin spaces are prominent
6. Gradient-echo sequences detect microhemorrhages in 30 to 50% of patients

Cerebral Autosomal Recessive Angiopathy with Subcortical Infarction and Leukoencephalopathy (CARASIL)

General Characteristics

1. More prominent in Asian and Japanese populations
2. Mutations of the HTRA1 gene
 - a. A serine peptidase/protease

Clinical Features

1. Ischemic stroke (ictal events) or stepwise neurologic deterioration
2. Premature baldness and spondylosis and disc disease

Pathology

1. Vascular fibrosis and overgrowth of the extracellular matrix
2. Intense arteriosclerosis of small penetrating arteries (without granular osmophilic material or amyloid as is seen in CADASIL)
3. Intimal thickening
4. Dense collagen fibers
5. Loss of vascular smooth muscle
6. Hyaline degeneration of the media
7. Putative mechanism
 - a. Failure to repress TGF-beta signaling
 - b. Increased TGF-beta found in cerebral small vessels along with fibronectin and versalan

Neuroimaging

MRI

1. Multiple lacunar infarctions of the basal ganglia and thalamus
2. Diffuse white matter leukoencephalopathy

Retinal Vasculopathy with Cerebral Leukodystrophy (RVCL)

Overview

The RVCL spectrum presents primarily as small vessel disease. Three variants that have been mapped to chromosome 3p21 are: Hereditary Retinal Vasculopathy (HRV), Cerebroretinal Vasculopathy (CRV) and Hereditary Endotheliopathy, Retinopathy and Nephropathy (HERNS).

An infantile syndrome that is similar but does not map to 3p21 is: Hereditary Infantile Hemiparesis with Arteriolar Retinopathy and Leukoencephalopathy (HIHARL).

Cerebroretinal Vasculopathy (CRV), HERNS and Hereditary Retinal Vasculopathy (HRV)

General Characteristics

1. Genetics
 - a. All three diseases are linked to a locus on chromosome 3p21
 - b. Autosomal Dominant
2. Causative gene mutations of TREX 1
 - a. Encodes a 3'-5' DNA repair exonuclease
 - b. Frame shift mutation
3. Other diseases with TREX-1 mutations that have clinical similarity but distinct clinical features:
 - a. Aicardi-Goutières syndrome (AGS)
 - b. Familial Chilblain Lupus (FCL)
 - c. Systemic Lupus Erythematosus (SLE)
4. The truncated protein from the mutation retains exonuclease activity but loses perinuclear localization
5. Hereditary systemic angiopathy (HSA) has recently been described and is also suggested to be on the retinal vasculopathy with cerebral leukodystrophy spectrum

Clinical Manifestations

1. Middle age at onset (4th–5th decade)
2. Predominant CNS involvement
3. TIA, stroke, focal motor and sensory deficits
4. Depression
5. Headaches
6. Cognitive dysfunctions
7. Decreased renal function
8. G.I. bleeding
9. Increased alkaline phosphatase
10. Migraine
11. Raynaud's Phenomena
12. 100% mortality in 5–10 years due to neurologic deficits

Neuropathology

1. Coagulative necrosis secondary to obliterative vasculopathy
2. Minimal inflammatory infiltrate
3. Fronto-parietal cortex motor involvement; lesions also occurs in the basal ganglia, cerebellum and pons
4. One third of patients have hepatic and renal involvement
5. Thickening and reduplication of the retinal capillary basal lamina

Neuroimaging

1. Retinal fluorescein angiography:
 - a. Capillary drop-out (macular region; decreased central vision)
 - b. Prominent juxtafoveolar capillary obliteration and telangiectasia
2. Lesions are most prominent in the fronto-parietal lobes
 - a. Lesions enhance

Differential Diagnosis of RVCL

1. Variants of RVCL with linkage to 3p21 (3p21 mutations)
 - a. CRV (Cerebral Retinal Vasculopathy)
 - b. HVR (Hereditary Vascular Retinopathy)
 - c. HERNS (Hereditary Endotheliopathy Retinopathy with Nephropathy)
 - i. Brain, kidney, GI tract and skin are involved
 - ii. Pathology (by electron microscopy) reveals multilaminated vascular basement membrane
 - d. HIHARL (Hereditary Infantile Hemiparesis with Arteriolar Retinopathy and Leukoencephalopathy)

HIHARL (Hereditary Infantile Hemiparesis with Arteriolar Retinopathy and Leukoencephalopathy)

General Characteristics

1. Not linked to 3p21

Clinical Manifestations

1. Migraine with aura
2. Hemiparesis
3. Retinal hemorrhage and tortuosity

Pathology

1. Vascular endothelial dysfunction
2. Possible increased susceptibility to decreased cerebral blood flow from cortical spreading depression

Neuroimaging

1. Cortical microbleeds
2. Dilatation of perivascular spaces

Collagen 4A1 and A2 Mutations

General Characteristics

1. Type IV collagen is pivotal for the structural integrity and function of the basement membrane:
 - a. Which surrounds vascular smooth muscle cells in the media
 - b. COL4A1 is the most abundant form of type IV collagen
 - c. COL4A2 (collagen IV alpha 2 chain) forms heterotrimers with COL4A1; an obligatory protein partner of COL4A1
 - d. Gene is localized on chromosome 13q

Clinical Manifestations

1. COL4A1 mutations:
 - a. Ocular, renal, muscular defects in addition to CNS vasculopathy
 - b. Ocular abnormalities:
 - i. Cataracts (congenital or juvenile onset)
 - ii. Retinal arteriolar tortuosity and hemorrhages
 - iii. Juvenile onset glaucoma
 - iv. Axenfeld-Rieger syndrome
 1. FOXC1 (eye) and PITX2 (eye and systemic) genes are mutated

2. Anterior segment dysgenesis with glaucoma
3. Optic nerve dysgenesis
4. Renal cysts and renal agenesis

Neurologic Manifestations

1. Sporadic and recurrent intracranial hemorrhages
2. Porencephaly from germinal matrix hemorrhages (COL4A2 > COL4A1)
3. Infantile hemiplegia

Pathology

1. Focal interruptions or expanded and thickened fragmented basal membranes of capillaries

Neuroimaging

MRI

1. Diffuse or periventricular leukoencephalopathy and calcifications
2. Lacunar infarctions both supra and infratentorial areas

Hereditary Angiopathy with Nephropathy, Aneurysms and Muscle Cramps (HANAC)

General Characteristics

1. Mutation of COL4A1 gene; chromosome 13q
 - a. CB3 encodes the integrin binding site

Clinical Manifestations

1. Multiple and complex carotid siphon aneurysms
2. Renal cysts, cramps or elevated CPK; retinal arteriolar tortuosity
3. Cerebral hemorrhages
4. Lacunar infarction
5. Cerebrovascular lesions are often asymptomatic

Pathology

1. Skin biopsy
 - a. Alterations of the basement membrane at the dermoepidermal junction
 - b. Expansion of extracellular matrix between smooth vascular cells in the arteriolar wall
 - c. Multi-lamination, thickening of basement membranes
2. White matter changes affecting subcortical, periventricular and pontine regions

Neuroimaging

MRI

1. Leukoaraiosis
2. Subcortical microbleeds
3. Lacunar infarction
4. Dilated perivascular spaces
5. Highest lesion load in the frontal and parietal white matter

Pontine Autosomal Dominant Microangiopathy and Leukoencephalopathy (PADMAL)

General Characteristics

1. Large German kindred evaluated as the basis of the syndrome
2. Mutated gene not determined

Clinical Manifestations

1. Age at onset (15–77 years)
2. Pontine lacunar infarctions
3. Generalized cognitive decline
4. Gait disorder
 - a. Broad based; short swing phase; slow velocity

Pathology

1. Sclerotic index demonstrates:
 - a. Subcortical white matter affected to a greater degree than gray matter
 - b. Glucose transporter (GLUT-1) protein immunoreactivity (indicates capillary degeneration in white matter) is affected
 - c. Frontal lobe is most the severely affected
 - d. Density of COL IV immunoreactivity is increased

Neuroimaging

MRI

1. Pontine lacunar infarcts
2. Subcortical and periventricular leukoencephalopathy
3. Temporal lobe involvement in 16% of patients
4. Cerebral microbleeds in 16% of patients

MRA

1. No atherosclerotic changes

Swedish Hereditary Multi-Infarct Dementia (SHMID)

General Characteristics

1. Gene has not been characterized

Clinical Manifestations

1. Recurrent lacunar infarction
2. Cognitive deficits
3. Gait disorder

Pathology

1. Sclerotic index not as severe as CADASIL, HERNs or PADMAL
 - a. No osmophilic material in skin biopsy or autopsy material

Neuroimaging

MRI

1. Lacks the hyperintense signals detected in the anterior temporal pole and external capsule as noted in CADASIL

Hereditary Vascular Leukoencephalopathy Mapping to Chromosome 20q13

General Characteristics

1. Two sisters and 21 relatives underwent clinical and genetic testing; pathological data was examined from one patient
2. Mutation was mapped to chromosome 20q13

Clinical Manifestations

1. Five of 14 patients were symptomatic; 9 of 14 demonstrated white matter lesions but were asymptomatic (ages 26–60 years)
2. Gait disturbance
3. Stroke
4. Cognitive decline
5. Transient movement disorder
6. Progressive and age related natural history

Pathology

1. Cerebral arteriopathy affecting small pre terminal arterioles
2. Pathology is more prominent in the hemispheres than the brainstem

Neuroimaging

MRI

1. Symmetric white matter hyperintensities of the hemispheres and brain stem

Summary of Monogenetic Causes of Small Vessel Disease

1. CADASIL
2. CARASIL
3. CAA
 - a. Dutch
 - b. Icelandic
 - c. Kindred founder mutations
 - d. Other mutations
4. Retinal vasculopathy with cerebral vasculopathy (RVCL)
 - a. Hereditary retinal vasculopathy (HRV)
 - b. Hereditary endotheliopathy, retinopathy and nephropathy (HERNS)
 - c. Cerebroretinal vasculopathy (CRV)
 - d. Hereditary infantile hemiparesis with arteriolar retinopathy and leukoencephalopathy (HIHARL)
5. COL4A1/COL4A2 mutations
 - a. Hereditary angiopathy with nephropathy aneurysm and muscle cramps (HANAC)
 - b. Hereditary porencephaly from germinial matrix hemorrhage (COLA2 mutation)
6. Swedish hereditary multi infarct dementia (SHMID)
7. Hereditary Vascular Leukoencephalopathy mapping to chromosome 20q13

Fabry's Disease

General Characteristics

1. X-linked disorder of glycosphingolipid metabolism:
 - a. Enzyme deficiency of a lysosomal alpha-galactosidase A that leads to:
 - i. An accumulation of neutral glycosphingolipids – predominantly globotriaosylceramide in the lysosomes of endothelial and smooth muscle cells in blood vessels
 - ii. Common polymorphisms of angiotensinogen (AGT), AGT promoter and angiotensinogen II receptor type I (AGTRI)
 1. AGT promoter and AGTRI genotypes are noted in Fabry's phenotypes in .6% of high risk populations
2. Prevalence 1:40,000 males
3. Heterozygotes present with no symptoms or a milder disease
4. Heterozygous females:
 - a. Asymptomatic or a milder disease phenotype
 - b. Occasionally they are as symptomatic as males
5. Cerebrovascular manifestations are common in both hemizygote and symptomatic heterozygote groups
 - a. 4% of cryptogenic strokes may have mutations in the α -galactosidase A gene

Clinical Manifestations

1. Early in the disease course:
 - a. Episodic crises of severe neuropathic pain
 - i. Precipitated by exercise, fever or increased ambient temperature
 - ii. Minute to hour duration
 - iii. Primarily acroparesthesias
 - b. Heat intolerance
 - i. Autonomic dysfunction with anhidrosis (infiltration of ceramide trihexoside in the autonomic ganglia and similar infiltration of 1 μ autonomic fibers to sweat glands)
2. Heterozygous males
 - a. Angiokeratomas (cherry red papules) are seen in the periumbilical area, extensor surfaces of elbows, knees and genitals (bathing suit distributions)
 - b. Corneal and lenticular opacities
 - c. Dilatation and tortuosity of conjunctival vessels
 - d. Retinal vessel abnormalities
 - e. Hypohidrosis (with heat intolerance)
 - f. Cardiac dysfunction
 - g. Renal failure
3. Heterozygote females
 - a. Lumbosacral degeneration
 - b. Some patients are asymptomatic
 - c. Some signs/symptoms similar to male patients

Cerebrovascular Disease

1. Male hemizygotes
 - a. Ischemic strokes in the fourth decade

- b. Anterior and posterior circulation involvement; posterior circulation more frequently involved than anterior
- c. Small vessel disease
- d. Cause of vascular dementia for patients less than 65 years old
2. Heterozygote women
 - a. Cerebrovascular symptoms a decade later than males
 - b. 50% involvement in vertebrobasilar system; 10% carotid involvement
 - c. Headaches are seen more commonly in females than males
 - d. Central retinal vein occlusion
3. Greater involvement of posterior circulation whose putative mechanisms are:
 - a. Vertebrobasilar dolichoectasia
 - b. Thickening and luminal compromise of medium and small arteries
 - c. Deep small cerebral infarcts
4. Cardiogenic embolism
 - a. Coronary artery disease (left ventricular wall dysfunction)
 - b. Valvular heart disease (mitral valve)
 - c. Mitral valve prolapse
 - d. Hypertrophic cardiomyopathy (especially in heterozygote women)
 - i. Often associated with atrial fibrillation
 - ii. Occurrence in women greater than men
5. Carotid artery atherosclerotic plaque
 - a. Less than controls
 - b. Greater intima to media thickness
6. Orthostatic hypotension due to autonomic nervous system dysfunction
7. Prothrombotic state:
 - a. Activation of platelets by endothelial dysfunction due to deposition of glycosphingolipids
8. Endothelial cell dysfunction with increased:
 - a. Soluble intercellular adhesion factors-1
 - b. Vascular cell adhesion molecule-1
 - c. P-selection
 - d. Plasminogen activator inhibitor
 - e. Integrin CD11b
 - f. Decreased thrombomodulin
9. Approximately 35% of patients have a factor V Leiden mutation
10. Intrinsic vascular abnormalities:
 - a. Down-regulation of nitric oxide pathway
 - b. Increased oxidative stress which leads to:
 - i. Accelerated atherosclerosis
 - ii. Vasodilatation
11. Intracranial arterial dolichoectasia causes:
 - a. Neurovascular compression syndromes
 - b. Triventricular hydrocephalus
 - c. Isolated III, V, VIII, XIIth nerve palsy by compression from the basilar or vertebral arteries
 - d. Cranial Nerve II compression from dolichoectatic supraclinoid carotid arteries

Pathology

1. Infarcts of:
 - a. Superficial hemispheric pial arteries
 - b. Small deep perforating vessels
 - c. Brainstem and cerebellum
2. Rare intracerebral hemorrhage
3. Narrowing of lumen secondary to glycosphingolipid deposits in lysosomes of both endothelial cells and smooth muscle of the arterial wall
4. Putative mechanism:
 - a. Deposition of glycosphingolipids in the lysosomes of smooth muscle of arterial walls
 - b. Possible cause of ICH (loss of structural integrity of vessel walls)
 1. Hypertension from concurrent vessel disease
 2. Both hemi and heterozygotes

Neuroimaging

MRI

1. Superficial territorial and deep perforating artery infarction of the hemispheric brainstem and cerebellar circulations
2. Dolichoectasia of the basilar and vertebral arteries
3. Small vessel disease pattern in patients older than 54 years
4. Approximately one third of younger patients may have no lesions

MRS (Magnetic Resonance Spectroscopy)

1. NAA/creatine and phosphocreatine were decreased
 - a. Suggestive of neuronal loss

Clinical Differential Diagnosis of Monogenic Small Vessel Disease

CADASIL

1. Severe and clearly genetic (AD)
2. Migraine headaches, behavioral disorders and cognitive deficits prominent in addition to stroke
3. MRI: extensive leukoencephalopathy: extreme capsule and anterior temporal pole are involved

CARASIL

1. Autosomal recessive
2. Early alopecia, disc disease and prominent lumbar spondylosis
3. More prominent in Asian populations (Japanese)
4. Lacunar infarctions prominent in basal ganglia and thalamus

Fabry's Disease

1. Severe acroparesthesias and neuropathy
2. Bleeding following minor surgical procedures
3. Heat intolerance (decreased sweating)
4. Kidney and heart involvement
5. MRI: pulvinar lesions as well as stroke
6. Characteristic angiomas in the genital areas

Congophilic Angiopathy (CAA)

1. Genetic and sporadic forms
2. Lobar hemorrhages that are superficial and may be multiple
3. Cerebral microbleeds are prominent in the cortex
4. Severe leukoencephalopathy with cortical microbleeds
5. May have TIA presentation

Retinal Vasculopathy with Cerebral Leukoencephalopathy

1. All variants have severe retinal arterial tortuosity and some with concomitant retinal artery obliteration and central visual loss
2. Secondary glaucoma (following hemorrhage)
3. Kidney as well as cerebral and ocular vessel involvement

COL4A1/A2 Mutations

1. Porencephalopathy (familial) is most suggestive of COL4A2
2. Migraine and Raynaud's phenomenon
3. Gastrointestinal bleeding
4. HANAC – almost pathognomonic carotid siphon aneurysms, muscle cramps
5. Severe ocular deficits including anterior segment defects and juvenile cataracts

PADMAL

1. Pontine lacunar infarctions with generalized cognitive decline
2. No atherosclerotic blood vessel changes

Summary of Pathologic Involvement in Monogenetic Small Vessel Disease by the Sclerotic Index

1. The sclerotic index measures:
 - a. Density of collagen IV immunoreactivity (basement membranes of blood vessels)
 - b. The number of perivascular macrophages
 - c. Glucose transporter-1 (GLUT-1) protein immunoreactivity (indicates capillary degeneration); white matter affected more than gray matter
2. Cortical Sclerotic Index of Severity of Small Vessel disease
 - a. CADASIL > HERNs > PADMAL > Swedish hMID > sporadic SVD
3. Basal Ganglia Sclerotic Index:
 - a. CADASIL > HERNs > Swedish hMID > PADMAL > sporadic SVD

General Characteristics and Definitions for Small Vessel Disease

1. Small Vessel disease cause:
 - a. Lacunar infarcts
 - b. White matter hyperintensities (WMH)
 - c. Microinfarction (smaller than lacunes)
 - d. Dilatation of perivascular spaces
 - e. Microbleeds

2. Small Vessel disease often occurs in association with atherosclerosis and affects large and medium-sized arteries
 - a. By intimal proliferation and accumulation of lipids and cholesterol within the vessel wall
 - b. Plaques form at bifurcations of arteries and in areas of blood flow derived shear stress (stenosis of the lumen)
 - c. Plaques rupture occurs from:
 - i. Local thrombosis (primarily due to endothelial dysfunction)
 - ii. Emboli from both cholesterol plaque material and fibrin-platelet clots
3. Vessel wall changes of small artery arteriosclerosis occur in 200–800 μm sized blood vessels
 - a. Similar to atherosclerosis but the vessels do not calcify
4. Lipohyalinosis:
 - a. Occurs in arteries of 30–300 μm size
 - b. Asymmetric fibrosis and hyalinosis associated with foam cells and accumulation of blood derived lipids and proteins within the vessel wall
5. Arteriolosclerosis
 - a. Occurs in arterioles between 50–150 μm in diameter
 - b. A concentric hyaline thickening of the vessel wall with stenosis
6. White matter hyperintensities (most easily seen on MRI) and associated with sporadic and familial SVD:
 - a. Most common in the elderly and may be seen frequently in normal subjects
 - b. White matter changes are characterized by:
 - i. Demyelination axonal loss
 - ii. Astroglisis
 - iii. Often severe in the deep white matter
 - iv. Spares U-fibers
 - v. Associated with microglial activation
 - c. White matter lesion progression:
 - i. Growth of existing lesions
 - ii. WMH are surrounded by regions of milder injury ('penumbra')
 - iii. Gradual spatial spreading
 - iv. New lesions accrue in approximately 20% of patients in addition to growth of prior lesions
 - d. Study of CADASIL patients (pure SVD) reveals that:
 - i. Lacunes develop at the edge of white matter hyperintensities along the course of perforating vessels
7. Leukoaraiosis
 - a. Age related (as well as disease caused) white matter hyperintensities
 - i. Major risk factors are age and hypertension
 - b. Pathology:
 - i. Demyelination/axonal loss/gliosis/infarcts
 - ii. Fibrohyalinosis of small vessels (30–150 μm) in size
 - iii. Venous collagenosis
8. Microinfarcts
 - a. Smaller than lacunar infarcts (1 mm or less)

- b. In SVD occurs in the white matter
- c. In CAA they occur in the cortex
- d. Watershed microinfarcts:
 - i. Occur in hyper perfused areas between two vascular territories

Lacunar Stroke

Overview

Lacunes are small ovoid lesions 1–2 mm in size noted in deep nuclear gray matter of the basal ganglia and thalamus as well as the internal capsules, centrum semiovale and pons. They are found in the setting of poorly controlled diabetes and hypertension. They are caused by fibrinoid necrosis of the endothelium and adventitia of the single perforating arterioles. The infarct is limited to the territory of deep perforators and is caused by in situ infarction. The process may also be caused by atheromatous occlusion of the mouth of these blood vessels. If a series or a group of perforators are involved simultaneously emboli are suspected as causal (this most often occurs in the lenticulostriate territory).

Discrete clinical syndromes are noted with infarctions of these perforators which outline their territory and allow anatomic localization.

Involvement of arm, face, and leg suggests lacunar infarction of the middle 1/3 of the posterior limb of the internal capsule. Genu involvement is suggested by more face than arm involvement and severe dysarthria. The posterior 1/3 of the capsule may be selectively involved with hemisensory numbness. Occasionally, a single extremity may become weak from involvement of the medullary stria arteries that perfuse the centrum semiovale. The motor and sensory fibers are separated in the deep fibers of the centrum semiovale. The dysarthria clumsy hand syndrome occurs from posterior ventral 1/3 pontine infarction in which the corticobulbar fibers, speech and arm fibers are closely opposed. Ataxic hemiparesis suggests pontine lacunar involvement at the midpontine level.

Lacunar infarctions rarely ever are associated with headache, visual field cut or aphasia. Pure motor, pure sensory and mixed deficits are common. There are no cortical sensory or behavioral manifestations which differentiates these from pial artery strokes. Pure motor hemiparesis with a IIIrd nerve pattern (Weber, Benedict; Claude's and Nothnagel's) places the lesion in the midbrain. Rarely hemiballisms occurs from lacunar infarction of the subthalamic nucleus due to paramedian thalamic involvement. Lacunes of basilar artery territories are suggested by dizziness, diplopia, and intranuclear ophthalmoplegic without weakness.

Arterial Territories Involved with Lacunar Stroke

1. Involvement of the territory of one single perforating arteriole

2. <1.5 cm lesion on CT or MRI; (ovoid in shape)
3. Infarct is limited to the territory of the deep perforators
4. Caused by in situ small vessel disease
5. Infarcts limited to the territory of deep perforators may occur with:
 - a. Cardiac emboli
 - b. Ipsilateral internal carotid artery stenosis or occlusion
6. Diabetes is a major risk factor for lacunes
7. The most suggestive clinical syndrome for lacunar infarction:
 - a. Pure motor hemiparesis with face, arm and leg involvement
8. Arterial networks that supply subcortical territories:
 - a. Deep perforating branches form the ACA
 - i. Recurrent artery of Heubner (A2)
 - ii. Direct anterior lenticulostriate branches
 - b. Deep perforating branches from the anterior choroidal artery
 - c. Thalamic arteries from P1 and P2 segments
 - i. Interpeduncular (top of the basilar)
 - ii. Thalamoperforate
 - iii. Thalamogeniculate
 - iv. Posterior choroidal artery
 - v. Tuberothalamic artery (from the posterior communicating artery) These arteries are perforators, but have collateral branches and are not terminal branches
 - d. White matter medullary arteries
 - i. Originate from the superficial (pial) branches of the MCA > ACA > PCA
 - ii. 2–5 cm long
 - iii. Selective territories
 - iv. No collaterals
 - v. Subserve the centrum semiovale
 - vi. Do not anastomose with the deep perforators (lenticulostriate arteries)
 - e. Cortical arteries with subcortical territories that supply:
 - i. U-fibers
 - ii. Extreme capsule
 - iii. External capsule
 - iv. Claustrum
 - f. Most commonly found lacunar strokes occur in the:
 - i. Centrum semiovale
 - ii. Basal ganglia
 - iii. Thalamus
 - iv. Midbrain
 - v. Pons
 - vi. Medulla
 - g. Lenticulostriate territories (M1 and M2)
9. Infarction in these territories are often not lacunar (i.e., from one perforator) but may be secondary to distal field ischemia (carotid stenosis) or cardiac thromboembolism

Epidemiology of Lacunar Stroke

1. Lacunes – 20–30% of ischemic strokes
2. Blacks and Hispanics have twice the incidence of whites
3. No increase in HCVD, DM, cigarette smoking, hypercholesterolemia or TIA compared to other ischemic strokes
4. Some series a 40–50% incidence of ischemic heart disease
5. If a specific lacunar syndrome is present: there is an 87% chance the patient has suffered a lacunar stroke
6. Predictive value for lacunar stroke:
 - a. Pure sensory stroke 100%
 - b. Highly correlated
 - i. Ataxia, hemiparesis
 - ii. Sensorimotor stroke
7. Ataxic hemiparesis can occur from: corona radiata, pons, basal ganglia or thalamus infarction
 - a. Pontine site is the most frequent
8. 25% of lacunes are due to a non-lacunar mechanism
 - a. Atherosclerosis
 - b. Cardiac source of emboli
 - i. 10–15 perforators are affected simultaneously
 - ii. Larger size

General Characteristics

1. Lacunes are the result of small vessel disease and are usually ovoid lesions
 - a. Minimal cerebral cortex involvement (occurs with sensorimotor lesions)
 - b. Imaging evidence of a lesion less than 15 mm
 - c. Often concomitant hypertensive cardiovascular disease or diabetes mellitus
 - d. Overlap both in risk factor profile and clinical symptoms with large artery disease
 - e. Lacunes are defined as occlusions of a single perforating artery:
 - i. Large lacunae are 15–20 mm in diameter
 - ii. Small lacunae are 3–4 mm
 - f. Generally, large lacunes have more symptoms; small lacunes are symptomatic if in a critical location of a sensory or motor tract
2. If a specific clinical syndrome is present there is an 87% chance the patient has suffered a lacunar stroke
3. Some series a 40–50% incidence of concomitant ischemic heart disease
4. Predictive value for lacunar stroke:
 - a. Pure sensory stroke 100%
 - b. Highly correlated:
 - i. Ataxic hemiparesis
 - ii. Sensorimotor stroke
5. 25% of lacunes are due to a non-lacunar mechanism
 - a. Atherosclerosis
 - b. Cardiac source of emboli
 - i. 10–15 perforators are occluded
 - ii. Larger size than those from small vessel disease
6. May have stuttering course over 2–3 days

7. No cortical sensory loss
8. May have behavioral changes; minimal cognitive deficits
9. No visual field deficit

Clinical Syndromes*Pure Sensory Stroke***General Characteristics**

1. Smallest of the symptomatic deep infarcts
2. Approximately 6% of lacunar strokes
 - a. The most common lacunar syndrome
 - i. 45–57% in 3 major stroke registries
 - ii. Approximately 9.5% of pure sensory strokes are not due to lacunar infarction

Clinical Manifestations

1. Numbness of a single extremity
2. Rarely, if larger in the thalamus, numbness of a portion of the hemibody (VLP nucleus) or rarely the face (VPM)
3. Nociceptive deficits
4. Proprioceptive deficits
5. Face, arm and leg (83% of pure sensory stroke)
6. Cheiro-oral-pedal syndrome
 - a. 80% are caused by lacunar stroke
7. Face and arm (7%)
 - a. 35% of this pattern are caused by lacunar stroke
8. Arm and leg (8%)
9. Partial pure sensory deficits
 - a. Isolated oral sensory loss with restricted acral sensory loss

Pathology

1. Territories involved:
 - a. Internal capsule (posterior one third of the posterior limb)
 - b. Ventral posterolateral nucleus (VPL) and ventral posteromedial nucleus (VPM) thalamic nuclei
 - c. Rostral pontine tegmentum that involves:
 - i. Medial lemniscus
 - ii. Lateral spinothalamic tracts
 - d. Anterior thalamic radiations
 - e. Anterior limb of the internal capsule
 - i. Facial brachial pattern of weakness
 - f. Leg weakness – the lesion is more posterior in the internal capsule
 - g. Distal upper limb – pontine infarction
 - h. Medullary pyramid – flaccid hemiparesis that spares the face
2. Pathologic mechanisms
 - a. Occlusion (atheroma at ostium) of deep perforating end artery
 - b. Lipohyalinosis of perforator
 - i. Fibrinoid necrosis of media of the perforating arteriole
 - c. Embolus to a group of perforators
 - d. Basilar artery branch disease in pontine infarction due to atherosclerosis of the basilar artery

Neuroimaging

1. Small ovoid lesions 1 to 3 mm in size in the expected clinical territory
2. Large (>15 mm lesion) more likely embolic

*Ataxic Hemiparesis***General Characteristics**

1. Ataxic hemiparesis accounts for 9 to 18% of lacunar strokes

Clinical Manifestations

1. Hemiparesis or cortical spinal signs associated with ipsilesional cerebellar signs
 - a. Lesion topology
 - i. Lesions in the white matter of the corticospinal tract (motor cortex to pontine nuclei)
 - ii. Afferents to the middle cerebellar peduncle or cerebellar afferent zone for proprioception
 - iii. Thalamic cerebellar nuclei (proprioceptive receiving area)
 - iv. 3a of SI in the sensory cortex that projects back to MI. There are subtle differences with lesions at each level of this pathway
2. Partial hemiparesis, nystagmus, dysarthria suggests an infratentorial lesion
3. No facial involvement, dysarthria or sensory loss suggests a cortical lesion
4. Painful ataxic hemiparesis
 - a. Edema or ischemia of the internal capsule
 - b. Pain and ataxia greater than weakness
 - i. Lesion in VPL of the thalamus
 - ii. Cerebellar nuclei: a zone that receives proprioceptive afferent fibers (VL, area X near the centralis lateralis intralaminar nucleus)
 - c. Frontal infarction associated with cerebellar diaschisis (opposite side of the infarction and demonstrated by SPECT scan)

Pathology

1. Lipohyalinosis or fibrinoid necrosis of arterioles
2. Lesion topology
 - a. Internal capsule – 39%
 - b. Thalamus – 13%
 - c. Corona radiata – 13%
 - d. Lentiform nucleus – 8%
 - e. Cerebellum – 4%
 - f. Frontal cortex – 4%

Neuroimaging*MRI*

1. Ovoid lesions with low signal intensity on T2-weighted images and high signal intensity on T2-weighted sequences in clinically relevant areas

*Sensorimotor Stroke Syndrome***General Characteristics**

1. This subtype may be classified by the associated sensory deficits in addition to the motor deficits
 - a. All sensory modalities affected
 - b. Solely nociceptive deficits
 - c. Only proprioceptive deficits
 - d. Involvement of only one limb

Pathology

1. Fibrinoid necrosis (hypertension)
2. Lipohyalinosis (lipid dysregulation)
3. Atherosclerosis (atheroma at the origin of the perforating vessel)
4. Territories involved:
 - a. Thalamic capsule component of the corona radiata and putamen
 - b. Ventral posterior lateral thalamus and internal capsule
 - c. Cortical infarction anterior to the Rolandic fissure
 - d. In the Stroke Data Bank Study, lesions were seen in:
 - i. Posterior limb of the internal capsule – 30%
 - ii. Corona radiata – 22%
 - iii. Genu of the internal capsule – 7%
 - iv. Thalamus – 9%
 - v. Anterior limb of the internal capsule – 6%

Neuroimaging

1. MRI/FLAIR
2. DWI
3. Tractography and magnetic transfer imaging
4. Define
 - a. Small strategic infarction
 - b. Degree of lacunar involvement

*Pure Motor Stroke***General Characteristics**

1. The most frequent lacunar syndrome
2. 85% of pure motor strokes are caused by a lacunar infarct
3. 28% have an associated dysarthria

Clinical Manifestations

1. Contralateral hemiparesis
2. Brachiorural distribution
3. Facial weakness with dysarthria
4. Dysarthria – lingual weakness
5. Isolated limb paresis
6. Bilateral
7. No associated cognitive, sensory or visual symptoms

Pathology

1. Stroke topology
 - a. Anterior and mid internal capsule
 - b. Pons
 - c. Cerebral peduncle
 - d. Corona radiata

- e. Centrum semiovale
- f. Medulla
- g. Bilateral capsule
- h. Medullary pyramids
- i. Motor knuckle of the cortex
- 2. Fibrinoid necrosis, lipohyalinosis and atheroma. Embolus (rare)

Neuroimaging

- 1. MRI/FLAIR
- 2. DWI
- 3. Tractography

Dysarthria Clumsy Hand Syndrome

General Characteristics

- 1. Isolated acute-onset dysarthria is an uncommon presentation of transient ischemic attack or stroke
 - a. Occurs in less than 1.3% of confirmed strokes

Clinical Manifestations

- 1. Dysarthria and clumsiness of one hand with or without central facial paralysis
- 2. Dysphagia
- 3. Tongue deviation

Pathology

- 1. Stroke topology
 - a. Upper basis pontis
 - b. Corona radiata
 - c. Genu of the internal capsule
- 2. Fibrinoid necrosis, lipohyalinosis and atheroma at the origin of perforating small vessels

Neuroimaging

- 1. MRI/FLAIR sequences
- 2. DWI
- 3. Tractography

Clinical Summary of Described Lacunar Syndromes

- 1. Pure sensory stroke (PSS) (primarily thalamus)
- 2. Pure motor hemiparesis
 - a. Corona radiata
 - b. Middle internal capsule
 - c. Cerebral peduncle (medial 3/5)
 - d. Ventral pons
 - e. Medullary pyramidal
 - i. At decussation with cruciate pattern (ipsilateral arm; contralateral leg)
- 3. Ataxic hemiparesis (AH) (pontine gray – MCP and descending CST)
- 4. Dysarthria clumsy hand syndrome (pons)
- 5. Pure motor hemiparesis sparing the face (farther posterior in the middle 1/3 of the posterior limb of the internal capsule)

- 6. Mesencephalic; decreased upgaze (Nothnagel's syndrome)
 - a. Rostral interstitial nucleus of the medial longitudinal fasciculus
 - b. Posterior commissure
- 7. Thalamic dementia (DM, AV nuclei)
- 8. PMH with horizontal gaze palsy – lower 1/3 of pons, PPRF (para pontine reticular formation)
- 9. PMH with IIIrd nerve (Weber's syndrome): midbrain
- 10. PMH with IIIrd nerve and ataxia (Claude's syndrome): midbrain
- 11. PMH with IIIrd and movement disorder (Benedict's syndrome): midbrain
- 12. PMH with VIth nerve palsy (Ramon's syndrome): pons
- 13. PMH with confusion (brainstem RF; thalamic AV/DM nuclei)
- 14. Sensorimotor stroke (thalamic capsular)
- 15. Hemiballism – (STN; paramedian mesencephalic vessels)
- 16. Lacunes of the basilar territory (dizzy, diplopia, gaze dysfunction)
- 17. Lateral medullary partial infarction (penetrators from the vertebral artery)
- 18. Lateral pontomedullary territory (partial AICA)
- 19. Loss of memory (DM nuclei of thalamus); paramedian perforator)
- 20. Locked in syndrome (infarction of ventral pons; bilateral cerebral peduncles)
- 21. Unusual lacunar syndromes:
 - a. Weakness in one leg with falling (corona radiata; ventral portion of ventral pons)
 - b. Pure dysarthria – posterior 1/3 of ventral pons and cerebral cortex
 - c. Acute dystonia (thalamoperforate artery to basal ganglia)
 - d. Lacunar strokes and cognitive deficits:
 - i. Silent lacunar infarct with:
 - 1. Brain atrophy
 - 2. Multiple subcortical sites
 - 3. Enlarged ventricles
 - ii. Decreased executive function
 - iii. Decreased visuospatial ability

Differential Diagnosis by Arterial Territory and Anatomical Structure of Pontine Stroke with Lacunar Infarction

- 1. Paramedian arteries from the basilar artery (BA)
 - a. Medial basis pontis
 - b. Ventral tegmentum:
 - i. Corticospinal tract
 - ii. VIth cranial nerve fibers as they exit
 - iii. Facial nerve fibers as they exit
 - iv. Rare PPRF (para pontine reticular formation by extension)
- 2. Short circumferential arteries (BA)
 - a. Lateral 3/5 of the pons involved

3. Long circumferential arteries (BA)
 - a. Lateral tegmentum
 - b. Tectum
 - i. Cerebellar projections
 - ii. Vth and VIIIth cranial nerves
 - iii. Part of sensory lemniscus infarcted
4. Large bilateral pontine infarcts:
 - a. Basilar artery lesions
 - i. PPRF, one-and-a-half syndrome
 - ii. Ocular bobbing and dipping
 - iii. <0.5 mm pupils
 - iv. Decreased consciousness
 - v. Decerebration
 - vi. Hyperactive reflexes
 - vii. Babinski signs

Differential Diagnosis Between Pontine Hemorrhages vs. Lacunar Infarction

1. Ischemic:
 - a. Prior TIA
 - b. Stuttering clinical course
2. Hemorrhage:
 - a. Abrupt headache
 - b. Nausea and vomiting
 - c. Meningeal irritation
 - d. Rapid decrease of consciousness
3. Lacunar syndrome may be due to hemorrhage or infarction; isolated small hemorrhage may be associated with:
 - a. Dysarthria clumsy hand syndrome
 - b. Pure sensory stroke
 - c. Ataxic hemiparesis

Differential Clinical Features in the Patterns of Pure Motor Hemiparesis (PMH) and Sensory Stroke

1. Motor Cortex Weakness
 - a. Hand and arm representation is in the precentral gyrus "motor knuckle"
 - i. C5–C6 roots are represented medially
 - ii. C8–T1 are more lateral
 - b. Infarction frequently appears as a pseudo radial palsy (wrist drop)
 - c. Embolic pathogenesis from the internal carotid artery
 - d. Midbrain infarction:
 - i. Rare that face is involved in isolation
 - ii. Cranial Nerve III or VI involved with pure hemiparesis, ataxia or movement disorder
 - e. Medullary pyramid infarction:
 - i. Flaccid hemiparesis that spares the face
2. Ataxic Hemiparesis or Corticobulbar Dysfunction
 - a. Ataxic hemiparesis:
 - i. Infarction of the descending corticospinal tracts and pontine crossing fibers (comprises the middle cerebellar peduncle)
 - ii. Leg more severely affected than the arm
 - b. Dysarthria – clumsy hand syndrome:

- i. Corticobulbar fibers to the Xth and XIIth nerve with contralateral ataxia of the hand and arm
3. Pure Sensory Stroke:
 - a. Lacune in the centrum semiovale (deep penetrating medullary arteries)
 - i. Usually a feeling of numbness or heaviness
 - b. Infarction of the ventrobasilar thalamic complex (VPM or VPL):
 - i. Patients may describe numbness, paraesthesias, formication or pain
 - ii. Bilateral intraoral loss of sensation (VPM). This is to be differentiated from a vascular brainstem stroke in which patients may feel numbness on one side of the tongue. VPL involvement may present as numbness of the trunk and extremities in 20% of patients. Dysesthetic, paraesthesia and burning occurs more often in the involved territory. Later this territory may be associated with the hyperpathia of Dejerine-Roussy syndrome (thalamic pain). Associated thermal and mechanical allodynia and hyperalgesia are frequently present concomitantly with this syndrome. Thalamic lesions respect the midline and may involve vibration sensibility. Exception is bilateral decreased periumbilical sensation
 - c. Thalamic-capsular lacunar infarction most often causes sensorimotor stroke. Feeling loss is perceived as numbness and heaviness
 - d. Involvement of the ventral medial spinothalamic tract (quintothalamic tract) by lacunar infarction at medullary levels causes unilateral or bilateral facial pain or numbness (onion skin distribution)
4. Hemiballism – infarction of at least 2/3 of the corpus Luysi (subthalamic nucleus. Usually thalamoperforate or paramedian thalamic penetrating artery is occluded)
5. Tetraplegia (locked in syndrome):
 - a. Overwhelmingly a large pontine or midbrain stroke
 - b. Patients are fully awake
 - c. Quadriplegic
 - d. Able to blink and look up and down on command
 - e. Unable to perform lateral eye movements
 - f. Involvement of the basis pontis (basilar artery) or the cerebral peduncles (bilaterally)
 - i. P1 segment of the PCA's (infarcts the cerebral peduncle)
6. Patterns of lacunar weakness with gait abnormality:
 - a. Weakness in one leg with falling
 - i. Basis pontis (ventral portion of medial pons)
 - ii. Posterior corona radiata fibers
 - b. Pure dysarthria: corona radiata, internal capsule, cerebral peduncle; basis pontis
 - i. No difference in dysarthria from any lesion
 - ii. Imprecise articulation of labials and glottals
 - iii. Monotonous voice
 - iv. Slowed rate

- v. Pontine or medullary areas have more severe dysarthria
- vi. Left paravermian cerebellar lesions pivotal in dysarthria
 - 1. Coordination of articulation and respiration is disrupted
- c. Acute dystonia:
 - i. Thalamus (VA, VL or VIM)
 - ii. 2) Putamen

Rarer Lacunar States

1. Loss of memory:
 - a. Anterior thalamic nuclei
 - b. Anterior limb of internal capsule that involves anterior thalamic efferent fibers
2. Thalamic dementia (dorsal medial nucleus from paramedian infarction)
3. Pure motor hemiparesis sparing the face
4. Multiple lacunar infarctions:
 - a. Primarily in the basal ganglia
 - b. "État" Lacunaire
5. Dysarthria, facial, lingual paresis
 - a. Genu capsular syndrome
6. Cerebellar lacunes:
 - a. Unusual small round lesions in the watershed between SCA, PICA, AICA
 - b. One case of giant lacune in the cerebellum
 - c. SCA greater deep territory supply from AICA or PICA
 - d. Large artery occlusion, cardiac embolic, end artery lesion

Overview of Cerebral Microbleeds (CMB)

General Characteristics

1. Blood extravasation into the perivascular or Virchow-Robin space without further parenchymal damage
2. Less than 10 mm in size
3. Hemosiderin engulfed by perivascular macrophages
4. CMBs are noted in 4.7–24.4% of normal elderly individuals
5. Risk factors for CMB:
 - a. Age
 - b. HCVD
 - c. Diabetes mellitus
 - d. Cow serum cholesterol
 - e. ApoE- ϵ 4 and 2 status
 - f. Smoking
 - g. CAA
6. Deep CMB mainly associated with HCVD; cortical microbleeds most often linked to CAA
7. CMBs are noted in 50% of patients with intracerebral hemorrhage
8. ApoE- ϵ 4 and ApoE- ϵ 2 are associated with increased burden of CMBs on MRI evaluation for both ischemic and hemorrhagic lesions

9. ApoE- ϵ 4 and ApoE- ϵ 2
 - a. Increase cortical cerebral blood vessel fragility (BBB dysfunction and leakage of blood proteins and lipids into the vessel wall)
 - b. APOE- ϵ 4 glycoprotein:
 - i. Enhances the disposition of amyloid peptide into the vessel wall
 - ii. Associated with blood vessel smooth muscle loss and blood vessel thickening
 - c. APOE- ϵ 2 allele
 - i. Increased fibrinoid necrosis of amyloid laden vessels
 - ii. Increased incidence of newly developed microbleeds and intracranial hemorrhage
 - d. APOE- ϵ 4 and APOE- ϵ 2 are associated with an increased burden on MRI for both hemorrhagic and ischemic cerebral vascular disease

Progression of Small Vessel Disease with Severe Uncontrolled Hypertensive Cardiovascular Disease

1. Effects the deep gray of the basal ganglia and contiguous white matter
 - a. Spreads to more peripheral white matter and leptomeningeal arteries
 - b. Spread to thalamic and cerebellar white matter vessels and then to the brainstem vessels
 - c. Cortical vessels are not involved

Binswanger's Disease

1. Noted in severe poorly controlled hypertensive patients
2. A subcortical vascular encephalopathy with widespread demyelination, axon loss which spares U-fibers (connect adjacent cortical convolutions)
 - a. A severe SVD of arteriosclerosis and lipohyalinosis
 - b. CADASIL has similar pattern of cerebral involvement

Microhemorrhages

General Characteristics

1. Small foci of hemorrhage that increase with age; less than 10 mm
2. Cortical microbleeds are primarily associated with CAA while hypertension is the primary cause of those seen subcortically and in the basal ganglia
3. Cortical microbleeds are more prevalent in the ApoE- ϵ 4 and ApoE- ϵ 3/ApoE- ϵ 3 genotype
4. Correlated with:
 - a. Leukoaraiosis (white matter disease of aging)
 - b. Ischemic and hemorrhagic stroke
 - c. Alzheimer's disease
5. Are present in about 36% of patients over the age of 80 years
6. May be associated with a disseminated process

Clinical Manifestations

1. Intracerebral hemorrhage
 - a. Increased risk in patients taking anticoagulant therapy
2. Lobar hemorrhage (occipital predominant) in association with CAA; deeper hemorrhages associated with HCVD
3. Possible relationship with convolutional cortical subarachnoid hemorrhage
4. TIA episodes in CAA may represent the clinical equivalent of cerebral microbleeds
5. Vascular cognitive dysfunction
 - a. Released heme activates microglia that induce inflammatory pathology by releasing inflammatory cytokines

Pathology

1. Cerebral microbleeds are related to microvascular dysfunction
 - a. Age dependent capillary hemorrhage
2. The primary mechanism for cerebral microbleeds is a focal tear in a small artery or arteriole:
 - a. Amplified by CAA and HCVD

Neuroimaging

1. MRI has well demarcated focal lesions
2. Gradient ECHO and susceptibility weighted MRI sequences are the preferred imaging techniques
3. The presence of cerebral microbleeds is correlated with:
 - a. Lower fractional anisotropy and higher mean diffusion tensor imaging in ApoE ϵ 4 patients
 - b. Suggestion that cerebral microbleeds that present focally are associated with diffuse microstructural white matter damage

Retinal, Vestibular Small Vessel Diseases of the Brain***Eales Disease****General Characteristics*

1. Disease of young men
2. Occurs in the second to fourth decades of life
3. Prevalent in the Middle East and India
 - a. In India it has been associated with tuberculosis
4. No systemic symptoms
5. Eye symptomatology is dominant
6. Systemic illnesses that can present with retinopathy and stroke include:
 - a. SLE
 - b. Sarcoidosis
 - c. Ulcerative colitis
7. A syndrome of retinal neovascularization
8. Human leukocyte antigen (HLA)
 - a. Higher phenotype frequency of human leukocyte antigen
 - b. HLAB5, DR1 and DR4 individuals may be susceptible to retinal vasculitis

9. Association with tuberculosis has been suggested
 - a. Patients may be hypersensitive to tuberculo-protein
 - b. Epiretinal membrane samples have been reported as positive for mycobacterium species
 - c. Some patients have been described with meningitis

Clinical Manifestations

1. Ophthalmological features are dominant:
 - a. May be asymptomatic
 - b. Retinal periphlebitis
 - c. Retinal revascularization that may cause vitreous hemorrhage
 - d. Retinal capillary ischemia
 - e. Perivenous and periarterial sheathing
 - f. Macular arteries are less severely affected:
 - i. Relative sparing of central vision
 - g. Uveitis
 - h. Signs and symptoms predominant and present in three stages
 - i. Venous inflammation (vasculitis)
 - ii. Occlusion
 - iii. Retinal neovascularization
2. Cerebrovascular Manifestations
 - a. Focal ischemic infarcts
 - b. Large vessel thrombosis
3. Patients may suffer focal small vessel infarcts or occasional large vessel stroke
4. Retinal vasculitis associated with CNS vasculitis
 - a. Retinal hemorrhages associated with epistaxis
 - b. Young men
 - c. Recurrent monocular vitreous hemorrhage; may involve the second eye
 - d. May be associated with:
 - i. Subacute myelopathy
 - ii. Chronic lymphocytic meningitis
 - iii. Middle cerebral artery stroke

Pathology

1. Retinal ischemia
 - a. Retinal and/or optic nerve revascularization that causes
 - i. Vitreous hemorrhage
 - ii. Retinal detachment
 - b. Cerebral vasculitis
 - c. Large vessel stroke

Neuroimaging

1. Cerebral vasculitis
2. Large vessel infarction
3. Intracranial hemorrhage

Laboratory Evaluation

1. Arterial fundoscopic evaluation (fluorescein)

Differential Diagnosis of Eales Retinopathy

1. Sickle cell disease
2. Diabetic retinopathy
3. Retinopathy of prematurity
4. Familial exudative vitreoretinopathy
5. Hyperviscosity syndromes
6. Idiopathic retinal vasculitis
7. Neuroretinitis (IRVAN syndrome)
8. Systemic illnesses that can present with retinopathy and stroke include:
 - a. SLE
 - b. Sarcoidosis
 - c. Ulcerative colitis
9. There is discussion that the neurologic features associated with the retinopathy may be due to the underlying condition and may not be specific to Eales disease

Susac's Syndrome (Retinocochleocerebral Syndrome)*Overview*

An autoimmune disease that is characterized by encephalopathy, branch retinal artery occlusion and sensorineural hearing loss.

General Characteristics

1. Clinical triad of encephalopathy, deafness, retinal artery branch occlusion
 - a. Microangiopathy: affects the precapillary arteriole of the brain, retina and inner ear
2. Age varies between 8–58; predominantly females between the age of 20–40
3. Fluctuating course

Clinical Manifestations

1. Headache and behavioral change may be premonitory
2. Diffuse encephalopathy in which decreased auditory and visual perception is common
3. Psychiatric and behavioral alterations can progress to dementia
4. Focal neurologic involvement
 - a. Cranial Nerves III, VI and VIII
 - b. Hemihypesthesia
 - c. Hemiparesis
 - d. Generalized seizures and myoclonus
5. Retinal involvement
 - a. Branch retinal artery occlusion (BRAO)
 - i. Fluorescein angiography demonstrates multifocal fluorescence
 - b. Amputated retinal arteries (branch occlusion)
 - c. Thickened arterial walls with “light streaking”
 - d. Edema; cherry red macula
6. Auditory and visual loss may be simultaneous
7. Auditory loss:
 - a. Unilateral or bilateral hearing loss
 - b. Cochlear hearing loss

- i. Loss of low and intermediate frequencies (microinfarction of the apical cochlea)
8. Vertigo and tinnitus may occur from infarction of the vestibular labyrinth
9. Cause of multiple bursts of activity over 3 years; final stage is 1 to 8 years in a self-limited disease
10. Encephalopathy
 - a. In approximately 25% of patients the process may be preceded by slowly progressive altered mentation

*Pathology***Cerebrovascular Manifestations**

1. Small vessel disease (arteriolar)
2. Obliteration of small intracranial arteries
3. Ischemic and hemorrhagic infarction
4. Thrombotic mechanisms are more common than embolic
5. Microinfarcts in end arterioles distribution (white and gray matter) as well as the retina and cochlea
6. Hypertrophic astrocytes in white matter surrounding arterioles
7. Non-specific periarteriolar cell infiltrate
8. Disease of the vascular wall with thrombosis
9. Anti-endothelial cell injury

*Neuroimaging***MRI**

1. Multiple small hyperintense T2-weighted lesions in supratentorial gray and white matter
2. Lesions may be round or linear
3. Lesions occur in the central corpus callosum
4. Infratentorial lesions of the middle cerebellar peduncle, cerebellum and brainstem
5. Leptomeningeal involvement is seen in 30% of patients
6. Fluctuation of lesions overtime

Fluorescein Retinal Angiography

1. Distal branch retinal occlusions
2. Pathognomonic multifocal fluorescence
3. Plaques (endothelial damage)
 - a. Mid arteriolar segment involvement

Laboratory Evaluation

1. CSF protein may be elevated
2. Factor VIII and vWF antigen is increased in some patients

Differential Diagnosis

1. Cogan's syndrome (interstitial keratitis prominent)
2. Brown-Vialetto-Van Laere syndrome
 - a. Pontobulbar palsy (lower cranial nerves)
 - b. Familial and sporadic forms have been identified
3. MS (hearing loss and arteriolar occlusive retinal disease don't occur)
 - a. Generalized corpus callosum demyelination
 - b. Callosal lesions are Dawson's fingers (rare)
4. Acute disseminated encephalomyelitis (ADEM)

- a. Monophasic; lesions are the same age
- b. Unusual for retinal and VIIIth nerve involvement
- 5. SLE
 - a. Psychosis, seizures and proximal myopathy are characteristic
- 6. Polyarteritis
 - a. Ocular and auditory involvement is rare
 - b. Systemic involvement (kidney is the most prominent)
 - c. Usual CNS presentation is encephalopathy
- 7. Wegener's granulomatosis
 - a. Sinus and respiratory tract involvement
 - b. Systemic necrotizing vasculitis
 - c. May have glomerulonephritis
- 8. Hypersensitivity vasculitis (Henoch-Schönlein purpura)
 - a. Neurologic, retinal, auditory involvement is rare
 - b. Skin and vein involvement is most prominent
- 9. CADASIL
 - a. Notch 3 gene
 - b. Foveal telangiectasia changes in the retina
 - c. Migraine, small vessel disease, dementia

Rare Diseases in the Differential Diagnosis

1. Usher's syndrome (autosomal recessive)
 - a. Retinitis pigmentosa
 - b. Labyrinthitis
2. Vogt-Koyanagi-Harada syndrome
 - a. Uveo-meningeal syndrome (recurrent meningitis)
 - b. Dementia
 - c. White forelock
 - d. Harada (prominent VIIIth nerve involvement)
 - e. Blindness from diffuse exudative choroiditis and retinal detachment
3. Rocky Mountain Spotted Fever (retinal arterioles)
4. Takayasu's syndrome
 - a. Aortic arch derived vessel involvement
 - b. Ischemia of the retina (positional blindness); claudication of vision (with walking); early cataracts
5. Mitochondrial encephalomyopathies
 - a. Kearns-Sayre syndrome
 - i. Ophthalmoplegia
 - ii. Heart block
 - b. MELAS
 - i. Stroke-like episodes that do not respect a vascular territory
 - ii. Manifestations of most mitochondrial diseases include:
 1. Short stature
 2. Diabetes
 3. Ophthalmoplegia
 4. Cardiomyopathy
 5. Fatigue
 6. Weakness
 7. Sensorineural hearing loss
 8. Migraines

Acute Posterior Multifocal Placoid Pigment Epitheliopathy (APMPPE)

Overview

APMPPE is a self-limiting chorioretinal inflammatory disease that affects healthy young adults with rapid loss of central vision.

General Characteristics

1. Primarily an ophthalmologic syndrome best evaluated with fluorescein angiography (indocyanine green angiopathy)
2. Associated with:
 - a. Infectious/post-infectious disorders (bacterial and viral)
 - i. Tuberculosis
 - ii. Streptococcus
 - iii. Syphilis
 - iv. Lyme's disease
 - v. Schistosoma mansoni
 - vi. Epstein-Barr Virus (EBV)
 - vii. Adenovirus
 - b. Vaccination
 - i. Swine flu
 - ii. Hepatitis B
 - iii. Meningococcal
3. Inflammatory conditions:
 - a. Lymphadenopathy
 - b. Nephritis
 - c. Wegener's granulomatosis
 - d. Crohn's disease
 - e. Ulcerative colitis
 - f. Thyroiditis
4. Autoimmune disorders
 - a. Post-streptococcal syndrome
 - b. Anticardiolipin antibodies
 - c. Juvenile rheumatoid arthritis
 - d. Grave's disease
5. Paraneoplastic syndrome
 - a. Renal cell cancer

Clinical Manifestations

1. Ophthalmologic syndrome characterized by:
 - a. Multiple cream-colored placoid lesions
 - b. At the posterior pole in the level of the pigment epithelium and choroid
 - i. Demonstrated by indocyanine green fluorescein angiography
 - c. Occlusive choroidal vasculitis
 - d. Papillitis
 - e. Optic neuritis
 - f. Entity may be a continuum of Harada's disease; a possible autoimmune cause of uveo-meningeal syndrome
 - g. Inflammatory yellow-white lesions at the level of the retinal pigment epithelium (probable choroidal hypoperfusion)

2. Both eyes are affected simultaneously; ocular involvement may occur seriatim
3. Visual blurring; scotoma and distortion of vision
4. Vision usually recovers after several weeks but deficits may be permanent
5. Fundoscopic examination
 - a. Pathology is in the retinal pigment epithelium
 - b. Well circumscribed gray-white flat lesions
6. Stroke
 - a. Arteritis pattern

Neurologic Features

1. Neurological complications (mean age 26.5)
2. VIIIth nerve involvement
3. CNS vasculitis
4. Optic neuritis
5. Neuro-otological signs (tinnitus, hearing loss, vertigo)
6. Headache
7. Aseptic meningitis
8. Pseudo tumor cerebri
9. Meningoencephalitis (associated with vasculitis of CNS)
10. MS like episodes

Cerebrovascular Disease Associated with APMPE

1. Similar to primary angiitis of CNS
2. Cerebral vein thrombosis
3. Cortical and tentorial strokes in 70% of patients
 - a. Posterior cerebral and MCA territories
 - b. 40% of patients with deep white matter infarcts
 - c. Striatocapsular infarcts
4. Ischemic and hemorrhagic stroke (rare)
5. Lobar hemorrhage from cortical venous thrombosis (rare)

Pathology

1. Vasculitis of the CNS
2. Primary involvement of:
 - a. Retinal pigment epithelium
 - b. Choriocapillary vasculitis
 - c. Partial occlusive vasculitis
 - d. May be a continuum between APMPE and Harada's disease
 - e. Possible uveo-meningeal syndrome similar to:
 - i. Vogt-Koyanagi-Harada disease
 - ii. Behcet's syndrome
 - iii. Sarcoid
 - iv. Wegener's granulomatosis
3. Granulomatous involvement of medium-sized blood vessels
4. Some autopsies have demonstrated granulomas with Langhans cells

Neuroimaging

1. Arteriographic evidence of vasculitis (approximately one third of cases)
2. Ocular computed tomography:

- a. The outer nuclear layer, external limiting membrane and the inner and outer segment (IS/OS) line are disrupted

Laboratory Evaluation

1. Elevated CSF leukocytes and protein

Differential Points Between APMPE, Eales and Susac's Disease

1. Eales primarily affects retinal arteries (neovascular proliferation and vitreous hemorrhage)
 - a. Young men (20 to 40)
 - b. Stroke is rare
2. Susac's (young women approximately age 30)
 - a. Microangiopathy of the retina, cochlea and brain
 - b. Lesions in the corpus callosum (middle area)
3. APMPE
 - a. Rapid decrease in central vision
 - b. Yellow-white multiple placoid lesions of the retina
 - c. Acute/chronic visual blurring, scotoma or metamorphopsia
 - d. Both eyes are involved simultaneously or less commonly sequentially within a few days
4. Inflammatory conditions that are associated with retinal edema
 - a. Vogt-Koyanagi-Harada disease
 - b. Ocular Toxoplasmosis

Hereditary Endotheliopathy with Retinopathy, Nephropathy and Stroke (HERNS)

General Features

1. Chromosome 3p21; mutation of the TREX1 gene
 - a. Codes for a 3'-5' DNA exonuclease
2. Progressive visual loss in the 3rd to 4th decade
3. Neurologic deficits begin 4 to 10 years after initiation of the disease

Clinical Manifestations (Clinical Features)

1. Central vision loss with decreased visual acuity
2. Premonitory behavioral and psychiatric symptoms (early as the second decade)
3. Stroke-like episodes may be presenting symptom; may progress over several days
4. Later in the course there are multifocal cortical and sub-cortical signs of small vessel stroke
 - a. Migraine is common
 - b. 50% of patients have renal dysfunction

Ophthalmologic Signs

1. Retinal vasculopathy
 - a. Loss of macular capillaries
 - b. Dilated tortuous telangiectatic vessels; capillary shunts
 - c. Fluorescein angiography
 - i. Juxtafoveolar capillary obliteration with microaneurysm
 - d. Peripheral retina is involved late in the disease's course

Pathology

1. Small blood vessels occluded by fibrin thrombi
2. Electron microscopy:
 - a. Multilaminated vascular basement membranes
 - b. Kidney, stomach, omentum and skin are concomitantly involved
 - c. Generalized vasculopathy with disruption of capillaries and arterioles
 - d. Breakdown of the blood-brain barrier
 - e. A primary endothelial injury

*Neuroimaging***MRI**

1. Reveals T2 sequence high intensity lesions in deep white matter (contrast enhancing)
 - a. Overtime, contrasting lesions in the deep frontoparietal area
2. May have space occupying mass lesions

Laboratory Evaluation

1. Fluorescein angiogram of the retina
 - a. Macular capillary dropout
2. Dilated tortuous telangiectasia vessels and capillaries

Cogan's Syndrome (Typical or Classic)*Overview*

A chronic inflammatory disorder, affecting multiple systems, characterized by interstitial keratitis and sensorineural hearing loss; may also be associated with systemic vasculitis (rare).

General Characteristics

1. Occurs in young adults (25 years mean age)
2. Men and women affected equally
3. Autoantigens: There is evidence of inner ear autoimmunity possibly triggered by a viral infection. Putative autoantigens are CD148 and Connexin 26
4. Cerebrovascular complications are large vessel stroke and cavernous sinus thrombosis

Clinical Features

1. Systemic features:
 - a. Headache, fever, weight loss, fatigue
 - i. Arthralgias and myalgias (30%)
 - b. 10% have systemic vasculitis
 - a. Aortic insufficiency (10%)
 - b. Distal coronary arteries may be affected
 - c. Skin
 - d. Viscera
 - e. Kidneys
 - f. CNS
 - g. Muscles
2. Neurological manifestations
 - a. Blindness (corneal opacification)

- b. Vertigo
- c. Ataxia
- d. Hearing loss
 - i. Vestibular auditory dysfunction from inflammation of the labyrinth
3. Ophthalmologic features
 - a. Acute interstitial keratitis
 - b. Bilateral interstitial keratitis (nonsuppurative cellular infiltrate of the corneal stroma)
 - c. Keratitis fluctuates
 - d. Patchy corneal involvement and absence of intraocular inflammation
 - e. Retinal hemorrhage and papilledema
 - f. Orbital pseudotumor
 - g. Central artery or vein occlusion
 - h. Presents with:
 - i. Red eyes
 - ii. Photophobia
 - iii. Reduced vision
 - iv. Interstitial keratitis
 - v. Uveitis (rare)
4. Vestibulocochlear manifestations:
 - a. Severe hearing loss in all cases
 - i. Asymmetric and sudden
 - b. Vertigo, tinnitus and ataxia
 - c. Inflammation of the labyrinths
 - d. Acute and often bilateral
 - e. Decreased caloric response
 - f. May be coincidental with visual loss
5. Stroke (pial arteries)

Typical Cogan's Signs and Symptoms

1. Photophobia, lachrymation, eye pain
2. Blurred vision
3. Intermittent symptoms for years
4. Ménière's-like attacks may precede eye pain
5. Total deafness and absence of vestibular function

Atypical Cogan's Syndrome*General Characteristics*

1. Vasculitis and systemic manifestations
2. Inflammatory ocular disease exemplified by
 - a. Uveitis
 - b. Scleritis
 - c. Episcleritis
 - d. Retinal vasculitis
 - e. Optic nerve edema without interstitial keratitis
3. There may be vestibular auditory dysfunction that occurs at more than 2 years after onset of eye symptoms

Clinical Manifestations

1. Involvement of the CNS or PNS varies from 5 to 50%
2. Vasculitis
 - a. Occurs in atypical disease

- b. Aortitis and aortic insufficiency in the classic syndrome
- c. Neurologic symptoms
 - i. Stroke
 - 1. Cerebrovascular disease
 - a. Cerebral venous sinus thrombosis
 - b. PICA thrombosis
 - c. Ischemic brain (cerebellar) lesions
 - d. Frequency of neurologic involvement about 13%
 - e. Emboli to large arteries from valvular disease (rare)
 - ii. Encephalopathy
 - ii. Seizure
 - iii. Myelopathy
 - iv. Mononeuritis multiplex
 - v. Cavernous sinus thrombosis
 - d. Differential diagnosis includes syphilis
- 3. Cerebrovascular disease
 - a. Cerebral venous sinus thrombosis
 - b. PICA thrombosis
 - c. Ischemic brain (cerebellar) lesions
 - d. Frequency of neurologic involvement about 13%
 - e. Emboli to large arteries from valvular disease (rare)

Neuroimaging for Typical and Atypical Cogan's Syndrome

MRI

1. Multiple ischemic brain lesions
2. Soft tissue obliteration of the membranous labyrinth

Angiography

1. Cerebral venous thrombosis
2. PICA thrombosis
3. Signs of suggestive of vasculitis

CT

1. Intralabyrinthine calcifications (rare)

Pathology

Typical Cogan's Syndrome

1. Vasculitic process affecting vessels of all sizes
2. Microscopic evaluation of the aorta
 - a. Inflammatory changes
 - b. Destruction of the internal elastic membrane
3. Autoantibodies against corneal, inner ear and endothelial antigens may be present

Atypical Cogan's Syndrome

1. Eye pathology includes:
 - a. Retinal hemorrhage
 - b. Papilledema
 - c. Orbital pseudotumor
 - d. Central artery or vein occlusion

Laboratory Evaluation for Typical and Atypical Cogan's Syndrome

1. Elevated erythrocyte sedimentation rate (ESR), anemia, leukocytosis and thrombocytosis
2. Lumbar puncture (LP) may demonstrate pleocytosis and elevated protein
3. Negative tests for syphilis and autoantibodies that include rheumatoid factor, anti-nuclear antibodies and ds DNA
4. Audiometry, electronystagmography and vestibular function deficits are positive

Retinal Vasculopathy with Cerebral Leukodystrophy (RVCL)

Overview

The RVCL spectrum presents primarily as small vessel disease. Three variants that have been mapped to chromosome 3p21 are: Hereditary Retinal Vasculopathy (HRV), Cerebroretinal Vasculopathy (CRV) and Hereditary Endotheliopathy, Retinopathy and Nephropathy (HERNS).

An infantile syndrome that is similar but does not map to 3p21 is: Hereditary Infantile Hemiparesis with Arteriolar Retinopathy and Leukoencephalopathy (HIHARL).

Cerebroretinal Vasculopathy (CRV), HERNS and Hereditary Retinal Vasculopathy (HRV)

General Characteristics

1. Genetics
 - a. All three diseases are linked to a locus on chromosome 3p21
 - b. Autosomal Dominant
2. Causative gene mutations of TREX 1
 - a. Encodes a 3'-5' DNA repair exonuclease
 - b. Frame shift mutation
3. Other diseases with TREX-1 mutations that have clinical similarity but distinct clinical features:
 - a. Aicardi-Goutières syndrome (AGS)
 - b. Familial Chilblain Lupus (FCL)
 - c. Systemic Lupus Erythematosus (SLE)
4. The truncated protein from the mutation retains exonuclease activity but loses perinuclear localization
5. Hereditary systemic angiopathy (HSA) has recently been described and is also suggested to be on the retinal vasculopathy with cerebral leukodystrophy spectrum

Clinical Manifestations

1. Middle age at onset (4th–5th decade)
2. Predominant CNS involvement
3. TIA, stroke, focal motor and sensory deficits
4. Depression
5. Headaches
6. Cognitive dysfunctions
7. Decreased renal function
8. G.I. bleeding
9. Increased alkaline phosphatase
10. Migraine
11. Raynaud's Phenomena
12. 100% mortality in 5–10 years due to neurologic deficits

Neuropathology

1. Coagulative necrosis secondary to obliterative vasculopathy
2. Minimal inflammatory infiltrate
3. Fronto-parietal cortex motor involvement; lesions also occur in the basal ganglia, cerebellum and pons
4. One third of patients have hepatic and renal involvement
5. Thickening and reduplication of the retinal capillary basal lamina

Neuroimaging

1. Retinal fluorescein angiography:
 - a. Capillary drop-out (macular region; decreased central vision)
 - b. Prominent juxtafoveolar capillary obliteration and telangiectasia
2. Lesions are most prominent in the fronto-parietal lobes
 - a. Lesions enhance

Differential Diagnosis of RVCL

1. Variants of RVCL with linkage to 3p21 (3p21 mutations)
 - a. CRV (Cerebral Retinal Vasculopathy)
 - b. HVR (Hereditary Vascular Retinopathy)

HERNS (Hereditary Endotheliopathy Retinopathy with Nephropathy)

1. Brain, kidney, GI tract and skin are involved
2. Pathology (by electron microscopy) reveals multilaminated vascular basement membrane
 - a. Hereditary Infantile Hemiparesis with Arteriolar Retinopathy and Leukoencephalopathy (HIHARL)
 - i. Not linked to 3p21
 - ii. Vascular endothelial dysfunction
 - iii. Possible increased susceptibility to decreased cerebral blood flow from cortical spreading depression
 - iv. Migraine with aura, retinal hemorrhage and tortuosity
 - v. Dilatation of perivascular spaces and microbleeds

Cerebroretinal Vasculopathy (CRV)**General Features**

1. Genetics
 - a. Autosomal dominant
 - b. 100% penetrance
 - c. Chromosome 3p21 mutation

Clinical Manifestations

1. Onset is middle age (4th to 5th decade)
2. Primarily retinal involvement
3. 100% mortality over a 5 to 10 year period
4. Macular edema, capillary obliteration, microaneurysms and telangiectasia
5. Strokes, visual loss, dementia
6. Neurologic manifestations
 - a. TIA and ischemic stroke

Pathology

1. Coagulative necrosis secondary to an obliterative vasculopathy
2. Minimal inflammatory infiltrate
3. Pons, cerebellum and basal ganglia also involved
4. One third of patients with concomitant hepatic and renal involvement
5. Fibrinoid necrosis without inflammation

Neuroimaging**CT/MRI**

1. Topographic stroke

Laboratory Evaluation

1. Ophthalmologic evaluation by retinal fluorescein angiography
 - a. Macular capillary dropouts with loss of central vision
 - b. Juxtafoveolar capillary obliteration and telangiectasia

Hereditary Vascular Retinopathy (HVR)**General Features**

1. Retinal vasculopathy
2. Migraines
3. Raynaud's phenomena
4. Visual acuity preserved
 - a. Primarily peripheral retinal involvement
5. Similar course to cerebroretinal vasculopathy (CVR) and Hereditary Endotheliopathy with Retinopathy, Nephropathy and Stroke (HERNS)

Venous Stroke**Venous Strokes Overview**

Venous strokes should be suspected in the setting of the last trimester of pregnancy and the first month of the perineurium, any prothrombotic state and dehydration. Clinically, there is a depressed mental status early in the course of the process as well as a step wise and progressive onset rather than an apoplectic initial event, which characterizes embolus, hemorrhage and ischemic stroke. Repeated seizures and vomiting are common associated with severe headache. Papilledema is more common than with ischemic or hemorrhagic events. The sinuses are commonly occluded. Lateral sinus involvement should be suspected with mastoid pain that may radiate to the sternocleidomastoid muscle associated with Vth and VIth nerve involvement. The temporal lobe and cerebellum may be involved concomitantly. Sagittal sinus thrombosis frequently presents with focal seizures of the leg or bilateral signs and symptoms. Severe headache, papilledema and rapid loss of consciousness strengthen the diagnosis. Cavernous sinus involvement is frequently heralded by periorbital headache, fever, stiff neck. There is progressive orbital and retinal congestion culminating in paresis of III, IV and VI.

Often there is complete ophthalmoplegia and frequent spread to the contralateral eye.

Occlusion of the internal cerebral veins, the vein of Galen and straight sinus present with stupor or coma. They often have had a severe headache and hemiparesis prior to depression of mental status.

Cortical cerebral venous occlusion presents with focal neurological signs, seizures at presentation, headache but minimal depression of consciousness.

Cerebellar venous occlusions often pursue a pseudotumoral course with brainstem compression.

MRI evaluation that demonstrates a delta sign at the confluences of sinuses, bilateral thalamic and basal ganglia hemorrhage, small compressed ventricles and vascular lesions out of a typical arterial distribution suggest venous stroke and sinus occlusion.

Specific Territories of Venous Drainage

1. Superior sagittal sinus (SSS) and its veins
 - a. Drain a major part of the cerebral hemispheres
2. Inferior sagittal sinus, straight sinus and tributaries drain:
 - a. Deep white matter of the cerebral hemispheres
 - b. Basal ganglia
3. At the torcular of Herophilus (confluens of sinuses):
 - a. SSS is continuous with the right lateral sinus
 - b. Straight sinus is continuous with the left lateral sinus
4. Lateral sinus has two segments:
 - a. Transverse (attached to the border of the tentorium)
 - b. Sigmoid (attached to the inner aspect of the mastoid bone)
5. Cavernous sinus:
 - a. Drains the periorbital and facial territories
 - b. Joins the internal jugular vein and transverse sinus through the petrosal sinus
 - c. Drains Sylvian the fissure through the sphenoparietal sinus

General Characteristics

1. Accounts for approximately .5% of all strokes
2. Approximately 5–7 cases per million children and 3–4 patient per million adults
3. Most cases are associated with sinus thrombosis
4. Women account for 75% of the cases

Clinical Manifestations

1. Headache is the most common symptom of sinus thrombosis
 - a. Usually it presents over several days but can occur acutely; a higher incidence in women than men and also carries a higher chance of hemorrhage
2. Patients with a chronic cause may have papilledema
3. Severe symptoms occur with:
 - a. Occlusion of the deep venous system
 - i. Coma

- ii. Bilateral motor deficits
- b. Parenchymal lesions
4. Focal or generalized seizures are common:
 - a. Focal neurological signs in the absence of increased intracranial pressure suggests isolated cortical vein thrombosis
 - b. Seizures occur more often with:
 - i. Parenchymal lesions
 - ii. Sagittal sinus thrombosis
 - iii. Cortical venous thrombosis
5. Coma occurs with large hemispheric infarcts or hemorrhage
 - a. Compression of the thalamus or mid-brain
6. Predictors of mortality and morbidity following venous infarction:
 - a. Coma
 - b. Seizures (more common with hemorrhage)
 - c. Depressed consciousness
 - d. Deep cerebral vein thrombosis
 - e. Right intracranial hemorrhage
 - f. Posterior fossa lesions
 - g. Worsening of previous deficits
7. Intracranial hemorrhage occurs in approximately 40% of patients with venous ischemia

Neuropathology

1. Superior sagittal sinus thrombosis with cortical vein thrombosis
 - a. Involves the superficial cerebral hemispheres
2. Thrombosis of the straight sinus involves the basal ganglia
3. Isolated cortical vein thrombosis is rare
4. Usual pathology: venous thrombosis with or without cerebral infarction; basal ganglia or thalamic hemorrhage
5. Venous obstruction causes:
 - a. Cerebral edema
 - b. Infarction or hemorrhagic infarction of the cortex
 - c. Petechial hemorrhage
 - d. Superior sagittal sinus thrombosis may cause:
 - i. Bilateral basal ganglia hemorrhage
 - ii. Unilateral or bilateral thalamic hemorrhage
 - e. Hemorrhagic infarction may be circumscribed or widespread that may involve cortical and deep structures
 - f. Multiple or single intracerebral hemorrhage

Neuroimaging

1. Most sensitive technique is a combination of MRI to visualize thrombosis vessel with consequent catheter angiography which detects the non-visualization of the same vessel
2. The delta sign (at the confluence of sinuses or the “cord” sign) is detected in approximately 30% of patients
3. Approximately 30% of scans may be negative
4. MRI alone or with DWI shows mixed patterns of edema, infarction and hemorrhage

Venous Sinus Thrombosis

General Characteristics

1. The Superior Sagittal Sinus (SSS) is the most commonly involved
 - i. Solely involved approximately 30 to 40% of the time
2. In 10 to 15% of patients with venous sinus thrombosis, the lateral sinus is unilaterally involved
3. Rarer sinus involvement includes:
 - a. Deep venous system
 - b. Isolated cortical veins

Clinical Manifestations

1. A stepwise and progressive onset
2. Headaches in 75 to 90% of patients
3. Vomiting is common
4. There is a depression of mental status early in the course of the illness
5. Recurrent seizures with severe headaches
6. Hemiparesis commonest focal deficit
7. Hemisensory deficit is seen in approximately 10% of patients
8. Neurologic signs are cumulative
9. Alternating or ascending hemiparesis is rare
10. Papilledema occurs in chronic conditions

Neuropathology

1. Clotting disorders:
 - a. Antithrombin III
 - b. Protein C and S deficiency
 - c. Factor V Leiden mutation
 - d. Prothrombin gene mutation
 - e. SLE anticoagulant
 - f. Activated Protein C resistance
 - g. Methylene tetrahydrofolate reductase deficiency
 - h. Anticardiolipin antibody
 - i. Increased factor VIII
 - j. Oral contraceptives
 - k. Ulcerative colitis
 - l. Regional enteritis
 - m. Polycythemia vera
 - n. Hemolytic anemia
 - o. Pregnancy and the puerperium
 - p. Leukemia
 - q. Paroxysmal nocturnal hemoglobinuria (decreased membrane glycoprotein)
 - r. Carcinoma (thrombin like material)
 - s. Idiopathic thrombocytosis
 - t. Nephrotic syndrome
 - u. Ménériér's syndrome (protein losing enteropathy)
 - v. Androgen therapy
 - w. Asparaginase therapy (blocks antithrombin III)
 - x. Cryofibrinogenemia
 - y. Disseminated intravascular dissemination
 - z. Behçet's disease

2. Structural changes in the venous sinus wall:
 - a. Metastatic disease (invasion)
 - b. Lung; breast, choriocarcinoma, prostate cancers
 - c. Lymphoma (invasion)
 - d. Non-Hodgkin's lymphoma
 - e. Behçet's disease
 - f. Arteriovenous malformations
 - g. Sarcoidosis
 - h. Leukemia (invasion of wall)
 - i. Meningitis
 - j. Chronic otitis media
 - k. Wegener's granulomatosis
 - l. Aspergillosis
 - m. Mastoiditis (lateral sinus)

3. Blood flow, rheology, systemic causes of venous occlusion:
 - a. Congestive heart failure
 - b. Cachexia and marasmus
 - c. Trauma
 - d. Cerebral artery thrombosis
 - e. Chronic obstructive airway disease
 - f. Trichinosis
 - g. Transvenous pacemaker placement
 - h. Dehydration
 - i. Hyperpyrexia (release of thromboplastin from platelets)
 - j. Congenital heart disease
 - k. Budd–Chiari syndrome
 - l. Diabetes mellitus
 - m. Vasculitis
 - n. Homocystinuria
 - o. Sickle cell (SS) disease
4. Cerebral edema
5. Ischemic or hemorrhagic infarction of the involved obstructed venous drainage territories
6. Basal ganglia or thalamic hemorrhage

Neuroimaging

1. Demonstration of thrombi in the sinuses and cerebral veins by MRI, MR venography or CT venography

Lateral Sinus Thrombosis

General Characteristics

1. Both otic and non-otic etiologies

Clinical Manifestations

1. Pain occurs:
 - a. Mastoid area
 - b. Sternocleidomastoid muscle
 - c. Headaches in frontotemporal and occipital areas
 - d. Vertigo, nausea and vomiting
 - e. Diplopia from involvement of the VIth nerve (Dorello's canal at the petrous apex under the petroclinoid ligament)
 - f. Paresthesias or pain in the face (involvement of the Vth nerve in Meckel's cave)

- g. Vth and VIth nerve concomitant involvement (Gradenigo's syndrome)
 - i. Nerves are affected at the petrous apex
 - ii. Requires pneumatized temporal bone
 - iii. Unilateral deafness
- h. Lethargy (increased ICP)
- i. Otic hydrocephalus
- j. Temporal lobe and cerebellum involved concomitantly
- k. Temporal lobe involvement
 - i. Posterior aphasia
 - ii. Superior quadrantanopia
 - iii. Agitation
- l. Cerebellar involvement
 - i. Gait ataxia
 - ii. Ipsilateral rotary nystagmus
- m. Spread of the thrombus
 - i. Into the jugular veins (if an axillary or jugular line is infected the spread is to the lateral sinus)
 - ii. Adjacent sinuses
 - iii. Rare concomitant pulmonary emboli

Neuropathology

1. Coagulopathy and systemic illness (inflammatory bowel disease)
2. Spread of infection from middle ear and mastoid
 - a. Draining ears and perforated ear drums
3. Spread of infection from the lateral sinus through jugular veins

Neuroimaging

1. Lytic lesions and opacification of the mastoid air cells
2. Eburnation and bone sclerosis
3. Concomitant secondary cholesteatoma
4. Demonstration of thrombi in the sinus by MRI, MR venography or CT venography

Superior Sagittal Sinus Thrombosis

General Characteristics

1. The superior sagittal sinus (SSS) is most commonly involved in venous sinus thrombosis
2. It is involved solely among the sinuses 30–40% of the time

Clinical Manifestations

1. Depends on concomitant involvement of cortical veins
 - a. Focal motor or sensory deficits
 - b. Seizures (leg more often than arm)
 - c. Often bilateral signs and symptoms
 - d. Signs and symptoms may be transient
2. Pseudotumor cerebri may occur if SSS is solely involved:
 - a. Severe headache
 - b. Papilledema
 - c. VIth nerve palsy
 - d. Decreased level of consciousness
 - e. Edema and hemorrhage of the medial dorsal cerebral hemisphere

Neuropathology

1. Associated with:
 - a. Puerperium
 - b. Parasagittal meningioma
 - c. Carcinomatosis of the meninges
 - i. Breast, lung and rarely prostate carcinoma
 - d. Head trauma
 - e. Behçet's disease
 - f. Prothrombotic states

Neuroimaging

1. Demonstrated by MRV
2. Parasagittal T2-weighted sequence hyperintensities
3. Bilateral basal ganglia on thalamic hemorrhages
4. Delta sign at confluences of sinuses (clot visualized)

Cavernous Sinus Thrombosis (CST)

General Characteristics

1. The primary source of CST may be a distant inflammatory focus in immune-compromised patients
2. May cause ischemic stroke (rare) by septic arteritis

Clinical Manifestations

1. Fever often with stiff neck
2. Headache (if early, it is often periorbital)
3. Facial pain (VIth nerve distribution)
4. Conjunctival edema and erythema
5. Orbital and retinal congestion
6. Involvement of IIIrd, IVth, VIth cranial nerves
7. V1 and occasionally V2 (usually slightly posterior to the sinus)
8. May cause complete ophthalmoplegia
9. Occlusion of ophthalmic artery (blindness)
10. Bilateral eye findings
11. Involvement of ICA with hemiparesis (rare)
12. Cavernous sinus thrombosis with spread to superior petrosal sinus
 - a. Causes Vth nerve involvement
13. Noninfectious clinical manifestations:
 - a. Indolent course
 - b. Proptosis
 - c. Conjunctival edema
 - d. Blood vessels do not reach the iris in infective or non-infective CST. Blood vessels do in cavernous arterial venous fistulae
 - e. No or minimal oculomotor involvement

Neuropathology

1. Infection of veins draining the medial face, orbit, nose and nasal sinuses
2. Infectious etiologies include:
 - a. Staphylococcus aureus
 - b. Pneumococci

- c. Streptococci
- d. Gram negative bacteria
- e. Mucormycosis
- f. Aspergillus
- 3. Noninfectious etiologies:
 - a. Surgery of sinuses/facial structures
 - b. Prothrombotic states
 - c. Thrombosis of dural A-V fistula

Neuroimaging

- 1. Ophthalmic veins (the superficial middle and inferior cerebral veins) connect with the sphenoparietal and sphenoid sinuses
- 2. Cavernous sinus drains into the pterygoid venous plexus via emissary veins and into the jugular vein and sigmoid sinus via the inferior and superior petrosal sinuses
- 3. Absence of valves in the cavernous sinuses underlie the spread of infection
- 4. MRV and catheter angiography if MRA does not adequately demonstrate thrombi in this system

Internal Cerebral Veins, Vein of Galen and Straight Sinus

General Characteristics

- 1. The deep venous system drains:
 - a. Thalamus
 - b. Basal ganglia
 - c. Midbrain
 - d. Geniculate bodies
 - e. Cerebellum

Clinical Manifestations

- 1. Occlusion of the internal cerebral vein and vein of Galen:
 - a. Clinical features:
 - i. Patients present stuporous or in coma
 - ii. Severe headache may precede decreased level of consciousness
 - iii. Hemiparesis
 - b. If thalamic and basal ganglionic hemorrhage supervene
 - i. Coma
 - ii. Decerebrate posture
 - iii. Vertical gaze palsy
 - iv. Apathy and abulia in some patients as a presenting sign

Neuropathology

- 1. Hemorrhagic infarction
- 2. Etiologies include:
 - a. Dehydration
 - b. Sickle cell disease
 - c. Infection
 - d. Ulcerative colitis
 - e. Oral contraceptives

Neuroimaging

- 1. Combination of MRI to visualize the thrombosed vessel and MRV to detect non-visualization of the identical vessel
- 2. Bilateral thalamic and basal ganglia lesions
- 3. DWI heterogeneous signal intensity in affected areas
 - a. Apparent diffusion coefficient map (ADC) may be close to normal

Jugular Vein Thrombosis

General Characteristics

- 1. The major cause of Lemierre's syndrome that is caused by infection in the oropharyngeal region with subsequent involvement (thrombophlebitis) of the internal jugular vein (IJV)
- 2. Involvement of the contiguous carotid sheath may occur which contains:
 - i. Internal jugular vein
 - ii. Carotid artery
 - iii. Vagus nerve
 - iv. Lymph nodes
 - v. Cranial nerves IX, XI XII that are in the upper sheath

Clinical Manifestations

- 1. Headache, fever and vomiting
- 2. Carotid artery occlusion (arteritis)
 - a. Cranial nerve IX–XII palsies
 - b. Horner's syndrome
 - c. Trismus if infection involves the pterygomandibular area

Neuropathology

- 1. Thrombus in the internal jugular vein can spread to the liver and lungs
- 2. Often internal jugular vein infection occurs from a palatine tonsil infection with the bacterium *Fusobacterium necrophorum*
- 3. Drug abuse (injection into jugular vein)
- 4. Other causes of internal jugular vein infection:
 - a. Dental procedures
 - b. Parotitis (HIV patients)
 - c. Mastoiditis
 - d. Otitis media

Neuroimaging

MRI/MRV

- 1. Identifies possible source of the infection (MRI) and extent of the thrombus (MRV)

Cortical Cerebral Venous Thrombosis

General Characteristics

- 1. In association with occlusion of the superior sagittal sinus
- 2. Pattern of neurological involvement is not in an arterial distribution

Clinical Manifestations

1. Seizures at presentation
 - a. Spread of affected body area (worsening) with each seizure
2. Focal neurological signs:
 - a. Aphasia
 - b. Hemiparesis
3. Headache
4. Less commonly a decreased level of consciousness

Neuropathology

1. Prothrombotic states
2. Puerperium
3. Associated superior sagittal sinus or other sinus involvement

*Neuroimaging***MRI**

1. Brain edema with hemorrhage (out of an arterial distribution)
2. Pial surface of the hemisphere is involved

MRV

1. Evaluates other sinuses and demonstrates the thrombotic veins

Cerebellar Venous Occlusion*General Characteristics*

1. Usually associated with lateral sinus disease
2. Prothrombotic states

Clinical Manifestations

1. Severe headache
2. Incoordination of the affected side
3. Lower cranial nerve palsies
4. Pseudotumoral course with brainstem compression

Neuropathology

1. Hemorrhagic infarction out of an arterial distribution
2. Tonsillar herniation

*Neuroimaging***MRI/MRV**

1. MRI/MRV to evaluate the cerebellar veins and the extent of edema

Differential Diagnosis of Tumors that Cause Venous Sinus Compression

1. Ewing's sarcoma (extension from occipital region of skull)
2. Plasmacytoma
3. Metastasis most commonly from breast and lung cancer
4. Neuroblastoma
5. Choriocarcinoma
6. Prostate cancer

Differential Diagnosis Between a Mass beneath the Inner Table of Skull vs Tumor Invasion of the Dura and Sinus

1. Diagnostic Features of Venous Occlusive disease:
 - a. Specific circumstances as noted
 - b. Headaches is often the presenting symptom
 - c. Seizure and lethargy more common than in arterial disease
 - d. Increased intracranial pressure in the absence of focal deficits
 - e. Slower and more indolent progression than arterial disease

*Imaging Evaluation***CT**

1. Evidence of sinus and middle ear disease
2. Cord sign
 - a. Cerebral vein imaged as high density linear, thin tubular structure
3. Delta sign at the confluens of sinuses
 - a. Hyperdense triangular mass within the sinus on contrast CT; which does not enhance
4. Bilateral thalamic and basal ganglia hemorrhage
5. Small compressed ventricles
6. Lesions out of a typical arterial distribution
7. Deep Venous Occlusion demonstration by CT
 - a. Bilateral hypodensity of thalamus and basal ganglia
 - b. Edema and compression of the IIIrd ventricle
 - c. Retention of contrast in thalamostriate veins, basilar vein of Rosenthal, non-opacification of vein of Galen

Contrast Enhanced CT

1. Dilated cortical and medullary veins
2. Gyral enhancement

MRI/MRV

1. May directly image the occluded venous sinus
2. Demonstrates collaterals
3. MRI may be negative in 30% of patients

Arteriography

1. Delineates all venous and arterial structures
 - a. Now necessary as angioplasty and intravenous thrombotics may be options
 - b. Better visualization of congenital variants
2. Multifocal and bilateral
3. Seizures and increased intracranial pressure
4. Cortical surface causes focal leg seizure (superior sagittal sinus) or arm (cortical vein)

Medical Causes of Stroke**Overview**

The medical causes of stroke occur in younger patients and are associated with cardiac disease, autoimmune vasculitis,

infection, mitochondrial deficits or clotting factor dysfunction. Dissection from trauma or in association with collagen vascular disease and migraine is also common. Specific diseases such as cerebral autosomal dominant arteriopathy with subcortical infarction and leukoencephalopathy (CADASIL), hereditary endotheliopathy, neuropathy, renal disease and stroke (HERNS) as well as mitochondrial disease and named diseases such as Susac, Eales, Sneddon's, Cogan's and Grönblad–Strandberg disease, all test the diagnostic acumen of the examiner. Clotting disorders of deficiency, inhibition of activated coagulation factors or hereditary fibrinolytic defects are AD, AR or acquired. The examiner needs to elicit the seminal characteristic of each entity to diagnose the category of medical illness and then the specific disease.

Genetic causes of embolic stroke are:

1. Mitral valve prolapse – autosomal dominant
2. Tuberous sclerosis – autosomal dominant
3. Familial atrial myxoma (autosomal dominant and recessive)
4. Hereditary cardiac conduction defects (long QT) – autosomal dominant
5. Hereditary cardiomyopathies (autosomal dominant and recessive, X-linked)
6. Mitochondrial disease (maternal inheritance)

Mitral valve prolapse has a prevalence rate of 5–21% in the population. It occurs occasionally in an AD form and rarely causes a cerebral embolus. Auscultation reveals a mid-systolic murmur and 2D-ECHO cardiography determines greater than 2 mm or more abnormal movement of the anterior or posterior leaflets.

Tuberous sclerosis patients are easily diagnosed by their characteristic skin manifestations, seizures and mental retardation. Rhabdomyosarcoma may be the cause of cerebral emboli and is autosomal dominant.

Hereditary long QT syndrome most frequently presents with syncope especially provoked by drugs that decrease cardiac conduction or with rare sudden death during strenuous athletics.

Hereditary cardiomyopathies with a dilated myocardium occur in mitochondrial disease, limb-girdle muscular dystrophy, congenital myopathies, Duchenne's MD, Becker's MD, and myotonic dystrophy. All of these entities have characteristic physical findings such as proximal weakness, calf hypertrophy, contracture of elbows, arms and ankles (Emery-Dreifuss muscular dystrophy) and rigid spine syndrome.

Mitochondrial disease should be suspected in short patients who suffer undue fatigue with exercise, sensorineural hearing loss, diabetes and dilated cardiomyopathy.

Atrial myxomas with emboli may present with fevers of unknown origin, petechiae across the chest wall, pial vessel emboli and peripheral cerebral aneurysms that bleed (myxomatous material grows through the walls of the affected arteries).

Genetic causes of thrombotic stroke are:

1. CADASIL

2. CARASIL
3. Fabry's
4. HANAC
5. HERNS
6. PADMAL
7. Hereditary infantile stroke
8. Ehlers-Danlos disease type IV
9. Marfan's disease
10. PXE (Pseudoxanthoma elasticum)
11. Mitochondrial diseases
12. Homocysteinemia
13. Neurofibromatosis
14. Menke's disease
15. Retinal diseases (HERNS, HANAC, Susac's disease, CRV)
16. Moyamoya
17. Progeria
18. Dyslipoproteinemias such as Tangier disease (orange tonsils, alpha hypolipoproteinemia and intermittent neuropathy)
19. Hemoglobinopathies particularly sickle cell disease which has conjunctival telangiectasis and arachnodactyl. Neurofibromatosis type I has characteristic coast of Maine hyperpigmented lesions and abnormalities of the renal vasculature

Clotting disorders secondary to polycythemia vera cause strokes primarily in the posterior circulation and tend to thrombose large cerebral vessels. Retinal venous occlusion in coagulopathies from clotting factor inhibitor deficiency is characteristically seen in young patients whose parents have had fetal wastage. Protein losing enteropathy, nephrotic syndrome and migraine with aura are all associated with stroke. Protein S deficiency and stroke occurs in middle aged women. Protein C deficiency often occurs concomitantly with the Factor V Leiden mutation. Antithrombin III deficiency should be suspected in the setting of severe resistance to heparin anticoagulation. Anticardiolipin antigen and lupus anticoagulant often are associated with migraine with visual aura. Cerebral sinus thrombosis is common in all defects of inhibitors of clotting.

Platelet abnormalities and stroke should be suspected in a setting of petechiae particularly of the lower extremities. The primary antiphospholipid antibody syndrome is associated with spontaneous abortion and fetal wastage. Valve cusps are affected and the syndrome may be associated with cerebral emboli. The lupus anticoagulant is an antibody to phospholipids (on platelets) which blocks the formation of the prothrombin activator and is most often associated with clotting and not hemorrhage (depends on titer). There is usually evidence of systemic venous clotting.

In general, platelet counts of greater than one million/mm³ are associated with hypercoagulability. Functional platelet abnormalities rather than absolute number may be the important parameter. This may occur in a small group of migraine patients and in essential thrombocythemia.

Heparin induced thrombocytopenia and thrombosis occurs as a transitory and asymptomatic reduction in platelet count or as an immunopathologic condition. The later (Type II) usually occurs after the 5th day of treatment and causes both arterial and venous thrombosis. Gangrene of a limb, thrombosis and stroke is the usual triad. White clots are noted in blood vessels (particularly visible in the retina).

Disseminated intravascular coagulation occurs in a setting of gram negative sepsis, cancer and obstetrical emergency. It is announced by oozing from all venipuncture sites and acrocyanosis. Arterial and venous clotting as well as hemorrhage dominates the clinical profile.

The following discussion highlights the major characteristics and differential features of the genetic causes of embolic and thrombotic stroke, coagulopathies and rheological abnormalities that are seen in clinical practice.

Genetic Causes of Embolic Stroke

General Characteristics

1. Mitral valve prolapse (MVP) – AD
 - a. Associated with:
 - i. Osteogenesis imperfecta
 - ii. Ehlers-Danlos syndrome
 - iii. Marfan's disease
 - iv. Duchenne's muscular dystrophy
 - v. Becker's muscular dystrophy
 - vi. von Willebrand's disease
 - vii. Fragile X syndrome
2. Tuberous sclerosis – AD
 - a. Cardiac rhabdomyomas that cause emboli
 - b. 80% are new mutations
 - c. Abnormalities of cerebral arteries and aorta also occur
3. Familial atrial myxoma (AD, AR)
 - a. AD/AR forms; most atrial myxomas are sporadic
 - b. 20% of familial atrial myxomas are associated with an AD heredity
 - c. Also associated with:
 - i. Myxoid fibroadenoma
 - ii. Lentiginous blue nevi
 - iii. Large cell calcifying Sertoli cell tumors
 - iv. Primary adrenocortical nodular dysplasia
4. Pituitary growth hormone tumors
5. Hereditary cardiac conduction defects (long QT) AD
6. Hereditary cardiomyopathy AD, AR, X-linked
7. Mitochondrial disease (maternal inheritance)

Hypertrophic Cardiomyopathy (HCM)

General Characteristics

1. Most common genetic cardiovascular disease affects 1 in 500 in the general population
2. Autosomal dominant; 24 genes identified (encode sarcomeric proteins)
 - a. Myocyte disarray which leads to premature death and remodeling

- b. Pathologies include hypertrophy, fibrosis, myocardial ischemia and coronary artery disease
- c. Dispersion of repolarization due to gap junction dysfunction that leads to:
 - i. Supraventricular arrhythmias (10–40% in hypertrophic cardiomyopathy)
 - ii. Atrial fibrillation is most common
3. Can occur at any age: annual mortality rate of 1%

Clinical Manifestations

1. Many patients are asymptomatic
2. Dyspnea in 90%
3. Exercise intolerance
4. Presyncope/syncope (often associated with arrhythmia)
5. Atrial fibrillation and ventricular tachycardia presentations
6. Sudden death

Cardiac Dysrhythmia with Emboli

Idiopathic Hypertrophic Subaortic Stenosis (IHSS)

General Characteristics

1. Syncope after exercise
 - a. Norepinephrine constricts the subaortic outlet; epinephrine dilates blood vessels in skeletal muscle. Severe hypotension results after strenuous exercise due to dilation of blood vessels from release of epinephrine in skeletal muscle
2. Atrial fibrillation occurs late in the course of the illness
 - a. Emboli during the arrhythmia
3. Females at greater risk than males for stroke
4. Hypertension a cause of stroke
5. Other stroke mechanisms:
 - a. Associated mitral annulus calcification
 - b. AV conduction defect

Dilated cardiomyopathy (DCM) with Arrhythmias

General Characteristics

1. DCM with and without conduction-system disease
2. Familial DCM with CSD (conduction syndrome) chromosome 1 p1-q21
3. X-linked dystrophinopathy (Becker's; Duchenne)
4. Female carrier of Becker's MD and Duchenne's MD
5. Sporadic and AR limb-girdle muscular dystrophy (2C–2F)
6. Emery-Dreifuss Muscular Dystrophy (severe arrhythmias that requires pacing)
7. Myotonia type I, LGMD 1b
8. Adhalinopathies
9. Barth syndrome
10. Rigid Spine syndrome
11. Welander's distal myopathy
12. Distal vacuolar myopathy
13. Systemic carnitine deficiency

Genetic Enzymatic Causes of Thrombotic Stroke

Hyperhomocysteinemia

General Characteristics

1. Enzymatic deficiencies of methionine metabolism that produce homocysteine. Its intracellular metabolism is complex and sequential:
 - a. Transsulfuration to cysteine
 - b. Remethylation to methionine
 - c. Homocysteine is catabolized to cystathionine by:
 - i. Pyridoxine dependent condensation with serine
 - ii. Cystathionine β -synthase catalyzes the first step in transsulfuration
 1. Deficient in classic homocystinuria
 - d. Mechanisms of hyperhomocystinuria:
 - i. Hereditary defects in enzymatic pathways
 - ii. Deficiencies of vitamin cofactors
 - e. Major enzyme deficits are:
 - i. Cystathionine β -synthase (pyridoxine dependent)
 - ii. Methylene tetrahydrofolate reductase
 - iii. Methionine synthase (MTHFR and cobalamin needed as cofactors)
 - f. Homocysteine elevation also occurs with:
 - i. Age
 - ii. Smoking
 - iii. Deficiency of B12, B6 or folic acid
 - iv. Specific drugs (statins, niacin, metformin, levodopa, antihypertensives, some oncologic agents and theophylline)
 - g. Incidence is 1:83,000 in the general population
 - h. Most common enzyme deficiency is:
 - i. Cystathionine β -synthase (24 mutations identified)
 1. Chromosome 21
 2. Homozygosity for homocystinuria is between 1.5%–3% in the general population

Clinical Manifestations

1. Presentation:
 - a. Peripheral venous thrombosis (most common)
 - b. Myocardial infarction
 - c. Cerebrovascular disease
2. Marfanoid habitus
3. Cognitive impairment
4. Livedo reticularis
5. Malar flush
6. Dislocated lenses in one or both eyes
7. Myopia
8. Glaucoma
9. Optic atrophy (rare)

Neuropathology

Stroke Mechanisms

1. Artery-to-artery embolism
2. Arterial dissection
3. Carotid artery disease
 - a. Dilation and medial wall damage rather than atherosclerosis

Putative Pathogenesis of Stroke Due to Elevated Homocysteine

1. Accelerated atherosclerosis
2. Arterial dilation
3. Increased:
 - a. Tissue factor expression
 - b. Platelet reactivity
 - c. Thrombin generation
 - d. Factor V activity
 - e. Monocyte chemotactic protein-I (MCP-1)
 - f. IL-8 (expression in vascular smooth muscle)
4. Decreased:
 - a. Fibrinolysis
 - b. Endothelial function
 - c. Thrombomodulin
 - d. Heparin sulfate
5. Homocystinuria may lead to a prothrombotic state

Recent Concepts

1. Lowering homocysteine by B group vitamin supplementation does not reduce cardiovascular risk; suggested that homocysteine levels are a “concomitant” marker rather than pathogenic
2. Elevated plasma homocysteine causes:
 - a. Reduced methylation potential
 - i. Due to decreased S-adenosyl-methionine (Adn Met)/S-adenosyl homocysteine (Ado Hcy) ratio
 - ii. Mechanism for CVD:
 1. Dependent on DNA methylation (epigenetic regulation) that induces inhibition of cyclin A transcription
 2. Leads to decreased endothelial cell growth

Neuroimaging

1. Small vessel disease of the brain
2. Large vessel disease of the cerebral arteries
3. Angiography

Methylenetetrahydrofolate Reductase (MTHFR)

General Characteristics

1. Autosomal recessive: located on chromosome 1P
2. Critical for the metabolism of folic acid and methionine
3. Prevalent in North Americans:
 - a. 50% are heterozygous for a thermolabile mutation
 - b. MTHFR mutation C6771 homozygous polymorphism:
 - i. Causes hyperhomocysteinemia and increases stroke risk

Clinical Manifestations

1. Congenital form:
 - a. Global developmental delay: failure to thrive
 - b. Seizures
 - c. Cardiovascular manifestations occur with age
2. Adult form
 - a. Possible increase in ischemic stroke

Neuropathology

1. Accelerated atherosclerosis
2. Small vessel disease

Neuroimaging

1. Small vessel disease
2. Topographic pial vessel stroke

Laboratory Evaluation

1. Low CSF folate and plasma methionine levels
2. No megaloblastic anemia

Organic Acidemias*Propionic Acidemia***General Characteristics**

1. An organic acidemia
2. Deficit of the enzyme propionyl-coenzyme A carboxylase (a mitochondrial enzyme)

Clinical Manifestations*Childhood Form*

1. Developmental delay
2. Episodic severe acidosis/encephalopathy triggered by infection or metabolic decompensation
3. Hyperammonemia
4. Visual hallucination
5. Movement disorder
6. Seizures
7. Central nervous and optic nerve involvement
8. Cognitive deficits
9. Metabolic stroke-like episodes

Adult Form

1. Progressive cognitive decline
2. Cardiac and G.I. dysfunction
3. Stroke-like episodes

Neuroimaging*MRI Evaluation*

1. Basal ganglia infarction (caudate, G.P., putamen)
2. Subcortical white matter demyelination
 - a. Often periventricular
3. Metabolic pattern dysfunction not in a vascular territory

MRS (Spectroscopy)

1. Decreased basal ganglia glutamate and glutamine
2. Decreased N-acetyl-aspartate (neuronal death)
3. Increased lactate
4. Indicative of switch to anaerobic metabolism

Neuropathology

1. Bio-energetic stroke
 - a. Deficits in Krebs cycle and respiratory chain function

*Methyl Malonic Aciduria (MMA)***General Characteristics**

1. Incidence is about 1:250,000 newborns

2. Inborn error of metabolism

3. May be seen in adults and is associated with B12 metabolism deficits

Clinical Manifestations*Neonates*

1. Retinopathy
2. Hydrocephalus
3. Microcephaly
4. Metabolic stroke
5. Seizures (children)

Adult Presentation

1. Subacute bilateral visual loss
2. Basal ganglia involvement

Neuropathology

1. Megamitochondria demonstrated in the kidney
2. Deficiency of methylmalonyl CoA mutase
3. Metabolic stroke

Neuroimaging*MRI Evaluation*

1. Bilateral globus pallidus (acute infarction) in all patients
2. Lacunar infarcts in pars reticulata of the substantia nigra

Laboratory Evaluation

1. Gas chromatograph-mass spectroscopy (GC-MS)
 - a. Methylmalonic acid demonstrated

*Glutaric Aciduria (Acidemia) Type I***General Characteristics**

1. Glutaryl-CoA dehydrogenase is the deficient enzyme; on the short arm of chromosome 19; Autosomal recessive
2. Mitochondrial nuclear enzyme defect
3. Incidence of 1:30,000 people

Clinical Manifestations*Presentation in Infancy*

1. Macrocephaly
2. Hypotonia/jitteriness/tremor
3. Fever of unknown origin; hyperhidrosis
4. Seizures
5. Coma
6. Metabolic crisis:
 - a. Precipitated by fever and dehydration
 - b. Leads to striatal necrosis

Adult Clinical Presentation

1. Majority of patients present as dystonic cerebral palsy with basal ganglia involvement; baseline axial hypotonia occurs with time
2. May evolve to rigid – Parkinsonian syndrome
 - a. Oral-facial involvement is prominent

Neuroimaging*MRI Evaluation*

1. Frontal temporal atrophy

2. Delayed myelination pattern
3. Increased T2-weighted sequence hyperintensities in the periventricular white matter and U-fibers
4. Ventriculomegaly
5. Subdural hygromas
6. Putamen may be involved solely or with:
 - a. Caudate and globus pallidus
 - b. Thalamus and dentate

Laboratory Evaluation

1. Accumulation of glutamic acid (GA) and 3-hydroxy glutamic acid (3-OHGA)

Neuropathology

1. Metabolic-mediated neuronal damage:
 - a. Excitotoxicity
 - b. Failure of energy production
 - c. Oxidative stress
2. Glutaric acid and 3-hydroxyglutaric acid (3-OHGA) accumulate:
3. During a metabolic crisis
4. Failure of BBB transport mechanism
5. Excretion of glutaryl carnitine may lead to secondary carnitine deficiency

Glutaric Aciduria (Acidemia) Type II

General Characteristics

1. Multiple acyl-CoA dehydrogenase deficiencies that cause electron transfer flavoprotein deficiencies
2. Neonatal, infantile, childhood and later onset forms

Clinical Manifestations

1. Vomiting
2. Hypoglycemia
3. Metabolic acidosis
4. "Sweaty feet" odor
5. Seizures
6. Aphasia
7. Myoclonus
8. Stroke-like episodes
9. Cyclic vomiting
10. Facial dysmorphism

Late Onset Phenotype

1. May present as proximal myopathy (increased fat in muscle)
2. Cyclic vomiting

Neuroimaging

MRI Evaluation

1. Increased T2-weighted signals in the putamen, middle cerebellar peduncle and splenium of the corpus callosum
2. Periventricular white matter hyperintensities in T2-weighted sequences

Pathology

1. Gliosis and heterotopias in the brain
2. Associated polycystic kidney
3. Genital defects

Laboratory Evaluation

1. Urinary excretion of organic acids

Ornithine Transcarbamylase Deficiency

General Characteristics

1. X-linked recessive; Xp21.1
2. The most common inherited cause of hyperammonemia secondary to ammonia cycle dysfunction

Clinical Manifestations

1. Severe neonatal form in males
2. Partial form in males and females
3. Late onset form

Neonatal and Infantile Forms

1. Developmental delay
2. Recurrent hyperammonemia
3. Encephalopathy
4. Coma
5. Female patients are often asymptomatic

Late Onset

1. Reported in patients taking valproic acid
2. In women heterozygous for the mutations during the postpartum period

Neurologic Features

1. Developmental delay
2. Seizures
3. Autistic signs
4. Hyperactivity (ADHD)
5. Ataxia
6. Dysarthria
7. Hyperammonemic crisis with stress

Cerebrovascular Signs and Symptoms

1. Recurrent stroke-like episodes
2. Cerebral ischemic infarction (rare)
3. Intracranial hemorrhage (rare)
4. Cerebral edema

Neuropathology

1. Similar to the changes of hepatic encephalopathy
2. Affects predominately white matter and astrocytes

Laboratory Evaluation

1. Unexplained hyperammonemia in an adult
2. Allopurinol challenge that induces an increase of orotate in the urine
3. Gene identification

*Neuroimaging***MRI**

1. As the severity of the illness increased:
 - a. Peri-insular white matter involvement progresses to the frontal, parietal, temporal and occipital lobes
 - b. Stroke-like episodes compatible with “bio-energetic failure”

MRS

1. Increased gln levels in frontal white matter
2. Decreased myoinositol in frontal white matter

Fabry's Disease*General Characteristics*

1. X-linked disorder of glycosphingolipid metabolism
 - a. A deficiency of lysosomal alpha-galactosidase A that leads to:
 - i. An accumulation of neutral glycosphingolipids – predominantly globotriaosylceramide in the lysosomes of endothelial and smooth muscle cells in blood vessels
 - ii. Common polymorphisms in the genes for angiotensinogen (AGT), AGT promoter and angiotensinogen II receptor type I (AGTRI)
 1. AGT promoter and AGTRI genotypes are noted in Fabry's phenotypes in .6% of high risk populations
2. Prevalence 1:40,000 males
3. Heterozygous patients present with no symptoms or a milder disease
4. Heterozygous females:
 - a. Asymptomatic or a milder disease phenotype
 - b. Occasionally they are as symptomatic as males
5. Cerebrovascular manifestations are common in both hemizygote and symptomatic heterozygote groups
 - a. 4% of cryptogenic strokes may have mutations in the α -galactosidase gene

*Clinical Manifestations***General Neurologic Features**

1. Early in the disease course:
 - a. Episodic crises of severe neuropathic pain
 - i. Precipitated by exercise and often associated with fever
2. Minute to hour duration
3. Primarily acroparesthesias
4. Heat intolerance
 - a. Autonomic dysfunction with anhidrosis (infiltration of ceramide trihexoside in the autonomic ganglia and the autonomic fibers to sweat glands)

General Signs and Symptoms

1. Heterozygous males

- a. Angiokeratomas (cherry red papules); periumbilical area, extensor surfaces of elbows and knees and genitals (bathing suit distributions)
- b. Corneal and lenticular opacities
- c. Dilatation and tortuosity of conjunctival vessels
- d. Retinal vessel abnormalities
- e. Hypohidrosis (with heat intolerance)
- f. Cardiac dysfunction
- g. Renal failure
2. Heterozygote females
 - a. Lumbosacral degeneration
 - b. Asymptomatic
 - c. Some signs/symptoms similar to male patients
3. Cerebrovascular disease
 - a. Male hemizygotes
 - i. Ischemic strokes in the fourth decade
 - ii. Anterior and posterior circulation involvement; posterior circulation more frequently involved than anterior
 - iii. Small vessel disease
 - iv. Cause of vascular dementia for patients less than 65 years old
 - b. Heterozygote women
 - i. Cerebrovascular symptoms a decade later than males
 - ii. 50% involvement in vb system; 10% certain carotid involvement
 - iii. Headaches greater than seen in males
 - iv. Central retinal vein occlusion
 - c. Greater involvement of posterior circulation whose putative mechanisms are:
 - i. VB dolichoectasia
 - ii. Thickening and luminal compromise of medium and small arteries
 - iii. Deep small cerebral infarcts
 - d. Cardiogenic embolism
 - i. Coronary artery disease (left ventricular wall dysfunction)
 - ii. Valvular heart disease (mitral valve)
 - iii. Mitral valve prolapse
 - iv. Hypertrophic cardiomyopathy (especially in heterozygote women)
 1. Often associated with AF
 2. Occurrence in women greater than men
 - e. Carotid artery atherosclerotic plaque
 - i. Less than controls
 - ii. Greater intima to media thickness
 - f. Orthostatic hypotension due to ANS dysfunction
 - g. Prothrombotic state:
 - i. Activation of platelets by endothelial dysfunction due to deposition of glycosphingolipids
 - ii. Endothelial cell dysfunction with increased
 1. Soluble intercellular adhesion factors-1
 2. Vascular cell adhesion molecule-1
 - iii. P-selection (increased)

- iv. Plasminogen activator inhibitor (increased)
- v. Integrin CD11b increased
- vi. Decreased thrombomodulin
- vii. Approximately 35% of patients have factor V Leiden mutations
- h. Intrinsic vascular abnormalities:
 - i. Down-regulation of nitric oxide pathway
 - ii. Increase oxidative stress which leads to:
 - 1. Accelerated atherosclerosis
 - 2. Vasodilatation
 - i. Intracranial arterial dolichoectasia causes:
 - i. Neurovascular compression syndromes
 - ii. Triventricular hydrocephalus
 - iii. Isolated III, V, VIII, XIIth nerve palsy by compression from basilar of vertebral arteries
 - iv. IIInd cranial nerve compression from dolichoectatic supraclinoid carotid arteries
 - v. Putative mechanism:
 - 1. Deposition of glycosphingolipids in the lysosomes of the smooth muscle of arterial walls
 - 2. Possible cause of ICH (loss of structural integrity of vessel walls)
 - a. Hypertension from concurrent renal vessel disease
 - b. Both hemi- and heterozygotes

Neuropathology

Cerebrovascular Pathology

1. Infarcts of:
 - a. Superficial hemispheric pial arteries
 - b. Small deep perforating vessels
 - c. Brainstem and cerebellum
2. Rare intracerebral hemorrhage
3. Narrowing of lumen secondary to glycosphingolipid deposits in lysosomes of both endothelial cells and smooth muscle of the arterial wall

Neuroimaging

MRI

1. Superficial territorial and deep perforating artery infarction of the hemispheres and brainstem and cerebellar blood vessels
2. Dolichoectasia of the basilar and vertebral arteries
3. Small vessel disease pattern in patients older than 54 years
4. Approximately one third of younger patients may have no lesions

MRS (Magnetic Resonance Spectroscopy)

1. NAA/creatine and phosphocreatine and are decreased
 - a. Suggestive of neuronal loss

Dyslipoproteinemias – Tangier Disease

General Characteristics

1. Familial hypoalphalipoproteinemia

- a. Autosomal recessive
- b. Due to mutations in both alleles of the ABCA1 gene
 - i. ABCA1 protein transports cellular cholesterol and phospholipids to the extracellular acceptor free apoA-1 to form high density lipoprotein (HDL)

Clinical Manifestations

1. Peripheral neuropathy occurs in approximately 50% of patients
 - a. Remitting relapsing multifocal neuropathy with sensory abnormalities
 - b. Sphingomyelia like neuropathy
 - i. Muscle wasting and anesthesia involve the face and upper extremities prior to spread to the lower extremities
 - 1. Putative neuropathy of the dorsal roots
 - c. Enlarged orange tonsils
 - d. Hepatosplenomegaly
 - e. Premature atherosclerosis with topographical stroke

Neuropathology

1. Hyperplastic foam cells
 - a. Inability to efflux cholesterol by the ABCA1 transporter
2. Lipid-laden cells to the reticuloendothelial system cause both the tonsillar enlargement on the hepatosplenomegaly
3. Premature atherosclerosis
 - a. Early coronary heart disease
 - b. Topographical stroke
4. Recurrent lobar intracerebral hemorrhage
5. Accumulation of cholesterol esters in many tissues

Neuroimaging

1. Recurrent lobar intracerebral hemorrhage
 - a. Demonstrated cerebral microbleeds
2. Large vessel stroke

Laboratory Evaluation

1. HDL less than 5mg/dL
2. Low plasma cholesterol – less than 150mg/dL
3. High plasma triglycerides

Genetic Cause of Thrombotic Stroke Overview

The genetic causes of stroke overlap with diseases of the vessel wall, coagulopathies, autoimmune, infectious diseases, enzyme deficiencies, mitochondrial disease, hemoglobinopathies and specific small vessel diseases.

Homocysteinemia, the glutaric acidurias, MMA, MTHFR and ornithine transcarbamoylase deficiency have been discussed primarily as enzymatic causes of thrombotic stroke. CADASIL, CARASIL and Fabry's are discussed primarily as causes of small vessel disease. Mitochondrial diseases fit many categories but are best classified as due to "bioenergetic failure".

This chapter will concentrate on those genetic causes of stroke with many systemic features. It will focus on Marfan's disease, pseudoxanthoma elasticum (PXE), Ehlers-Danlos, neurofibromatosis, progeria, Menkes disease and Moyamoya syndrome.

Marfan's Syndrome

General Characteristics

1. Connective tissue disorder that is system wide:
 - a. Skeleton and skin abnormalities
 - b. Cardiovascular system (aortic root dilation)
 - c. Lens dislocation and myopia
 - d. Lung involvement (emphysema)
 - e. MASS – myopia, mitral valve prolapse, aortic dilatation, skin and skeletal abnormalities

Genetics

1. Autosomal dominant; sporadic in about 25% of patients
 - a. Chromosome 15: mutation in the FBN1 gene that encodes fibrillin-1
 - b. Possible second locus:
 - i. 3p24-25
 - ii. Possible mutations in genes coding for TGF- α (important for angiogenesis)
 - c. Fibrillin-1
 - i. Major component of the extracellular matrix; the fibrillary structure for elastin deposition
 - d. Diagnosis requires a major criteria in two organ systems and involvement in a third

Clinical Manifestations

1. Dissection of the ascending aorta, the carotid and vertebral arteries
 - a. Arch dissection: pain in the face and carotid artery stroke
 - b. Dissection below the subclavian artery – pain straight through to the back with paraplegia
 - c. An excess of cerebral aneurysm but not subarachnoid hemorrhage
2. Emboli:
 - a. Cardiac arrhythmia
3. Spinal defects:
 - a. Craniospinal junction
 - i. Greater than 50% of patients have increased atlantoaxial translation (greater than 5 mm with neck flexion) causes odontoid compression of the spinal cord
 - ii. 36% have basilar impression (greater than 135° angle between the planum sphenoidale and the clivus)
4. Ectasia of the dural sac with irritation of lumbosacral nerve roots and back pain
5. Laryngeal nerve paralysis from aortic compression of the recurrent laryngeal nerve
6. Severe scoliosis
7. Multiple facial anomalies with retrognathia
8. Congenital ectopia lentis (may be the most specific finding)

Neuropathology

1. Defect is primarily in the vessel media with profound diminution of elastic fibers

Neuroimaging

1. Embolic stroke of cerebral vessels
2. Intracranial artery dissection
3. Arterial (cerebral) tortuosity and aneurysm
4. Dilatation of the aortic root

Differential Diagnosis

1. Homocystinuria
 - a. Mental retardation
 - b. Autosomal recessive
2. Congenital contractural arachnodactyly (Beals syndrome)
 - a. Marfanoid features; Autosomal dominant
 - b. Heart defects
 - c. Ocular defects
3. Loeys-Dietz syndrome
 - a. Transforming growth factor β receptor
 - i. 11(TGBRA) gene mutation
 - ii. Arterial tortuosity and aneurysms
 - iii. Hypertelorism
 - iv. Bifid (bifurcated) uvula/cleft palate

Pseudoxanthoma Elasticum (PXE) (Grönblad–Strandberg Syndrome)

General Characteristics

1. Female predominance (2:1)
2. Mutations in the ABCC6 gene on the short arm of chromosome 16 (16p13.1); Autosomal dominant and recessive forms; Autosomal dominant form possibly has more severe vascular disease
3. ABCC6 gene encodes:
 - a. Multi-drug resistance associated protein 6 a trans membrane transporter protein of the ABC (ATP binding cassette) family
 - b. β – Thalassemia patients have high prevalence of PXE

Clinical Manifestations

1. Systemic Signs
 - a. Additional eye signs
 - i. Choroid retinal atrophy
 - ii. Subretinal edema
 - iii. Pattern dystrophy-like changes
 - iv. Retinal drusen
2. Heart
 - a. Premature coronary artery disease
 - i. Sudden death
 - ii. Cardiomyopathy
 - b. Endocardial changes (elastic fiber changes)
 - i. Thickened mitral valves
 - ii. Mitral stenosis; MVP
 - iii. Restrictive cardiomyopathy (calcification of the endocardium)

3. GI tract
 - a. Gastrointestinal hemorrhage
 - i. Often the presenting symptom
 - ii. Degeneration of small-sized arteries
 - iii. Microaneurysms and angiomatous malformations
4. Skin: linear, round or oval yellow orange elevated lesions (resemble xanthomas)
 - a. Face, neck, axilla, inguinal, umbilical topography
 - b. Late stage – lax and redundant skin
 - c. Involvement of skin and mucosa in:
 - i. Lips
 - ii. Mouth
 - iii. Vagina
 - iv. Rectum
 - d. Gastric mucosa
 - e. Endocardium and heart valves
5. Eye involvement
 - a. Classic
 - i. Angioid streaks
 1. Red, brown or gray
 2. Wider than veins
 3. Radiate from the disc
 - ii. Rupture of Bruch's membrane (a thin membrane separating the blood vessel-rich layer from the pigmented layer of the retina)
 - b. "Peau d'orange" (a French term meaning that the retina resembles the skin of an orange)
 - c. Chorioretinal scarring and hemorrhage
 - d. Optic nerve infarction
 - i. Involvement of the posterior ciliary arteries
 - ii. Comet bodies

Cerebrovascular Disease in PXE

1. Hypertension
2. Aneurysmal dilation of the aorta
3. Calcification of peripheral arteries with intermittent claudication
4. Occlusive cervicocranial arterial disease; intra- and extracranial
5. Subarachnoid hemorrhage
6. Carotid artery
 - a. Increased thickness; more elastic with increased intimal-medial thickness
 - b. Tortuosity and ectasia
7. Ischemic symptoms develop in the 5th and 6th decades
8. Concomitant pathology of hypertensive cardiovascular disease
 - a. ICH
 - b. Lacunar infarction
 - c. Microvascular disease (Binswanger)
9. Aneurysm formation and SAH
 - a. Cavernous sinus
 - i. May present with cranial nerve palsy rather than SAH
10. Possibly increased incidence of dissection

Neuroimaging

1. Occlusive cervicocranial disease that is intra- or extracranial
2. Tortuosity and ectasia of cervical arteries
3. Lacunar infarction
4. Microvascular disease
5. Hyperintensive changes

Neuropathology

1. Decreased calcium extracellular homeostasis
2. Loss of elastic tissue, fragmentation of the internal elastic membrane; calcifications between the intima and media

Differential Diagnosis of Identified Genes for Arterial Calcification

1. ENPPI
2. ABCC6 (PXE)
3. NTSE
4. SLC20A2
5. CD73 deficiency

Differential Diagnosis of Angioid Streaks

1. Sickle cell anemia
2. Paget's disease
3. Hypophosphatemia
4. Ehlers-Danlos syndrome
5. Lead poisoning
6. PXE
7. ITP
8. Trauma
9. Pituitary disease

Differential Diagnosis of Arterial Calcification

1. Aging
2. Diabetes mellitus
3. Chronic kidney disease
4. Generalized arterial calcification of infancy
5. PXE
6. Familial idiopathic basal ganglia calcification

Moyamoya Syndrome

General Characteristics

1. Prevalence in asymptomatic Japanese population is 50.7/100,000 people
 - a. Patients in Northeast Asia have genetic disease and not syndrome
 - b. Two peak ages:
 - i. Children younger than 14 years
 - ii. Young adults between 25–49 years
 - iii. Japanese female to male ratio is 1.6- to 1.8: 1
 - c. Genetics
 - i. AD with incomplete penetrance
 - ii. Complex chromosome rearrangements at 6p25.3; variant RNF 213c14576G7A
 - iii. Genetic form is more common in children

*Clinical Manifestations**Cerebrovascular Disease in Adults*

1. Recurrent stroke or TIA is a common presentation
 - a. Border zone territorial stroke between MCA/ACA and MCA/PCA
2. Infarctions in the cortex, deep hemispheric white matter or basal ganglia
3. Progressive ischemic frontal lobe syndrome occurs with behavioral changes
4. Brainstem strokes are rare
5. Less frequent: headache and seizures than in children
6. May present with ICH
 - a. Asymptomatic microhemorrhages
 - b. Recurrent hemorrhages are frequent
 - c. Pathogenesis of hemorrhages can be rupture of collateral blood vessel, small false aneurysm or vascular malformation
 - d. Hemorrhages
 - i. More frequent in 46–55 year old patients
 - ii. Intracerebral in 60% (BG and thalamus)
 - iii. Intraventricular in 30%
 1. Extension from the thalamus
 2. Direct from the caudate
 - iv. Deep penetrating arteries
 1. Degenerative changes; hypertrophied
 2. Develop microaneurysms
 3. Small asymptomatic hemorrhages in the paraventricular white matter, subcortex
 - v. Rare: SAH; high incidence of posterior circulation aneurysm
 1. Small false aneurysms along the ventricular surface and Moyamoya collaterals are a source of SAH
 - vi. A unilateral process is against Moyamoya disease

Neuroimaging

1. There are six angiographic stages from narrowing of the distal ICA (stage I to the cerebral circulation supply from meningeal pial collaterals of the external carotid)
2. Collaterals from the ethmoidal arteries
3. Intracranial saccular aneurysms: posterior > anterior circulation
 - a. Arise at arterial bifurcations

MRI

1. Infarctions are primarily in deep hemispheric nuclei and hemispheric white matter
2. Border zone topography infarction primarily between ACA/MCA
3. Dilated leptomeningeal and transdural collateral arteries

Neuropathology

1. Bilateral severe stenosis or occlusion of the terminal ICA and proximal ACA and MCA; can affect the PCA; superficial temporal artery and the middle meningeal artery

Microscopic Evaluation of Large Intracranial Arteries

1. Thickening of the intimal and medial layers
2. Proliferation and degeneration of smooth muscle cells
3. Fragmentation of the internal elastic membrane
4. No inflammatory, calcification or lipid droplets
5. Ethmoidal collaterals involve the frontal basal areas, vault and Moyamoya vessels are collaterals (a generalized vascular network)
6. Collaterals develop from external carotid artery as well as the thalamoperforators, the dorsal branches of the PCA, tectal plexus and posterior choroidal vessels
7. Associated with a greater number of illnesses

Menkes Disease*General Characteristics*

1. Mutations in the ATP7A gene on the long arm of the X chromosome (xq12-q13)
2. P-type ATP protein that is encoded functions to translocate metal cations across cellular membranes; transports copper to those enzymes that require it
3. ATP7A mutations also cause:
 - a. Occipital horn disease
 - b. Distal hereditary motor neuropathy
4. Patients have low copper levels in the brain
5. Signs and symptoms are due to deficiencies of Cu^{2+} dependent enzymes such as ceruloplasmin; superoxide dismutase; dopamine β -hydroxylase (DBH)

*Clinical Manifestations**Neurologic Signs and Symptoms*

1. Classic presentation:
 - a. Neonatal
 - i. Hypothermia
 - ii. Poor feeding
 - iii. Failure to thrive
 - iv. Seizures
 - b. Scalp hair
 - i. Twisted, colorless, friable
 - ii. Fractures of the hair shaft at regular intervals
2. Severe tortuosity of blood vessels
3. Long bone-metaphyseal spurring and a diaphyseal periosteal reaction
4. Hydronephrosis; bladder diverticula

*Neuroimaging***MRI**

1. Vascular tortuosity
2. Cerebral atrophy
3. Infarcts of deep gray matter and the cortex
4. Asymptomatic subdural hematoma

Pathology

1. Tortuous arteries
 - a. Irregular lumen

- b. Split intimal lining
- c. Non sulfate and sulfate chondroitin are deposited within elastin fibers
 - i. Poor elastin formation and cross linking
 - ii. Dysfunction of copper dependent lysyl hydroxylase
 - iii. Focal degeneration of gray matter with gliosis
 - iv. EM demonstrates increased mitochondria in Purkinje cells and cortical neurons

Progeria

General Characteristics

1. Characterized by premature aging
2. Childhood form: Hutchinson-Gilford progeria syndrome (HGPS)
3. Adult Progeria: Werner's syndrome
4. Several progeria-like syndromes have been defined genetically and clinically

Genetics

1. Genetics of progeria and progeroid syndromes
 - a. Progeria is caused by mutation of the LMNA gene that encodes lamins A and C
 - i. Lamins are nuclear intermediate filaments; their basic nuclear functions are:
 1. Chromatin organization
 2. DNA replication
 3. Transcription
 4. Cell cycle progression
 - ii. Cell lines from HGPS demonstrated lack of transcriptional deregulation due to:
 1. Lack of functional lamin A
 2. Progerin acceleration
 3. Lamin β 1 silencing
 - iii. Progerin is a truncated version of the lamin A protein that has a deletion of 50 amino acids near the C-terminus. This mutated lamin A does not properly integrate into the lamina, which disrupts the scaffold protein structure and leads to significant disfigurement of the nucleus
 - iv. The autosomal recessive form is due to a germ line mosaicism. This mutation causes a phenotypic spectrum of disease
2. Progeroid Disorders
 - a. Two major groups
 - i. Disorders of LMNA gene that codes for lamin A
 1. Progeria
 2. Mandibuloacral dysplasia (MAD); mutation of lamin A/C gene
 - ii. Disorders of abnormal DNA repair
 1. Werner's syndrome
 - a. Short arm of chromosome 8
 - b. Causes genomic instability

Clinical Manifestations

1. Scleroderma-like skin at birth (over the abdomen) in some children

2. Head and facial dysmorphism
 - a. Head to face ratio is increased
 - b. Dilated scalp veins
 - c. Alopecia is present by adolescence
 - d. Spares eye brows and lashes
 - e. Narrow beak nose
 - f. Ears and mandible are small
 - g. High pitched voice
3. Bones are thin; clavicles are thin
4. Loss of bone from distal phalanges
5. Severe premature cardiovascular disease
 - a. Myocardial infarction is the major cause of death (mean age is 13 years)

Cerebrovascular Disease

1. Clinical occlusive infarctions
 - a. Affects the cervical carotid and vertebral arteries
 - b. Intracranial large artery disease
 - c. Perforating artery disease of the basal ganglia and white matter

Imaging Evaluation

MRI

1. MRI demonstrates infarctions of:
 - a. Pial vessels
 - b. Watershed territories
 - c. White matter
 - d. Lacunar
 - e. Arterioles
 - f. Large arteries
 - g. Silent infarcts in 60% of patients

Angiography

1. Distal stenosis of vertebral arteries
2. Calcified cervical and internal carotid arteries
3. Stenosis of intra/extracranial vessels

Neuropathology

1. Dramatically accelerated cardiovascular disease similar to CVD of aging (atherosclerotic disease)
2. Vessels exhibit prominent adventitial fibrosis
3. Progerin found in blood vessels at higher rate than controls
4. Down regulation of mitochondrial oxidative phosphorylation

Werner's Syndrome

General Characteristics

1. Autosomal recessive with genetic instability
2. Werner's syndrome gene (WRN)
 - a. Encodes a member of the human RecQ helicase protein family; chromosome 8p12
 - b. WRN deficient cells:
 - i. Reduced cell division
 - ii. Chromosomal instability (variegated translocation mosaicism)
 - iii. Sensitive to DNA damaging agents

Clinical Manifestations

1. Short stature
2. Cataracts (posterior, cortical, subcapsular)
3. Scleroderma-like skin
4. Hyperkeratotic ulcerated skin (hands/feet)
5. Premature hair graying and hair loss
6. Increased:
 - a. Osteoporosis
 - b. Diabetes mellitus, Type II
 - c. Atherosclerosis (cardiovascular disease)
 - d. Cancer
 - e. Severe macular degeneration
7. Dysmorphic features
8. Retinitis pigmentosa
9. Hypogonadism
10. Atrophy of skeletal muscle

Neurologic Features

1. Development of meningiomas and neural sheath tumors

*Neuropathology**Cardiovascular Pathology*

1. Increased arterial wall density as measured by carotid duplex in the intima-media and adventia
2. Generalized atherosclerotic lesions with stenosis and plaque formation in coronary and cerebral arteries
3. Accelerated atherosclerosis
 - a. Calcification of aortic and great vessels
 - b. Calcification of mitral and aortic valves
4. Pulmonary arterial lesions
5. Strokes in all topographical distributions; silent infarcts
6. Cardiac death more common than stroke related death

Cerebrovascular Pathology

1. Intracranial steno occlusive arterial lesions
2. Basal cistern collateral vessels
3. Infarction by MRI in 60% of patients (approximately 50% were silent)

Related Syndromes

1. Mandibuloacral dysplasia
2. Wiedemann-Rautenstrauch syndrome

Neurofibromatosis, Type I*General Characteristics*

1. Mutation of gene on chromosome 17
 - a. Protein encoded is neurofibromin; a GTPase-activating enzyme
2. Incidence ranges from 1:2500 to 1:3000 live births

Clinical Manifestations

1. Café-au-lait spots (greater than 6) Lisch nodules (iris) neurofibromas
2. Increased incidence of glial malignant tumors: myelogenous leukemia, pheochromocytoma (benign)

3. Peripheral nerve sheath tumors, malignant peripheral nerve sheath tumors
4. Vasculopathy
5. Optic nerve glioma
6. Learning disabilities
7. Attention deficit disorder
8. Sphenoid wing dysplasia
9. Pseudoarthrosis of the tibia

Neuropathology

1. NF1 vasculopathy affects arterial and venous blood vessels of all sizes
2. Two major vascular pathologies in NF1
 - a. Occlusive intimal form that affects small arteries
 - b. Aneurysmal form with replacement of the muscular wall with fibrohyaline thickening in arterioles of .1–1 mm
3. Arterial lesions caused by:
 - a. Proliferation of Schwann cells within arteries and proliferation of smooth muscle
 - b. Secondary fibrosis
 - c. Other arteries affected include:
 - i. The abdominal aorta
 - ii. The mesenteric arteries
 - iii. Visceral arteries
 - iv. Muscular arteries
 - d. May also present with multiple arterial aneurysms and venous thrombosis
4. Vascular anomalies:
 - a. Intra and extracranial arterial connections
 - b. Often present with concomitant intravascular occlusive disease
 - c. Large and medium-sized arteries are affected in any territory
 - d. Possible dysfunction of neurofibromin in blood vessel endothelial and smooth muscle cells
 - e. Recurrent strokes occur in the same or different territories
 - i. Internal carotid artery > MCA > PCA are affected
 - f. Both intra and extracranial vessels can accrue stenotic lesions
 - g. Hemispheric territorial infarction is most common
 - h. Lacunar infarction and ocular ischemia (retinal) and global occur
5. Aneurysm:
 - a. Occurs in the vertebral or other large neck arteries that can present as:
 - i. Large neck mass
 - ii. Brachial plexus lesion
 - iii. Medullary compression syndrome
 - b. Intracranial saccular and fusiform aneurysms occur at:
 - i. Circle of Willis
 - ii. Distally (posterior choroidal artery)
 - iii. Fusiform aneurysm of the intrapetrosal carotid artery cause:

1. Spheroid wing dysplasia or VIth nerve palsy
- c. The form of the disease associated with cerebral aneurysms is the intimal aneurysmal form
- d. Moyamoya disease
 - i. Slowly progressive distal carotid stenosis
- e. Arteriovenous malformations
- f. Renal artery stenosis with hypertension

Neuroimaging

Angiography

1. Occlusive arterial disease
 - a. Focal concentric stenosis
 - b. Long segment irregular narrowing
 - c. Hypoplasia without luminal narrowing
 - d. Does not occur at bifurcations (as opposed to atherosclerosis)
2. Arteriovenous fistula particularly of the vertebral arteries is associated with:
 - a. Stenosis and pseudo-aneurysmal dilatation of the feeding vessel
3. Moyamoya changes (lenticulostriate collaterals) from gradual bilateral carotid occlusion
 - a. Extensive leptomeningeal collaterals from the external carotid to the Circle of Willis due to proximal occlusions of major intracranial vessels

Ehlers–Danlos Syndrome

General Characteristics

1. Ehlers–Danlos syndrome is a group of connective tissue diseases (approximately 10 subtypes) with overlapping clinical features
 - a. Major types are I, II, or III (approximately 80% of patients)
 - b. Subtype IV most important for cerebrovascular complications; incidence is 1 in 50,000–500,000 persons
 - c. Decreased synthesis of type III collagen
 - i. All of these patients demonstrate autosomal dominant inheritance
 - ii. COL 3A1 gene (mutations) on chromosome 2
 1. Exon skipping and multi-exon deletions of COL 3A1 gene chromosome 2
 2. Encodes for alpha-1 chain of type III collagen; produces a pro-collagen that causes it to be thin and friable

Clinical Manifestations

1. Hyperelastic skin
2. Hyperextensible joints
3. Increased scarring after injury
4. Platelet dysfunction
5. Cardiac defects
6. Type IV EDS may have dysmorphic facial features and easy bruising but no hyperextensibility of joints or hyperelastic skin

Cerebral and Vascular Complications

1. Aneurysms (type IV; type I rare)
 - a. Intra and extracranial aneurysms
 - b. Multiple aneurysms
 - c. Most common aneurysm is of the internal carotid artery
 - i. In the cavernous sinus
 - ii. At the site of emergence from the sinus
2. Presentation
 - a. Rupture in the cavernous sinus cavity
 - b. SAH
 - c. Carotid cavernous fistula
 - i. Spontaneous rupture or following minor head trauma
 - ii. Symptoms include:
 1. Periorbital swelling
 2. Conjunctival erythema with arterioles reaching the iris
 3. Pulsatile tinnitus
 4. Retinal engorgement
 5. Increased ocular pressure
 6. Proptosis occurrence
3. Arterial dissection
 - a. Documented in both intra and extracranial vessels
 - b. Dissection of intrathoracic artery can secondarily occlude cervical vessels
 - c. Dissection occurs in intra-abdominal, pelvic, and intrathoracic vessels
 - d. Complications during arteriography are common due to friability of the tissue
 - e. Spontaneous dissections
 - f. During surgery and procedures

Neuroimaging

1. Carotid cavernous fistula
2. Intra and extracranial aneurysms. Rarely in both carotid and vertebral arteries concomitantly
3. Arterial dissection of cerebral as well as thoracic, abdominal, and pelvic vessels
4. Intracranial carotid artery is the most common site of aneurysm

Neuropathology

1. Fragmentation of intimal elastic membrane
2. Fibrosis of the arterial wall
3. Microscopic rupture between media and adventia
4. Abnormal Type III collagen in blood vessels

Differential Diagnosis Between Marfan's Syndrome and Ehlers-Danlos Disease

1. Marfan's syndrome has fewer cerebrovascular aneurysms
2. Aortic arch and pulmonary arteries affected more in Marfan's syndrome
3. Carotid-cavernous fistula (both)
 - a. May follow minor head trauma

- b. Spontaneous occurrence
- c. May occur concomitantly with intracranial aneurysms
- 4. Arterial Dissections (both)
 - a. Arteries fail to hold sutures (EDS)
 - b. Dissection of both intra and external arteries (EDS)
 - c. Carotid and basilar arteries are thin walled, enlarged and tortuous (EDS > Marfan's)
 - d. Arteriograms are dangerous (EDS)
 - e. More friable tissue (EDS)

Hemoglobinopathies – Sickle Cell Disease

General Characteristics

1. Autosomal inheritance
 - a. β globulin gene substitution in codon 6 that forms abnormal hemoglobin (HbSS) disease
 - b. HbSS constitutes 60–70% of the hemoglobinopathies
 - c. Hemoglobin is a heterotetramer with 2α and 2β chains
2. Risk factors for ischemic stroke in children
 - a. Overt or silent stroke (MRI)
 - b. Increased cerebral blood flow
 - c. Aplastic crises
 - d. Nocturnal hypoxemia
 - e. Acute chest syndrome
 - f. Seizures
 - g. SEM globin gene haplotype
3. Risk factors for ischemic stroke in adults
 - a. Increased homocysteine
 - b. Prior TIA
 - c. Atrial fibrillation
 - d. Hyperlipidemia
 - e. Diabetes mellitus
4. HbS > HbC for risk of ischemic stroke; HbA has little or no risk of ischemic stroke

Clinical Manifestations

1. HbS disease
 - a. Scleral telangiectasia
 - b. Arachnodactyly
 - c. Auto-splenectomy
 - d. Pneumococcal peritonitis
 - e. Meningitis
 - f. Bone marrow infarction
 - g. Severe joint and abdominal pain
 - h. Acute chest syndrome
 - i. Numb chin syndrome

Neurological Complications

1. Occlusive disease of large intracranial arteries and small penetrating vessels
2. Silent infarcts
 - a. About 20% in children
 - b. Cognitive impairment without overt ischemic stroke in children
3. Dilated and ectatic arteries
4. Moyamoya collateral patterns (MCA or terminal carotid occlusion)
5. SAH (rare)

SSA Disease

1. Stroke propensity

SC Disease

1. “Sea fan” macular sign (abnormal collection of blood vessels)
2. Propensity of strokes during pregnancy
3. Aseptic necrosis of the hip

Neuropathology

1. Thickened arterial walls from intimal and subintimal proliferation
2. Rare thrombosis of veins and cerebral sinuses
3. Deoxygenated HbS interaction with other HbS molecules leads to RBC polymerization
 - a. Decreased RBC deformability
 - b. Vaso-occlusion of vessels and the vaso-vasorum
4. Sickled cells
 - a. Adhere to the endothelium
 - b. Activate inflammatory cells and clotting factors that form the nidus for thrombosis
 - c. Initiate small vessel sludging
 - d. Deficiency of endothelial nitric oxide which decreases compensatory vaso dilation

Neuroimaging

1. MRI/MRA
 - a. Silent infarction
 - b. Cortical and subcortical infarction
 - c. Border zone infarction
 - d. Moyamoya syndrome

Laboratory Evaluation

1. Trans Cranial Doppler (TCD)
 - a. Velocities above 200 cm/second may occur in large vessels

Mitochondrial Disease and Stroke

Overview

1. Mitochondrial DNA mutation in 75% of affected patients
2. Affects 9.2/100,000 adults less than 65 years; disease occurs in about 1 in 5000 individuals
3. Cardiac involvement is progressive
 - a. Sudden death
 - b. Cardiomyopathy
 - c. Ventricular pre-excitation
 - d. Conduction system disease

Mitochondrial Encephalomyopathy, Lactic Acidosis, and Stroke-Like Episodes (MELAS)

General Characteristics

1. Multisystem disease affecting organs with high energy demands (heart, CNS, skeletal muscle)
2. Mitochondrial genome:
 - a. Circular DNA within the mitochondrion

- b. Tissue dependent copy number (heteroplasmy: ratio of mutated vs wild type mitochondria in each cell)
- c. Maternal transmission
- d. Encodes:
 - i. Mitochondrial transfer RNA (tRNA)
 - ii. Ribosomal RNA
 - iii. 13/80 proteins in the respiratory chain
- e. Mitochondria are exposed to free radicals generated by the respiratory chain and have poor repair mechanisms
- f. Mitochondrial dysfunction causes ATP depletion due to failure of the respiratory chain
- g. Mutations identified in both tRNA, rRNA and protein encoding genes
- h. MELAS most often is caused by point mutation in mtDNA m3243 within the tRNA encoding gene tRNA^{Leu(UUR)}

Clinical Manifestations

- 1. Fever and infection possible triggers
- 2. Episodic vomiting, migraine headaches and seizures
- 3. May occur in adolescence
- 4. Siblings of MELAS patients with the 3243 mutation may present with different phenotype:
 - a. Diabetes and deafness
 - b. Myopathy
- 5. Clinical associations of MELAS:
 - a. Diabetes
 - b. Short stature
 - c. Hearing loss
 - d. Ophthalmoplegia
 - e. Ataxia
 - f. Pigmentary retinopathy
 - g. MERRF (Myoclonic Epilepsy with Ragged Red Fibers)
 - h. Ischemic colitis
 - i. Hypertrophic cardiomyopathy
 - j. Fatigue
 - k. Cognitive impairment
 - l. Nephropathy
 - m. Hypothyroidism
 - n. Hypogonadism
- 6. Most common presentation of MELAS is migraine headache and seizures with recurrent stroke-like episodes
- 7. Stroke-like episodes:
 - a. In general do not follow a vascular distribution
 - b. Involve the posterior parietal and occipital lobes
 - c. Rare brain embolization from cardiac involvement (CHF; arrhythmia)
 - d. Episodes most consistent with mitochondrial dysfunction and alterations in calcium homeostasis

Neuropathology

- 1. Mutations in subunits of components of the respiratory chain
 - a. Oxidative stress
 - b. Energy failure in the affected tissues
 - c. Ragged red fibers on muscle biopsy

Neuroimaging

MRI Findings and Differential Diagnosis from Other Mitochondrial Diseases

- 1. MELAS and Alpers' disease
 - a. Primarily cerebrocortical lesions
- 2. Leigh's syndrome
 - a. Basal ganglia involvement
- 3. Congenital lactic acidosis with or without pyruvate dehydrogenase deficiency
 - a. Cerebrocortical atrophy
 - b. Agenesis or atrophy of the corpus callosum
- 4. Associated other mitochondrial syndromes from the A32437G mutation
 - a. Maternal inherited deafness with diabetes
 - b. Progressive external ophthalmoplegia

Laboratory Evaluation

- 1. Elevated resting lactate and pyruvate levels (blood and CSF)
- 2. Muscle biopsy:
 - a. Ragged red fibers (abnormal collection of mitochondria on Gomori trichrome stain)
- 3. Genetic mutation analysis of peripheral blood leukocytes

Myoclonic Epilepsy with Ragged Red Fibers (MERRF)

General Characteristics

- 1. Double point mutations causing MELAS-like presentation
 - a. m.8356T>C (MERRF)
 - b. m.3243A>G (MELAS)
- 2. Heteroplasmy in the blood of 4 described patients

Clinical Manifestations

- 1. MERRF followed by a MELAS presentation occurs in the double mutation
- 2. Migraine with stroke-like episodes associated with lactic acidosis and dementia
 - a. Ataxia and myoclonic epilepsy

Neuropathology

- 1. Mutations in the MT-TK gene are the most common cause of MERRF; contained in mitochondrial DNA
 - a. The most prominent deficiencies involve the NADH-CoQ reductase of C complex I and in cytochrome C oxidase (COX, complex IV)
- 2. Ragged red fibers in muscle biopsy

Neuroimaging

- 1. May demonstrate calcification of the basal ganglia
- 2. Occipital lobe atrophy

Kearns-Sayre Syndrome

General Characteristics

- 1. Large mitochondrial deletions

2. Red ragged fibers rarely seen in children
3. Mitochondrial electron microscope defects noted in children
4. May involve intramuscular capillaries

Clinical Manifestations

1. Cardiac complications
 - a. Early right bundle branch block
 - b. May progress rapidly to AV block
 - c. First or second degree AV block
 - d. QT prolongation
 - e. Torsades de Pointes ventricular tachycardia
 - f. Late dilated cardiomyopathy
2. Syncope or sudden death may be presenting feature
3. Proximal myopathy
4. Slowly progressive external ophthalmoplegia
5. Short stature; growth hormone failure
6. Cardioembolic stroke

Leigh's Syndrome (Subacute Necrotizing Encephalomyelopathy)

General Characteristics

1. Genetically heterogeneous
 - a. Affects nuclear or mitochondrial DNA
2. Most common biochemical deficits
 - a. COX complex and pyruvate dehydrogenase complex
3. Infantile form diagnosed by developmental delay and elevated serum and CSF lactate
4. Late onset cases occur

Clinical Manifestations

Juvenile Form

1. Spastic paraparesis
2. Visual disorder
3. Acute sensorimotor neuropathy, ataxia, deafness and retinitis pigmentosa (NARP)
4. Myopathy and cardiomyopathy
 - a. Respiratory depression and coma
5. Emboli from cardiomyopathy

Imaging Evaluation

MRI

1. Symmetric hypointense T1/hyperintense on T2-weighted sequences; lesions in the basal ganglia
 - a. Putamen and brainstem
 - b. Sparing of red nuclei and mammillary bodies (occasionally the mammillary bodies are hemorrhagic)

Neuropathology

1. Gray matter degeneration
2. Brainstem and spinal cord necrosis
 - a. Spongiosis, endothelial proliferation and demyelination

Saguenay-Lac Saint Jean (Cox Deficiency)

General Characteristics

1. Autosomal recessive; the largest known cohort of patients with a genetically homogeneous nuclear encoded congenital lactic acidosis
 - a. A354V mutation in LRPPRC (leucine-rich pentatricopeptide repeat containing)

Clinical Manifestations

1. Developmental delay
2. Facial dysmorphism
3. Fulminant lactic acidotic crises
4. Leigh's syndrome like
5. Stroke-like episodes

Neuropathology

1. Cytochrome oxidase deficiency in the brain and liver
2. Necrotizing encephalopathy involving the thalamus, brainstem and spinal cord
3. Vascular proliferation and gliosis

Neuroimaging

MRI

1. Hypointense signal on T1-weighted sequences with hyperintense signal with T2-weighted sequences

Laboratory Evaluation

1. High CSF lactate

Disorders of Cerebral Thrombosis and Hemostasis

Overview

1. Physiology
 - a. The brain has an intrinsic capacity to regulate thrombosis and hemostasis
 - b. Hemostasis is defined as the arrest of bleeding and the maintenance of blood flow within a vessel
 - c. Thrombosis is the formation of clot within a blood vessel
 - d. Coagulation refers to the transformation of liquid into a semisolid mass
 - e. The classic Virchow triad model of thrombosis and hemostasis illustrates the complex interplay between blood flow, clotting factors and the endothelium of the vessel wall. It explains features of both thrombosis and maintenance of hemostasis
2. Circulating cells are the components of primary hemostasis and coagulation factors comprise secondary hemostasis
3. Four component model of coagulation comprise:
 - a. Hepatic factors
 - b. Bone marrow derived hematopoietic cells (platelets and monocytes)
 - c. The vascular endothelium
4. Blood Vessel Injury

- a. Platelets initiate the process of primary hemostasis at the site of injury (burst plaque, trauma, dissection by forming a plug)
 - i. Platelets adhere to subendothelial von Willebrand factor (vWF) and exposed collagen through glycoprotein1b/IX/V and glycoprotein1a/IIa receptor complexes
 1. Platelet endothelial complex adherence initiates platelet intracellular signaling cascades that induce their activation
 2. Activated platelets:
 - a. Undergo structural change
 - b. Secrete their granules
 - c. Produce thromboxane A2 (TXA2)
 - d. Aggregate
 3. Platelet plug forms by:
 - a. Recruitment of additional platelets by secreted TXA2
 - b. Secreted adenosine diphosphate (ADP)
 - c. Thrombin
 4. Activated platelet surface phospholipids:
 - a. Serve as a platform for the enzyme complexes of the clotting cascade
 - b. Coagulation
 - i. Tissue factor is the primary initiator of coagulation (extrinsic cascade)
 1. Tissue factor (TF) binds factor VII. The TF-VIIa complex activates factor IX and X
 2. Activated IXa binds to VIIIa on membrane surfaces that activate factor X that then forms the prothrombinase complex. Factor Xa converts prothrombin to thrombin
 - c. Generated thrombin
 - i. Converts fibrinogen to fibrin
 - ii. Activates coagulation factors V and VIII that amplify its own generation
 - iii. Activates factor XIII that stabilizes the fibrin clot
 - iv. Activates factor XI (intrinsic pathway) to maintain Xa generation
 - d. The extrinsic pathway activation is amplified by the intrinsic pathway
 - e. Regulation of fibrin clot generation:
 - i. The generation and removal of the fibrin pathways, three of which are endothelial based. The coagulation system is regulated by the fibrinolytic system and natural coagulation inhibitors
 - ii. Regulatory pathways for fibrin generation
 - iii. Tissue factor inhibiting pathway (TFIP)
 1. Blocks the reaction between tissue factor and VIIa
2. Circulating thrombin III and its cofactor heparin sulfate proteoglycan (HSPS):
 - a. Inhibit all coagulation proteases involved in the coagulation cascade
 - b. Limits coagulation to the site of injury
 - c. Protects the circulation from liberated proteases
3. Thrombomodulin/Protein C pathway
 - a. Thrombin binding to the endothelial cell receptor Thrombomodulin activates circulating protein C (APC)
 - b. Activated protein C:
 - i. Degrades factor Va and VIIIa
 - ii. Protein S is a cofactor of protein C
 - iii. Binding of thrombin to the thrombomodulin
 1. Inhibits cleavage of fibrinogen
 2. Decreases activation of platelets
 3. Inhibits thrombin
4. Fibrinolytic pathway
 - a. Vascular endothelial cells modulate blood fluidity through secretion of membrane associated thrombo-resistance molecules (as noted above)
 - b. Fluid phase proteins:
 - i. Endothelin
 - ii. Nitric oxide
 - iii. Tissue plasminogen activator
 - iv. Prostacyclin
 - c. Cell surface protein regulators
 - i. TFPI (tissue factor pathway inhibitor I)
 - ii. Antithrombin III-HSPG (also circulates)
 - iii. Thrombomodulin-protein C pathway
 - d. Endothelial cells assemble fibrinolytic proteins and express urokinase receptor and annexin A2
 - e. Annexin A2
 - i. Multifunctional calcium regulated membrane binding protein
 - ii. It forms a heterotetramer with protein P11 (also known as S100A) which chaperones A2 to the plasma membrane

- iii. The A2-P11 complex:
 1. Binds tissue plasminogen activator (tPA) as well as plasminogen which accelerates the catalytic generation of plasmin
 2. Plasmin limits fibrin accumulation

Organ-Specific Thrombosis and Hemostasis

1. Local organ expression of endothelial factors and receptors determine thrombosis and hemostasis in the face of systemic changes in coagulation parameters
 - a. Differential expression of coagulant and anticoagulant factors in different locations within the vascular tree
 - b. Endothelial Protein C receptor
 - i. Predominately expressed in large arteries and veins
 - ii. Tissue factor pathway inhibitor
 1. Expressed in capillaries
 - iii. Nitric oxide
 1. Expressed in arteries
 - iv. vWF expressed in veins
 - c. Protein C, Protein S or antithrombin III deficiency
 - i. Predispose to venous thrombosis of the lower extremity at valve pockets due to concomitant stagnant blood flow and hypoxia
 - d. Polycythemia vera, paroxysmal nocturnal hemoglobinuria and essential thrombocythemia
 - i. Preferentially effect intra-abdominal veins (Budd-Chiari syndrome)
 - e. Erythromelalgia
 - i. Thrombotic occlusion of arterioles (not the painful Nav1.7 neuropathy) primarily localizes to the toes, fingers and is caused by myeloproliferative disease, polycythemia vera and essential thrombocythemia
 - f. Warfarin induced skin necrosis
 - i. Effects buttocks, thighs and the breast
 - ii. Caused by the thrombotic occlusion of venules
 - iii. Deficiency of protein C

Organ Specific Hemorrhage

1. Possibly dependent on deficiencies within the intrinsic or extrinsic pathways
 - a. Murine model: decreased expression of VII and tissue factor cause hemorrhage in heart, lung testes, uterus and placenta
 - i. Low factor VIII and IX lead to hemorrhages in joint muscles and joints (tissue factor expression is low)
 - b. Subdural hematoma (often with minimal trauma)
 - c. Experimental evidence supports low levels of tissue factor and hemorrhage in:
 - i. Heart
 - ii. Lung
 - iii. Testis
 - iv. Uterus
 - v. Placenta

Brain-Specific Regulation of Thrombosis and Hemostasis

1. Blood-Brain Barrier:
 - a. Tight junction proteins (transmembrane)
 - i. Occludins and claudins that interact with the actin cytoskeleton and zonula occludin (ZO) proteins
 - ii. Limits molecular transport into the brain
 - iii. Protects against hemorrhage
 - b. The brain has increased ladder-like adherens junctions formed by:
 - i. Cadherin and catenin proteins
 - ii. At endothelial junctions
 - c. The blood-brain barrier (BBB) pericyte junctions
 - i. Paracrine production of trophic factors that enhance the BBB as do adjacent astrocytes
 - ii. Forms another structural support for tight junctions
 - iii. Phagocytic function that blocks egress of erythrocytes from capillaries
 - iv. Protection against capillary brain hemorrhage

Specific Functional Characteristics of the Vascular Endothelium

1. Thrombomodulin
 - a. Enhanced expression in small arteries concomitant with small vessel pathology
 - b. Endothelial protein C receptor
 - i. Located adjacent to thrombomodulin in the endothelial membrane enhances its expression
 - ii. Preferentially located in the endothelium of arteries and veins and has minimal expression in the brain and other organ capillaries
2. Fibrinolytic pathway: tPA and plasminogen activator inhibitors – 1:
 - a. tPA
 - i. Pivotal endothelial-dependent serine protease
 - ii. Binds to fibrin
 - iii. Activates the fibrinolytic pathway
 - iv. Almost no capillary expression
 - v. Systemic endothelial cells release tPA after stimulation by factorX-thrombin
 - b. Plasminogen activator inhibitor-1
 - i. The major fibrinolytic inhibitor
 - ii. Enhanced expression of PAI-1 In brain microvascular endothelium (BBB models) support:
 - a. Restricted tPA and increased expressions of PAI-1 in the microvascular endothelium
 - b. Regulation of brain microvascular fibrin types may be regulated by the BBB
3. Tissue Factor
 - a. The principal inducer of the coagulation cascades
 - b. Surrounds blood vessels and encases organs
 - c. The brain has a high concentration of tissue factor
 - d. The CNS sources of tissue factor are:
 - i. Astrocytes
 - ii. BBB associated astorcytes
 - iii. Brain surface pericytes

4. Tissue Factor Pathway Inhibitor (TFPI)
 - a. Protease inhibitor and synthesized by endothelial cells
 - b. Action mediated by Xa inhibition of the TF-VIIa complex
 - c. Low brain expression
5. Antithrombin III-HSPG
 - a. Protease inhibitor synthesized by the liver
 - b. Actions amplified when bound to its cofactor HSPG (absent in brain capillaries)
 - c. Covalent inhibitory complex is associated with coagulation factor
6. Protease Nexin I
 - a. A serine protease inhibitor
 - b. Synthesized by smooth muscle cells and platelets
 - c. Inhibits thrombin and plasminogen activation
 - d. Localized to pericytes and astrocytes
 - e. Function is uncertain
7. Prostacyclin and endothelial nitric oxide
 - a. Pivotal endogenous platelet aggregate inhibitors
 - b. Prostacyclin synthesized by prostacyclin synthetase from prostaglandin H₂ primarily from endothelial cells
 - i. Experimental studies suggest less brain expression than in other organs
 - c. Endothelial NOS (eNOS), also known as nitric oxide synthase 3 (NOS3)
 - i. The primary nitric oxide synthase
 - ii. Experimental support for equal brain and organ expression
 - iii. Endothelial derived NO a major regulator of platelet function and aggregation

Clinical Conditions from Factor and Inhibitor Dysfunction

Antithrombin III

General Characteristics

1. 58-kDa serpin (serine protease inhibitor)
2. Inhibits thrombin, factor Xa and factor IXa
3. Activity amplified by heparin
4. Defect may be quantitative or qualitative
5. Acquired loss from protein losing enteropathy and the nephrotic syndrome
6. Genetics:
 - a. Most often AD
 - b. Type I antithrombin deficiency:
 - i. Reduction in both activity and antigen concentration
 - c. Type II antithrombin deficiency:
 - i. Decreased activity but normal antigen concentration

Clinical Manifestations

1. Strong family history of venous thrombosis
2. Approximately 50% of patients suffer:
 - a. Venous thrombo-embolism (VTE)
 - i. Less than 60% activity carries a 10 fold risk of thrombo-embolism
 - ii. Homozygous defect associated with in utero or perinatal death

3. Pulmonary embolism
4. Rare myocardial infarction
5. Rare peripheral arterial disease
6. Occasional stroke

Laboratory Evaluation

1. Antithrombin activity (heparin cofactor) assay
2. Immuno assay for antithrombin antigen
3. Test confounders
 - a. Liver failure
 - b. Unfractionated or low molecular weight heparin

Protein C

General Characteristics

1. Serine protease zymogen of the vitamin K dependent family
2. In the presence of thrombomodulin, thrombin converts it to the active form which then inhibits factors Va and VIIIa
3. Usually autosomal dominant
 - a. Heterozygotes suggested by protein C level of less than 70%; increased venous thromboembolism approximately 4 fold higher
 - b. Homozygote presentation:
 - i. Life threatening thrombosis at birth
 - ii. Neonatal puerpera fulminans with extremity necrosis and gangrene
 - c. Protein C to S ratio a determinant of protein C gene mutation or carrier status

Clinical Manifestations

1. Lower extremity venous thrombosis
2. Cerebral venous thrombosis
3. Occasional arterial thrombosis
4. Rare cerebral embolus from the heart

Laboratory Evaluation

1. Protein C activity (clotting assay)
2. Protein C amidolytic and immune assays
3. Test confounders
 - a. Vitamin K antagonist
 - b. Liver failure
 - c. Vitamin K deficiency

Protein S

General Characteristics

1. Is the cofactor for activated protein C (APC)
 - a. True plasma protein S (about 40%) has APC cofactor activity
 - b. 60% of plasma protein S is bound to C4b binding protein which increases during infection
2. Levels of Protein S are decreased with:
 - a. Nephrotic syndrome
 - b. Protein losing enteropathy
 - c. Liver disease
 - d. Antibodies to protein S occur with post-viral purpura fulminans

Clinical Manifestations

1. Risk factor for stroke in middle aged women (arterial stroke)
2. Dural venous thrombosis
3. Stroke in young patients with the concomitant risk factor of smoking
4. 4–5 fold risk of venous thromboembolism

Laboratory Evaluation

1. True protein S antigen evaluation by immune assay
2. Total protein S antigen and APC cofactor activity (clotting assay)
3. Test confounders
 - a. Vitamin K antagonists and deficiency
 - b. Liver failure
 - c. Pregnancy
 - d. Oral contraceptive
 - e. Hormone replacement therapy

*Factor V Leiden Mutation***General Characteristics**

1. Most common cause of decreased Protein C function
 - a. Activated Protein C (APC)
 - i. Inactivates Factors V and VIII_a
 - ii. Proteins that APC inactivates, Factor V_a and Factor VIII_a, are highly procoagulant cofactors and therefore promotes thrombosis
2. Mutation of the gene that codes for factor V (factor V G1691A)
3. Factor V Leiden prevalence in the general population:
 - a. Heterozygote 7.7%
 - b. Homozygote .2%

Clinical Manifestations

1. Thromboembolism in pregnancy
2. Venous thromboembolism of the lower extremities
3. Cerebral venous and dural sinus thrombosis
4. Increased risk of arterial stroke in young patients

Laboratory Evaluation

1. APC resistance (APTT-based assay)
2. Factor V Leiden genotyping (PCR)

*Prothrombin Gene Mutation***General Characteristics**

1. Second most common gene mutation causing a prothrombic state
2. AR, mutation in the gene (G20210A)
3. Two phenotypes:
 - a. Hypo-prothrombinemia
 - i. Can increase levels of coagulant activity
 - ii. Antigen type
 - b. Dysprothrombinemia
 - i. Low coagulant activity
 - ii. Borderline or normal antigen levels

Clinical Manifestations

1. Cerebral venous thrombosis
2. Rare arterial clotting
3. Recurrent peripheral venous thrombosis embolism

Laboratory Evaluation

1. Prothrombin genotyping by PCR

*Coagulation Factor Deficiency***General Characteristics**

1. Hemophilia A (factor VIII) and B (factor IX) with von Willebrand disease account for more than 95% of inherited coagulation deficiencies
2. Hemophilia A is five times more prevalence than hemophilia B
3. Genetics:
 - a. X-linked
 - b. F8 and F9 are the genes encoding factor VIII and IX respectively
 - c. Sporadic mutations in 30% of patients
4. Severity depends on the level of clotting factors VIII or IX
 - a. Severe disease <1%
 - b. Moderate 1–5%
 - c. Mild 5–40%
5. Approximately 1/3 of patients develop inhibitory antibodies to the replacement factor
 - a. Inhibitory antibodies directed against factor VIII is a CD4+ dependent process

Clinical Manifestations

1. Bleeding into the joints, skin, abdomen and cranium
2. Intracranial bleeding occurs in 2–14% of severe hemophilia
 - a. Following mild head trauma
 - b. Neonatal hemorrhage (approximately 3%)
 - c. Associated with acute and chronic subdural hematoma

*von Willebrand Factor Deficiency***General Characteristics**

1. The most common inherited bleeding disorder
2. Severity depends on degree of the defect
3. Von Willebrand factor is a glycoprotein that:
 - a. Induces platelet adhesion to exposed subendothelium at the site of injury
 - b. Causes platelet aggregation
4. Genetics
 - a. Both AD or AR inheritance

Clinical Manifestations

1. Mucocutaneous bleeding
2. Too much bleeding in the setting of mild trauma (tooth extraction)
3. Rare spontaneous intracranial bleeding

Laboratory Evaluation

1. Bleeding time and PFA-100 closure time may be prolonged
2. Abnormal ristocetin induced platelet aggregation

*Acquired Low Levels of Coagulation Factors***General Characteristics**

1. Most of the Factor VIII and IX deficits are due to autoantibodies in treated patients
2. Acquired hemophilia:
 - a. Rare autoimmune disease
 - b. Caused by antibodies against factor viii and ix
 - c. In patients older than 65 years:
 - i. Solid tumors
 - ii. Lymphoproliferative diseases
 - iii. Autoimmune diseases
 - iv. Pregnancy
 - v. Intolerance to drug therapy

Clinical Manifestations

1. Severe bleeding episodes occur in 80–90% of patients
2. Mortality rate of 10–25%

Laboratory Evaluation

1. Prolonged a PTT
2. Low Factor VIII or IX activity
3. Detectable inhibitor (Bethesda assay)

*Multiple Coagulation Deficiencies***General Characteristics**

1. Most common causes
 - a. Vitamin K deficiency
 - b. Liver disease
 - c. Disseminated intravascular coagulation
2. Vitamin K
 - a. Pivotal for post-translation (gamma) – carboxylation of factors II, VII, IX, X, protein C and S
 - b. Deficiencies of Vitamin K in adults occur most often from:
 - i. Malabsorption
 - ii. Vitamin K antagonists
 - iii. Antibiotics
 - iv. Rodenticides
3. Liver disease
 - a. Synthesizes most coagulation factors except factor VIII, vWF and coagulation regulatory proteins
 - b. Gamma – carboxylation of vitamin K dependent proteins is impaired in liver failure and cholestasis
 - c. Severe hepatic failure is associated with:
 - i. Decreased factor V
 - ii. Hypo and dysfibrinogenemia
 - iii. Impaired syntheses of antithrombin, plasminogen, α -2, antiplasmin and plasminogen activator inhibitor type I (tPAI-1)

- iv. Causes fibrin deposition and activation of the coagulation cascades
- v. A consumptive coagulation may occur when:
 1. Decreased clearance of activated factors and t-PA
 2. Impaired syntheses of PAI-1 and α -2 antiplasmin

Clinical Manifestations

1. Coagulation deficits: vitamin K antagonists
 - a. Intracranial hemorrhage
 - i. International normalized ratio (INR) greater than 5 often seen in a hemorrhage
 - ii. 70% of bleeds are intracranial and 80% are subdural
 - iii. Vitamin K antagonists account for about 10% of ICH (2–9/100,000 population/year)
 - iv. May unmask brain bleeding in otherwise asymptomatic patients particularly those with CVD, hypertension or vascular malformations
 - v. Intracranial risk of hemorrhage is increased with vitamin K antagonists and the use of antiplatelet agents
 - vi. Drugs that interfere with Vitamin K antagonists include:
 1. Amiodarone
 2. Miconazole
 3. Phenylbutazone
 4. Quinidine
 5. Cimetidine
 6. Thyroid hormones
 7. Antibiotics

*Post Thrombolysis***General Characteristics**

1. Use of streptokinase, urokinase or primarily intravenous or intra-arterial t-PA for ischemic stroke

Clinical Manifestations

1. Intracranial hemorrhage occurs
 - a. In infarctions that occur in greater than 2/3 of the territory of the affected vessel
 - b. Setting of hypertension
 - c. Longer the time window from ictus (thrombolytic therapy)
 - d. In the setting of MCA occlusion by CT
 - i. Loss of the insular stripe
 - ii. Indistinct caudate head
 - iii. Corical effacement

*Acquired Deficiency of Coagulation Inhibitor***General Characteristics**

1. Accelerated consumption of antithrombin III, protein C and protein S occurs with:
 - a. An ischemic or thromboembolic incident

- b. Disseminated intravascular coagulation
- c. Surgery
- d. Sepsis and DIC
- 2. Antithrombin deficiency occurs with:
 - a. Decreased hepatic syntheses
 - b. Disseminated intravascular coagulation
 - c. Loss in ascites and inflammatory bowel disease
 - d. Nephrotic syndrome
 - e. Heparin
- 3. Protein S deficiency may occur with kidney disease
- 4. Protein C and S deficiency occur with vitamin K antagonists
- 5. L-asparaginase
 - a. Utilized for acute lymphoblastic leukemia
 - b. Decreases antithrombin, protein C and S (inhibits synthesis)
- 6. Oral contraceptives
 - a. Combination of estrogen and progesterone
 - b. Increase VII, IX, and X
 - c. Decrease antithrombin and protein S
 - d. Induce a mild prothrombotic state
 - e. Cerebral vein and sinus thrombosis are increased particularly in patients with the G120A prothrombotic mutation
- 7. Tamoxifen
 - f. Estrogen receptor modulator
 - g. Decreased antithrombin, protein C and S, increased free protein S and factors VIII, IX, and vWF

Thrombocytopenia

General Characteristics

1. Differential diagnostic points for inherited thrombocytopenia
 - a. Family history of low platelets
 - b. Lack of platelet increase following anti-immune modulations
 - c. Abnormal size of platelets
 - d. Increased bleeding in proportion to platelet number
 - e. Birth onset
 - f. Absent radii
 - g. Stable platelet levels for a prolonged period

Acquired Thrombocytopenia in Adults

General Characteristics

1. Most common cause of thrombocytopenia but rarely causes intracranial hemorrhage
2. Bleeding occurs with levels less than 10,000–20,000/mm³ (in absence of platelet functional deficit)
3. Major causes of acquired thrombocytopenia
 - a. Bone marrow failure
 - i. Myeloproliferative disease
 - ii. Metastatic infiltration
 - b. Vitamin B12 deficiency
 - c. Acute alcohol toxicity
 - d. Drug interference (quinine, quinidine, sulfonamides)

4. HIV induced thrombocytopenia
5. Hepatitis C infection
 - a. Autoimmune thrombocytopenia develops in about 3% of patients
6. Sepsis
7. Abciximab treatment
 - a. Anticoagulants during endovascular procedures can cause acute thrombocytopenia (within hours) or can be delayed (5–8 days)

Platelet Dysfunction

Overview

Inherited platelet disorders are rare and can compromise adhesion, aggregation or storage pool release.

Glanzmann's Thrombasthenia

General Characteristics

1. Autosomal recessive
2. Defect in GPIIb/IIIa which causes failure of platelet aggregation

Clinical Manifestations

1. Childhood onset
2. Lifelong mucosal bleeding
3. Intracranial hemorrhage may occur

Laboratory Evaluation

1. Platelet count, size and morphology are normal
2. Bleeding time and PFA-100 closure time are prolonged
3. Platelet aggregometry demonstrate no platelet aggregation with all platelet tests except collagen and ristocetin

Bernard-Soulier Syndrome

General Characteristics

1. Lack of the glycoprotein GPIIb-IX-X complex (receptor for vWF)
2. Macrothrombocytopenia

Clinical Manifestations

1. Disproportionate bleeding for platelet numbers
2. Acquired platelet dysfunction occurs with:
 - a. Aspirin
 - b. NSAIDs
 - c. GPIIb/III inhibitors
 - d. Myeloproliferative disease

Inherited Cause of Thrombophilia and Stroke

General Characteristics

1. Children may be at risk for ischemic stroke if they have inherited thrombophilia which includes deficient:
 - a. Antithrombin III
 - b. Low levels of protein C and S
 - c. APC resistance
 - d. Factor V Leiden

- e. Prothrombin G20210A mutation
- f. Methylenetetrahydrofolate reductase (MTHFR) C6 77T mutation
- g. Plasma hematocrit greater than 95th percentile
- 2. Adults
 - a. Association of thrombophilia and ischemic stroke occurs with:
 - i. Factor V Leiden mutation
 - ii. MTHFR C 677T mutation
 - iii. Prothrombin 20210A mutation
- 3. Thrombophilia causes about 1–4% of ischemic strokes in young adults

Clinical Manifestations

- 1. Thrombophilia increases the risk of stroke during:
 - a. Pregnancy and puerperium along with comorbid conditions that include:
 - i. Pregnancy associated with hypertension
 - ii. Caesarean section
 - iii. Non-white ethnicity
 - iv. Cardiomyopathy
 - v. Congestive heart failure
 - b. Hormone replacement therapy
 - c. A possible association with PFO

Increased Factor VIII

General Characteristics

- 1. Associated with:
 - a. Spontaneous abortion
 - b. Thrombophlebitis
 - c. Preceding infection
 - d. Crohn's disease
 - e. Ulcerative colitis
- 2. Coagulopathy of inflammatory bowel disease caused by:
 - a. Increased Factor VIII
 - b. Elevated Factor V
 - c. Decreased antithrombin III
 - d. Platelet dysfunction

Clinical Feature

- 1. Ischemic stroke

Autoimmune Induced Coagulopathy

Heparin Induced Thrombocytopenia (HIT)

Type I HIT

General Characteristics

- 1. Non-immune-mediated
- 2. Occurs in 10–20% of patients utilizing heparin
- 3. Causes slight non-progressive thrombocytopenia ($>100,000/\text{mm}^3$)
- 4. Platelet count returns to baseline within a few days even with continued heparin

Clinical Manifestations

- 1. No bleeding or thrombosis

Type II HIT

General Characteristics

- 1. Immune-mediated associated with IgG antibodies
- 2. There are three subtypes:
 - a. IgG antibodies without thrombocytopenia
 - b. HIT subtypes
 - i. Thrombocytopenia
 - ii. No clinical symptomatology
 - iii. Thrombocytopenia with clinically relevant thrombosis

HIT with Thrombosis

General Characteristics

- 1. Exposure to heparin induces platelet factor-4 (PF-4) release which binds to heparin
- 2. The PF-4 heparin complex activates platelets which induces the clotting cascade
- 3. HIT 3 occurs in 3–5% of patients who have utilized unfractionated heparin for 5 days or longer
- HIT 3 occurs in approximately 1% of patients who have utilized low molecular weight heparin

Clinical Manifestations

- 1. No other explanation for thrombocytopenia
- 2. Diagnostic points:
 - a. Greater than 50% fall in platelets
 - b. Occurs between 5–10 days, may be seen on the first day if the patient has had heparin within prior 30 days
 - c. Thrombosis with skin necrosis or acute systemic reaction after intravenous unfractionated heparin
- 3. Patient at higher risk:
 - a. Elderly patients
 - b. Post-surgical prophylaxis for deep vein thrombosis (orthopedic and cardiovascular surgery)
 - c. Prothrombotic concomitant risks associated with 60% of patients
- 4. Associated cutaneous allergic reactions with skin necrosis
- 5. Major clinical systemic and neurologic complications
 - a. Arterial and venous thrombosis
 - b. May occur in the absence of thrombocytopenia
 - c. Greater occurrence in patients suffering cardiovascular disease
 - d. Arterial complications most common in large vessels that cause:
 - i. Gangrene of a limb
 - ii. Coronary artery thrombosis
 - iii. Ischemic arterial stroke
 - e. Venous complications:
 - i. Deep vein thrombosis
 - ii. Pulmonary embolism
 - iii. Clotting of dialysis shunts
- 6. Cerebral sinus thrombosis:
- 7. Rare systemic complications:
 - a. Hemorrhagic adrenal necrosis
 - b. Disseminated intravascular coagulation

- c. "White" clots in blood vessels (particularly evident in the retinal circulation)
- 8. Cerebrovascular sequelae:
 - a. Ischemic arterial stroke
 - b. Spinal ischemia
 - c. Transient global amnesia
 - d. No primary ICH

Laboratory Evaluation

- 1. Carbon 14-serotonin release assay (SRA test):
 - a. Heparin dependent HIT antibodies release carbon 14-labeled serotonin from platelets
 - b. Heparin induced platelet aggregation test
 - c. Serology

Primary Antiphospholipid Antibody Syndrome

General Characteristics

- 1. IgA, IgM, IgG antibodies are formed against platelet epitopes that include:
 - a. Phosphatidyl ethanolamine
 - b. Phosphatidyl serine
- 2. The specific antibodies measured are:
 - a. Lupus anticoagulant
 - b. Anticardiolipin
 - c. Anti-beta 2-glycoprotein I
 - d. Anti-prothrombin
- 3. There is no other causative autoimmune disease
- 4. Clinical criteria:
 - a. One or more clinical episodes of arterial, venous or small vessel thrombosis
 - b. Confirmed by appropriate imaging studies
 - c. Thrombosis without significant evidence of inflammation in the vessel wall
- 5. Pregnancy morbidity:
 - a. One or more unexplained deaths of a morphologically normal fetus at or beyond 10 weeks of gestation
 - b. One or more premature births of a morphologically normal neonate at or before the 34th week of gestation due to:
 - i. Eclampsia or pre-eclampsia
 - ii. Placental insufficiency
 - c. Three or more unexplained consecutive spontaneous abortions before the 10th week of gestation that are not due to:
 - i. Maternal anatomic or hormonal abnormalities
 - ii. Maternal and paternal chromosomal abnormalities
- 6. Laboratory criteria:
 - a. Lupus anticoagulant is present in the plasma at two times at least 12 weeks apart
 - b. Anticardiolipin antibody of IgG or IgM isotype is present in serum or plasma in medium or high titer on two or more occasions at least 12 weeks apart
 - c. Anti-b2 GP-1 antibody of IgG and/or IgM isotype in serum or plasma is present in two or more occasions at least 12 weeks apart

- 7. Most thrombotic events are venous; if arterial they often occur in the cerebral circulation
- 8. Antiphospholipid syndrome (APS) is classified as secondary if it occurs with SLE or other collagen vascular diseases. They are similar clinically
- 9. Antiphospholipid antibodies may also be seen with infection or specific medicines and in normal subjects. They may not be pathogenic
- 10. B2 GP-1 is a phospholipid binding protein that is needed to detect most antiphospholipid antibodies

Clinical Manifestations

- 1. Cerebral vascular ischemia:
 - a. Can occur in any vascular territory
 - b. Cardiac valvular lesions may be an embolic source; primarily mitral valve thickening
 - c. Increased risk of first ever stroke in young patients
 - d. An increased risk is present in patients with anticardiolipin antibodies and lupus coagulants
 - e. Increased risk of stroke and TIA in women (absolute risk 4.5%)
 - f. Probably no increased recurrent stroke risk
 - g. Presence of Lupus Anticoagulant (LA) and other prothrombotic factors increase stroke risk
 - h. Antiphosphatidyl serine antibodies may be an important biomarker for ischemic stroke
 - i. Antiphosphatidyl serine correlate with LA
 - i. Antiphosphatidyl serine antibodies and b2GP-1 antibodies are a possible cause of arterial stroke
 - j. Antiphosphatidyl antibodies may be important antipathogenic factor for recurrent thrombosis in SLE patients
- 2. Recurrent thrombosis:
 - a. Relatively uncommon
 - b. The recurrence may be within the first year or late (5–10 years)
 - c. The recurrence is similar to the initial thromboembolic event
 - d. Risk factors for a recurrent arterial event:
 - i. Caucasian ethnicity
 - ii. High titers of antibodies in serum
 - e. Risk factors for recurrent venous thrombosis:
 - i. Oral contraceptives
 - ii. Puerperium
- 3. Secondary APS related to systemic lupus erythematosus (SLE):
 - a. Combined anticardiolipin antibodies and LA associated with thrombosis which is arterial
 - b. Venous sinus thrombosis:
 - i. Occurs at a younger age
 - ii. Maybe more severe than the usual causes of venous sinus thrombosis
 - iii. Hemorrhagic infarction

Laboratory Evaluation

1. Lupus anticoagulant
 - a. Clot based assays
 - i. Partial Thromboplastin Time – Lupus Anticoagulant (PTT-LA)
 - ii. dRVVT (Dilute Russell's viper venom time)
 - iii. Dilute prothrombin time (dPT) tests
 - b. Test confounders
 - i. Heparin affects the PTT-LA
 - ii. Vitamin K antagonist prolongs the dRVVT and the dPT tests
2. Anticardiolipin antibodies
 - a. Immune assay for IgM and IgG isotypes
 - b. Test confounders:
 - i. Serum preferably tested 12 weeks following the thrombotic event
3. Anti- β 2-GPI antibodies:
 - a. Immuno-assay for IgM and IgG isotypes
 - b. Test cofounders:
 - i. Serum preferably tested 12 weeks following a thrombotic event

Antiphospholipid Antibody Syndrome Associations*General Characteristics*

1. SLE associated in 1/3 of patients
2. SLE like syndrome in 5% of patients

Clinical Manifestations

1. Most patients have a higher frequency of:
 - a. Myocardial infarction
 - b. Arterial thrombosis of the lower extremities
 - c. After age 50 males are affected more than females
2. Migraine
3. Seizure
4. Chorea
5. Anterior ischemic optic neuropathy

Other Neurological Manifestations of APS

1. Sensorineural hearing loss:
 - a. Sudden or progressive sensorineural hearing loss
 - i. Sudden deafness occurs
 - ii. SLE patients with anticardiolipin antibodies may suffer sudden deafness:
 1. Possibly vascular basis
2. Transient global amnesia
3. Ocular signs:
 - a. Anterior ischemic optic neuropathy
 - b. Branch and central retinal artery occlusion
 - c. Cilioretinal artery occlusion
 - d. Amaurosis fugax
 - e. Combined artery and vein occlusion

Neuropathology

1. Antiphospholipid antibodies effect platelets, coagulation factors, and endothelial cells:

- a. Antiphospholipid antibody binding to phospholipid complexes on platelets and vascular endothelial cells:
 - i. Activates these cells through Fc-gamma receptors binding to phosphatidyl serine or b2GP-1
 1. Induces aggregation of platelets
- b. b2 GP-1
 - i. Binds to endothelial cells through heparin-sulfate proteoglycan
 - ii. Possible role in the function of VEGF (Vascular endothelial growth factor)
- c. Infection may trigger pathologic antiphospholipid antibody response
- d. Receptors, co-receptors, and accessible molecules are involved in the pathogenic effects of a PLA

*Neuroimaging***MRI**

1. Multiple small vessel infarction in all vascular territories
2. Rare hemorrhagic infarction
3. Cerebral atrophy with frontal lobe predominance
4. Small foci of high signal intensity on T2-weighted sequences noted in sub cortical white matter (WMH)
5. Greater than 8 mm (WMH) have been correlated with high anticardiolipin IgG levels

Catastrophic Antiphospholipid Syndrome*General Characteristics*

1. Multiple system involvement
2. Develops over a short period of time
3. Causes microthrombosis
4. Algorithm of Catastrophic Antiphospholipid syndrome
 - a. History of APS or persistently elevated antiphospholipid antibody levels
 - b. 3 or more organ system involvements in less than one week
 - c. Biopsy diagnosis of microthrombosis
 - d. Less than 1% of patients with APS develop catastrophic APS syndrome
 - e. The recurrence rate is low

Sneddon's Syndrome*General Characteristics*

1. Combination of skin and ischemic cerebral lesions in the absence of connective tissue or chronic infective disease
2. Categorized as idiopathic, autoimmune and thromboembolic
3. No definite ethnic predilection
4. In hospital-based series the incidence of .25% to .5% of stroke patients
 - a. 80% are women
 - b. Average age at onset: 40 years
 - c. Possible autosomal dominant genetics in familial cases

Clinical Manifestations

1. Livedo reticularis (mottling, bluish lace-like discoloration with pale center) is often the first manifestation of the dis-

ease and may precede neurological symptoms although it may occur concurrently or afterwards

2. Topography of the lesions:
 - a. Lower trunk, buttocks, proximal thighs
 - b. Lesions may generalize to upper body
 - c. Temporary vasoconstriction
 - i. Exacerbation with cold and concomitantly with exacerbation of neurologic symptoms
 - d. Some patients demonstrate area cyanosis and Raynaud's phenomena
3. Livedo reticularis is associated with:
 - a. Sneddon's
 - b. Divry–Van Bogaert syndrome
 - c. SLE
 - d. Antiphospholipid syndrome
 - e. Polyarteritis nodosa
 - f. Cholesterol embolization
 - g. Livedoid vasculopathy

Neurological Manifestations

1. Headache and vertigo in greater than 50% of patients
2. TIA in more than 50%
3. Cognitive dysfunction: dementia in some late stage patients
4. Multiple TIA and strokes
 - a. Cortical and subcortical topography in anterior and posterior circulations
 - b. Lacunar and white matter lesions
 - c. Spinal cord is rarely involved
 - d. Case reports of SAH and ICH
5. Recurrent transient global amnesia
6. Focal and generalized seizures
 - a. Tremor with a high incidence of seizure (rare)
7. Valvular heart disease
8. Retinal and mesenteric artery involvement
9. Patients with antiphospholipid syndrome may present with full syndrome
10. Cognitive dysfunction
 - a. Evidence for relationship between sustained titers of anticardiolipin antibody IgG levels and cognitive decline

Neuropathology

1. Non-specific cortical and subcortical infarction (data derived from one autopsy)
2. Cortical infarctions; occlusion of medium-sized arteries; focal smooth muscle hyperplasia
3. Putative pathogenesis
 - a. Hypercoagulable state
 - b. Small vessel vasculopathy

Neuroimaging

MRI

1. Multiple subcortical and white matter lesions in separate arterial territories
2. Lacunar infarction
3. Mild to moderate cortical and subcortical atrophy

Angiography

1. Normal in many patients
2. A subset demonstrate distal arterial occlusions with extension collaterals

Circulating Lupus Anticoagulant

General Characteristics

1. A lupus anticoagulant is;
 - a. An anti-IgA, IgG or IgM anticardiolipin (antiphospholipid antibody to phosphatidyl serine and phosphatidyl ethanolamine epitopes)
2. Requirement for laboratory diagnosis:
 - a. Prolongation of a phospholipid dependent screening assay
 - b. Demonstrate inhibitory activity when mixed with healthy pooled plasma
 - c. Documentation that the inhibitory activity is phospholipid dependent
 - d. Blocks the formation of the prothrombin activator:
 - i. Causes a prolonged activated partial thromboplastin time (aPTT) that is not corrected by added plasmin
 - ii. Positive dRVVT and/or dPT test
3. One third of the patients with these antibodies have SLE; these antibodies without another autoimmune disease constitute primary antiphospholipid antibody syndrome

Clinical Manifestations

1. Evidence of systemic venous clotting
2. Large and small artery occlusions
3. Mitral and aortic valve lesions

Neurologic Manifestations

1. Amaurosis fugax
2. Chorea
3. Migraine
4. Transverse myelitis
5. Intracranial occlusive arterial disease
6. Venous and sinus thrombosis
7. Atypical extracranial arterial occlusion
8. Binswanger leukoencephalopathy

Neuropathology

1. Thrombosis of large and small arteries

Neuroimaging

1. Topographical large vessel stroke
2. Generalized small vessel infarction

Diseases of Complement Activation and Thrombotic Microangiopathy (TMA)

Overview

Abnormal activation of complement causes vascular endothelial injury, exposure of the subendothelial matrix and platelet

activation. This deleterious sequence leads to thrombotic microangiopathy (TMA). The process affects arterioles and capillaries primarily and induces vessel wall thickening, detachment of endothelial cells from the basement membrane and intraluminal thrombosis. TMA occurs primarily in hemolytic uremic syndrome (HUS) and thrombotic thrombocytopenic purpura (TTP). There are two major forms of HUS: 1. associated with Shiga toxin-producing *E. coli* (STEC-HUS) 2. atypical HUS with dysregulated complement activation. The kidney, lungs, gastrointestinal tract and brain are the most affected. In a full-blown attack there is platelet activation, aggregation, hemolysis and the development of a prothrombotic and inflammatory state. The usual precipitating causes are infection, pregnancy, drugs or trauma. Mutations in complement regulatory proteins (factor H, factor I, MCP/CD46, thrombomodulin) or those that increase it through alternative pathways (C3, factor B) as well as anti-factor H antibodies cause aHUS. The fundamental defect in aHUS is a complement attachment on cellular surfaces.

In paroxysmal nocturnal hemoglobinuria (PNH), there is dysregulation of complement generation. A variety of cancers demonstrate Terminal Complement (C5-9) deposition on both endothelial and tumor cell membranes which may contribute to their induction of a prothrombotic state. The antiphospholipid syndrome also demonstrates dysregulated complement activation.

These complement dependent diseases include:

1. Thrombotic Thrombocytopenic Purpura (TTP)
2. Atypical Hemolytic Uremic Syndrome (aHUS)
3. Shiga Toxin-producing *E. coli* Hemolytic Uremia Syndrome (STEC-HUS)
4. Disseminated Intravascular Coagulation (DIC)
5. Paroxysmal Nocturnal Hemoglobinuria (PNH)
6. Antiphospholipid Antibody Syndrome (APLA)

Paroxysmal Nocturnal Hemoglobinuria

General Characteristics

1. Non-immune hemolytic anemia with pancytopenia and venous thrombosis
2. Expansion of hematopoietic stem cells and progeny mature cells that are deficient in cell surface proteins that regulate complement activation
3. An acquired somatic mutation in the phosphatidyl inositol glycan (PIGA) gene in hematopoietic stem cells:
 - a. RBC cells derived from the clone form decreased anchored cell surface protein (CD55 and CD59) and are sensitive to complement mediated hemolysis
4. Decreased hematopoiesis
5. Budd-Chiari hepatic vein thrombosis may be prominent
6. Pulmonary hypertension
7. Renal dysfunction
8. Mortality is from thromboembolism
9. Associated myelodysplastic syndrome and leukemia may occur

Clinical Manifestations

1. Hepatic and cerebral vein thrombosis
 - a. Large paroxysmal nocturnal hemoglobinuria granulocytic clones (>50%) predict venous thromboembolism
2. Cerebral arterial thrombosis
3. Platelet counts of <50,000 mm³ in about 50% of patients and may be associated with ICH

Neuroimaging

1. Cortical vein thrombosis
2. Rarely large vessel cortical stroke

Laboratory Evaluation

1. Flow cytometry demonstrate absence of CD55, CD59 on RBCs and neutrophils
2. Absence of CD14, CD16, CD24, CD48, CD52 and CD66 on the surface of neutrophils

Atypical Hemolytic Uremic Syndrome (aHUS)

General Characteristics

1. Recognized by the laboratory signs of microangiopathic hemolysis that includes:
 - a. Schistocytes
 - b. Elevated lactic dehydrogenase
 - c. Low haptoglobin
 - d. Low hemoglobin
 - e. Thrombocytopenia

Clinical Manifestations

1. Focal strokes from small vessel pial involvement
2. Seizures
3. Altered mental status
4. Primarily kidney involvement but gastrointestinal and pulmonary involvement occurs

Neuropathology

1. Uncontrolled activity of the alternative complement pathway
2. Genetic defect in soluble and/or membrane-bound complement regulatory protein. Complement factor H is most often involved
3. Microthrombosis of arterioles and capillaries in affected organs
4. Excellent response to eculizumab that blocks complement activation

Neuroimaging

1. Primarily cortical small vessel infarction
2. Arteriole infarction

Differential Diagnosis

1. TTP often presents a diagnostic dilemma. The diagnosis is secured by demonstrating an ADAMTS13 inhibitor in TTP (less than 10% activity)

2. ADAMTS13 is:
 - a. A disintegrin and metalloproteinase with a thrombospondin type I motif, member 13
 - b. Inhibitor is present in both the idiopathic and acute forms of TTP
 - c. DIC is differentiated due to an increase in D-dimer and decreased factor V and VIII levels. Abnormal clotting profile
 - d. Antiphospholipid antibody syndrome is associated with clotting events and miscarriage

Shiga Toxin-Producing *E. coli* Hemolytic Uremia Syndrome (STEC-HUS)

General Characteristics

1. Arterioles and capillaries are affected
2. Thrombotic microangiopathy

Clinical Manifestations

1. Patients present with HUS signs and symptoms but have active severe diarrhea
2. Kidney injury by microthrombi occurs in all ages but is most severe in children *E. coli* O104
3. H4 was responsible for a large outbreak in Europe in 2011

Neuropathology

1. The Shiga toxin from the *E. coli* triggers endothelial complement deposition by:
 - a. Up regulation of P-selectin
 - b. Putatively interfering with complement regulatory proteins
2. Vessel wall thickening in arterioles
3. Endothelial detachment from basement membranes

Neuroimaging

1. Generalized WMH due to small vessel microangiopathy

Thrombotic Thrombocytopenic Purpura (TTP)

General Characteristics

1. Mutation in ADAMTS-13
 - a. vWF cleaving protease
2. Incidence in females is twice as high as in males; incidence rate about 4 to 6 cases/million individuals
3. Fever (interleukin 1)
4. Peripheral digit ischemia
5. Acute respiratory distress
6. Renal failure
7. Thrombocytopenia
8. Microangiopathic hemolytic anemia
9. Concomitant primarily cortical neurologic symptoms
10. Associated with:
 - a. Pregnancy
 - b. Bone marrow transplantation
 - c. HIV
 - d. SLE

- e. Sjögren's syndrome
- f. Rheumatoid arthritis
- g. Autoimmune disease
- h. Ticlopidine
- i. Influenza
- j. D-penicillamine
- k. Cyclosporine
- l. Cytomycin

Clinical Manifestations

1. Diffuse encephalopathy with:
 - a. Visual hallucinations
 - b. Headache
 - c. Seizure
 - d. Visual loss
2. Transient focal deficits:
 - a. Aphasia
 - b. Papilledema
 - c. Relapsing course
 - d. Posterior leukoencephalopathy

Neuropathology

1. Microvascular thrombosis in arterioles and capillaries
2. Non-familial form:
 - a. Antibodies to ADAMT-13
 - b. Inhibitor of von Willebrand factor cleaving protease
3. Familial form:
 - a. Constitutional deficiency of the protease
 - b. Large multimeres of von Willebrand factor (vWF) adhere to and aggregate platelets
4. Platelet rich thrombosis
5. Multi-focal microinfarctions

Neuroimaging

1. Primarily cortical microinfarcts
2. WMH throughout the brain above the tentorium

Laboratory Evaluations

1. Coombs-negative hemolytic anemia and severe thrombocytopenia due to platelet clumping ($<20,000/\text{mm}^3$ – $<10,000/\text{mm}^3$) thrombocytopenia may be correlate with levels of ADAMTS-13 activity
2. RBC fragmentation on peripheral blood smear
 - a. Anisocytosis
 - b. Poikilocytosis
3. Reticulocyte count and indirect bilirubin are high; haptoglobin is low
4. High lactate dehydrogenase levels

Disseminated Intravascular Coagulation

General Characteristics

1. Simultaneous clotting and activation of the fibrinolytic system
2. Causative disease entities:

- a. Sepsis
- b. Obstetrical emergencies (amniotic fluid emboli)
- c. Cancer (release of thromboplastic-like substances)
- d. Damage to blood vessel endothelium
- e. Severe brain injury or surgery
- f. Heat stroke (platelet activation)
- g. Treatment of leukemia and lymphoma (after IV chemotherapy)
- h. SAH
- i. Vascular malformations (Kasabach-Merritt syndrome)
3. Abnormal activation of intravascular thrombin and the fibrinolytic system
 - a. Deposition of fibrin throughout systemic and intracranial vasculature

Clinical Manifestations

1. Large and small vessel arterial thrombosis
2. SAH
3. SDH (subdural hematoma)
4. NBTE (emboli) in cancer patients
5. Intracranial hemorrhage in non-hypertensive areas
6. Multifocal encephalopathy
7. Severe acrocyanosis
8. Bleeding from prior venipuncture sites

Neuropathology

1. Infections:
 - a. Release of IL-1, IL-6 and TNF- α from macrophages, monocytes and lymphocytes during sepsis:
 - i. Converts antithrombotic endothelium to a pro-thrombotic state
 - ii. Lipopolysaccharides from gram negative cell walls and release of endotoxins activate TNF- α and IL-1 that induces coagulation
2. Tissue factor is released from endothelial cells with burns, trauma and cancer induced coagulation
3. Collagen vascular diseases, viremia, microangiopathic hemolytic anemias may all dysregulate the endothelial cell membrane and the high affinity thrombin receptor thrombomodulin to induce clotting
 - a. IL- β and TNF- α are increased in DIC and down regulate endothelial expressed thrombomodulin
 - b. Thrombomodulin and thrombin, when complexed, activate Protein C inhibit factor V and VIII_a. Lack of this inhibition from decreased thrombomodulin induces clotting
4. Increased fibrinolytic activity is induced by the release of plasminogen activators from endothelial cells
5. Fibrin is deposited throughout small arterioles and capillaries of the brain and systemic organs. Occasionally larger extracranial cerebral vessels may be occluded
6. Recent studies demonstrate:
 - a. Activation of vascular endothelial factors 1 and 2 and the angiotensin (Ang)-Tie ligand receptor system
 - b. Activation of vascular endothelial growth factor (VEGF) which increases vascular permeability during inflammation and ischemia

Neuroimaging

MRI

1. Large and small vessel strokes in all circulations
2. SDH
3. SAH

Laboratory Evaluation

1. Platelets and clotting factors
 - a. $<30\text{--}50,000/\text{mm}^3$
 - b. Decreased factors V and VIII
 - c. Decreased fibrinogen levels
 - d. Prolonged PT and partial thromboplastin time
 - e. D-dimer (new antigen) appears in the blood
2. Molecular hemostatic markers:
 - a. Thrombin-antithrombin complex
 - b. D-dimer
 - c. Soluble fibrin (SF)
 - d. Plasmin-plasmin inhibitor complex

Chronic Myeloproliferative Disorders

Overview

1. Myeloproliferative disorders are:
 - a. Clonal disorders
 - b. Myeloproliferative disorders include:
 - i. Essential thrombocythemia
 - ii. Polycythemia vera
 - iii. Chronic myeloid leukemia
 - iv. Myelofibrosis/myeloid metaplasia
 - v. Chronic neutrophilic, eosinophilic and basophilic leukemia
 - vi. Systemic mastocytosis
2. The most important in regard to coagulation dysfunction in the nervous system are polycythemia vera and essential thrombocythemia

Polycythemia Vera

General Characteristics

Genetics

1. Increased sensitivity of erythroid precursors to erythropoietin
2. Related to mutation in JAK2 V617F, a tyrosine protein kinase, other JAK mutations are found in patients with myeloproliferative neoplasms and leukemia
 - a. Janus kinases (JAKs) are involved in cytokine signaling
 - b. JAK2 – pivotal in hematopoiesis
 - c. JAK2 – JAK2 V617F point mutation is present in the majority of Philadelphia chromosome-negative myeloproliferative neoplasms that include:
 - i. Polycythemia vera
 - ii. Essential thrombocythemia
 - iii. Primary myelofibrosis
 - d. JAK2V617F is rarely found in:
 - i. Hypereosinophilic syndrome
 - ii. Chronic myelomonocytic leukemia

- iii. Acute myeloid leukemia
- e. JAK2V617F mutation is:
 - i. An acquired somatic event of hematopoietic stem cells

Clinical Manifestations

1. Mortality due to thrombosis, rare bleeding complications:
 - a. Thrombotic events occur in approximately 4–9% of patients
 - b. Low incidence in young patients less than 40 years of age; higher incidence in patients older than 70
 - c. Greater incidence in those treated with phlebotomy rather than hydroxyurea
 - d. Thrombosis reported 2 years preceding diagnosis
2. Thrombosis of large cerebral arterial vessels:
 - a. Posterior circulation infarctions are more common than anterior circulation infarctions
 - b. Scattered lesion pattern:
 - i. Suggestive of embolic microcirculation stroke
3. Retinal venous occlusions
4. Large arteries are involved in the cardiovascular and peripheral arterial systems
5. Ischemic stroke and TIA occur in 4–5% of patient/year
6. Cerebral venous thrombosis is frequent:
 - a. Aggravating factors are decreased cerebral blood flow and elevated hematocrit

Essential Thrombocytosis

General Characteristics

1. Sustained thrombocytosis of greater than 450,000 platelets/mm³ after exclusion of reactive causes
2. Persistently elevated levels of thromboxane A₂ due to platelet activation
3. Approximately 50% of patients have the JAK 2 V617F mutation
4. Aspirin more effective than Coumadin in treatment

Clinical Manifestations

1. Migraine or non-specific headache
2. TIA and arterial strokes
3. Ocular scintillating scotoma
4. Thrombotic events occur (15–89%) with a 5% annual incidence
 - a. Thrombosis more prevalent in patients older than 60
 - b. In those who have suffered previous events
 - c. Thrombotic risk is not proportional to platelet count >1,000,000 mm³
5. Cerebral venous sinus thrombosis

Neuropathology

1. Increased responsiveness of megakaryocytes to thrombopoietin
2. Thrombocythemia
 - a. Shortens platelet survival

- b. Increased beta-thromboglobulin in the serum
- c. Increased platelet factor 4 level in the serum
- d. Increased urinary tract excretion of thromboxane B₂ (TxB₂)
 - i. Marker of platelet activation
- 3. Most thrombotic events are in large arteries, platelet/thrombin clots also occur in arterioles

Neuroimaging

1. Large artery strokes
2. Venous sinus thrombosis

Short Clinical Classification of Thrombotic and Bleeding Disorders

1. Thrombophilia
 - a. Any disorder inherited or acquired with increased thrombosis
2. Coagulopathies
 - a. Common gene mutations:
 - i. Factor V (R1691A) mutation
 - ii. Prothrombin (G20210A) mutation
 - iii. Methylenetetrahydrofolate reductase (MTHFR) mutation
3. Rare Genetic Deficiencies
 - a. Protein C
 - b. Protein S
 - c. Antithrombin
 - d. Plasminogen
 - e. Homocysteine
4. Probable Genetic Risk Factors
 - a. Increased:
 - i. Fibrinogen
 - ii. Factor IX
 - iii. Factor VIII
 - iv. Decreased Factor XII
5. Most Common Deficiencies of Inhibitors of Clotting
 - a. Antithrombin III
 - b. Protein C
 - c. Protein S
 - d. Factor V Leiden

Organ-Specific Thrombosis and Hemostasis

1. Local organ expression of endothelial factors and receptors determine thrombosis and hemostasis in the face of systemic changes in coagulation parameters:
 - a. Differential expression of coagulant and anticoagulant factors in different locations within the vascular tree
 - b. Endothelial Protein C receptor
 - i. Predominately expressed in large arteries and veins
 - ii. Tissue factor pathway inhibitor
 1. Expressed in capillaries
 - iii. Nitric oxide
 1. Expressed in arteries
 - iv. vWF expressed in veins

- c. Protein C, Protein S or antithrombin III deficiency:
 - i. Predispose to venous thrombosis of the lower extremity at valve pockets due to concomitant stagnant blood flow and hypoxia
- d. Polycythemia vera, paroxysmal nocturnal hemoglobinuria and essential thrombocythemia:
 - i. Preferentially effect intra-abdominal veins (Budd-Chiari syndrome)
- e. Erythromelalgia:
 - i. Thrombotic occlusion of arterioles (not the painful Nav1.7 neuropathy) primarily localizes to the toes, fingers and is caused by myeloproliferative disease, polycythemia vera and essential thrombocythemia
- f. Warfarin induced skin necrosis:
 - i. Effects buttocks, thighs and the breast
 - ii. Caused by the thrombotic occlusion of venules
 - iii. Deficiency of protein C

Organ Specific Hemorrhage

1. Possibly dependent on deficiencies within the intrinsic or extrinsic pathways:
 - a. Murine model: decreased expression of VII and tissue factor cause hemorrhage in heart, lung testes, uterus and placenta
 - i. Low factor VIII and IX lead to hemorrhages in joint muscles and joints (tissue factor expression is low)
 - b. Subdural hematoma (often with minimal trauma)
 - c. Experimental evidence supports low levels of tissue factor and hemorrhage in:
 - i. Heart
 - ii. Lung
 - iii. Testis
 - iv. Uterus
 - v. Placenta

Antithrombotic Factors

1. Vascular endothelium is characterized by constitutive expression of antithrombotic factors:
 - a. Differentially expressed
2. Thrombomodulin:
 - a. Expressed in brain capillaries (low levels in areas of lacunar stroke)
 - b. Increased expression in small arteries occur with small vessel disease
 - c. Endothelial protein C receptor is:
 - i. Adjacent to thrombomodulin
 - ii. Enhances protein C deactivation of factors V and VIII
 - d. Preferentially expressed in the endothelium of arteries and veins
 - e. Minimal expression in brain capillaries

Fibrinolytic Pathway: tPA and Plasminogen Activator Inhibitor-1

1. tPA is the pivotal endothelial dependent serine protease that binds fibrin and activates the fibrinolytic system:
 - a. tPA capillary expression in the brain is absent
 - b. Alpha-thrombotin induces tPA release from endothelial cells
 - c. Brain microvascular endothelium expresses tissue plasminogen activator inhibitor-1
 - d. The BBB may be the regulator of the brain microvascular fibrinolytic system

Tissue Factor

1. The brain is a major source of tissue factor:
 - a. Astrocytes are the principal source in the CNS; also on the surface of pericytes
 - b. Brain hemostatic envelope

Tissue Factor Pathway Inhibitor (TFPI)

1. Synthesized by endothelial cells
2. Low expression in the brain

Antithrombin III – Heparin Sulfate – Polyglycan

1. Protease inhibitor synthesized by the liver:
 - a. Forms covalent complexes with coagulation factors
 - b. Function is amplified when bound to heparin-sulfate – polyglycan (HSPG) which is absent in brain capillaries (in rat)

Cerebral Venous Thrombosis (Genetic Causes)

1. Thrombophilia risk factors occur in approximately 30–60% of patients and include:
 - a. Antithrombin III deficiency
 - b. Protein C and S deficiency
 - c. Factor V Leiden mutation
 - d. Dysfibrinogenemia with increased factor VIII
 - e. Thrombomodulin mutations
 - f. Prothrombin G 20210A mutation
2. Acquired Prothrombotic Disorders:
 - g. Antiphospholipid antibodies
 - h. Lupus anticoagulant
 - i. APC resistance
 - j. Acquired deficiency of antithrombin III, protein C, S and hyper homocysteinemia

Cerebral Venous Thrombosis (Acquired)

1. All causes of venous stasis
2. Advanced age
3. Multiple trauma
4. Surgical procedures
5. Pregnancy (second and third trimester) and is further increased by inherited thrombophilia, increased CVST risk
6. During puerperium
7. Malignancy:
 - a. Risk increased if patients have Factor V Leiden or prothrombin G20210A mutations

Summary of Coagulopathies That Cause Arterial and Venous Strokes

Coagulopathies

1. General Categories:
 - a. Decreased inhibitors of activated coagulation factors
 - b. Hereditary fibrinolytic deficits
 - c. Clotting factor deficiencies
 - d. Approximately 5% of stroke
2. Autosomal Dominant Defects:
 - a. Heparin cofactor II
 - b. Protein C deficiency
 - c. Decreased release of plasminogen activator
 - d. Homozygote XII deficits (thrombotic tendency)
 - e. Prothrombin gene defect
3. Autosomal Recessive Defects:
 - a. Prekallikrein deficiency (Fletcher factor)
4. Propensity for Thrombosis:
 - a. Antithrombin III defects
 - b. Protein S deficiency
 - c. Plasminogen defects
 - d. Factor V Leiden defect
5. Acquired Causes of Hypercoagulability:
 - a. Diabetes mellitus
 - b. Hyperlipidemic states
 - c. Disseminated intravascular coagulation (consumption with fibrinolysis)
 - d. Platelet disorders
 - e. Vasculitis
 - f. Malignancy (thromboplastin-like substances released into the circulation)
 - g. Hyperaggregable (sticky) platelets
 - h. Endothelial damage
 - i. Cardiopulmonary bypass:
 - i. Increased fibrinolytic activity
 - ii. Decreased coagulant activity
 - iii. Increased plasminogen activator inhibitor level
 - iv. Platelets $>1,000,000 - 7 \times$ risk of bleeding
 - j. Antiphospholipid antibody
 - k. Anticardiolipin antibody
 - l. Lupus anticoagulant
 - m. Heparin induced thrombosis
 - n. Rheological Abnormalities
 - i. Hyperviscosity
 - ii. Deficits in laminar and pulsatile flow

Coagulopathies: General Categories That Warrant a Laboratory Screening

1. Comprehensive Procoagulant Screen:
 - a. Common gene mutations:
 - i. Factor V (R1691A) mutation
 - ii. Prothrombin (G20210A) mutation
 - iii. MTHFR (C677T); methyl tetrahydrofolate reductase mutation
 - b. Rare genetic deficiencies:

- i. Protein C
- ii. Protein S
- iii. Antithrombin III
- iv. Plasminogen
- c. Putative candidates for genetic thrombophilia:
 - i. Elevated lipoprotein
 - ii. Homocysteine

Probable Genetic Risk Factors

1. Increased:
 - a. Fibrinogen
 - b. Factor IX
 - c. Factor VIII
 - d. Decreased factor XII

Hereditary Cause of Hemorrhagic Stroke

General Characteristics

1. X-linked VIII and IX deficiency
2. AR-afibrinogenemia
3. Factor VII, X, XI, XIII deficiency

Clinical Manifestations

1. Rare bleeding in factor XI deficiency
2. VIII deficiency less than 10% of normal values are necessary to bleed
3. Latent period of deficits prior to stroke

Platelet Dysfunction

General Characteristics

1. Increased platelet counts – above 1 million:
 - a. Associated with hypercoagulability
2. Increased coagulability may occur with increased adhesion and aggregation:
 - a. Functional platelet abnormality more than absolute platelets number may be the important parameter:
 - i. Sticky platelets
3. Essential Thrombocythemia:
 - a. Associated with stroke and digital artery infarction
 - b. Transient ischemic attacks
 - c. Major ICH
4. Glanzmann Thrombocythemia
5. Bernard Soulier Thrombocythemia

Leukemia

General Characteristics

1. Rheological abnormalities occur with WBC $> 250,000/\text{mm}^3$
 - a. Capillary sludge
 - i. Infarction
 - ii. Small brain hemorrhages
2. SAH
 - a. Vaginal bleed prior to cerebral bleed at approximately $30,000 \text{ platelets}/\text{mm}^3$

Decreased Natural Inhibitors of Coagulation

1. Antithrombin III
2. Low levels of heparin releasable tissue factor inhibitor in young patients with thrombosis
 - a. Coincidence of defect with thrombosis is putative
3. Prekallikrein deficiency
 - a. Severely prolonged activated partial thromboplastin time (a PTT)
 - b. Due to Factor XII activation
 - c. No increased bleeding risk if defect is solitary
 - d. Bleeding risks occur in association with hereditary defects of:
 - i. VIII, IX, XI

Most Common Deficiencies of Inhibitors of Clotting

1. Antithrombin III
2. Protein C
3. Protein S
4. Factor V Leiden

Rheology*Overview*

1. Viscosity is the ratio of the shear stress to shear rate
 - a. Shear stress – the tangential force between flowing layers of a fluid
 - b. Shear rate – the velocity gradient between layers of flow
2. Whole blood viscosity varies as its shear rate
 - a. Low viscosity increase with low flow rates
3. Blood viscosity is determined by:
 - a. Hematocrit
 - b. Plasma protein
 - c. Fibrinogen concentration
 - d. Cellular aggregation
 - e. Red cell deformability
 - f. Axial migration
 - g. Vessel diameter
 - h. Flow rate
4. Viscosity in small blood vessels
 - a. Blood viscosity approximates plasma viscosity which becomes an important determinant of capillary flow
 - b. Red cell aggregation determines a major proportion of blood viscosity
 - i. Fibrinogen and globulin decrease electronic repulsion between RBCs (increase aggregation)
 - ii. In long blood vessels RBCs migrate to the vessel axis which increases fluidity and oxygen transport
 - iii. Higher velocities and shear rate break up RBC aggregation; the reverse occurs in low flow states
 - iv. RBC aggregation increases in most conditions with high sedimentation rates
 - v. Low flow rate increases viscosity logarithmically due to low shear rates which occur with:
 1. Arterial stenosis

2. Hypervolemia

3. Stasis or low shear rate causes RBC structural deficits that increase viscosity (stiffening of red blood cells)

Hyperviscosity Syndromes*Overview*

1. Three major categories:
 - a. Plasma viscosity abnormalities
 - b. Increased blood cellularity
 - c. Structural changes in RBCs (deformability)

Putative Associations

1. Binswanger disease
2. Pathogenesis and progression of atherosclerosis
 - a. Occurs in areas of low shear stress
3. Spontaneous echo contrast (smoke) in heart chambers
 - a. Increased risk for cardiac emboli
 - b. In atrial fibrillation, mitral stenosis, left atrial enlargement
 - c. Pathology is putative protein mediated RBC aggregation as a consequence of low shear force

Plasma Viscosity Abnormalities*General Characteristics*

1. Plasma viscosity is determined by positively charged, non-spherical, high molecular weight proteins:
 - a. Fibrinogen (principal determinant)
 - b. α -2 macroglobulins
 - c. Immunoglobulins
2. Increased high-molecular weight globulins occur in:
 - a. Lymphoma
 - b. Waldenström's macroglobulinemia
 - c. Multiple myeloma (uncommon)

Clinical Manifestations

1. Mucous membrane bleeding
2. Blurred vision and visual loss
3. Lethargy
4. Dizziness/vertigo
5. Tinnitus
6. Paraesthesias
7. Seizures (rare)

Clinical Signs

1. Enlarged tortuous retinal veins
2. Retinal hemorrhages
3. "Box-car" formation of RBC's in retinal veins (abnormal clumping; Rouleaux formation)
4. Bleeding gums and mucous membranes
5. Poor perfusion of distal extremities; acrocyanosis (particularly in cryoglobulinemia)
6. Lower leg petechiae (Waldenström's macroglobulinemia)
7. Altered mental states
8. Small vessel stroke

*Pathology***Pathological Mechanisms**

1. Increased plasma viscosity
2. Hypervolemia
3. Increased red cell aggregation (due to elevated paraproteins)
4. Intravenous Immunoglobulin Therapy
 - a. Possible association with strokes; mechanisms include:
 - i. Increased viscosity of plasma and whole blood
 1. Decreased cerebral blood flow
 - ii. Platelet activation
 - iii. Vasospasm

Neuroimaging

1. MRI
2. Large and small vessel stroke
3. Venous sinus thrombosis

Increased Blood Cellularity*General Characteristics*

1. Polycythemia vera
 - a. Increased peripheral blood cell counts and increased red cell mass that leads to:
 - i. Decreased vertebral blood flow
 - ii. Increased platelet counts and reactivity
2. Types of strokes recorded include:
 - a. Cerebral venous infarction, Binswanger disease, intracerebral hemorrhage, large cerebral artery thrombosis and watershed infarction
3. Increased white blood cell counts particularly in forms of leukemia that have hyperviscosity
 - a. WBCs less deformable than RBCs
 - i. Global dysfunction (poor perfusion)
 - ii. Microinfarcts
 - iii. Petechial infarction (particularly in white matter)

Structural Changes in RBCs (Decreased Red Cell Deformability)*General Characteristics*

1. In sickle cell disease with hypoxia or low pH:
 - a. Hemoglobins polymerize
 - b. Cell shape becomes sickled thus increasing viscosity, decreasing flow and causes sludging of the microcirculation and cerebral veins
2. Associated with occlusion of the distal internal carotid artery and Circle of Willis which may cause:
 - a. Moyamoya disease with distal carotid occlusion (lenticulostriate collaterals appear as a “puff of smoke” in the MCA territory)
 - b. Endothelial injury and possibly sickle cell stimulation of smooth muscle and fibrous elements of the vessel wall

- c. Stasis in the vaso vasorum (blood supply to blood vessels)
3. Sickle cell disease patient strokes occur:
 - a. Convexity border zones
 - b. Deep and subcortical territories
 - c. Brainstem, spinal cord and retinal territories

Differential Diagnosis of Strokes Associated with Hyperviscosity

1. Diabetes mellitus
2. Low flow states (dehydration, burns, shock)
3. Arterial hypertension
4. Lipoproteins including LDL, triglycerides, chylomicrons and VLDL which cause:
 - a. Concentration dependent increase of plasma viscosity (dehydration)
 - b. Red cell aggregation (increased LDL)
5. Smoking associated with:
 - a. Increased hemoglobin
 - b. Red cell aggregation
 - c. Increased fibrinogen
 - d. Increased leukocytosis
 - e. Increased plasma viscosity

Putatively Associations

1. Binswanger disease
2. Pathogenesis and progression of atherosclerosis
 - a. Occurs in areas of low shear stress
3. Spontaneous echo contrast (smoke) in heart chambers
 - a. Increased risk for cardiac emboli
 - b. In atrial fibrillation, mitral stenosis, left atrial enlargement
 - c. Pathology is putative protein mediated RBC aggregation as a consequence of low shear force

Bone Disorders and Cerebrovascular Disease*General Characteristics*

1. Low bone mineral density (BMD)
 - a. Predictor of cardiovascular mortality in older men
 - b. Low BMD is related to stroke mortality and incidence of stroke in women
 - c. Relationship between BMD and stroke has not been supported by some studies

Clinical Manifestations

1. Fibrocartilaginous emboli
 - a. Rare cause of stroke:
 - i. Source is nucleus pulposus
 - ii. 32 patient study demonstrated:
 1. Women affected more than men
 2. Bimodal age distribution (20's and 60's)
 3. Embolization was arterial and venous; some purely arterial
 - b. Ischemic myelopathy occurred
 - i. Cervical > lumbosacral areas

Neuropathology

1. Schmorl's nodes (nucleus pulposus eroding the vertebral body)
2. Larger volume of nucleus pulposus in younger patients
3. Prolonged flexed position during lumbar puncture

Neuroimaging

1. Large vessel embolic stroke

Osteopetrosis*General Characteristics*

1. An abnormal accumulation of bone mass
 - a. Diminished bone resorption
2. Autosomal recessive
 - a. Multiple genes have been described: SNX10 and TC1RG1 are related to osteoclast function

Clinical Manifestations

1. Associated cerebrovascular disease:
 - a. Compression of the carotid and vertebral arteries in transcervical and carotid canal from excessive bony overgrowth

Neuropathology

1. Communication between Ephrin type-B receptor 2 and Ephrin type-B receptor 4 within the osteoblast lineage are pivotal in bone mineralization

Neuroimaging

1. Entrapped arteries in their bony canals

Paget's Disease*General Characteristics*

1. Incidence appears to be decreasing
2. Genetic features:
 - a. Mutation in the SQSTM1 gene occur in 25–50% of familial Paget's disease
 - b. Disturbance of bone modeling and remodeling

Clinical Manifestations

1. Steal syndrome
2. Spinal epidural hematomas; reported case of subdural hematoma
3. Mechanical compression of cerebral vasculature in bony canals

Neuropathology

1. Overactivity of Pagetic osteoclasts
2. Focal and disorganized increases in bone turnover

Neuroimaging

1. MRI/CT
2. Arterial compression in bony canals with topographical stroke

Schimke Immuno-Osseous Dysplasia*General Characteristics*

1. Autosomal recessive
 - a. Biallelic mutation in SMARCAL1 (SWI/SNF-related matrix-associated, actin-dependent regulator of chromatin, subfamily-like 1)
 - b. Decreased regulation of elastin expression
2. Associated with atherosclerosis and emphysema
3. Atherosclerosis characterized by:
 - a. Intimal and medial hyperplasia
 - b. Smooth muscle cell hyperplasia
 - c. Disorganized elastin fibers
 - d. Microdontia, hypodontia, malformed deciduous and permanent molars
4. Associated medical conditions:
 - a. Spondyloepiphyseal dysplasia
 - b. Triangular face
 - c. Short neck and short limbs
 - d. Hyperpigmented macules

*Clinical Manifestations**Cerebrovascular Complications*

1. 2 girls described with Moyamoya disease
2. Several children described with TIA

Imaging Evaluation

1. PET study revealed hypoperfusion of cerebral and cerebellar arterial territories

Neuropathology

1. Low brain weight
2. Defective neuron-glial migration with:
 - a. Heterotopia
 - b. Irregular cortical thickening
 - c. Incomplete gyral formation
3. Cortical dysplasia

Camurati-Engelmann Disease*General Characteristics*

1. Autosomal dominant disorder
 - a. Chromosome 19q.13 gene mutations
 - b. Encodes TGFB1
 - c. Occasional incomplete penetrance
2. Progressive diaphyseal dysplasia
 - a. Cortical bone sclerosis of the diaphyses and metaphyses of long bones
 - b. Cranial hyperostosis (skull base)
 - c. Exophthalmos
 - d. Waddling gait
 - e. Muscle weakness
 - f. Leg pain
 - g. Cranial nerve constriction at the skull base

*Clinical Manifestations***Cerebrovascular Manifestations**

1. Premature onset of arteriopathy causing:
 - a. Dissection of vessels
 - b. Vertebral atherothrombosis

Neuropathology

1. TGFBI-dependent vascular remodeling
 - a. Thickening of the intima and media
 - i. Increase in extracellular matrix and proteoglycan synthesis

Neuroimaging

1. Dissection of vertebral vessels
2. Atherosclerotic circulation
 - a. Posterior > anterior

Cancer and Paraneoplastic Strokes*Overview*

1. The syndromes may develop in parallel with the development and growth of the tumor or precede it
2. 15% of patients with cancer have cerebrovascular disorders related to their neoplastic disease
3. Paraneoplastic strokes often present with specific clinical manifestations
4. The frequency of hemorrhages equals infarcts

Cerebrovascular Disease and Cancer

1. Brain infarction is more common in patients with carcinoma and leukemia
2. Leukemia most often is the cause of hemorrhage
3. Diffuse and progressive encephalopathy occurs with:
 - a. DIC, non-bacterial endocarditis and paraneoplastic vasculitis
 - b. Associated with or without focal deficits
 - c. Due to multiple infarcts
4. Approximately 10% of cancer patients suffer a stroke
5. Venous thrombotic disease:
 - a. Diffuse moderate to severe headache
 - b. Focal or generalized seizures:
 - i. Cortical vein induced seizures progressively incorporate a larger territory with each seizure
6. Strokes with disseminated intravascular coagulation:
 - a. Occur in both large and small vessels
 - b. Primarily anterior circulation
 - c. Associated with subarachnoid hemorrhage
 - d. Often accompanied by NBTE and emboli
 - e. May occur following chemotherapy and often with gram negative sepsis
 - f. Acrocyanosis and bleeding from peripheral venipuncture sites
7. Hemorrhagic stroke is as common as bland infarction:
 - a. More frequent with leukemia than lymphoma or solid tumors

- b. Myelogenous greater than lymphocytic leukemia
- c. Acute greater than chronic disease
- d. Hemorrhages are often smaller than with usual causes
 - i. Associated with diffuse encephalopathy
- e. Subdural hematoma occurs in all stages
- f. Subarachnoid hemorrhage (SAH) is the rarest form of hemorrhagic stroke with cancer

Mechanisms of Stroke in Cancer Patients

1. Autoimmune in primary paraneoplastic syndromes ("molecular mimicry")
 - a. Most common with small cell cancer of the lung and gynecological tumors
2. Secondary neurological paraneoplastic syndromes:
 - a. Most common cause of cerebrovascular disease and cancer
 - b. Autoimmune mechanism
 - c. Release of procoagulant proteins (tissue-factor VII like) by the tumor; occurs with breakdown of tumor cells during treatment – particularly with leukemia and lymphoma
 1. Cause both hemorrhagic and bland infarctions
3. Autoimmune blood element involvement occurs with:
 - a. Microangiopathic hemolytic anemia:
 1. Associated with mucinous adenocarcinomas of the stomach, breast and lung
 - a. Associated thrombocytopenia
 - b. Thrombocytopenia
 1. Usually platelets are less than 30,000/mm³
 2. Most common tumors are chronic lymphocytic leukemia, b-cell lymphoma, lung and rectal carcinoma
 3. Thrombotic thrombocytopenic purpura
 - a. Fibrin and platelet aggregates form throughout the brain microcirculation
 - b. Microinfarcts
 - c. Intracranial and subdural hemorrhages
 - d. Antibodies to vWF
 - i. Associated with lympho- and myeloproliferative neoplasms
 - ii. Systemic and intracranial bleeding
4. Antiphospholipid antibodies:
 - a. Associated with arterial and venous thrombosis
 - b. Venous sinus occlusion
5. Tumor induced vasculitis:
 - a. Immune complex deposition on vascular endothelium
 - b. Hodgkin's disease, lymphoma, hairy cell leukemia and lung cancer are the most common neoplasms
6. Granulomatous angiitis:
 - a. Herpes Zoster infection (distribution of V₁)
 - b. Delayed onset of proximal intracranial large vessel infarction
7. Temporal arteritis:
 - a. Estimated incidence concomitant with neoplasm is 3.5%–16%
 - i. TIA and infarction occur in less than 10% of these patients

Neoplasms and a Prothrombotic State

1. Tumor derived procoagulants
2. Non-bacterial thrombotic endocarditis:
 - a. Most common cause of symptomatic cerebral infarction in cancer patients
 - i. Fibrin-platelet deposits on cardiac valves (primarily mitral or aortic)
 - ii. Highest incidence
 1. Lymphomas
 2. Gastric and lung cancer
 3. Prostate adenocarcinoma
 4. Medullary thyroid cancer (rare)
 - iii. Associated with compensated disseminated intravascular coagulation (DIC) and intravascular thrombosis
 - iv. 1–2% of autopsied cancer patients
 1. Approximately 1/3 with cerebral emboli
 - v. May occur with any cancer at either the early or late stage of disease
 - b. 20% of acute leukemia patients develop DIC
 - i. Release of procoagulants
 - c. Compensated DIC:
 - i. Platelets approximately 30,000/mm³
 - ii. Increased fibrin degradation products
 - iii. Hyperfibrinogenemia; decreased factor V and VIII
 - iv. Infarction of small cerebral arteries and venules
 - v. Venous sinus thrombosis
 - vi. NBTE
 - vii. Second most common cause of vascular disease in cancer patients
3. Mechanisms of hypercoagulability in DIC
 - a. Fibrinopeptide A, a marker of thrombosis, is elevated in many neoplasms
 - b. Sialic acid residues released by mucinous tumors
 - c. Pancreatic enzyme release
 - d. Tissue factors and phospholipids
 - e. Inflammatory cytokines (IL-1, IL-6, IL-8, ICAM, tumor necrosis factor α) released by the neoplasms:
 - i. Activate platelets
 - ii. Induce clotting
 - f. IL-6 induces thrombosis
 - g. Paraproteins and immunoglobulins (Waldenström's, IgG and IgM)
 - i. Hyperviscosity syndrome
 - ii. Interferes with fibrin polymerization and causes hemorrhage

Intravascular Lymphoma*General Characteristics*

1. Extra nodal large B-cell lymphoma
 - a. Neoplastic lymphoid cells proliferate within the lumina of small to medium-sized vessels
 - b. Past terminology: angioendotheliomatosis
 - i. Presently intravascular lymphoma or intravascular lymphomatosis

2. Ischemic damage to various organ systems
3. Incidence of less than 1 case per million
4. Primary occurrence in sixth or seventh decade (range between 34 to 90 years of age)
5. No gender preference
6. An asian variant associated with:
 - a. Hemophagocytic syndrome
 - b. Less neurologic symptomatology
 - c. No cutaneous involvement
7. Women in Western countries may have:
 - a. Cutaneous variant
 - b. Good prognosis

Clinical Manifestations

1. Untreated patients: medium survival of 4 to 7 months
2. Poor prognostic factors
 - a. Greater than 60 years of age
 - b. Thrombocytopenia
3. Most common areas of involvement are skin and CNS
4. Non-neurologic presentations include:
 - a. Fever of unknown origin
 - b. Rash
 - c. Night sweats
 - d. Weight loss
 - e. Renal failure
 - f. Dyspnea

Neurological Features

1. Cerebral infarction:
 - a. Multifocal infarcts in greater than 75% of patients with neurologic symptoms
 - b. Recurrent focal deficits cause a progressive encephalopathy dementia
 - c. Supratentorial strokes most common
 - d. Differential diagnosis of vascular presentation
 - i. CNS angiitis
 - ii. Acute disseminated encephalomyelitis
 - iii. Creutzfeldt-Jakob disease
2. Encephalopathy and rapidly progressive dementia
 - a. Gradual cognitive decline, subacute encephalopathy or fluctuating level of consciousness
 - b. Encephalopathy in approximately 30% of patients
 - i. Focal deficits and seizures may occur
3. Spinal cord and radicular syndrome
 - a. Spinal cord involvement
 - i. Greater than 1/3 of patients with neurologic involvement
 - ii. Spastic or flaccid paraparesis associated with pain and incontinence
 - iii. Involvement of blood vessels with infarction of the cord or roots at any level
4. Neuropathy
 - a. Both peripheral and cranial nerve involvement
 - i. Vasa nervorum involved
 - b. Cranial nerve involvement

- i. VII, VI, VIII, III, V and II most often involved
 - ii. Axonal neuropathy
- 5. Venous stroke
 - a. Proliferation of lymphomatous cells within the venules and dural sinuses
 - i. Venous occlusion with infarction and hemorrhagic transformation

Neuropathology

1. Brain biopsy may be non-diagnostic (need involved tissue)
2. Occlusion of small vertebral and meningeal capillaries, arterioles and venules by malignant lymphocytes
 - a. β -cell phenotype
 - b. Rare T-cell or natural killer cell (NK) derivation
 - c. Infarctions may be hemorrhagic; distributed throughout the brain and spinal cord
- d. Extra-CNS involvement
 - i. Skin
 - ii. Liver
 - iii. Spleen
 - iv. Bone marrow
 - v. Kidney
 - vi. Lung
 - vii. Prostate
 - viii. Adrenal gland
 - ix. Thyroid
 - x. Gall bladder
 - xi. Lymph nodes are usually spared

Imaging Evaluation

MRI

1. May have high false negative rate
 - a. Spinal cord lesions are difficult to detect
 - b. Multifocal abnormalities:
 - i. Non-specific white matter hyperintensities: 45%
 - ii. Infarcts: 36%
 - iii. Focal mass lesions: 36%
 - iv. Meningeal/parameningeal enhancement: 64%
 - v. Multifocal lesions on DWI
 1. Fluctuation of lesions (resolution and recurrence) during the course of the illness
 - vi. Lesion enhancement with gadolinium
 - vii. One patient reported with posterior leukoencephalopathy

Laboratory Evaluation

1. Elevated ESR, lactic dehydrogenase and anemia
2. Bone marrow negative
3. CSF analysis:
 - a. May be normal
 - b. Most demonstrate elevated protein
 - c. 50% show mild to moderate pleocytosis:
 - i. Rarely malignant cells demonstrated
 - d. Elevated immunoglobulin G index

Differential Diagnosis

1. Intravascular lymphoma should be considered in the differential diagnosis of multifocal brain infarction and insidious or rapidly progressive dementia

Lymphomatoid Granulomatosis

General Characteristics

1. Angiocentric lymphoproliferative disease
2. Primarily affects the lungs
3. Abnormal lymphoid collections are centered around arteries and veins
4. Men are affected 2:1 more than women
5. Illness develops in the fifth or sixth decade (rarely adolescences)

Clinical Manifestations

1. Prolonged course but may be remittent
2. Pulmonary signs and symptoms are predominant
3. Skin lesions
 - a. Raised erythematous rash and rarely skin nodules (trunk)
4. Neurologic manifestations
 - a. Gradual onset of focal deficits including cognitive decline
 - b. Multifocal small and large lesions that involve the cerebral hemisphere more than the cerebellum and brainstem

Imaging Evaluation

MRI

1. Multifocal large and small mass lesions of the cerebral hemispheres and rarely the cerebellum and brainstem
2. Lesions in enhance with gadolinium
 - a. Punctate
 - b. Linear
 - c. Ring enhancement is rare
 - d. Brain atrophy occurs overtime
 - e. Enhancement of the leptomeninges and dura mater
 - f. Enhancement of cranial nerves
 - g. Lesions may involve the orbit and cavernous sinus

Neuropathology

1. Classified as an Epstein-Barr Virus associated form of lymphoproliferative disease
 - a. Lower grades: a β -cell proliferation
2. Severe disease: mature diffuse β -cell form of lymphoma associated with an extensive benign T-cell reaction
3. Areas of necrosis in the brain and lung
 - a. Related to infarction caused by the vascular infiltrate

Differential Diagnosis

Lymphomatoid Granulomatosis vs Intravascular Lymphoma

1. Lymphomatoid granulomatosis abnormal cells invade the vessel wall where as in intravascular lymphoma blood vessels are blocked by lymphomatous cells
2. Cranial and peripheral nerves may be involved with lymphomatoid granulomatosis

Hypereosinophilic Syndrome

General Characteristics

1. General eosinophilia is caused by
 - a. Allergic conditions
 - b. Neoplastic process (eosinophilic leukemia, Hodgkin's disease)
 - c. Drug reaction
 - d. Not clonal and are produced in response to eosinophilopoietic cytokines
2. Idiopathic hypereosinophilic syndrome (HES)
 - a. HES is a group of disorders
 - i. Sustained overproduction of eosinophils
 - ii. Eosinophilic degranulation; releases 4 major cationic proteins
 1. Causes organ damage
 - b. Requires:
 - i. Persistent eosinophilia of greater than 1,500/ μ l for longer than 6 months
 - ii. Lack of parasitic, allergic or other known causes of eosinophilia
 - iii. Signs and symptoms of organ involvement including diffuse or focal nervous system involvement

Clinical Manifestations

1. Cerebral infarction caused by:
 - a. Medial basic protein mediated endothelial damage
 - b. Eosinophil-cationic protein mediated hypercoagulability
 - c. Eosinophil cardiomyopathy
2. Loeffler's endomyocarditis (a restrictive cardiomyopathy) associated with:
 - a. Cardiac thrombi (rare emboli)
 - b. Peripheral small and large arterial occlusive thrombosis
3. Axonal peripheral neuropathy
4. Dementia

Neuropathology

1. Putative mechanisms:
 - a. Clonal eosinophilic proliferation
 - i. Primary defect in hematopoietic stem cells
 - ii. Overproduction of eosinophilopoietic cytokines (IL-5) or their dysfunction
 - b. Eosinophilic induced neural damage
 - i. Toxic proteins released by degranulation
 1. Medial basic protein
 2. Eosinophilic cationic protein
 3. Eosinophilic derived neurotoxic
 - c. Medial basic protein
 - i. Damages endothelial cells which promotes thrombosis and artery-to-artery emboli
 - ii. Eosinophil-cationic protein
 1. Prothrombotic
 - iii. Eosinophil-derived neurotoxin
 1. Direct toxin action on neuronal tissue and myelin

Neuroimaging

MRI

1. Large and small vessel stroke
2. Cranial nerve involvement (rare enhancement with gadolinium)
3. Increased white matter hyperintensities

Stroke in Young Patients

Overview

Approximately forty percent of cerebral thrombosis in young patients will be caused by HCVD 23%, diabetes mellitus 11%, and migraine 6%. Dissection certainly must be considered in a patient with neck or face pain. Carotid dissection will often be announced by oculosympathetic paresis. Posterior neck pain, occasionally accompanied by lateral eyebrow pain occurs with vertebral obstruction and dissection. Migraine headaches are characteristic of mitochondrial disease, collagen vascular disease and CADASIL. Sporadic hemiplegic migraine has a greater chance of permanent stroke than familial migraine. Migraine with multiple visual auras is suggestive of anticardiolipin antibody syndrome. Prothrombotic states should always be sought in the context of a family history of thrombophlebitis or venous clotting in the upper extremity or chest wall. Vasospastic occlusion as well as hemorrhage from underlying vascular malformation or aneurysms is characteristic of strokes from cocaine or other sympathomimetic drugs. Oral contraceptives, hypertension and diabetes cause strokes of PICA and the thalamoperforate and thalamogeniculate arteries. Cigarette smoking in this context exacerbates this risk in young patients.

Sickle cell disease, leukemia and lymphoma cause approximately 5–10% of thrombotic strokes in young patients. Sickle cell disease is particularly dangerous during pregnancy. Stroke is frequent during chemotherapy for leukemia and lymphoma possibly due to the release of thromboplastin from lysed neoplastic cells that cause DIC.

Cardiac causes of stroke in young patients are similar to those in adults except that congenital anomalies, infective endocarditis (drug use), mitral valve prolapse and PFO are more common.

General Characteristics

1. Approximately 3% of cerebral infarctions occur in patients <40 years of age
2. Specific age related vascular disease:
 - a. 70% of subarachnoid hemorrhage <40 years of age
 - b. 97% of cerebral infarction >40 years of age
 - c. 60% of cerebral infarctions occur between 65 to 84 years of age
3. Differential diagnosis of cerebral thrombosis in young patients:
 - a. HCVD (23%)
 - b. Diabetes mellitus (11%)
 - c. Migraine (6%)

- d. Collagen vascular disease (5%)
- e. Cryptogenic (10–30%)
- f. Dissection of carotid or vertebral artery (10%)
- g. Prothrombic states (5%)
- h. Hematologic diseases (5%)
- 4. Stroke in women (15–45 years old)
 - a. Aneurysm or AVM without hemorrhage in 3.4%
 - b. Hemorrhage – 42%
 - c. SAH – Berry aneurysm > AVM
 - d. Intracranial hemorrhage
 - i. Leukemia
 - ii. Thrombotic thrombocytopenia
 - iii. Aplastic anemia
 - e. Infarction – 18%
 - f. Embolism – 56% cardiac (33% from cardiovascular surgery)
 - g. Thrombosis
 - i. Carotid 30%
 - ii. Vertebrobasilar 7%
- 5. Early onset atherosclerosis with or without HCVD associated with:
 - a. Evidence of: coronary artery disease, peripheral vascular disease or arterial occlusive disease
- 6. Oral contraceptive risk (general)
 - a. 1/10,000 women
 - b. Death from stroke

Causes of Stroke in Young Patients

Migraine

- 1. 5% of stroke in young women
- 2. No relation to specific attack
- 3. Vasospasms, vessel occlusion, platelet hyper aggregability (subset of migraine patients)

Pregnancy

- 1. Pregnancy and the puerperium
 - a. 3% of cerebral thrombosis in young women
 - b. 4% within 30 days

Cardiac Source – High Risk

- 1. Ischemic heart disease and dyskinetic left ventricular segment
- 2. Atrial Fibrillation (AF)
- 3. AF with dilated left atrium
- 4. Mechanical prosthetic valve with AF
- 5. Rheumatic mitral stenosis, atrial fibrillation, dilated left atrium
- 6. Left ventricular thrombus
- 7. Dilated cardiomyopathy with left ventricular clot
- 8. Atrial myxoma
- 9. Infective endocarditis
- 10. Congenital heart disease – atrial septal defect perioperative
- 11. Congenital heart disease – Ebstein's anomaly
- 12. Congenital heart disease – Tetralogy of Fallot

Cardiac Source – Medium Risk

- 1. Patent foramen ovale (PFO)
- 2. Atrial septal aneurysm and PFO
- 3. Mitral valve prolapse (MVP)
- 4. Hypertensive heart disease and hypokinetic left ventricular segment

Cardiac Valve Tumors

- 1. Have risk of cardiac emboli:
 - a. Aortic > mitral > pulmonary > tricuspid
 - b. Mean age 52 (2–88 years)
 - c. Male patients more than female
 - d. Less aggressive than non-valve tumors
 - e. Less than 10% of cardiac tumors are on the valve
- 2. Clinical presentation
 - a. Most are asymptomatic
 - b. Cardiopulmonary symptoms
 - i. Coronary artery occlusion
 - ii. Congestive heart failure
 - c. Embolic stroke (usually pial vessels)
 - d. Rare occurrence of sudden death
 - e. Left-sided more symptomatic than right-sided lesions
 - f. A few patients have multiple tumors

Differential Diagnosis

Cardiac Tumors

- 1. Papillary fibroelastoma (most common)
- 2. Myxoma (medium stroke risk)
- 3. Fibroma
- 4. Sarcoma (rhabdomyosarcoma; tuberous sclerosis)
- 5. Hemangioma
- 6. Histiocytoma
- 7. Undifferentiated

Age Relation to Stroke in Young Patients

Ages 15–29	Approximate percentages
1. Atherosclerosis	3%
2. Lacunar infarction	3%
3. Cardiac Embolism	30%
4. Other determined causes	25%
a. Dissection	
b. Sickle cell disease	
c. Arteritis	
d. Infection	
5. Undetermined	17%
Ages 15–40	
1. Hematologic disorder	
2. Arterial dissection	
3. Vasculitides	
4. SLE	
5. Primary antiphospholipid antibody syndrome	
6. Migraine	
7. Neurocysticercosis (specific populations)	
8. Eclampsia	
9. Oral contraceptives	

10. Extracranial carotid aneurysm
11. Central venous thrombosis
12. Vasospasm after subarachnoid hemorrhage
13. Complication of angiography
14. Moyamoya disease

Cerebral Embolism (Ages 15–40 Order of Frequency)

1. Apical aneurysm
2. Segmental hypokinesia
3. Acute myocardial infarction
4. Aseptic endocarditis (NBTE)

Ischemic Stroke Due to Deficiency of Coagulation Inhibitors (Young Patients)

1. Thromboses secondary to hematologic or clotting disorders occurs in approximately 4% of young patients
2. Hematologic disturbances young stroke patients:
 - a. Abnormalities of platelet function
 - b. Coagulation inhibitors
 - c. Fibrinolysis defects
3. Free protein S enhances inhibition of V and VIII by activated Protein C; oral contraceptives and inflammatory conditions may decrease its concentration
4. Antithrombin III; inhibits thrombin (factor Xa, IXa, XIa, XIIa – minor effect) deficits may be AD; acquired deficits
 - a. Inhibits thrombin
 - b. Minor effect inhibits clotting factors
 - c. AD form
 - d. Acquired deficits
 - i. Failure to synthesize due to cirrhosis
 - ii. Diabetes
 - iii. Age
 - iv. Protein malnutrition
 - v. Low serum albumin
5. Acquired deficiencies of coagulation inhibitory proteins occur with:
 - a. Malignancies
 - b. Plasmapheresis
 - c. Hemolysis
 - d. Nephrotic syndrome
 - e. Hepatic failure
 - f. Oral contraceptives
6. Factor V Leiden defect (effects on protein C)
7. Prothrombin gene defect
8. Increased fibrinogen and factor VIII levels and acquired hyperfibrinolysis occur in young adults with ischemic stroke
9. Strong predictors of myocardial infarction and stroke:
 - a. Plasma levels of fibrinogen (increased)
 - b. Tissue plasminogen activator concentration (decreased)
 - c. Plasminogen activator inhibitor type I (PAI-1) concentrations (decreased)
10. Decreased fibrinolytic factors:
 - a. Obesity

b. Hyperlipidemia

11. Young stroke patients (subgroup) have:
 - a. Generalized defect in fibrinolytic system
 - b. Diurnal circadian rhythm of tPA and PAI-1 tPA
 - i. PA I-1 activity doubles from early morning until afternoon
 - c. Genetic control of circulating PAI-1 (plasminogen activator inhibitor type I)

Differential Diagnosis of Stroke from Cross Section of Community or Referral Hospitals

1. Stroke in patients (15 to 44); heterogeneous population
 - a. 50% probable cause
 - b. 20% possible cause
 - c. 30% (cryptogenic); arch of aorta source, PFO and atrial septal aneurysm discovery are decreasing this percentage
2. First Stroke
 - a. 50% women
 - b. 60% black patients (38% of population studies)
 - c. 35% Caucasian patients (60% of population studied)
3. Patients with recurrent stroke:
 - a. 60% women
 - b. 70% black patients
 - c. 16% <30 years old
 - d. <2% more than one probable cause
4. Probable cause (approximately percentage)
 - a. Cardiac embolism – 16%
 - b. Lacunar stroke – 10%
 - c. Hematologic – 10%
 - d. Non-atherosclerotic vasculopathy – 6%
 - e. Illicit drug use 5% (probably much higher)
 - f. Oral contraceptive 5%
 - g. Large artery atherosclerosis <2%
 - h. Migrainous <1% (probably higher)

Stroke and Substance Abuse

Heroin

General Characteristics

1. Heroin is a semisynthetic derivative of opium
2. Crosses the BBB easily
3. Heroin most widely abused opiate
 - a. Administration:
 - i. I.V. or subcutaneously
 - ii. Smoked or sniffed
4. When injected the initial effect or “rush” occurs within minutes and peaks in approximately 10 minutes
 - a. Sedation then ensues and last for about one hour
5. Heroin and other opiates cause death from violence, suicide, its association with HIV, sepsis and overdose

Clinical Manifestations

1. Hypotension
 - a. Decreased peripheral vascular resistance

2. Bradycardia (inhibits the baroreceptor reflex)
3. Respiratory depression (decreased respiratory centers response to carbon dioxide and low oxygen)
4. Infective endocarditis
5. Pulmonary hypertension
6. Foreign bodies injected with heroin include:
 - a. Starch
 - b. Sugar
 - c. Ajax
 - d. Quinine
 - e. Lactose
 - f. Mannitol caffeine
 - g. Lidocaine
 - h. Strychnine
 - i. Talcum powder
7. Induced lung granulomatous reaction that induces pulmonary hypertension
 - a. Causes or exacerbates a right-to-left pulmonary shunt

Cerebrovascular Complications

1. I.V. use:
 - a. Septic embolization with staphylococcus aureus and candida that cause:
 - i. Mycotic aneurysm (may have premonitory symptoms)
 - ii. Infectious vasculitis
 - b. Septic aneurysms are peripheral and may rupture with or without treatment
2. Hemorrhagic stroke:
 - a. Consequence of hepatitis (decreased production of clotting factors)
 - b. Heroin nephropathy (hypertension and uremia)
 - c. Meningitis
 - d. HIV/AIDS
3. Decreased perfusion of the medial prefrontal cortex; anterior cingulate cortex and precuneus
4. Increased arterial stiffness which contributes to vascular aging

Neuropathology

1. Septic emboli (I.V. use)
2. Hypotension and hypoxic changes induced by overdose (hypoxic-ischemic injury) in vulnerable brain regions (hippocampus layers III, V of the cortex, Purkinje cells of the cerebellum and globus pallidus)
3. Minimal evidence for vasculitis

Imaging Evaluation

MRI

1. Areas of signal change on T1 and T2 sequences in brain areas vulnerable to ischemia/hypoxic injury
2. Some patients demonstrate "beaching" on arteriography
3. Topical large vessel stroke from septic emboli
4. Mycotic aneurysms
 - a. Most common in MCA territory (peripherally)
5. Cerebral hemorrhage in areas of septic embolic infarction
6. Hemorrhagic stroke

Angiography

1. Some patients demonstrate large or small vessel arteritis
 - a. Possible autoimmune etiology (eosinophilia, hypergammaglobulinemia)
2. Stroke mechanisms in heroin abuse:
 - a. Vascular aging
 - b. Hypotension and hypoventilation (acute)
 - i. Bilateral GP infarction
 - c. Infective endocarditis with mycotic aneurysm
 - d. Embolization of adulterants:
 - i. Pentazocine and antihistamines
 - ii. Parenteral paregoric, meperidine and hydromorphone
 - e. Heroin myelopathy:
 - i. Some patients with ischemia of the anterior spinal arteries
 - ii. Acutely associated with pulmonary edema

Cocaine

General Characteristics

1. Blocks reuptake of monoamine neurotransmitters at synaptic nerve endings (binds to transporter proteins)
2. Intranasal preparation
 - a. Cocaine hydrochloride
 - b. Ischemic stroke; intracranial hemorrhage
3. Smokeable form:
 - a. Alkaloid form "crack"
 - b. Can be utilized in large doses over a long duration (hours to days)
 - c. Ischemic and hemorrhagic stroke

Clinical Manifestations

Cerebrovascular Complications

1. TIA
2. Infarctions of cortical and subcortical territories that include the hemispheres; thalamus, brainstem, spinal cord and retina
3. Strokes in pregnant women and neonates
 - a. Vasospasm
 - b. Premature separation of the placenta (cocaine taken prior to delivery)
4. Rare vasculitis
5. Delayed vasospastic ischemic infarction is common (hours to days)
6. Hemorrhagic stroke
 - a. Intracerebral and subarachnoid hemorrhage
 - b. 20% of hemorrhages have underlying
 - i. Vascular malformation
 - ii. Saccular aneurysm
 1. Increase vasospasm after aneurysmal rupture
 - iii. Bleeding into embolic infarction or glioma
 - c. Other cocaine induced stroke mechanisms:
 - i. Myocardial infarction and cardiomyopathy with embolus
7. Multiple infarcts occur:

- a. High incidence of hemorrhagic transformation
- 8. Aggregation and de-aggregation of platelets; effects on antithrombin III, protein C, NF- κ B (nuclear factor kappa-light-chain-enhancer of activated B-cells), activator protein-1
- 9. Platelet rich arterial thrombi
- 10. Activates the endothelium that promotes platelet vWF interaction
- 11. Vasoconstrictive metabolites can last for days to weeks

Neuropathology

- 1. Hyperintense surge (ICH)
- 2. Hyperintensive surgery
 - a. Most common cause of ICH and SAH
 - i. Possibly 20% have underlying vascular malformation or aneurysm
 - ii. ICH occurs in the usual locations
- 3. Vasospasm
 - a. Sudden and usually reversible changes in vascular caliber
 - i. Due to smooth muscle dysfunction
 - ii. Tunica media and elastic lamina changes damage in arteries in multiple vascular territories
 - b. Effects on calcium channels in smooth muscle cells of arteries and arterioles by release of calcium from the endoplasmic reticulum
 - c. Accumulation of catecholamines occur due to prevention of reuptake
 - d. Effects of endothelin-1
 - e. Vasospasms induces:
 - i. Endothelial injury that resulting in:
 - 1. Intimal hyperplasia
 - 2. Platelet activation which then causes:
 - a. α -granule release
 - b. Increased platelet responsiveness to arachidonic acid
 - c. Platelet release of thromboxane, β 2 and plasminogen activity factor-1 inhibitor (PAI-1)
 - d. Facilitates thrombosis
- 4. Enhanced platelet aggregation
 - a. Caused by platelet activation
- 5. Cerebral vasculitis
- 6. Vasculitis
 - a. Biopsy demonstrates
 - i. Hypersensitivity vasculitis
 - ii. Rarely demonstrated
- 7. Accelerated atherosclerosis
 - a. Cocaine causes increased permeability to atherogenic lipoproteins
- 8. Cardiac emboli
 - a. Infective endocarditis (injection of the hydrochloride forms)
 - b. Arrhythmia
 - c. Acute and chronic dilated cardiomyopathy
- 9. Endocarditis
 - a. Septic cerebral arteritis
 - b. Mycotic aneurysms

Neuroimaging

MRI

- 1. Dose-dependent vasoconstriction of cerebral vessels on MRA
- 2. Microvascular white matter changes in chronic users
- 3. ICH in standard hypertensive locations
- 4. SAH (hypertension)
- 5. Ischemic and hemorrhagic stroke of cerebral vessels

Amphetamines

General Characteristics

- 1. Amphetamines have a chemical similarity to epinephrine and dopamine
- 2. Synthetic modifications have different properties and effects
- 3. They are weak bases that can be absorbed through different routes
- 4. Drug half-life is dependent on the specific drugs used and its dosages
 - a. Half-life varies between 10 to 30 hours depending on the above
- 5. These agents include:
 - a. Dextroamphetamine
 - b. Methamphetamine
 - c. Methylphenidate
 - d. Ephedrine
 - e. Pseudoephedrine
 - f. Phenylpropanolamine (PPA)
- 6. Methamphetamine is the most potent and most frequently abused:
 - a. Half-life of 12 hours
 - b. Metabolized in the liver
 - c. Has an active metabolite that is hallucinogenic
- 7. Blocks the presynaptic uptake of dopamine, epinephrine and serotonin
- 8. Administration is oral, sniffed or smoked
 - a. Crystalline form ("ice", "crystal meth")

Clinical Manifestations

- 1. Acute ischemic stroke
- 2. ICH
- 3. SAH
- 4. Disproportionate rate of hemorrhagic stroke
- 5. Approximately 75% of patients with methamphetamine induced stroke are hypertensive at admission

Neuropathology

- 1. Necrotizing periarteritis
 - a. Spontaneous ICH (hypertensive surge)
 - i. Usual locations for hypertensive hemorrhages
 - b. Chronic use causes:
 - i. Vessel wall necrosis
 - ii. Microinfarcts in small vessels
 - iii. Atherosclerosis is accelerated

Neuroimaging

1. ICH and cerebral edema
 - a. Usual areas of hypertensive hemorrhage
 - b. Petechial hemorrhages in white matter

Angiography

1. "Beading" of cerebral cortical vessels consistent with arteritis
2. Embolic thrombosis in large vessels in patients with cardiomyopathy
3. SAH

*Phencyclidine***General Characteristics**

1. Chemical name: 1-(1-phenylcyclohexyl)piperidine
2. Dissociative anesthetics similar to ketamine
3. Effects NMDA (antagonist), nACh (antagonist) and dopamine (agonist) receptors
4. Possible PCP receptors on cerebral vessels
5. Stored in fat and therefore re-mobilization can occur with recurrent symptoms for days or months

Clinical Manifestations*Cerebrovascular Disease*

1. Hypertension occurs following use or can be delayed
2. Hypertensive encephalopathy
3. Transient monocular blindness
4. PCP related SAH
5. Hemorrhagic stroke

Neuropathology

1. Experimental:
 - a. Neuronal degeneration on retrosplenial cortex, posterior cingulate gyrus, entorhinal cortex and hippocampus

Neuroimaging

1. Edema (occipital lobe) from hypertensive encephalopathy
2. SAH
3. Cortical hemorrhagic stroke

*Lysergic Acid Diethylamide (LSD)***General Characteristics**

1. Chemical name: (6aR,9R)-N,N-diethyl-7-methyl-4,6,6a,7,8,9-hexahydroindolo-[4,3-fg]quinoline-9-carboxamide
2. An ergotamine derivative that causes hypertension
3. Potent hallucinogen

Clinical Manifestations*Cerebrovascular Disease*

1. Ischemic vascular disease (patients less than 25 years of age)
 - a. Large artery involvement
 - b. Delayed stroke occurs
2. Mechanism:
 - a. May effect serotonin receptors to cause vasospasm

Neuropathology

1. Binding to serotonin receptors in the brainstem (5HT_{2A} receptor) and the cerebral cortex

Neuroimaging*Angiography*

1. Progressive narrowing and occlusion of ICA
2. Generalized arterial beading

*Marijuana***General Characteristics**

1. Most widespread recreational drug in the USA
2. Active component: tetrahydrocannabinol (THC) or (-)-(6aR,10aR)-6,6,9-Trimethyl-3-pentyl-6a,7,8,10a-tetrahydro-6H-benzo[c]chromen-1-ol
3. Cannabinoids have physiological role in:
 - a. Cerebral circulatory autoregulation
 - b. Vascular tone
 - c. Cardiac physiology

Clinical Manifestations

1. Associations with stroke, myocardial infarction and lower limb arteritis
 - a. Myocardial infarction may occur with concomitant use
 - b. Extremity arterial disease occurred in younger male patients primarily in one extremity

Cerebrovascular Disease

1. Ischemic stroke; majority of reported cases
2. Reversible vasoconstriction syndrome (described in 2 patients)
3. Stroke associated with concomitant anabolic steroid use
4. PRES reported

*Synthetic Cannabinoids***General Characteristics**

1. Heterogeneous group of compounds
2. "Spice" and "K2" synthetic cannabinoids
 - a. Not detectable by standard screening
 - b. Greater binding affinity at the CB₁ receptor than does Δ^9 tetrahydrocannabinol
 - c. Greater binding affinity at the CB₁ receptor than CB₂ receptor
 - d. Animal studies demonstrate 2-100x greater potency than THC

Clinical Manifestations

1. Nausea and vomiting
2. Shortness of breath
3. Depressed breathing
4. Hypertension
5. Tachycardia
6. Chest pain
7. Cognitive dysfunction
8. Acute renal failure
9. Cerebral vascular manifestations
 - a. Ischemic stroke

Neuropathology

1. No specific pattern of infarct distribution
2. Putative mechanisms for marijuana-ischemic stroke
 - a. Hypotension
 - b. Vasospasm
 - c. Arrhythmia
 - d. PRES
 - i. Possible vasospasm

Neuroimaging

1. Large vessel thrombotic stroke (rare reports: associated myocardial infarction)

MDMA (“Ecstasy”), MDMC (“Methylone”) and MDPV (“Bath Salts”)**General Characteristics**

1. Chemical names:
 - a. MDMA: *N*-methyl-1-(3,4-methylenedioxyphenyl)propan-2-amine or methylenedioxymethamphetamine; most used
 - b. MDMC: 3,4-methylenedioxy-*N*-methylcathinone
 - c. MDPV: (RS)-1-(Benzo[d][1,3]dioxol-5-yl)-2-(pyrrolidin-1-yl)pentan-1-one or Methylenedioxypyrovalerone
2. Alternatives to cocaine and methylenedioxymethamphetamine
 - a. 3,4 methylenedioxymethcathinone (methylone)
 - b. 3,4-Methylenedioxypyrovalerone (MDPV)
3. Increases the release and inhibits uptake of NE, serotonin, DA
4. Peak concentration at two hours after ingestion
5. Synthetic cathinones
 - a. Target plasma membrane transporters for DA, NE and serotonin
 - i. Mephedrone and methylone act as non-selective transporter substrates
 - b. Stimulates non-exocytotic release of DA, DA and serotonin. Effects are analogous to amphetamines
 - c. MDPV only blocks dopamine and norepinephrine

Clinical Manifestations

1. Mechanisms of stroke similar to those of cocaine and amphetamine
2. Cardiac arrhythmias and embolism may be important
3. Causes both ischemic and hemorrhagic stroke
4. I.V. use of crushed methylphenidate tablets: microembolization of talc in lungs

Neurological Complications

1. Hallucinations
2. Delirium
3. Euphoria
4. Tachycardia
5. Hyperthermia
6. Delayed responses
7. Agitation/psychosis
8. Cardiomyopathy
9. Myoclonus/seizures

Cerebrovascular Effects

1. Ischemic and hemorrhagic stroke
2. Cardiac dysfunction and hypertension are prominent

Neuropathology**Ecstasy**

1. Increases the release and reuptake of serotonin and norepinephrine; lesser effects on dopamine
2. Ischemic and hemorrhagic stroke
 - a. Cardiac arrhythmia with embolus
 - b. Cardiomyopathy in Ecstasy users with stroke (CHF and arrhythmia)
3. Vasospasm and necrosis in the vasculature of the globus pallidus
4. Chronic Vasospasm
 - a. Thrombosis and aneurysmal dilation of cerebral vessels
 - b. High fever that triggers DIC
 - i. Microinfarctions throughout the brain
 - c. Minimal evidence for vasculitis
5. Hypertensive surge:
 - a. ICH in hypertensive locations
 - b. SAH – underlying aneurysm
 - c. Microinfarction from DIC

Neuroimaging

1. ICH (hypertensive locations)
2. Ischemic and hemorrhage large vessel stroke
3. Microinfarctions (DIC)
4. SAH underlying aneurysm, AV malformation or hypertension

Ethanol**General Characteristics**

1. Ethanol consumption and coronary artery disease fits a “J-shaped” curve (a small amount is protective and larger amounts are detrimental)
 - a. Cardioembolic risk from MI occurs in heavy drinkers (>300 grams/week)
 - b. Thromboembolism in alcoholic cardiomyopathy
2. A J-shaped curve exists for ischemic stroke and ethanol consumption:
 - a. Linear correlation with ICH
 - b. Greater than 60 grams per day increased stroke risk for ischemic and hemorrhagic stroke

Clinical Manifestations

1. Heavy ethanol consumption:
 - a. Increases carotid artery atherosclerosis
 - b. Hemorrhagic stroke from thrombocytopenia
 - c. Subdural hematoma
2. Causes hypertension cardiomyopathy and atrial fibrillation

Neuropathology

1. SDH
2. Petechial hemorrhage in white matter
3. Ischemic and hemorrhagic stroke

Neuroimaging*MRI*

1. SDH
2. Atrophy (primarily white matter) with ventricular megally
3. Mammillary body hemorrhage (Wernicke's syndrome)
4. SAH (trauma)
5. Topographical ischemic and hemorrhagic stroke

Laboratory Evaluation

1. Lowers LDL and increases HDL
2. Lowers fibrinogen activity
3. Decreases plasma fibrinogen levels
4. Increases factor VIII levels
5. Increases platelet reactivity to adenosine diphosphate
6. Increases prostacyclin
7. Stimulates endothelial release of endothelin
8. Alcohol withdrawal
 - a. Causes hemoconcentration
 - b. Rebound platelet hyperaggregability

*Tobacco***General Characteristics**

1. Active component: (S)-3-[1-Methylpyrrolidin-2-yl]pyridine or nicotine
2. Heavy use is defined as smoking more than half a pack per day or 10 packs a year
3. Smokers have a higher incidence of coronary artery disease, peripheral vascular disease, chronic obstructive pulmonary disease as well as specific cancers (>30 carcinogens)
4. Tobacco smoke injures all major organs of the body

Clinical Manifestations

1. Linked to both small and large vessel atherosclerosis
2. Induces aneurysm formation

Neuropathology

1. In cultures smooth muscle cells (SMC) exposure to cigarette smoke causes
 - a. Decreased promoter activity and mRNA expression of key SMC contractile genes (SM-a-actin, SM-22a, SM-MHC)
 - b. Decreased transcription factor myocardin in a dose dependent manner
2. Induced proinflammatory/matrix remodeling genes (MCP-1, MMPs, TNF- α , IL1 β , NF- κ B)
3. Increased expression of KLF4, a regulator of SMC differentiation
4. Cigarette smoke causes phenotypic modulation of cerebral SMC through myocardin and KLF4 dependent mechanisms
5. Impairs the baroreflex sensitivity which may increase blood pressure
6. Decreases vasodilatory response to carbon dioxide
7. Smokeless tobacco:

- a. Increases ischemic stroke risk and acute coronary dysfunction
- b. Accelerates atherothrombosis
- c. Increases HCVD and metabolic syndrome

Cerebrovascular Disease

1. Mechanisms for smoking and cerebrovascular disease
 - a. Ischemic and hemorrhagic stroke is increased with concomitant oral contraceptive use
 - b. Increases atherosclerosis
 - c. Decreases blood oxygen carrying capacity (carbon monoxide from smoke has a higher affinity for hemoglobin than does oxygen)
 - d. Nicotine damages the vascular endothelium
 - e. Increased platelet reactivity
 - f. Decrease prostacyclin
 - g. Increases blood fibrinogen levels
 - h. Induced polycythemia increases blood viscosity
 - i. Paradoxical benefit effect on in-hospital mortality
 - j. May have benefit in blood pressure and flow in MCA
 - i. Changes in baroreflex sensitivity (lowers)

Neuroimaging

1. Large and small vessel ischemic stroke patterns
2. Exacerbate or induce aneurysm formation

Autoimmune Disease and Stroke*Overview*

Almost all autoimmune diseases are associated with stroke, especially during exacerbations of the dysimmune process. The patient's symptoms and signs may be dominated by organ system failure or by the other aspects of cerebral involvement such as seizures, dementia or movement disorder. The specific pattern of organ, central and peripheral nervous system involvement are the clinical clues that differentiate the entities. Neurologic manifestations and stroke frequently occur in the setting of:

1. Systemic Lupus Erythematosus (SLE)
2. Periarthritis Nodosa
3. Microscopic Polyangiitis
4. Sjögren's syndrome
5. Neurosarcoidosis
6. Rheumatoid Arthritis
7. Scleroderma
8. Churg-Strauss syndrome
9. Henoch-Schönlein Purpura
10. Kawasaki's disease
11. Wegener's granulomatosis
12. Allergic arteritis
13. Thrombotic thrombocytopenia purpura (TTP)
14. Mixed connective tissue disease
15. Reiter's syndrome
16. Relapsing polychondritis
17. Ulcerative colitis and regional enteritis
18. Celiac disease

Systemic Lupus Erythematosus (SLE) is generally dominated by renal, cardiac and serosal surface involvement. If there is a rash in the hand it is between the interphalangeal joints as opposed to dermatomyositis where the rash is over the joint (Groton's sign). The malar rash is characteristic. Periungual telangiectasia and fingertip pain occur with disease activity. Pial vessel strokes occur although seizures, psychosis and proximal myopathy are the most common neurologic features. A vasculopathy rather than a vasculitis is the predominant pathology of cerebral blood vessels.

Periarteritis nodosa usually affects the peripheral nervous system with mononeuritis multiplex or a multiradicular pattern of involvement. Renal medullary artery involvement with severe hypertension dominates the active phase of the disease. Late onset asthma, testicular and hepatic artery infarctions occur. Eosinophilia is common. Stroke is rare.

Microscopic polyangiitis is a variant of periarteritis nodosa that affects venules, arterioles and small arteries. It is the most common pulmonary renal vasculitic syndrome. It, like periarteritis nodosa, most commonly affects the peripheral nervous system, but ischemic and hemorrhagic infarction may be seen secondary to hypertension.

Sarcoid affects both the PNS and CNS. It usually comes to medical attention from its diffuse infiltrative or periaortic node involvement. Ankle pain is characteristic as are cardiac conduction abnormalities. MRI evaluation demonstrates posterior hypothalamic, chiasmatic and parenchymous granulomata. Characteristically, the dura is involved. It is associated with a cerebral vasculitis and retinal inflammation (a periphlebitis). A VIIth nerve palsy in association with uveitis (Heerfordt's syndrome) is diagnostic.

Sjögren's syndrome is very prevalent in the population and is most often associated with rheumatoid arthritis. Its cardinal diagnostic feature is keratoconjunctivitis sicca and xerostomia (dry mouth). Peripherally there is a large fiber sensory loss with dorsal column spinal cord involvement. Both conducting and pial vessels may be involved in the CNS.

Rheumatoid arthritis is most often associated with a severe motor neuropathy of the hands that causes intrinsic muscle wasting in association with CTS. Subluxation (atlantoaxial) at C2–C3 is a feared complication. Localized vasculitis is rare.

Scleroderma produces a microvascular pathology that produces characteristic fibrosis of multiple organ systems. Gastrointestinal tract and renal involvement as well as its skin manifestations are characteristic. It frequently affects the Vth cranial nerve (as does Sjögren's syndrome). A disseminated cerebral vasculitis has been noted.

Churg-Strauss syndrome should be considered in a patient presenting with asthma, eosinophilia and pituitary infarction. A CNS small vessel necrotizing arteritis may accompany the medical triad.

Henoch-Schönlein is usually a disease of childhood and presents with abdominal pain, arthritis and prominent purpura. Allergies to drugs may be a precipitant. Rare small vessel stroke has been reported.

Wegener's granulomatosis should always be borne in mind in the setting of refractory chronic sinus disease. The usual medical evaluation reveals upper respiratory tract necrotizing vascular lesions. Orbital involvement is common with extraocular muscle and Vth nerve paresthesia. A cerebral arteritis with pial vessel infection occurs.

Hypersensitivity vasculitis primarily affects the skin in the form of a purpuric skin rash. Specific allergies trigger the process (particularly sulfa). The extremities are symmetrically swollen, erythematous and painful. Stroke is rare.

Mixed connective tissue disease is an overlap of SLE, scleroderma and polymyositis. Encephalopathy, seizure and aseptic meningitis are much more common CNS manifestations than stroke from vasculitis. Peripheral nerve involvement is more common than are CNS manifestations.

Thrombotic thrombocytopenic purpura often has a dramatic explosive onset manifested by seizures, hallucinations, fever and renal failure. Transient focal neurologic deficits dominate its course. Multifocal microinfarctions of the cortex are seen pathologically.

Reiter's syndrome should be suspected in a patient with diarrhea and heel pain associated with optic neuritis, encephalitis and pial artery stroke.

Relapsing polychondritis is an autoimmune disease of cartilage. It may present with inflamed sore ear lobes (also occurs in ochronosis) conjunctivitis, lip scleritis and laryngotracheal involvement. Stroke is rare.

Ulcerative colitis and regional enteritis are associated with both venous and cerebral sinus thrombosis as well as large vessel stroke.

Celiac disease presents most commonly with severe diarrhea. Its neurologic manifestations are proximal myopathy and ataxia. Occasionally, patients suffer conducting vessel and pial strokes.

The following is a detailed description of the major neurologic and general medical features that differentiate the autoimmune entities that cause stroke.

Systemic Lupus Erythematosus

General Features

1. A complex disease characterized by autoantibodies and multisystem involvement
2. A central role for β cells in pathogenesis as evidenced by early breakdown of β tolerance
3. Autoantibodies pathogenic role in autoimmunity include:
 - a. Immune complex mediated type III hypersensitivity reactions
 - b. Type II antibody-dependent cytotoxicity
 - c. Innate immune cell production of inflammatory cytokines
4. A role for toll-like receptors in the link between the innate and adaptive immune systems in SLE immunopathogenesis
5. Associated neurologic manifestations
 - a. Psychosis

- b. Proximal myopathy
- c. Mononeuritis multiplex
- d. Migraine headaches
- e. Sensorimotor neuropathy
- f. Chorea
- g. Seizures
- h. Stroke (pial arteries; multifocal)
- i. Retinal findings:
 - i. Cytoid bodies
 - ii. Increased nicking of arterioles

Clinical Features

1. Stroke

- a. Embolic stroke (Libman-Sacks endocarditis)
- b. Coagulopathy
 - i. Lupus anticoagulant
 - ii. Anticardiolipin antibody
- c. Non-inflammatory vasculopathy
- d. Small deep infarcts
 - i. Associated HCVD
- e. Intracranial branch artery occlusion
- f. Cortical and subcortical infarcts (arteritis)
- g. Large Vessel Stroke (Atherosclerosis)
 - i. In approximately 86% of patients the disease is active at stroke occurrence
 - ii. Stroke occurs after 4–5 years of disease
 - iii. Headache is common at onset
 - iv. Often associated with low protein S activity
 - v. Antiphospholipid antibody associated with Libman-Sacks endocarditis
 - vi. Global depression of left ventricular function
 - 1. Cardiac small vessel arteritis
 - 2. Poor ejection fraction and embolus
 - 3. Thrombogenic cytokines
- h. Unusual Vascular Manifestations:
 - i. Vertebrobasilar territory infarction at presentation
 - ii. Vascular monocular or binocular optic neuropathy
 - iii. Posterior ischemic optic neuritis

Pathology

- 1. Widespread microinfarcts in the cerebral cortex and brainstem
 - a. Destructive and proliferative changes in arterioles and capillaries
 - b. Attachment of immune complexes to the vessel walls in mechanism of vascular injury
 - c. Immune components to hemispheric white matter and spinal cord lesions
 - d. Endocarditis (Libman-Sacks)
 - e. Hypertensive changes
 - f. Active necrotizing vasculitis

Neuroimaging

- 1. Territorial localization of cortical, border zone infarcts and basal ganglia lesions

- a. More common in patients with antiphospholipid antibodies
- 2. Lacunar infarcts
- 3. Focal cortical infarcts (vasculitis)
- 4. Longitudinal involvement of the spinal cord

Laboratory Evaluation

- 1. CSF is normal or has a mild lymphocytic pleocytosis with slight increase in protein
- 2. Antibodies to double-stranded DNA (anti-ds DNA)

Periarteritis Nodosa

General Features

- 1. Prevalence of 6.3 per 100,000 individuals
- 2. Association with hepatitis B virus surface antigen
- 3. Putatively associated with hairy cell leukemia, Sjögren's syndrome and rheumatoid arthritis
- 4. Male and females are equally affected
- 5. Onset between 40 and 60 years of age
- 6. Organ-limited varieties:
 - a. Lobar liver
 - b. Testicular
 - c. Cutaneous (ulcers/livedo reticularis)
 - d. Striated muscle
 - e. Primary angiitis of the CNS
- 7. Multisystem involvement:
 - a. Late onset asthma
 - b. Testicular infarction
 - c. Lobar hepatic infarction
 - d. Eosinophilia
 - e. Severe hypertension from renal involvement
 - f. Palpable arteriolar lesions in the skin
 - g. May occur with hepatitis B and C infection

Clinical Features

- 1. Peripheral nerve involvement
 - a. Mononeuritis multiplex
 - b. Guillain-Barré-like syndrome
 - c. Mixed polyneuropathy
- 2. CNS involvement is rare
 - a. Stroke is rare but may occur in less than 1 year of illness
 - b. Ischemic and hemorrhagic strokes may occur late in the illness
 - i. Hemorrhagic strokes in one third of patients that suffer stroke
 - ii. Often secondary to renal induced severe hypertension
 - iii. Illness never presents with stroke
- 3. Ocular manifestations
 - a. Conjunctivitis
 - b. Episcleritis
 - c. Extraocular muscle palsy
 - d. Optic neuritis
 - e. Orbital pseudotumor

Pathology

1. Involvement of medium-sized arteries
 - a. Disease occurs at branch points
2. Necrotizing arteritis:
 - a. Increased levels of adhesion molecules
 - b. Invasion of arterial wall by leukocytes and monocytes
 - c. Fibrinoid destruction of the vessel wall
 - d. Endothelial proliferation with thrombosis
3. Rare ANCA antibodies (pANCA); anti-nuclear cytoplasmic antibodies
4. Cerebral miliary microaneurysms (Charcot–Bouchard aneurysms)
5. Microinfarcts

Genetics

1. Recessive mutation in:
 - a. CECRI gene
 - i. Encodes adenosine deaminase 2 (ADA2)
 - ii. A growth factor

Neuroimaging

1. Microinfarcts of the cortex
2. Spinal cord infarcts (rare)
3. Posterior reversible encephalopathy

Angiography

- a. Microaneurysms of the renal vasculature

Laboratory Evaluation

1. Elevated C-reactive protein and erythrocyte sedimentation rate
2. Skin biopsy
3. Renal arteriogram

*Microscopic Polyangiitis (Periarteritis Nodosa Variant)***General Features**

1. A form of necrotizing small vessel vasculitis
 - a. Affects venules, arterioles and small arteries
 - b. Rarely medium-sized arteries are affected
2. Fever, weight loss and fatigue in the majority of patients
3. Associated medical conditions:
 - a. Immune necrotizing and crescentic glomerulonephritis
 - b. Hemorrhagic, pulmonary capillaritis
 - c. Most common cause of pulmonary renal vasculitic syndrome

Clinical Features

1. Optic neuritis
2. Peripheral nervous system involvement
 - a. Guillain-Barré syndrome
 - b. Mononeuritis multiplex
 - c. Vasculitic induced sensorimotor neuropathy
3. Ischemic and hemorrhagic infarction

Pathology

1. Vasculitis similar to:
 - a. Wegener's Granulomatosis
 - b. Churg-Strauss disease

- a. Wegener's Granulomatosis
 - b. Churg-Strauss disease
2. Putative role for neutrophils/monocytes in vascular injury
 - a. Enzymes and proteins within the cytoplasmic granules
 3. Minimal immunoglobulin in vessel walls

Neuroimaging

1. Microinfarcts of the cortex
2. Spinal cord infarcts (rare)

Laboratory Evaluation

1. Elevated C-reactive protein and erythrocyte sedimentation rate
2. pANCA titer
 - a. Myeloperoxidase is in the epitope that pANCA binds
3. Hematuria > 10 red blood cells per high powered field

*Kawasaki's Disease***General Features**

1. A systemic vasculitis complicated by coronary and peripheral aneurysms
2. An infectious trigger in a genetically predisposed patient
3. Necrotizing panarteritis affecting all vessels
 - a. Coronary arteries in particular
4. More common in Asians; 80% of patients less than 5 years of age
5. Rare recurrence (against autoimmune etiology)

Clinical Features*Systemic Features*

1. Erratic high fever
2. Conjunctivitis
3. Involvement of vallate papillae ("strawberry tongue")
4. Confluent erythematous lesions of the palms and soles
5. Painful swelling of the hands and feet
6. Acute cervical lymphadenopathy (50–75%)
7. Later in the course:
 - a. Coronary artery aneurysms
 - b. Left ventricular dysfunction
 - c. Mortality from coronary disease
8. Hyponatremia
9. Nephrotic syndrome

Neurological Signs and Symptoms

1. Mild encephalopathy in children
2. Aseptic meningitis (30–40%)
3. Myositis
4. Peripheral VIIth nerve palsy
5. Hearing loss
6. Seizures

Cerebrovascular Signs and Symptoms

1. Subdural hemorrhage
2. Ischemic stroke:
 - a. Hemiparesis in children
 - i. Associated with coronary aneurysms
 - ii. No demonstrated cerebral aneurysms

Pathology

1. Coronary artery aneurysm (25%)
2. Antigen-driven IgA oligoclonal response directed against cytoplasmic inclusions
3. Vasculitis of cerebral vessels

Neuroimaging

1. Aseptic meningitis (increased T-2 weighted hyperintensities of the dura)
2. Topographic stroke
3. Demonstration of coronary artery aneurysms by ECHO

Laboratory Evaluation

1. Thrombocytosis and increased liver enzymes
2. Decreased plasma total cholesterol and HDL
3. Elevation of triglycerides

Neurosarcoidosis**General Characteristics**

1. An inflammatory granulomatous disease
2. CNS involvement (neurosarcoidosis) occurs in approximately 25% of afflicted patients with systemic sarcoidosis (often subclinical)
3. Systemic involvement includes:
 - a. Pulmonary diffuse infiltration pattern
 - b. Periaortic nerve involvement
 - c. Cardiac conduction abnormalities
4. Diffuse infiltrative lung pattern
5. Articular (rheumatologic) manifestations (ankle involvement is prominent)
6. Skin manifestations (neck and nose)

Clinical Features**Neurological Signs and Symptoms**

1. Peripheral nervous system involvement:
 - a. Cranial nerve VII (with uveitis is Heerfordt's syndrome)
 - b. Optic nerve (compression by meningeal infiltration)
 - c. Sensorimotor neuropathy
 - d. Myopathy
 - e. Optic chiasmatic involvement
2. Central nervous system involvement:
 - a. Chiasm
 - b. Parenchymatous granuloma occur in the:
 - i. Posterior hypothalamus
 - ii. Pituitary
 - iii. Hemisphere
 - c. Meningeal involvement; may compress optic nerves
 - d. Compressive myelopathy
 - e. Meningitis inflammation results in CSF elevation:
 - i. Glucose 30–40 mg%
 - ii. Slightly elevated protein 60–80 mg%
 - iii. Lymphocytic pleocytosis (30 cells mm³)

Vascular Features

1. Stroke:
 - a. Cerebral vasculitis
 - b. Associated with pleocytosis
 - c. Retinal inflammation (periphlebitis)
 - d. Spread of inflammatory cells from the meninges through the Virchow–Robin spaces to pial vessels
 - e. Predilection for veins (phlebitis)
2. Stroke pattern
 - a. TIA
 - b. Superficial pial artery stroke
 - c. Dural sinus thrombosis
3. Retinal changes:
 - a. Periphlebitis (diffuse sheathing of retinal veins)
 - b. Hard exudates (“taches de bougie”; candle wax dripping)
 - c. Chorioretinal scars

Pathology

1. Active sarcoid granuloma
 - a. A central mass of epithelioid cells and multinucleated giant cells surrounded by lymphocytes (β and T-cells), monocytes and fibroblasts
 - b. Multinucleated giant cells less frequent in neural lesions. Less fibrous tissue in neural lesions

Neuroimaging**MRI**

1. T2-weighted hyperintense parenchymal lesions are the most common lesions
2. Pituitary and posterior hypothalamic involvement
3. Meningeal enhancement

Sjögren's Syndrome**General Characteristics**

1. May affect 3% of population
2. Women > men
3. In 50% of patients it is secondary (occurring with other diseases)
4. Lymphoid invasion of exocrine tissues of the body:
5. Characterized by:
 - a. Keratoconjunctivitis sicca
 - b. Xerostomia
6. Associated with other connective tissue diseases
 - a. Otitis (eustachian tube dysfunction)
 - b. Recurrent bronchial infection
 - c. Dryness of genital mucosa
 - d. Atrophic gastritis
 - e. Atrophy of the oral mucosa

Clinical Features**Neurological Manifestations**

1. Peripheral nervous system:
 - a. Large fiber sensory loss
 - b. Dorsal column involvement

- i. Dorsal root ganglionitis
- c. Autonomic impairment
 - i. Adies pupil (tonic pupil)
 - ii. Anhidrosis
 - iii. Orthostatic hypotension
- d. Vth nerve involvement
 - i. Gasserian ganglionitis
- 2. Central nervous system involvement:
 - a. Myelitis
 - b. Seizure
 - c. Dementia
 - d. Meningoencephalitis
 - e. Focal brain infiltrates
 - f. Associated with primary progressive multiple sclerosis (putative)
- 3. Vascular Features
 - a. Pial vessel stroke
 - b. Large vessel occlusion
 - c. Spontaneous ICH
 - d. Hemiparesis, aphasia, ataxia
 - e. Cognitive and behavioral deficits

Neuroimaging

MRI

- 1. T2-weighted signal hyperintensities throughout the hemispheres
- 2. Longitudinal extensive spinal cord lesions (dorsal column)
- 3. Lesions resemble those of MS
- 4. Discrete cortical lesions that resemble infarcts

Pathology

- 1. Autopsy dorsal root ganglion biopsy
 - a. Mononuclear and lymphocytic infiltration associated with neural loss

Laboratory Evaluation

- 1. Elevated SSA/SSB antibodies in the serum
- 2. Lip biopsy
- 3. Peripheral nerve biopsy
 - a. Necrotizing vasculitis

Rheumatoid Arthritis

General Features

- 1. Crippling arthritis associated with:
 - a. Ocular manifestations (keratoconjunctivitis)
 - b. Cardiac involvement
 - c. Vasculitis of the bowel
- 2. Possibly affects 1% of the population

Clinical Features

Associated Neurological Manifestations

- 1. Myopathy (proximal)
- 2. Neuropathy (severe atrophy of intrinsic hand muscles)
- 3. Atlantoaxial subluxation (C2–C3; spinal cord compression)

- 4. Rheumatoid pachymeningitis
- 5. Rheumatoid dural nodules (seizures)
- 6. Encephalopathy
- 7. Generalized sensorimotor neuropathy
- 8. Mononeuritis multiplex (rare)
- 9. C2 pannus with spinal cord compression
- 10. Carpal Tunnel syndrome
- 11. Rheumatoid vasculitis
 - a. Occurrence of cerebral vasculitis in rheumatoid arthritis is 1 to 8%
 - b. Usually occurs in long-standing, active and erosive rheumatoid arthritis and in patients with extra-articular manifestations

Pathology

- 1. Arteritis of small vessel fibrinoid type
- 2. Immunoglobulins are demonstrated in vessel walls

Neuroimaging

MRI

- 1. T2-weighted sequences demonstrate high signal intensity in cortical and subcortical junctional areas

Laboratory Evaluation

- 1. Increased C-reactive protein, IgM rheumatoid factor, IgG and IL-1 β , IL-1RA, IL-2, IL-8 and MIP-1 α

Scleroderma

General Features

- 1. Microvascular pathology and diffuse tissue fibrosis that affects:
 - a. Skin
 - b. Gastrointestinal tract
 - c. Lungs
 - d. Heart
 - e. Kidneys

Clinical Features

Neurological Manifestations

- 1. Peripheral nervous systems:
 - a. Myopathy in 17% of patients
 - b. Cranial nerve involvement
 - i. Vth nerve most often involved
 - 1. Mental nerve involvement causes “numb chin” syndrome
 - c. Sensorimotor neuropathy
 - d. Mononeuritis multiplex
 - e. Carpal tunnel syndrome
 - f. Cranial neuropathies (Vth nerve)
 - g. Autonomic neuropathy
 - h. Myelopathy (rare)

Vascular Feature

- 1. Stroke
 - a. Disseminated cerebral arteritis (debated point)

- b. Hemorrhage (due to severe hypertension from renal involvement)
- c. SAH (rare)
- d. Cardiac emboli (rare)
- 2. Coagulopathy
- 3. Vasospasm

Pathology

- 1. Progressive fibrinosis of the skin and internal organs
- 2. The pathogenesis of systemic sclerosis (SSC) involves 3 interrelated processes:
 - a. Inflammation and autoimmunity
 - b. Vasculopathy
 - c. Increased extracellular matrix deposition
- 3. Dendritic cells, T-cells and macrophages are involved in an inflammatory response that activates fibroblasts and myofibroblasts
- 4. Transforming growth factor growth β (TGF β) stimulates fibroblasts and myofibroblasts to produce large amounts of ECM which leads to fibrosis
- 5. The intracellular pathways that cause fibrosis include:
 - a. TGF β
 - b. Type I interferon
 - c. Wnt/catenin
 - d. Cadherin

Neuroimaging

- 1. Topographical pial vessel stroke
- 2. Cerebral vasculitis (rare)

Laboratory Evaluation

- 1. SSC autoantibodies in the serum
 - a. Topoisomerase I
 - b. Centromere
 - c. RNA polymerase

Churg-Strauss Syndrome

General Characteristics

- 1. Also known as eosinophilic granulomatosis with polyangiitis (EGPA) is a systemic small-vessel vasculitis
- 2. Associations include:
 - a. Asthma
 - b. Eosinophilia
 - c. Previous allergic disorder
 - d. Lung involvement
 - e. Pituitary infarction
- 3. >60% of patients have CNS involvement

Clinical Features

- 1. EGPA most commonly presents with upper airway and lung involvement
- 2. Cardiac dysfunction
- 3. Skin lesions

Neurological Manifestations

- 1. Encephalopathy

- 2. Distal sensorimotor neuropathy
- 3. Small vessel stroke

Neuroimaging

MRI

- 1. Microinfarction
- 2. Intracranial hemorrhage
- 3. SAH (2 patients)

Laboratory Evaluation

- 1. Increased CRP and ESR
- 2. Eosinophilia
- 3. Antibodies p-ANCA

Henoch-Schönlein Disease

General Characteristics

- 1. A systemic vasculitis of small vessels
- 2. Primarily affects children
- 3. If adults are affected:
 - a. More severe illness
 - b. Associated with cancer

Systemic Features

- 1. Adult involvement may be preceded by a mucosal infection of the upper respiratory tract
- 2. Palpable skin purpura
- 3. Abdominal pain
- 4. Arthritis
- 5. Renal involvement
- 6. Carcinoma of respiratory and GI tract

Clinical Features

- 1. Occasional small vessel stroke
- 2. ICH (children)
- 3. Factor XIII deficiency
- 4. Vasculitis possible cause of ICH
- 5. Peripheral nerve involvement; facial palsy

Pathology

- 1. Leukocytoclastic vasculitis that involves venules, capillaries and arterioles
- 2. Deposition of immune IgA complexes

Neuroimaging

Angiography

- 1. Magnetic resonance angiography (MRA) and digital subtraction angiography (DSA) demonstrate vasculitis of blood vessels (if negative standard angiography)

MRI

- 1. T2-weighted sequences with bilateral hyperintensities that are diffuse
- 2. PRESS has been demonstrated
- 3. Vascular lesions involve two or more blood vessels
- 4. Thrombosis of superior sagittal sinus

Laboratory Evaluation

1. Elevated IgA
2. High sed rate, proteinuria

Behçet's Disease**General Features**

1. Behçet's disease is a systemic chronic relapsing vasculitis. This inflammatory disorder is characterized by painful oral and genital ulcers, uveitis, well circumscribed skin lesions, large artery stroke and vasculitis
2. Diagnostic criteria:
 - a. Oral ulcers at least 3 times in 12 months and any 2 of the following:
 - i. Recurrent genital ulcers or sores
 - ii. Eye inflammation (loss of vision)
 - iii. Skin lesions
 - iv. Positive pathology (skin prick test)
3. Involvement of the CNS occurs in 11 to 50% (pediatric patients)

Clinical Features

1. Clinical manifestations of neuro Behcet's
 - a. Cranial nerve palsies
 - b. Altered consciousness
 - c. Seizures
 - d. Meningoencephalitis
 - e. Focal cortical/brainstem deficits
 - f. Neurologic manifestations may occur from 1 to 10 years after onset of the disease
 - g. Cerebral venous thrombosis

Pathology

1. Vasculitis in both arterial and venous system (venous disease more common than arterial)
2. Thrombosis and false aneurysms
3. Perivascular infiltration of memory T-cells

Neuroimaging**MRI**

1. T2-weighted sequences reveal high intensity lesions scattered throughout the basal ganglia, brainstem and internal capsule
2. Topographic stroke
3. White matter hyperintensities may enhance with gadolinium
4. Cerebral venous thrombosis

Laboratory Evaluation

1. Association at IL23R and IL12RB2 locus from GWAS studies
2. CSF
 - a. IL-21 and IL-17A producing T-cells; elevated protein and normal glucose
 - b. Usually lymphocytic pleocytosis
3. Rarely the ESR, CRP and acute phase reactants are elevated in serum

4. Rarely there is elevated factor VIII, immune circulating complexes and cryoglobulins
5. Positive HLAB%1 allele is not diagnostic
6. Skin biopsy may demonstrate vasculitis with immune complex deposition

Wegener's Granulomatosis (Granulomatous Polyangiitis)**General Characteristics**

1. Granulomatous polyangiitis is a necrotizing vasculitis that primarily effects the sinuses, lungs, upper respiratory tract and kidneys

Clinical Features

1. Approximately one third to one half of affected patients suffer neurologic complications
2. Neurologic complications include:
 - a. Peripheral neuropathy and mononeuritis multiplex
 - b. Cranial nerve involvement from direct extension of nasal and sinus granulomas
 - c. Episodic hemicrania with periorbital ecchymosis
 - d. Intracranial spread causes:
 - i. Seizures
 - ii. Cerebritis
 - iii. Spastic paraparesis
 - iv. Horner's syndrome
 - v. Papilledema
 - e. Orbital involvement occurs in 20% of patients – similar to orbital pseudotumor, cellulitis or lymphoma
 - i. Extraocular muscle palsies
 - ii. Retinal involvement
 - iii. Optic nerve ischemia
 - iv. Posterior ischemic optic neuropathy
 - f. Cerebral arteritis and pial vessel infarcts

Pathology

1. Involves small arteries and veins
2. Fibrinoid necrosis of vessel walls with neutrophilic and histiocytic infiltration

Neuroimaging**CT and MRI**

1. Evaluation of the nasal sinuses
 - a. Mucosal thickening
 - b. Air-fluid level and opacification of the sinus
 - c. Bony destruction of the nasal septum
 - d. Sclerosing osteitis

MRI

1. Orbit
 - a. Granulomatous infiltration is hypo intense in both T1 and T2-weighted sequenced but enhance with gadolinium
2. Cerebral MRI
 - a. Diffuse linear dural thickening with enhancement contiguous with orbital, nasal and paranasal sinuses
 - b. T2-weighted sequences reveal high intensity lesions in the cortex and brainstem
 - c. Cerebral vasculitis

Laboratory Evaluation

1. Elevated c-ANCA levels in the serum
2. Sed rate: a good measure of disease activity
3. Overlap with other serum markers of hypersensitivity disease

*Hypersensitivity Vasculitis***Overview**

Hypersensitivity vasculitis (HV) and Henoch-Schönlein purpura (HSP) are the most common cutaneous vasculitides.

General Features

1. Palpable purpuric skin lesions
 - a. Legs more commonly affected than arms
 - b. Extremities may be symmetrically swollen and erythematous
2. Precipitants are specific allergens (Penicillin and sulfa drugs are common)

Clinical Features

1. Sensorimotor neuropathy
2. Plexopathy
3. Diffuse petechiae in centum semiovale
4. Low platelets

Pathology

1. Leukocytolytic vasculitis
 - a. Medium and small-sized vessel
 - b. Due to IgG or IgM containing immune complexes; has less systemic involvement
2. IgA deposition is predictive of associated renal and gastrointestinal organ involvement

Neuroimaging*MRA or Conventional Arteriogram*

1. Demonstrates vasculitis

MRI

1. T2-weighted sequences with diffuse hyperintensities
2. Large vessel stroke (rare)

Laboratory Evaluation

1. Skin biopsy
2. Determination of immune globulin complex type and vessel wall

Differential Diagnosis

1. Cryoglobulinemia
2. Urticaria
3. ANCA-associated
4. Leukocytolytic vasculitis associated with vasculopathy and coagulopathy in scleroderma/SLE
5. Bacteria/sepsis

*Mixed Connective Tissue Disease***General Features**

1. Mixed connective tissue disease has components of:

- a. SLE
 - b. Scleroderma
 - c. Polymyositis
2. Frequently there are concomitant high titers of antibody to:
 - a. V1 snRNP proteins
 - b. ds DNA

Clinical Features

1. Raynaud's phenomenon
2. Arthralgia
3. Swollen joints
4. Esophageal dysmotility
5. Muscle weakness

Neurological Manifestations

1. Headache
2. Seizure
3. Psychosis
4. Encephalopathy
5. Traverse myelitis
6. Ataxia
7. Aseptic meningitis
8. Monocular blindness
9. Vth nerve involvement
10. Sensorimotor neuropathy
11. Entrapment neuropathy
12. Stroke
 - a. Cerebral vasculitis
 - b. Rare association with thrombotic thrombocytopenic purpura

Pathology

1. Dependent on the manifestations of primarily SLE, scleroderma or polymyositis

Neuroimaging

1. Cerebral vasculitis
2. Topical stroke

Laboratory Evaluation

1. High titer of anti-V1-RNP antibody

*Thrombotic Thrombocytopenic Purpura (Moschcowitz Syndrome)***Overview**

A disease of small blood vessels combined with microangiopathic hemolytic anemia. Dominated by fever, anemia, renal and hepatic signs and symptoms and thrombocytopenia.

General Features

1. Caused by an acquired circulating IgG inhibitor of the von Willebrand factor cleaving protease
 - a. A disintegrin and metalloproteinase with thrombospondin type 1 motif member 13: ADAMTS13

- b. There is a rare familial deficit of ADAMTS13 (Upshaw-Schulman syndrome)
- 2. 3.8–6.5 cases per million individuals (2:1 ratio of females to males)

Clinical Features

- 1. Fever (interleukin I)
- 2. Renal failure
- 3. Thrombocytopenia
- 4. Microangiopathic hemolytic anemia
- 5. Associated with:
 - a. Pregnancy
 - b. Bone marrow transplantation
 - c. SLE
 - d. Ticlopidine
 - e. Sjögren's syndrome
 - f. Influenza vaccination
 - g. D-penicillamine
 - h. Cyclosporine
 - i. Rheumatoid arthritis
 - j. Mitomycin
 - k. Cancer
 - l. Autoimmune disease
 - m. HIV

Neurological Manifestations

- 1. Diffuse encephalopathy:
 - a. Visual Hallucination
 - b. Headache
 - c. Seizures
 - d. Visual loss
 - e. Transient focal deficits
 - f. Aphasia
 - g. Papilledema
 - h. Posterior leukoencephalopathy
 - i. Relapsing course
 - j. Non-convulsive status epilepticus
- 2. Overlap occurs with:
 - a. Hemolytic uremia syndrome
 - b. Hemolytic anemic with elevated liver function and platelets (HELLP syndrome)
 - c. Toxemia of pregnancy
 - d. Hyperintensive encephalopathy
 - e. Posterior reversible leukoencephalopathy (PRESS)

Pathology

- 1. Arteriolar and capillary involvement
- 2. Platelet rich thrombi in small vessels
- 3. Multifocal microinfarctions
- 4. Thrombosis affects the microvessels of both gray and white matter
 - a. Cortical and subcortical infarcts
- 5. Branch occlusions of the MCA/PCA (rare)
- 6. Restricted ischemia of the brainstem or cerebellum (rare)
- 7. Hemorrhagic presentation (rare)

- 8. Renal involvement less frequent and severe than neurological
- 9. Pathogenesis
 - a. Non-familial form (antibodies to ADAMTS-13)
 - i. Inhibitor of von Willebrand factor (cleaving protease)
 - b. Familial form
 - c. Large multimeres of von Willebrand Factor adhere to and aggregate platelets
 - i. Microvascular thrombosis in arterioles and capillaries
 - ii. Mutation in ADAMS-13 (a metalloproteinase)

Neuroimaging

- 1. Diffuse microinfarction
- 2. Large vessel stroke (rare)

Laboratory Evaluation

- 1. Microangiopathic hemolytic anemia
- 2. Assay for ADAMS13
- 3. Coombs negative hemolytic anemia
- 4. Severe thrombocytopenia
- 5. Elevation of serum LDH
- 6. Schistocytosis of RBCs
- 7. Gingival biopsy demonstrates microvascular thrombosis

Differential Diagnosis

- 1. Between thrombotic thrombocytopenic purpura (TTP) and hemolytic-uremic syndrome (HUS)
 - a. Both are thrombotic microangiopathic disorders
- 2. HUS:
 - a. Severe renal dysfunction always (not common in TTP)
 - b. Primarily in children after an incidence of severe bloody diarrhea
 - i. E. coli strain or Shigella dysenteriae that produces Shiga toxin

Reiter's Disease (Reactive Arthritis)

Overview

A classic triad of arthritis, urethritis and conjunctivitis that usually occurs within six weeks of a genitourinary or gastrointestinal infection.

General Characteristics

- 1. May follow GI illness
- 2. Severe heel pain
- 3. Conjunctivitis
- 4. Arthritis
- 5. Urethritis
- 6. Balanitis and sacroiliitis occur commonly

Neurologic Complications

- 1. Optic neuritis
- 2. Encephalitis
- 3. Ascending motor paralysis (GBS like syndrome)

4. Seizures
5. Brainstem dysfunction
6. Acute transverse myelitis
7. Neuralgic amyotrophy
8. Large vessel vasculitis

Pathology

1. Large vessel vasculitis
2. Aortitis
3. Inflammatory synovium

Vascular Features

1. Pial vessel stroke

Neuroimaging

1. Sacroiliitis (PET/CT)
2. Thoracic magnetic imaging (aortic involvement)
3. Large vessel vasculitis

Laboratory Evaluation

1. Ferritin antibodies demonstrated in patient with aortitis
2. HLA-B27 positive

Relapsing Polychondritis

Overview

An illness that causes inflammation of cartilage throughout the body.

Clinical Characteristics

1. Predominant systemic manifestations include:
 - a. Auricular chondritis (pain and tenderness of cartilaginous portions of the ear in 85% of patients)
 - b. Polyarthritits
 - c. Nasal chondritis ("saddle nose deformity")
 - d. Ocular inflammation
 - e. Audiovestibular involvement
 - f. Tracheal and laryngeal inflammation

Clinical Features

1. 40% of patients suffer inner ear disease with:
 - a. Hearing loss
 - b. Tinnitus
 - c. Vertigo
 - d. Rarely deafness
2. Ocular involvement:
 - a. Conjunctivitis, episcleritis, scleritis
 - b. Iritis and iridocyclitis
 - c. Keratoconjunctivitis sicca
 - d. Choroiditis
 - e. Optic neuritis
 - f. Retinal vasculitis
 - g. Orbital pseudotumor (proptosis)
3. Nasal cartilage inflammation
 - a. 70% of patients
 - b. Saddle nose deformity
4. Aortic insufficiency
5. Laryngotracheal involvement in 50%

Neurologic Signs and Symptoms

1. Occurs in 3% of patients
2. Extraocular muscle palsy
3. Optic neuritis
4. Bilateral VIIIth nerve
 - a. Associated with inner ear disease
5. Mononeuritis multiplex
 - a. Associated with PAN

CNS Manifestations

1. Meningoencephalitis
2. Headache
3. Altered consciousness
4. Papilledema
5. Seizure
6. Ischemic stroke
7. IIIrd and Vth cranial neuropathy
8. Meningeal signs

Pathology

1. Perivascular lymphocytic cuffing and infiltration of small vessels and hemispheric white matter
2. Inflammatory destruction of myelin sheaths
3. Neuronal loss and gliosis
4. Pathogenesis
 - a. IL-6 involvement

Neuroimaging

MRI

1. Brain atrophy

Associated Diseases

1. Rheumatoid Arthritis
2. Systemic lupus erythematosus
3. Reiter's syndrome
4. Ankylosing spondylitis
5. Ulcerative colitis
6. Hashimoto's thyroiditis
7. 25% have myelodysplastic syndrome

Ulcerative Colitis and Regional Enteritis

Overview

Also known as inflammatory bowel disease.

General Characteristics

1. Dominant bowel symptoms
2. Extra intestinal and bowel features:
 - a. Large joint arthritis
 - b. Keratoconus
 - c. Primary sclerosing cholangitis
 - d. Rare non-neurologic complications
 - i. Acute pancreatitis
 - ii. Gluten-sensitive enteropathy
 - iii. Pulmonary bronchiectasis
 - e. Thrombosis
 - i. Deep vein thrombosis

- ii. Pulmonary embolism
- f. Coagulation dysfunctions
- 3. Extra intestinal manifestations may be the first manifestations of disease
- 4. Neurologic complications are more common in men and occur in approximately 3% of patients

Clinical Features

1. The risk of arterial and venous thrombosis and thromboembolic disease is increased in IBD
2. Cerebrovascular events have been documented in .12 to 4% of all IBD patients
3. Active disease is the most important predisposing factor
4. Arterial thromboembolism:
 - a. More frequent in younger patients
 - b. Total colitis a risk factor
 - c. Large vessel emboli
 - i. Hypercoagulable state
5. Venous and sinus thrombosis
 - a. More common in ulcerative colitis than Crohn's disease
 - b. Superior sagittal and lateral sinuses most frequently affected
 - c. Accompanied at times by cerebral infarction

Pathology

1. Embolic stroke
2. Ischemic stroke mechanisms
 - a. Large artery disease
 - b. Small vessel disease
 - c. Endocarditis with embolus
 - d. Vasculitis
 - e. Associated with anti-TN α therapy

Neuroimaging

1. Topologic large vessel stroke (ischemic)
2. Embolic stroke
3. Cerebral vasculitis

Laboratory Evaluation

1. Endoscopy with biopsy
2. Low sensitivity of p-ANCA and anti-Saccharomyces cerevisiae antibodies are not useful for diagnosis of VC or CD

Celiac Disease

General Features

1. An immune-mediated enteropathy
2. Approximate prevalence of 1% in USA and European populations
3. Increased disease prevalence in high risk groups that include patients with:
 - a. Autoimmune conditions
 - i. Insulin dependent diabetes
 - ii. Addison's disease
 - iii. Thyroid disease
 - iv. Sjögren's syndrome

- b. Osteoporosis
- c. First degree relatives of Crohn's disease patients
4. Diarrhea abdominal pain and constipation are common symptoms

Clinical Features

Neurologic Manifestations

1. Proximal myopathy
2. Sensorimotor peripheral neuropathy
3. Spinal cord dysfunction
4. Cerebellar degeneration with ataxia
5. Celiac disease, epilepsy and cerebral calcifications (CEC)
 - a. Primarily in patients from Italy, Spain and Argentina
6. Approximately 10 to 20% of patients have neurological disease

Vascular Features

1. Stroke
 - a. Large conducting and pial vessel stroke

Pathology

1. Gluten ataxia is a distinct disease process and may occur without enteropathy
 - a. Associated with anti-gliadin antibody
2. Cerebellar atrophy
3. Lymphocytic infiltration and perivascular cuffing in the cerebellar cortex and peripheral nerves
4. Anti-gliadin antibodies are directed against gluten
5. Association with other autoimmune diseases

Neuroimaging

1. Celiac disease, epilepsy and cerebral calcification
2. Possible vascular calcification malformation (a type of Sturge-Weber like phacomatosis)

MRI

1. Diffuse T2-weighted sequence hyperintensities seen in 20% of 75 diet-treated patients
2. Consistent with vasculitis or inflammatory demyelination

Laboratory Evaluation

1. High titers of serum and CSF anti-gliadin antibodies
2. Small bowel biopsy to document villous atrophy
3. Anti-endomysium and anti-transglutaminase are markers for sprue but do not correlate with neurologic disease

Temporal Arteritis (Giant Cell Arteritis)

General Features

1. Primarily affects the external carotid system (particularly the temporal branches) in older patients
2. It may involve the aortic arch, axillary, iliac and femoral arteries
3. Incidence is approximately 1 to 20 patients per 100,000 populations in the USA
4. Rare familial patients

5. Presents as a systemic illness
 - a. Low grade fever
 - b. Weakness of proximal muscles (coexisting polymyalgia rheumatica)
 - c. Weight loss
 - d. Onset of headache
 - i. Painful burning scalp
 - ii. Not pulsatile headache
 - e. Jaw claudication (facial artery involvement)
 - f. Perforated nasal septum
 - g. Ischemic tongue lesions (similar appearance to carcinoma)
 - h. Painful cord-like superficial temporal arteries (only 30 to 40% positive by blind biopsy)
 - i. Rare sites of involvement
 - i. Pial and brainstem arteries
 - j. Extracranial giant cell arteritis
 - i. Occurs in 10 to 15% of patients with polymyalgia rheumatica
 - k. Relapses may occur after successful treatments
- c. Ischemic tongue lesion
 - i. Similar to squamous cell carcinoma in appearance
8. Facial pain:
 - a. Arteritis of the facial branch of the external carotid artery
9. Myelopathy:
 - a. Vasculitis of the vertebral and anterior spinal artery with cervical cord infarction
10. Peripheral neuropathy:
 - a. Distal symmetrical sensorimotor neuropathy
 - b. Mononeuritis multiplex
 - c. One month after onset
11. Myopathy:
 - a. Steroid related proximal myopathy
12. Encephalopathy
 - a. Arteritis of pial and superficial arteries
13. Multiinfarct dementia
14. Infarction of major branches of both anterior and posterior circulations
 - a. Posterior circulation most often affected at:
 - i. Top of the basilar distribution
 - ii. Lateral medullary stroke
 - iii. Occipital lobe infarction
 - b. Arteries with the most internal elastic membrane are affected most severely
15. Carotid bruits noted in 10–20% of patients:
 - a. Bilateral bruits:
 - i. 60% of these patients have associated involvement of the aortic arch
16. Vertebrobasilar arterial involvement may present with:
 - a. Acute confusional state
 - b. Coma
17. Mechanism:
 - a. Arteritis
 - b. Hypercoagulable state

Clinical Features

Neurological Manifestations

1. Blindness from:
 - a. Occlusion of the posterior ciliary arteries (derived from the internal carotid) or their collaterals (from the external carotid)
 - b. Central retinal artery occlusion
 - c. Ischemic optic neuropathy from infarction at the optic disc
 - d. Visual loss occurs suddenly:
 - i. May occur in the second eye within minutes or at approximately 2 months
 - ii. Men > women with severe ocular problems
 - iii. Visual loss is permanent due to infarction of the optic nerve head and retina
2. Visual field deficits
 - a. Altitudinal rather than central
3. Anterior optic nerve involvement:
 - a. Mild papilledema
 - b. Infrequent disk hemorrhage
 - c. Resolves over 10 days
4. Retrobulbar ischemic optic neuropathy:
 - a. Gradual optic pallor and atrophy
5. Diplopia:
 - a. 2–14% of patients
 - b. Vasculitis of extraocular muscles with total ophthalmoplegia (rare)
6. Cranial nerve palsies:
 - a. Rare that VIIIth cranial nerve is involved
 - b. Infarction of the internal auditory artery (origin is AICA)
7. Tongue:
 - a. Hemianesthesia of the tongue (lingual artery)
 - b. Lingual paralysis
- Pathology
 1. Subacute Granulomatous inflammatory exudate affecting the involved arteries
 - a. Lymphocytes and monocytes, neutrophils and giant cells are seen in the artery
 - b. Thrombosis occurs at the most severely affected part of the artery
 - c. Intracranial arteries are rarely affected
 - d. Posterior ciliary artery branches of the ophthalmic artery and the choroidal circulation that supplies the anterior optic nerve may be infarcted
- Neuroimaging
 1. Vertebral artery stroke and anterior circulation strokes occur
 2. Embolic stroke
 3. Less than 1% of patients suffer cerebral vein thrombosis
 4. Rare intracranial arteritis
- Laboratory Evaluation
 1. The sedimentation rate is usually above 80 to 120 mm/hr

- a. Some patients have documented disease with an ESR of less than 50 mm/hr
- 2. Elevated sedimentation rate (or may be normal)
- 3. Mild normocytic anemia
- 4. Mild peripheral leukocytosis
- 5. Biopsy of the temporal artery is the gold standard

Isolated Angiitis of the CNS

General Features

- 1. This is putatively an immune-mediated arteritis of strictly cerebral blood vessel
- 2. Other names for the process:
 - a. Isolated granulomatous angiitis
 - b. Giant cell granulomatous angiitis of the CNS
- 3. Mean age of onset 49; any age can be affected
- 4. Male predominance 2:1
- 5. Vasculitis isolated to the CNS:
 - a. Exclusion of systemic inflammation, infection or other causes of CNS vasculitis; rarely associated with angiod angioopathy
- 6. Segmental necrotizing granulomatous vasculitis that involves:
 - a. Cortical arteries
 - b. Spinal arteries
 - c. Leptomeningeal arteries may be predominant
 - d. Usual vessel size involved is 200–500 μm (microns)
 - i. Any size vein or artery may be involved
 - ii. Precapillary arterioles of less than 500 μm are involved
 - e. Intima and adventitia of arteries are infiltrated with:
 - i. Lymphocytes, giant cells, and granulomas
 - ii. Granulomas may invade the cortex
 - f. Veins may be affected in 50% of patients

Clinical Features

Neurologic Manifestations

- 1. Earliest symptoms:
 - a. Headache
 - b. Phonophobia
 - c. Photophobia
 - d. Unusual stroke-like presentation
 - e. Diffuse encephalopathy (usual presentation)
 - f. Gradual onset
 - g. Retinal perivascular lesions
 - h. SAH
 - i. Root pain
- 2. Later signs and symptoms:
 - a. Altered mental status
 - b. Dementia
 - c. Myelopathy
 - d. Hemiparesis
 - e. Diffuse encephalopathy
 - f. Rare: territorial stroke
 - g. Pathology of intracranial vessels
 - i. Thrombosis

- ii. Rare: small aneurysms develop on arteries
- h. Myelopathy may precede encephalopathy
- i. Seizures occur
- j. Usual progression
 - i. Step-like deterioration of a progressive encephalopathy
- k. SAH (rare)

Pathology

- 1. Infiltration of vascular wall by lymphocytes, macrophages and histiocytes
- 2. Occasional fibrinoid necrosis
- 3. 85% of patients demonstrate granulomas with:
 - a. Epithelial cells
 - b. Giant Langerhans cells
- 4. Inflammatory lesions preserve the media
- 5. Small and middle sized arteries are involved
 - a. Involvement of veins and vessels occur
 - b. Arteries less than 500 microns may be solely affected
- 6. Non-specific T-cell mediated inflammatory reaction important in pathogenesis

Imaging Evaluation

- 1. MRI
 - a. Positive 68% of the cases
 - b. Infarcts demonstrated (ischemic)
 - c. Hemorrhagic infarction (rare)
 - d. Small hematoma (rare)
 - e. Intracerebral aneurysm (rare)
 - f. Combination of ischemic and hemorrhagic stroke
 - g. Increased diffuse number of T2-weighted lesions
 - h. Intracranial hemorrhagic is more frequent than that seen with infectious etiologies
 - i. Linear and punctate pattern of leptomeningeal enhancement associated with:
 - i. Hemispheric and penetrating vessel involvement
 - ii. Diffuse DWI lesions
 - j. Unusual MRI patterns
 - i. Pseudotumoral
 - ii. Multiple sequential parenchymal and ventricular hemorrhages
 - iii. Miliary appearance from multiple small lesions
 - iv. Diffuse white matter involvement
- 2. Arteriogram
 - a. Positive in approximately 50% of patients; involved vessels of less than 500 μm may be negative
 - b. Segmental narrowing, dilatation and beading
 - c. Rare: intracranial aneurysm

Laboratory Evaluation

- 1. Elevated sed rate in 2/3 of patients; increased incidence of anticardiolipin antibodies
- 2. CSF
 - a. Mononuclear and lymphocytic pleocytosis
 - b. CD4+ lymphocytes involved
 - c. Protein elevated in 80% of patients to >100 mg/dl

*Nongranulomatous Angiitis of the CNS***General Characteristics**

1. Segmental necrotizing angiitis without granulomata
2. Male: female 1.8 to 1
3. Multiple small but occasionally large foci of infarction throughout the CNS
4. Mean age at onset 49
5. Evolution of the disease
 - a. Stepwise occurrence of focal neurologic deficits

Neurological Manifestations

1. Acute presentation
 - a. Stupor or coma within days to weeks
2. Classic presentation:
 - a. Fever and weight loss are uncommon
 - b. Mental status change
 - c. Headache
 - d. Hemiparesis
 - e. Impairment of consciousness
 - f. Focal, multifocal or diffuse encephalopathy
3. Rare neurologic presentations:
 - a. Increased intracranial pressure (ICP)
 - b. Chronic meningitis or arachnoiditis
 - c. Cerebral hemorrhage
 - d. Radiculopathy

Vascular Features

1. Rare vascular presentation:
 - a. TIA
 - b. Large vessel stroke
 - c. SAH
 - d. Multiinfarct stroke

Imaging Evaluation

1. MRI:
 - a. White and gray matter involvement
 - b. Occasional hemorrhage
 - c. Bilateral subcortical lesions
 - d. Enhanced meninges
2. Arteriography
 - a. Abnormal in approximately 60%
 - i. Segmental narrowing and sausage shaped dilatation (beading)
 - ii. Rarely: avascular mass or intracerebral aneurysm
 - iii. Affected vessels < 500 μm
3. Leptomeningeal biopsy more often positive than brain biopsy

Laboratory Evaluation

1. Mild elevation of ESR in 2/3 of patients
2. CSF mononuclear pleocytosis (mean of 70 monocytes/mm³)

*Differential Diagnoses of Mimicking Conditions***Overview**

The following are different conditions that mimic immune vasculitis and vasculitis differentiated by pathologic process,

association with neoplastic disease, site of involvement, topography, vessel size and segmental narrowing on arteriogram.

Differential Diagnosis of Conditions Mimicking Vasculitis

1. Dissecting aneurysm
2. Antiphospholipid syndrome
3. Drugs
 - a. Methamphetamine
 - b. Sympathomimetic drugs
 - c. Ginseng
 - d. Ephedrine
 - e. Propylethanolamine
 - f. Cocaine
4. Cholesterol emboli
5. Intravascular lymphomatosis
6. Coll-Fleming syndrome

Differential Diagnosis of Arteritis Associated with Autoimmune Diseases

1. SLE
2. Polyarteritis Nodosa
3. Neurosarcoidosis
4. Sjögren's
5. Rheumatoid arthritis
6. Scleroderma
7. Churg-Strauss
8. Wegener's granulomatosis
9. Hypersensitivity arteritis
10. Mixed connective tissue disease
11. Giant cell arteritis
12. Reiter's syndrome
13. Relapsing polychondritis
14. Ulcerative colitis
15. Regional enteritis
16. Celiac disease
17. Serum sickness
18. Henoch-Schönlein purpura
19. Cryoglobulinemia
20. Polyangiitis

Differential Diagnosis of Systemic Necrotizing Arteritis

1. Wegener's granulomatosis
2. Lymphomatoid granulomatosis
3. Sarcoid
4. Hairy cell leukemia

Differential Diagnosis of Arteritis with Neoplasia

1. Hodgkin's disease
2. Non-Hodgkin's lymphoma
3. Neoplastic angioendotheliosis
4. Hairy cell leukemia
5. Angiocentric endothelial lymphomatosis

Differential Diagnosis of Isolated Angiitis of the CNS

1. Necrotizing vasculitis

2. HZ
3. Hodgkin's disease
4. HIV
5. Sarcoid
6. Hypersensitivity arteritis
7. PAN
8. Lymphomatoid granulomatosis
9. Methamphetamine
10. Sympathomimetic drugs
11. Coll-Fleming syndrome
12. Wegener's granulomatosis
13. Multiple Sclerosis
14. Behçet's disease
15. Giant cell arteritis
16. Posterior leukoencephalopathy

Differential Diagnosis of Systemic Vasculitis Resembling Isolated Angiitis of the CNS

1. Vasculitis with connective tissue disease
2. PAN
3. Wegener's granulomatosis
4. Giant cell arteritis
5. Takayasu's disease
6. Behçet's disease

Differential Diagnosis of Vasculitis Associated with Granulomatous Parenchymal Lesions

1. Wegener's granulomatosis
2. Sarcoid
3. Lymphomatoid granulomatosis
4. Granulomatous angiitis
5. Hodgkin's disease

Differential Diagnosis of Vasculitis by Characteristic Sites of Involvement

1. Takayasu's disease:
 - a. Arch of the aorta
 - b. Mid common carotid artery
 - c. Mid descending aorta
2. Sneddon's syndrome
 - a. Skin (livedo reticularis)
3. Köhlmeier–Degos syndrome
 - a. Atrophic skin lesions
4. Giant cell arteritis
 - a. Primarily external carotid system
 - b. May affect the ICA, and arch of the aorta

Differential Diagnosis of Vasculitis by Topography

1. Focal:
 - a. Herpes Zoster
 - i. Proximal MCA; ACA (occur on the side of the skin lesions)
2. Multifocal:
 - a. SLE
 - b. Primarily separate areas of the cortex
3. Disseminated:
 - a. Isolated or primary angiitis of the CNS

Differential Diagnosis of Vasculitis of Medium-Sized Arteries

1. PAN
2. SLE
3. RHA
4. Sjögren's syndrome
5. Buerger's disease

Differential Diagnosis of Vasculitis of Small-Sized Arteries

1. Churg-Strauss
2. Polyarteritis nodosa (microangiopathic variant)
3. Wegener's granulomatosis
4. Hypersensitivity arteritis

Differential Diagnosis of Segmental Narrowing of Cerebral Arteries on Arteriogram

1. Arteritis (infective; inflammatory; necrotizing)
2. Leptomeningitis (infective, chemical, carcinomatous)
3. Vasospasm:
 - a. SAH
 - b. Migraine
 - c. Hypertensive encephalopathy
 - d. Coll-Fleming syndrome
4. Atherosclerosis
5. Fibromuscular dysplasia
6. Recanalization of emboli
7. Sickle cell disease
8. Sympathomimetic drug abuse
9. Neoplasms:
 - a. Angioendotheliosis
 - b. Glial and meningeal tumors
 - c. Atrial myxoma
10. Closed head injury
11. Radiation therapy (X-RT)
12. Neuroectodermal dysplasia
 - a. Neurofibromatosis
 - b. Tuberous sclerosis

Infectious Disease and Stroke

Overview

The differential diagnosis of the infections that cause stroke rests on the specific pathologic mechanisms induced or associated with each infection. The neurological manifestations of each infection are different and often the extracranial manifestations of the infection provide the clue to the specific diagnosis. Bacteria, viruses and fungi cause stroke as do spirochetes and protozoa.

Stroke may occur in the setting of bacterial meningitis. Pus may directly involve the pial vessels and encase them on the cortex. Pneumococcal meningitis may be associated with endocarditis that causes mycotic aneurysms that hemorrhage. Stroke may occur 6–8 weeks after the primary infection due to endocarditis.

Meningococcal infection occurs frequently in settings in which young healthy adults are living in close quarters. The

evolution of the infection (headache to coma) may occur within hours. The clinical course is dominated by the meningitis. Stroke is rare.

Listeria infections occur following head and neck surgery and during pregnancy and delivery. The seminal feature is brainstem infarction with dorsal pontine involvement. *Bartonella henselae* infection follows exposure or inoculation from cats. Seizures and retinitis are the seminal features following extremity lymphadenitis.

Syphilis has made a comeback as a serious cause of infection due to HIV. It may be telescoped where in all three stages are seen within a short period of time. In the past, brainstem strokes were noted in the meningovascular stage. This pattern persists, but may be more associated with gumma formation and less with syphilitic optic nerve and pretectal involvement (Argyll-Robertson pupils). If meningitis is seen concomitantly, the CSF sugar is usually normal.

Lyme's disease is the most common vector borne infection in the United States and has protein manifestations. If VIIth nerve palsy and characteristic rash and large joint arthritis is present diagnosis is straight forward. Unfortunately, many patients present in later stages with asthenia and low grade encephalopathy weeks or months after the infection. Strokes are rare, but are described.

Tuberculosis causes strokes because of cortical and basilar exudates. It is a more chronic illness in Western countries and is often seen as a low grade dementing illness. It should always be suspected in HIV infected patients with lower cranial nerve abnormalities (particularly the VIIIth nerve).

Fungal infections occur most frequently in the immunocompromised host. Disorders of B-lymphocyte function are associated with encapsulated bacterial pathogens. Impaired T-lymphocyte or macrophage function causes infection by intracellular pathogens such as aspergillus, nocardia (bacterial), viruses and parasites (toxoplasmosis gondii).

Extra-CNS sites of infection suggest aspergillus and nocardia both of which may present subacutely or chronically. T-lymphocyte dysfunction with meningitis is *Listeria* or *Cryptococcus*. *Aspergillus* can present as a CNS mass lesion or stroke but most often as meningitis.

Mucormycosis is associated with all forms of immunosuppression, but particularly with diabetic ketoacidosis and renal failure. The fungus is associated with sinus infection and venous infarction. It should be suspected in this circumstance in a patient with ophthalmoplegia.

Aspergillosis infects isolated lung abscesses and is associated with osteomyelitis of the base of the skull. It is notorious for fungal hyphae occluding cerebral conducting vessels. Fungal balls from valve leaflets are large enough to occlude peripheral extremity arteries.

Cryptococcus usually presents as a chronic dementia in the setting of immunocompromise. It spreads through the Virchow-Robin spaces to involve the basal ganglia. This is most helpful in the setting of stroke and T2 enhancement of the caudate and putamen. Proximal MCA branches and ves-

sels in the posterior perforated substance are most frequently involved.

Coccidiomycosis is common in the American SW. Extracranially it affects lungs and joints. Sacral involvement is frequent as is involvement of the jaw. Proximal MCA and the arteries of the perforated posterior substance are most often involved.

Histoplasmosis is most often encountered in the Mississippi Valley. It may be associated with adrenal failure with concomitant splenic calcification. Arteries are inflamed in the chronic basilar exudate.

Viral infections cause stroke by direct invasion of the vessel wall or its endothelium, an immune response triggered by vessel epitopes or immune complex deposition.

Herpes Zoster causes a middle cerebral artery stroke ipsilaterally to the Vth nerve involvement. This characteristically occurs 6–8 weeks following the rash, but has been seen within two weeks. Both anterior and posterior circulation large vessels may be involved. Immune compromised HIV patients may suffer small vessel disease. One mechanism is involvement of the vessel wall endothelial antithrombotic systems.

HIV itself is associated with stroke from various mechanisms:

1. Immune complex formation
2. Cell mediated vasculitis
3. Inflammation from direct viral invasion
4. Associated infections that cause stroke

Most often the pathology is in medium-sized arteries. The clinical manifestations of severe HIV infection suggest the diagnosis.

Cerebral malaria may be the most widespread CNS infection with stroke as a consequence. It most often occurs with *plasmodia falciparum* and occurs due to obstruction of capillaries by parasitized RBC.

The following is a more detailed description of the various infections that cause stroke.

Clinical Manifestations of Stroke Inducing Infections

1. Bacterial meningitis
 - a. *Pneumococcus*:
 - i. Early hematogenous spread from the lung
 - ii. Simultaneous infection of the heart valve (may occur); later SBE
 - iii. Stroke of superficial pial vessels
 - iv. Course clinically dominated by meningitis
 - b. Meningococcal infection:
 - i. Early headache, nausea and vomiting; "flu-like"
 - ii. Rapid progression to lethargy in 6–12 hours
 - iii. Pial artery strokes
 - iv. Adrenal failure (Waterhouse-Frederickson syndrome)
 - v. Clustered infection
 1. Close living quarters (army barracks' camp, college dormitories)

- vi. Bacteria may be seen in cerebral spinal fluid prior to neutrophils
- c. *Listeria monocytogenes*
 - i. Head and neck cancer patients
 - ii. Abrupt onset of symptoms
 - iii. Clinical involvement of:
 - 1. Medulla
 - 2. Pontine tegmentum (seminal feature)
 - 3. Lower cranial nerve palsies
 - 4. Arteritis of the brainstem with multiple infarcts
 - 5. Focal encephalitis
 - 6. Monocytic cerebral spinal fluid pleocytosis
- d. *Bartonella henselae* (cat-scratch fever)
 - i. Lymphadenopathy in drainage area of the scratch
 - ii. Seizures (generalized)
 - iii. Retinitis
 - iv. Intracranial stenosis and arteritis

Syphilis

General Characteristics

1. Most prominent in HIV patients
2. All stages may occur simultaneously
3. 3 major stages:
 - a. Stage 1 (primary infection)
 - i. Dissemination throughout the CNS from the primary lesion (2 to 12 weeks)
 - b. Stage 2 ("early neurosyphilis")
 - i. Syphilitic meningitis
 - ii. Asymptomatic neurosyphilis
 - iii. Last for up to 2 decades after the initial infection
 - c. Stage 3
 - i. Asymptomatic neurosyphilis
4. Genome is a single circular chromosome that lacks transposable elements
5. Rare transmission: from mother to fetus; accidental inoculation, close contact with a primary lesion
6. Neurosyphilis begins in the second stage
 - a. Meningitis
 - b. Asymptomatic neurosyphilis
 - c. Meningovascular syphilis
 - d. Lasts for two decades
7. Late neurosyphilis
 - a. Spirochete involvement of the brain and spinal cord

Clinical Manifestations

1. Dissemination from the primary lesion (2 to 12 weeks)
2. Secondary syphilis (12 weeks to 2 decades)
3. Tertiary stage (late syphilis) decades

Meningovascular Syphilis

1. Most patients do not develop meningitis
2. Subgroups develop:
 - a. Aseptic meningitis
 - b. Unilateral or bilateral cranial palsies (VII; VIII; difficulty protruding or maintaining the tongue protruded ("tombone tongue"))
 - c. Strokes

Cerebrovascular Disease with Meningovascular Syphilis

1. Syphilitic endarteritis involves medium-to-large arteries (Heubner's endarteritis)
2. Basilar meninges are often concomitantly involved with a perivascular infiltrate that causes brainstem strokes and cranial nerve palsies
3. Young age at stroke onset (90% are between 30 and 50 years of age)
4. Patients may have a prodromal headache, dizziness and emotional disturbance

Spinal Cord Stroke

1. Rare in isolation: usually associated with cerebral syphilis
2. Insidious or sudden onset of transverse myelitis (usually at a thoracic level)
 - a. Chronic spinal cord meningitis
 - b. Heubner's arteritis
 - c. MRI evaluation
 - i. Enhancement of the superficial spinal cord
 - ii. Extremely rare cervical cord gumma or syphilitic hypertrophic pachymeningitis

HIV and Concomitant Syphilis

1. Cause of neurosyphilis (accelerates the infection)
2. Higher HIV load
3. CSF-VDRL and FTA-ABS are diagnostic
4. 10% have cranial palsies (VIIIth and cranial nerve; 30% have abnormal pupils)
5. Stroke may evolve over days
6. Cognitive decline in some patients

Neuropathology

1. Syphilitic endarteritis
 - a. Medium-to-large arteries (Heubner's endarteritis); concentric collagen thickening of the intima with thinning of the media
 - b. Elastic lamina intact
 - c. Endothelial proliferation
 - d. MCA most often causative of stroke; also ACA, PCA, BA branches are involved
 - e. Meningeal involvement:
 - i. Involved at base of the brain with chronic inflammation
 - ii. Heubner's arteritis affects some vessels
 - iii. Perivascular infiltrate may occur around brainstem vessels (lymphocytes and plasma cells)

CSF Evaluation in Meningovascular Syphilis

1. Mononuclear cell pleocytosis (20 to several hundred cells/mm³)
2. Normal glucose
3. Protein normal to 250 mg/dl
4. Oligoclonal bands are often present
5. Increased IgG
6. CSF-VDRL is diagnostic

*Neuroimaging***Angiography**

1. Compatible with CNS vasculitis

MRI

1. May demonstrate meningeal enhancement
2. Spinal cord stroke
 - a. Enhancement of the superficial spinal cord
 - b. Extremely rare cervical cord gumma or syphilitic hypertrophic pachymeningitis

*Laboratory Evaluation***CSF Evaluation in Meningovascular Syphilis**

1. Mononuclear cell pleocytosis (20 to several hundred cells/mm³)
2. Normal glucose
3. Protein normal to 250 mg/dl
4. Oligoclonal bands are often present
5. Increased IgG
6. CSF-VDRL is diagnostic

Lyme's Disease*General Characteristics*

1. The most common vector borne infection in the United States:
 - a. 15,000 cases/year
 - b. Three distinct foci in the USA
 - i. Maine to Maryland
 - ii. Wisconsin and Minnesota
 - iii. Northern California and Oregon
2. *Borrelia burgdorferi*:
 - a. Tick borne spirochete
 - i. Ixodes ricinus complex
 - b. Vectors are:
 - i. Deer; white footed mice; dusky footed wood rats

*Clinical Manifestations***Medical Complications**

1. Early infection
 - a. Localized erythema migrans (stage 1)
 - b. Disseminated infection (stage 2):
 - i. Nervous system
 - ii. Heart
 - iii. Joints
 - iv. Occurs within days or weeks of infection
 - c. Late or persistent (stage 3)
 - i. Weeks or months after infection

Medical System Involvement

1. Skin
 - a. Erythema migrans
2. Cardiac
 - a. AV block; subendocardial myocarditis
3. Joints
 - a. Oligoarticular arthritis
 - b. Treatment resistant arthritis in 10% of patients
4. Asymptomatic infection about 10% of patients

Neurological Complications

1. Acute phase:
 - a. Severe headaches
 - b. Meningitis (lymphocytic)
 - c. Neck stiffness
 - d. Radiculoneuritis
 - e. Mononeuritis multiplex
 - f. Cerebellar ataxia
 - g. Myelitis
 - h. There is very little evidence that Lyme's disease is associated with stroke
2. Chronic phase:
 - a. Uni or bilateral VIIth nerve palsy
 - b. Encephalopathy
 - c. Cognitive dysfunction
 - d. Sensory polyneuropathy
 - i. No acrodermatosis

Neuroimaging

1. Generalized white matter hyperintensities; often larger than those of small vessel disease

Laboratory Evaluation

1. An antibody response to *B. burgdorferi* by enzyme-linked immunoabsorbent assay (ELISA)
2. Western blotting of CSF (positive)
3. Intrathecal production of IgM, IgG or IgA antibody
4. Post antibiotic treatment:
 - a. Antibody titers fall slowly and may persist for years

Tuberculosis*General Characteristics*

1. HIV pandemic has caused a resurgence of the disease; an increase in all developing countries
2. Tuberculosis meningitis (TBM):
 - a. Most important and common cause of neurotuberculosis (about 70 to 80% of cases)
 - b. TBM is secondary to primary infection most often of the lung
 - c. The cause of the infection is determined by:
 - i. Time between infection and treatment
 - ii. Virulence of the bacillus and its drug sensitivity
 - iii. Immune status of the host
 - iv. Age of the patient

Neuropathology

1. Exudate at the base of the brain encompassing MCA > ACA > PCA
 - a. MCA and its branches preferentially involved
2. Microscopic evaluation:
 - a. Endarteritis
 - b. Periarthritis
 - c. Fibrinoid necrosis of blood vessels

- d. Vascular edema
- e. Thrombosis
- 3. "Throttling and occlusion" by exudate of MCA and its branches:
 - a. Basal ganglia infarction
 - b. Vasospasm-induced by eicosanoids or cytokines
 - c. Immunological injury to blood vessels
 - d. HIV infected patients:
 - a. Minimal inflammatory response in the brain
 - b. Basal ganglia and cortical infarction

Clinical Manifestations

1. Prodromal fatigue and low grade fever
2. Tubercular meningitis
3. Cranial nerve palsy (VII & VIII)
4. Hydrocephalus (late)
5. Depressed consciousness
6. Dementia
7. Strokes usually occur in moderate to severe stages (2 and 3)
8. Stroke characteristics
 - a. Focal deficits occur in 10 to 47% of patients with TBM
 - b. Occur acutely and involve basal ganglia and subcortical structures
 - c. Infarction in vertebrobasilar circulation; intracerebral hemorrhage is rare
9. Seizures in 37% of patients with stroke
10. HIV infected patients have the same clinical phenomenology

Neuroimaging

1. Majority of infarcts are in the territory supplied by the lenticulostriate and thalamoperforating arteries of the MCA
2. TB zone:
 - a. Caudate/putamen/genu and posterior limb of the internal capsule

CT and MRI Evaluation

1. Enhancement of the base of the brain
2. Communicating and non-communicating hydrocephalus
3. Cerebral infarcts
4. Tuberculoma (rare)

MRI

1. HIV infected patients
 - a. Less basal exudate
 - b. Ventricular dilatation from atrophy
 - c. Tuberculoma and toxoplasma granulomas (in HIV patients)

Angiography

1. Angiographic evidence of arteritis

Cerebral Nervous System (CNS) Infections in the Immunologically Compromised Host

General Characteristics

1. General neurological manifestations:
 - a. Meningeal signs
 - b. Mass lesions
 - c. Encephalopathy
 - d. Seizures
 - e. Stroke-like presentation
2. Presentation depends on specific characteristics of the organism
3. CNS mass lesions
 - a. Subacute or chronic presentation
4. Meningitis and encephalitis
 - a. Acute presentation
5. Disorders affecting B-lymphocyte function:
 - a. Meningitis caused by encapsulated bacterial pathogens
 - b. Bacterial meningitis similar presentation in normal and compromised hosts
6. Impaired T-lymphocyte or macrophage function:
 - a. Infection caused by intracellular pathogens
 - i. Aspergillus and fungi
 - ii. Nocardia (bacteria)
 - iii. Viruses:
 1. HSV
 2. JC
 3. CMV
 4. HH-6
 - iv. Parasites
 1. Toxoplasmosis gondii
7. Extra-CNS sites of infection
 - a. Lung and brain infection:
 - i. Aspergillus
 - ii. Nocardia
 - iii. Subacute or chronic presentation
8. T-lymphocyte dysfunction with meningitis:
 - a. Listeria
 - b. Cryptococcus
9. Failure of anti-toxoplasmosis therapy for a mass lesion:
 - a. Probable central nervous system lymphoma
10. Aspergillus presentation:
 - a. Mass lesion
 - b. Stroke
 - c. Rare as meningitis

Fungus Infections

Mucormycosis

General Characteristics

1. Ubiquitous, angioinvasive filamentous fungi; found in soil, manure, decaying matter
2. Airborne and most commonly infects immunocompromised patients through the lungs and sinuses
3. Mortality in disseminated disease is 95%

4. Usual pathogens in the Mucorales order are: Rhizopus, Absidia, and Rhizomucor
5. Usual risk factors are:
 - a. Diabetes
 - b. Immunosuppression (steroid use, renal failure)
 - c. Hematological disorders
 - d. Leukemia
 - e. Bone marrow and transplantation (rare)

Clinical Manifestations

1. Most common presentation is rhinocerebral
 - a. Fungus enters the brain from nasal passages, sinus and orbit
 - b. Extends from the cavernous sinus into the carotid artery which causes complete ophthalmoplegia
 - i. Infarcts vascular supply from the meningo-hypophyseal trunk
 - c. Brain abscess and meningitis are presentations
 - d. Hematogenous spread to the brain following pulmonary infection

Neuropathology

1. Arteritis
 - a. Branch hyphae in affected blood vessels
 - b. Often hemorrhagic lesions

Neuroimaging

1. Hemorrhagic infarction; bland infarction
2. Intracranial vessel thrombosis
3. Intracranial hemorrhage
4. Septic emboli
5. Frontal lobe lesions with diffusion deficits

Aspergillus

General Characteristics

1. The most likely fungus to present as stroke
 - a. Most common pathogen is *Aspergillus fumigatus* (also reported with *A. flavus*, *A. niger*, *A. terreus*)
 - b. Malignancy and bone marrow transplant are the most common settings
 - c. Foci of fungus may be in hospital ventilation systems
2. Pulmonary infection leads to hematogenous spread; rare airborne spores infect open wounds; inhalation of spores from the environment

Clinical Manifestations

Cerebrovascular Disease

1. Hemorrhagic stroke due to:
 - a. Direct invasion of the artery
 - b. Rupture of mycotic aneurysm
2. Invasion from the orbit or ethmoid sinus to the cavernous sinus
3. Rupture of arteries from inflammation
4. Subacute mycotic endocarditis
5. Skull-based infection from sinuses:
 - a. Stroke
 - b. Brain abscess

Associated Clinical Features

1. Cranial nerve involvement
2. Skull-based osteomyelitis
3. Rare spinal involvement

Neuropathology

1. Necrotizing arteritis

Neuroimaging

1. Multifocal hemorrhagic lesions

Differential Diagnosis

Differential Diagnostic Clues for Aspergillosis

1. Gradual extension of an infarction over a few days
2. Involvement of different vascular territories
3. A setting of organ transplantation, depressed immune system, sinus involvement and malignancy
4. CSF pleocytosis: minimal, if any

Cryptococcus

General Characteristics

1. Common in all immunocompromised patients (especially those with HIV and organ transplantation)
2. Spores inhaled from the ground
3. "Flu-like" illness

Clinical Manifestations

1. Chronic dementia with headache
2. Pial vessel stroke
3. Basal ganglia involvement
4. Affects cranial nerve II

Neuropathology

1. Spreads to the basal ganglia through Virchow-Robin space from cortical meningitis
2. Possible Heubner's proliferative endarteritis of vessels in the anterior and posterior perforated substance

Neuroimaging

1. Basal ganglia thin-walled cysts
2. Pial territorial strokes
3. Basilar meningitis

Laboratory Evaluation

CSF

1. Sugar 30–40 mg%
2. Mild lymphocytic pleocytosis
3. Moderate protein elevation of 50–80 mg%
4. PCR positive

Coccidioidomycosis (Coccidioides immitis)

General Characteristics

1. Endemic in deserts of SW USA
2. Spores inhaled from the soil
 - i. Pulmonary route of infection presents as "flu-like" illness

Clinical Manifestations

1. Propensity to invade bone (jaw, knee and sacrum); erythema nodosa
2. Chronic basilar meningitis
3. Proximal MCA and arteries of the posterior perforated substance involved

Neuropathology

1. Thin-walled spherules filled with endospores

Neuroimaging

1. Musculoskeletal findings are non-specific
 - a. Multiple lytic punched out lesions (lumbosacral)
 - b. Hypertrophied synovium of joints
 - c. Meningitis with enlargement of the basal cistern

Laboratory Evaluation

1. Serologic testing reveals IgM antibodies in the acute stage and IgG in the chronic stage

Candida**General Characteristics**

1. One of the most frequent infections in immunosuppressed patients
2. Causes 8 to 10% of nosocomial blood stream infections
3. Superficial and minimal clinical manifestations include:
 - a. Esophageal infection
 - b. Oropharyngeal candidiasis
4. Serious infections include:
 - a. Blood stream infections
 - b. Disseminated candidiasis
 - c. Endocarditis
 - d. CNS infections and endophthalmitis
 - e. Osteomyelitis

Risk Factors

1. Host related (immunosuppression)
2. Health care associated factors that include
 - a. Catheter use
 - b. Total parenteral nutrition
 - c. Surgical interventions
 - d. Antimicrobial drugs

Clinical Manifestations

1. Neurologic manifestations
 - a. Usually candida causes meningitis
 - b. Rarely it causes a cerebritis and stroke-like syndrome
2. Chronic mucocutaneous candidiasis
 - a. 2 reported patients with stroke

Neuropathology

1. Hemorrhagic infarction
2. Not angioinvasive

Imaging Evaluation

1. Numerous microabscesses of less than 3 mm in the cortico-medullary junction, basal ganglia or cerebellum

Histoplasmosis (*Histoplasma capsulatum*)**General Characteristics**

1. Endemic in the Mississippi Valley of USA
2. Pulmonary route of infection
3. Histoplasmosis of the CNS occurs in 10 to 20% of patients with disseminated histoplasmosis or an association with immunocompromised patients

Clinical Manifestations

1. Clinical neurological manifestations:
 - a. Meningitis
 - b. Arachnoiditis
 - c. Hydrocephalus
 - d. Relapses following therapy are common
 - e. Proximal great vessel involvement (infected emboli)
 - f. Pontine infarction

Neuropathology

1. Parenchymal abscess
2. Meningitis

Neuroimaging

1. Hydrocephalus and basilar meningitis
2. Isolated ring enhancing lesions

Laboratory Evaluation

1. Antigen and serologic tests: low sensitivity of CSF culture

Fungal Aneurysms**General Characteristics**

1. Fusiform in shape
2. Involve longer and more proximal segments of intracranial vessels
3. Intradural portion of the carotid artery is most common site of a fungal aneurysm

Clinical Manifestations

1. Vessel invasion occurs from extension of the hyphae into the lumen which cause:
 - a. In situ thrombosis
 - b. Embolization of hyphal masses
 - c. Major portions of vessels are involved
 - i. Large infarctions

Neuroimaging**CT and MRI**

1. Signs of Fungal Infection of a Sinus
 - a. Sclerotic thickening
 - b. Erosion
 - c. Remodeling
 - i. All of the above are rare in bacterial infections
 - d. Central area of high density within the sinus cavity
 - e. Low signal on MRI in all sequences
 - i. Paramagnetic substances within fungal mycetomas
 - f. Aggressive extension of fungus from the sinus to:

- i. Orbit
- ii. Facial tissues
- iii. Intracranial cavity
- g. Vascular invasion

Viral Infections and Stroke

Overview

1. Vasculitis from a viral infection effected by:
 - a. Direct invasions of central nervous system vessels
 - b. Triggering an immune response to epitopes of the vessel wall
 - c. Immune complex deposition

Varicella

General Characteristics

1. Annual incidence of 1010/100,000 people aged 80–90 years of age
2. Immunocompetent host CNS involvement occurs in 1.5 to 4% of patients
 - a. Higher incidence in immunocompromised patients
3. Thoracic dermatomes are most commonly involved: severely painful with dynamic mechanoallodynia

Clinical Manifestations

Neurological Complications

1. Cranial neuropathy
2. Post herpetic neuralgia
3. Encephalomyelitis
4. Optic neuritis
5. Leukoencephalopathy
6. Ventriculitis
7. Traverse myelitis

Cerebrovascular Manifestations

1. Delayed brain infarction following infection
2. Contralateral hemiplegia from ipsilateral MCA involvement
3. Days to 6–8 weeks following onset of the rash
4. Concomitant encephalitis
5. Rash may occur in V2 or V3 as well as V1
6. Rare involvement of posterior cerebral artery (PCA) or the vertebrobasilar territory

Neuropathology

1. Productive virus in infected cerebral arteries (both large and small)
2. Occasional signs of arteritis
3. Concomitant VZV infiltration into the parenchyma (frontal and temporal lobe)
4. Rare SAH
5. Basilar meningitis (rare)

Neuroimaging

1. Stenosis of proximal MCA and basilar artery
 - a. Induce large infarction

2. Occlusion of the supraclinoid ICA:
 - a. May be preceded by TIA
 - b. Usual clinical onset is that of an abrupt stroke
3. Stenosis of intracranial large conducting vessels
4. Small artery involvement is less common
5. Multiple superficial and deep infarcts

HIV

General Characteristics

1. Clear increased risk of stroke in HIV infected individuals
2. Putative mechanisms:
 - a. Associated vasculitic changes from concomitant viral infection that includes:
 - i. Epstein-Barr Virus
 - ii. Hepatitis B
 - iii. HS
 - iv. CMV
 - b. Prothrombotic state:
 - i. Associated decrease of protein S (probable epiphenomenon)
 - c. Cardiac emboli
 - i. HIV associated cardiomyopathy
 - ii. Infective endocarditis
 - iii. NBTE (Non-bacterial thrombotic emboli)
 - d. Opportunistic organisms
 - i. Usual CD4+ count is less than 200 mm³
 - ii. Causes infective vasculitis with ischemic/hemorrhagic infarction
 1. Angioinvasive
 - a. Aspergillosis
 - b. VZV
 2. Constriction of proximal vessels by basilar meningitis
 - iii. Associated malignancies
 1. Primary CNS lymphoma
 2. Metastasis from Kaposi sarcoma
 - e. Hypercoagulable state
 - i. Decreased protein S (minimal evidence)
 - ii. Increased antiphospholipid antibodies
 - iii. Possible DIC
 - iv. Dehydration, cachexia and cerebral vein thrombosis
 - v. Associated substance abuse (cocaine, heroin, methamphetamine)
 - vi. Accelerated atherosclerosis with combination antiretroviral therapy are associated with:
 1. Increased glucose
 2. Insulin resistance
 3. Increased cholesterol and triglycerides
 4. Increased peptide C
 5. Abnormal deposition of body fat
 6. Derangement of lipid metabolic and inflammatory cytokine networks

Neuropathology

HIV Associated Vasculopathy/Vasculitis

1. Possible HIV association with systemic vasculitis:

- a. Polyarteritis
- b. Chung-Strauss
- c. Hypersensitivity vasculitis
- d. Primary angiitis of the CNS
2. HIV-specific vasculitis
 - a. Direct involvement of the vascular endothelium
 - b. Endothelial cell release of chemotactic factors promoting an autoimmune response
3. Small Vessel HIV associated vasculopathy
 - a. Hyaline small vessel wall thickening
 - b. Perivascular space dilatation
 - c. Perivascular cell infiltrate
 - d. Microinfarction
 - e. Concomitant VZV infiltration into the parenchyma (frontal and temporal lobe)
 - f. Rare SAH; basilar meningitis
4. HIV associated large and medium vessel vasculopathy in children
 - a. Vasculopathy with aneurysm
 - b. Fusiform dilatation of the arteries of the Circle of Willis; less common – saccular aneurysm
 - i. Destruction of the internal elastic membrane
 - ii. Medial fibrosis loss of the muscularis
 - iii. Intimal hyperplasia
 - iv. HIV genomic material found in 2 of 4 autopsied patients
5. Large and medium vessel HIV associated vasculopathy in adults
 - a. Adult age range 18–38 years
 - i. Aneurysms (often multiple)
 - ii. Occlusive disease
 - b. Clinical presentation
 - i. TIA
 - ii. Aneurysmal rupture
 - iii. Hypertension
 - iv. Ischemia of the lower extremities
 - v. Most affected arteries are: the carotid, abdominal aorta, iliac, femoral and popliteal

Herpes Zoster

General Characteristics

General Vascular Manifestations

1. Delayed brain infarction following infection
 - a. Contralateral hemiplegia from ipsilateral MCA involvement
 - b. Days to 6–8 weeks following onset of the rash
 - c. Occlusion or stenosis of the carotid siphon, ACA or MCA
 - i. May be preceded by a TIA
 - ii. Usual clinical onset is that of an abrupt stroke
 - d. Concomitant encephalitis
 - e. Recurrent and multiple infarcts
 - f. Rash may occur in V2, V3 or vertebrobasilar territory
 - g. Rare involvement of PCA or vertebrobasilar territory
 - h. Infarct and stenosis may occur in young adults

Clinical Manifestations

Herpes Zoster Cerebral Vascular Disease in HIV-Infected Patients

1. HZ ophthalmicus:
 - a. Delayed contralateral stroke (1 week to 6 months)
 - i. Granulomatous arteritis
 - ii. Patient's may have no preceding rash prior to stroke
 - iii. Similar pathology to non-infected patients
 1. Segmental arteritis of the carotid siphon
 - iv. Concomitant acute retinal necrosis
2. Immune competent HZ patients
 - a. Large vessel disease (usually MCA)
3. HIV patients
 - a. Small vessel diseases
 - b. Leukoencephalitis
 - c. Ventriculitis
4. Children with concomitant HIV and HZ
 - a. Dilatation arteriopathy with fusiform aneurysms of intracranial arteries
 - b. Subarachnoid hemorrhage
5. Children with non-HIV, VZV stroke
 - a. Typical delayed proximal intracranial arteritis

Neuropathology

1. Leukocytoclastic vasculitis of the vaso vasorum causing ischemia of the media
2. Fragmentation of the internal elastic lamina
3. Occlusive disease of large arteries (internal and external carotid)
4. Some patients have aneurysmal dilatation of the terminal carotid
5. Ectasia and focal stenoses of the medium and small-sized cerebral arteries

Neuroimaging

MRI

1. Atrophy out of proportion to age
2. Severe periventricular WMH
3. Opportunistic infections
4. Aneurysms of the carotid and abdominal aorta

Arteriographic Evaluation

1. Stenosis of proximal MCA and basilar artery
 - a. Induces large infarction
2. Occlusion of the supraclinoid ICA
3. Stenosis of intracranial large conducting vessels
4. Small artery involvement

Parasitic Infections

Cysticercosis (Taenia solium)

General Characteristics

1. Infection with the larval stage of *Taenia solium* (the pork tapeworm)
2. Humans are definitive hosts and may carry the adult parasites in the small intestine
3. In one large study from Mexico, 2.5% of ischemic strokes were secondary to neurocysticercosis

Clinical Manifestations*Cerebrovascular Presentations*

1. May cause ischemic or hemorrhagic stroke
2. Transient ischemic attacks caused by:
 - a. Intermittent stenosis of major intracranial arteries secondary to meningeal inflammation; may proceed to infarction
 - b. Lacunar stroke:
 - i. Inflammatory occlusion of small penetrating MCA branches
 - ii. Posterior limb of the internal capsule
 - iii. Large artery occlusion of the ICA, ACA or MCA
 - iv. Inflammatory occlusion of small branches of the basilar artery
 1. Due to subarachnoid cysticerci
 - v. Hemorrhagic stroke
 1. Rupture of a mycotic aneurysm
 - vi. Intracranial hemorrhage due to small artery rupture in a parenchymal cyst

Neuropathology

1. Parenchymal brain cysticerci (less than 10 mm) lodge in the cerebral cortex and basal ganglia
2. Subarachnoid cysticerci lodge within the cortical sulci in cisterns at the base of the brain
3. Ventricular cysticerci (attached to the choroid plexus or are free floating)
4. Rarer locations:
 - a. Subdural space
 - b. Sellar region
 - c. Spinal cord
5. Meningeal cysticerci cause a severe inflammatory reaction in the subarachnoid space resulting in leptomeningeal thickening
 - a. Small and medium-sized arteries from the Circle of Willis are affected by this inflammatory reaction
 - b. Penetrating arteries are involved by inflammatory cells that lead to endarteritis (fibrosis of the media, endothelial hyperplasia)
 - c. Large vessels may be occluded by atheroma-like material from the endothelium
 - d. Mycotic aneurysms develop from cysticerci adherence to subarachnoid blood vessels
 - e. MCA > PCA > ACA infarctions

Neuroimaging*MRI*

1. Enhancement of leptomeninges
2. Hydrocephalus
3. Cystic lesions at the Sylvian fissure or basal cisterns
4. Magnetic resonance angiography or arteriography
 - a. Segmental narrowing or occlusion of the intracranial arteries

*Cerebral Malaria (Plasmodium falciparum)***General Characteristics**

1. Plasmodium falciparum is the most prominent organism
2. Anopheles mosquitos is the vector

Clinical Manifestations*Signs and Symptoms*

1. Signs and symptoms begin approximately 8 to 25 days following infection and include:
 - a. Vomiting
 - b. Fever and shivering
 - c. Retinal damage (retinal whitening)
 - d. Convulsions
 - e. Coma
2. Sudden coldness followed by shivering, fever and sweating
 - a. Occurs every two days in P. vivax and P. ovale and every 3 days in P. falciparum
3. Severe malaria most often caused by P. falciparum

Associated Medical Conditions

1. Respiratory distress in 25% of adult patients
 - a. Concomitant pneumonia
 - b. Severe anemia
 - c. Non-cardiogenic pulmonary edema
2. Splenomegaly
3. Renal failure
4. Hepatomegaly/liver dysfunction
5. Severe anemia
6. Circulatory collapse
7. Acidosis
8. Hypoglycemia

Neurologic Manifestations

1. Neurologic manifestations of P. falciparum
 - a. Retinal whitening
 - b. Encephalopathy
 - c. Rare: hemiparesis, cranial nerve and brainstem signs and symptoms
 - d. Seizures
 - e. Cerebellar ataxia
 - f. Cognitive impairment
 - g. Coma

Neuropathology

1. Mechanical
 - a. Obstruction of the cerebral microvasculature and impaired brain perfusion
 - i. Neuropathological analysis that demonstrates brain capillaries packed with parasitized RBCs. Interaction between RBCs and vascular endothelium
 - ii. Pivotal are parasitic proteins expressed from infected RBCs (P. falciparum erythrocyte membrane protein-1 (PEMP-1))
 - iii. Host receptors that include intracellular adhesion molecule-1 (ICAM-1) and vascular cellular adhe-

- sion molecule – (VCAM-1); Thrombospondin-1, CD36 and E-elastin
- iv. Cytoadherence and decreased pliability are major mechanisms of vasculature obstruction
- v. Patients surviving cerebral malaria do not have signs of cerebral ischemia
- b. Vascular permeability putative mechanisms:
 - i. BBB damage is the underlying mechanism of cerebral malaria
 - 1. Allows toxic molecules to invade the parenchyma
 - 2. Possible histamine involvement
 - ii. Humoral hypothesis
 - 1. Proinflammatory mediators, cytokines and chemokines enter the brain through the damaged BBB
 - 2. Possible role of nitric oxide
 - iii. Evidence exists for the role of matrix metalloproteins (MMPs) in pathogenesis of cerebral malaria

Neuroimaging

Children

1. Children with retinal involvement
 - a. Cerebral edema
 - b. Basal ganglia involvement (Globus pallidus)
 - c. Thalamic and brainstem (T2 sequence abnormalities)
 - d. Corpus callosum (T2-weighted sequence lesions and seen on DWI sequences)

Adults

1. Periventricular white matter involvement
2. Corpus callosum lesions
3. Cortical hemorrhages
4. Thalamic involvement

Chaga's Disease (American trypanosomiasis)

General Characteristics

1. Caused by *Trypanosoma cruzi*
2. Transferred to humans by bites from a bug (family Reduviidae); bites are often around the face
3. Other means of transmission:
 - a. Blood transfusion
 - b. Organ transplantation
 - c. Pregnancy
 - d. Oral outbreaks (contamination from fecal material of the insect)

Clinical Manifestations

1. Acute phase is associated with fever, myalgia, hyperhidrosis, hepatosplenomegaly and swollen lymph glands (severe parasitemia)
2. Chronic stage
 - a. Cardiomyopathy (dilated)
 - b. Mega esophagus and megacolon

3. Approximately 30% of *T. cruzi*-infected individuals develop the chronic stage of the disease
4. Neurologic presentation includes:
 - a. Encephalitis
 - b. Meningoencephalitis
 - c. Tumor-like chagoma
5. Cardiomyopathy
 - a. Progressive to dilated cardiomyopathy
 - b. Arrhythmias
 - c. Intraventricular conduction defects
 - d. Sudden death

Cerebrovascular Disease

1. Stroke occurs in 5 to 15% of patients
2. MCA most affected territory
3. Cardiac embolism is the primary mechanism
 - a. Apical aneurysm is the hallmark of the cardiomyopathy

Neuroimaging

MRI

1. White matter hyperintensities (increased in those with parasympathetic disease)
2. Top of the basilar topology has been described
3. Embolic stroke pattern

Bacterial Infections

Periodontal Disorders

General Characteristics

1. Gingivitis
 - a. Mildest form of periodontal disease
 - i. A bacterial biofilm (dental plaque) that forms on teeth adjacent to the gingiva
 - b. Periodontitis
 - i. Loss of connective tissue and bone structure of the gum
 - ii. An independent risk factor for cardiovascular disease or stroke
2. Putative stroke mechanisms:
 - a. Systemic increase of bacteria, endotoxin and bacterial products
 - b. Periodontal bacteria
 - i. Found in atheromatous plaque of stroke patients
 - ii. Increased C-reactive protein; fibrinogen, C-reactive protein that promote atherogenesis
 - iii. *Actinobacillus actinomycetemcomitans* frequently found in edentulous stroke patients
 - iv. Associated periodontal disease causes increased IL-6 and s-ICAM in the serum of stroke TIA patients

Neuropathology

1. Maintenance of a proinflammatory state
2. Promotion of atherogenesis
3. Includes an increase of IL-6 and/or ICAM in the serum of stroke patients

Neuroimaging

1. Accelerated atherosclerosis of large vessels
2. Thrombotic stroke
3. Increased white matter hyperintensities

Stroke in Association with Named Vascular Syndromes

Overview

It is surprising how many named stroke syndrome have seminal skin manifestations. Köhlmeier-Degos syndrome is associated with characteristic whitish or erythematous papules with a porcelain white center. Associated severe gastrointestinal symptoms are diagnostic. Mencke's syndrome has diagnostic coarse, stiff hair associated with severe hypotonia, seizures, and branch artery occlusion. There is often survival to early adulthood. Vogt-Koyanagi disease is distinguished by a white forelock, eye lashes and eyebrows. The skin manifestations are noted with a uveal meningeal presentation, ocular and brainstem signs; if symptoms of the VIIIth nerve occur then the syndrome becomes Vogt-Koyanagi-Harada disease.

Sneddon's syndrome is characterized by severe livedo reticularis in the extremities and is associated with stroke in young adults. Divry-Van Bogaert disease is seen in older patients, has livedo reticularis and is associated with seizures and dementia.

The skin is clearly hyperelastic in pseudoxanthoma elastica (Grönblad-Strandberg disease) and has a characteristic cigarette paper thinness in the posterior neck area. Hyperelastic skin may also be noted in Ehlers-Danlos Type I and IV as well as Marfan's syndrome. Characteristic dissections of extracranial arteries (often bilateral), aortic disease and aneurysms distinguish these entities. Fabry's disease has characteristic angiomas in the bathing suit distribution and other seminal features of heat sensitivity, renal failure, premature coronary artery disease and painful neuropathy.

Hemorrhage rather than a stroke syndrome is characteristic of Von Hippel-Lindau disease, Sturge-Weber, Cobb's disease and Klippel-Trénaunay-Weber syndrome. The strawberry hemangioma covers the upper eyelid (V1) distribution in Sturge-Weber syndrome. Its most characteristic features are intractable seizures, mental retardation and tram-track calcification of the parieto-occipital cortex. Von Hippel-Lindau has characteristic retinal artery venous malformations with lesions also noted in the cerebellum and spinal cord. Associated renal carcinoma is expected. Wyburn-Mason is characterized by strawberry hemangioma on the face or trunk with a mid-brain hemangioma. Cobb's syndrome presents with a massive truncal hemangioma and spinal AVM. Osle-Weber-Rendu often presents with telangiectasia of the lower lip, conjunctiva and nasal mucous membrane. Stroke may be embolic from pulmonary shunts.

Thrombophlebitis with dilated veins in the upper extremity or chest wall (Mondor's syndrome) suggests non-bacterial

thrombotic endocarditis from an underlying malignancy. Well known in this regard is pancreatic cancer.

Petechiae and purpura are frequently associated with syndromic stroke. Thrombotic thrombocytopenic purpura (Moschcowitz's syndrome) presents with generalized purpura, seizures, hallucinations, focal neurologic signs and renal failure. Waldenström's macroglobulinemia may be associated with rheological causes of stroke and difficulty with perfusion of capillaries due to high concentrations of IgM. The petechiae are characteristically noted below the knee. Cryoglobulinemia may present similarly, but often with acrocyanosis. The Bing-Neel syndrome is inclusive of all disease processes that interfere with cerebral perfusion. The syndrome is primarily associated with lymphoplasmacytoid cell infiltration. Bleeding from the gums, petechiae and depressed consciousness are diagnostic. Small cortical strokes may occur. Kawasaki's disease frequently presents with an explosive course and mucous membrane involvement. Unusual coronary artery occlusion and stroke occur. Behçet's syndrome may present with painful erythematous, well demarcated skin lesions and stroke. Most frequently mouth and genital ulcers are seen concomitantly.

Eye findings and named stroke syndromes are common. Susac disease is a combination of retinitis and VIIIth nerve involvement with stroke. It is a microangiopathy of the main vestibulocochlear complex and retina. There is striking obliteration and amputation of retinal vessels. Acute posterior multifocal placoid pigment epitheliopathy affects young adults and is a putative autoimmune process. The patients may suffer arteritic strokes. The major pathology is in the retinal pigment epithelium although the optic nerve may be involved concomitantly.

Cogan's syndrome and its variants affect young adults and cause an acute interstitial keratitis as well as vestibular and auditory dysfunction. Central retinal artery or vein occlusion occurs in association with pial artery stroke. Atypical variants have vasculitis and systemic manifestations.

Eales disease occurs in young men and is prevalent in the Middle East and India. Retinal periphlebitis and vitreous hemorrhage are common with occasional large vessel stroke. The ophthalmologic symptoms predominate.

Eye findings in association with stroke occur in osteogenesis imperfecta (robin's egg blue sclera); PXE (angioid streaks-disruption of Bruch's membrane); homocystinuria and Marfan's syndrome (lens dislocation), cat-scratch fever (infectious retinitis) and syphilis (retinitis pigmentosa, Argyll-Robertson pupil, optic atrophy).

The defects in Ehlers-Danlos disease cause arterial dissection, intracerebral and extracranial aneurysm and cavernous sinus fistula. Gastric hemorrhage, skin manifestations, mitral valve prolapse due to elongated chordae tendineae and aortic root ectasia occur. Marfan's, osteogenesis imperfecta, Ehlers-Danlos type I and IV are the primary named entities associated with arterial dissection.

Strokes and bowel defects are related most often due to protein losing enteropathy known as Ménétriér's syndrome. Ulcerative colitis and regional enteritis are associated with large vessel stroke due to loss of protein C and S. Behçet's disease may affect the gastrointestinal tract with mucosal ulcers. Köhlmeier–Degos disease frequently is initiated by abdominal pain and diarrhea and blue rubber bleb nevus syndrome is also associated with gastric hemorrhage. Henoch–Schönlein purpura may be attended by early and severe joint and abdominal pain.

Loeffler's syndrome and Churg–Strauss disease are associated with pulmonary interstitial disease, eosinophilia and stroke. Pituitary infarction is peculiarly common with Churg–Strauss disease. Vasculitic sarcoid affects the lung and cerebral vessels as does the hyper eosinophilic syndrome (20,000 eosinophil/mm³).

Arterial involvement as the primary disease process occurs in both Moyamoya syndrome and Buerger's disease. In Moyamoya disease there is progressive relentless occlusion of the proximal carotid arteries. The resulting collateral circulation and exuberance of lenticulostriate arteries produce the characteristic "puff of smoke" on arteriograms. In the United States it is seen with sickle cell disease, tuberculosis that affects the origin of the great vessels as well as X-ray therapy. Frequently it is idiopathic. Surprisingly, it may present in elderly patients and as a primary subarachnoid hemorrhage rather than occlusive ischemic stroke. Buerger's disease often presents with severe occlusive disease below the knee rather than the distal 1/3 of aorta or iliac arteries that is characteristic of atherosclerosis. A dementia secondary to a generalized granular cortical atrophy is more common than conducting vessel stroke.

Erdheim-Gesell syndrome is medial cystic necrosis. Dissection of the great vessel is common. Arterial thickening of the radial artery at the wrist and aortic insufficiency bolster the diagnosis. As noted above, osteogenesis imperfecta, Marfan's syndrome and homocystinuria (accelerated atherosclerosis) all present as primary disease of blood vessels. May-Thurner disease is iliofemoral deep vein thrombosis that is associated with embolus to the top of the basilar artery.

Takayasu's disease dramatically affects the blood vessels emanating from the aortic arch and the aorta itself. Subclavian steal is prominent arteriographically, but is rarely clinically significant. Cataracts and facial atrophy are prominent due to loss of nutritive blood supply to the face. The strokes are primarily in the anterior circulation. Claudication of vision occurs with head position and walking due to the tenuous blood supply to the retina. It occurs with rheumatic diseases as reported from Scandinavia.

HERNS disease is a hereditary stroke syndrome associated with endotheliopathy, renal disease neuropathy and stroke. Polyarteritis, polyangiitis and Fabry's disease are other vascular arteritides which are associated with renal disease.

Cerebral autosomal dominant arteriopathy with subcortical infarction and leukoencephalopathy (CADASIL) is a

named disease associated with dementia. Severe migraines are common. Binswanger small vessel microangiopathy also is associated with dementia. Mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes (MELAS) are also associated with dementia and migraine. Posterior leukoencephalopathy is characteristic in parietal occipital areas. In a similar syndrome reported in French Canadians, Saguenay-Lac St. John syndrome, the leukoencephalopathy is frontal rather than parieto-occipital. Divry–Van Bogaert's disease is also associated with dementia.

Named Syndromes in Association with Stroke

1. Eales disease
2. Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL)
3. Buerger's disease (thromboangiitis obliterans)
4. Ehlers-Danlos syndrome (type IV)
5. Homocystinuria
6. Moyamoya disease
7. Antiphospholipid antibody syndrome (APL)
8. Sneddon's syndrome
9. Susac syndrome (microangiopathy of the retina, inner ear, and brain)
10. Takayasu's disease
11. Divry–Van Bogaert syndrome
12. Grönblad–Strandberg disease (pseudoxanthoma elasticum) PXE
13. Köhlmeier-Degos disease (malignant atrophic papulosis)
14. Behçet's disease
15. Moschcowitz syndrome (thrombotic thrombocytopenic purpura) TTP
16. Disseminated intravascular coagulation (DIC)
17. Sturge–Weber disease
18. Osler-Weber Rendu
19. Bing-Neel syndrome
20. Kawasaki syndrome
21. Loeffler's syndrome
22. Ménétriér's syndrome
23. Acute posterior multifocal placoid pigment epitheliopathy (APMPPE)
24. Vogt-Koyanagi-Harada syndrome
25. Hereditary endotheliopathy renal neuropathy syndrome (HERNS)
26. Fabry's disease
27. Leigh's syndrome
28. Sanguinary-Lac-St. John syndrome
29. Erdheim-Gesell syndrome (medial cystic necrosis)
30. May-Thurner syndrome
31. Cogan's syndrome
32. Churg-Strauss disease

Eales Disease

General Characteristics

1. Disease of young men
2. Occurs in the second to fourth decades of life
3. Prevalent in the Middle East and India
 - a. In India it has been associated with tuberculosis

4. No systemic symptoms
5. Eye symptomatology is dominant
6. Systemic illnesses that can present with retinopathy and stroke include:
 - a. SLE
 - b. Sarcoidosis
 - c. Ulcerative colitis/regional enteritis
7. A syndrome of retinal neovascularization
8. Human leukocyte antigen (HLA)
 - a. Higher phenotype frequency of human leukocyte antigen
 - b. HLAB5, DR1 and DR4 individuals may be susceptible to retinal vasculitis
9. Association with tuberculosis has been suggested
 - a. Patients may be hypersensitive to tuberculo protein
 - b. Epiretinal membrane samples have been reported as positive for mycobacterium species
 - c. Some patients have been described with meningitis
10. Other conditions with peripheral retinal revascularization without inflammation include:
 - a. Sick cell disease
 - b. Diabetic retinopathy
 - c. Retinopathy of prematurity
 - d. Familial exudative vitreoretinopathy
 - e. Hyperviscosity syndromes
 - f. Idiopathic retinal vasculitis
 - g. Neuroretinitis (IRVAN syndrome)

Clinical Manifestations

1. Ophthalmological features:
 - a. May be asymptomatic
 - b. Retinal periphlebitis
 - c. Retinal revascularization that may cause vitreous hemorrhage
 - d. Retinal capillary ischemia
 - e. Perivenous and periarterial sheathing
 - f. Vitreous hemorrhage
 - g. Macular arteries are less severely affected:
 - i. Relative sparing of central vision
 - h. Uveitis
 - i. Signs and symptoms predominant and present in three stages
 - i. Venous inflammation (vasculitis)
 - ii. Occlusion
 - iii. Retinal neovascularization
2. Cerebrovascular Manifestations
 - a. Focal ischemic infarcts
 - b. Large vessel thrombosis
3. Patients may suffer focal small vessel infarcts or occasional large vessel stroke
4. Retinal vasculitis may also be associated with CNS vasculitis
 - a. Retinal hemorrhages associated with epistaxis
 - b. Young men
 - c. Recurrent monocular vitreous hemorrhage; may involve the second eye

- d. May be associated with:
 - i. Subacute myelopathy
 - ii. Chronic lymphocytic meningitis
 - iii. Middle cerebral artery stroke
5. Meningitis
6. Tuberculosis
 - a. Hypersensitivity to tuberculo protein
 - b. Some epiretinal membranes samples are positive for mycobacterium species
7. Human leukocyte antigen (HLA)

Neuropathology

1. Retinal ischemia
 - a. Retinal and/or optic nerve revascularization that causes
 - i. Vitreous hemorrhage
 - ii. Retinal detachment
 - b. Cerebral vasculitis
 - c. Large vessel stroke

Neuroimaging

1. Cerebral vasculitis
2. Large vessel infarction
3. Intracranial hemorrhage

Laboratory Evaluation

1. Arterial fundoscopic evaluation (fluorescein)

Differential Diagnosis of Eales Retinopathy

1. Sick cell disease
2. Diabetic retinopathy
3. Retinopathy of prematurity
4. Familial exudative vitreoretinopathy
5. Hyperviscosity syndromes
6. Idiopathic retinal vasculitis
7. Neuroretinitis (IRVAN syndrome)
8. Systemic illnesses that can present with retinopathy and stroke include:
 - a. SLE
 - b. Sarcoidosis
 - c. Ulcerative colitis
9. There is discussion that the neurologic features associated with the retinopathy may be due to the underlying condition and may not be specific to Eales disease

CADASIL

Overview

CADASIL (cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy) is an inherited cerebral small vessel disease whose clinical features include recurrent transient ischemic attacks and strokes, severe migraines, cognitive decline and cerebral microbleeds.

General Characteristics

Genetics

1. Autosomal Dominant inheritance:
 - a. Mutation of the NOTCH 3 gene; chromosome 19

- b. Involved in cell fate determination and development
- c. If associated with APOE- ϵ 2 allele:
 - i. Increased hemorrhage
 - ii. Vasculopathy
- 2. Expressed only in arterial smooth muscle cells
- 3. Mutations are in exon 3 and 4 (70%) which encodes a transmembrane receptor with epidermal growth factor repeats
- 4. Regulates differentiation and maturation of vascular smooth muscle cells

Clinical Manifestations

1. Onset 30 to 50 years of age
2. Migraine with aura starting between 20 to 40 years of age may be the initial presentation
3. Cerebral ischemic events supervene between 4th and 5th decade associated with behavioral changes and cognitive dysfunction
4. Dementia is apparent between age 50 to 60
5. Approximately 50% of patients suffer atypical migraine auras that include basilar hemiplegia or long duration. A few suffer coma
6. 60 to 85% of patients suffer TIAs or strokes. 2/3 of ischemic events are classic lacunar strokes. TIAs and strokes may occur in the absence of classical risk factors
7. May have a gradual or step-wise progression
8. Gait disturbances
9. Seizures and small cortical infarcts are rare
10. 5 to 10% of patients have seizures that may be focal or generalized
11. Apathy is common while aphasia, apraxia or agnosia is rare
12. Dementia is associated with corticospinal tract signs, gait disturbance and urinary incontinence. Pseudobulbar palsy is demonstrated in approximately 50% of patients

Neuropathology

1. In small and medium-sized blood vessels
 - a. Basophilic granular material replaces the smooth muscle cells of the media
 - b. Dense granular osmophilic deposits are seen in the media close to the cell membranes of smooth muscle cells
 - c. The dense granular osmophilic deposits are seen in the media of arteries in internal organs (spleen, liver, and kidney) as well as skin and muscle
2. Leukoaraiosis and multiple small infarcts in deep white matter, basal ganglia, thalamus, pons and cerebellum
3. Granular osmophilic material (GOM)
 - a. Accumulates around the basement membrane of blood vessels
4. Blood vessel changes are noted in the myocardium, spinal cord, skin and muscle
 - a. Foveal telangiectasia changes in the retina
5. Diffuse hemispheric demyelination with sparing of U-fibers, periventricular and centrum semiovale predominance

6. Lacunar infarction is noted in the thalamus and basal ganglia
7. Deep infarcts and dilated Virchow-Robin spaces are frequent
8. Walls of cerebral and leptomeningeal arterioles are thickened
9. Smooth muscle cells are swollen and degenerated

Neuroimaging

MRI

1. MRI reveals widespread T2-weighted signal in white matter with focal hyperintensities in the basal ganglia, thalamus and brainstem
2. Younger patients have a periventricular predominance
3. External capsule and anterior temporal lobe lesions are distinctive
4. Corpus callosal lesions occur. Pontine lesions predominate in the brainstem
5. Lacunar lesions and enlarged Virchow-Robin spaces are prominent
6. Gradient-echo sequences detect microhemorrhages in 30 to 50% of patients
7. Superficial siderosis
8. Spinal cord hemorrhage (rare)
9. Diffuse leukoencephalopathy (posterior predominant)

Differential Diagnosis

1. Vasculitis
2. Hexosaminidase A deficiency
3. Adrenomyeloneuropathy (AMN)
4. Adrenoleukodystrophy (ALD)

CARASIL

General Characteristics

1. More prominent in Asian and Japanese populations
2. Mutations of the HTRA1 gene
 - a. A serine peptidase/protease
 - b. HTRA1 gene mutation on chromosome 10:
 - i. Encodes chaperone and serine proteases
 - ii. Mutant HTRA1 demonstrates decreased protease activity and failure to repress TGF- β signaling (therefore causing the arteriopathy)

Clinical Manifestations

1. Ischemic stroke (ictal events) or stepwise neurologic deterioration
2. Stepwise loss of cognitive function
3. Premature baldness
4. Severe back pain (disk disease/spondylosis)

Neuropathology

1. Intense arteriosclerosis of small penetrating arteries (without granular osmophilic material or amyloid as is seen in CADASIL)

2. Increased expression of the extra domain-A region of fibronectin and versican in the thickened tunica intima; TGF- β 1 in the tunica media
3. Vascular fibrosis and overgrowth of the extracellular matrix
4. Intimal thickening
5. Dense collagen fibers
6. Loss of vascular smooth muscle
7. Hyaline degeneration of the media
8. Putative mechanism
 - a. Non-repression of transforming growth factor β -family signaling
 - b. Increased TGF-beta found in cerebral small vessels along with fibronectin and versican

Neuroimaging

MRI

1. Diffuse white matter changes
2. Multiple lacunar infarcts in the basal ganglia and thalamus

Mitochondrial Encephalomyelopathy with Lactic Acidosis Stroke-Like Episodes (MELAS)

Overview

MELAS is a maternally inherited mitochondrial disorder that may have deficient cerebral blood flow due to nitric oxide deficiency. One of its complications is stroke-like episodes that are not in a vascular distribution. It is a multisystem disorder clinically dependent on heteroplasmy.

1. Multisystem disease affecting organs with high energy demands (heart, CNS, skeletal muscle)
2. Mitochondrial genome:
 - a. Circular DNA within the mitochondrion
 - b. Tissue dependent copy number (heteroplasmy: ratio of mutated vs wild type mitochondria in each cell)
 - c. Maternal transmission
 - d. Encodes:
 - i. Mitochondrial transfer RNA (tRNA)
 - ii. Ribosomal RNA
 - iii. 13/80 proteins in the respiratory chain
 - e. Mitochondria are exposed to free radicals generated by the respiratory chain and have poor repair mechanisms
 - f. Mitochondrial dysfunction causes ATP depletion due to failure of the respiratory chain
 - g. Mutations identified in both tRNA, rRNA and protein encoding genes
 - h. MELAS most often is caused by point mutation in mtDNA m3243 within the tRNA encoding gene tRNA^{Leu(UUR)}

Clinical Manifestations

1. Fever and infection possible triggers of stroke-like episodes
2. Episodic vomiting, migraine headaches and seizures
3. May occur in adolescence

4. Siblings of MELAS patients with the 3243 mutation may present with different phenotype:
 - a. Diabetes and deafness
 - b. Myopathy
5. Clinical associations of MELAS:
 - a. Short stature
 - b. High incidence of diabetes
 - c. Migraine-like headaches
 - d. Sensorineural hearing loss
 - e. Visual dysfunction
 - i. Ophthalmoplegia
 - ii. Pigmentary retinopathy
 - f. Hemiparesis
 - g. Ataxia
 - h. Fatigue with exercise
 - i. Hypertrophic cardiomyopathy
 - j. MERRF (Myoclonic Epilepsy with Ragged Red Fibers)
 - k. Ischemic colitis
 - l. Seizures
 - m. Cognitive impairment
 - n. Nephropathy
 - o. Hypothyroidism
 - p. Hypogonadism
6. Most common presentation of MELAS is migraine headache and seizures with recurrent stroke-like episodes
7. Stroke-like episodes:
 - a. In general do not follow a vascular distribution
 - b. Involve the posterior parietal and occipital lobes
 - c. Rare brain embolization from cardiac involvement (CHF; arrhythmia)
 - d. Episodes most consistent with mitochondrial dysfunction and alterations in calcium homeostasis

Neuropathology

1. Ischemic brain lesions:
 - a. Metabolic dysfunction of mitochondria
 - b. Decreased COX activity (mitochondrial complex III)
 - c. Arteries supplying (ischemic areas) are open
2. Petechial hemorrhages along cortical gyri
3. Magnetic resonance spectroscopy reveals decrease of N-acetyl aspartate and an increase in lactate
4. Mitochondrial cytopathy
5. Mutations in subunits of components of the respiratory chain causes:
 - a. Oxidative stress
 - b. Energy failure in the affected tissues
 - c. Ragged red fibers on muscle biopsy

Neuroimaging

MRI

1. Multifocal lesions
2. Parieto-occipital predominance
3. Cortex and underlying white matter is affected
4. High incidence of basal ganglia calcification
5. Elevated DWI in early studies in acute stroke
 - a. Some later studies demonstrate a decrease in ADC

Laboratory Evaluation

1. Elevated resting lactate and pyruvate levels (blood and CSF)
2. Mitochondrial myopathy
 - a. Most often a proximal myopathy with ragged red fibers (abnormal aggregates of subsarcolemmal mitochondria) on the Gömöri trichrome stain
3. COX deficiency on muscle biopsy
4. Genetic mutation analysis of peripheral blood leukocytes
5. Point mutation A3243G
 - a. Severe occipital infarcts

Differential Diagnosis*Differential Diagnosis from Other Mitochondrial Diseases*

1. MELAS and Alpers' disease
 - a. Primarily cerebrocortical lesions
2. Leigh's syndrome
 - a. Basal ganglia involvement
3. Congenital lactic acidosis with or without pyruvate dehydrogenase deficiency
 - a. Cerebrocortical atrophy
 - b. Agenesis or atrophy of the corpus callosum
4. Associated other mitochondrial syndromes from the A32437G mutation
 - a. Maternal inherited deafness with diabetes
 - b. Progressive external ophthalmoplegia

*Susac's Syndrome (Retinocochleocerebral Syndrome)***Overview**

An autoimmune disease that is characterized by encephalopathy, branch retinal artery occlusion and sensorineural hearing loss.

General Characteristics

1. Clinical triad of encephalopathy, deafness, retinal artery branch occlusion
 - a. Microangiopathy: affects the precapillary arteriole of the brain, retina and inner ear
2. Age varies between 8–58; predominantly females between the age of 20–40
3. Fluctuating course

Clinical Manifestations

1. Headache and behavioral change may be premonitory
2. Diffuse encephalopathy in which decreased auditory and visual perception is common
3. Psychiatric and behavioral alterations can progress to dementia
4. Focal neurologic involvement:
 - a. Cranial Nerves III, VI and VIII
 - b. Hemihypesthesia
 - c. Hemiparesis
 - d. Generalized seizures and myoclonus
5. Retinal involvement:
 - a. Branch retinal artery occlusion (BRAO)

- i. Fluorescein angiography demonstrates multifocal fluorescence
- b. Amputated retinal arteries (branch occlusion)
- c. Thickened arterial walls with “light streaking”
- d. Edema; cherry red macula
6. Auditory and visual loss may be simultaneous
7. Auditory loss:
 - a. Unilateral or bilateral hearing loss
 - b. Cochlear hearing loss
 - i. Loss of low and intermediate frequencies (microinfarction of the apical cochlea)
8. Vertigo and tinnitus may occur from infarction of the vestibular labyrinth
9. Multiple bursts of over 3 years; final stage is 1 to 8 years in a self-limited disease
10. Encephalopathy
 - a. In approximately 25% of patients the process may be preceded by slowly progressive altered mentation

Neuropathology

1. Small vessel disease (arteriolar)
2. Obliteration of small intracranial arteries
3. Ischemic and hemorrhagic infarction
4. Thrombotic mechanisms are more common than embolic
5. Microinfarcts in end arterioles distribution (white and gray matter) as well as the retina and cochlea
6. Hypertrophic astrocytes in white matter surrounding arterioles
7. Non-specific periarteriolar cell infiltrate
8. Disease of the vascular wall with thrombosis
9. Anti-endothelial cell injury

Neuroimaging*MRI*

1. Multiple small hyperintense T2-weighted lesions in supratentorial gray and white matter
2. Lesions may be round or linear
3. Lesions occur in the central corpus callosum
4. Infratentorial lesions of the middle cerebellar peduncle, cerebellum and brainstem
5. Leptomeningeal involvement is seen in 30% of patients
6. Fluctuation of lesions overtime

Fluorescein Retinal Angiography

1. Distal branch retinal occlusions
2. Pathognomonic multifocal fluorescence
3. Plaques (endothelial damage)
 - a. Mid arteriolar segment involvement

Laboratory Evaluation

1. CSF protein may be elevated
2. Factor VIII and vWF antigen are increased in some patients

Differential Diagnosis

1. Cogan's syndrome (interstitial keratitis prominent)

2. Brown-Vialetto-Van Laere syndrome
 - a. Pontobulbar palsy (lower cranial nerves)
 - b. Familial and sporadic forms have been identified
3. MS (hearing loss and arteriolar occlusive retinal disease don't occur)
 - a. Generalized corpus callosum demyelination
 - b. Callosal lesions are Dawson's fingers (rare)
4. Acute disseminated encephalomyelitis (ADEM)
 - a. Monophasic; lesions are the same age
 - b. Unusual for retinal and VIIIth nerve involvement
5. SLE
 - a. Psychosis, seizures and proximal myopathy are characteristic
6. Polyarteritis
 - a. Ocular and auditory involvement is rare
 - b. Systemic involvement (kidney is the most prominent)
 - c. Usual CNS presentation is encephalopathy
7. Wegener's granulomatosis
 - a. Sinus and respiratory tract involvement
 - b. Systemic necrotizing vasculitis
 - c. May have glomerulonephritis
8. Hypersensitivity vasculitis (Henoch-Schönlein purpura)
 - a. Neurologic, retinal, auditory involvement is rare
 - b. Skin and vein involvement is most prominent
9. CADASIL
 - a. Notch 3 gene
 - b. Foveal telangiectasia changes in the retina
 - c. Migraine, small vessel disease, dementia

Rare Diseases in the Differential Diagnosis

1. Usher's syndrome (autosomal recessive)
 - a. Retinitis pigmentosa
 - b. Labyrinthitis
2. Vogt-Koyanagi-Harada syndrome
 - a. Uveo-meningeal syndrome (recurrent meningitis)
 - b. Dementia
 - c. White forelock
 - d. Harada (prominent VIIIth nerve involvement)
 - e. Blindness from diffuse exudative choroiditis and retinal detachment
3. Rocky Mountain Spotted Fever (retinal arterioles)
4. Takayasu's syndrome
 - a. Aortic arch derived vessel involvement
 - b. Ischemia of the retina (positional blindness); claudication of vision (with walking); early cataracts
5. Mitochondrial encephalomyopathies
 - a. Kearns-Sayre syndrome
 - i. Ophthalmoplegia
 - ii. Heart block
 - iii. Loss of consciousness
 - b. MELAS
 - i. Stroke-like episodes that do not respect a vascular territory
 - ii. Manifestations of most mitochondrial diseases include:
 1. Short stature

2. Diabetes
3. Ophthalmoplegia
4. Cardiomyopathy
5. Fatigue
6. Weakness
7. Sensorineural hearing loss
8. Migraines

Acute Posterior Multifocal Placoid Pigment Epitheliopathy (APMPPE)

Overview

APMPPE is a self-limiting chorioretinal inflammatory disease that affects healthy young adults with rapid loss of central vision.

General Characteristics

1. Primarily an ophthalmologic syndrome best evaluated with fluorescein angiography (indocyanine green angiopathy)
2. Associated with:
 - a. Infectious/post-infectious disorders (bacterial and viral)
 - i. Tuberculosis
 - ii. Streptococcus
 - iii. Syphilis
 - iv. Lyme's disease
 - v. Schistosoma mansoni
 - vi. Epstein-Barr Virus (EBV)
 - vii. Adenovirus
 - b. Vaccination
 - i. Swine flu
 - ii. Hepatitis B
 - iii. Meningococcal
3. Inflammatory conditions:
 - a. Lymphadenopathy
 - b. Nephritis
 - c. Wegener's granulomatosis
 - d. Crohn's disease
 - e. Ulcerative colitis
 - f. Thyroiditis
4. Autoimmune disorders
 - a. Post-streptococcal syndrome
 - b. Anticardiolipin antibodies
 - c. Juvenile rheumatoid arthritis
 - d. Grave's disease
5. Paraneoplastic syndrome
 - a. Renal cell cancer

Clinical Manifestations

1. Ophthalmologic syndrome characterized by:
 - a. Multiple cream-colored placoid lesions
 - b. At the posterior pole in the level of the pigment epithelium and choroid
 - i. Demonstrated by indocyanine green fluorescein angiography

- c. Occlusive choroidal vasculitis
 - d. Papillitis
 - e. Optic neuritis
 - f. Entity may be a continuum of Harada's disease; a possible autoimmune cause of uveo-meningeal syndrome
 - g. Inflammatory yellow-white lesions at the level of the retinal pigment epithelium (probable choroidal hypoperfusion)
2. Both eyes are affected simultaneously; ocular involvement may occur seriatim
 3. Visual blurring; scotoma and distortion of vision
 4. Vision usually recovers after several weeks but deficits may be permanent
 5. Fundoscopic examination:
 - a. Pathology is in the retinal pigment epithelium
 - b. Well circumscribed gray-white flat lesions
 6. Stroke
 - a. Arteritis pattern

Neurologic Features

1. Neurological complications (mean age 26.5 years)
2. VIIIth nerve involvement
3. CNS vasculitis
4. Optic neuritis
5. Neuro-otological signs (tinnitus, hearing loss, vertigo)
6. Headache
7. Aseptic meningitis
8. Pseudo tumor cerebri
9. Meningoencephalitis (associated with vasculitis of CNS)
10. MS like episodes

Cerebrovascular Disease Associated with APMPE

1. Similar to primary angitis of CNS
2. Cerebral vein thrombosis
3. Cortical and tentorial strokes in 70% of patients:
 - a. Posterior cerebral and MCA territories
 - b. 40% of patients with deep white matter infarcts
 - c. Striatocapsular infarcts
4. Ischemic and hemorrhagic stroke (rare)
5. Lobar hemorrhage from cortical venous thrombosis (rare)

Neuropathology

1. Vasculitis of the CNS
2. Primary involvement of:
 - a. Retinal pigment epithelium
 - b. Choriocapillary vasculitis
 - c. Partial occlusive vasculitis
 - d. May be a continuum between APMPE and Harada's disease
 - e. Possible uveo-meningeal syndrome similar to:
 - i. Vogt-Koyanagi-Harada disease
 - ii. Behcet's syndrome
 - iii. Sarcoid
 - iv. Wegener's granulomatosis
3. Granulomatous involvement of medium-sized blood vessels

4. Some autopsies have demonstrated granulomas with Langhans cells

Neuroimaging

Arteriography

1. Arteriographic evidence of vasculitis (approximately one third of cases)

Ocular Computed Tomography

1. The outer nuclear layer, external limiting membrane and the inner and outer segment (IS/OS) line are disrupted

Laboratory Evaluation

1. Elevated CSF leukocytes and protein

Differential Points Between APMPE, Eales and Susac's Disease

1. Eales primarily affects retinal arteries (neovascular proliferation and vitreous hemorrhage):
 - a. Young men (20 to 40)
 - b. Stroke is rare
2. Susac's (young women approximately age 30)
 - a. Microangiopathy of the retina, cochlea and brain
 - b. Lesions in the corpus callosum (middle area)
3. APMPE
 - a. Rapid decrease in central vision
 - b. Yellow-white multiple placoid lesions of the retina
 - c. Acute/chronic visual blurring, scotoma or metamorphopsia
 - d. Both eyes are involved simultaneously or less commonly sequentially within a few days
4. Inflammatory conditions that are associated with retinal edema
 - a. Vogt-Koyanagi-Harada disease
 - b. Ocular toxoplasmosis

Takayasu's Disease

Overview

Takayasu's disease is an arteritis of large vessels that involves the aorta and its major branches and the pulmonary arteries.

General Characteristics

1. Most common in Asia; may be seen sporadically in the West
2. Prodrome of fever and night sweats
3. High sedimentation rate; anemia; increased gammaglobulin; and positive C reactive protein
4. Gradual obliteration of:
 - a. Major arterial branches of the arch of the aorta
 - b. Vertebral arteries are relatively spared

Clinical Manifestations

1. Constitutional symptoms, limb claudication, asymmetric blood pressure between the arms, claudication of vision, hypertension and stroke. Usually presents in 3rd decade

Neurological Manifestations

1. Loss of extremity and neck pulses

2. Asymptomatic subclavian steal
3. Intermittent claudication of vision
 - a. Tenuous blood supply to the optic nerve and retina
4. Early onset of cataracts
5. Facial atrophy
6. Headache
7. Dizziness
8. Hypothyroidism
 - a. Increase thyrocervical trunk collaterals destroy the thyroid gland
9. Claudication
 - a. Arm and leg
 - b. Vision (with head position and walking)

Neuropathology

1. Ischemic stroke
 - a. Less frequent than expected from the radiologic evaluation
 - b. Media and adventitia of blood vessels are involved in an inflammatory response
 - c. Late stage fibrosis of affected vessels
 - d. Extensive collateral circulation associated with
 - i. SAH
 - ii. ICH
 - e. Ischemic stroke primarily of the anterior circulation
2. Collateral circulation
 - a. May be associated with subarachnoid and intracranial hemorrhage

Neuroimaging

Arteriographic Evaluation

1. Occlusion, stenosis, ectasia, aneurysm formation at vessel origins of the aortic arch
2. Most common sites of involvement:
 - a. Mid portion of the left common carotid artery
 - b. Left and right subclavian arteries
 - c. Mid portion of the innominate artery

Laboratory Evaluation

1. Biomarkers:
 - a. Pentaxin-3, a protein produced by endothelial cells in response to inflammatory signals
 - b. ESR and CRP are usually increased

Differential Diagnosis of Takayasu's Syndrome

1. Arteriosclerosis
2. Burger's disease
3. Behçet's disease
4. Coarctation of the aorta
5. Aortic dissection
6. Congenital anomalies

Behçet's Disease

Overview

A systemic inflammatory disorder characterized by painful oral and genital ulcers, uveitis, well circumscribed skin lesions, large artery stroke and vasculitis.

General Characteristics

1. Relapsing remitting course
2. Major features:
 - a. Oral ulcers
 - b. Genital ulcers
 - c. Uveitis
3. High incidence in Turkey and Japan
 - a. World-wide distribution
4. Systemic involvement:
 - a. Skin:
 - i. Aphthous mouth ulcers
 - ii. Folliculitis
 - iii. Erythema nodosum
5. Ulcerative lesions of bowel and bladder mucosa
6. Stomach ulcers
7. Synovitis
8. Large joint arthritis
9. Thrombophlebitis
10. Affects young adults
11. Male > female 2:1
12. Neurologic involvement in less than 10%
13. An immune-mediated illness that often responds to TNF- α inhibitors if standard immunosuppression fails

Clinical Manifestations

Clinical manifestations include ocular (uveitis and optic nerve inflammation), large joint arthritis, synovitis, ulcerative lesions of the bowel mucosa, oral and genital ulcers. It may have a relapsing course. Large vessel stroke, dural venous thrombosis, and branch occlusions occur.

1. Pattern of involvement:
 - a. Ocular
 - i. Uveitis
 - ii. Optic nerve inflammation
 - b. Brainstem
 - i. Cranial nerve inflammation
 - c. Cortical:
 - i. Subcortical dementia
 - d. Stroke:
 - i. Large artery stroke
 - ii. Vasculitis
 - iii. Cerebral venous thrombosis in 10%
 1. Hetero or homozygous for Factor V Leiden defect
 - e. Dementia:
 - i. Frontal lobe type
 - ii. Subcortical
 - iii. Rarely accompanied by:
 1. Seizures
 2. Aphasia
 - f. Late stage disease
 - i. Quadriparesis
 - ii. Pseudo bulbar palsy

Neuropathology

1. Branch occlusion > large vessel thrombosis

2. Dural venous sinus thrombosis
3. Primarily ocular manifestations
4. Brainstem syndrome (rhombencephalitis)
5. Spinal cord may be involved
6. Retinal vasculitis
7. Demyelinative and/or ischemic foci in:
 - a. Midbrain (most extensive)
 - b. Basis pontis
 - c. Medulla
 - d. Optic nerve
 - e. Globus pallidus
 - f. Spinal cord
 - g. Hypothalamus

Neuroimaging

MRI

1. Topography of involvement
 - a. Pons > midbrain > basal ganglia > thalamus
2. Small well delineated T2-weighted lesions
 - a. Brainstem lesions
 - i. Not in arterial territories
 - b. Gray and white matter lesions
 - c. 10 mm sharply margined irregular and confluent lesions in affected areas

Laboratory Evaluation

1. Increase in IL-6 and IL-8 vs control subjects
2. HLA-B51
3. Genomic wide association studies reveal associations with ERAP-1, CCR1-CCR3 and KLRC4

Cogan's Syndrome (Typical or Classic)

Overview

A chronic inflammatory disorder, affecting multiple systems, characterized by interstitial keratitis and sensorineural hearing loss; may also be associated with systemic vasculitis (rare).

General Characteristics

1. Occurs in young adults (25 years mean age)
2. Men and women affected equally
3. Autoantigens: There is evidence of inner ear autoimmunity possibly triggered by a viral infection. Putative autoantigens are CD148 and Connexin 26
4. Cerebrovascular complications are large vessel stroke and cavernous sinus thrombosis

Clinical Manifestations

1. Systemic features:
 - a. Headache, fever, weight loss, fatigue
 - i. Arthralgias and myalgias (30%)
 - b. 10% have systemic vasculitis
 - a. Aortic insufficiency (10%)
 - b. Distal coronary arteries may be affected
 - c. Skin

- d. Viscera
- e. Kidneys
- f. CNS
- g. Muscles

2. Neurological manifestations
 - a. Blindness (corneal opacification)
 - b. Vertigo
 - c. Ataxia
 - d. Hearing loss
 - i. Vestibular auditory dysfunction from inflammation of the labyrinth
3. Ophthalmologic features
 - a. Acute interstitial keratitis
 - b. Bilateral interstitial keratitis (nonsuppurative cellular infiltrate of the corneal stroma)
 - c. Keratitis fluctuates
 - d. Patchy corneal involvement and absence of intraocular inflammation
 - e. Retinal hemorrhage and papilledema
 - f. Orbital pseudotumor
 - g. Central artery or vein occlusion
 - h. Presents with:
 - i. Red eyes
 - ii. Photophobia
 - iii. Reduced vision
 - iv. Interstitial keratitis
 - v. Uveitis (rare)
4. Vestibulocochlear manifestations:
 - a. Severe hearing loss in all cases
 - i. Asymmetric and sudden
 - b. Vertigo, tinnitus and ataxia
 - c. Inflammation of the labyrinths
 - d. Acute and often bilateral
 - e. Decreased caloric response
 - f. May be coincidental with visual loss
5. Stroke (pial arteries)

Typical Cogan's Signs and Symptoms

1. Photophobia, lachrymation, eye pain
2. Blurred vision
3. Intermittent symptoms for years
4. Ménière's-like attacks may precede eye pain
5. Total deafness and absence of vestibular function

Neuropathology

1. Cerebral venous sinus thrombosis
2. Vasculitic process affecting vessels of all sizes
3. Microscopic evaluation of the aorta
 - a. Inflammatory changes
 - b. Destruction of the internal elastic membrane
4. Autoantibodies against corneal, inner ear and endothelial antigens may be present
5. Autoantibodies to corneal, inner ear and endothelial antigens
6. Acute interstitial keratitis

7. Rare emboli to large arteries from valvular disease
8. Aortic insufficiency in 10%
9. Skin and visceral involvement
10. Inflammation of the labyrinth
11. Ocular pathology (in both typical and atypical Cogan's):
 - a. Retinal hemorrhage
 - b. Papilledema
 - c. Orbital pseudotumor
 - d. Central artery or vein occlusion

Neuroimaging

For both Typical and Atypical Cogan's syndrome.

MRI

1. Multiple ischemic lesions
2. Angiography (topographic stroke)
3. Signs of vasculitis

Angiography

1. Cerebral venous thrombosis
2. PICA thrombosis
3. Signs of suggestive of vasculitis

CT

1. Occasional intralabyrinthine calcifications

Laboratory Evaluation

Typical and Atypical Cogan's Syndrome

1. Elevated erythrocyte sedimentation rate (ESR), anemia, leukocytosis and thrombocytosis
2. Lumbar puncture (LP) may demonstrate pleocytosis and elevated protein
3. Negative tests for syphilis and autoantibodies that include rheumatoid factor, anti-nuclear antibodies and ds DNA
4. Audiometry, electronystagmography and vestibular function deficits are positive

Atypical Cogan's Syndrome

General Characteristics

1. Vasculitis and systemic manifestations
2. Inflammatory ocular disease exemplified by
 - a. Uveitis
 - b. Scleritis
 - c. Episcleritis
 - d. Retinal vasculitis
 - e. Optic nerve edema without interstitial keratitis
3. There may be vestibular auditory dysfunction that occurs at more than 2 years after onset of eye symptoms

Clinical Manifestations

1. Involvement of the CNS or PNS varies from 5 to 50%
2. Vasculitis
 - a. Occurs in atypical disease
 - b. Aortitis and aortic insufficiency in the classic syndrome
 - c. Neurologic symptoms
 - i. Stroke
 - ii. Encephalopathy

- ii. Seizure
- iii. Myelopathy
- iv. Mononeuritis multiplex
- v. Cavernous sinus thrombosis
- d. Differential diagnosis includes syphilis
3. Cerebrovascular disease
 - a. Cerebral venous sinus thrombosis
 - b. PICA thrombosis
 - c. Ischemic brain (cerebellar) lesions
 - d. Frequency of neurologic involvement about 13%
 - e. Emboli to large arteries from valvular disease (rare)

Neuroimaging

MRI

1. Multiple ischemic brain lesions
2. Soft tissue obliteration of the membranous labyrinth

Angiography

1. Cerebral venous thrombosis
2. PICA thrombosis
3. Signs of suggestive of vasculitis

CT

1. Intralabyrinthine calcifications (rare)

Neuropathology

1. Cerebral venous sinus thrombosis
2. PICA stroke; cerebellar lesions
3. Rare emboli to large arteries from valvular disease
4. Ocular pathology (in both typical and atypical Cogan's):
 - a. Retinal hemorrhage
 - b. Papilledema
 - c. Orbital pseudotumor
 - d. Central artery or vein occlusion

Laboratory Evaluation

Typical and Atypical Cogan's Syndrome

1. Elevated erythrocyte sedimentation rate (ESR), anemia, leukocytosis and thrombocytosis
2. Lumbar puncture (LP) may demonstrate pleocytosis and elevated protein
3. Negative tests for syphilis and autoantibodies that include rheumatoid factor, anti-nuclear antibodies and ds DNA
4. Audiometry, electronystagmography and vestibular function deficits are positive

Buerger's Disease (Thromboangiitis Obliterans)

Overview

A non-atherosclerotic segmental inflammatory disease that most often affects small and medium-sized arteries and veins in the upper and lower extremities. Cigarette smoking is important in etiology.

General Characteristics

1. Cigarette smoking: Possible immune reaction to some component of tobacco that causes an inflammatory small vessel occlusive disease

Clinical Manifestations

1. Migratory thrombophlebitis or vascular insufficiency in the extremities (lower greater than upper)
2. Occasional large vessel stroke
3. Two or more limbs are involved in most patients
4. Systemic characteristics
 - a. Intermittent claudication of the legs
 - i. Involvement of the in-step rather than the calf
 - b. Upper extremity claudication of the arms as the disease progresses
 - c. Claudication particularly prevalent in smokers
 - i. Regresses with cessation of tobacco use

Neurological Manifestations

1. Monoparesis
2. Hemiparesis
3. Visual field deficits
4. Dementia

Neuropathology

1. Immune mechanism: There is evidence for an autoimmune mechanism with antibodies directed against the vascular endothelium due to antigens in tobacco. The antibodies demonstrated are anti-nuclear anti-elastin, anti-collagen I and III and anti-nicotine antibodies. Immunoglobulins are deposited in blood vessels
2. Vasculitis of medium and small vessels
3. Primary involvement in distal extremity vessels
 - a. Severe peripheral vascular disease. Extremity lesions are typically below the knee in the posterior and anterior arteries rather than the distal 1/3 of the aorta or the iliac arteries as in atherosclerosis
4. Rarely affects veins
5. Coronary and renal arteries may be affected
6. Granular cortical atrophy

Neuroimaging

1. Brain vessel topography:
 - a. Watershed zones infarctions between ACA/MCA and MCA/PCA territories
 - b. Possibly two vessel sizes involved:
 - i. Arteries <1 mm
 - ii. Large proximal arteries

*Collagen, Type IV Alpha Disorders***General Characteristics**

1. Heterotrimers composed of collagen type IV alpha (COL4A1) and alpha2 (COL4A2) a major component of all basement membranes
 - a. Mutations are pleiotropic
2. Type IV collagens are encoded by 3 pairs of paralogous genes (collagen type IV alpha (COL4A1 – COL4A6)
3. Mutations in COL A3 cause Alpert syndrome that affects:
 - a. Retina
 - b. Cochlea

c. Kidney

4. Large deletions of COL4A5 and COL4A6 cause diffuse leiomyomatosis
5. COL4A1 and COL4A2 mutations
 - a. Chromosome 13q34; controlled by microRNAs that regulate collagen synthesis

Clinical Manifestations*Neurological Diseases Caused by Mutations in COL4A1 and COL4A3*

1. Porencephaly (arises from germinal matrix hemorrhage)
2. Ocular, cerebral, renal, muscular defects
3. Retinal vascular tortuosity highly penetrant in COL4A1 mutations
4. Hereditary angiopathy with nephropathy, aneurysms and muscle cramps (HANC) is associated

Cerebrovascular Disease Associated with COL4A1 and COLA2 Mutations

1. Intracranial hemorrhage
2. Silent infarcts (small vessel disease)
3. Periventricular leukoencephalopathy with calcification

Neuroimaging*MRI*

1. Dolichoectasia
2. COL2 alpha
 - a. Germinal matrix hemorrhage
 - b. Porencephaly
3. Large vessel dissection

Neuropathology

1. Electron microscopy:
 - a. Focal interruptions or expanded and thickened basement membranes
 - b. Fragmented basement membranes in capillaries

*Ehlers-Danlos Syndrome***Overview**

Ehlers-Danlos syndrome is a hereditary connective tissue disorder whose main characteristics are skin and joint hypermobility, poor wound healing and atrophic scarring.

In classic EDS (type I and type II), approximately 50% of patients have mutations in COL5 A1 or COL5A2 genes that encode the $\alpha 1$ and $\alpha 2$ chain of collagen V. In the EDS vascular type (EDS type IV), molecular genetic testing is used to identify the mutation in the COL3A1 gene with defective type III collagen.

General Characteristics

1. Ehlers–Danlos syndrome (EDS) is a group of connective tissue diseases (approximately 10 subtypes) with overlapping clinical features
 - a. Major types are I, II, or III (approximately 80% of patients)

- b. Subtype IV most important for cerebrovascular complications; incidence is 1 in 50,000–500,000 persons
- c. Decreased synthesis of type III collagen
 - i. All of these patients demonstrate autosomal dominant inheritance
 - ii. COL 3A1 gene (mutations) on chromosome 2
 - 1. Exon skipping and multi-exon deletions of COL 3A1 gene chromosome 2
 - 2. Encodes for alpha-1 chain of type III collagen; produces a pro-collagen that causes it to be thin and friable

Clinical Manifestations

- 1. Hyperelastic skin
- 2. Hyperextensible joints
- 3. Increased scarring after injury
- 4. Platelet dysfunction
- 5. Cardiac defects
- 6. History of sudden death
- 7. Hemorrhage after minor trauma
- 8. Hemorrhage after surgery
- 9. Bowel rupture
- 10. 80% of vascular complications by age 40
- 11. Ten subtypes of the syndrome
 - a. Major types are I, II, or III (approximately 50% of patients)
 - b. Subtype IV most important for cerebrovascular lesions:
 - c. Decreased synthesis of type III collagen
 - i. All of these patients demonstrate AD inheritance
 - ii. COL 3A1 gene (mutations); chromosome 2
 - 1. Codes for alpha-1 chain of type III collagen

Cerebral and Vascular Complications

- 1. Aneurysms (type IV; type I rare)
 - a. Intra- and extracranial aneurysms
 - b. Multiple aneurysms
 - c. Most common aneurysm is of the internal carotid artery
 - i. In the cavernous sinus
 - ii. At the site of emergence from the sinus
- 2. Presentation
 - a. Rupture in the cavernous sinus cavity
 - b. SAH
 - c. Carotid cavernous fistula
 - i. Spontaneous rupture or following minor head trauma
 - ii. Symptoms include:
 - 1. Periorbital swelling
 - 2. Conjunctival erythema with arterioles reaching the iris
 - 3. Pulsatile tinnitus
 - 4. Retinal engorgement
 - 5. Increased ocular pressure
 - 6. Proptosis occurrence

- 3. Arterial dissection:
 - a. Documented in both intra and extracranial vessels
 - b. Dissection of intrathoracic artery can secondarily occlude cervical vessels
 - c. Dissection occurs in intra-abdominal, pelvic, and intrathoracic vessels
 - d. Complications during arteriography are common due to friability of the tissue
 - e. Spontaneous dissections
 - f. During surgery and procedures

Neuropathology

- 1. Fragmentation of the internal elastic membrane
- 2. Fibrosis of the arterial wall
- 3. Microscopic rupture between media and adventia

Neuroimaging

Arteriography/MRA

- 1. Carotid cavernous fistula
- 2. Intra and extracranial aneurysms. Rarely in both carotid and vertebral arteries concomitantly
- 3. Arterial dissection of cerebral as well as thoracic, abdominal, and pelvic vessels
- 4. Intracranial carotid artery is the most common site of aneurysm

Differential Diagnosis

Differential Diagnosis Between Marfan's Syndrome and Ehlers-Danlos Disease

- 1. Marfan's syndrome has fewer cerebrovascular aneurysms
- 2. Aortic arch and pulmonary arteries affected more in Marfan's syndrome
- 3. Carotid-cavernous fistula (both)
 - a. May follow minor head trauma
 - b. Spontaneous occurrence
 - c. May occur concomitantly with intracranial aneurysms
- 4. Arterial Dissections (both)
 - a. Arteries fail to hold sutures (EDS)
 - b. Dissection of both intra and external arteries (EDS)
 - c. Carotid and basilar arteries are thin walled, enlarged and tortuous (EDS > Marfan's)
 - d. Arteriograms are dangerous (EDS)
 - e. More friable tissue (EDS)

Marfan's Syndrome

Overview

Marfan's syndrome is a heritable connective tissue disorder whose cardinal features are cardiovascular, ocular and dolichostenomelia skeletal abnormalities (increased length of limbs with respect to the trunk).

General Characteristics

- 1. A connective tissue disorder that is system wide:
 - a. Skeleton and skin abnormalities
 - b. Cardiovascular system (aortic root dilation)
 - c. Lens dislocation and myopia

- d. Lung involvement (emphysema)
- e. MMASS – myopia, mitral valve prolapse, aortic dilatation, skin and skeletal abnormalities

Genetics

1. Autosomal dominant; sporadic in about 25% of patients
 - a. Chromosome 15: mutation in the FBN1 gene that encodes fibrillin-1
 - b. Possible second locus:
 - i. 3p24-25
 - ii. Possible mutations in genes coding for TGF- α (important for angiogenesis)
 - c. Fibrillin-1
 - i. Major component of the extracellular matrix; the fibrillary structure for elastin deposition
 - d. Diagnosis requires a major criteria in two organ systems and involvement in a third

Clinical Manifestations

Neurological Complications of Marfan's Syndrome

1. Dissection of the ascending aorta, the carotid and vertebral arteries:
 - a. Arch dissection: pain in the face and carotid artery stroke
 - b. Dissection below the subclavian artery – pain straight through to the back with paraplegia
 - c. An excess of cerebral aneurysms but not subarachnoid hemorrhage

General Complications of Marfan's Syndrome

1. Emboli:
 - a. Cardiac arrhythmia
2. Spinal Defects:
 - a. Craniospinal junction
 - i. Greater than 50% of patients have increased atlantoaxial translation (greater than 5 mm with neck flexion; causes odontoid compression of the spinal cord)
 - ii. 36% have basilar impression (greater than 135° angle between the planum sphenoidale and the clivus)
3. Ectasia of the dural sac with irritation of lumbosacral nerve roots and back pain
4. Laryngeal nerve paralysis from aortic compression of the recurrent laryngeal nerve
5. Severe scoliosis
6. Multiple facial anomalies with retrognathia
7. Congenital ectopia lentis (may be the most specific finding)

Neuroimaging

1. Evaluation of the acute aortic syndrome that includes:
 - a. Aortic and cervical cephalic arterial dissection
 - b. Intramural hematoma
 - c. Penetrating atherosclerotic ulcer
2. Embolic stroke of cerebral vessels
3. Atlantoaxial dislocation
4. Enlarged dural sac

CT

1. Findings demonstrate “beak sign” and aortic “cobwebs”

MRI

1. Topographic embolic stroke

Angiography

1. Dissection of the ascending aorta, carotid and vertebral arteries
2. Arterial malformations
3. Tortuosity and dilatation of intracranial cerebral vessels

Neuropathology

1. Defect is primarily in the vessel media with profound diminution of elastic fibers
2. Decreased fibrillin in microfibrillar fibers in the skin
3. Mutation in fibrillin causes a disordered microfibril matrix
4. Release of sequestered latent transforming growth factor β :
 - a. Mediator of vascular remodeling
5. Regional biomechanical dysfunction

Differential Diagnosis

1. Homocystinuria:
 - a. Mental retardation
 - b. Autosomal recessive
2. Congenital contractural arachnodactyly (Beals syndrome):
 - a. Marfanoid features; Autosomal dominant
 - b. Heart defects
 - c. Ocular defects
3. Loeys-Dietz syndrome:
 - a. Transforming growth factor β receptor mutation
 - i. TGBRA gene mutation
 - ii. Arterial tortuosity and aneurysms
 - iii. Hypertelorism
 - iv. Bifid (bifurcated) uvula/cleft palate

Pseudoxanthoma Elasticum (PXE)

Overview

PXE (Grönblad–Strandberg syndrome) is an ectopic mineralization disorder-associated with ocular and cardiovascular manifestations.

General Characteristics

1. Female predominance (2:1)
2. Mutations in the ABCC6 gene on the short arm of chromosome 16 (16p13.1);
 - a. Autosomal dominant and recessive forms
 - b. Autosomal dominant form possibly has more severe vascular disease
3. ABCC6 gene encodes:
 - a. Multi-drug resistance associated protein 6 a trans membrane transporter protein of the ABC (ATP binding cassette) family
 - b. β -Thalassemia patients have high prevalence of PXE

Clinical Manifestations

1. Systemic Signs
 - a. Additional eye signs:
 - i. Choroid retinal atrophy
 - ii. Subretinal edema
 - iii. Pattern dystrophy-like changes
 - iv. Retinal drusen
2. Heart:
 - a. Premature coronary artery disease:
 - i. Sudden death
 - ii. Cardiomyopathy
 - b. Endocardial changes (elastic fiber changes):
 - i. Thickened mitral valves
 - ii. Mitral stenosis; MVP
 - iii. Restrictive cardiomyopathy (calcification of the endocardium)
3. GI tract
 - a. Gastrointestinal hemorrhage:
 - i. Often the presenting symptom
 - ii. Degeneration of small-sized arteries
 - iii. Microaneurysms and angiomatous malformations
4. Skin:
 - a. Linear, round or oval yellow orange elevated lesions (resemble xanthomas)
 - b. Papular lesions in flexure areas
 - c. Face, neck, axilla, inguinal, umbilical topography
 - d. Late stage – lax and redundant skin
 - e. Involvement of skin and mucosa in:
 - i. Lips
 - ii. Mouth
 - iii. Vagina
 - iv. Rectum
 - f. Gastric mucosa
 - g. Endocardium and heart valves
5. Eye involvement
 - a. Classic
 - i. Angioid streaks
 1. Red, brown or gray
 2. Wider than veins
 3. Radiate from the disc
 4. Rupture of Bruch's membrane (a thin membrane separating the blood vessel-rich layer from the pigmented layer of the retina)
 5. "Peau d'orange" (a French term meaning that the retina resembles the skin of an orange)
 6. Chorioretinal scarring and hemorrhage
 - b. Optic nerve infarction
 - i. Involvement of the posterior ciliary arteries
 - ii. Comet bodies

Cerebrovascular Disease in PXE

1. Hypertension
2. Aneurysmal dilation of the aorta
3. Calcification of peripheral arteries with intermittent claudication

4. Occlusive cervicocranial arterial disease; intra and extracranial
5. Subarachnoid hemorrhage
6. Carotid artery:
 - a. Increased thickness; more elastic with increased intimal-medial thickness
 - b. Tortuosity and ectasia
7. Ischemic symptoms develop in the 5th and 6th decades
8. Concomitant pathology of hypertensive cardiovascular disease:
 - a. ICH
 - b. Lacunar infarction
 - c. Microvascular disease (Binswanger)
9. Aneurysm formation and SAH
 - a. Cavernous sinus
 - i. May present with cranial nerve palsy rather than SAH
10. Possibly increased incidence of dissection

Neurologic Manifestations

1. Large artery infarction
2. Hemorrhage from saccular aneurysms hypertension and microaneurysm
3. Cavernous artery aneurysm

Neuropathology

1. Decreased calcium extracellular homeostasis
2. Loss of elastic tissue, fragmentation of the internal elastic membrane; calcifications between the intima and media
3. Dystrophic mineralization and fragmentation of elastic fibers, Large and medium-sized vessels
4. Fibrosis of the arterial wall
5. Microscopic ruptures between media and adventia
6. Carotid artery
 - a. Increased intimal-medial thickness
 - b. Tortuosity and ectasia
7. Concomitant pathology of HCVD:
 - a. ICH
 - b. Lacunar infarction
 - c. Microvascular disease (Binswanger)
8. Aneurysm formation and SAH:
 - a. Cavernous sinus
 - i. May present with cranial nerve palsy rather than SAH
9. Possible increased incidence of dissection

Neuroimaging

1. Occlusive cervicocranial disease that is intra or extracranial
2. Tortuosity and ectasia of cervical arteries
3. Lacunar infarction
4. Hyperintensive changes
5. Aneurysm with SAH
6. Thicker carotid arteries
7. Moyamoya syndrome
8. Binswanger type microvascular disease

Laboratory Evaluation

1. Identified genes for the disease:
 - a. ENPPI
 - b. ABCC6 (PXE)
 - c. NT5E
 - d. SLC20A2
 - e. CD73 deficiency

Differential Diagnosis*Differential Diagnosis of Identified Genes for Arterial Calcification*

1. ENPPI
2. ABCC6 (PXE)
3. NT5E
4. SLC20A2
5. CD73 deficiency

Differential Diagnosis of Angioid Streaks

1. Sickle cell anemia
2. Paget's disease
3. Hypophosphatemia
4. Ehlers-Danlos syndrome
5. Lead poisoning
6. ITP
7. PXE
8. Trauma
9. Pituitary disease
10. Additional eye signs:
 - a. Choroid retinal atrophy
 - b. Subretinal edema
 - c. Pattern dystrophy-like changes
 - d. Retinal drusen

Differential Diagnosis of Arterial Calcification

1. Aging
2. Diabetes mellitus
3. Chronic kidney disease
4. Generalized arterial calcification of infancy
5. PXE
6. Familial idiopathic basal ganglia calcification

Moyamoya Syndrome**Overview**

Moyamoya disease is a progressive intracranial arteriopathy due to unilateral stenosis of the distal portion of the internal carotid artery and the proximal anterior and middle cerebral arteries that cause TIA and strokes.

General Characteristics

1. Prevalence in asymptomatic Japanese population is 50.7/100,000 people
 - a. Patient in Northeast Asia have genetic disease and not syndrome
 - b. Two peak ages:
 - i. Children younger than 14 years
 - ii. Young adults between 25–49 years
 - iii. Japanese female to male ratio is 1.6- to 1.8: 1

Genetics

1. Autosomal dominant with incomplete penetrance
2. Complex chromosome rearrangements at 6p25.3; variant RNF 213c14576G7A
3. Genetic or acquired form
 - a. Genetic form more common in children

Clinical Manifestations*Cerebrovascular Disease in Adults*

1. Recurrent stroke or TIA is a common presentation
 - a. Border zone territorial stroke between MCA/ACA and MCA/PCA
2. Infarctions in the cortex, deep hemispheric white matter or basal ganglia
3. Progressive ischemic frontal lobe syndrome occurs with behavioral changes
4. Brainstem strokes are rare
5. Less frequent: headache and seizures than in children
6. May present with ICH:
 - a. Asymptomatic microhemorrhages
 - b. Recurrent hemorrhages are frequent
 - c. Pathogenesis of hemorrhages can be rupture of collateral blood vessel, small false aneurysm or vascular malformation
 - d. Hemorrhages:
 - i. More frequent in 46–55 year old patients
 - ii. Intracerebral in 60% (BG and thalamus)
 - iii. Intraventricular in 30%
 1. Extension from the thalamus
 2. Direct from the caudate
 - iv. Deep penetrating arteries:
 1. Degenerative changes; hypertrophied arterioles
 2. Develop microaneurysms
 3. Small asymptomatic hemorrhages in the paraventricular white matter and subcortex
 - v. Rare: SAH; high incidence of posterior circulation aneurysm
 1. Small false aneurysms along the ventricular surface and Moyamoya collaterals are a source of SAH
 - vi. A unilateral process is against Moyamoya disease

Neuropathology

1. Bilateral severe stenosis or occlusion of the terminal ICA and proximal ACA and MCA; can affect the PCA; superficial temporal artery and the middle meningeal artery can be affected

Microscopic Evaluation of Large Intracranial Arteries

1. Thickening of the intimal and medial layers
2. Proliferation and degeneration of smooth muscle cells
3. Fragmentation of the internal elastic membrane
4. No inflammatory, calcification or lipid droplets
5. Ethmoidal collaterals involve:
 - a. The frontal basal areas
 - b. The vault where Moyamoya collaterals are a generalized vascular network

6. Collaterals develop from external carotid artery as well as the thalamoperforators, the dorsal branches of the PCA, tectal plexus and posterior choroidal vessels
7. Associated with a greater number of illnesses that include:
 - a. Sickle cell disease
 - b. Neurofibromatosis type I
 - c. Tuberculosis
 - d. Severe atherosclerosis

Neuroimaging

1. There are six angiographic stages from narrowing of the distal ICA (stage I to the cerebral circulation supplied from meningeal pial collaterals of the external carotid)
2. Collaterals from the ethmoidal arteries
3. Intracranial saccular aneurysms: posterior > anterior circulation
 - a. Arise at arterial bifurcations

MRI

1. Infarctions primarily in deep hemispheric nuclei and hemispheric white matter
2. Border zone topography infarctions occur primarily between the ACA/MCA
3. Dilated leptomeningeal and transdural collateral arteries

Sneddon's Syndrome

Overview

Sneddon's syndrome is characterized by livedo reticularis of the skin and pial artery stroke. Approximately 80% of Sneddon's syndrome patients have an antiphospholipid antibody marker.

General Characteristics

1. No definite ethnic predilection; hospital based studies possible incidence of .25% to .5% of stroke patients
2. Hospital derived patients
 - a. 80% are women
 - b. Average age at onset: 40 years
 - c. Possible autosomal dominant genetics in familial patients

Clinical Manifestations

1. Livedo reticularis (mottling, bluish lace-like discoloration with pale center) precedes neurological symptoms although it may occur concurrently or afterwards
2. Topography of the lesions:
 - a. Lower trunk, buttocks, proximal thighs
 - b. Lesions may generalize to upper body
 - c. Exacerbation with cold and concomitantly with exacerbation of neurologic symptoms
 - d. Some patients demonstrate area cyanosis and Raynaud's phenomena

Systemic Signs

1. Hypertension (60–80%)
2. Valvular heart disease

3. Thrombosis of peripheral arteries
4. Pulmonary embolus
5. Retinal and mesenteric artery involvement

Neurological Manifestations

1. Headache and vertigo in >50% of patients
2. TIA in >50%
3. Cognitive dysfunction: dementia in some late stage patients
4. Patients with antiphospholipid antibodies have
 - a. Seizures
 - b. Thrombocytopenia
 - c. Mitral valve disease
5. Rare: tremor with a high incidence of seizure

Cerebrovascular Manifestations

1. Multiple TIA and strokes
 - a. Cortical and subcortical topography in anterior and posterior circulations
 - b. Lacunar and white matter lesions
 - c. Spinal cord is rarely involved
 - d. Case reports of SAH and ICH

Neuropathology

1. Skin biopsy
 - a. Medium-sized arteries of deep dermal or subcutaneous tissue are involved
 - b. Endotheliitis; inflammatory infiltrate
 - c. Fibrin occlusion of small vessels
 - d. Late stage subendothelial occlusion
2. Non-specific subcortical infarction with gliosis; no inflammation or fibrinoid necrosis
3. One autopsy study:
 - a. Cortical infarction of medium-sized arteries; hyperplasia of smooth muscle
4. Some patients have a non-vasculitic small and medium-sized vessel arteriopathy

Coagulation Associated Defects

1. Antiphospholipid, lupus anticoagulant and prothrombin antibodies are frequently found
2. Less frequently seen:
 - a. Platelet aggregation defects
 - b. Antithrombin III deficiency
 - c. Protein Z deficiency in patients that are antiphospholipid negative
 - d. Deficiency of Factor V Leiden in 10% of patients
 - e. Deficiency of Protein S

Neuroimaging

MRI

1. Multiple subcortical and white matter lesions in separate arterial territories
2. Cortical and subcortical atrophy

Angiography

1. Normal in many patients

2. A subset demonstrates distal arterial occlusions with extensive collaterals

Differential Diagnosis Between Sneddon's Syndrome and APL (Antiphospholipid Syndrome)

1. Antiphospholipid antibody titers (APL) approximately equal in both
2. APL Sneddon's patients are older than APL patients
3. Miscarriages more frequent in APL patients
4. Cardiac valve abnormalities more common in APL than Sneddon's syndrome patients (marantic endocarditis)
5. Venous thrombosis more common in APL than Sneddon's syndrome patients
6. Digital artery narrowing and dilation demonstrated angiographically; acrocyanosis (Sneddon's)
7. Early inflammatory skin lesions (Sneddon's)
 - a. Medium-sized arteries between the dermis and subcutis affected
8. May be familial (Sneddon's)
9. May have antiphospholipid antibodies (Sneddon's)
10. Valvular cardiac defects less common in Sneddon's syndrome than APL
11. Neurological manifestations of Sneddon's syndrome
 - a. Multifocal cortical infarcts
 - b. Lesions in the cerebral white matter
 - c. Intranuclear ophthalmoplegia
12. Arteriography
 - a. Branch occlusions of intracranial arteries

Differential Diagnosis of Livedo Reticularis

1. Collagen vascular disease
 - a. SLE
 - b. Rheumatoid arthritis
 - c. PAN
2. Tuberculosis
3. Syphilis
4. Complex regional pain syndrome, types I and II (usually allodynia/hyperalgesia associated)
5. APL syndrome
6. TTP
7. Thrombocythemia
8. DIC
9. Oral contraceptives
10. Neoplasm
11. Cryoglobulinemia (legs)
12. Cholesterol emboli syndrome (legs and toes are blue)
13. Divry-Van Bogaert syndrome

Mencke's Disease

Overview

Menckes disease is an X-linked recessive neurodegenerative disorder in the gene that encodes the copper transporting ATPase (ATP7A). Majority of patients are male.

General Characteristics

1. Mutations in the ATP7A gene on the long arm of the X chromosome (xq12-q13)

2. P-type ATP protein encoded functions to translocate metal cations across cellular membranes and transport copper to those enzymes that require it
3. ATP7A mutations also cause:
 - a. Occipital horn disease
 - b. Distal hereditary motor neuropathy
4. Patients have low copper levels in the brain
5. Signs and symptoms are due to deficiencies of Cu^{2+} dependent enzymes such as ceruloplasmin; superoxide dismutase; dopamine β -hydroxylase (DBH)

Clinical Manifestations

Neurologic Signs and Symptoms

1. Classic presentation:
 - a. Neonatal
 - i. Hypothermia
 - ii. Poor feeding
 - iii. Failure to thrive
 - iv. Seizures
 - b. Scalp hair abnormalities that include:
 - i. Twisted, colorless, friable hair
 - ii. Fractures of the hair shaft at regular intervals
2. Severe tortuosity of blood vessels
3. Long bone-metaphyseal spurring and a diaphyseal periosteal reaction
4. Hydronephrosis; bladder diverticula

Neuropathology

1. Tortuous arteries:
 - a. Irregular lumen
 - b. Split intimal lining
 - c. Non sulfate and sulfate chondroitin are deposited within elastin fibers:
 - i. Poor elastin formation and cross linking
 - ii. Dysfunction of copper dependent lysyl hydroxylase
 - iii. Focal degeneration of gray matter with gliosis
 - iv. EM demonstrates increased mitochondria in Purkinje cells and cortical neurons

Neuroimaging

MRI

1. Vascular tortuosity
2. Cerebral atrophy
3. Infarcts of deep gray matter and the cortex
4. Asymptomatic subdural hematoma

Vogt-Koyanagi-Harada Syndrome

General Characteristics

1. Uveomeningeal process
2. White forelock and eyelashes
3. Alopecia
4. Iridocyclitis
5. Choroiditis
6. HLA-DRB1-040 carrier

Clinical Manifestations

1. Meningeal signs (cause of recurrent meningitis)

2. Adhesive arachnoiditis
3. Papilledema
4. Increased intracranial pressure
5. Dementia
6. Cerebellar signs
7. May remit after 6–12 months

Neuropathology

1. Inflammatory infiltrates composed of CD3+ T-lymphocytes
2. CD68 positive macrophages that contain melanin
3. Granulomatous pan uveitis
4. Antigenic targets for VKH are tyrosine family proteins

Neuroimaging

1. Diffuse pachymeningeal enhancement and thickening

Laboratory Evaluation

1. CSF lymphocytic pleocytosis
2. Elevated protein

Hereditary Endotheliopathy with Retinopathy, Nephropathy and Stroke (HERNS)

General Characteristics

1. Chromosome 3p21; mutation of the TREX1 gene
 - a. Codes for a 3'-5' DNA exonuclease
2. Progressive visual loss in the 3rd to 4th decade
3. Neurologic deficits begin 4 to 10 years after initiation of the disease

Clinical Manifestations

Neurologic Manifestations

1. Central vision loss with decreased visual acuity
2. Premonitory behavioral and psychiatric symptoms (early as the second decade)
3. Stroke-like episodes may be presenting symptoms; may progress over several days
4. Later in the course there are multifocal cortical and sub-cortical signs of small vessel stroke
 - a. Migraine is common
 - b. 50% of patients have renal dysfunction

Ophthalmologic Signs

1. Retinal vasculopathy
 - a. Loss of macular capillaries
 - b. Dilated tortuous telangiectatic vessels; capillary shunts
 - c. Fluorescein angiography
 - i. Juxtafoveolar capillary obliteration with microaneurysm
 - d. Peripheral retina is involved late in the disease's course

Neuropathology

1. Small blood vessels occluded by fibrin thrombi
2. Electron microscopy:
 - a. Multilaminated vascular basement membranes

- b. Kidney, stomach, omentum and skin are concomitantly involved
- c. Generalized vasculopathy with disruption of capillaries and arterioles
- d. Breakdown of the blood-brain barrier
- e. A primary endothelial injury

Neuroimaging

MRI

1. Reveals T2 high intensity lesions in deep white matter
 - a. Overtime, contrast enhancing lesions in the deep frontoparietal area
2. May have space occupying mass lesions

Laboratory Evaluation

1. Fluorescein angiogram of the retina
 - a. Macular capillary dropout
2. Dilated tortuous telangiectasia vessels and capillaries

Hereditary Cerebroretinal Vasculopathy (CRV)

Clinical Manifestations

1. Macular edema, capillary obliteration, microaneurysms and telangiectasia
2. Strokes, visual loss, dementia

Neuropathology

1. Fibrinoid necrosis without inflammation

Hereditary Vascular Retinopathy

1. Migraines, Raynaud's phenomena and visual loss

Divry–Van Bogaert Syndrome (DVBS)

General Characteristics

1. Diffuse meningocerebral angiomas
 - a. Autosomal recessive
 - b. Involves children and adults
2. Infantile form:
 - a. Starts after age 3
 - b. Skin and neurologic lesions
 - i. Skin lesions may be absent but if present resemble those seen in adults
 - c. Neurologic involvement includes seizures, cognitive dysfunction and focal motor deficits
3. Adult onset-form:
 - a. Skin lesions and neurologic dysfunction

Clinical Manifestations

Adult Form

1. Skin lesions present as diffuse symmetrical livedo reticularis
2. May increase at the onset of neurologic signs and symptoms
3. Neurologic signs and symptoms:
 - a. Focal motor deficits (infarctions)
 - b. Seizures
 - c. Dementia
 - d. Cognitive/behavioral abnormalities predominate
 - e. Death occurs approximately 10 to 15 years after onset

Neuropathology

1. Skin biopsy demonstrates increased dermal capillaries with absent “zonulae occludens” between endothelial cells
2. Brain infarcts
3. White matter demyelination
4. Cerebromeningeal angiomatosis
 - a. A large corticomeningeal network
 - b. Vascular congestion and vessel occlusion
 - c. Fibrotic changes of the vascular walls with fatty degeneration and amyloid deposits

Neuroimaging

1. Multifocal cerebral infarctions of both gray and white matter
 - a. Axonal and oligodendrocytes loss
 - b. Astrogliosis (also known as astrocytosis)

Differential Diagnosis of Neurologic Livedo Reticularis

1. Sneddon's syndrome
2. Divry-Van Bogaert syndrome
3. SLE
4. Antiphospholipid antibody syndrome
5. Polyarteritis nodosa
6. Cholesterol embolization syndrome
7. Livedoid vasculopathy

Blue Rubber Bleb Nevus Syndrome**General Characteristics**

1. Blue Rubber Bleb Nevus syndrome (also known as Bean syndrome and formerly called Gascoyen syndrome) is a systemic disorder characterized by cutaneous and visceral cavernous hemangiomas
2. Skin lesions are rubbery and compressible over the trunk and extremities
3. Gastrointestinal angiomas occur most frequently in the small bowel resulting in anemia from bleeding

Clinical Manifestations

1. Brain angiomas (present in childhood)
2. Angiomas may involve the orbit
3. Seizures
4. Progressive neurologic deficits
5. Spinal cord compression

Neuropathology

1. Cutaneous and visceral cavernous hemangiomas
2. Skin lesions
 - a. Rubbery texture and compressible
 - b. Bluish purple
 - c. Present in childhood
 - d. Primarily over the trunk and/or extremities
3. Gastrointestinal angiomas
 - a. Most often in the small intestine
 - b. May bleed throughout life
4. Dilated venous channels

5. Myxoid degeneration of the wall

6. A venous malformation

Neuroimaging**MRI**

1. Multiple angiomatous lesions with contrast enhancement
2. Phleboliths in the orbit

Leigh's Syndrome (Subacute Necrotizing Encephalomyelopathy)**General Characteristics**

1. Genetically heterogeneous
 - a. Affects nuclear or mitochondrial DNA
2. SURF-1 gene
 - a. Milder phenotype
3. Most common biochemical deficit
 - a. COX complex and pyruvate dehydrogenase complex deficits
4. Late onset cases occur

Clinical Manifestations**Juvenile Form**

1. Spastic paraparesis
2. Visual disorder
3. Acute sensorimotor neuropathy, ataxia, deafness and retinitis pigmentosa (NARP)
4. Myopathy and cardiomyopathy
 - a. Respiratory depression and coma
5. Emboli from cardiomyopathy
6. Stroke-like attacks
7. Infantile form diagnosed by developmental delay and elevated serum and CSF lactate

Neuropathology

1. Gray matter degeneration
2. Brainstem and spinal cord necrosis
3. Spongiosis, endothelial proliferation and demyelination

Neuroimaging**MRI**

1. Symmetric hypointense T1/hyperintense on T2-weighted sequences; lesions in the basal ganglia
 - a. Putamen and brainstem
2. Sparing of red nuclei and mammillary bodies (occasionally the mammillary bodies are hemorrhagic)
3. Olivary nucleus hypertrophy
4. Some patients with SURF-1 mutations

Laboratory Evaluation

1. Infantile form diagnosed by developmental delay and elevated serum and CSF lactate

Saguenay-Lac Saint Jean (Cox Deficiency)**Overview**

Saguenay-Lac Saint Jean disease, the French Canadian variant of Leigh's disease, is a nuclear encoded cytochrome c-oxidase deficiency.

General Characteristics

1. Autosomal recessive; the largest known cohort of patients with a genetically homogeneous nuclear encoded congenital lactic acidosis
 - a. A354V mutation in LRPPRC (leucine-rich pentatricopeptide repeat containing)

Clinical Manifestations

1. Developmental delay
2. Facial dysmorphism
3. Fulminant lactic acidotic crises
4. Leigh's syndrome like

Neurological Manifestations

1. Frontal cortical lesions
2. Stroke-like episodes

Neuropathology

1. Decreased cytochrome oxidase in tissues
 - a. Cytochrome oxidase deficiency in the brain and liver
2. Necrotizing encephalopathy involving the thalamus, brainstem and spinal cord
3. Vascular proliferation and gliosis

Laboratory Evaluation

1. High CSF lactate

Differential Diagnosis*Differential Point*

1. MELAS affects parietoccipital areas primarily
2. SLSJ-COX differs from SURF1 Cox deficiency

*Disseminated Intravascular Coagulation (DIC)***Overview**

Disseminated intravascular coagulation (DIC) is a severe coagulopathy whose pathophysiology is multifactorial that involves feedback loops between coagulant, immune and inflammatory pathways. Inciting injury may be infection, trauma obstetrical disasters and trauma. Clinical picture is often dominated by systemic inflammation and sequential organ failure. Cerebral vascular manifestations are large and small vessel stroke, subarachnoid and ICH and subdural hematoma.

General Characteristics

1. Occurs in a setting of:
 - a. Septicemia
 - b. Cancer
 - c. Obstetrical procedures with release of amniotic fluid into the circulation
 - d. Neurosurgical procedures (release thromboplastin)
 - e. Chemotherapy
 - f. Viremia:
 - i. HIV
 - ii. Hepatitis

iii. Varicella

- g. Intravascular hemolysis
 - h. Heat stroke
 - i. Burn patients
 - j. Liver disease
 - k. Prosthetic devices
 - l. Collagen vascular disease
2. Clotting and fibrinolytic system are activated simultaneously
 3. Usually systemic hemorrhage and thrombosis:
 - a. Hypotension
 - b. Fever
 - c. Hypoxia
 - d. Acidosis
 - e. Shock
 - f. Acrocyanosis (distal)
 - g. Bleeding from all punctures sites

Clinical Manifestations

1. May present in coma with a non-focal neurological exam
2. Large vessel occlusion
3. Lethargy; stupor
4. Cranial nerve palsies
5. Seizure
6. SAH
7. Emboli from NBTE
8. Multifocal hemorrhage and infarction

Laboratory Evaluation

1. Peripheral blood smear:
 - a. Schistocytes (fragmented RBC's) in 50% of patients
 - b. Thrombocytopenia $<50,000$ platelets mm^3
 - c. Reticulocytosis
 - d. Slight shift to immature leukocytes
2. Clotting abnormalities:
 - a. Prothrombin time decreased
 - b. Activated partial thromboplastin time (aPTT) decreased
 - c. Exception:
 - i. 25% of DIC patients have a normal PT or fast time due to circulating activated clotting factors or early degradation products
 - ii. 40–50% of patients may have normal or fast aPTT for similar reasons
 - d. Decreased factors II, V, VIII
 - e. Decreased antithrombin III
 - f. Elevated levels of B-peptides 15–42
 - g. D-dimer neoantigen DD-3B6/22 is noted
 - h. Elevated levels of platelet factor IV

Differential Diagnosis of DIC from Multiorgan Thrombotic Illness

1. SLE with or without antiphospholipid syndrome
2. Thrombotic thrombocytopenic purpura hemolytic uremia syndrome (TTP-HUS)

*Sturge-Weber Syndrome***Overview**

Sturge-Weber syndrome, also called encephalotrigeminal angiomas, is a neurocutaneous disorder characterized by vascular lesions in the skin, eye, and brain.

General Characteristics

1. Facial port-wine stain (cutaneous nevus) in VI
2. Ipsilateral parietal-occipital leptomeningeal angioma

Genetics

1. Sporadic
2. Somatic mosaicism
3. Occurs in all ethnic groups; no gender preference

Clinical Manifestations

1. Cutaneous nevus
 - a. Usually involves the forehead and upper eyelid (VI distribution)
 - i. May involve the face bilaterally and extend to the trunk
 - ii. Trunk or V2 or V3 distribution lesions (without V1) rarely have intracranial lesion
 - iii. Rarely patients have intracranial lesion without skin manifestations
2. Bilateral cerebral lesions occur in 15% of patients with unilateral facial nevus
 - a. The extent of the nevus increases the risk of a bilateral intracranial lesion
 - b. Similar cutaneous lesions on the limb with hypertrophy comprise Klippel-Trénaunay-Weber syndrome
3. Ophthalmologic features
 - a. Glaucoma if the nevus is adjacent to the eyes
 - b. Newborns have buphthalmic amblyopia (rare)
 - i. Abnormal anterior chamber angle
4. Seizures and hemiparesis
 - a. Develop acutely during the first or second year; often triggered by a febrile illness
 - b. Early onset and refractoriness of seizures are correlated with cognitive deficits
5. Adult patients with Sturge-Weber syndrome: greater than 50% suffer contralateral motor deficits
6. Intracranial hemorrhage is rare
7. Seizures occur in:
 - a. 72–80% of patient with unilateral lesions and greater than 90% of those with bilateral lesions
 - i. Early seizures are focal (infantile spasm, myoclonic and atonic seizures also occur)
 - ii. Adults have complex partial seizures or focal motor seizures
8. Patients may develop stroke-like episodes without seizures suggestive of TIA
9. Occipital lobe involvement
 - a. Visual field deficits
 - b. Cognitive deficit occurs in approximately 50% of patients; particularly severe if there is bilateral involvement

Neuropathology

1. Parietal and occipital lobe involvement is greater than in the frontal lobe
2. Leptomeninges:
 - a. Thickened
 - b. Angiomatous vessels may obliterate the subarachnoid space
 - c. Tortuous deep draining veins
 - i. Thin walled
 - ii. May extend into the parenchyma
 - iii. Ipsilateral choroid plexus may be involved
 - iv. Hyalinization and subependymal proliferation occurs in some vessels
 - d. Cerebral atrophy adjacent to the angioma
 - i. Neural loss and gliosis which may extend into normal appearing tissue
 - ii. Gyriiform (“train track”) calcification is seen in outer cortical layers; calcium may be seen adjacent to blood vessels
 - e. Chronic venous stasis

Neuroimaging

1. Gyral calcification; bilateral calcification is common
2. Calcification more apparent with age; may be present at birth
3. Cerebral atrophy
4. Accelerated myelination in young patients
5. Hypoperfusion:
 - a. Impaired venous drainage
 - b. Several impaired regions demonstrate arterial perfusion deficits

PET

1. Decreased brain glucose utilization beyond the leptomeningeal lesion

SPECT

1. Decreased cerebral perfusion that may include areas with normal glucose uptake; often deficit is larger than that noted by MRI

Angiography

1. Rare arterial occlusion
2. Decreased number of superficial cortical veins; enlarged and tortuous draining veins
 - a. Failure of opacification of the ipsilateral sagittal sinus due to occluded cortical veins

*Von Hippel-Lindau Syndrome***Overview**

Von Hippel-Lindau disease is a rare, autosomal dominant multisystem disorder associated with hemorrhagic blastomas of the CNS, retinal angiomas as well as cysts and tumors of the viscera. The most common tumors are retinal and CNS hemangioblastomas, clear cell renal carcinoma, pheochromocytoma, pancreatic islet cell tumors and endolymphatic sac tumors.

General Characteristics

1. Autosomal dominant; 95% penetrance by age 60 with incomplete expression
 - a. Von Hippel-Lindau (vHL) suppressor gene on chromosome 3p25-26 is mutated
2. Development of benign and malignant tumors and cysts
 - a. Hemangioblastoma (HB) in the CNS
 - b. Retinal hemangioblastoma (RA)
 - c. Pheochromocytoma (Pheo)
 - d. Clear cell renal carcinomas (RCC)
 - e. Renal cysts
 - f. Pancreatic cystadenoma
 - g. Pancreatic neuroendocrine tumors
3. vHL protein mutations cause:
 - a. Decreased ubiquitination of hypoxia-inducible factor 1 α (HIF1 α)
 - b. Dysfunction of vascular endothelial growth factor in stromal cells
 - c. Upregulation of VEGFR1 and 2 in tumor endothelial cells
 - d. vHL protein regulates extracellular matrix formation and the ability of cells to exit the cell cycle
 - e. Major effect of vHL mutation:
 - i. Causes altered vHL protein and Elongin BC complex

Clinical Criteria for the Diagnosis of vHL Disease

1. Positive family history
2. Development of hemangioblastoma in the CNS, retinoblastomas, renal cell cancer, pheochromocytoma, pancreatic tumors or cysts
3. Patients who develop hemangioblastomas or retinal hemangioblastomas concomitant with renal cell carcinoma and the usual associated tumors
4. 80% of patients have a family history
 - a. Inter- and intrafamilial phenotypic variability
 - b. 20% are sporadic and require two manifestations: included requirements are CNS or retinal hemangioblastoma

Clinical Classification

1. vHL type I
 - a. No pheochromocytoma
2. vHL type II
 - a. Type 2A
 - i. Has pheochromocytoma
 - ii. Associated hemangioblastoma in the CNS
 - iii. No renal cell cancer
 - iv. Low risk of renal cell cancer and neuroendocrine pancreatic tumor
 - b. Type 2B
 - i. Has pheochromocytoma, renal cell cancer and other CNS tumors
 - ii. High risk of renal cell cancer and pancreatic endocrine tumor
 - c. Type 2C
 - i. Has only pheochromocytoma

Clinical Manifestations

1. Isolated hemangioblastoma present in early adulthood (20 to 40 years of age)
 - a. Type 1 (no pheochromocytoma) or type 2A in 70% of vHL patients
 - b. Males 1.5:1 females
 - c. Location:
 - i. Cerebellum (83–95%)
 - ii. Spinal cord (3.2–13%)
 - iii. Medulla (2%)
 - d. Multiple spinal hemangioblastoma occur
 - e. In 40%, hemangioblastoma may be first manifestation of disease
2. Posterior fossa signs and symptoms
3. High hemoglobin occurs from overproduction of erythropoietin from hypoxia inducible factor (HIF)
4. Hemangioblastomas from vHL disease are 5–30% of cerebellar hemangioblastomas and 10% of spinal hemangioblastomas
5. Asymptomatic vHL gene carriers are approximately 4%
6. Intracranial or intramedullary subarachnoid or intraparenchymal hemorrhage is low (less than 5%)
 - a. Tumors size (1.5 to 5 cm); the average size that bleed is 2.7 cm (larger than average HB)
 - b. Size of the tumor is associated with hemorrhage both spontaneous and following surgery
 - c. Subarachnoid hemorrhage occurs in a high percentage of patients that bleed
 - i. Superficial location of medullary HBs
 - ii. Cerebellar hemangioblastoma bleeds occur in the parenchyma
 - iii. Large solid hemangioblastoma have a higher risk of peri- and post-operative hemorrhage
7. Patients with complete deletion mutation of the vHL gene (as opposed to missense or protein-truncating mutations)
 - a. Better visual acuity
 - b. Decreased tumorigenesis incidence of hemangioblastomas
8. Higher levels of vascular endothelial growth factor VEGF, hypoxia-inducible factor (HIF) and ubiquitin have ocular hemangioblastomas

Neuropathology

1. Association with:
 - a. Visceral cysts of the kidney, pancreas and epididymis
 - b. Pheochromocytoma (type II, VHL)
 - c. Pancreatic neuroendocrine tumors
 - d. Endolymphatic carcinoma
 - e. Head and neck paraganglioma
2. Stroma:
 - a. Foamy vacuolated cells
 - b. Tumorlet dells (retinoblastoma) are poorly differentiated, small cells, prominent dark nuclei
3. Epithelial clear cell morphology
4. Increased expression (retinoblastoma) of erythropoietin (Epo); CD133; and the chemokine CXCR4

Neuroimaging

MRI

1. Should be of the entire neuraxis to rule out multiple hemangioma
2. Lesions are well circumscribed and are often associated with a cyst
3. Cystic lesions are hypointense on T1-weighted images and hyperintense on T2-weighted images
4. Minimal or no edema
5. Enhancement of a mural nodule with gadolinium
6. May have vascular flow voids (MRA)
7. Solid HB enhance homogeneously with gadolinium

Differential Diagnosis

Neuroradiologic Differential Diagnosis

1. Pilocytic astrocytoma (children; spreads through the brainstem)
2. Astrocytoma (solid or cystic)
3. Metastasis (usually surrounding edema)
4. AVM (appear similar to large solid hemangioblastoma)

Angiography of vHB

1. May demonstrate a large vascular peduncle
2. Early draining vein (AV shunting)
3. Absence of a cystic component suggests metastatic renal cell carcinoma

Cobb's Syndrome

Overview

Cobb's syndrome (cutaneous meningospinal angiomatosis) is a somatic disorder characterized by vascular abnormalities of the spinal cord with associated skin, muscle and dura involvement at the same metameric level.

General Characteristics

1. Cutaneous nevus
2. Associated vascular lesion at the same dermatologic level
3. Vascular skin, muscle, bone and dural involvement at the same somite

Clinical Manifestations

1. Large AVM may be associated with congestive heart failure
2. Compression, bleeding and deterioration of spinal cord function
3. May just have extradural and paraspinal components

Neuropathology

1. Progressive myelopathy
 - a. Venous congestion of an extradural nidus or fistula
 - b. May cause similar neurologic dysfunction as is seen with dural-based intradural lesions
 - c. Large epidural venous lakes

Neuroimaging

1. Type A – spinal extradural AVF

- a. Diffuse high signal intensity of the spinal cord on T2-weighted MR images
 - b. No mass effect
 - c. Primarily thoracolumbar and lumbar location
2. Type B – lesions
 - a. Normal signal intensity of the cord
 - b. Severe mass effect due to enlarged extradural venous plexus
 - c. Cervical and upper thoracic locations

Hereditary Hemorrhagic Telangiectasia (Osler-Weber-Rendu Disease)

Overview

Hereditary Hemorrhagic Telangiectasia (Osler-Weber-Rendu) is autosomal dominant, characteristic by epistaxis, cutaneous telangiectasia, visual and cerebral malformations. Epistaxis occurs in childhood, pulmonary AVMs at puberty, cutaneous and gastrointestinal telangiectasia in adulthood. Arteriovenous fistulas occur in childhood, small AVMs in adolescents and micro-AVMs in young adults.

General Characteristics

1. Autosomal dominant; high penetrance
2. Incidence of 1 in 5,000–8,000 persons
3. Telangiectasias are found:
 - a. Face
 - b. Nasal mucosa (nose bleeds)
 - c. Conjunctiva (30%)
 - d. Hands > legs and trunk
 - e. Anterior tongue
 - f. Retina (10%)
4. Telangiectasia – enlarge and multiply
5. Telangiectasia occur in internal organs
 - a. Lungs
 - b. GI tract
 - c. Genitourinary tract

International Diagnostic Criteria

1. Epistaxis
 - a. Spontaneous
 - b. Recurrent
2. Multiple telangiectosis
 - a. Lips, oral cavity, fingers, nose
3. Visceral lesions
 - a. Gastro-intestinal telangiectosis
 - b. Pulmonary arteriovenous malformation; hepatic, cerebral and spinal AVM
4. Family history of first degree relative involvement
5. Clinical manifestations develop with age
6. Epistaxis in childhood, pulmonary AVM from puberty, microcutaneous and gastrointestinal telangiectosis in adulthood
7. Approximately 2/3 of patients have some sign of HHT by 16 and 90% by 40 years of age
8. Neurologic symptoms occur in approximately 10–20% of patients

Genetics

1. Autosomal dominant; 2 genes described:
 - a. Endoglin – chromosome 9q24(CD105)
 - b. Activin – chromosome 12q HTT2
 - i. Proteins expressed are found in vascular endothelial cells
2. No definite relationship between the type of mutation and the phenotype of the disease
3. Protein levels from the mutated genes suggest haploinsufficiency
4. Endoglin and Activin receptor-like kinase 1(ALK1) involved in:
 - a. Transforming growth factor signaling pathway
 - b. Cell development
 - c. Vascular remodeling by control of the production of the extracellular matrix
 - d. Endoglin and ALK1 influence angiogenesis by binding with transforming growth factor β proteins
5. Some patients have HTT-juvenile polyposis overlap syndrome
6. HTT3 subgroup:
 - a. Chromosome 5 locus; SMAD-4
 - b. Prominent pulmonary involvement

Clinical Manifestations

1. Nasal and mucocutaneous telangiectosis
 - a. Epistaxis from nasal mucosa is the first complaint in about 50% of patients
 - i. Common in childhood
 - ii. Recurrent in 50 to 80% of patients
2. Skin telangiectasia
 - a. Later in life
 - b. Located on the face, lips, tongue, palate and finger tips
 - c. Size and number increase with age
3. Gastrointestinal telangiectasia
 - a. Recurrent hemorrhages occur in about 30% of patients usually starting in the fifth to sixth decade
 - b. Telangiectasia more prominent in stomach and duodenum than colon
 - i. Rarely AVM or aneurysms
 - c. Rare liver AVMs
 - i. Multiple AVMs may cause portal hypertension and biliary disease
 - ii. Cardiac failure from right to left shunt
 - iii. Hepatic encephalopathy (rare)

Pulmonary AVM (PAVM)

1. Occurs in 5–20% of the 5HTT 3 subgroups
2. About 70% of all PAVMs occur in 5HTT patients
3. Location is primarily in the lower lobes
 - a. Enlarge with age and become symptomatic during the third or fourth decade
4. Associated with:
 - a. Decreased arterial oxygen saturation (right to left shunt)

- b. Fatigue, dyspnea and cyanosis
 - c. Hemoptysis and hemothorax
 - d. Polycythemia
 - e. Clubbing and cyanosis
 - f. Platypnea-orthodeoxia (improved breathing with supine position; hypoxemia in sitting position)
5. Differential diagnosis of pathologic arteriovenous defects:
 - a. Patent ductus arteriosus
 - b. PFO
 - c. Right to left congenital heart defect
 - d. PAVM

Neurologic Features of PAVM

1. Occur at all ages; peak incidence is in 3rd–4th decade
2. Primary mechanisms:
 - a. PAVM (60%)
 - b. Brain vascular malformations (28%)
 - c. Spinal cord malformations (8%)
 - d. Hepatic encephalopathy (3%)
3. Neurologic complications from PAVM
 - a. Bland emboli to cerebral circulation
 - b. Septic emboli associated with SBE that cause cerebral abscess, meningitis and mycotic aneurysms
 - c. Cerebral abscess most frequently a septic complication:
 - i. Usually solitary
 - ii. Supratentorial (MCA territory most frequent)
 - iii. Incidence 3–5%; much higher if there is a recurrence
 - d. Embolic patterns:
 - i. Paradoxical from peripheral sources such as DVT
 - ii. In a large ectatic PAVM a clot may develop in the wall of the malformation
 - iii. MCA territory most often affected (40 to 50% of CBF)
 - iv. Rarely CNS embolism is the initial symptom
 - v. Overall risk of emboli is related to the number of PAVMs
 1. Single PAVM infarction occurs in about 30%
 2. 60% of them are multiple PAVMs
 - vi. Other mechanisms of cerebral ischemia:
 1. Hyperviscosity from polycythemia
 2. An embolism

Differential Diagnosis of PAVM

1. Hepatopulmonary syndrome
2. Mitral stenosis
3. Trauma
4. Actinomycosis
5. Schistosomiasis
6. Metastatic thyroid cancer
7. Fanconi syndrome
8. Surgery in congenital heart case
9. Bronchiectasis
10. Venous atresia

Hemorrhagic CNS Complications

1. About 30% of HTT patients suffer hemorrhages from cerebral or spinal vascular malformation
2. Prevalence of cerebrovascular malformations by MRI is about 20%
 - a. Large malformations bleed at a rate of 1.4–2% per year
3. Symptoms from malformations also occur due to
 - a. Thrombosis of the venous pouch
 - b. Venous ischemia
 - c. Rarely SAH from AVF or arterial aneurysm
4. Spinal malformations (AVFs):
 - a. Often large
 - b. High risk of hemorrhage
 - i. Progressive para or tetraparesis the usual premonitory sign

Neuropathology

1. Telangiectosis is the most prominent lesion:
 - a. Focal dilatations of post-capillary venules
 - b. Some perivascular lymphocytic infiltration
 - c. Enlargement of telangiectasias associated with excessive layers of smooth muscle without elastic fibers
 - d. Connecting arterioles dilate and connect to venules by-passing a capillary bed
2. Associated arteriovenous malformation and arteriovenous fistula
 - a. Most often responsible for neurologic sequelae
 - b. Largest arteriovenous malformations occurs in the lungs, liver and CNS
 - c. Rare aneurysm
 - d. Multiple types of malformations may occur concomitantly
3. Three different malformations occur:
 - a. Large fistula
 - i. Direct arteriovenous shunt
 - ii. No nidus
 - iii. Ectatic draining vein
 - b. Small AVMs (1–3 cm)
 - i. Nidus
 - c. Micro-AVMs
 - i. Nidus smaller than 1 cm
4. Malformations most often are near the surface of the CNS
5. Venules are the initial component of the pathologic process
6. PAVM may enlarge during pregnancy (increased hemorrhagic risk)

Neuroimaging

1. Cerebral and spinal AVM's (16%)
2. No evidence of different features of AVMs among different genetic groups
3. Multiple brain AVMs (23%)
4. AVMs are of small size and tend to be cortical
5. Associated arteriovenous malformation and arteriovenous fistula
 - a. Most often responsible for neurologic sequelae

- b. Largest arteriovenous malformations occurs in the lungs, liver and CNS
- c. Rare aneurysm
- d. Multiple types of malformations may occur concomitantly

*Bing-Neel Syndrome**General Characteristics*

1. Increased blood viscosity with decreased or slowed cerebral laminar flow
2. Hematocrit greater than 67
3. Hemoglobin at 18–22 grams/ml
4. Bleeding from the gums
5. Dilated tortuous retinal veins
 - a. Box car phenomena (pressure on the globe with clumping of RBC's in the central retinal veins)
6. Petechiae of the lower extremities
7. Associated with:
 - a. IgM > IgG monoclonal gammopathy
 - b. Waldenström's macroglobulinemia

Neurological Manifestations

1. Encephalopathy
 - a. Poor cerebral perfusion
 - b. Cerebral small vessel ischemia

*Köhlmeier-Degos Disease**Overview*

Köhlmeier-Degos disease (Malignant Atrophic Papulosis) is a thrombo-obliterative vasculopathy characterized by papular skin lesions with a central porcelain-white atrophy and a surrounding telangiectatic rim. Clinical manifestations include skin lesions and multiple limited infarcts of the intestine, CNS, lungs (pleuritic and/or pericarditis) and the eyes. The benign form only affects the skin.

General Characteristics

1. Two distinct forms
 - a. Systemic form with G.I and CNS involvement
 - b. Cutaneous benign variant
2. Most common in Caucasians
3. Age of onset 3 weeks to 67 years

*Clinical Manifestations**Systemic Signs*

1. Any organ can be involved from multifocal infarctions
2. Cutaneous signs usually precede visceral involvement
3. Multiple lesions
4. Involve the trunk and upper limbs (skin lesions)
5. Red macules that evolve to a porcelain white necrotic scaly center with an erythematous border
6. Differential diagnosis includes
 - a. SLE
 - b. Dermatomyositis
 - c. Atrophic blanche
 - d. Allergic necrotizing vasculitis

Gastrointestinal Tract

1. Microvascular infarction of the intestines with perforation and peritonitis
2. Abdominal symptoms often start after the appearance of skin lesions
3. Lesions also occur in the esophagus, duodenum, stomach, colon and rectum

Major Organ Involvement

1. Infarctions of the heart, pericardium, kidneys, bladder, lungs, liver and pancreas occur – often asymptomatic

Neurological Signs

1. CNS involvement occurs in about 20% of patients
2. May precede the skin lesions by years (mean is 2 years)

CNS Signs

1. Cranial nerve deficits
2. Cognitive decline
3. Ophthalmoplegia
4. Focal motor and sensory deficits
5. Multifocal infarction and hemorrhage
6. SAH (rare)
7. Demyelinating peripheral neuropathy (rare)
8. Polyradiculopathy (rare)

Neuropathology

1. Non-inflammatory occlusive endarteriopathy
 - a. Primarily of arterioles
 - b. Endothelial proliferation with superimposed thrombosis
 - c. Media is spared
2. Leptomeningeal, cranial nerve, spinal root and posterior lateral spinal cord infarction occurs
3. Extracutaneous organs demonstrate a fibromucinous occlusive arteriopathy
4. Evidence of high expression of interferon α (a type 1 interferon-inducible protein)
5. Endothelial tubuloreticular inclusions
6. MXA tissue expression with C5b-9 deposition
7. A distinct vascular injury
 - a. Dysregulated interferon α response
 - b. Membranolytic attack complex deposition

*Neuroimaging**Angiography*

1. Occlusions and beading of arteries
2. Distal branches of intracranial vessels are affected

MRI

1. Infarction and intraparenchymal hemorrhages in different territories

*Erdheim-Gsell Disease**Overview*

Erdheim-Gsell disease, also known as medial cystic necrosis, is defined by non-inflammatory smooth muscle cell loss, frag-

mentation of elastic fibers, and accumulation of basophilic ground substance within cell-depleted areas of the medial layers of the vessel wall.

General Characteristics

1. Associated with bicuspid aortic valve and aortic root dilatation
2. Cystic medial necrosis prevalent in congenital heart disease with dilated aortic root
3. Transcriptional regulator NOTCH 1 gene on chromosome 9q3y.3 linked to non-syndromic associated bicuspid aortic valves
4. Possible spontaneous arterial dissection

Neuropathology

1. Necrosis of smooth muscle of the lamina media

*May-Thurner Disease**Overview*

May-Thurner syndrome comprises left lower extremity swelling secondary to left iliac vein compression. This anatomic abnormality can predispose patients to increased risk of paradoxical embolism and stroke.

General Characteristics

1. The left iliac vein compresses the right iliac artery at the level of the fifth lumbar vertebrae
2. Left lower extremity edema pain, varicosities and deep venous thrombosis
3. Source of paradoxical emboli is from right to left cardiac shunt
4. Typically presents in the second to fourth decades of life; more common in women than men (3:1)

Clinical Manifestations

1. Possible paradoxical embolism to the basilar apex
2. Possible increased risk of paradoxical emboli
3. Deep vein thrombosis

Neuropathology

1. Compression of the left common iliac vein
 - a. Risk factor for lower-extremity deep vein thrombosis

Neuroimaging

1. Stenosis of the left common iliac vein
2. Normal LCIV diameter in 6.5 mm
3. 4 mm in those with DVT (LCIV)
4. The odds of left DVT increased by a factor of 1.68 for each millimeter decrease in LCIV

*Progeria**General Characteristics*

1. Characterized by premature aging
2. Childhood form: Hutchinson-Gilford progeria syndrome
3. Adult Progeria: Werner's syndrome

4. Several progeria-like syndromes have been defined genetically and clinically
5. Genetics of progeria and progeroid syndromes
 - a. Progeria is caused by mutation of the LMNA gene on chromosome 1q
 - i. Encodes lamins A and C (filamentous structural protein of the nuclear lamina)
 - ii. Exon II mutation responsible for 80% of progeria patients
 1. The mutation causes the accumulation of progerin (farnesylated prelamin protein A) that interferes with nuclear membrane function
 2. Most often paternally imprinted
 3. Also autosomal recessive, germline and somatic mosaicism mutations cause a phenotypic spectrum of disease
 - iii. Werner syndrome gene
 1. Short arms of chromosome 8
 2. Encodes a DNA helicase
 - iv. Incidence is about 1 in 4 million persons

Clinical Manifestations

1. Some patients have scleroderma-like abdominal skin at birth
2. Poor weight gain prominent veins over the scalp, alopecia by adolescence
3. Facial dysmorphism
4. Deficient subcutaneous fat and lax skin
5. Delayed or absent sexual maturation
6. Bone and joint destruction
7. Premature vascular disease
8. Most patients succumb in the second decade; some survive to middle age

Neurological Manifestations

1. Atherosclerotic stroke of both anterior and posterior circulations
2. Cerebral aneurysms

Neuropathology

Cerebrovascular Disease

1. Occlusive infarctions of the cervical carotid and vertebral arteries
2. Perforating artery disease
3. Intracranial large artery disease
4. WMH from arteriole and capillary involvement

Neuroimaging

MRI

1. MRI demonstrates infarctions of:
 - a. Pial vessels
 - b. Arterioles
 - c. Watershed territories
 - d. Lacunar
 - e. Large arteries
 - f. Silent infarcts in 60% of patients

Angiography

- a. Calcified cervical and internal carotid arteries
- b. Stenosis of intra/extracranial vessels
- c. Distal stenosis VA stenosis

Werner's Syndrome (Adult Onset Progeria)

General Characteristics

1. Autosomal recessive; DNA Rec Q helicase/exonuclease (WRN)
2. Encodes a DNA helicase (chromosome 8p 12)
 - a. Induces wide range of premature aging phenotypes
 - b. Abnormal pattern of tumors
 - c. Mutation causes dysfunction of telomeres
 - d. Dysfunction of telomeres activates the TP53 gene which:
 - i. Suppresses cell growth and shortens cellular life span
 - ii. Decrease mitochondrial biogenesis
 - iii. Increases reactive oxygen species that causes multiple aging phenotypes
 - iv. Telomere dysfunction is correlated with tumorigenesis

Clinical Manifestations

1. Premature hair graying and hair loss
 - a. Alopecia starts age 2–3 years
2. Dysmorphic features:
 - a. Receding mandible
 - b. Beaked nose
3. Dermal atrophy:
 - a. Atrophic hyperkeratotic skin over the hands and feet
 - b. Scleroderma-like skin
4. Atrophic appendicular muscle
5. Loss of subcutaneous fat
6. Cardiovascular disease
7. Cancer predilection
8. Progeria, xeroderma pigmentosum and Cockayne's syndrome (as well as Werner syndrome):
 - a. Segmental progeria
 - b. Demonstrates some, but not all aspects of aging
9. Absence of a growth spurt at puberty
10. Type II diabetes mellitus
11. Voice changes (hoarse/high pitched)
12. Colorectal, skin, thyroid, pancreatic and soft tissue sarcoma have an increased risk
13. Hypogonadism
14. Posterior cortical, bilateral cataracts
15. Liver dysfunction
16. Appear 20–30 years older than stated age
17. Osteoporosis
18. Clavicular hypoplasia, acro-osteolysis of distal phalanges
19. Macular degeneration

Cardiovascular Manifestations

1. Accelerated atherosclerosis

- a. Calcification of the aorta and great vessels
- b. Calcification of the mitral and aortic valve

Neuropathology

1. Dramatically accelerated cardiovascular disease similar to CVD of aging (atherosclerotic disease):
 - a. Affects the cervical carotid and vertebral arteries
 - b. Intracranial large artery disease
 - c. Perforating artery disease of the basal ganglia and white matter
2. Vessels exhibit prominent adventitial fibrosis
3. Progerin found in blood vessels at higher rate than controls
4. Down-regulation of mitochondrial oxidative phosphorylation

Cardiovascular Pathology

1. Increased arterial wall density as measured by carotid duplex in the intima-media and adventia
2. Generalized atherosclerotic lesions with stenosis and plaque formation in coronary and cerebral arteries
3. Valvular heart calcification
 - a. Calcification of the aorta and great vessels
 - b. Calcification of mitral and aortic valves
4. Pulmonary arterial lesions
5. Strokes in all topographical distributions; silent infarcts
6. Cardiac death more common than stroke related death

Cerebrovascular Pathology

1. Intracranial steno-occlusive arterial lesions
2. Basal cistern collateral vessels

Related Syndromes

1. Mandibuloacral dysplasia
2. Wiedemann-Rautenstrauch syndrome

Neuroimaging

Arteriography

1. Intracranial steno occlusive arterial lesions
2. Basal cistern collateral vessels

MRI

1. Infarction by MRI in 60% of patients (approximately 50% were silent)

Binswanger's Disease

General Characteristics

1. A small vessel vascular dementia caused by extensive white matter damage

Clinical Manifestations

1. Loss of memory and executive function that presents in the 5th and 6th decade

Neuropathology

1. Irregular loss of axons and myelin associated with widespread gliosis

2. Arterioles of the subcortical white matter are more involved than capillaries

Neuroimaging

1. Severe leukoaraiosis with occipital predominance
2. Increase diffusion in the periventricular and deep white matter

Wyburn-Mason Syndrome

General Characteristics

1. Wyburn-Mason syndrome (Bonnet-Dechaume-Blanc syndrome) is a phakomatosis associated with congenital retinal orbital and brainstem arteriovenous malformations; rarely facial vascular malformations

Clinical Manifestations

1. Retinal AVM: rare loss of visual acuity from orbital cranial AVM
2. Primarily midbrain AVM with focal findings after hemorrhage

Thrombotic Thrombocytopenic Purpura

Overview

Thrombotic Thrombocytopenic Purpura (Moschowitz's disease) is a thrombotic microangiopathy causing damage to many organs including the kidneys, heart and brain. Most cases of TTP arise from inhibition of the enzyme ADAMTS13, a metalloprotease responsible for cleaving large multimers of von Willebrand factor (vWF) into smaller units.

General Characteristics

1. Incidence of 3.8–6.5 patients per million individuals
2. Incidence associated with ADAMTS-13 (von Willebrand cleaving protease) deficiency in approximately 1/7 patients per million individuals
3. Sex ratio of 3:1 females to males
 - a. Possible increased incidence in those of Afro-Caribbean origin

Clinical Manifestations

1. Onset is usually between the ages of 20–40 years
2. Three presentations:
 - a. A single episode with recovery with no recurrence
 - b. Intermittent episodes with rare relapses and normal hematologic evaluation between attacks
 - c. Chronic relapsing form with continuing hematologic abnormalities
 - d. Intermittent and persistent forms predominate in childhood
3. The classic form presents with:
 - a. Microangiopathic hemolytic anemia
 - b. Thrombocytopenia
 - c. Neurologic signs and symptoms
 - d. Fever
 - e. Renal alterations
 - f. Occurs in 20 to 40% of patients

Neurologic Manifestations

1. One third of patients do not have neurologic signs and symptoms at onset. Almost all have neurologic impairment during the course of the illness
2. Neurologic manifestations include:
 - a. Headache
 - b. Dizziness
 - c. Behavioral changes
 - d. Altered level of consciousness
 - e. Focal and generalized seizures
 - f. Focal cortical neurologic signs
 - g. Fluctuating neurological signs
3. Systemic manifestations include:
 - a. Hematuria and oliguria that may progress to renal failure
 - b. Purpura, petechiae and ecchymosis occur in approximately 1/3 of patients
 - c. Retinal hemorrhages
 - d. Epistaxis
 - e. Gingival, vaginal and gastrointestinal bleeding
4. Atypical presentation:
 - a. Acute abdominal pain
 - b. Pancreatic involvement
 - c. Peripheral digit ischemia

Neuropathology

1. Thrombosis of the microvessels of both gray and white matter
 - a. Cortical and subcortical infarction
2. Branch occlusions of the MCAs and PCAs; rarely the entire MCA artery is infarcted
3. Rarely ischemia is restricted to the brainstem or cerebellum
4. Rare supratentorial or brainstem hemorrhages are seen
5. ADAMTS-13
 - a. A metalloprotease and:
 - i. Disintegrin with a thrombospondin type I motif
 - ii. Deficient in the plasma with acute and relapsing TTP
 - iii. A failure of proteolysis of hyper adhesive and ultra large von Willebrand factor multimers in terminal arterioles and capillaries that cause:
 1. Adhesion and aggregation of platelets under high-flow, high-shear stress
 2. Platelet clumping and microvascular thrombosis in arterioles and capillaries but spare veins
6. Two types of TTP
 - a. Autoimmune type from antibodies that inhibit ADAMTS-13
 - b. Hereditary form from mutations of ADAMTS-13; chromosome 9q34
7. Most TTP adult patients:
 - a. Present with severe (<5% of ADAMTS-13 activity in the plasma) or moderate deficiency
 - i. These abnormalities have been seen in association with neutralizing IgG and IgM antibodies

8. Secondary TTP may occur with:

- a. Drugs
- b. Pregnancy
- c. Organ transplantation
- d. Infections
- e. Autoimmune diseases
- f. Cancer

*Neuroimaging**MRI*

1. Cerebral edema predominately in white matter more than gray
2. PRES appearance when lesions are predominate in the posterior parietal and occipital lobes
3. Increased or normal signal in ADC maps
4. Increased signal with t2-weighted and FLAIR sequences (in affected cortical and subcortical areas)
5. Large and small infarctions throughout the brain
6. Rarely petechial brainstem or supratentorial hemorrhages are noted

Laboratory Evaluation

1. Coomb-negative hemolytic anemia
2. Severe thrombocytopenia
 - a. Platelet count <20,000 mm³
3. Red blood cell fragmentation on peripheral blood smear
 - a. Anisocytes
 - b. Poikilocytes
 - c. Schistocytes
4. Increased lactic dehydrogenase levels in the serum
5. In approximately 50% of TTP patients creatinine and blood urea nitrogen are elevated
6. Gingival biopsy:
 - a. Hyaline thrombi in 50% of patients

*Kawasaki Disease**Overview*

Kawasaki disease is a self-limited, necrotizing pan vasculitis that affects all vessels but primarily the coronary arteries.

Clinical Manifestations

1. Systemic panvasculitis of medium-sized blood vessels
2. Cerebrovascular disease includes ischemic stroke, Moyamoya disease and subdural hemorrhage
3. Coronary artery but no cerebral aneurysms

Systemic Manifestations

1. Fever, conjunctivitis erythematous lesions of the palms and soles, painful swelling of extremities and acute cervical adenopathy. Coronary artery aneurysms are noted

*Sweet's Syndrome**Overview*

Sweet's syndrome is an acute febrile neutrophil dermatosis. It is characterized by tender red inflammatory nodules and occurs with infection, malignancy, connective tissue disease and drug exposure.

General Characteristics

1. Etiology:
 - a. Idiopathic
 - b. Para-inflammatory
 - c. Drug exposure related
 - d. Pregnancy related
2. Granulocytic growth factor appears pivotal
3. Mucosal Sweet's syndrome suggests an underlying malignancy
4. Cerebrovascular manifestations are rare and include vasculitis-like small vessel involvement. Cytokines have an etiologic role

Vasculopathy**Overview**

The term vasculopathy as used for this section denotes an abnormality of the vascular wall that predisposes to occlusion, emboli, hemorrhage or compression of neighboring structures. They most frequently occur in younger patients and are a significant component of the differential diagnosis of stroke in the young. The following is a description of the major vasculopathies and their differential diagnosis.

Differential Diagnosis of Vasculopathy

1. Antiphospholipid syndrome
2. Recanalization of atherosclerotic emboli
3. Fibromuscular dysplasia
4. Thrombotic thrombocytopenia purpura
5. Sarcoid
6. Neurofibromatosis 1
7. Tuberous sclerosis
8. SLE
9. X-RT (irradiation treatment)
10. Pseudoxanthomata elastica (PXE)
11. Marfan's disease
12. Medial cystic necrosis
13. Cerebral arterial ectasia and dolichoectasia
14. Congophilic amyloid angiography
15. PHACES
16. VZV
17. Sickle Cell disease

Cerebral Amyloid Angiopathy (Congophilic Angiopathy)**General Characteristics**

1. Increase of E2/E4 alleles
2. Amyloid AB 39–43 amino acids
 - a. Usual vascular amyloid 39–40 aa
3. Younger at first hemorrhage
4. Rare association with isolated cerebral angiitis

Genetics

1. Groups Affected:

- a. Hereditary cerebral amyloidosis (Dutch); Icelandic
- b. Chromosome 21 p11
- c. APP gene (amyloid precursor protein) gene
- d. Clinical manifestations:
 - i. Ocular vessels involved
 - ii. Leptomeningeal deposits of amyloid
 - iii. Lobar hemorrhages
- e. Icelandic
 - i. Cystatin C gene (chromosome 21 p11)

Clinical Manifestations

1. Cerebral hemorrhages
 - a. Multiple
 - b. Superficial
 - c. Subcortical lobar
 - d. Recurrent
2. Rare TIA
3. Multiple infarcts
4. SAH
5. Leukoencephalopathy
 - a. Concomitant multiple infarcts
 - b. Clinically similar to Binswanger microangiopathy
6. Dementing illness from:
 - a. Concomitant multiple infarcts
 - b. Alzheimer's pathology

Imaging Evaluation

1. Gradient ECHO MRI
 - a. Demonstrates old hemorrhages (residual hemosiderin)

Recanalization of Embolus with Thrombus

1. Embolus:
 - a. Fragments and moves distally
 - b. Movement occurs most often in the first 48 hours
2. Recanalization of a thrombosed intracranial artery:
 - a. Evident by 14–21 days
 - b. Irregular vascular wall of the affected vessel

System Lupus Erythematosus**General Features**

1. Cardiac:
 - a. Luminal narrowing from:
 - i. Sub-endothelia accumulation of immunoglobulins and complement components
 - ii. Activated platelets
 1. Express adhesion molecules that interact with endothelial cells and leukocytes
 - iii. Small arteries and arterioles are primarily affected
 - b. Chilblain Lupus:
 - i. Cutaneous lupus; bluish-red infiltrate in acral body locations
 - ii. Affects middle aged women primarily
 - iii. Mutation in the TREX 1 gene that encodes:
 1. 3–5 repair exonuclease 1

- iv. 20% develop systemic SLE
- v. Associated cerebral vasculopathy with ischemic stroke

Sickle Cell Disease (SCD)

General Features

1. SCD in adults
 - a. Thrombin antithrombin complexes (TAT) and D-dimer are correlated with a history of stroke and retinopathy
 - b. Chronic vasculopathy in adults is correlated with:
 - i. Stroke
 - ii. Silent infarcts
 - iii. Ischemic lesions in white matter and basal ganglia
 - c. Lung vasculopathy associated
 - d. Significant increase of thrombin generation and fibrin degradation products
2. Transcranial Doppler Evaluation
 - a. <170 cm/sec decreased risk
 - b. >200 cm/sec increased risk of stroke
3. Remodeling of the arterial wall leading to stenosis and occlusion of primarily small > large vessels

Varicella Zoster Viruses (VZV)

General Features

1. Early VZV infected arteries contain
 - a. CD4+ and CD8+ T-cells
 - b. Macrophages
 - c. Rare: B-cells and neutrophils
2. Perivascular inflammatory cells underlie areas of thickened intima (suggestive that soluble factors are released)
 - a. Infection is initiated in the adventitia
 - b. Hypertrophic intima is composed of cells expressing smooth muscle actin
 - c. Decreased smooth muscle cells
3. Late VZV Infection:
 - a. Viral antigens, but not leukocytes (no inflammation) in the media
4. Ischemic Strokes are predominant with approximately 18% being multifocal
 - a. Usually in the carotid artery 2 weeks following the rash in V₁
 - b. Some hemorrhagic multifocal strokes

Posterior Fossa Malformations, Hemangiomas, Arterial Malformations, Cardiac Defects, Eye Abnormalities and Sternal Cleft Syndrome (PHACES Syndrome)

General Features

1. A significant number of children with a facial hemangioma have PHACES syndrome
2. Posterior fossa malformations
3. Facial hemangiomas
4. Arterial cerebrovascular malformations
5. Cardiovascular anomalies

6. Eye abnormalities
7. Sternal clefting or supraumbilical raphe
8. Rare that all features occur in one patient
9. Abnormal neural crest migration is the putative cause
10. Female to male predilection of 9:1
11. A childhood disease but does occur in adults
 - a. ischemic stroke usually occurs prior to one year of age

Neuropathology

Cerebrovascular Features

1. Dysplasia of large cerebral arteries
2. Arterial stenosis or occlusion with or without Moyamoya collaterals
3. Absence or moderate to severe hypoplasia of the large cerebral arteries
4. Persistence of embryonic arteries and arrest of normal vasculature development
5. Vascular abnormalities often are ipsilateral to the cutaneous hemangiomas; may be bilateral

Categories of Arterial Anomalies

1. Dysplasia
2. Narrowing
3. Aberrant course or origin
4. Persistence of embryonic anastomosis
5. Progressive vasculopathy
 - a. Putatively related to the proliferative phase of hemangioma evolution

Imaging Evaluation

1. Agenesis of cervical carotid arteries
2. Persistent embryological vessels
3. Arterial stenosis
4. Dolichoectasia of intracranial arteries

Erdheim-Gesell Disease (Medial Cystic Necrosis)

General Characteristics

1. Medial cystic necrosis

Clinical Features

1. Spontaneous arterial dissection

Pathology

1. Necrosis of smooth muscle of the lamina media

Fibromuscular Dysplasia (FMD)

General Characteristics

1. Affects systemic arteries:
 - a. Renal arteries are affected with consequent hypertension
2. May involve the entire arterial wall
3. Incidence of 6% in selected arteriograms
4. Most common in middle aged women
5. Bilateral ICA involved in 86% of patients

6. Spares the carotid bifurcation:
 - a. Most common in the pharyngeal carotid artery
 - b. Spares the in the intracranial carotid artery
7. 20% of patients have concomitant extracranial vertebral artery involvement (ECVA)
8. The media is most often involved
 - a. Constricting bands (MRA; arteriogram)
 - b. Proliferation of smooth muscle cells that alternate with media thinning and disruption of the elastic membrane
 - c. Hypertrophy of fibrous tissue leads to focal stenosis
 - d. Band-like diaphragms within enlarged carotid bulb (mega bulbs)
 - i. Embolic source
 - e. Affects medium-sized muscular intracranial arteries
9. Associations:
 - a. Aneurysms of intracranial arteries
 - b. Arterial dissections

Clinical Features

Neurological Manifestations of FMD

1. TIA
2. Embolus
3. Stroke
4. Dissection
5. Horner's syndrome
6. Headache
7. Syncope
8. Intracranial hemorrhage
 - a. Renal hypertension
9. Neurological complications of dissection
10. Stroke recurrence is rare
11. Internal carotid involvement
 - a. Periorbital pain

Neurofibromatosis Type I

General Characteristics

1. Vasculopathy in the setting of other general manifestations of the disease
2. May also overlap with tuberous sclerosis that also demonstrates arteriopathy
3. Dilated vascular wall
4. Rarely causes stroke

X-Ray Therapy (X-RT)

General Characteristics

1. Occurs following >3000 rads delivered to the arterial wall
2. Carotid artery involvement most frequent after the irradiation of:
 - i. Pharyngeal tumors
 - ii. Hodgkin's and other lymphomas
 - iii. Little soft tissue mass to protect the artery in the neck
3. Characteristics of bifurcation atherosclerosis
4. Arterial calcification

Clinical Features

1. TIA in the carotid and MCA territory
2. Stroke in similar distributions from
 - a. Embolic
 - b. Thrombotic
 - c. Distal field ischemia

Pathology

1. Long segments of arteries are involved; frequently calcify
2. Dose dependent endothelial apoptosis
3. Vascular rarefaction
4. Disruption of the BBB
5. Thickening of vascular basement membranes

Tuberous Sclerosis Complex (TSC)

General Features

1. Arteriopathy is usually asymptomatic
2. May overlap syndromically with NF Type I
 - a. Gaps in the internal elastic membrane
 - b. Decrease in the muscularis layer
 - c. Fibrotic arterial segments
 - d. Elastic tumor degeneration

Clinical Features

Cerebrovascular Manifestations

1. Ischemic changes in territory of the affected vessels
2. Emboli from thrombi in ectatic aneurysms
3. SAH (rare) from ruptured aneurysms
4. Dolichoectasia

Cerebral Arterial Ectasia

General Characteristics

1. May be seen in children
2. Often involves several arteries
3. Familial tendencies noted:
 - a. One family with alpha-glucosidase deficiency
4. If severe the condition is known as dolichoectasia
5. Most frequent location:
 - a. Posterior fossa
 - b. Basilar and vertebral artery
 - c. Middle cerebral artery
 - d. Both anterior and posterior circulations may be involved concomitantly

Clinical Features

1. Spasticity (ventral pontine compression)
2. Dysarthria (XIIth nerve compression)
3. Hydrocephalus (pressure on the IIIrd ventricle); obliterates the prepontine cistern
4. Ischemia in the distribution of the affected arteries:
 - a. Emboli from thrombi in ectatic aneurysms
 - b. Plaque or clot obstruction in penetrating arteries
 - c. Rare rupture of aneurysms with SAH
 - d. Distortion and elongation of arteries cause reduced blood flow

Pathology

1. Gaps in the internal elastic lamina
2. Decrease in the muscularis layer
3. Fibrotic arterial segments
4. Elastic tissue degeneration and increase in the vasa vasorum

Imaging Evaluation

1. CT, MRA > MRI are diagnostic
 - a. Reveals dilated, enlarged tortuous vessels
2. Transcranial Doppler Evaluation:
 - a. Reduced mean-flow velocities
 - b. Preserved peak-flow velocities
 - c. Reduced antegrade flow
 - i. To and fro movement within the dilated vessel

Familial Occipital Calcification*General Characteristics*

1. Late onset of dementia
2. Patchy leukoencephalopathy
3. Intracerebral hemorrhages
4. Bilateral occipital calcifications
5. External carotid artery dysplasia

Clinical Features

1. Late onset dementia
2. Intracerebral hemorrhage
3. Probable AD inheritance
4. Ischemic stroke

Pathology

1. Skin biopsy:
 - a. Multilayered round shaped calcifications in the basal lamina of capillaries
 - b. Capillary vasculopathy

Imaging Evaluation

1. Fine tram tracking bilateral occipital calcifications
2. Severe leukoencephalopathy
3. Bilateral external carotid dysplasia

Oculo Meningeal Amyloid*General Features*

1. Primary uveal veil (vitreous)
2. SAH with secondary vasospasm and stroke
3. Thickened dura
4. Acquired factor V deficiency

Vasoconstriction Syndromes and Stroke**Migraine/Pre-Eclampsia/Eclampsia/RVCS***Overview*

Migraine headache and vasoconstriction following subarachnoid hemorrhage are the two most common causes of cere-

bral artery vasoconstriction and consequent stroke. During migraine headache there may be demonstrated arteriographic vasoconstriction, a reduced cerebral blood flow and increased velocity measurement by TCD. 18F-2-deoxy-D-glucose (18FDG) PET studies have also demonstrated a spreading posterior to anterior oligemia often preceding change in blood vessel diameter. This spreading cortical depression of metabolic activity with consequent lessened production of H^+ from decreased production of lactic acid may also cause vasoconstriction. The DRASIC receptor (along with other vasoactive agents) on cerebral blood vessels interacts with H^+ to dilate the vessel. This autoregulation with a match between the local cerebral metabolic rates for glucose (LCMRglu) and the local cerebral blood flow (LCBF) may determine the caliber of cerebral blood vessels during migraine attacks. The locus coeruleus (norepinephrine) may contract proximal cerebral blood vessels whereas out flow from the superior nucleus salivatorius may dilate cerebral blood vessels during a migraine attack. The relationship between spreading depression and cerebral blood flow has not been fully elucidated. Migraine has been associated with severe intense vasoconstriction with infarction. Vasoconstriction in migraine may be associated with ICH and arterial dissection.

Reversible cerebral segmental vasoconstriction usually affects young women following delivery, but may also occur during menopause. It may occur after carotid endarterectomy and involves large, medium and small vessels. There are focal regions of vasodilation and vasoconstriction.

Vasoconstriction following subarachnoid hemorrhage is a major cause of death and morbidity from this event. It is most often seen at 4–7 days following the bleed and is correlated with the amount of blood surrounding the affected vessels. Mechanisms and characteristics will be discussed in the section on subarachnoid hemorrhage from aneurysms. Pre-eclampsia and eclampsia are major etiologies of cerebral vasospasm.

Migraine and Stroke*General Characteristics*

1. Higher prevalence of stroke occurs in migraineurs particularly those with aura (3 times the risk) and young women
2. Definition of a migraine stroke:
 - a. Occurs in a patient with migraine and aura
 - b. The aura persists for more than one hour
 - c. Neuroimaging reveals a deficit concomitant with the clinical symptoms and signs

Migraine and Associated Medical Conditions

1. Inherited disorders:
 - a. CADASIL
 - b. MELAS
 - c. Channelopathies
2. Connective tissue disorders
 - a. SLE is prominent

3. Dissection of the carotid and vertebral arteries (migraine may also predispose to dissection)
4. Arteriovenous malformations
5. Rare in cavernous hemangioma
6. Glioma
7. Patent foramen ovale
8. Mitral valve prolapse
9. Drugs of abuse (cocaine and sympathomimetic)
10. Antiphospholipid syndrome
11. Prosthetic heart valves

Clinical Manifestations

1. Transient global amnesia (TGA):
 - a. Higher prevalence of TGA in migraineurs
 - b. Migraine may occur with the amnesic event
2. Bartleson syndrome:
 - a. Occurs primarily in young men
 - b. Severe headache with focal neurologic signs
 - c. Clustered attacks similar to migrainous aura
 - d. Maybe associated with fever
 - e. Episodes may last for 6 to 12 weeks
 - f. CSF lymphocytic pleocytosis (greater than 100 lymphocytes/mm³ with an elevated protein; no autoimmune markers; no glucose depression or infectious etiology)
 - g. MRI is usually normal but infarctions have been seen

Late Stroke-Like Migraine After Radiation Therapy (SMART)

1. May occur several years after XRT:
 - a. Therapy usually was prolonged
 - b. The whole brain was irradiated
2. The migraine is prolonged and often preceded by auras
3. MRI demonstrates diffuse cortical enhancement
4. No correlation with radiation dose, tumor type or chemotherapy

Intracranial Hemorrhage After Migraine

1. Severe prolonged migraine
2. Reperfusion hemorrhage in formerly ischemic areas

Neuropathology

1. Silent brain infarction:
 - a. Increased prevalence of silent infarcts in migraineurs
 - b. Putative mechanism is spreading depression
 - c. Women with migraines have a higher prevalence of silent deep white matter lesions that may be small infarcts
2. Migraine is associated with edema of vascular walls:
 - a. Susceptibility for arterial dissection (putative)
3. Cortical spreading depression:
 - a. Pivotal mechanism for aura
 - b. Causes vasoconstriction, decreased cerebral blood flow and activation of the endothelium
 - c. Endothelial activation:
 - i. Initiates the clotting cascade
 - ii. Platelet aggregation
4. Bilateral hypoperfusion may occur during a migraine without aura

Neuroimaging

MRI

1. White matter abnormalities (WMA):
 - a. Higher incidence of WMAs are seen in migraineurs with subclinical hyperthyroidism and hypothyroidism and elevated homocysteine levels
 - b. Infarct-like lesions (ILLs):
 - i. Preferentially localized in the cerebellum and deep gray matter
2. Volumetric changes in gray matter and white matter:
 - a. Sites of volume loss include:
 - i. Bilateral insula
 - ii. Frontal, prefrontal, temporal, parietal and occipital cortices
 - iii. Anterior cingulate gyrus
 - iv. Basal ganglia
 - v. Cerebellum
 - b. Sites of volume gain:
 - i. Dorsolateral pons
 - ii. PAG

Differential Diagnosis

Differential Points Between Migraine and Ischemic Stroke

Migraine

1. Several modalities are involved sequentially in migraine
 - a. Vision, parietal, sensory, motor, speech
 - i. Several modalities are involved concomitantly in stroke
 - ii. Negative symptoms predominate in stroke
2. Symptoms tend to be positive in migraine:
 - a. Scintillating scotoma
 - b. Paresthesia
 - c. Teichopsia
 - d. Brightness in a visual field (VF)
3. Positive symptoms followed by negative symptoms occur in migraine
4. Headache follows neurologic symptoms by 10 to 15 minutes in migraine
 - a. Rarely headache precedes symptoms
5. Average attack lasts 20 minutes in migraine (neurologic manifestations)
6. Migraine occurs more often in women than men
7. Attacks last over the lifetime of the patient
 - a. Acephalgic form of migraine occurs more frequently in older patients
8. May not have atheromatous risk factors in migraine

Ischemic Symptoms

1. Several modalities are involved concomitantly (motor/sensory/speech)
2. Negative symptoms predominate
3. Headache concomitant with the deficit
4. Small white platelet fibrin emboli cause deficits for less than 2 minutes; large emboli (red; primarily of cardiac origin) cause a deficit for greater than 5 minutes
5. Occurs more in men than women
6. Clear atherosclerotic risk factors

Reversible Cerebrovascular Constriction Syndrome*General Characteristics*

1. A collective term for transient non-inflammatory, non-atherosclerotic segmental constriction of cerebral arteries
2. Transient condition (relatively good prognosis)
3. Angiographic mimic of vasculitis
4. Presentation usually is severe headache, delirium, seizure or cerebral ischemia and/or hemorrhage
5. Possible mechanism is alteration in vascular tone

Clinical Manifestations

1. Affect women more than men; peak incidence is between 20–50 years; children also affected
2. Sudden severe headache ('thunderclap'):
 - a. Reaches maximally intensity instantly
 - b. Occipital or diffuse
 - c. Severe and throbbing
 - d. May also be accompanied by nausea, vomiting and photophobia
 - e. May persist or recur for days or weeks then gradually decrease
 - f. May occur spontaneously or be precipitated by exercise or valsalva maneuvers
 - g. May have migraine and depression history; may develop migraine after the headache onset
3. Precipitants:
 - a. Pregnancy and the puerperium
 - b. Sympathomimetic drugs/drugs of abuse
 - c. Blood products
 - d. Head trauma
 - e. Neurosurgical procedures
 - f. Emotional episodes
 - g. Immunosuppressants
 - h. Chemotherapeutic agents
4. Blood pressure may be normal or mildly elevated
5. Cerebral vascular manifestations:
 - a. Focal neurologic deficits depending upon the ischemic territory and affected artery
 - b. Brain hemorrhage (ICH)
 - c. Sulcal subarachnoid hemorrhage
 - d. Focal or generalized seizures from the ischemic cortex
 - e. Neurological deficits:
 - i. Occur during the first few days
 - ii. In parieto-occipital lobes
 - iii. Borderline arterial territories
 - iv. Visual dysfunction is frequent:
 1. Bálint's syndrome
 2. Cortical blindness (Anton's syndrome)
 3. Scotoma and flashing lights
6. Other signs and symptoms reported are:
 - a. Apraxia
 - b. Dysarthria
 - c. Aphasia
 - d. Ataxia

- e. Hemiparesis
7. Severe attacks rarely cause death
8. Benign CSF analysis

Neuropathology

1. Disturbance in the control of cerebrovascular tone
2. Migrainous vasospasms
3. Abnormalities of catecholamines, nitric oxide, endothelium, serotonin and calcium metabolism
4. Hormonal changes during pregnancy
5. Medium-sized cerebral arteries are involved and demonstrate segmental narrowing and vasodilatation
6. Putative mechanism of cerebral hemorrhage:
 - a. Ischemia – reperfusion
 - b. Rupture of cortical vessels due to sudden hypertension and dysfunctional autoregulation
7. Rarely the extracranial carotid can be occluded from vasoconstriction
8. Rare unruptured cerebral aneurysms (most probably incidental)
9. Complete or near complete reversibility of the vasoconstriction by 3 months

*Neuroimaging***MRI and CT**

1. Approximately 1/3 of patients have negative CT and MRI evaluations in the face of segmental narrowing by arteriography (opposite of cerebral vasculitis)
2. MRI and CT evaluations:
 - a. Bi-hemispheric symmetric infarcts in arterial border zone territories
 - b. Ischemic lesions are often crescentic or horseshoe shaped
 - c. Wedge shaped lesions with severe ischemia
 - d. FLAIR images on MRI reveal:
 - i. Dot-shaped or linear hyperintensities on the cortical surface
3. One third of patients suffer ICH:
 - a. Cortical sulcal SAH
 - b. ICH often in hypertensive areas
4. ICH's tend to occur early and infarcts in the second week after onset of the headache

Angiography

1. Demonstrates segmental cerebral artery vasoconstriction; the diagnosis is confirmed with:
 - a. Reversibility of the angiographic abnormalities within 12 weeks after onset
 - b. Autopsy rules out:
 - i. Vasculitis
 - ii. Intracranial atherosclerosis
 - iii. Aneurysmal subarachnoid hemorrhage

Transcranial Doppler

1. Blood flow through the brain: velocities almost always elevated at onset

*Laboratory Evaluation***CSF**

1. Has been found to be normal in 80% of patients
2. 95% of patients had cell counts of $<10/\text{mm}^3$; protein levels $<80 \text{ mg/dl}$

Blood

1. Useful blood test to rule out alternate diagnosis include:
 - a. ESR, rheumatoid factor, anti-nuclear and anti-neutrophil cytoplasmic antibody titers
 - b. 5-hydroxyindoleacetic acid levels
 - c. Serum calcium and parathyroid levels
 - i. Hypercalcemia may cause cerebral vasoconstriction

Urine

1. Vanillylmandelic acid to rule out pheochromocytoma

*Differential Diagnosis***Differential Diagnosis of Thunderclap Headache**

1. SAH (depressed consciousness/neck stiffness)
2. Embolus (focal signs)
3. ICH (focal signs, vomiting)
4. Arterial dissection (neck/occipital pain for vertebral artery; face pain and Horner's syndrome for the carotid)
5. Viral meningitis (stiff neck; consciousness preserved)
6. Spontaneous intracranial hypotension (exacerbated by standing)
7. Pituitary apoplexy (pain infrabrow area; cranial nerve III and VI involvement)
8. Cerebral venous thrombosis (seizures in one leg; papilledema)
9. Migraine (past history, phono and photophobia, nausea)

Differential Diagnosis of Reversible Cerebral Vasoconstriction Syndrome

1. Migraine
2. Intracranial atherosclerosis
3. Infectious arteritis
4. Fibromuscular dysplasia
5. Autoimmune vasculitis
6. Subarachnoid hemorrhage (vasoconstriction in 4–11 days)

Differential of RCVS from Primary Angiitis of the CNS (PACNS)

1. Headache and neurologic signs and symptoms may be similar
2. PACNS:
 - a. Headache:
 - i. Dull; insidious progression
 - b. Cognitive deficits
 - c. Multifocal infarction of gray and white matter
 - d. Abnormal CSF

Differential Diagnosis of RCVS from Posterior Reversible Encephalopathy Syndrome (PRES)

1. Associated conditions of eclampsia, immunosuppressant drugs, hypertensive encephalopathy and porphyria (RCVS)

2. Headache in PRES not as explosive as noted in RCVS
3. Visual symptoms often prominent in PRES
4. Gray and white lesions on MRI; rarely are the lesions in the frontal and parietal lobe, cerebellum or the brainstem in PRES
5. Negative angiographic pattern in PRES

Eclampsia*General Characteristics*

1. New onset of hypertension ($>140/90 \text{ mmHg}$) and proteinuria >20 weeks of gestation
2. Eclampsia:
 - a. Life threatening; severe proteinuria and hypertension complicated by:
 - i. Generalized seizure
 - ii. Depressed consciousness
 - iii. Visual dysfunction to blindness
 - iv. Occurs in a pre-eclamptic patient
3. Severe pre-eclampsia and eclampsia may be complicated by:
 - a. HELLP syndrome that includes:
 - i. Hemolysis
 - ii. Elevated liver enzymes
 - iii. Low platelet count
 - iv. Occurs in about 20% of severely pre-eclamptic women
 - v. Poor prognosis for the pregnancy
 - b. HELLP syndrome associated with:
 - i. DIC
 - ii. Abruptio placentae
 - iii. Acute renal failure
 - iv. Hepatic failure
 - v. Pulmonary edema
 - vi. Cerebral edema
 - vii. Stroke
 - c. Develops in the 3rd trimester or 48 hours after delivery; delayed post-partum eclampsia has similar symptoms but occurs >48 hours (usually within 1 week)
 - d. Incidence of pre-eclampsia in the US is approximately 5–10% of pregnancies; mortality is 2–5/100 patients
 - e. Occurs more frequently in women with chronic hypertension, renal disease, diabetes and antiphospholipid antibodies

Risk Factors

1. First pregnancy
2. Pre-eclampsia in past pregnancies
3. Family history of pre-eclampsia
4. Malnutrition
5. Women older than 35
6. BMI greater than 35
7. Elevated C-reactive protein
8. Elevated homocysteine
9. African-American ethnicity
10. Multiple pregnancies

Putative Genes

1. ACVR2A
2. STOX 1

Putative Biomarkers

1. Neutrophil gelatinase associated lipocalin (NGAL)

Clinical Manifestations

1. Most patients with pre-eclampsia are asymptomatic

Neurologic Symptoms of Pre-Eclampsia

1. Headache
2. Photophobia
3. Depressed consciousness
4. Scotoma
5. Eclampsia is diagnosed after progression that includes:
 - a. Pulmonary edema, kidney and liver failure, abruptio placentae, DIC, HELLP syndrome, elevated uric acid, decreased platelets and thrombin III
 - b. Seizures, stroke, posterior reversible leukoencephalopathy (PRES)

Cerebral Vasculature Disease and Severe Pre-Eclampsia/Eclampsia (SPE/E)**General Characteristics**

1. The most common cause of stroke in pregnancy is eclampsia:
2. In severe pre-eclampsia/eclampsia (SPE/E):
 - a. 24–47% of patients have ischemic stroke
 - b. ICH occur in 14–47% of patients
 - c. Brain hemorrhage is the major cause of morbidity and mortality in SPE/E

Clinical Manifestations

1. Headache
2. Agitation and cognitive dysfunction
3. Visual hallucination to cortical blindness
4. Bálint's syndrome
5. Gerstmann's syndrome (rare)
6. Hemianopia (rare)
7. Motor signs and ataxia (not severe)
8. Encephalopathy similar to hypertensive crisis
9. Most often reversible with treatment

Visual Symptoms with SPE/E

1. Cortical blindness (Anton's syndrome):
 - a. Normal pupillary reaction to light
 - b. Confabulation of vision; patient is blind but confabulates that he can see objects
 - c. Failure to follow optico-kinetic stimuli
 - d. May have slight peripheral visual spared so that he can walk in a room without hitting furniture
 - e. May be euphoric
2. Visual complaints occur concordantly with headache, nausea and seizures

3. Rarely Bálint's syndrome occurs:

- a. Optic apraxia with under reaching
- b. Poor visual scanning
- c. Inability to voluntarily break fixation

4. Simultagnosia

- a. Inability to integrate parts of an object into a whole; patient can see eyes, mouth and nose but can't integrate the parts to see a face

5. Alexia

6. Homonymous hemianopsia

7. Most patients have complete visual recovery

8. Peripheral visual loss can occur from choroidal infarction with serous retinal detachment and optic nerve ischemia and infarction

Neuropathology

1. Capillary leak syndrome (endothelial damage of cerebral blood vessels) causing vasogenic edema
2. Small hemorrhage and microinfarction (0.3–1. Mm):
 - a. Scattered throughout the cerebral cortex asymmetrically
 - b. Arterial border zone proclivity
 - c. Occipital > parietal > frontal lobes; rarely the cerebellum is involved
3. Subcortical hemorrhages:
 - a. 2–6 mm in size
 - b. Deep white matter, basal ganglia and brainstem topology
4. Large intraparenchymal hemorrhages in hypertensive distribution
5. Congested capillaries with surrounding hemorrhage
6. Small cerebral blood vessels may demonstrate:
 - a. Fibrinoid necrosis
 - b. Occlusive fibrin thrombi

General Placental Pathology

1. Placental pathology is causative of eclampsia
 - a. Removal of the placenta cures the disease
2. Cytotrophoblasts invade maternal spiral arterioles
 - a. Transforms these resistance vessels to larger conducting vessels
 - b. Cytotrophoblasts differentiate from an epithelial to an endothelial phenotype (pseudo-vasculogenesis)
 - c. The process requires growth factors and cytokines
 - d. Failure of the epithelia to endothelial phenotypic switch allows spiral arterioles to remain as resistance vessels and causes:
 - i. Defective uteroplacental circulation and decreased placental perfusion
 - ii. The placenta becomes hypoxic within the intervillous space that leads to oxidative stress, apoptosis, endothelial dysfunction and an inflammatory response
 - e. Angiogenic factors direct the regulation of placental vascular development. They include:

- i. Soluble Fms-like tyrosine kinase-1 (sFlt-1)
- ii. VEGF-1 and 2 (vascular endothelial growth factors)
- iii. Placental growth factor (PlGF)
- f. The disruption of the interplay of these factors leads to loss of the endothelial control of vascular development that causes:
 - i. Hypertension
 - ii. Increased vascular permeability
 - iii. Disturbed endothelial expression of coagulation factors and coagulopathy
- g. Placenta may also be the source of circulating inflammatory cytokines that are systemically deleterious

Putative Mechanisms

1. Hypertension with a decrease of cerebral autoregulation primarily in the occipital lobe (less sympathetic innervation to posterior cerebral arteries)
 - a. May also occur in other cortical lobes and the brainstem

Laboratory Evaluation

Biomarkers

1. Angiogenic factors for the development of the placental vascular system
 - a. VEGF and PlGF:
 - i. Decrease of VEGF seen in pre-eclamptic patients due to an increase of its soluble receptor – receptor Flt-1 (VEGFR-1)
 1. Neutralizes both VEGFs and PlGF
 - b. A rise in Flt-1
 - c. Endoglin:
 - i. Transmembrane glycoprotein
 - ii. Co-receptor for transforming growth factors which regulate angiogenesis and vascular tone
 - iii. S-endoglin (sEng) is an anti-angiogenic factor:
 1. Blocks binding of TGFβ1 to its receptor
 2. Decreases nitric oxide vasodilatation and capillary formation by endothelial cells
 3. sEng increases with pre-eclampsia
 - d. Placental protein 13 (PP-13):
 - i. Important in placenta implantation and remodeling of maternal arteries
 - ii. Increases with pre-eclampsia
 - e. Neutrophil gelatinase associated lipocalin (NGAL)
 - i. Upregulated in damaged epithelial cells, during inflammation, renal disease, CV disease
 - ii. Best and earliest marker of kidney disease

Neuroimaging

CT

1. Scan particularly useful in discriminating hemorrhage from ischemia or encephalopathy
2. White matter hypo densities that are often symmetric in:
 - a. Cerebral cortex
 - b. Subcortical white matter

- c. Supratentorial deep gray nuclei
3. In patients with acute encephalopathy syndrome hemorrhages are predominately in the parietal and occipital lobes but spare:
 - a. Paramedian areas
 - b. Calcarine cortex
 - c. Peristriate areas

MRI

1. Abnormal in 48–100% of patients and include:
 - a. Confluent or punctate lesions on T2-weighted sequences in:
 - i. Centrum semiovale
 - ii. Deep white matter of the posterior parietal and occipital lobes
 - iii. Gray-white junction
 - iv. External capsule
 - v. Basal ganglia
 - vi. Cerebellum (rare)
 - b. Occipital lobe is the predominant site but frontal, parietal and temporal lobes may be involved solely
 - c. Eclamptic patients demonstrate curvilinear lesions at the gray-white junction
 - d. MRI evaluation in pre-eclampsia patients:
 - i. May be present in white matter only
 - ii. Predominantly frontal and parietal areas rather than the gray-white junction
 - iii. No curvilinear topography of lesions
 - iv. PRES may be seen with eclampsia

Angiography

1. Vasoconstriction generally involves large arteries and circumferential branch arteries:
 - a. Constriction is usually multifocal but can be diffuse
 - b. Vasoconstricted segments can alternate with areas of vasodilation
 - c. Angiographic abnormalities are usually reversible

Transcranial Doppler Evaluation

1. Elevated blood flow velocity and lower average pulsatility index in eclampsia but not in pre-eclampsia

FDG-PET Evaluation

1. Decreased glucose metabolism in areas that demonstrated T2-signal abnormalities

Differential Diagnosis of Eclampsia

1. Dural sinus thrombosis:
 - a. More common in puerperium than during pregnancy
 - b. Not hypertensive
 - c. More focal neurologic exam
2. Reversible cerebral vasoconstriction syndrome:
 - a. Sudden severe ‘thunderclap’ headache
 - b. Seizures
 - c. Focal (not severe) neurologic deficits

- d. Angiographic multifocal vasoconstriction
- e. Less white matter involvement than SPE/E
- f. Not hypertensive
- 3. Cocaine
- 4. Sympathomimetic drugs
- 5. Benign cerebral vasculitis
- 6. Migraine
- 7. Post-partum angiopathy
- 8. Subarachnoid hemorrhage (aneurysm or malformation rupture)
- 9. Embolic stroke
- 10. Long chain-3-hydroxyacyl-coenzyme A dehydrogenase deficiency
- 11. SLE
- 12. Budd-Chiari syndrome
- 13. Hypertensive encephalopathy
- 14. Vasculitis

Vascular Wall and Vasculopathy

Diseases of the Arterial Wall

Overview

Dilatative arteriopathy comprises a group of hereditary and acquired pathologies that cause cerebral arteries to enlarge, dilate and develop tortuosity. The most severely affected vessels are the intracranial vertebral and basilar arteries although the carotid and middle cerebral arteries may also be involved. The most prominent genetic diseases that demonstrate the process of dolichoectasia are Marfan's syndrome, Ehlers-Danlos disease, fibromuscular dysplasia and Gesell-Erdheim disease. A far more common pathology with arterial wall involvement leading to cerebral vascular disease is congophilic angiopathy. Dissection of the arterial wall occurs with connective tissue disease and with prolonged hypertension and is primarily an arterial wall disease. These diseases are a prominent cause of both large and small vessel disease in both young and elderly patients.

Congophilic Angiopathy (CAA)

Overview

Cerebral amyloid angiopathy (CAA) is a heterogeneous group of biochemical and genetic disorders that demonstrate amyloid fibrils in the walls of small to medium-sized arterial blood vessels. In some conditions amyloid fibrils are found in capillaries of the CNS parenchyma and the leptomeninges.

Amyloid is composed of insoluble 8 to 10 nm wide fibrils formed from aggregation and polymerization of soluble circulating proteins. They are converted from a random-coil secondary structure into β -sheet conformations. Once these protofibrillar intermediate structures exceed a critical level high-ordered amyloid fibrils form. Amyloid is formed by proteolytic modifications of a larger precursor protein (amyloid

precursor protein (APP)) by β and γ secretases or processing by furin of mutated β R12 precursor protein. In this instance ABri or ADan amyloid proteins are produced that cause British (FBD) or familial Danish dementia (FDD).

Mechanisms that destabilize the secondary structure of soluble native proteins include:

1. Genetic modifications
2. Post-translational modifications
3. Low pH
4. Presence of metal ions

Other mechanisms that cause toxic misfolded proteins to form from naturally soluble proteins are:

1. Missense mutations in the coding region of genes that can change the rate of conversion of a native protein to a fibrillary conformer
2. "Pathologic chaperons" that co-deposit with different parenchymal or cerebrovascular amyloids

Clinical Manifestations

1. Amyloid deposition in blood vessel walls has been associated with:
 - a. Cognitive decline
 - b. Microhemorrhages (lobar primarily)
 - c. Alteration of cerebral microvascular tone and reactivity
 - d. CAA-related ischemia
 - e. CAA-angiitis

Neuropathology

1. Vessels affected by CAA
 - a. Cortical small and medium-sized arteries and arterioles
 - b. Veins
2. Predilection sites of CAA due to A β deposition are the occipital, parietal frontal and temporal lobes; medial temporal and hippocampal structures are spared
3. Cerebrovascular amyloid deposition is sequential:
 - a. It first appears around smooth muscle cells in the subluminal side of the tunica media and adventitia
 - b. Progresses through the intimal layers and replaces the smooth muscle
 - c. Degenerative changes follow with fibrous thickening of the vessel wall, microaneurysm formation and fibrinoid necrosis
 - d. Blood breakdown products accumulate around the affected vessels
 - e. A perivascular inflammatory response from the deposition of A β that includes:
 - i. Activated microglia and astrocytes
 - ii. Activation of the complement cascade
 - f. CAA-associated angiitis (from the perivascular inflammatory response) is associated with:
 - i. Adventitial and perivascular inflammation of lymphocytes and histiocytes
 - ii. Multinucleated giant cells
 - iii. A β phagocytosis
 - g. Microhemorrhages are seen with or without lobar hemorrhages due to weakening of the vessel wall from

the loss of smooth muscle and degenerative changes.

ApoE2 allele increases hemorrhage risk

- h. Cerebral infarctions and focal or diffuse white matter ischemic changes
 - i. $A\beta$ deposited in blood vessel walls:
 - j. Heterogeneous at both N and C termini
 - k. $A\beta$ 40 is usually predominant
 - l. $A\beta$ 42 is predominant in capillaries

Neuroimaging

MRI

1. Cerebral microhemorrhages
2. Cortical lobar hemorrhages
3. Small vessel infarctions
4. Diffuse leukoaraiosis of hemispheric white matter
5. Gradient ECHO (for microhemorrhage)
6. Superficial cortical siderosis

Dilatative Arteriopathy (Dolichoectasia)

General Characteristics

1. Dolichoectasia refers to enlarged, tortuous and dilated arteries
2. The dilatative process may form fusiform aneurysms
3. Dilatative arteriopathy preferentially involves the intracranial vertebral and basilar arteries although it does involve the carotid and middle cerebral arteries

Associated General Risk Factors

1. Older age
2. Male sex
3. Hypertension
 - a. Left ventricle hypertrophy
 - b. Dilated and pulsatile brachial arteries with prominent aortic notch pulsations
4. History of myocardial infarction
5. Increased diameter of the thoracic aorta

Clinical Manifestations

1. Distortion of brain structure by tortuous elongated arteries (particularly in the medulla and pons)
2. Stretching of cranial nerves upon their exit from the brainstem that causes:
 - a. "Tic douloureux" – Vth cranial nerve
 - b. Hemifacial spasm – VIIth cranial nerve
 - c. Vertigo/tinnitus – VIIIth cranial nerve
 - d. Torticollis – XIth cranial nerve
3. Hydrocephalus:
 - a. Compression of the IIIrd ventricle
4. Ataxia and motor weakness from compression of:
 - a. The brainstem
 - b. Middle cerebellar peduncle
 - c. Pontine tracts
 - d. Pyramidal tract
 - i. Tic douloureux

Neuropathology

1. Distortion of the orifices of arterial branches

2. Decreased blood flow of penetrating branches
 - a. Decreased blood flow velocities
 - b. Reduced antegrade flow
 - c. Increased contact factor-endothelial contact time that increases thrombus formation and emboli

3. Fusiform aneurysms

Histology

1. Intimal thickening
2. Deficiencies in the muscularis and internal elastic lamina
3. Areas of fibrosis
4. Elastic tissues degeneration
5. Increase in the vasa vasorum

Dolichoectasia in Specific Diseases

1. Marfan's syndrome (young patients)
2. Ehlers-Danlos syndrome
3. AIDS (children)
4. Fabry's disease
5. Sickle cell disease (children and adults)

Small Vessel Disease Features of Dolichoectasia

1. Lacunar infarction
2. Leukoaraiosis
3. Dilated Virchow-Robin spaces around penetrating arterioles ("état criblé")

Arterial Disease

1. Arterial media disease may be associated with up-regulation of metalloproteinases
2. Penetrating arterial disease and dilatative arteriopathy demonstrate:
 - a. Disease of the arterial wall rather than intimal endothelium
3. Penetrating arterial vessel pathology includes:
 - a. Increased amount of fibrinoid material and lipids
 - b. Abnormal connective tissue elements within the arterial wall affect matrix metalloproteinases which may alter the vascular permeability of the BBB

Neuroimaging

MRI

1. Enlarged, tortuous and dilated arteries most prominently affecting the vertebrobasilar system
2. Fusiform basilar artery aneurysms
3. Lacunar infarction, leukoaraiosis and enlarged Virchow-Robin spaces
4. Increased white matter hyperintensities

Fibromuscular Dysplasia

General Characteristics

1. Probably multitietologic; HLA association
2. May affect any cerebral somatic artery
3. Primarily affects medium-sized muscular arteries at specific sites:
 - a. Distal 2/3 of renal arteries

- b. Distal extracranial vertebral artery (adjacent to C2 vertebrae)
- c. Distal carotid artery with rare involvement of:
 - i. Cavernous carotid
 - ii. Arteries of the Circle of Willis

Clinical Manifestations

1. Most commonly affects Caucasian women in the 4th to 6th decades
2. Occurs in infants and children with involvement of:
 - a. Renal arteries that causes severe hypertension
 - b. Splanchnic arteries
 - c. Cervical-cranial vessels
3. Incidence of less than 1% of routine cerebral arteriograms
4. Associated with intracranial aneurysms and dissections
5. ICH from associated HCVD due to renal artery involvement (including dissection)
6. Spontaneous cervical and intracranial artery dissection
7. Male presentation described:
 - a. Abdominal pain
 - b. Systemic signs
 - c. Hypertension
8. Associated dissection of the coronary arteries occur
9. Subarachnoid hemorrhage from rupture of thin walled blood vessels
10. Arterial dissection with appropriate territorial infarction
11. A relatively benign condition
 - a. Few recurrent cerebrovascular episodes

Neuropathology

1. Fragmentation of the arterial media with rings of fibrous and muscular hyperplasia cause:
 - a. Saccular dilations of the artery
 - b. Arterial wall involvement:
 - i. Adventitial form:
 1. Narrowing of the vascular lumen by fibrous tissue hypertrophy that surrounds the artery
 - ii. Intimal form:
 1. An increase of the fibrous components of the intima
 - a. Concentric narrowing of the lumen
 - b. About 5% of patients
 - c. Children and adolescents are the most commonly affected
 - iii. Medial form:
 1. Most common form
 2. Constricting bands of fibrous dysplastic tissue and proliferating muscle cells in the media
 3. Alternating with areas of medial thinning (disruption of the elastic membrane)
 - a. Leads to luminal dilatation
 - b. "String of beads" arteriographic pattern

Neuroimaging

1. Bilateral ICA involvement is frequent
 - a. Pharyngeal component of the artery

- i. Level of C2 and spares the bifurcation and intracranial carotid artery
- ii. 20% of patients have concomitant involvement of the vertebral arteries
- b. Rare: intracranial FMD
- c. "String of beads" arterial lesions may be concurrent with tertiary constrictions and aneurysmal dilatation
- d. Shelf-like segmental stenosis from fibrous septa and webs
- e. Enlarged carotid bulbs

Aortic Medial Wall Abnormalities [Gsell-Erdheim]

General Characteristics

1. Ascending aorta may dilate in congenital heart disease
2. Aortic dilatation is well recognized in:
 - a. Marfan syndrome
 - b. Turner syndrome
 - c. Bicuspid aortic valve
 - d. Coarctation of the aorta
3. Congenital heart disease (CHD) and aortic medial abnormalities occur with:
 - a. Single ventricle
 - b. Persistent truncus arteriosus
 - c. Transposition of the great arteries
 - d. Hypoplastic left heart syndrome
 - e. Tetralogy of Fallot
4. The CHDs with aortic dilatation are associated with:
 - a. Decreased elasticity and stiffness of the aorta and cause
 - i. Increased afterload and ventricular hypertrophy

Clinical Manifestations

1. Aortic dissection
2. Coronary artery dissection
3. Carotid artery aneurysm
4. Giant aneurysm of the ascending aorta

Neuropathology

1. Cystic medial necrosis
2. Elastin fragmentation
3. Fibrosis
4. Media necrosis

Mechanisms of Structural Alteration of the Ascending Aorta Media

1. Systemic hypertension
 - a. Abnormalities of medial elastin and collagen
2. Aging
 - a. Parallel aortic elastic fibers fragment
 - b. Decrease of smooth muscle cells
3. Pregnancy
 - a. Elastic fiber fragmentation
 - b. Hypertrophy/hyperplasia of smooth muscle cells
4. Chromosome abnormalities
 - a. Marfan's syndrome
 - i. Defect of fibrillin-1; increased elastin

5. Gene abnormalities
 - a. Fibrillin-1 defect (15q 21.1)
 - b. Deletion of TGF-B receptor
 - c. ALK 5 (activin receptor-like kinase 5)
6. Medial smooth muscle apoptosis
7. Metalloproteinase and elastin up-regulation
8. Hemodynamic abnormality (increased aortic flow)
9. Intrinsic abnormalities of the aortic wall in congenital heart diseases

Neuroimaging

Arteriography

1. Coronary artery dissection
2. Enlargement of the aortic root
3. Aortic artery dissection

Radiation Induced Arterial Disease

General Characteristics

1. Delayed radiation-related strokes most often reported following X-RT for:
 - a. Leukemia
 - b. Hodgkin's disease
 - c. Brain tremors
2. Risk of stroke
 - a. Leukemia survivors: about 6%
 - b. Brain tumor: 29%
 - c. Hodgkin's disease: 83/100,000 patients
 - d. Increased in a dose-dependent manner
3. Major pathology in vascular injury; dependent upon:
 - a. Dose of irradiation
 - b. Location of irradiated nervous tissue – those areas with more surrounding tissue receive less dose
 - c. Order of vessel vulnerability:
 - i. Capillaries and sinusoids (most sensitive)
 - ii. Arterioles and small vessels
 - iii. Medium-sized vessels
 - iv. Large arteries (least sensitive)
 - d. Typical lesions are not in the usual areas for atherosclerosis
 - i. Often not at bifurcations
 - ii. Long arterial segments are involved

Neuropathology

1. Denudation of the endothelial layer
2. Infiltration of foam cells, histiocytes and fibroblasts
3. Collagen formation in the subendothelium
4. Myointimal proliferation and fibrosis
5. Calcification and adventitial fibrosis
6. Fragmentation of the internal and external elastic membranes; inflammatory changes
7. A proliferative small vessel endarteritis

Clinical Manifestations

1. Chronic dementing illness

- a. All systems may be involved (Parkinsonism, ataxia, corticospinal deficits, subcortical apraxia and cognitive slowing)
2. Moyamoya disease of basal arteries
 - a. Children and young adults are the most affected
 - b. Prevalent with NF1 and higher doses of X-RT
3. Focal brain infarcts and strokes
4. Spinal cord
 - a. Sulcal artery infarction with Brown-Séquard syndrome
 - b. Upper extremity parathesias (C5–C6)
 - c. Spastic paraparesis
 - d. Transient ischemia
 - e. Stroke
 - f. Intracranial vascular occlusive disease
5. Delayed symptoms
 - a. Months to years after X-RT
 - b. Mass lesions in the brain or spinal cord
 - c. Fibrinoid degeneration of blood vessels, coagulative necrosis and gliosis
6. Delayed dementia with focal signs
 - a. Brain atrophy and leukoencephalopathy
 - b. Diffuse loss of white matter
 - i. Some patients demonstrate enhancement of focal lesion

Neuroimaging

1. Acute radionecrosis presenting as a mass (MR spectroscopy demonstrates no lactic acid peak which distinguishes it from recurrent glioma)
2. Generalized atrophy and leukoencephalopathy
3. Long segment stenosis of extracranial vessels with calcification

Arterial Dissections

Cerebral Artery Dissections

Overview

1. Cervico-cephalic arterial dissection (CAD)
 - a. A heterogeneous group of arteriopathies that have an intramural hemorrhage
 - b. Affects extracranial arterial segments (88%)
 - i. ICA (58–75%)
 - ii. Vertebral artery (19–30%)
 - iii. Multiple arteries (16–28%)
 - c. Intracranial dissections occur in 12%
 - i. VA > carotid branches > basilar artery branches
2. There are 3 forms of dissection:
 - a. Stenotic (45–66%)
 - b. Occlusive (21–42%)
 - c. Aneurysmal (12–49%)
 - d. Combined stenosis and dissecting aneurysms
3. Multiple vessel dissections women > men
4. Dissections cause 2.5%* of all strokes (primarily by artery-to-artery embolism)
 - a. 10–20% of strokes in those <40 years

*Carotid Artery Dissection***General Characteristics**

1. Location
 - a. Pharyngeal portion
2. Above the bifurcation
 - a. Artery is mobile in this section
 - b. Involves redundant portion of the artery

Clinical Manifestations

1. Ipsilateral headache:
 - a. >65% of patients
 - b. Facial pain 34–53%; periorbital pain above the brow; periauricular pain
 - c. Neck pain (frequently along the sternocleidomastoid muscle)
 - d. In approximately 20% of patients all of these pains are concurrent
 - e. Rare bilateral, occipital or hemicranial pain
 - f. Pain may be progressive and develop later in the course of the illness
 - g. Throbbing, constrictive or pulsatile; rare thunder-clap headache
 - h. Pain as the only symptom occurs in 5% of patients
2. Pulsatile tinnitus in stenotic lesions (<20%); rare carotid bruit

Clinical Signs

1. Horner's syndrome (ischemia of the superior cervical ganglion (SCG) or of ocular sympathetic fibers that surround the carotid artery)
 - a. May occur at onset or later concurrently with stroke
2. Cranial palsies:
 - a. Involvement of branches of the meningeohypophyseal trunk from the cavernous portion of the carotid; cranial nerves III and IV most often involved
 - b. XII most commonly involved with compression by the carotid sheath. Accessory and vagal nerves may be involved; possible compression of the ascending pharyngeal artery
 - c. Dysgeusia (compression of the chorda tympani)
 - d. Compression and stretch of the nerves in the neck; ischemia of the peripheral vascular cranial nerve supply or compromise of the cranial nerves' vasa vasorum (small blood vessels that supply the nerves)
3. Ipsilateral partial Horner's syndrome:
 - a. Ptosis (not severe)
 - b. Meiosis (occasionally a dilated pupil is seen from iris ischemia)
 - c. Apparent enophthalmos (sympathetic denervation of Mueller's muscle and the sympathetic fibers in the tarsal plates)
 - d. Facial sweating intact (these sympathetic fibers follow the external carotid)
4. Pharyngeal carotid segment aneurysm:
 - a. Horner's syndrome (complete)

- b. Dysgeusia
- c. Tongue atrophy
 - i. Compression of the hypoglossal nerve in the carotid sheath
5. TIA affecting the ipsilateral eye and hemisphere (MCA territory)
 - a. If extremely frequent, they may be termed 'carotid al-legro'
 - b. Occurs in 15–29% of patients

Cerebral Ischemia

1. 82% of ischemic strokes occur within the first week:
 - a. 2/3 of ischemic strokes have a preceding TIA or amaurosis fugax
 - b. Artery-to-artery embolus rather than distal field ischemia is the major mechanism
 - c. Territorial infarct in the MCA distribution:
 - i. Rarely concomitant border zone infarction
 - ii. Concomitant ACA infarction 4% and PCA infarction in 2%
 - iii. Watershed infarction 3–15%

Ocular Ischemia

1. Amaurosis fugax occurs in approximately 30% of patients
2. Monocular scintillating scotoma or flashing lights
3. Retinal infarction is rare
4. Ischemic optic neuropathy:
 - a. Dissection reaches the carotid sinus
 - b. Often followed by a stroke; may be delayed for days to weeks
 - c. Symptoms caused by emboli or a distal cause of ischemia (hemodynamic) of the retina, choroid or optic nerve
 - d. Rare anterior or posterior ischemic optic neuropathy from severe stenosis or occlusion (slightly dilated, poorly reactive pupil from ciliary ganglion or iris ischemia)

Persistent Neck Pain

1. Suggests extension of the dissection
2. Vertebral and carotid dissection can occur concomitantly
 - a. Suggests underlying collagen defect
3. Asymptomatic internal carotid dissection
 - a. May occur simultaneously with symptomatic vertebral artery dissection
 - b. Concomitant contralateral ICAD

*Vertebral Artery Dissection***General Characteristics**

1. Precipitating factors:
 - a. Neck trauma (often rotational at C1–C2)
 - b. Chiropractic manipulation
 - i. Patients frequently go to the chiropractor because of neck pain
 - ii. Further manipulation extends the dissection

- c. Maintenance of the neck in a fixed posture
 - i. Prolonged surgical procedures
 - ii. Following intubation and resuscitation
- d. Cervical fractures (C2 – transcervical canal compromise)

Clinical Manifestations

1. Posterior headache or neck pain occurs in 88% of patients (innervated by C2–C4; posterior auricular nerve)
 - a. Ipsilateral to the dissection: occasionally the pain is bilateral, frontal or generalized
 - b. Steady or pulsatile quality
 - c. Headache and neck pain may be the only symptom
 - d. Intracranial extension or primary intracranial VAD may be associated with:
 - i. SAH (sudden onset; great intensity)
 1. Rare spinal SAH with severe neck and back pain
2. C5–C6 root irritation (rare)
3. Rarely causes brainstem compression

Cerebral Vascular Features of VAD

1. Primarily posterior circulation signs and symptoms (ischemic)
2. Wallenberg syndrome is most common
3. Less frequent territorial involvement:
 - a. Medial medullary arteries (brainstem)
 - b. Cerebellar arteries
 - c. Pontine
 - d. Thalamic
 - e. PCA
4. Stroke (ischemic infarction) occurs in approximately 60% of patients
 - a. 10–15% with preceding TIA
 - b. 10% no preceding TIA
 - c. Stroke from first TIA is rapid
 - d. Rarely spinal cord ischemia occurs from involvement of the anterior spinal arteries (paralysis; infarction of the medullary pyramids) or severe proprioceptive deficits from infarction of posterior column nuclei

Risk Factors for ICA and VA Dissection

1. Trauma:
 - a. Head and neck
 - i. Severe hyperextension and rotation:
 1. Traction in ICA from crossing transverse process C2–C3
 2. Severe neck flexion:
 - a) Entrapment of ICA between angle of the mandible and upper cervical spine
 - b. Elongated styloid process compression of the ICA during neck rotation
 - c. Traumatic VAD occurs with extreme neck rotation:
 - i. Injured at V3 segment (C2/C1 > C3/C2)
 - ii. Compressed by muscle and fascial bands at arterial junction V1 and V2

- iii. Osteophytes in the transcervical canal (V2 segment)
- d. Minimal trauma:
 - i. Coughing
 - ii. Sleep
 - iii. Posture
 - iv. Sexual activity
2. Genetic causes of arterial wall pathology:
 - a. Marfan's syndrome
 - b. Ehlers–Danlos type IV
 - c. Osteogenesis imperfecta
 - d. COL A1/A2 gene mutations
 - e. Fibromuscular dysplasia (FMD)
 - f. Pseudoxanthoma elasticum (PXE)
 - g. Adult polycystic kidney disease
 - h. Cystic medial necrosis
3. Congenital arterial anomalies:
 - a. Coils, kinks, loops of a redundant ICA
 - b. Dilated aortic root diameter > 34 mm
 - c. Mitral and bicuspid aortic valve (BAV) associations
4. Associated arterial manifestations of dissection:
 - a. Multivessel dissections that include the renal and visceral arteries
 - b. Higher incidence of intracranial aneurysms with ICAD
 - c. Familial ICAD and lentiginosis
 - d. CAD and cerebral aneurysms
5. Infection
 - a. Induces a proinflammatory state
6. Migraine headache

Neuropathology

1. Subintimal dissection
 - a. Blood between the tunica intima and media
 - i. Primarily associated with stenosis
 - b. Subadventitial dissection
 - i. Blood is between the tunica media and adventitia
 - ii. Associated with pseudoaneurysms and local symptoms

Neuroimaging

Arteriography

1. Elongated, irregular tapered stenosis
2. Dissecting aneurysm
3. Occlusion
4. Intimal flap

Intracranial Dissection

General Characteristics

1. Intracranial dissections cause:
 - a. Infarction
 - b. SAH
 - c. Mass effect
2. Anterior circulation
 - a. Supraclinoid carotid affected and may dissect into the intracranial MCA

3. Posterior intracranial extension affects
 - a. Intracranial vertebral artery
 - b. Basilar artery
4. Media and adventitial dissections are associated with:
 - a. SAH (may be recurrent)
5. Aneurysmal mass from dissection may cause:
 - a. Compression of cranial nerves and brain parenchyma
6. Chronic dissections:
 - a. Lesions are of different ages
 - b. Multifocal sites
 - c. Abnormal arterial media and internal elastic membrane
 - d. Most frequent with fibromuscular dysplasia
7. Recanalization:
 - a. Occurs if some lamina are patent

Neuroimaging

Neuroimaging of Arterial Dissections

1. Newer MRI and MRA sequences detail wall and luminal irregularities as well as some flow characteristics

Neuroimaging of ICA

MRI/MRA

1. Irregular and elongated tapered stenosis ('string sign')
2. Reconstitution at the skull base
3. Pseudoaneurysms
4. Tortuosity
5. Intimal flap
6. Slow ICA – MCA flow
7. Lesions usually initiated 1–2 cm above the bifurcation
8. "Flame Sign" at the site of occlusion
9. Distal branch occlusion (if embolization has occurred)
10. Occlusion and pseudoaneurysm more frequent with traumatic dissections

Neuroimaging of Vertebral Artery Dissection

MRI/MRA

1. Elongated, irregular tapered stenosis
2. Dissecting aneurysm
3. Occlusion
4. Intimal flap

Neuroimaging of Basilar Artery Dissection

MRI/MRA

1. Elongated stenosis with occlusion
2. Double lumen
3. Dissecting aneurysm

Neuroimaging of MCA and PCA Dissection

MRI/MRA

1. Non-specific stenotic segment with luminal irregularity that may be associated with dilatation
2. Differential diagnosis
 - a. Vasculitis
 - b. Meningeal infection
 - c. Inflammation

Aortic Dissections

General Characteristics

1. Divided into 2 types:
 - a. Type A – involves the ascending aorta
 - b. Type B – dissection initiated beyond the aortic arch
2. Origins of dissection:
 - a. 2/3 are in the ascending aorta
 - b. 10% are in the transverse portion of the aortic arch
 - c. 20% are in the proximal descending aorta beyond the origin of the left subclavian artery
 - d. Distal descending aorta dissection occurs in 5% of patients
3. Length of dissections is variable
 - a. May extend a few centimeters
 - b. May be extremely long from the ascending aorta to the iliac arteries
4. Cleavage plane:
 - a. Media of the artery
 - b. Follows the curvature of the ascending aorta and arch; partial circumference of the artery
 - c. False lumen occurs by an intimal tear
 - i. Located near the proximal end of the dissection
5. Arterial occlusion
 - a. Ascending aorta dissection
 - i. Brain and arm large arteries are occluded
 - ii. Dissection may extend into the proximal cervical arteries
 - iii. Dissection may extend into the aortic valve and obstruct coronary ostia
6. Medical manifestations
 - a. Acute aortic insufficiency
 - b. Myocardial infarction
 - c. Rupture into the chest (shock)
 - d. Pericardium (tamponade)
 - e. Obstruction of the vena cava
7. Aortic dissection 2–3 times more frequent in men than women

Clinical Manifestations

1. Pain
 - a. Can be in the chest, abdomen, back, face, head and neck
 - b. Rarely painless
 - c. Pain in the face suggests arch and proximal carotid artery
 - d. Pain straight through to the back suggests dissection below the subclavian artery
2. Hypertension
 - a. Classic aortic hypertensive dissection occurs in an obese middle aged plethoric, hyperhidrotic male
 - i. Most present with hypertension
 - ii. Approximately 25% of patients present with hypotension and a few in frank shock
3. Pulse/bruit
 - a. Loss of pulse in common carotid, left subclavian and femoral arteries

- b. Occasionally heard over the carotid and in the supra-clavicular fossa

Neurologic Manifestations

1. Stupor and coma
 - a. Cerebral infarction
 - b. Systemic hypotension
2. Focal or multifocal infarction
 - a. Occlusion of brachiocephalic arteries
3. Flaccid Paraparesis
 - a. Spinal cord infarction (blocked artery of Adamkiewicz)
4. Ischemic peripheral neuropathy
 - a. Blockage of arterial supply to the limbs

Neuropathology

1. Marfan's syndrome
 - a. Defect is primarily in the vessel media with profound diminution of elastic fibers
 - b. Decreased fibrillin in microfibrillar fibers in the skin
 - c. Mutation in Fibrillin causes a disordered microfibril matrix
 - d. Release of sequestered latent transforming growth factor β :
 - i. Mediator of vascular remodeling
 - e. Regional biomechanical dysfunction
2. Gesell-Erdheim syndrome
3. Hypertension
4. Atherosclerosis

Neuroimaging

1. Evaluation of the acute aortic syndrome that includes:
 - a. Aortic and cervical cephalic arterial dissection
 - b. Intramural hematoma
 - c. Penetrating atherosclerotic ulcer
2. Embolic stroke (all causes)
3. Atlantoaxial dislocation (Marfan's syndrome)
4. Enlarged dural sac (Marfan's syndrome)

CT

1. Findings demonstrate "beak sign" and aortic "cobwebs" (FMD)

Recanalization of Thrombosed Vessels

General Characteristics

1. The initial occlusion is the most dangerous time for stroke
 - a. Approximately 60% of strokes occur in the hemisphere ipsilateral to the occlusion (carotid artery)

Clinical Manifestations

1. Transient hypotension may result from low flow state that causes watershed infarction
2. Embolism occurs from:
 - a. The distal component of the occluded artery
 - b. Stump syndrome

- i. A proximally patent area and a patent extracranial carotid artery with retrograde flow
- c. Trans hemispheric migration of clot through the circle of Willis

Neuropathology

1. Spontaneous recanalization of a thrombosed intracranial artery:
 - a. Evident by 14–21 days
 - b. Irregular vascular wall of the affected vessel
 - c. Emboli:
 - i. Fragments and moves distally
 - ii. Movement occurs most often in the first 48 hours

Neuroimaging

MRI

1. In the case of embolic occlusion, the presence of a hyperdense MCA sign and a hypointense signal on T2-GRE imaging diagnoses a red thrombus
2. DWI sequences determine the infarcted core

CT

1. Dense MCA or vessel sign

MRA and DSA Angiography

1. Used to determine the topography of the arterial wall

Systemic Lupus Erythematosus

General Characteristics

1. Stroke occurs in approximately 3.5% of SLE patients under the age of 45 years old
2. Risk of recurrent strokes is increased
3. Major systemic features of SLE include:
 - a. Skin (malar rash and discoid lesions)
 - b. Arthritis
 - c. Serositis
 - d. Renal
 - e. Hematologic
 - f. Immunologic markers
4. A complex disease characterized by autoantibodies and multisystem involvement
5. A central role for β cells in pathogenesis as evidenced by early breakdown of tolerance
6. Autoantibodies pathogenic role in autoimmunity include:
 - a. Immune complex mediated type III hypersensitivity reactions
 - b. Type II antibody-dependent cytotoxicity
 - c. Innate immune cell production of inflammatory cytokines
7. A role for toll-like receptors in the link between the innate and adaptive immune systems in SLE immunopathogenesis
8. Associated neurologic manifestations
 - a. Psychosis

- b. Proximal myopathy
- c. Mononeuritis multiplex
- d. Migraine headaches
- e. Sensorimotor neuropathy
- f. Chorea
- g. Seizures
- h. Stroke (pial arteries; multifocal)
- i. Retinal findings:
 - i. Cytoid bodies
 - ii. Increased nicking of arterioles

Clinical Manifestations

1. Stroke
 - a. Embolic stroke (Libman-Sacks endocarditis)
 - b. Coagulopathy
 - i. Lupus anticoagulant
 - ii. Anticardiolipin antibody
 - c. Non-inflammatory vasculopathy
 - d. Small deep infarcts
 - i. Associated HCV
 - e. Intracranial branch artery occlusion
 - f. Cortical and subcortical infarcts (arteritis)
 - g. Large Vessel Stroke (Atherosclerosis)
 - i. In approximately 86% of patients the disease is active at stroke occurrence
 - ii. Stroke occurs after 4–5 years of disease
 - iii. Headache is common at onset
 - iv. Often associated with low protein S activity
 - v. Antiphospholipid antibody associated with Libman-Sacks endocarditis
 - vi. Global depression of left ventricular function
 1. Cardiac small vessel arteritis
 2. Poor ejection fraction and embolus
 3. Thrombogenic cytokines
 - h. Unusual Vascular Manifestations:
 - i. Vertebrobasilar territory infarction at presentation
 - ii. Vascular monocular or binocular optic neuropathy
 - iii. Posterior ischemic optic neuritis

General Neurologic Manifestations

1. Seizures
2. Psychiatric
3. Proximal myopathy
4. Peripheral neuropathy (mononeuritis multiplex)

Cerebrovascular Manifestations

1. Microinfarcts and hemorrhages
 - a. May be asymptomatic
 - b. Noted at autopsy
2. Minimal evidence to support vasculitis as a cause of stroke
 - a. Vasculitis does occur in the kidney and skin
 - b. Vasculopathy is well documented in the cerebral circulation
3. Cardiac emboli
 - a. Libman-Sacks endocarditis

- i. Non-endothelium covered verrucous deposition of hyalinized blood and platelet thrombi on cardiac valves
- ii. Mitral valve is most commonly affected with Libman-Sacks endocarditis
- iii. SBE may occur
- iv. Cardiac valvular lesions are associated anticardiolipin antibodies

Hypercoagulable State

1. Lupus anticoagulant and anticardiolipin antibody associated with:
 - a. Spontaneous abortions
 - b. Venous thrombosis
 - c. Stroke
2. Lupus anticoagulant may have higher risk of stroke than anticardiolipin antibodies:
 - a. Anti- β_2 glycoprotein I antibodies patients may have a high risk of stroke
 - i. Facilitate the binding of antiphospholipid antibodies to phospholipids
3. Deficits on endothelial function and fibrinolytic pathways occur with SLE
 - a. Decreased endogenous tissue plasminogen activator (tPA)
4. Accelerated atherosclerosis
 - a. Steroid induced atherogenic lipid profile
 - b. Increased low-density lipoprotein immune complexes

Neuropathology

1. Vasculopathy
 - a. Perivascular inflammatory infiltrates and hemorrhages
 - b. Proliferation of blood vessels
 - i. Vascular occlusions with recanalization
 - c. Small arteries and arterioles primarily affected
2. Widespread microinfarcts in the cerebral cortex and brainstem
 - a. Destructive and proliferative changes in arterioles and capillaries
 - b. Attachment of immune complexes to the vessel walls in mechanism of vascular injury
 - c. Thrombocytopenia
 - d. Platelet abnormalities
 - e. Thrombotic thrombocytopenic like syndrome:
 - i. Platelet thrombi in arteries and capillaries
 - ii. Subendothelial hyalin deposits
 - iii. Arterial microaneurysm

Neuroimaging

1. Decreased fractional anisotropy in frontal white matter
2. Voxel based morphometry and diffusion tensor imaging demonstrate deficits in both white and gray matter
3. Microinfarcts in the cerebral cortex
 - a. Destructive and proliferative changes in arterioles and capillaries

- b. Attachment of immune complexes to the vessel wall
- c. No cellular infiltration
- 4. ICH from hypertension
- 5. Cerebral emboli with topographic localization from Libman-Sacks endocarditis
- 6. TTP in the terminal phase

MRI

- 1. 3 Tesla
 - a. Multifocal with matter hyperintensities
 - b. Embolic stroke of major arteries
- 2. 7 Tesla
 - a. Microvascular lesions detected with ultrahigh field MRI
 - b. Minute punctate/linear hyperintense lesions in cortical and subcortical locations

Laboratory Evaluation

- 1. Antibodies to double-stranded DNA (anti-ds DNA)
- 2. Positive anti-nuclear antibodies
- 3. Increased ESR and C-reactive protein; increased alarmin expression
- 4. Antiphospholipid antibodies
- 5. CSF
 - a. May be normal
 - b. Mild lymphocytic pleocytosis
 - c. Slight increase in protein

Sickle Cell Disease

General Characteristics

- 1. Autosomal recessive inheritance
 - a. β globulin gene substitution in codon 6 that forms abnormal hemoglobin (HbSS) disease
 - b. HbSS constitutes 60–70% of the hemoglobinopathies
 - c. Hemoglobin is a heterotetramer with 2α and 2β chains
 - d. Substitution of glutamine to valine in codon 6 of the β globin gene
- 2. Risk factors for ischemic stroke in children
 - a. Overt or silent stroke (MRI)
 - b. Increased cerebral blood flow
 - c. Aplastic crises
 - d. Nocturnal hypoxemia
 - e. Acute chest syndrome
 - f. Seizures
 - g. SEM globin gene haplotype
- 3. Risk factors for ischemic stroke in adults
 - a. Increased homocysteine
 - b. Prior TIA
 - c. Atrial fibrillation
 - d. Hyperlipidemia
 - e. Diabetes mellitus
- 4. HbS > HbC for risk of ischemic stroke; HbA has little or no risk of ischemic stroke

Clinical Manifestations

- 1. Risk of ischemic stroke is higher in homozygous SS disease than SC disease

- 2. HbS disease < 30–50% of total hemoglobin decreases risk of ischemic stroke
- 3. Sickle cell disease in children
 - a. Ischemic brain disease often manifest by:
 - i. Silent brain infarction
 - ii. Microvascular infarction with cognitive decline
 - b. Increased risk of ischemic stroke may be associated with:
 - i. History of seizure
 - ii. Leukocyte count > 11.8 grams/L
 - iii. Low pain event rate
 - c. Significant risk of ischemic stroke occurs with:
 - i. Elevated flow rate by transcranial Doppler

Rarer Cerebrovascular Manifestations

- 1. Primarily in children
 - a. Subdural hematoma
 - b. Subarachnoid hemorrhage
 - c. Moyamoya syndrome
 - d. ICH

Clinical Manifestations of Chronic Vasculopathy in Adults

- 1. Large and small vessel stroke
- 2. Silent infarcts

Clinical Manifestations

- 1. HbS disease
 - a. Scleral telangiectasia
 - b. Arachnodactyly
 - c. Auto-splenectomy
 - d. Pneumococcal peritonitis
 - e. Meningitis
 - f. Bone marrow infarction
 - g. Severe joint and abdominal pain
 - h. Acute chest syndrome
 - i. Numb chin syndrome

Neurological Complications

- 1. Occlusive disease of large intracranial arteries and small penetrating vessels
- 2. Silent infarcts
 - a. About 20% in children
 - b. Cognitive impairment without overt ischemic stroke in children
- 3. Dilated and ectatic arteries
- 4. Moyamoya collateral patterns (MCA or terminal carotid occlusion)
- 5. SAH (rare)

SSA Disease

- 1. Stroke propensity

SC Disease

- 1. “Sea fan” macular sign (abnormal collection of blood vessels)
- 2. Propensity of strokes during pregnancy
- 3. Aseptic necrosis of the hip

Neuropathology

1. Large infarcts and/or hemorrhages in the cerebral hemispheres
2. Thrombosis of major branches of the Circle of Willis
3. Arterial occlusive disease in the terminal portions of the internal carotid arteries as well as their proximal segments
4. Microinfarcts
 - a. Diffuse gliotic scars in the deep white matter and cerebral gray
5. Vaso-occlusive disease
 - a. Thrombin and antithrombin complexes (TAT) and D-dimer are correlated with both stroke and retinopathy
6. Other pathologic mechanisms include:
 - a. Platelet activation from endothelial injury
 - b. Sickled erythrocyte adhesion to endothelium
 - c. Decreased erythrocyte deformability
 - d. Remodeling of the arterial wall leading to stenosis and occlusion
 - i. Small vessels affect more than large vessels
7. Thickened arterial walls from intimal and subintimal proliferation
8. Rare thrombosis of veins and cerebral sinuses
9. Deoxygenated HbS interaction with other HbS molecules leads to RBC polymerization
 - a. Decreased RBC deformability
 - b. Vaso-occlusion of vessels and the vaso-vasorum
10. Sickled cells
 - a. Adhere to the endothelium
 - b. Activate inflammatory cells and clotting factors that form the nidus for thrombosis
 - c. Initiate small vessel sludging
 - d. Deficiency of endothelial nitric oxide which decreases compensatory vaso dilation

*Neuroimaging***MRI**

1. Infarction and ischemic lesions (children) involve both cortex and deep white matter
2. Silent lesions most often seen in deep white matter

Transcranial Cranial Doppler

1. <170 cm/sec decreases risk of ischemic stroke
2. >200 cm/sec increases risk of ischemic stroke
 - a. Velocities above 200 cm/second may occur in large vessels

MRI/MRA

1. Silent infarction
2. Cortical and subcortical infarction
3. Border zone infarction
4. Moyamoya syndrome

Varicella Zoster Virus*General Characteristics*

1. Stroke most often occurs after Vth cranial nerve infection (first division of the Vth cranial nerve)

2. Annual incidence of 1010/100,000 people aged 80–90 years of age
3. Immunocompetent host CNS involvement occurs in 1.5 to 4% of patients
 - a. Higher incidence in immunocompromised patients
4. Thoracic dermatomes are most commonly involved: severely painful with dynamic mechcanoallodynia

Clinical Manifestations

1. Middle cerebral artery stroke may occur 10 to 14 days after the skin lesions appear

Neurological Complications

1. Cranial neuropathy
2. Post herpetic neuralgia
3. Encephalomyelitis
4. Optic neuritis
5. Leukoencephalopathy
6. Ventriculitis
7. Transverse myelitis

Cerebrovascular Manifestations

1. Delayed brain infarction following infection
2. Contralateral hemiplegia from ipsilateral MCA involvement
3. Days to 6–8 weeks following onset of the rash
4. Concomitant encephalitis
5. Rash may occur in V₂ or V₃ as well as V₁ distributions
6. Rare involvement of OCA or the vertebrobasilar territory

*Neuropathology***Early VZV Infection**

1. Infected arteries contain:
 - a. CD4+ and CD8+ T-cells
 - b. Macrophages
 - c. Rare B-cells and neutrophils
2. Perivascular inflammatory cells underlie areas of thickened intima (suggestive that soluble factors are released)
 - a. Infection is initiated in the adventitia
 - b. Hypertrophic intima is composed of cells expressing smooth muscle actin
 - c. Decreased smooth muscle cells

Late VZV Arterial Infection

1. Viral antigens, but not leukocytes (no inflammation) are seen in the media
2. Ischemic strokes are predominant with approximately 18% being multifocal
3. Some multifocal strokes are hemorrhagic
4. Productive virus in infected cerebral arteries (both large and small)
5. Occasional signs of arteritis
6. Concomitant VZV infiltration into the parenchyma (frontal and temporal lobe)
7. Rare SAH
8. Basilar meningitis (rare)

*Neuroimaging***MRI**

1. Middle cerebral artery stroke (stem artery involvement)
2. Hemorrhagic multifocal strokes

MRA

1. Signs of angiitis; small arteries more than large arteries
2. Stenosis of proximal MCA and basilar artery
 - a. Induce large infarction
3. Occlusion of the supraclinoid ICA
 - a. May be preceded by TIA
 - b. Usual clinical onset is that of an abrupt stroke
4. Stenosis of intracranial large conducting vessels
5. Small artery involvement is less common
6. Multiple superficial and deep infarcts

Laboratory Evaluation

1. VZV specific IgG antibodies in CSF
2. Detection of VZV DNA by PCR

Posterior Fossa Malformations, Hemangiomas, Arterial Malformations, Cardiac Defects, Eye Abnormalities and Sternal Cleft Syndrome (PHACES Syndrome)*General Characteristics*

1. Occurs in a significant number of children with a facial hemangioma have PHACES syndrome
2. Female to male predilection of 9:1
3. A childhood disease but does occur in adults
4. Arterial cerebrovascular malformations
5. Abnormal neural crest migration is the putative cause

Clinical Manifestations

1. Posterior fossa malformations
2. Facial hemangiomas
3. Cardiovascular anomalies
4. Eye abnormalities
5. Sternal clefting or supraumbilical raphe lesion
6. Ischemic stroke usually occurs prior to one year of age
7. Rare that all features occur in one patient

Neuropathology

1. Abnormal neural crest migration is the putative cause

Cerebrovascular Manifestations

1. Dysplasia of large cerebral arteries
2. Arterial stenosis or occlusion with or without Moyamoya collaterals
3. Absence or moderate to severe hypoplasia of the large cerebral arteries
4. Persistence of embryonic arteries and arrest of normal vasculature development
5. Vascular abnormalities often are Ipsilateral to the cutaneous hemangiomas; may be bilateral

Categories of Arterial Anomalies

1. Dysplasia

2. Narrowing
3. Aberrant course or origin
4. Persistence of embryonic anastomosis
5. Progressive vasculopathy
 - a. Putatively related to the proliferative phase of hemangioma evolution

Neuroimaging

1. Agenesis of cervical carotid arteries
2. Persistent embryological vessels
3. Arterial stenosis
4. Dolichoectasia of intracranial arteries

Neurofibromatosis, Type I*General Characteristics*

1. NF1 is the most prevalent autosomal dominant disease in humans
 - a. Mutation in the NF1 gene located on chromosome 17q11.2
2. Mutation of gene on chromosome 17
 - a. Protein encoded is neurofibromin; a GTPase-activating enzyme
3. Incidence ranges from 1:2500 to 1:3000 live births

Clinical Manifestations

1. General Neurologic Complications
 - a. Seizures
 - b. Learning disabilities
 - c. Attention deficit disorder
2. Intracranial lesions include:
 - a. Optic gliomas
 - b. Sphenoid wing dysplasia or absence (unilateral pulsatile exophthalmos)
3. NF1 vasculopathy includes:
 - a. Arterial system is most commonly affected
 - b. Occlusion of vessels
 - c. Pseudoaneurysm formation
 - d. Aneurysm
 - e. Ectasia
 - f. Fistula
 - g. Moyamoya syndrome
4. Café-au-lait spots (greater than 6) Lisch nodules (iris) neurofibromas
5. Increased incidence of glial malignant tumors: myelogenous leukemia, pheochromocytoma (benign)
6. Peripheral nerve sheath tumors, malignant peripheral nerve sheath tumors
7. Vasculopathy
8. Optic nerve glioma
9. Learning disabilities
10. Attention deficit disorder
11. Sphenoid wing dysplasia
12. Pseudoarthrosis of the tibia

Neuropathology

1. Most commonly affects arteries. The process does affect veins and vessels of all sizes

2. The carotid artery is most commonly affected followed by the middle and posterior cerebral artery
3. Occlusion of the lumen and hyperplasia of the intima
 - a. Dysfunction of neurofibromin that causes excessive proliferation of vascular smooth muscle cells
 - b. Neurofibromin putatively helps with the maintenance of the endothelial cell layer
4. Moyamoya syndrome in patients with NF1 often involves anterior circulation territories
 - a. Progresses to bilateral disease in 10% of patients
5. NF1 vasculopathy affects arterial and venous blood vessels of all sizes
6. Two major vascular pathologies in NF1
 - a. Occlusive intimal form that affects small arteries
 - b. Aneurysmal form with replacement of the muscular wall with fibrohyaline thickening in arterioles of .1–1 mm
7. Arterial lesions caused by:
 - a. Proliferation of Schwann cells within arteries and proliferation of smooth muscle
 - b. Secondary fibrosis
 - c. Other arteries affected include:
 - i. The abdominal aorta
 - ii. The mesenteric arteries
 - iii. Visceral arteries
 - iv. Muscular arteries
 - d. May also present with multiple arterial aneurysms and venous thrombosis
8. Vascular anomalies:
 - a. Intra- and extracranial arterial connections
 - b. Often present with concomitant intravascular occlusive disease
 - c. Large and medium-sized arteries are affected in any territory
 - d. Possible dysfunction of neurofibromin in blood vessel endothelial and smooth muscle cells
 - e. Recurrent strokes occur in the same or different territories
 - i. Internal carotid artery > MCA > PCA are affected
 - f. Both intra- and extracranial vessels can accrue stenotic lesions
 - g. Hemispheric territorial infarction is most common
 - h. Lacunar infarction and ocular ischemia (retinal) and global occur
9. Aneurysm
 - a. Occurs in the vertebral or other large neck arteries that can present as:
 - i. Large neck mass
 - ii. Brachial plexus lesion
 - iii. Medullary compression syndrome
 - b. Intracranial saccular and fusiform aneurysms occur at:
 - i. Circle of Willis
 - ii. Distally (posterior choroidal artery)
 - iii. Fusiform aneurysm of the intrapetrosal carotid artery cause:
 1. Spheroid wing dysplasia or VIth nerve palsy

- c. The form of the disease associated with cerebral aneurysms is the intimal aneurysmal form
- d. Moyamoya disease
 - i. Slowly progressive distal carotid stenosis
- e. Arteriovenous malformations
- f. Renal artery stenosis with hypertension

Neuroimaging

MRI/MRA

1. “Unidentified bright objects” throughout the hemispheres
 - a. Multiple small foci noted in T2-weighted sequences

MRA/DSA

1. Demonstrates occlusion of the terminal branches of the internal carotid arteries

Angiography

1. Occlusive arterial disease
 - a. Focal concentric stenosis
 - b. Long segment irregular narrowing
 - c. Hypoplasia without luminal narrowing
 - d. Does not occur at bifurcations (as opposed to atherosclerosis)
2. Arteriovenous fistula particularly of the vertebral arteries is associated with:
 - a. Stenosis and pseudo-aneurysmal dilatation of the feeding vessel
3. Moyamoya changes (lenticulostriate collaterals) from gradual bilateral carotid occlusion
 - a. Extensive leptomeningeal collaterals from the external carotid to the Circle of Willis due to proximal occlusions of major intracranial vessels

Tuberous Sclerosis Complex

General Characteristics

1. Tuberous sclerosis complex (TSC)
 - a. Autosomal dominant
 - b. Cardiac rhabdomyomas that cause emboli
 - c. 80% are new mutations
 - d. Abnormalities of cerebral arteries and aorta also occur
2. Characterized by the development of hamartomas in several organs that include:
 - a. Renal angiomyolipomas
 - b. Cardiac rhabdomyoma
 - c. Subependymal giant cell astrocytoma

Clinical Manifestations

1. Epilepsy
2. Mental retardation
3. Autism
4. Arteriopathy is usually asymptomatic

Cerebrovascular Manifestations

1. Ischemia in territories of the affected vessels
2. Emboli from thrombi in ectatic aneurysms
3. SAH from ruptured aneurysms
4. Dolichoectasia

Neuropathology

1. Tubers throughout the brain
2. Subependymal giant cell astrocytoma
3. Peripheral and central aneurysms (rare)
4. Dolichoectasia

Neuroimaging

1. Multiple tubers throughout the brain
2. Subependymal giant cell astrocytoma of the IIIrd ventricle
3. Poor white-gray matter junction demarcation in many cortical gyri

Familial Occipital Calcification*General Characteristics*

1. Probable autosomal dominant inheritance
2. Late onset of dementia
3. Patchy leukoencephalopathy
4. Intracerebral hemorrhages
5. Bilateral occipital calcifications
6. External carotid artery dysplasia

Clinical Manifestations

1. Late onset dementia
2. Intracranial hemorrhage
3. Ischemic stroke

Neuropathology

1. Skin biopsy:
 - a. Multilayered round shaped calcifications in the basal lamina of capillaries
 - b. Capillary vasculopathy

*Neuroimaging***MRI**

1. Fine tram tracking bilateral occipital calcifications
2. Severe leukoencephalopathy
3. Bilateral external carotid dysplasia

Emboli and Valvular Disease**Cerebral Emboli****Overview of Cerebral Emboli**

The overwhelming source of embolic material that blocks the cerebral circulation comes from artery-to-artery (burst plaque cholesterol, lipid and fibrous debris) or larger red fibrin clots from the heart. The specific setting and medical history are pivotal in determining the source and mechanism of the event. The neurological deficit occurs suddenly, usually during activities of daily living. As noted earlier thrombotic infarction often occurs in the early morning (4–6 AM from acidosis with platelet activation, REM sleep induced cardiac arrhythmias, circadian induced hypotension). The deficit often progresses over several days. Intracranial

hemorrhage from hypertension occurs during wakefulness. Headache, nausea and neurologic deficit progresses and does not clear. SAH causes severe headache that reaches maximum intensity instantly often with minimal neurologic deficit (IIIrd cranial nerve with P-Com aneurysm, behavioral change and leg weakness with an A-Com aneurysm and mild to moderate hemiparesis with an MCA aneurysm). Headache and seizures do occur with cerebral emboli in about 10% of patients but are non-specific. The deficits from emboli start to clear early. This occurs from break-up of the clot, the development of the collateral circulation and early recanalization of the artery. The development and use of both thrombolysis and mechanical thrombectomy have opened a new chapter in the diagnosis and treatment of cerebral embolization. In general, thrombolysis is most effective with distal embolization and mechanical thrombectomy with larger proximal vessel occlusion. Age, the severity of the initial deficit (NIHSS > 14), the time from ictus to treatment, hyperglycemia and comorbidities determine success. The degree of recanalization of the affected vessel and the time to treatment (cerebral parenchymal ischemic time) determine the clinical outcome. Multiple protective devices are being utilized and tested to decrease cerebral emboli from aneurysmal coiling, treatment of vascular malformations and stenting procedures. Rarely fat emboli occur from long bone fracture in the young to hip replacement in the elderly. The problem may be fat coming out of solution triggered by a small amount of fat that enters the circulation from the trauma. Chest petechia, fat globules in the retina and urine are diagnostic. The pO₂ is often low at presentation due to concomitant pulmonary involvement. A late stage encephalopathy may occur. Air emboli occur from cardiac, neurosurgical, ENT and obstetrical procedures (primarily from the patient in the sitting position or severely dilated pelvic veins) and cause severe arterial spasm. Rarely nitrogen bubbles (diving), food particles (esophageal atrial fistula) and calcium block the cerebral circulation.

Other unusual sources of artery-to-artery emboli are from:

1. Giant aneurysm (tip of the basilar to PCA)
2. AVM (usually embolic material during treatment)
3. The intimal flap of dissections
4. Carotid allegro (multiple episodes of amaurosis fugax) or neurologic symptoms and signs from a burst carotid plaque

Simultaneous ACA and MCA involvement is characteristic of a carotid siphon localization for embolic material. Broca's and Wernicke's aphasia without hemiparesis can occur in this instance from simultaneous involvement of branches of the superior and inferior MCA.

Cardioembolic stroke is:

1. The mechanism for approximately 25% of cerebral emboli
2. Its incidence increases with age and in patients greater than 85 years old, may be as high as 36%
3. Basic mechanisms are due to any of the following:
 - a. An enlarged left atrium, atrial appendage or ventricle
 - b. Valvular emboli

c. Paradoxical embolism

d. Low ejection fraction

Cardiac emboli are:

1. Large, red (fibrin platelet clots) and tend to cause large strokes
2. The risk of early recurrence is between 1–10%
3. The underlying potential source of cardiac embolism in the absence of significant arterial disease is pivotal for diagnosis. It becomes more difficult when arterial disease and a cardiac cause coexist (atrial fibrillation and concomitant ulcerated carotid plaque)

The clinical features of an embolus are:

1. Sudden onset with maximum deficit at ictus (less than 5 minutes is present in 47–74% of patients)
2. Sudden neurological deficit occurs in approximately 80% of patients while less than 50% in thrombotic stroke and less than 40% in lacunar strokes
3. In a small number of patients (5–12%) there is a spectacular shrinking deficit syndrome on MRI (distal migration and breakup of the clot and recanalization of the affected vessel)
4. Wernicke's aphasia (inferior division of the MCA temporoparietal occipital branch) or global aphasia (stem MCA) without hemiparesis is a common clinical features

Posterior circulation emboli typically cause:

1. Visual field deficits (often superior quadrants)
2. Complete or partial Wallenberg syndrome
3. Top of the basilar syndrome (occlusion of the top of the basilar artery)
4. Multilevel infarcts (brain stem, midbrain, thalamic, parietal and occipital lobe) from tumbling emboli that fragment
5. PCA infarction

In general, visual field deficits, neglect, and a posterior aphasia, (particularly Wernicke's) are more common in cardioembolic than in thrombotic disease.

Perhaps more common but non-specific clinical features of cardioembolism are seizures (irritation of the cortex), headache and onset with activity. Onset of a neurologic deficit with a Valsalva maneuver (coughing, lifting and strain causing an increase of right atrial pressure) are suggestive. Lacunar syndromes occur from emboli but are rare (3–5%).

Hemorrhagic transformation and early recanalization of the occluded vessel suggest cardiac emboli.

Hemorrhagic transformation:

1. Occurs in approximately 70% of cardioembolic stroke
2. Are primarily petechial or multifocal
3. Hemorrhagic transformation may be predicted from:
 - a. A depressed level of consciousness
 - b. Total vessel occlusion
 - c. NIH Stroke Scale score greater than 14
 - d. Stem MCA occlusion
 - e. Greater than one third of MCA territory ischemia by CT
 - f. Decreased collateral perfusion

The most common etiologies of cardiac embolism are:

1. Atrial fibrillation
2. Recent myocardial infarction
3. Mechanical prosthetic valves (mitral > aortic)
4. Dilated cardiomyopathy (ejection fraction < 30%)
5. Infective and marantic endocarditis
6. Atrial myxoma

Less common causes of cardiac emboli are:

1. Patent foramen ovale (PFO) with or without atrial septal defect
2. Atrial or ventricular septal defects
3. Calcific aortic stenosis
4. Mitral annular calcification
5. Complex aortic arch atheromatosis

Early and late embolic recurrences are common and are associated with a higher mortality.

The recurrence occurs (in less than 15%) within two weeks, possible risk factors for recurrence are:

1. Alcohol abuse
2. Hypertension with valvular heart disease and atrial fibrillation
3. Nausea and vomiting
4. Previous cerebral infarct
5. In hospitalized patients, recurrent embolization is associated with:
 - a. Tachyarrhythmias
 - b. Congestive heart failure
 - c. Acute myocardial infarction

Clinical Manifestations of Cerebral Emboli

1. An abrupt onset of a neurological deficit, aphasia (particularly Wernicke's without hemiparesis) in a setting of atrial fibrillation, low ejection fraction, prosthetic heart valve or SBE
2. MCA > PCA > ACA are the most frequent arterial territories affected
 - a. Large fibrin/platelet clots are associated with major deficits
 - i. Rare lacunar territory stroke
 - ii. Early resolution of the deficit

Preceding Symptoms and Signs of Cerebral Emboli

1. Approximately 10% of patients have prodromal symptoms prior to the presenting ictus:
 - a. Stuttering focal deficits due to:
 - i. Distal movement of prior embolus
 - ii. Development of the collateral circulation
 - iii. Recanalization
 - b. Cerebral infarction from cardiac emboli may be preceded by transient ischemic attacks, that are longer than artery-to-artery (cholesterol, platelet, plaque debris) emboli
 - i. Cardiogenic emboli cause deficits that last minutes to hours
 - ii. Artery-to-artery emboli cause a 2 minute deficit (particularly retinal emboli with amaurosis fugax);

the larger the embolus, the longer the deficit (in general)

2. Anterior circulation pattern:
 - a. Focal motor, sensory deficits with or without aphasia
 - b. Muteness:
 - i. Stem MCA (global aphasia)
 - ii. ACA (supplementary motor area; causes an acute apraxia of speech)
 - c. Seizures occur in approximately 10% of patients (along with headache are not specific for emboli)
 - d. About 10% of patients lose consciousness at ictus

Neuropathology of Cerebral Emboli

1. Atheromatous plaque located in the internal carotid artery at the origin from the common carotid:
 - a. In the cervical component of the vertebral arteries and at the junction that forms the basilar artery
 - b. At the stem or bifurcation of the MCA
 - c. Proximal posterior cerebral arteries (perimesencephalic portion)
 - d. Proximal anterior cerebral arteries
 - e. Rare for plaque to develop:
 - i. After the first major branching from the Circle of Willis
 - ii. In the ophthalmic and cerebellar arteries
2. Alternate sites of embolic material
 - a. Thrombus from the heart
 - b. From the distal end of a thrombus within the lumen of an occluded or severely stenotic vessel
 - c. Thrombotic material from involved heart valves
 - d. Subacute Bacterial Endocarditis
3. Non-bacterial thrombotic emboli
4. Clots from prosthetic heart valves
5. Rare embolic material:
 - a. Fat
 - b. Air
 - c. Tumor cells
 - d. Fibrocartilage
 - e. Amniotic fluid
 - f. Calcium particles
6. Atheromatous plaque from the aorta
7. Hemorrhagic infarction is suggestive of embolism

Neuroimaging of Cerebral Emboli

MRI of Cerebral Emboli

1. Wedge shaped deficit (involving the cortex)
2. Multiple deficits in different vascular territories (need to rule out intracranial atherosclerosis)
3. Evidence of prior deficits
4. Rule out mimics (metastasis, subdural hematoma, conophilic angiopathy)

Cardiac Emboli

Vertebrobasilar Signs and Symptoms of Cardiac Emboli

1. Partial Wallenberg syndrome

2. Diplopia (particularly IIIrd > VIth cranial nerve, interpeduncular artery to the midbrain rather than a branch artery from the basilar artery)
3. Ataxia
4. Vertigo
5. Crossed or bilateral sensory or motor deficits
6. Rarely depressed levels of consciousness at onset
7. Top of the basilar syndrome

Neuropathology of Cardiac Emboli

1. Clots breakup an infarction can be seen in the medulla, thalamus and parietal or occipital cortex

Neuroimaging of Cardiac Emboli

MRI of Cardiac Emboli

1. Bilateral cerebellar deficits
2. Multilevel deficits (brainstem, midbrain, thalamus, cortex)

MRA/DSA of Cardiac Emboli

1. Sharp, tapering cut off in the affected artery

Angiography of Cardiac Emboli

1. Abrupt tapering of an artery
2. Rarely long segment may be vasoconstricted

Myocardial Infarction and Ischemic Heart Disease as a Source of Emboli

General Characteristics of Myocardial Infarction and Ischemic Heart Disease as a Source of Emboli

1. Arterial emboli occur in 2–4% of patients after myocardial infarction

Clinical Manifestations of Myocardial Infarction and Ischemic Heart Disease as a Source of Emboli

1. Time of occurrence:
 - a. 10% in the first week
 - b. 35% in the second week
 - c. 15% in the third week
 - d. 5% in the 3rd month
 - e. Newer studies suggest the first 5 days are the major time of risk
2. Mural thrombi occur with higher incidence in:
 - a. Large infarctions
 - b. Transmural infarction involving the intraventricular septum
 - c. Associated congestive heart failure
 - d. Anterior > posterior wall infarction
 - e. Severe apical wall dyskinesia
 - f. 75% of major anterior transmural infarctions have dyskinesias

Neuroimaging of Myocardial Infarction and Ischemic Heart Disease as a Source of Emboli

Echocardiography of Myocardial Infarction and Ischemic Heart Disease as a Source of Emboli

1. Most mural thrombi identified by TEE (transthoracic echocardiography) can be seen in 3–5 days

- a. Embolize at 4 days
- b. Rare embolization after 4 to 6 weeks
2. Echocardiographic correlates of ventricular dysfunction are:
 - a. Spontaneous ECHO contrast ("smoke")
 - i. Swirling haze within cardiac chambers
 - ii. Interaction of plasma protein, erythrocytes and shear rate
 - b. Determinants of "smoke":
 - i. Slow intracardiac flow
 - ii. Hematocrit
 - iii. Fibrinogen level

Neuropathology of Myocardial Infarction and Ischemic Heart Disease as a Source of Emboli

1. Thrombi within cardiac chambers are due to:
 - a. Stasis of blood that initiates:
 - i. Activation of factor XII and the endothelium of the cardiac surface
 - b. Endothelial cardiac wall injury causes:
 - i. Loss of the endothelium
 - ii. Change of negative to positive charge on the cardiac endothelial surface and exposed collagen
 - iii. Platelet aggregation at the site of charge change
 - c. Prothrombotic state is initiated by:
 - i. Low shear rate of circulating RBC within the cardiac chambers

Left Ventricular Thrombi

General Characteristics of Left Ventricular Thrombi

1. Occur in 20–40% of patients with anterior wall myocardial infarction
2. Form in the apical wall of the left ventricle

Clinical Manifestations of Left Ventricular Thrombi

1. Long duration (>1 hour) of neurologic deficits

Neuropathology of Left Ventricular Thrombi

1. Superior branch of the MCA territory
2. Large cerebral artery occlusions may occur in two arterial circulations
3. Mechanisms include:
 - a. Low ejection fraction
 - b. Left ventricular aneurysm
 - c. Dyskinesia from decreased contractility
4. Concomitant with antiphospholipid syndrome
5. Axillary vein I.V. access

Mural Thrombi in Ventricular Aneurysms

Neuropathology of Mural Thrombi in Ventricular Aneurysms

1. 7.6% of patients develop intraventricular aneurysms after an myocardial infarction (MI)
2. Mural thrombi occur in 50% of ventricular aneurysms
3. Clinical emboli occur in 1–3% of patients per year
4. Usually occur within 4–6 weeks after myocardial infarction

Impaired Left Ventricular Contraction

Clinical Manifestations of Impaired Left Ventricular Contraction

1. Risk of stroke is 4.6%
2. Ejection fraction of less than 28% is the highest risk
3. Asymptomatic or unexpected cardiac ventricular thrombi occur in
 - a. A patient with stroke is noted to have cardiac thrombi without known coronary artery disease
 - b. Known cardiac thrombi may regress

Arrhythmia and Cerebral Emboli

Clinical Manifestations of Arrhythmia and Cerebral Emboli

1. Most common arrhythmias associated with stroke:
 - a. Chronic atrial fibrillation
 - b. Intermittent atrial fibrillation
 - c. Sick sinus syndrome
2. The majority of cardiogenic emboli are cerebral

Cardiac Arrhythmia – Atrial Fibrillation (AF)

General Characteristics of Atrial Fibrillation

1. 2–5% of the population > 60 have atrial fibrillation
2. 35% of patients with untreated atrial fibrillation will have an ischemic stroke over their life time
3. Approximately 4% of atrial fibrillation patients suffer a stroke each year
4. Atrial fibrillation with no associated risk factors <2% of stroke per year
5. Atrial fibrillation with known risk factors:
 - a. Approximately 6% strokes per year
 - b. Atrial fibrillation and stroke; 75% have had an ischemic event secondary to Atrial fibrillation
 - c. Atrial fibrillation plus rheumatic heart disease (RHD)
 - i. 17 fold increase of stroke risk
 - d. Atrial fibrillation without rheumatic heart disease
 - i. 5.6 fold increase of stroke risk
 - e. Atrial fibrillation increases risk of stroke with age
 - f. Atrial fibrillation increases the risk of silent infarction
 - g. 25% of stroke patients >70 years of age have non-valvular atrial fibrillation (NVAf)
 - h. Non-valvular atrial fibrillation (NVAf) – 3× greater risk of stroke related death
 - i. Left atrial enlargement and decreased function causes increased risk of cardiac emboli
 - j. Embolus rate highest after the onset of dysrhythmia
 - k. 12% of patients' cardioverted for AF suffer an embolus within the first few days of the procedure
6. Causes of atrial fibrillation:
 - a. 10–30% of AF no identifiable cardiovascular disease
 - b. Identified causes include:
 - i. Dilated left atrium in mitral stenosis
 - ii. Thyrotoxicosis
 - iii. Pericarditis
 - iv. Ischemic cardiac disease
 - v. Hypertension
 - vi. Alcohol abuse

Neuropathology of Atrial Fibrillation

1. Origin of embolic material:
 - a. Left atrium or the left atrial appendage
 - i. 15–50% of valvular atrial fibrillation (VAF) have thrombi in the left atrium
 - ii. Autopsy evidence of arterial emboli in 40% of non-valvular atrial fibrillation (NVAF)
 - b. Valvular disease with atrial fibrillation
 - i. 9–29% have left atrial thrombi
2. Stasis of blood in the AF heart are associated with:
 - a. Increased concentration of fibrinogen D-dimer
 - b. von Willebrand disease

Clinical Manifestations of Atrial Fibrillation

1. Acute Wernicke's aphasia as sole clinical finding:
 - a. Embolus to the temporal-parietal occipital branch of the inferior division of the MCA
2. Highest risk for embolization:
 - a. Evidence of rheumatic heart disease
 - b. Onset of atrial fibrillation within the preceding 3 months
 - c. An enlarged left atrium

Recurrent Embolism in Non-Valvular Atrial Fibrillation (NVAF)

1. 50% of patients with cerebral embolism from atrial fibrillation suffer a second embolic stroke
2. Recurrence is greatest during the first days to weeks (15–20% of patients); some evidence that the greatest risk is at 12–24 hours

Cardiac Arrhythmia – Paroxysmal Atrial Fibrillation*General Characteristics of Paroxysmal Atrial Fibrillation*

1. Cerebral emboli occur during a paroxysm of atrial fibrillation
2. Thrombi form during the arrhythmia
3. Cerebral rather than peripheral arteries are affected
4. 2% may occur at the time of cardioversion
5. Chronic and recurrent atrial fibrillation carry the same risk
6. Paroxysmal atrial fibrillation is being uncovered in an even larger proportion of cryptogenic stroke patients with prolonged monitoring

Neuropathology of Paroxysmal Atrial Fibrillation

1. Occlusion of large arteries
 - a. MCA territory
 - b. Top of the basilar artery
 - c. Inferior division of the MCA
 - d. Multiple circulations
 - e. In young patients with minimal atherosclerotic plaque

Cardiac Arrhythmia – Sick Sinus Syndrome*General Characteristics of Sick Sinus Syndrome*

1. Chaotic atrial activity
2. 29.9% of men and 1.5% of women over 75 years of age may suffer the syndrome
 - a. 14–18% of patients suffer cerebral emboli

Clinical Manifestations of Sick Sinus Syndrome

1. Associated arrhythmias:
 - a. Atrial fibrillation or atrial flutter with slow rate of response (70 beats per minute)
 - b. Sinoatrial arrest
 - c. Atrial tachycardia
 - d. Sinus bradycardia
2. The sinoatrial disease at greatest risk for embolism is the brady-tachy syndrome
 - a. Emboli are more common with prolonged atrial asystole
 - b. Tachyarrhythmias > bradyarrhythmias are more likely to embolize

Neuroimaging of Sick Sinus Syndrome

1. Changing p wave contour
2. Bradycardia with:
 - a. Multiple recurrent ectopic beats
 - b. Runs of atrial and nodal tachycardia
3. Similar to large emboli as seen with AF
 - a. Multiple vascular territory involvement

Neuropathology of Sick Sinus Syndrome

1. Loss of function mutations in Na(v)1.5 cause sodium channelopathies, Brugada syndrome, dilated cardiomyopathy and sick sinus syndrome
2. The cardiac sodium current causes the rapid depolarization of cardiac cells and their consequent contraction
3. Mutations in the gene SCN5A is a congenital cause of sick sinus syndrome
4. Autoimmune, infiltrating entities (such as carcinoma and amyloid) may also destroy the sinoatrial node

Rare Causes of Emboli from Genetic Arrhythmias*General Characteristics of Rare Causes of Emboli from Genetic Arrhythmias*

1. Long QT syndrome
 - a. Jervell and Lang-Nielsen
 - i. Autosomal recessive
 - ii. Sensorineural hearing loss
 - iii. Syncope
 - iv. Sudden death
 - b. Romano-Ward
 - i. Autosomal dominant
 - ii. No sensorineural hearing loss
 - iii. Defective slowly activating rectifier K⁺ current is dysfunctional
 - iv. Generates a normal T wave and QT interval

Rheumatic Heart Disease*General Characteristics of Rheumatic Heart Disease*

1. Majority of RHD patients with cerebral emboli have mitral stenosis (10–20%)
2. Mitral insufficiency (MI) and aortic valve disease are the second most common cause of cerebral emboli in RHD

Clinical Manifestations of Rheumatic Heart Disease

1. 50–75% of RHD patients have AF or other arrhythmias at the time of an embolus
2. Majority of RHD patients with mitral stenosis have a normal sinus rhythm
 - a. AF greatly increase stroke risk
3. Systemic emboli occur in 10–49% of patients with RHD with valve disease

Neuropathology of Rheumatic Heart Disease

1. Mitral stenosis:
 - a. Thrombi form in the left atrium
 - b. Rarely on the valve

*Neuroimaging of Rheumatic Heart Disease***MRI of Rheumatic Heart Disease**

1. Patterns of large vessel obstruction
2. Multiple territories are involved

Sites of Origin for Artery-to-Artery Emboli*Overview of Site of Origin for Artery-to-Artery Emboli*

1. Artery-to-artery embolism:
 - a. Carotid System:
 - i. Bifurcation of common and external carotid arteries
 - ii. T-portion (ACA and MCA) at the siphon
 - iii. From giant distal aneurysms (carotid; MCA)
 - iv. Embryologic connections from the basilar artery to the carotid (rare cause of a posterior circulation embolus to reach the anterior circulation) that include persistent:
 1. Trigeminal
 2. Otic
 3. Hypoglossal
 4. Proatlantal
 - b. Intimal tears from dissection of the carotid are a source of emboli
 - i. Repair of carotid ulcers or stenosis (that cause flap intimal defects or dissection)
2. Vertebrobasilar system sources:
 - a. Arch of the aorta (mobile plaques); rarely descending aorta plaques
 - b. Vertebral artery
 - c. Basilar artery
 - d. Dolichoectatic vertebral basilar arteries
 - e. Giant aneurysms (particularly at the top of the basilar)
3. Predilection for specific sites of embolic termination:
 - a. Arterial bifurcations
 - b. Pial superficial MCA branches
 - c. Upper and lower trunks of the MCA
 - d. Distal basilar artery (top of the basilar)
 - e. Posterior cerebral arteries
 - f. Areas of greatest cerebral blood flow (CBF):
 - i. 40% of the anterior circulation emboli go to the MCA territory

- ii. Tendency to affect same location within an arterial territory due to laminar flow
- g. Aortic arch is the source of 25% of posterior circulation emboli
- h. 25% of emboli go to VB system (less than 20% of blood flow goes to this circulation)

Differential Diagnosis of Artery-to-Artery Embolism

1. Proximal extracranial and intracranial arteries
 - a. Ulcerated and stenotic lesions
2. Dissection of arteries
 - a. Thrombus at the site of the intimal tear
3. Post-surgical sites (flaps, sutures)
4. Inflammatory arterial disease:
 - a. Giant cell arteritis
 - b. Takayasu's disease
 - c. Infectious arteritis
 - d. Autoimmune arteritis
5. Thrombi within aneurysms:
 - a. Dolichoectatic arteries
 - b. Saccular (giant aneurysms)
 - c. Fusiform aneurysms
6. Fibromuscular dysplasia
7. Cancer:
 - a. Direct invasion of arteries
 - b. Promotion of clots within arteries encased by tumor
8. Hypercoagulable states
9. Aortic arch atherosclerosis with embolus:
 - a. Infarcts MCA territory and brachial plexus
 - b. Supraclavicular portions of the brachial plexus are supplied by ascending deep and transverse arteries
 - c. Infraclavicular portions of the plexus are supplied by 3–4 branches of the axillary arteries
10. Multiple brain gas embolisms:
 - a. Ingestion of hydrogen peroxide:
 - i. O₂ embolism
 - ii. Predominantly to gray matter
 - b. Air embolism
 - i. Vascular surgical procedures:
 1. Open heart surgery
 2. Head and neck surgery in the sitting position. Air enters the jugular vein
 - c. Pelvic vein insufflation (air) during pregnancy
11. Spectacular shrinking deficit (MRI evaluation):
 - a. Profound hemispheric ischemia
 - b. Resolves over hours to days
 - c. Minimal residual deficits
 - d. Rapid embolic lysis and fragmentation
 - e. 90% of emboli migrate or are recanalized within 2–3 weeks
12. Fat embolism:
 - a. Broken long bones in young patients
 - b. Hip replacement surgery (even in elderly patients)
 - c. Acute syndrome:
 - i. Interstitial lung involvement with low pO₂
 - ii. Petechiae across the anterior chest wall

- iii. Site predilection for emboli:
 1. Retina (fat globules visible)
 2. Corpus callosum
 3. Centrum semiovale
 4. Superficial pial vessels
- iv. Fat globules noted in the urine
- v. Mechanism
 1. Emboli pass through the lungs into the arterial circulation
 2. Precipitation of fat from chylomicra
- d. Late syndrome:
 - i. 4–7 days following the event
 - ii. Acute confusion
 - a. Decreased pliability
 - b. Irregular surfaces
 - c. Turbulent blood flow
- 3. Platelets are activated by turbulence
- 4. Thrombus formation is related to valve device turbulence
- 5. Abnormalities of blood flow distal to stenotic or incompetent valves cause:
 - a. Prolonged contact of blood and platelets
 - b. Formation of platelet and red cell fibrin thrombi
- 6. Atrial and ventricular enlargement from stenotic or incompetent valves:
 - a. Enlarged left atria (mitral stenosis or incompetence)
 - b. Prolonged contact of blood and platelets with cardiac and valve surfaces induces thrombus formation
- 7. Lambl's excrescences on valve cusps

Cardiogenic Sites of Origin for Cerebral Emboli

General Characteristics of Cardiogenic Origin Sites for Cerebral Emboli

1. Ejection fraction less than 30%:
 - a. Contact factors of clotting mechanisms are activated (slow blood flow)
 - b. Large atria
 - c. Areas of muscle hypokinesia in the ventricles
2. Valve leaflets:
 - a. Activation of platelets by shear forces
 - b. Consequent dilatation of left atrium with arrhythmia
 - c. Nidus for infection
 - d. Platelet fibrin deposition from prothrombotic conditions
 - i. Non-bacterial thrombotic emboli (DIC; cancer)
 - e. Myxomatous valve and chordae tendineae degeneration
 - f. Calcific aortic valve degeneration
3. Patent foramen ovale (PFO)
4. Atrial septal aneurysm (ASA)
5. Combination of PFO + ASA
6. Cardiac tumors:
 - a. Primary
 - b. Metastatic
7. Less common types and sources of emboli:
 - a. Lodge in the carotid artery (Calcium; cartilage)
 - b. Vertebrobasilar arteries at sites of narrowing
 - c. Esophageal cardiac fistula ("MAC attack"); swallowed food particles can embolize

Valvular Heart Disease as a Source of Emboli

General Characteristics of Valvular Heart Disease as a Source of Emboli

1. Approximately 10–20% of patients with valvular heart disease embolize

Neuropathology of Valvular Heart Disease as a Source of Emboli

1. Valvular outlet obstruction is caused by:
 - a. Commissural adhesions
 - b. Leaflet dystrophic calcification
2. Functional properties of stenotic valves:

Structural Causes of Valvular Heart Disease Associated with Emboli

Neuropathology of Structural Causes of Valvular Heart Disease Associated with Emboli

1. Rheumatic mitral and aortic valve stenosis and incompetence
2. Bicuspid aortic valve (congenital)
3. Mitral annulus calcification
4. Calcific aortic stenosis
5. Mitral valve prolapse
6. Bacterial endocarditis
7. Non-bacterial thrombotic endocarditis
8. Prosthetic heart valves
9. Left ventricular assist devices (LVAD)
10. Antiphospholipid syndrome
11. Fibrin valvular Lambl's excrescences

Aortic Valve Disease as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Aortic Valve Disease Associated with Emboli

1. Embolization occurs more commonly after cardiac catheterization than spontaneously
 - a. Emboli possibly as high as 33% for patients with calcific stenosis
 - b. The mitral valve embolizes more frequently than the aortic valve

Clinical Manifestations of Aortic Valve Disease Associated with Emboli

1. Topographical strokes in large vessels
2. Associated emboli to:
 - a. Retina (white and irregular, calcium deposits)
 - b. Coronary arteries
 - c. Renal arteries

Neuropathology of Aortic Valve Disease Associated with Emboli

1. Calcific aorta valve disease (CAVD) is the most common cause of acquired valve disease
2. Initial phase is the cause of thickening of the cusps

3. Advanced stages are associated with biomineralization and reduction of the aortic valve area. The former (early phase) is aortic valve sclerosis (AVS)
4. Patients with AVS and AS have higher osteopontin levels than controls
5. Lipoprotein-associated phospholipase A2 (encoded by the PLA2G7 gene) may play a pivotal role:
 - a. Valve tissue is infiltrated by lipids and inflammation may play a role in the destructive process by mineralization of valve interstitial cells
6. Microthrombi are found in up to 53% of aortic stenotic valves at necropsy

Neuroimaging of Aortic Valve Disease Associated with Emboli

1. Post transcatheter aortic valve implantation (TAVI)
 - a. Stroke of major arteries approximately 3%
 - b. Silent cerebral embolic lesions
 - i. Higher rates after TAVI compared with standard aortic valve repair

CT of Aortic Valve Disease Associated with Emboli

1. Rarely demonstrates calcific material in large arteries

Mitral Valve Disease as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Mitral Valve Disease Associated with Emboli

1. This valve most often involved in rheumatic fever
2. There is often concomitant aortic valve disease

Clinical Manifestations of Mitral Valve Disease Associated with Emboli

1. Embolism in mitral stenosis:
 - a. Occurs in 10–20% of patient's
 - i. Approximately 50–75% of these are to the brain
 - b. Atrial fibrillation greatly increases the risk of embolism
 - c. Incidence of embolization possibly 1.5% per year
 - d. Mitral insufficiency is a rare cause of cerebral embolism

Neuropathology of Mitral Valve Disease Associated with Emboli

1. Percutaneous trans-septal mitral commissurotomy (PTMC) has replaced surgical commissurotomy in selected patients with rheumatic mitral stenosis
 - a. Systemic embolism occurs in .5 to 5% of procedures with 1% going to the brain
 - b. Periprocedural embolism during PTMC is caused by a pre-existing thrombus in the left atrial appendage
 - c. Papillary fibroelastoma occurs on leaflets

Neuroimaging of Mitral Valve Disease Associated with Emboli Transesophageal Echocardiographic (TEE) of Mitral Valve Disease

1. TEE to evaluate the valve along with cardiac catheterization:

- a. Thrombus in the left atrial appendage is a contraindication to PTMC

MRI of Mitral Valve Disease

1. Topographical stroke in usual embolic sites
2. Increased incidence of silent brain infarction; increased if AF present

Mitral Annulus Calcification (MAC) as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Mitral Annulus Calcification

1. Degeneration of the fibrous support of the valve
2. Common in the elderly
3. Associated with chronic kidney disease
4. More common in women than men
5. Caseous calcification of the mitral annulus (CCMA) is a rare variant:
 - a. Liquifactive necrosis within a spheroid zone of mitral annular calcification

Clinical Manifestations of Mitral Annulus Calcification

1. Increased risk of stroke:
 - a. Each millimeter of thickening as documented by echocardiogram increases the relative risk of stroke (RR) by 1.24X
2. MAC is accompanied by myocardial infarction and AF
3. May develop superimposed SBE
4. Concomitant atrial and ventricular enlargement
5. AF conduction defect

Neuropathology of Mitral Annulus Calcification

1. Calcification occurs:
 - a. Posterior portion of the mitral annulus ring
 - b. May project into the cavity of the left ventricle

Neuroimaging of Mitral Annulus Calcification

1. Topographic patterns of embolic stroke

CT/MRI of Mitral Annulus Calcification

1. ECHO CT and MRI used to evaluate the valve lesion and to differentiate MAC from other cardiac lesions

Mitral Valve Prolapse as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Mitral Valve Prolapse

1. Mid systolic murmur:
 - a. Failure of mitral valve leaflets to coapt
 - b. Some patients have abnormal left ventricular contractions
2. Most commonly diagnosed cardiac valve lesion:
 - a. Prevalence of 5–20% in the general population
 - b. More common in women than men

Clinical Manifestations of Mitral Valve Prolapse

1. Clinical symptomatology:
 - a. Small percentage of patients develop severe mitral insufficiency with congestive heart failure (CHF)

- b. Atrial fibrillation may develop in elderly patients with myocardial infarction (MI) and enlarged left atria
- c. Associated with Marfan's syndrome, osteogenesis imperfecta and Ehlers–Danlos syndrome
- d. Rare endocarditis on myxomatous valves
- e. Low rate of cerebral embolization

Neurologic Features of Mitral Valve Prolapse

1. Emboli occur in young patients often without other associated risk factors
2. Strokes and transient ischemic attack (TIA) occur
3. Approximately 10% of patients have atrial fibrillation concomitantly with the stroke
4. Platelet dysfunction is reported in some patients with mitral valve prolapse:
 - a. Shortened survival time
 - b. Increased levels of beta-thromboglobulin and platelet factor IV
5. Recurrent embolic stroke is rare

Neuropathology of Mitral Valve Prolapse

1. Disruption of valve collagen by infiltration of myxomatous material
2. Thickened and elongated chordae tendineae
3. Infiltration of the mitral valve annulus
4. Fibrosis and thickening of the endocardial surface of the valve leaflets
5. Transferring growth factor β family cytokines may be pivotal

Neuroimaging of Mitral Valve Prolapse

Echocardiography of Mitral Valve Prolapse

1. Echocardiographic evaluation:
 - a. 2 mm or greater movement of the coapted anterior or posterior valve leaflets
 - b. Valve leaflets are displaced into the left atrium during systole
 - c. Mitral valve thickening or redundancy
 - d. Regurgitation
 - e. Commissural prolapse of the mitral valve identified on 3 dimensional Transesophageal echocardiography (TEE)
 - f. Topographic stroke from embolization

Prosthetic Heart Valves as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Prosthetic Heart Valves

1. Mechanical valves are:
 - a. Metal and carbon alloys
 - b. Bioprosthetic valves:
 - i. Heterography from pig and cow pericardium or valves
2. Non-tissue valves:
 - a. Thrombus forms at the component tissue interface or in areas of stenosis

3. Incidence of embolization is related to the degree of thrombogenicity:
 - a. Non cloth covered prosthetic valves > cloth covered prosthetic valves > tissue valves

Clinical Manifestations of Prosthetic Heart Valves

1. Increased risk for embolization:
 - a. Caged ball valve prosthesis
 - b. Mitral valve (associated with atrial fibrillation)
 - c. Multiple prosthetic valves
 - d. Age > 70 years
 - e. Atrial fibrillation
 - f. Decreased left ventricular ejection fraction
 - g. Subacute bacterial endocarditis (SBE)
 - h. Pregnancy and the puerperium
2. Mitral valve embolize > aortic valves
3. Risk of bioprosthetic valve embolization equals that of mechanical valves that are adequately anti-coagulated
4. Size of the cerebral infarction is due to:
 - a. Size of the embolus
 - b. Stability of the embolus
 - c. Adequacy of the collateral circulation

Neuropathology of Prosthetic Heart Valves

1. Dacron rings are a nidus for platelet activation and adhesion
2. Prosthetic material activates intrinsic clotting cascade; erythrocyte-fibrin thrombi form
3. Degeneration of bioprosthetic valves:
 - a. Deposition of white platelet fibrin thrombi
 - b. Cusp sinuses of bioprosthetic mitral valves:
 - i. Undergo fibrosis and calcification
 - ii. Nidus for thrombi

Neuroimaging of Prosthetic Heart Valves

MRI of Prosthetic Heart Valves

1. Topographical large vessel stroke

Transesophageal Echocardiography (TEE) of Prosthetic Heart Valves

1. TEE to evaluate the valves

Endocarditis on Prosthetic Valves as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Endocarditis on Prosthetic Valves

1. Occurs in 3–6% of patients:
 - a. Early endocarditis <60 days; from perioperative bacteremia: skin, wound or contaminated valves; organisms: staph epidermidis or aureus; gram-negative bacteria; diphtheroids; fungi; mycobacteria; and legionella
 - b. Late prosthetic valve endocarditis >60 days post-operatively; streptococci, staph epidermidis
 - c. The risk of endocarditis is similar for mechanical and bioprosthetic valves
 - d. Most common symptoms and signs; fever, new or changing murmur, systemic embolization or congestive heart failure

- e. Early endocarditis: rapid hemodynamic deterioration, conduction defects, poor peripheral perfusion
- f. Mortality for prosthetic valve endocarditis is 30–80% for the early form and 20–40% for the late form
- g. Infection with organisms other than streptococcus usually results in valve replacement

Neuroimaging of Endocarditis on Prosthetic Valves

1. In patients with left-sided infective valve endocarditis (study of 139 patients):
 - a. Acute ischemic lesions (55%)
 - i. Small lesions of less than 10 mm (60%)
 - ii. Multiple lesions (77%)
 - iii. Lesions were noted in multiple vascular territories (64%)
- b. Silent brain infarcts (>50%)
 - i. Peripheral intracranial aneurysm
 - ii. Peripheral hemorrhages from mycotic aneurysms
 - iii. Rare SAH

Laboratory Evaluation of Endocarditis on Prosthetic Valves

CSF Evaluation of Endocarditis on Prosthetic Valves

1. Pleocytosis < 300 cells/mm³
2. Neutrophilic early and lymphocytic late
3. Slight increase of protein
4. Sugar if affected (30 to 40 mg/dl)
5. May have normal CSF

Subacute Bacterial Endocarditis (SBE) as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Subacute Bacterial Endocarditis

1. Natural valves: staph epidermidis, staph aureus and group D streptococcus are the most common organisms
2. Prosthetic valves: aspergillus most common for early emboli; strep viridans for late emboli
3. New epidemiology:
 - a. Older patients
 - b. Intravenous drug abuse patients
 - c. Tricuspid valve is more frequently involved
4. 20% of patients with endocarditis suffer cerebral emboli:
 - a. Small cortical or subcortical bland infarcts
 - b. Large infarcts are secondary often to staph aureus
5. 50% of infected prosthetic valves cause cerebral emboli
6. Neurologic complications are similar for native and prosthetic valves

Neuropathology of Subacute Bacterial Endocarditis

1. Valve pathology:
 - a. Calcified valves
 - b. Prosthetic valves
 - c. Rheumatoid valves
 - d. Mitral valve prolapse
 - e. Myxomatous mitral valves
2. 30–40% of emboli may occur from normal valves
 - a. Aortic > mitral
3. Sterile vegetations may embolize

Clinical Manifestations of Subacute Bacterial Endocarditis

Systemic Symptoms of Subacute Bacterial Endocarditis

1. Intermittent fever and fatigue
2. Backache is common, early
3. Embolization to other organs; large artery occlusion suggests fungus
4. Loss of weight and appetite
5. Multiple immune abnormalities

Neurologic Signs and Symptoms of Subacute Bacterial Endocarditis

1. Cerebral and retinal transient ischemic attack (TIA)
 - a. Most common early in the course of the infection
2. Brain ischemia
 - a. 15–19% of patients
3. Ischemic stroke may occur after treatment has started
4. Intracranial hemorrhage:
 - a. 2.8–7% of patients
 - b. Hemorrhagic transformation of bland infarcts
 - c. Large hemorrhages occur:
 - i. Concomitant use of anticoagulants
 - d. Rupture of mycotic aneurysms
 - i. Occur in peripheral subpial vessels
 - e. Intracranial hemorrhage occurs at or near time of presentation
 - i. May have had a preceding transient ischemic attack
 - f. Mycotic aneurysms may rupture after bacterial treatment
 - g. Hemorrhagic transformation may occur with tissue plasminogen activator (tPA) therapy

Encephalopathy as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Encephalopathy Associated with Emboli

1. Most common with staph aureus:
 - a. Toxic metabolic factors
 - b. Secretion of interleukins (IL-6) with subsequent cerebral edema
 - c. Associated brain infarcts and micro-abscesses

Meningitis as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Meningitis Associated with Emboli

1. Embolization of bacteria to meningeal arteries:
 - a. Presentation with neck and back pain prior to neurologic symptoms
 - b. 1.1–6.4% of patients with endocarditis have meningitis

Vegetations as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Vegetations Associated with Emboli

1. Millimeters to centimeters in size

- a. Fungi are the largest
2. Potential for embolization is related to:
 - a. Size
 - b. Friability
3. Valve most likely to embolize
 - a. Mitral > aortic > tricuspid
4. May be culture negative
5. May occlude peripheral arteries (usually fungus)

Non-Infective Endocardial Lesions as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Non-Infective Endocardial Lesions Associated with Emboli

1. Occurs primarily in systemic lupus erythematosus (SLE), the antiphospholipid antibody syndrome (APLS) and non-bacterial thrombotic endocarditis (NBTE) from cancer
2. Probable similar pathogenesis
3. All three entities are associated with:
 - a. Hypercoagulability
 - b. Thrombocytopenia
 - c. Embolic stroke
 - d. Platelet thrombi on valve and endocardial tissues
 - e. Emboli to the spleen, kidney and rarely, to the heart
4. Non-infective valve lesions are associated with:
 - a. Ergotamine
 - b. Methysergide
 - c. Dexfenfluramine
 - d. Phentermine
 - e. Carcinoid (high serotonin levels)
 - f. Leukemia
 - g. Elevated proinflammatory cytokines
 - h. Increased VIII, vWF and fibrinogen
5. Strands
 - a. May be demonstrated by transesophageal echocardiography:
 - i. Strands of mobile tissue attached to valve and endocardial surfaces

Clinical Manifestations of Non-Infective Endocardial Lesions Associated with Emboli

1. Association of stroke and strands:
 - a. Young patients
 - b. Mitral and aortic strands
 - c. Low recurrent stroke risk
 - d. Occurs in patients with SLE, APLAS and NBTE

Neuropathology of Non-Infective Endocardial Lesions Associated with Emboli

1. Filamentous strands are known as Lambl excrescences:
 - a. Located on the atrial surfaces of mitral valves or the ventricular surfaces of aortic valves
 - b. Strands are composed of:
 - i. Cellular connective tissue core covered by epithelium
 - ii. 1–10 mm in length

- iii. May be related to fibrinous deposits on valve surfaces
- iv. May spread to the endocardium and papillary muscles
- c. Prevalence by TEE (transesophageal echocardiography)
 - i. Approximately 4% on mitral valves
 - ii. 1.7% on aortic valves
 - iii. Incidence possibly 10% in patients who have suffered embolization

Antiphospholipid Antibody Syndrome as a Structural Cause of Valvular Heart Disease Associated with Emboli

General Characteristics of Antiphospholipid Antibody Syndrome Associated with Emboli

1. Antiphospholipid antibodies are a heterogeneous family
2. In general the venous system is more involved than the arterial
3. The antiphospholipid antibody is classified as primary or secondary:
 - a. Secondary forms can occur with systemic lupus erythematosus or other collagen vascular diseases
 - b. Primary and secondary forms are clinically indistinguishable

Clinical Manifestations of Antiphospholipid Antibody Syndrome Associated with Emboli

1. Some patients may have antibodies and are asymptomatic
2. If the antibodies are associated with infection or medications:
 - a. They are often transient
 - b. Have a restricted range of immunoreactivity
 - c. Are not associated with clinical symptomatology
3. Ischemia can occur in any vascular territory
4. Embolic mechanism from predominantly mitral valve lesions (demonstrated by 2-dimensional transthoracic echocardiography)
5. Women may be at higher risk
6. Recurrent transient ischemic attack (TIA) and stroke with presence of anticardiolipin antibodies and lupus anticoagulant

Neuropathology of Antiphospholipid Antibody Syndrome Associated with Emboli

1. Vegetations are prominent along valve closure lines and leaflets
2. They may spread to papillary muscle and endocardium
3. Same pathology is noted with lupus verrucous endocarditis (Libman-Sacks)
4. Thickened valves

Neuroimaging of Antiphospholipid Antibody Syndrome Associated with Emboli

Trans Doppler Echocardiography of Antiphospholipid Antibody Syndrome

1. Cerebral microemboli may be detected
2. Abnormal in 1/3 of patients

MRI of Antiphospholipid Antibody Syndrome

1. Small foci of high signal intensity in T2-weighted sequences throughout the brain
2. Demonstrated in one study:
 - a. Number and size of white matter lesions with clinical symptoms (>8 mm size)
 - b. Verebral atrophy

Laboratory Evaluation of Antiphospholipid Antibody Syndrome Associated with Emboli

1. Patients demonstrate lupus anticoagulant
2. Anticardiolipin antibody (IgG or IgM)
3. Patients with clinical features of antiphospholipid antibody syndrome may have embolic stroke and a negative screen for antibodies

Non-Bacterial Thrombotic Endocarditis as a Structural Cause of Valvular Heart Disease Associated with Emboli**General Characteristics of Non-Bacterial Thrombotic Endocarditis Associated with Emboli**

1. Associated most often with cancer (particularly mucinous adenocarcinoma, prostate, lung, or melanoma)
2. Other Associations:
 - a. SLE
 - b. APLAS
 - c. Pneumonia
 - d. Perforated ulcer
 - e. Wasted immunosuppressed patients
 - f. Severe gram negative infection
 - g. Pheochromocytoma
 - h. Compensated disseminated intravascular coagulation (DIC)

Clinical Manifestations of Non-Bacterial Thrombotic Endocarditis Associated with Emboli

1. Both small and large vessel occlusions occur in the cerebral or systemic circulation
 - a. Cerebral emboli with stroke occur in 50% of patients with valve lesions
2. Often associated with DIC but also occur concomitantly with SAH, ICH and thrombotic stroke
 - a. Elevated D-dimer seen in this context

Neuropathology of Non-Bacterial Thrombotic Endocarditis Associated with Emboli

1. Order of valve involvement:
 - a. Mitral > aortic > tricuspid > pulmonary
 - b. Deposits are along lines of valve coaptation and consist of degenerating platelets, fibrin and leukocytes
 - c. Bivalvular lesions occur
 - d. Vegetations are bland and less than 5 mm in size

Lupus Verrucous Endocarditis as a Structural Cause of Valvular Heart Disease Associated with Emboli

1. Fibrous thickening of valves
2. Vegetations prominent along valvular closure lines and leaflets

3. Spread to the papillary muscles and endocardium
4. Associated with cerebral embolism
5. Aortic and mitral valves are primarily affected

Cardiomyopathy as a Structural Cause of Heart Disease Associated with Emboli**Overview of Cardiomyopathy Associated with Emboli**

1. Embolism is most common in dilated cardiomyopathies with an ejection fraction less than 30%
2. Loss of normal subendocardial trabeculations
3. Stasis of blood; prolonged contact of platelets and contact factor XIII
4. Mural thrombi form within the trabeculae of the cardiac apex
5. Embolism is less frequent in hypertrophic cardiomyopathy unless there is concomitant atrial fibrillation
6. Associated with the stasis of blood with congestive heart failure (CHF)
7. The cardiomyopathies associated with emboli:
 - a. Idiopathic
 - b. Post-partum
 - c. Viral
 - d. Myocarditis (idiopathic)
 - e. Ischemic cardiomyopathy
 - f. Sarcoidosis
 - g. Amyloidosis
 - h. Endocardial fibroelastosis
 - i. Mitochondrial myopathies
 - j. Dystrophinopathy (Duchenne muscular dystrophy; Becker's muscular dystrophy)
 - k. Inflammatory muscle disease (Inclusion body myositis; dermatomyositis; polymyositis)
 - l. Nemaline myopathy
 - m. Glycogen storage disease (glycogen debrancher deficiency)
 - n. Scapuloperoneal dystrophy with mental retardation
 - o. Desmin myopathy
 - p. Myofibrillar lysis myopathy
 - q. Fabry's disease
 - r. Cocaine abuse
 - s. Endocrinopathies (acromegaly, hypothyroidism, adrenal insufficiency)
 - t. Congenital myopathies
 - u. Barth syndrome
 - v. Senger's syndrome
 - w. McCloud syndrome
 - x. Emery-Dreifuss muscular dystrophy

Hypertrophic Cardiomyopathy as a Structural Cause of Heart Disease Associated with Emboli**General Characteristics of Hypertrophic Cardiomyopathy Associated with Emboli**

1. Hypertrophic Cardiomyopathy (HCM) is the most common genetic disease of the heart
2. Greater than 1000 mutations have been identified primarily in genes that encode sarcomeric proteins

3. Prevalence of 1:500 in the general population
4. The most common cause of sudden death in young patients and athletes
5. Predominantly autosomal dominant
 - a. Autosomal recessive, X-linked and mitochondrial patterns of inheritance have been reported
6. Asymmetric hypertrophy of the left ventricular septum that causes:
 - a. Variable obstruction of left ventricular outflow from systolic anterior displacement of the mitral valve
 - b. Concomitant structural abnormality of the mitral valve
7. The penetrance of left ventricular hypertrophy (LVH) is age-dependent and incomplete
8. Annual mortality rate of HCM is <1% in the general community

Clinical Manifestations of Hypertrophic Cardiomyopathy Associated with Emboli

1. Asymmetric hypertrophy of the left ventricular septum that causes:
 - a. Variable obstruction of the left ventricular outflow from systolic anterior displacement of the mitral valve
 - b. Concomitant structural abnormality of the mitral valve
2. Syncope with prolonged exercise
3. Atrial fibrillation associated with left atrial enlargement occurs late in the course of the disease with a low rate of cerebral embolization
4. Rare concomitant subacute bacterial endocarditis (SBE) of mitral valve or of the annulus calcification or may be causative
5. Sudden death

Neuropathology of Hypertrophic Cardiomyopathy Associated with Emboli

1. Increased left ventricular mass and thickened wall
2. Increased interventricular septum
3. Fibrosis at the junction of the septum to the anterior and posterior walls of the left ventricular
 - a. The thickened septum may bulge into the left ventricular that diminishes the end diastolic lumen space which may block ventricular outflow
 - b. Valve leaflets and chordae tendineae become thickened by fibrosis
 - c. Histological findings
 - i. Myocyte and myofibrillar disarray; "herringbone" or "pin wheel" configurations occur

Neuroimaging of Hypertrophic Cardiomyopathy Associated with Emboli

MRI of Hypertrophic Cardiomyopathy

1. Cardiac-MR methods assess diastolic dysfunction

Trans Doppler Echocardiography of Hypertrophic Cardiomyopathy

1. TDE evaluation of decreased myocardial relaxation velocities

Hereditary Cardiomyopathies as a Structural Cause of Heart Disease Associated with Emboli

General Characteristics of Hereditary Cardiomyopathies Associated with Emboli

1. Categories of familial dilated cardiomyopathies (FDCM):
 - a. Mutations in contractile protein genes
 - b. Dystrophinopathies:
 - i. Affected boys and men
 - ii. Women carriers of Becker or Duchenne mutations
 - iii. Mitochondrial disorders
 - iv. Sarcoglycanopathies
 - v. Limb girdle myopathies
 - vi. Rare disorders
2. Genetics of FDCM
 - a. Allelic and locus heterogeneity

Clinical Manifestations of Hereditary Cardiomyopathies Associated with Emboli

1. Syncope
2. Palpitations
3. Dyspnea
4. Heart failure
5. Exertion induced sudden death
6. Angina
7. Anesthetic complications (malignant hyperthermia)

Neurologic Features of Hereditary Cardiomyopathies Associated with Emboli

1. Cerebral emboli occur in patients with:
 - a. Ejection fractions of <30%
 - b. Trans echo cardiogram that demonstrate:
 - i. "Smoke" (echoic signals that signal altered intracardiac blood flow)

Familial Hypertrophic Cardiomyopathy (FHCM) as a Structural Cause of Heart Disease Associated with Emboli

General Characteristics of Familial Hypertrophic Cardiomyopathy Associated with Emboli

1. Clinical onset from fetal life to adulthood
2. Mutations in genes that encode cardiac contractile proteins:
 - a. Most frequent mutations:
 - i. B-myosin heavy chain
 - ii. High penetrance
 - iii. High incidence of sudden death
 - b. Less common mutations in genes for:
 - i. Essential light chain proteins
 - ii. Regulatory light chain proteins
 - iii. Myosin-binding proteins

Clinical Manifestations of Familial Hypertrophic Cardiomyopathy Associated with Emboli

1. Clinical syndromes of familial hypertrophic cardiomyopathy

- a. Autosomal dominant in some families
- b. Penetrance is age dependent
- c. Clinical heterogeneity within families

Neuropathology of Familial Hypertrophic Cardiomyopathy Associated with Emboli

1. Penetrance:
 - a. B-myosin high penetrance
 - i. High incidence of sudden death
 - b. B-myosin low penetrance
 - i. Benign course
2. Mutation specific causes of sudden death:
 - a. Myocardial ischemia that induces:
 - i. Syncope
 - ii. Presyncope
 - iii. Sudden death
 - b. Heart block
 - c. Pre-excitation syndrome
3. Mutations causing functional deficits:
 - a. B-myosin heavy chain
 - i. Affects head-rod junction
 - b. Expression of mutations in skeletal muscle that cause:
 - i. Decreased isometric force
4. Mutations expressed in skeletal muscle:
 - a. Heart and skeletal muscle affected concomitantly
 - b. B-myosin heavy chain; myosin light chains, and tropomyosin are affected
5. Variance in degree of heart muscle pathology
 - a. Focal heart muscle pathology vs generalized heart muscle involvement

Dystrophinopathy as a Structural Cause of Heart Disease Associated with Emboli

General Characteristics of Dystrophinopathy Associated with Emboli

1. The more limited the patients' exercise tolerance is proportional to lesser symptomatic cardiomyopathy
2. EKG abnormalities in Becker and Duchenne muscular dystrophy increase dramatically with age
3. Duchenne muscular dystrophy carrier women
 - a. 38% abnormal cardiograms
4. Becker muscular dystrophy carrier women
 - a. 34% abnormal cardiograms
5. 8% of Duchenne muscular dystrophy carriers suffer dilated cardiomyopathy
6. X-linked cardiomyopathy:
 - a. Similar dystrophin gene type mutation in some; others are new mutations:
 - i. High CPK
 - ii. Dystrophic myopathy by skeletal muscle biopsy
7. Sarcoglycanopathy:
 - a. Patients with dilated cardiomyopathy:
 - i. Point mutation in gene for alpha sarcoglycan

Mitochondrial Cardiomyopathy as a Structural Cause of Heart Disease Associated with Emboli

General Characteristics of Mitochondrial Cardiomyopathy Associated with Emboli

1. Dilated cardiomyopathy:
 - a. More common in patients with maternally inherited point mutations
 - b. Mutations most common in:
 - i. Mitochondrial DNA-encoded t RNA's
2. MELAS-3243 mutation
 - a. Dilated cardiomyopathy
3. Progressive external ophthalmoplegia (PEO):
 - a. Dilated cardiomyopathy
 - b. Multiple mitochondrial DNA deletions
 - c. Eastern Arabian Peninsula (most common)
4. Kearns-Sayre syndrome:
 - a. Dilated cardiomyopathy
 - b. Adolescents with stroke
 - c. Predominant cardiac feature is heart-block
5. Patients with dilated cardiomyopathy identified with:
 - a. Complex I, III, and IV mitochondrial complex deficits

Rare Myopathies with Emboligenic Cardiomyopathy

1. Myofibrillar lysis myopathy
2. Scapuloperoneal dystrophy with mental retardation
3. Glycogen debrancher deficiency
4. Nemaline myopathy
5. Desmin myopathy
6. Left ventricular non-compaction syndrome
7. Centronuclear myopathy

Hereditary Dysrhythmias Associated with Embolic Stroke – Prolonged QT Syndromes

General Characteristics of Prolonged QT Syndromes Associated with Embolic Stroke

1. Prolongation of the QT interval
 - a. Corrected for heart rate
2. T-wave abnormalities
3. Bradycardia
4. Ventricular tachyarrhythmias
5. Polymorphic ventricular tachycardias
6. Torsades de pointes (Ventricular fibrillation)
7. Defects of cardiac repolarization

Clinical Manifestations of Prolonged QT Syndromes Associated with Embolic Stroke

1. Syncope
2. Seizure
3. Sudden death
4. Triggers:
 - a. Exercise
 - b. Emotion
 - c. Noise

- d. Lack of sleep
- 5. Romano-Ward syndrome
 - a. Autosomal dominant
 - b. Most common form
 - c. No hearing loss
- 6. Jervell
 - a. Rare
 - b. Autosomal recessive; gene is HERG (or KCNH2 in new nomenclature)
 - c. Sensorineural deafness
- 7. Lang Nielson
 - a. Cardiac defect is autosomal dominant
 - b. Deafness is recessive

Neuropathology of Prolonged QT Syndromes Associated with Embolic Stroke

- 1. Heterogeneous genetic defects:
 - a. Mutation in the cardiac potassium channel HERG (KCNH2)
 - b. Reduces the delayed rectifier KCN currents
 - c. A trafficking defect that cause failure of delivery of the mutant protein to the plasma membrane

Cardiac Tumors That Embolize – Atrial Myxoma

General Characteristics of Atrial Myxoma Associated with Emboli

- 1. Cardiac myxoma is the most common benign cardiac tumor
- 2. 75 to 80% are situated in the left atrium
- 3. Occurrence is 2:1 female preponderance
- 4. Age of onset between 30 and 60 years of age
- 5. Familial form – Carney complex

Clinical Manifestations of Atrial Myxoma Associated with Emboli

- 1. Congestive heart failure
- 2. Constitutional symptoms occur in up to 90% of patients and include:
 - a. Muscle weakness
 - b. Arthralgia
 - c. Fever
 - d. Weight loss
 - e. Fatigue
- 3. Cardiac symptoms:
 - a. Syncope (change of cardiac output)
 - b. Tripopnea:
 - i. Right atrial myxoma
 - ii. Shortness of breath with position change (blockage of right ventricle outflow)
 - c. Heart murmur usually MI > MS (with mitral valve disease)
 - d. Occasionally a cardiac “plop” can be auscultated. Tumor falls into the valve and obstructs it
 - e. Rare bilateral myxomas
 - i. Project from right atrium to left and through a patent foramen ovale
 - f. Less than 10% are in the ventricles

Neurological Signs and Symptoms of Atrial Myxoma Associated with Emboli

- 1. Superficial pial MCA territory most commonly affected (by emboli)
- 2. Peripheral aneurysm of superficial blood vessels:
 - a. Some aneurysms are proximal
 - b. Small proportion are located in the posterior circulation
- 3. Rupture of the aneurysms with SAH or hemorrhagic infarctions
- 4. Delayed progressive neurologic signs may be rarely seen
- 5. 30–50% of cardiac myxomas embolize (common presentation)
- 6. Rare embolization to the spinal cord
- 7. Sudden death (possible coronary artery embolus)
- 8. Intraparenchymal metastasis

Neuropathology of Atrial Myxoma Associated with Emboli

- 1. Atrial myxoma:
 - a. Arise from either side of the atrial septum in the region of the fossa ovalis
 - b. Left atrium > left ventricle:
 - i. May have simultaneous origin from both atria
 - c. Attached to the atrial wall or are pedunculated and cause valve obstruction
 - d. Gelatinous round, polypoid masses covered with platelet fibrin clots
- 2. Myxomatous aneurysm:
 - a. Fusiform in shape
 - b. Multiple
 - c. Located distally on the arterial tree
 - d. Putative mechanism of aneurysm formation:
 - i. Viable tumor emboli penetrate the endothelium
 - ii. Grow subintimally
 - iii. Destroy the arterial wall
 - iv. Accompanied by displacement of smooth muscle, connective tissue proliferation and a mild inflammatory response

Neuroimaging of Atrial Myxoma Associated with Emboli

- 1. Ischemic stroke in embolic territorial distributions
- 2. Multiple distal fusiform aneurysms primarily in the anterior circulation
- 3. Intraparenchymal microhemorrhages

Cardiac Tumors That Embolize – Papillary Fibroelastoma

General Characteristics of Papillary Fibroelastoma Associated with Emboli

- 1. A rare benign cardiac tumor that is approximately 10% of all primary cardiac tumors
- 2. Approximately 90% of these tumors occur in cardiac valves

Clinical Manifestations of Papillary Fibroelastoma Associated with Emboli

- 1. Most tumors are asymptomatic

2. Myocardial infarction
3. Rare manifestations:
 - a. Pulmonary embolism
 - b. Congestive heart failure
 - c. Syncope
 - d. Ventricular fibrillation
 - e. Sudden death
4. Neurologic complications
 - a. Embolic stroke

Neuropathology of Papillary Fibroelastoma Associated with Emboli

1. Tumors most commonly involve the aortic valve followed by the mitral valve
2. Rare sites of origin:
 - a. Mitral chordae tendineae
 - b. Right atrial endocardium
 - c. Endocardial surface of both ventricles
 - d. Papillary muscles and the interventricular septum
3. Gelatinous masses with a characteristic “sea anemone” appearance due to multiple delicate papillary fronds
 - a. Tumors are usually less than 15 mm in diameter
 - b. Attached to the endocardium by a short thin stalk
 - c. Histologic evaluation:
 - i. Myxoid connective tissue containing a mucopolysaccharide matrix and elastic fibers covered by endothelial cells

Neuroimaging of Papillary Fibroelastoma Associated with Emboli

MRI of Papillary Fibroelastoma

1. Topographic MRI embolic stroke

Echocardiography of Papillary Fibroelastoma

1. Small mobile homogeneous valvular or endocardial masses that are attached to the valves or endocardium by short pedicle
2. Speckled appearance near its edges that correlates with the papillary projection on the tumor surface

Cardiac Tumors That Embolize – Rhabdomyoma

General Characteristics of Rhabdomyoma Associated with Emboli

1. Benign cardiac tumors that are often associated with tuberous sclerosis and less frequently neurofibromatosis, type 1 (NF1)
2. Almost any organ of the body may be affected
3. The tumors may spontaneously regress

Clinical Manifestations of Rhabdomyoma Associated with Emboli

1. Cardiac:
 - a. Heart failure
 - b. Arrhythmias
 - c. Obstruction
 - d. Wolff-Parkinson-White syndrome (WPW)
2. Emboli to the cerebral circulation of tumor fragments

Neuropathology of Rhabdomyoma Associated with Emboli

1. Sites of origin:
 - a. Right ventricle (35%)
 - b. Interventricular septum (33%)
 - c. Left ventricle (22%)
2. Approximately 50% show partial regression
3. In approximately 60% of patients the tumor is associated with tuberous sclerosis
 - a. Some of the cells in the cardiac rhabdomyomas are identical to cardiac Purkinje cells
4. Tumors may be located deep in the myocardium

Neuroimaging of Rhabdomyoma Associated with Emboli

MRI of Rhabdomyoma

1. Topographic embolic stroke

Transthoracic Echocardiography of Rhabdomyoma

1. Used to monitor the tumor

Differential Diagnosis of Cardiac Tumors Associated with Emboli

1. Rhabdomyoma
2. Atrial and ventricular myxomas
3. Fibroelastoma
4. Histiocytoma
5. Hemangioma
6. Hamartoma
7. Undifferentiated
8. Fibroma
9. Metastatic tumors
10. Leiomyosarcoma
11. Angiosarcoma

Differential Diagnosis of Intracardiac Lesions Associated with Emboli

1. Cardiac tumors
2. Metastatic tumors to the heart
 - a. Hypernephroma (through the inferior vena cava)
 - b. Squamous cell lung carcinoma (through the pericardium)
 - c. Malignant melanoma (able to attach to the endocardium)
3. Ball valve thrombus
4. Mural thrombus:
 - a. Following myocardial ischemia
 - b. Within ventricular aneurysm
5. Thrombi within septal aneurysms

Paradoxical Emboli

General Characteristics of Paradoxical Emboli

1. Primarily a venous origin clot that accesses an intracardiac shunt to cause a stroke
2. Four criteria for diagnosis:

- a. A venous thrombus in the peripheral venous system or rare causes (fat, air, fibrocartilage, amniotic fluid)
- b. A right to left cardiac shunt is present
- c. An increased right to left pressure gradient exists:
 - i. Occurs transiently during the cardiac cycle but can be exacerbated by Valsalva maneuvers
- d. A thrombus is identified in the arterial circulation
3. A probable major cause of cryptogenic stroke (a pathophysiological mechanism is not determined)
 - a. Possibly 30%–40% of all strokes
 - b. Increased in younger stroke patients
6. Atrial septal aneurysm associated with focal thrombosis (at the septal bulge)
7. Thromboses have been imaged as they transverse a patent foramen ovale and have been identified in a patent foramen ovale at autopsy
8. Higher incidence of deep venous thrombosis in cryptogenic stroke
9. Isolated calf and pelvic vein thrombosis may be associated with cryptogenic stroke; May-Thurner syndrome has an increased incidence of cryptogenic stroke
10. There is a possible relationship between patent foramen ovale, pulmonary embolus and stroke
11. Air embolism:
 - a. Central vein catheter insertion and removal
 - b. Disconnection of a central catheter
 - c. Thoracic or cardiac surgery
 - d. Pulmonary barotrauma
 - e. Cardiac ablation procedures
12. Risk of air emboli from central catheter is 1–2%; increased by:
 - a. Sitting position
 - b. Deep inspiration (during insertion or removal)
 - c. Hypovolemia
 - d. Injection sclerotherapy for varicose veins

Clinical Manifestations of Paradoxical Emboli

1. Pulmonary hypertension is a setting that favors a paradoxical embolus
 - a. May be induced by prior pulmonary emboli
2. Most common setting is an abnormal connection between the right and left sides of the heart
3. Possibly associated with valsalva maneuvers, coughing, defecation and urination

Criteria for Paradoxical Embolism

1. A venous thrombus as a source
2. An anatomical connection from the venous to the arterial circulation
3. A pressure gradient that promotes venous to the arterial circulation
4. A thrombus in the arterial circulation

Neuropathology of Paradoxical Emboli and a Patent Foramen Ovale (PFO)

1. Autopsy material demonstrates that approximately 25–30% of subjects have a patent foramen ovale whose mean diameter is 5 mm; younger patients have slightly larger patent foramen ovals
2. Echo studies demonstrate patent foramen ovale at 10–22% of normal people
3. Possibly a patent foramen ovale is associated with a large percentage of cryptogenic stroke
4. Agitated saline injected into a femoral vein is more sensitive than echo alone in demonstrating a patent foramen ovale:
 - a. Right atrial blood more easily detected toward the interatrial septum if it originate from the inferior rather than the superior vena cava

Associated Features of Patent Foramen Ovale That Favor a Clinical Paradoxical Embolism

1. Atrial septal aneurysm (ASA)
 - a. Also associated with recurrence
2. Motion of the atrial septal aneurysm that directs flow from the inferior vena cava to the interatrial septum
3. Size of the patent foramen ovale
4. Prominent eustachian valve
5. Right atrial filamentous strands

Neuroimaging of Paradoxical Emboli

1. Higher probability of pelvic deep vein thrombosis
 - a. External iliac vein the most commonly involved
 - b. Secundum atrial septal defects
 - i. Flat elliptical shape
 - c. Patent foramen ovale that are large and associated with an atrial septal aneurysm
 - d. Impending paradoxical emboli
 - i. Entrapped in a patent foramen ovale

May-Thurner Disease

Overview of May-Thurner Disease

May-Thurner syndrome comprises left lower extremity swelling secondary to left iliac vein compression. This anatomic abnormality can predispose patients to increased risk of paradoxical embolism and stroke.

General Characteristics of May-Thurner Disease

1. The left iliac vein compresses the right iliac artery at the level of the fifth lumbar vertebrae
2. Left lower extremity edema pain, varicosities and deep venous thrombosis
3. Source of paradoxical emboli is from right to left cardiac shunt
4. Typically presents in the second to fourth decades of life; more common in women than men (3:1)

Clinical Manifestations of May-Thurner Disease

1. Possible paradoxical embolism to the basilar apex
2. Possible increased risk of paradoxical emboli
3. Deep vein thrombosis

Neuropathology of May-Thurner Disease

1. Compression of the left common iliac vein
 - a. Risk factor for lower-extremity deep vein thrombosis

Neuroimaging of May-Thurner Disease

1. Stenosis of the left common iliac vein
2. Normal Left Common Iliac Vein diameter is 6.5 mm
3. Patients with deep vein thrombosis have a left common iliac vein diameter of 4 mm
4. The odds of deep vein thrombosis increased by a factor of 1.68 for each millimeter decrease in left common iliac vein

Differential Diagnosis of Cardiac Sources of Emboli*Ischemic Heart Disease as a Cardiac Source of Emboli*

1. Mural thrombus
2. Congestive heart failure
3. Ejection fraction of less than 30%
4. Ventricular aneurysm
5. Akinetic or hypokinetic segments

Cardiac Arrhythmia as a Cardiac Source of Emboli

1. Chronic or paroxysmal atrial fibrillation
2. Sick sinus syndrome
3. Brady-tachyarrhythmia
4. Long QT interval syndrome
5. Romano-Ward syndrome (AD)
6. Jervell syndrome (AD)
7. Lang-Nielsen syndrome (AR)

Valvular Heart Disease as a Cardiac Source of Emboli

1. Rheumatic mitral stenosis
2. Rheumatic mitral insufficiency (rare)
3. Rheumatic aortic stenosis
4. Bicuspid aortic valve (congenital)
5. Calcific aortic stenosis
6. Mitral annulus calcification
7. Bacterial endocarditis
8. NBTE (marantic endocarditis)
9. SLE (verrucous endocarditis)
10. Antiphospholipid syndrome (APLS)
11. Left ventricular assist devices
12. Prosthetic heart valves
13. Fibrous and fibrinous endocardial lesions

Cardiomyopathy as a Cardiac Source of Emboli

1. All dilated cardiomyopathies
2. Idiopathic
3. Post-partum
4. Viral
5. Ischemic cardiomyopathy
6. Sarcoidosis
7. Amyloidosis
8. Endocardial fibroelastosis

9. Multiple mitochondrial myopathies
10. Duchenne muscular dystrophy
11. Becker's muscular dystrophy
12. Idiopathic dilated cardiomyopathy
13. Variants of dystrophinopathy
14. Inclusion body myositis
15. Dermatomyositis/polymyositis complex
16. Nemaline myopathy
17. Debrancher glycogen storage disease
18. Scapuloperoneal dystrophy with mental retardation
19. Desmin myopathy
20. Myofibrillar lysis

Intracardiac Lesions as a Cardiac Source of Emboli

1. Cardiac tumors (primary):
 - a. Myxoma
 - b. Fibroma
 - c. Fibroelastoma
 - d. Hamartoma
 - e. Hemangioma
 - f. Histiocytoma
 - g. Rhabdomyoma (sarcoma)
 - h. Undifferentiated
 - i. Leiomyosarcoma
 - j. Angiosarcoma
2. Metastatic tumors:
 - a. Hypernephroma
 - b. Melanoma
 - c. Squamous cell carcinoma of the lung
 - d. Colon
 - e. Hepatocellular
 - f. Lymphoma
3. Ball valve thrombus
4. Mural thrombus
5. Ventricular aneurysm with thrombus
6. Septal aneurysm with thrombus

Intracardiac Defects with Paradoxical Embolus

1. Atrial septal defects
2. Ventricular septal defects
3. Patent foramen ovale (PFO)
4. Atrial septal aneurysms
5. PFO plus atrial septal aneurysm

The Aorta as a Source of Emboli*General Characteristics of the Aorta as a Source of Emboli*

1. Large plaques of greater than 4 mm are involved in first-ever cerebral infarction and stroke recurrence

*Clinical Manifestations of the Aorta as a Source of Emboli***Neurologic Signs and Symptoms of the Aorta as a Source of Emboli**

1. Protruding atheroma:
 - a. Related to emboli

2. Ulcerated plaque in the aortic arch may not correlate with atheromatous carotid disease
3. Ascending aorta and arch junction
 - a. Important site for plaques that embolize as is the origin of the innominate artery
4. Frequency of brain infarction correlated with thickness of the aortic wall
5. Complex, thick or mobile plaques > 5 mm have 3 times greater incidence of stroke than patients with plaques <5 mm
6. MCA distribution of emboli
7. Rare brachial plexus arterial supply

Neuropathology of the Aorta as a Source of Emboli

1. Average diameter of an aortic plaque is 19 mm
2. Plaques are frequently on the anterior or posterior right side of the ascending aorta
3. The upper and lower half of the ascending aorta are equally involved
4. Aortic arch plaques
 - a. At the orifice of the innominate artery
5. Complex thick or mobile plaques are most likely to embolize
6. Plaques have disappeared after anticoagulant therapy
7. Anticoagulants theoretically could potentiate cholesterol emboli by:
 - a. Blocking protective clot thrombi that cover plaque ulceration
8. Retrograde flow in aorta causes emboli to both the anterior or posterior circulation
9. Emboli during catheterization

Neuroimaging of the Aorta as a Source of Emboli

Transesophageal Echocardiography (TEE) of the Aorta as a Source of Emboli

1. Plaque grading system:
 - a. 0 mm – 0
 - b. 1 mm – grade 1
 - c. 2 mm – grade 2
 - d. 3 mm – grade 3
 - e. 4 mm – grade 4
 - f. 5 mm – grade 5; mobile complex

Unusual Sources of Emboli – Air Embolism

General Characteristics of Air Embolism

1. Specific settings:
 - a. Extracorporeal membrane oxygenation (ECMO)
 - b. Vascular surgical procedures
 - c. Open heart surgery
 - d. Head and neck surgery in the sitting position (air enters the jugular vein)
 - e. Pelvic vein insufflation (air) during pregnancy
 - f. Complication of gastrointestinal endoscopy
 - g. Ingestion of hydrogen peroxide
 - h. Insertion or removal of a central venous catheter
 - i. Frequency of air embolism in this setting is .1 to 2%
 - ii. Increased risk occurs

Clinical Manifestations of Air Embolism

1. Systemic air embolism
 - a. Arrhythmia
 - b. Hypotension
 - c. Myocardial ischemia
 - d. Right heart failure
 - e. Cardiovascular collapse
 - f. Cardiac arrest
2. Hypoxia cyanosis, respiratory failure
3. Focal neurologic signs
 - a. Eye deviation and hemiparesis
 - b. Failure to regain consciousness after anesthesia
 - c. Cerebral hypoperfusion
 - d. Cerebral edema and coma
4. In the case of ERCP initiated air embolism
 - a. Exacerbated signs when repositioned from a prone to supine position

Neuropathology of Air Embolism

1. High flow ECMO
 - a. Venous gas embolism occurs because of the extracorporeal perfusion system is not efficient enough to remove air microbubbles:
 - i. Any factor that reduces central venous pressure that include:
 1. Deep inspiration during insertion or removal
 2. Hypovolemia
 3. Upright position
 - b. Arterial air embolism occurs:
 - i. Entry of gas into the pulmonary vein
 - ii. Directly into the arteries of the systemic circulation
 - c. Arterial spasm
 - d. Widespread hemispheric distribution
 - e. Air bubbles in subarachnoid vessels

Neuroimaging of Air Embolism

MRI of Air Embolism

1. Diffusion-weighted sequences demonstrate diffuse hyperintensity
2. Air bubbles in cerebral arteries

CT of Air Embolism

1. Low attenuation lesions in the right atrium

Transthoracic Echocardiography of Air Embolism

1. Demonstrates air bubbles in the aorta and ventricular outflow tract

Trans Doppler Echocardiography of Air Embolism

1. Demonstrates microemboli during procedures

Unusual Sources of Emboli – Fat Emboli

General Characteristics of Fat Emboli

1. Fat embolism syndrome (FES):
 - a. Multi-organ disorder
 - b. Long bone fractures; particularly of the femur
 - c. Incidence of .5 to 11% of long bone fractures

Clinical Manifestations of Fat Emboli

1. Systemic complications:
 - a. Hypoxia
 - b. Pulmonary dysfunction
 - c. Petechiae (often over the chest wall)
 - d. Fever
 - e. Tachycardia
 - f. Thrombocytopenia
2. Setting:
 - a. Broken long bones in young patients
 - b. Hip replacement surgery (even in elderly patients)
3. Late syndrome:
 - a. 4–7 days following the event
 - b. Acute confusion
4. Altered mental status
5. Focal neurologic signs
6. Generalized seizures
7. Occurs most frequently in the second to third decade most often 12 to 72 hours after traumatic bone fracture

Neuropathology of Fat Emboli

1. Less common non-traumatic causes of fat embolus syndrome include:
 - a. Soft tissue injury liposuction
 - b. Hepatic failure
 - c. Propofol infusion
 - d. Burns
 - e. Acute sickle cell crisis
 - f. Acute pancreatitis
 - g. Altitude sickness

Pathogenesis of Fat Emboli (2 Theories)

1. Theory 1: release of fat droplets into the circulation from the site of trauma
 - a. Emboli pass through the lungs into the arterial circulation
2. Theory 2: fat droplets reach the capillary bed of the lung from the right heart which causes a ventilation-perfusion mismatch and the acute respiratory distress syndrome:
 - a. The intramedullary pressure in long bones may be the most significant factor in producing fat embolism syndrome
 - b. Multi-trauma patients demonstrate lung intravascular fat is similar to bone marrow fat
3. Experimental studies demonstrate:
 - a. Nitrous oxide mediated disruption of the blood-brain barrier by arterial fat globules cause:
 - i. Transient cerebral edema
 - ii. Neutrophil infiltration
 - iii. Activation of metalloproteinases

Neuroimaging of Fat Emboli

1. Site predilection for emboli:
 - a. Retina (fat globules visible)

- b. Corpus callosum
- c. Centrum semiovale
- d. Superficial pial vessels

CT of Fat Emboli

1. Hypointense areas at the gray-white matter junction consistent with fat globules

MRI of Fat Emboli

1. Brain images at 3 days
 - a. T2-weighted hyperintense areas with restricted diffusion in involved territories

Unusual Sources of Emboli – Decompression Sickness (DCS)*General Characteristics of Decompression Sickness*

1. Type 1 Decompression Sickness – Symptoms of musculoskeletal pain
2. Type 2 Decompression Sickness – Primarily related to the central nervous system
3. Spinal evidence that right to left heart shunts are relevant to decompression sickness
4. Arterial bubbles are more often associated with more serious cases of decompression sickness injury
5. Multiple cerebral infarction in the terminal and watershed areas of pial arteries
6. Subclinical forms of decompression illness exist

Neuropathology of Decompression Sickness

1. Venous gas emboli effects in the endothelium may be the central mechanism in decompression sickness
2. Stationary bubbles are formed in the tissue and produce local damage and intravascular arteriole blockage
3. Nitrogen bubbles are filtered out in the lungs
4. Arterial bubbles block and damage blood vessels in the brain and heart
5. Venous gas emboli cause changes in vessel permeability and disrupt endothelial function
 - a. Pivotal may be the generation of reactive oxygen species

*Neuroimaging of Decompression Sickness**MRI of Decompression Sickness*

1. Terminal and border zone ischemic lesions
2. Cerebral arterial gas embolism (CAGE)
 - a. Multiple lesions
 - b. Large size of the lesions
 - c. Frontal and parietal lobes are primarily affected
 - d. Involvement of cortical gray matter and subcortical white matter
 - e. Cerebellum may be involved

Differential Diagnosis of Unusual Sources of Emboli

1. Air (cardiac and neck surgery, diving accidents)

2. Fat emboli (diabetic ketoacidosis, trauma, pancreatitis)
 3. Nitrogen bubbles from diving (bends), pressure from underwater construction (Caisson's disease)
 4. Calcium (calcific aortic valves, calcified mitral valve annulus)
 5. Fungus balls (subacute bacterial endocarditis; Aspergillus endocarditis)
 6. Bullets (shot gun pellets; rare bullet fragments)
 7. Ectatic arteries (source of emboli)
 8. Aneurysms (giant > 1 cm; tip of the basilar, carotid, middle cerebral artery)
 9. Tumor material
 10. Thrombolytic therapy (lysis of clots that then expose underlying collagen which then forms new less adherent clots)
 11. Iatrogenic occlusive therapy (embolization of AVM's; Gelfoam)
 12. Catheters
 13. Defoaming agents
 14. MAC attack (esophageal fistula to veins)
 15. Talc (IV drug addicts; increased right heart pressure from pulmonary fibrosis; paradoxical embolus)
 16. Fibrocartilage (following orthopedic procedures)
- b. A state of internally oriented cognitive content:
 - i. Self-referential
 - ii. Social cognition
 - iii. Mind wandering
 - iv. Autobiographical memory recall
 - c. Areas that demonstrate fMRI activity of the default mode network (DMN) are:
 - i. Medial prefrontal cortex
 - ii. Anterior cingulate gyrus
 - iii. Precuneus
 - iv. Bilateral temporoparietal junction
 - d. Patients in coma demonstrate no fMRI DMN connectivity
 - i. If some activity is demonstrated the patient may regain consciousness
 - e. DMN/EEG synchrony:
 - i. Absent in VS/UWS; intermediate in MCS and highest in healthy controls
 - f. Brain metabolism in these midline structures:
 - i. Disrupted in VS/UWS and MCS compared to those who have emerged from MCS or are in a locked in state
 - ii. Deactivation of the medial DMN is absent in VS/UWS and decreased in MCS
 - iii. Changes in DMN functional connectivity relate to self-related conscious mentation
 - iv. Normal wakefulness has resting state activity in:
 1. Posterior cingulate
 2. Frontal areas
 3. Areas important for self-referential thought
 - v. The "intrinsic" network
 1. Coincides with the default mode network (DMN)
 - vi. The "extrinsic network"
 1. The lateral frontoparietal areas
 2. Activated during goal-directed behavior
 3. Linked to cognitive processes of external sensory input (somatosensory, visual, auditory stimuli)
 - vii. Metabolic activity in the vegetative state/unresponsive wakefulness syndrome (VS/UWS)
 1. Decreased activity in a widespread fronto-temporo-parietal associative cortical network associated with decreased levels of consciousness
 - viii. PET data:
 1. Recovery of MCS
 - a. Right lateralized recovery of the external awareness network
 2. Ability to follow commands:
 - a. Recovery of dominant left lateralized language network
 3. Similar findings occur in transient dissociative states of unresponsive wakefulness:
 - a. Absence seizures

Ischemic Encephalopathy

Consciousness

Overview

1. Consciousness is a combination of both the waking states and experience
 - a. A linear relationship exists between wakefulness and awareness of the surroundings and ourselves
2. Vegetative state/unresponsive wakefulness syndrome (VS/UWS)
 - a. Maintain awake periods evidenced by eye opening
 - b. Never respond to visual, somatosensory or auditory stimuli
 - c. Sleep-wake cycle is entrained
3. Minimal conscious state (MCS)
 - a. Fluctuating signs of awareness
 - b. Demonstrates non-reflexive behaviors
 - i. Visual pursuit
 - ii. Follow some commands
4. Self-consciousness
 - d. Response to stimuli that modify behavior which implies awareness of patient's surroundings and an action
 - e. Response to self-referential stimuli – patients own name or face (self-detection)

Neuroanatomical Correlate of Consciousness

Overview

1. During the resting state determined by fMRI: the default mode network (DMN)
 - a. Subjects are not performing a task

- b. Complex partial seizures
- c. Sleep walking
- d. Automatic reflex motor behavior in absence of response to commands
- e. Transient decreased activity in fronto-temporo-parietal associative areas
- ix. Functional separation of the dorsal and ventral posterior cingulate cortex (PCC):
 1. Ventral PCC is integrated within the DMN:
 - a. Involved with memory retrieval and planning (internally directed cognition)
 - b. Dorsal PCC:
 - i. Connectivity to the frontal lobes
 - c. Differential regional activity of the PCC dependent upon:
 - i. Arousal state
 - ii. Internal vs external attention
 - iii. Breadth of attention (narrow vs broad)
 - d. Dorsal PCC involved with the control of attentional focus (interactive with PFC)
- 2. An Operational Definition of Unconsciousness:
 - a. A within-network loss of connectivity of a widespread fronto-parietal network
 - b. A between-network hyper connectivity of the medial 'intrinsic' network
- 3. Post-anoxic/ischemic levels of consciousness:
 - a. Minimally conscious state:
 1. Intrinsic network/thalamic connectivity involved
 2. Altered internal self-awareness
 - b. Vegetative state/unresponsive wakefulness (VS/UWS):
 1. Dysfunction of the extrinsic/intrinsic networks and thalamus
 - c. Emergence from the minimally conscious state:
 1. Involvement of the posterior cingulate and retrosplenial cortices
 - d. Locked-in syndrome
 1. Involvement of infratentorial nuclei

Arousal Component of Consciousness

1. Arousal pathways originate in the brainstem
 - a. Activate awareness networks in the cerebral cortex:
 - i. From synapses in the thalamus and basal forebrain
 - ii. Direct cortical innervation

The Anatomy of the Ascending Reticular Activating System

Overview

1. Neurotransmitter specific pathways from the brainstem nuclei to:
 - a. Cortex via thalamic and extrathalamic pathways
 - i. Serotonergic pathways from the raphe subnuclei of the rostral pons and midbrain
 - ii. Noradrenergic projections from the locus coeruleus of the rostral pons

- iii. Dopaminergic projections from the ventral tegmental area to the caudal midbrain
 - iv. Cholinergic projections from the pedunculopontine nucleus and laterodorsal tegmental nuclei of the caudal midbrain and rostral pons
 - v. Glutamatergic fibers from the parabrachial nuclear complex of the rostral pons
2. Further networks associated with arousal through connectivity with the ascending reticular activating system (ARAS):
 - a. Hypothalamus
 - i. Regulation of autonomic function
 - ii. Circadian sleep – wake cycles
 - b. Basal forebrain
 - i. Cortical activation
 - ii. ANS integration

The Anatomical Components of the ARAS

Overview

1. The reticular core:
 - a. Mesencephalic and pontine reticular formation
 - b. Bilateral fiber bundle that connects the cuneiform/subcuneiform nuclei in the rostral midbrain to the thalamus, hypothalamus and basal forebrain (demonstrated by Moruzzi and Magoun)
 - i. Includes projections from the pontis oralis nuclei of the rostral pons
 - c. In the rostral midbrain
 1. Bilateral fiber bundle from the mesencephalic/pontine reticular formation bifurcates into a ventral tegmental tract and dorsal tegmental tract
 - a. Ventral tegmental tract (VTT) projects to the hypothalamus
 - b. Dorsal tegmental tract (DTT) projects to the thalamic reticular nuclei
2. Transmitter specific nuclei of the brainstem
3. Projections to the hypothalamus, thalamus, basal forebrain and cortex
4. The thalamus integrates and modulates the brainstem arousal networks. The involved nuclei are:
 - a. The reticular nucleus
 - b. Central lateral nuclei (component of the intralaminar complex)
 - c. Centromedian-parafascicular nuclear complex

New Methodologies

1. Advanced imaging techniques of high angular resolution diffusion imaging (HARDI)
 - a. Elucidate the structural connectivity of the ARAS that is being applied to pathological states of arousal and consciousness

Hypoxic-Ischemic Encephalopathy

General Characteristics

1. Decreased brain perfusion, oxygenation or both

2. Decreased perfusion
 - a. Cardiac arrhythmia or arrest
 - b. Pump failure

The brain is differentially susceptible to hypoxia, hypoglycemia and hypoperfusion. In general, areas most susceptible to hypoxia have the greatest metabolic rate for glucose utilization and ATP requirement. In the case of cardiac arrest, pump failure, and ventilatory failure they suffer first and most severely.

In general, respiratory arrest without circulatory compromise carries a better prognosis. Complete circulatory arrest induces rheological changes that include endothelial cell swelling and viscosity changes that preclude reperfusion of cortical, basal ganglia and thalamic capillary networks. This constitutes the no-reflow phenomena. Hyperglycemia and acidosis at the time of an arrest increase neuronal death. Pre arrest vascular compromise leads to distal field ischemia and stroke primarily in the anterior circulation in those under 40 and in the vertebral basilar system in elderly patients. Prolonged hypoperfusion and anoxia lead to border zone infarction (posterior zone between MCA/PCA territory > anterior zone (MCA/ACA territory). Specific toxins or circumstances involve specific brain areas. Carbon monoxide preferentially affects the medial globus pallidus, cortex and cerebellum. Isolation of speech areas, from perisylvian involvement has also been described. Strangulation or hanging preferentially involves the medial globus pallidus. A single hypoxic event may cause a delayed but progressive leukoencephalopathy that begins 4–10 days following the insult. Cognitive dysfunction, irritability and apathy are prominent as is rigidity of the limbs and ataxia of gait. Some patients with delayed hypoxic leukoencephalopathy have reduced aryl sulfatase A activity. Therapeutic hypothermia has effects on neurologic recovery.

Post-Cardiac Arrest Syndrome

General Characteristics

1. Differential neuronal susceptibility
2. Myocardial dysfunction
3. Systemic ischemia/reperfusion (I/R) response
4. Persistent precipitating pathology

Systemic I/R Response Causes

1. Production of reactive oxygen species (ROS) occurs during arrest
2. Oxidative stress:
 - a. Is a major factor responsible for secondary damage and inflammation in brain ischemia and traumatic injury

Therapeutic Hypothermia

1. Usually applied at 33–34°C for 12–24 hours (increases lactate clearance)
 - a. Associated drugs utilized during treatment:
 - i. Midazolam (GABA agonist)

- ii. Sufentanil (opioid)
 - iii. Cisatracurium (neuromuscular blockade)
- b. Intravascular methods:
 - i. Reach target temperature faster
 - ii. More stable hypothermia
 - iii. Better control of rewarming

2. Benefit of therapeutic hypothermia:
 - a. Control of oxidative stress in I/R induced injury (ischemia/reperfusion)

Side Effects of Therapeutic Hypothermia

1. Immunosuppression
2. Increased infection risk
3. Cold diuresis and hypovolemia
4. Electrolyte disorder
5. Insulin resistance
6. Impaired drug clearance
7. Mild coagulopathy
 - a. Rewarming phase:
 1. Elevation of intracranial pressure
 2. Increased neuroinflammation

Clinical and Pathological Aspects of Post-Cardiac Arrest Hypoxic Encephalopathy

1. Appearance of new ischemic foci
2. Neurologic degeneration associated with accumulation of amyloid protein (AB)
3. Injury of vascular epithelium
 - a. Platelet activation
 - b. Thrombosis of the microvasculature is due to the inflammatory response from leukocyte, T-cell, and macrophage recruitment to ischemic areas:
 - i. Release of proinflammatory chemokines, interleukins and cytokines
 - ii. Disruption of the blood-brain barrier

Differential Susceptibility of Neurons to Hypoxia

1. Hippocampus:
 - a. Sumner's section V, and the amygdaloid complex
 - b. Pyramidal neurons
 - c. CA1 zone
2. Medial laminae of the cerebral cortex
 - a. Layer III–V
 - b. Thalamic projecting neurons to the cortex
3. Globus pallidus/caudate/putamen
 - a. Internal segment of GPi
4. Thalamus:
 - a. Anteroventral nuclei
 - b. Dorsomedial nuclei
 - c. Pulvinar
5. Cerebellum
 - a. Purkinje cells
6. Brainstem tegmental nuclei:
 - a. V, IX, Xth nerves
 - b. Inferior colliculus

- c. Superior olive
- d. Vestibular nuclei
- 7. Spinal cord
 - a. Renshaw cells
 - b. Anterior 2/3 of the cord
 - c. Distribution of the artery of Adamkiewicz (T₁₀–L₁–L₂)

Border Zone Infarction

1. Anterior; ACA/MCA
2. Posterior; MCA/PCA
3. Vascular stripe (between descending pial blood vessels and ascending lenticulo striate arteries)
 - a. 1 cm from the lateral ventricle on MRI
4. Border zone of the cerebellum (level of the dentate nucleus)
5. Subinsular cortical areas
6. Cerebellar cortical artery border zones:
 - a. SCA/PICA
 - b. SCA/AICA

Clinical Patterns of Circulatory Arrest

Brain-Stem Coma

Overview

1. Prolonged hypoperfusion-anoxia
 - a. Dilated pupils
 - b. Absent corneal reflexes
 - c. No doll's eye response (absent vestibular ocular response)
 - d. No response to ice-water caloric (absent VOR)
 - e. Frequent loss of spontaneous respiration
 - f. No spontaneous movement
 - i. Decorticate or decerebrate posture may be seen
2. Selective necrosis of brainstem nuclei
 - a. Affects children and infants most frequently; (Vth nerve involvement) occasionally seen in adults
 - b. No oculoccephalic eye movements (VOR)
 - c. Loss of branchial muscle functioning including the gag reflex
 - d. Stiff extremities; no spontaneous movement
 - e. Automatic movements with stimuli
 - f. Autonomic disinhibition
 - i. Fluctuating blood pressure and cardiac rate
 - g. Loss of spontaneous respiration
3. Brainstem coma secondary to bi-hemispherical coma
 - a. Patients regain brainstem reflexes
 - b. Spontaneous respiration occurs

Cortical Coma (Bilateral Cortical Lesions)

Overview

1. Unresponsive to noise, bright light or voice
2. Respond to painful stimuli
3. Spontaneous movements of the extremities
4. Pupils are normal or small; react to light
5. Eye movements:

- a. Roving from side to side
- b. Midline
- c. Deviated upward
- d. Hyperactive doll's eyes maneuver
 - i. Loss of ocular fixation reflexes that inhibit the vestibular ocular reflex (VOR)
 - ii. Vertical eye movements are present to vestibular ocular reflex (VOR) maneuvers:
 - iii. May be difficult to deviate downward if patient has fixed upward deviation
- 6. Gag reflex intact
- 7. Branchial innervated movements are intact
 - a. Spontaneous blink and swallow reflexes

Corticospinal Tract Dysfunction

Overview

1. Patients may have preserved:
 - a. Adduction/flexion of the shoulder, arms and wrists
2. Noxious stimulation of extensor or flexor upper extremity surface:
 - a. Elicits flexion/adduction of the arms and shoulder
3. Noxious stimulation of lower extremities elicits:
 - a. Extension/adduction of the lower limbs
4. External rotation of the foot; cortical thumb

Intact Corticospinal Tract Signs

Overview

1. Noxious stimuli elicits movements away from afferent input
2. Movement of individual fingers
3. Spontaneous or reactive extension of the upper extremity
4. Abducting movements of the arm or forearm
5. Lower limb noxious stimuli elicits
 - a. Flexion/adduction
6. Supination of the arm at rest and normal position of the foot (extension)
7. Thumb abducted

Progression from Bi-Hemispherical Coma

Overview

Specific features of selective vulnerability of the anoxic-ischemic episode may become prominent. Many patients demonstrate agitation, restlessness, confusion and delirium as they regain consciousness. If the insult has been primarily hypotensive with less generalized anoxia, border zone infarction may be prominent.

Posterior Border Zone Infarction

General Characteristics

1. Bilateral infarction of the MCA/PCA overlap territory
 - a. Parieto-occipital junction
2. Complete or partial Bálint's syndrome
 - a. Simultagnosia:
 - i. Inability to see all objects in the visual field
 - ii. Inability to see all components of one object

- iii. Inability to merge components of an object into a whole
- iv. Optic ataxia:
 - 1. Damage to parietal area 5 and 7. Patients under reach for objects. They have poor eye/hand coordination
- v. Apraxia of gaze:
 - 1. Poor initial scanning of a visual field
 - 2. Inability to look at a specific object on command
 - 3. Inability to break a fixed gaze
- 3. Clumsiness and dysarthria
- 4. Ideomotor, limb kinetic, ideational apraxias
 - a. Laminar necrosis of area 6, 8 (ideomotor; callosal apraxia); posterior parietal areas (ideational apraxia)
- 5. Cortical blindness:
 - a. Laminar necrosis of the occipital cortex
 - b. Anton's syndrome
- 6. Seizures:
 - a. Most often generalized
 - b. Difficult to treat
- 7. Myoclonus:
 - a. Multifocal
 - b. Generalized
 - c. Exaggerated by stimuli or movement
 - d. Repetitive and generalized > 30 minutes is a bad prognostic sign following cardiac arrest
- 8. Persistent Vegetative state/unresponsive wakefulness syndrome (VS/UWS):
 - a. Severe laminar necrosis:
 - i. Appear awake and have brain stem function
 - ii. No response to stimuli:
 - 1. Eyes may track a moving object
 - iii. Retain sleep-wake cycle
 - iv. Eyes intermittently open
- 9. Cerebellar dysfunction
 - a. Metronomic eye movements; eyes rhythmically oscillate side to side
 - b. Generalized ataxia
 - c. Lance-Adams syndrome:
 - i. Spontaneous, arrhythmic fine and course movements
 - ii. Exaggerated by voluntary movement
 - iii. Action myoclonus
 - iv. Associated with gait ataxia
 - v. Damage to dorsal raphe serotonergic neurons in addition to Purkinje cells and cerebellar pathways
 - vi. Probable associated border zone cerebellar infarcts of the PICA/SCA and AICA
 - vii. May progress after the initial insult

Anterior Border Zone Infarction

General Characteristics

- 1. Bilateral infarction of the anterior and middle cerebral artery border zone territories
- 2. "Man in the Barrel" syndrome:
 - a. Shoulder and arm are primarily affected; hand stronger than shoulder; legs spared
 - b. Frontal eye fields involved (area 8, 10):
 - i. Roving cortical eye movements (disinhibited from gaze centers)
 - ii. Too easily obtained doll's eye maneuvers (uninhibited VOR)
- 3. Asymmetries have been described:
 - a. Unilateral arm paralysis
 - b. Head and eye deviation to the more affected side
- 4. Stupor from extensive bilateral lesions

Memory Loss Following Cardiac Arrest

General Characteristics

- 1. Severe damage to the pyramidal cells of the hippocampus
 - a. CA I; Sumner's section V
 - b. Amygdaloid complex
 - c. Medial temporal lobes
- 2. Clinical sequelae
 - a. Severe short term memory loss. Poor encoding of new memories over 3 minutes. Registration is intact (object recall less than 15 seconds). Long term memory and retrieval are relatively spared

Laminar Necrosis

General Characteristics

- 1. Layers III–V of the cortex are damaged throughout. Speech, motor, and visual areas affected clinically more prominently than the parietal lobe
- 2. Isolation of the speech areas:
 - a. Combination of laminar necrosis and anterior and posterior border zone infarction
 - b. Transcortical motor and sensory aphasia
 - c. Complete perisylvian involvement
 - i. Patient can only repeat; cannot initiate or perceive speech
 - d. Severe dysarthria
 - i. Damage to corticobulbar fibers for speech emanating from the frontal operculum

Basal Ganglia and Thalamus Dysfunction After Cardiac Arrest

General Characteristics

- 1. Prolonged partial ischemia:
 - a. Hypoxia precedes circulatory insult
 - b. Damage most severe in the globus pallidus interna, caudate, putamen, AV, DM and pulvinar nuclei of the thalamus
 - c. Hanging, strangulation, carbon monoxide poisoning produce a similar dissociation between blood flow and oxygenation
 - d. Clinical sequelae:
 - i. Eyes open and fixed
 - ii. Abnormal twitches and movements (choreoathetosis)

- iii. Rigidity of extensor and flexor muscles
- iv. Decorticate posturing
- v. Mute and unresponsive

Delayed Leukoencephalopathy

General Characteristics

1. Generally young patients who have suffered strangulation, drowning, inhalation of noxious gases or carbon monoxide poisoning

Neuropathology

1. Diffuse demyelination that may progress to hemorrhagic white matter necrosis
2. Basal ganglia involvement (GP)
3. Possible relationship to decreased Arylsulfatase A in some patients

Clinical Manifestations

1. Initial coma associated with:
 - a. Quadriplegia
 - b. Atonia
 - c. Involuntary limb movements
2. Progression to:
 - a. Dystonic rigid state
 - i. Relative preservation of the cortex
 - ii. Severe damage to basal ganglia
 - iii. Generalized demyelination
3. Delayed deterioration starts between 4–40 days in some patients; activity may worsen the process
4. Parkinsonism
5. Psychosis
6. Cognitive decline

Neuroimaging

MRI

1. Diffuse hyperintensity of cerebral white matter on FLAIR sequences

Hypoxic-Ischemic Spinal Cord Damage

General Characteristics

1. Selective vulnerability of the spinal cord:
 - a. Upper and lower thoracic cord is most often involved
 - b. Territory of the great radicular artery of Adamkiewicz
 - i. Origin T10–T12 to L-2; supplies the lumbar cord and the conus medullaris
 - c. Upper and lower thoracic regions border zones of the anterior feeding vessels (those that comprise the unpaired anterior spinal artery) ASA
 - d. Sulcal arteries from the anterior spinal arteries supply the ventral horns; circumferential arteries from the posterior paired spinal arteries and the circumferential branches of the ASA supply the lateral components of the cord. The internal spinal cord watershed is the corticospinal tracts, the border zone between the sulcal and circumferential arteries. Paired dorsal spinal arteries supply the posterior columns

Clinical Manifestations

1. Spinal cord hypotensive damage is unusual as the cord is perfused at a much lower pressure than the cerebral circulation (approximately 60 mm Hg)
2. Ischemic injury involves the anterior 2/3 of the cord
3. Flaccid paralysis of the lower extremities is noted early; spasticity supervenes:
 - a. Loss of bowel and bladder continence
 - b. Sensory level to temperature and pin prick at lower thoracic levels
 - c. Atrophy and fasciculation of the legs/supervenes
4. Rare acute rigidity

Neuropathology

1. Renshaw cell involvement
2. Loss of glycine and spinal cord inhibition

Prognostic Indicators in Patients That Have Suffered Ischemic-Hypoxic Injury

Early (Minutes to 6 Hours)

Vital Signs

1. Blood pressure
 - a. Severe hypertension
 - i. Increased ICP
 - ii. Normal cardiac function
 - b. Profound hypotension
 - i. Severe cardiac damage
 - ii. Vasomotor center damage (brainstem)
 - c. Fluctuating blood pressure
 - i. Vasomotor center or connections are damaged (dorsolateral medulla and pons)
 - ii. Autonomic disruption (posterior hypothalamus afferents to intermediolateral column of the spinal cord)
 - d. Herniation
 - i. Hypertension to sudden hypotension
 1. Disruption of the vasomotor centers and connections in the dorsolateral medulla and pons
2. Pulse
 - a. Regular full slow pulse (50–60/min)
 - i. Kocher–Cushing reflex from ICP
 - b. Thready rapid pulse (120 minute)
 - i. Cerebral herniation
 - ii. Cardiac failure
 - iii. Disruption of vasomotor centers and their connections at a brainstem level
3. Respiratory pattern by CNS Level
 - a. Cheyne’s–Stoke (basal ganglia/thalamic)
 - b. Periodic breathing (basal ganglia/thalamic)
 - c. Central neurogenic-hyperventilation (midbrain)
 - i. Need to Rule out:
 1. Acidosis
 2. Low pO₂
 3. Uninhibited breathing Kölliker–Fuchs nucleus
 - a. Pneumotatic center

4. Apnea (Pons)
5. Cluster (medullary)
6. Ataxic (medullary)
7. Biot's (medullary couplet breathing)
4. Temperature
 - a. General rule is that temperatures above 105 degree F° are central rather than from sepsis

Hyperthermia

General Characteristics

1. Anterior hypothalamic damage
2. Drugs: dopamine receptor D₂ agonists or their sudden withdrawal, INH (isoniazid), cocaine, amphetamine, phenothiazine (rare)
3. Blood in the 3rd ventricle

Hypothermia

General Characteristics

1. 92–93 degree F° (posterior hypothalamic damage)
 - a. Hypothyroidism; pan-hypopituitarism
 - b. Drugs (phenothiazine based)
2. 97–98 degrees Fahrenheit
 - a. Endocrine failure (thyroid; pan-hypopituitarism)
 - b. Hypoglycemia
 - c. Liver and renal failure (usually 1 degree Fahrenheit decrease)
 - d. Phenobarbital

Level of Consciousness

Overview

Profound coma implies damage to the lateral medullary reticular formation, the dorsal pontine tegmentum periaqueductal gray of the midbrain, intralaminar nuclei of the thalamus or bilateral cerebral cortex. The brainstem is much less vulnerable to hypoperfusion and anoxia than the cortex and therefore severe brainstem dysfunction implies hemispheric damage with a poor prognosis for a good functional recovery. A patient who is fully alert and awake 6 hours after a cardiac arrest or hypoxic-ischemic event improves rapidly over twelve hours and has a good prognosis. Twenty four hours to alertness may be a very important prognostic assessment time.

Acute Levels to Be Assessed Are:

1. Fully Alert
2. Lethargic
3. Obtunded
4. Stuporous
5. Comatose

Chronic Levels of Consciousness

1. Vegetative state/unresponsive wakefulness syndrome (VS/UWS)
2. Recovery from Minimal conscious state (MCS)
3. Locked-In syndrome (fully awake; can respond to commands with vertical eye movements)

Brainstem Reflex Assessment at 6 Hours

General Characteristics

1. Gag reflex – IX, X (medulla)
2. Corneal – V – pons
3. Vestibular ocular reflexes (VOR)
 - a. VIIIth cranial nerve (vestibular nuclear afferents)
 - b. Medial longitudinal fasciculus (innervation of EOM)
 - c. VIth and IIIrd cranial nerve
4. Pupils
 - a. Dilated to 4–5 mm after 3–4 minutes of cardio-pulmonary arrest
 - i. Rule out atropine or sympathomimetic drug administered during resuscitation procedures
 - b. Cortical or pretectal level
 - i. Non-reactive to light
 - c. Dilated to 3 mm and non-reactive to light or noxious stimuli
 - i. Midbrain level
 - ii. Cadaveric
 - d. Dilated to 2–3 mm
 - i. Reactive to light
 - ii. Thalamic/basal ganglia level
 - e. 0.5 mm pupil
 - i. Pontine level
 - ii. Reactive to light
 - f. 1 mm pupil
 - i. Medullary level
 - ii. Sympathetically denervated (unopposed parasympathetic input)
 - iii. Rule out narcotics
 1. Demerol may not affect pupils; 1/3 of the time it does
 - iv. Rule out drugs with parasympathomimetic action (antidepressants)
5. Persistent pupillary dilatation poor prognostic indicator
6. Return of brainstem reflexes early is a good prognostic sign

Evoked and Spontaneous Limb Movements

General Characteristics

1. Spontaneous limb movement – good prognostic sign
2. Evoked decerebration and decortication – poor prognostic indicator
3. Myoclonus:
 - a. Persistent and stimulus sensitive – poor prognostic sign
 - i. Loss of cortical inhibition
 - ii. Damage to the nucleus gigantocellularis of the brainstem
4. Seizure
 - a. First 24 hours not prognostic
 - b. Status epilepticus – poor prognostic sign at any time after an ictus

Clinical Manifestations

Late Prognostic Signs (More than 24 Hours)

Good

1. Awake and alert

2. Return of brainstem reflexes
3. Eye opening with ocular fixation reflexes
4. Noxious stimuli evoke withdrawal reflexes

Bad

1. Persistent depressed level of consciousness
2. Absent brainstem reflexes
3. Noxious stimulation evoke decortication or decerebration
4. Eyes open with:
 - a. Roving eye movements
 - b. Uninhibited doll's eye maneuver
 - c. Persistent vertical ocular deviation
5. Spontaneous and evoked myoclonus
6. Status epilepticus
7. Persistently dilated pupils

Neuroimaging

MRI

1. Watershed infarcts of cortical and deep territories
2. Cortical infarcts
3. Blurring of the gray white junction
4. Obliteration of the perimesencephalic cisterns with mid-brain compression
5. T₂ weighted signal abnormalities of laminar necrosis (areas III and V of the cerebral cortex)

EEG

1. Diffuse slowing in the delta and theta range
 - a. All survivors at some point
2. Periodic lateralizing epileptiform discharge
 - a. Isolated areas of cortex
3. Epileptiform activity
4. Alpha coma (bad prognostic sign)
 - a. 9–12 cycles/second
 - b. Transitory
 - c. Frontal central parietal rather than occipital distribution
 - d. Does not vary with external stimuli

Angiography, Doppler or SPECT

1. Brain Death: absence of intracranial circulation

fMRI

1. Brain Death: no activity of either the intrinsic or extrinsic network

Sepsis Following Successful Cardiopulmonary Resuscitation

General Characteristics

1. Early development of a systemic inflammatory response syndrome that includes increased levels of:
 - a. C-reactive protein (CRP)
 - b. Tumor necrosis factor alpha
 - c. Interleukin 6
 - d. Procalcitonin (PCT)

2. PCT (Procalcitonin):
 - a. Marker of bacterial infection
 - b. Predictor of sepsis (associated mortality)
 - c. May be the result of post-resuscitation disease
 - d. Levels may be modulated by hypothermia
 - e. 1 mg/ml threshold for bad outcome
3. Ischemia (reperfusion injury)
 - a. Occurs with the return of spontaneous circulation

Dilatative Arteriopathy

General Characteristics

1. Enlarged tortuous dilated arteries
2. Primary involvement of the intracranial vertebral and basilar arteries
 - a. Carotid and intracranial anterior circulation less frequently involved
3. Diminished blood flow of the penetrating branches of large arteries
 - a. Branch territory pontine infarcts
4. Transcranial Doppler studies:
 - a. Reduced mean blood flow velocity
 - b. Normal peak flow velocity
5. Reduced antegrade flow within the ectatic artery
6. Thrombus formation may occur in dilated arteries with obstruction of perforators and distal embolization

Clinical Features

1. Causes compression parenchyma: particularly of the medulla and pons as well as cranial nerves. The latter is associated with:
 - a. Tic douloureux (V)
 - b. Vertigo/tinnitus (VIII)
 - c. Torticollis (XI)
 - d. Hemifacial spasm (VII)
 - e. Facial palsy (VII)
 - f. Lower cranial neuropathies (dysarthria)
 - i. Less frequently compressed
2. Hydrocephalus:
 - a. Compression of the IIIrd ventricle
3. Ataxia and motor weakness:
 - a. Compression of the brainstem; middle cerebellar peduncle and pontine and pyramidal tract
4. Compression of medulla and pons
 - a. Severe hypertension from irritation of the vasomotor centers
 - b. Spastic gait and dysarthria
 - c. Vestibular deficits
 - d. Cerebellar ataxia

Associated Specific Diseases

1. Marfan's syndrome
2. Ehlers-Danlos syndrome

3. Children with AIDS
4. Fabry's disease
5. Children and adults with sickle cell disease

Associated General Risk factors

1. Older age
2. Male sex
3. Hypertension
 - a. Left ventricle hypertrophy
 - b. Dilated and pulsatile brachial arteries with prominent aortic notch pulsations
4. History of myocardial infarction
5. Increased diameter of the thoracic aorta

Mechanisms of Cerebrovascular Disease

1. Distortion of the orifices of arterial branches
2. Decreased blood flow of penetrating branches
 - a. Decreased blood flow velocities
 - b. Reduced antegrade flow
 - c. Increased contact factor-endothelial contact time including thrombus formation and emboli
3. Fusiform aneurysms

Pathology

1. May occur in children and adolescents (some evidence of familial tendency)
2. Deficiencies of the muscularis and internal elastic lamina
3. Irregular thickness of the media
4. Thickening of the media
 - a. Increased fibrinoid material and lipids
5. Gaps in the internal elastic lamina
6. Intimal thickening
7. Increase in the vaso vasorum
8. Fusiform aneurysms

Molecular Mechanisms Underlying Dilatative Arteriopathy

1. Penetrating arterial diseases and dilatative arteriopathy are:
 - a. Arterial wall rather than the intima and endothelium
2. Arterial media disease may be associated with up regulation of metalloproteinases
 - a. Increased metalloproteinases may increase the permeability of the BBB
 - b. Permeability of the BBB is a factor in leukoaraiosis

Small Vessel Disease Features of Dolichoectasia

1. Lacunar infarction
2. Leukoaraiosis
3. "État criblé"
 - a. Dilated Virchow-Robin spaces around penetrating arterioles

Intracranial Arterial Dolichoectasia

General Characteristics

1. Neurovascular compression syndromes

2. Triventricular hydrocephalus
3. Isolated IIIrd, Vth, and VIIIth, XIIth nerve palsy by compression from basilar of vertebral arteries
4. IIth nerve compression from dolichoectatic supraclinoid carotid arteries
5. Putative mechanism:
 - a. Deposition of glycosphingolipids in the lysosomes of the smooth muscle of arterial walls
 - b. Possible cause of ICH (loss of structural integrity of vessel walls)
 - i. Hypertension from concurrent vessel disease
 - ii. Both hemi and heterozygotes

Fibromuscular Dysplasia

General Characteristics

1. Probably multietiological; HLA association
2. May affect any cerebral somatic artery
3. Primarily affects medium-sized muscular arteries at specific sites:
 - a. Distal 2/3 of renal arteries
 - b. Distal extracranial vertebral artery (adjacent to C2 vertebrae)
 - c. Distal carotid with rare involvement of:
 - i. Cavernous carotid
 - ii. Arteries of Circle of Willis

Clinical Features

1. Most commonly affects Caucasian women in the 4th to 6th decades
2. Occurs in infants and children with involvement of:
 - a. Renal, severe hypertension
 - b. Splanchnic
 - c. Cervical-cranial vessels
3. Incidence of less than 1% of routine cerebral arteriograms
4. Associated with intracranial aneurysms and dissections
5. ICH from associated HCVD due to renal artery involvement (including dissection)
6. Spontaneous cervical and intracranial artery dissection
7. Male presentation described:
 - a. Abdominal pain
 - b. Systemic signs
 - c. Hypertension
8. Associated dissection of the coronary arteries occur
9. Subarachnoid hemorrhage presentation
10. Arterial dissection with appropriate territorial infarction
11. A relatively benign condition
 - a. Few recurrent cerebrovascular episodes

Neuropathology

1. Fragmentation of the arterial media with rings of fibrous and muscular hyperplasia cause:
 - a. Saccular dilatations of the artery
 - b. Arterial wall involvement:
 - i. Adventitial form:

1. Narrowing of the vascular lumen by fibrous tissue hypertrophy that surrounds the artery
- ii. Intimal form:
 1. An increase of the fibrous components of the intima
 - a. Concentric narrowing of the lumen
 - b. About 5% of patients
 - c. Children and adolescents
- iii. Medial form:
 1. Most common
 2. Constricting bands of fibrous dysplastic tissue and proliferating muscle cells in the media
 3. Alternating with areas of medial thinning (disruption of the elastic membrane)
 - a. Leads to luminal dilatation
 - b. "String of beads" arteriographic pattern
2. Aging
 - a. Parallel aortic elastic fibers fragment
 - b. Decrease of smooth muscle cells
3. Pregnancy
 - a. Elastic fiber fragmentation
 - b. Hypertrophy/hyperplasia of smooth muscle cells
4. Chromosome abnormalities
 - a. Marfan's syndrome
 - i. Defect of fibrillin-1; increased elastin
5. Gene abnormality
 - a. Fibrillin-1 defect (15q 21.1)
 - b. Deletion of TGF-B receptor
 - c. ALK 5 (activin receptor-like kinase 5)
6. Medial smooth muscle cell apoptosis
7. Metalloproteinase and elastin
8. Hemodynamic abnormality (increased aortic flow)
9. Intrinsic abnormalities of the aortic wall in congenital heart diseases

Neuroimaging

1. Bilateral ICA involvement is frequent
 - a. Pharyngeal component of the artery
 - i. Level of C2 and spares the bifurcation and intracranial carotid artery
 - ii. 20% of patients have concomitant involvement of the vertebral arteries
 - b. Rare: intracranial FMD
 - c. "String of beads" arterial lesions may be concurrent with tertiary constrictions and aneurysmal dilatation
 - d. Shelf-like segmental stenosis from fibrous septa and webs
 - e. Enlarged carotid bulbs

Aortic Medial Abnormalities [Gsell-Erdheim]

General Characteristics

1. Ascending aorta may dilate in congenital heart disease
2. Aortic dilatation is well recognized in:
 - a. Marfan syndrome
 - b. Turner syndrome
 - c. Bicuspid aortic valve
 - d. Coarctation of the aorta
3. Congenital heart disease and aortic medial abnormalities occur with:
 - a. Single ventricle
 - b. Persistent truncus arteriosus
 - c. Transposition of the great arteries
 - d. Hypoplastic left heart syndrome
 - e. Tetralogy of Fallot
4. The CHDs with aortic dilatation are associated with:
 - a. Decreased elasticity and stiffness of the aorta and cause
 - i. Increased afterload and ventricular hypertrophy

Mechanisms of Structure Alteration of the Ascending Aorta Media

1. Systemic hypertension
 - a. Abnormalities of medial elastin and collagen

Pathology

1. Cystic medial necrosis
2. Elastin fragmentation
3. Fibrosis
4. Media necrosis

Clinical Features

1. Aortic dissection
2. Coronary artery dissection
3. Carotid artery aneurysm
4. Giant aneurysm of the ascending aorta

Radiation Induced Arterial Disease

General Characteristics

1. Delayed radiation-related strokes most often reported following X-RT for:
 - a. Leukemia
 - b. Hodgkin's disease
 - c. Brain tremors
2. Risk of stroke
 - a. Leukemia survivors: about 6%
 - b. Brain tumor: 29%
 - c. Hodgkin's disease: 83/100,000 patients
 - d. Increased in a dose-dependent manner
3. Major pathology in vascular injury; dependent upon:
 - a. Dose of irradiation
 - b. Location of irradiated nervous tissue – those areas with more surrounding tissue receive less dose
 - c. Order of vessel vulnerability:
 - i. Capillaries and sinusoids (most sensitive)
 - ii. Arterioles and small vessels
 - iii. Medium-sized vessels
 - iv. Large arteries (least sensitive)
 - d. Typical lesions are not in the usual areas for atherosclerosis

- i. Often not a bifurcation
 - ii. Long arterial segments are involved
- 4. Cellular pathology
 - a. Denudation of the endothelial layer
 - b. Infiltration of foam cells and histiocytes and fibroblasts
 - c. Collagen formation in the subendothelium and intima
 - d. Myointimal proliferation and fibrosis
 - e. Calcification; adventitial fibrosis
 - f. Fragmentation of the internal and external elastic membranes; inflammatory changes
 - g. A proliferative small vessel proliferative endocarditis

Clinical Features

1. Acute radionecrosis presenting as a mass (MR spectroscopy demonstrates no lactic acid peak which distinguishes it from recurrent glioma)
2. Chronic dementing illness
 - a. All systems may be involved (Parkinsonism, ataxia, corticospinal deficits, subcortical apraxia and cognitive slowing)
3. Moyamoya disease of basal arteries
 - a. Children and young adults
 - b. Prevalent with NF1 and higher doses of X-RT
4. Focal brain infarcts and strokes
5. Spinal cord
 - a. Sulcal artery infarction with Brown-Sequel syndrome
 - b. Upper extremity parenthesis (C5–C6)
 - c. Spastic paraparesis
6. Long segment stenosis of extracranial arteries
 - a. Transient ischemia
 - b. Stroke
 - c. Intracranial vascular occlusive disease
7. Delayed symptoms
 - a. Months to years after X-RT
 - b. Mass lesions in the brain or spinal cord
 - c. Fibrinoid degeneration of blood vessels, coagulative necrosis and gliosis
8. Delayed dementia with focal signs
 - a. Brain atrophy and leukoencephalopathy
 - b. Diffuse loss of white matter
 - i. Some patients demonstrate enhancement of focal lesion

Stroke and Substance Abuse

Opiates

General Features

1. Heroin most widely abused opiate
 - a. Administration:
 - i. I.V. or subcutaneously
 - ii. Smoked or sniffed

Cerebrovascular Complications

1. Decreased perfusion of the medial prefrontal cortex; anterior cingulate cortex and precuneus

2. Increased arterial stiffness and contributes to vascular aging
3. I.V. use:
 - a. Septic embolization with *Staphylococcus Aureus* and candida that cause:
 - i. Mycotic aneurism (may have premonitory symptoms)
 - ii. Infectious vasculitis
 - b. Septic aneurysms are peripheral and may rupture with or without treatment
4. Hemorrhagic stroke:
 - a. Consequence of hepatitis (decreased clotting factors)
 - b. Heroin nephropathy (hypertension and uremia)
 - c. Meningitis
 - d. HIV/AIDS

Angiography

1. Some patients demonstrate large or small vessel arteritis
 - a. Possible autoimmune etiology (eosinophilia, hypergammaglobulinemia)
2. Stroke mechanisms in heroin abuse:
 - a. Vascular aging
 - b. Hypotension and hypoventilation (acute)
 - i. Bilateral GP infarction
 - c. Infective endocarditis with mycotic aneurysm
 - d. Embolization of adulterants:
 - i. Pentazocine and tripeleminamine
 - ii. Parenteral paregoric, meperidine and hydromorphone
 - e. Heroin myelopathy:
 - i. Some patients with ischemia of the anterior spinal arteries

Amphetamines

General Features

1. These agents include:
 - a. Dextroamphetamine
 - b. Methamphetamine
 - c. Methylphenidate
 - d. Ephedrine
 - e. Pseudoephedrine
 - f. Phenylpropanolamine (PPA)
2. Cause increased dopamine and serotonin nerve neurotransmission
3. Damage dopamine and serotonin nerve terminals; methamphetamine causes cardiomyopathy
4. Administration is oral, sniffed or smoked in a crystalline form (“ice”, crystal meth”)
5. Necrotizing periarteritis; spontaneous ICH (often in hypertensive areas; microinfarcts in small vessels and atherosclerosis is accelerated)
6. Autopsy of overdose patients reveal:
 - a. Petechial hemorrhage and cerebral edema
 - b. Dextroamphetamine predominated
 - c. Severe headache concomitant with drug use

- d. CT: SAH or ICH
- e. Some patients demonstrated bleeding/vasculitis
- 7. I.V. methamphetamine:
 - a. Necrotizing arteritis
 - b. Infarction or hemorrhage in the hemisphere, the cerebellum and brainstem
 - c. Involved vessels are smaller than those affected by PAN
- 8. PPA cerebrovascular involvement
 - a. Hemorrhagic stroke

MDMA

(N-methyl-1-(3,4-methylenedioxyphenyl)propan-2-amine or methylenedioxymethamphetamine: "Ecstasy")

- 1. Causes both ischemic and hemorrhagic stroke
- 2. I.V. use of crushed methylphenidate tablets: microembolization of talc
- 3. Increases the release and inhibits uptake of NE, serotonin, DA
- 4. Mechanisms of stroke similar to those of cocaine and amphetamine
- 5. Cardiac arrhythmias and embolism may be important

General Characteristics of Both Salts

- 1. Alternatives to cocaine and methylenedioxymethamphetamine
- 2. 3,4 methylenedioxymethcathinone (methylone)
- 3. 3,4-methylenedioxypyrovalerone (MDPV)
- 4. Synthetic cathinones
 - a. Target plasma membrane transporters for DA, NE and serotonin
 - i. Mephedrone and methylone act as non-selective transporter substrates
 - b. Stimulates non-exocytotic release of DA, DA and serotonin. Effects are analogous to amphetamines
 - c. MDPV only blocks dopamine and norepinephrine

Clinical Features

- 1. Neurological complications
 - a. Hallucinations
 - b. Delirium
 - c. Euphoria
 - d. Tachycardia
 - e. Hyperthermia
 - f. Delayed responses
 - g. Agitation/psychosis
 - h. Cardiomyopathy
 - i. Myoclonus/seizures
- 2. Cerebrovascular effects
 - a. Non-specifically reported
 - b. Cardiac dysfunction and hypertension are prominent

Cocaine

General Features

- 1. Blocks reuptake of monoamine neurotransmitters at synaptic nerve endings (binds to transporter proteins)

- 2. Intranasal preparation
 - a. Cocaine hydrochloride
 - b. Ischemic stroke; intracranial hemorrhage
- 3. Smoke-able form:
 - a. Alkaloid form "crack"
 - b. Can be utilized in large doses over a long duration (hours to days)
 - c. Ischemic and hemorrhagic stroke

Clinical Features

- 1. Cerebrovascular complications
 - a. TIA
 - b. Infarctions of cortical/subcortical territories that include the hemispheres; thalamus, brainstem, spinal cord and retina
 - c. Strokes in pregnant women and neonates
 - i. Vasospasm
 - ii. Premature separation of the placenta (cocaine taken prior to delivery)
 - d. Rare vasculitis
 - e. Delayed vasospastic ischemic infarction is common (hours to days)
 - f. Hemorrhagic stroke
 - i. Intracerebral and subarachnoid hemorrhage
 - ii. 20% of hemorrhages have underlying
 - 1. Vascular malformation
 - 2. Saccular aneurysm
 - a. Increase vasospasm after aneurysmal rupture
 - 3. Bleeding into embolic infarction or glioma
 - 4. Post-partum patients and their neonate
 - iii. Other cocaine induced stroke mechanisms:
 - 1. Myocardial infarction and cardiomyopathy with embolus
 - g. Multiple infarcts occur:
 - i. High incidence of hemorrhagic transformation
 - h. Aggregation and de-aggregation of platelets; effects on antithrombin III, protein C, NF- κ B (nuclear factor kappa-light-chain-enhancer of activated B-cells), activator protein-1
 - i. Platelet rich arterial thrombi
 - j. Activates the endothelium that promotes platelet vWF interaction
 - i. vWF-platelet strings
 - k. Vasoconstrictive metabolite can last for days to weeks

Phencyclidine

General Features

- 1. Phencyclidine (PCP: a dissociative anesthetics similar to ketamine
- 2. Effects NMDA (antagonist), nACh (antagonist) and dopamine (agonist) receptors
- 3. Possible PCP receptors on cerebral vessels
- 4. Stored in fat and therefore re-mobilization can occur with recurrent symptoms for days or months

Clinical Features

1. Cerebrovascular disease and PCP
 - a. Hypertension occurs following use or can be delayed
 - b. Hypertensive encephalopathy
 - c. Trans-monocular blindness
 - d. PCP related SAH
 - e. Hemorrhagic stroke

Lysergic Acid Diethylamide (LSD)*General Features*

1. LSD is an ergot that, in high doses, causes hypertension
2. Patent hallucinogen

Clinical Features

1. LSD and cerebrovascular disease
 - a. Ischemic vascular disease (patients less than 25 years of age); 2 patients with large artery involvement; delayed stroke occurs
 - b. Mechanism:
 - i. May effect serotonin receptors with consequent vasospasm
 - c. Angiography
 - i. Progressive narrowing and occlusion of ICA
 - ii. Generalized arterial bleeding

Marijuana*General Features*

1. Most widespread recreational drug in the USA
2. Cannabinoids have physiological role in:
 - a. Cerebral autoregulation
 - b. Vascular tone
 - c. Cardiac physiology

Clinical Features

1. Associations with stroke, myocardial infarction and lower limb arteritis
 - a. Myocardial infarction may occur with concomitant use
 - b. Extremity arterial disease occurred in younger male patients primarily in one extremity
2. Cerebral vascular disease
 - a. Ischemic stroke
 - b. Reversible vasoconstriction syndrome (described in 2 patients)
 - c. Stroke associated with anabolic steroid use

Ethanol*General Features*

1. Ethanol consumption and coronary artery disease fits a "J-shaped" curve (a small amount is protective and larger amounts are detrimental)
 - a. Cardioembolic risk often MI in heavy drinkers (>300 grams/week)
 - b. Thromboembolism in alcoholic cardiomyopathy

2. A J-shaped curve exists for ischemic stroke and ethanol consumption
 - a. Linear correlation of ICH
 - b. >60 grams/day increased stroke risk for ischemic and hemorrhagic stroke
3. Heavy ethanol consumption:
 - a. Increases carotid artery atherosclerosis
4. Putative mechanisms
 - a. Ethanol acutely and chronically increases blood pressure
 - b. Lowers LDL and increases HDL
 - c. Lowers fibrinogen activity
 - d. Increases factor VIII levels
 - e. Increases platelet reactivity to adenosine diphosphate
 - f. Decreases plasma fibrinogen levels
 - g. Increases prostacyclin
 - h. Stimulates endothelial release of endothelin
5. Alcohol withdrawal
 - a. Causes Hemoconcentration
 - b. Rebound platelet hyperaggregability

Tobacco*General Features*

1. Increases the risk for both ischemic and hemorrhagic stroke
2. Smokeless tobacco:
 - a. Increases ischemic stroke risk and acute coronary dysfunction
 - b. Accelerates atherothrombosis
 - c. Increases HCVD and metabolic syndrome
3. Mechanisms for smoking and cerebrovascular disease
 - a. Ischemic and hemorrhagic stroke is increased with concomitant oral contraceptive use
 - b. Increases atherosclerosis
 - c. Decreases blood oxygen carrying capacity (carbon monoxide from smoke has a higher affinity for hemoglobin than does oxygen)
 - d. Nicotine damages the vascular endothelium
 - e. Increased platelet reactivity
 - f. Decrease prostacyclin
 - g. Increases blood fibrinogen levels
 - h. Induced polycythemia increases blood viscosity
 - i. Paradoxical benefit effect on in-hospital mortality
 - j. May have benefit in blood pressure and flow in MCA
 - i. Changes in baroreflex sensitivity (lowers)

Hemorrhagic Vascular Disease**Epidemiology of Hemorrhagic Vascular Disease***Overview*

Hypertension is the major cause of intracranial hemorrhage. The age of the patient and underlying medical condition point to specific other etiologies of hemorrhagic vascular disease.

Spontaneous intracranial and subarachnoid hemorrhage cause approximately 10 to 15% of strokes. In patients less than 40 years of age, vascular malformations, aneurysms, cavernous angioma, illicit drugs and head trauma are the usual causes. In elderly patients, congophilic angiopathy accounts for approximately 10% of intracranial hemorrhages. Approximately 10% of patients treated with fibrinolytic agents after myocardial infarction bleed. Approximately 5 to 10% of patients on warfarin or heparin bleed at some point during their therapy. The rate of ICH on anticoagulation is approximately 0.3% per year. Evidence of prior vascular disease is common as patients with ICH have T₂ weighted hyperintensities in cerebral white matter, lacunes and old infarction 68% of the time. There is a correlation of spontaneous ICH with small chronic microhemorrhages, hemorrhages, and ischemic lesions in elderly patients. Hemorrhagic transformation occurs after tPa in approximately 6% of patients.

Hypertensive Hemorrhagic

General Characteristics

1. The most common cause of ICH
2. Blood pressure is generally 220–240 mm of Hg systolic and 110–120 mm of Hg diastolic
 - a. In several studies the peak systolic pressure is 160–190 mm Hg
 - b. The pressure may be confounded by the Kocher-Cushing reflex
 - i. Secondary hypertension due to pressure on the vasomotor neurons of the dorsolateral medulla and dorsal tegmental pons
3. Many patients present without a known prior history of hypertension
 - a. Examination often reveals
 - i. An enlarged aortic knob (uncoiled)
 - ii. Thickened and tortuous peripheral blood vessels (radial and brachial arteries)
 - iii. Hypertensive changes in the retinal arteries
 - iv. Loud A2 and a prominent S4 gallop
 - v. Sustained cardiac impulse

Risk Factors

1. Exposure to cold weather
 - a. Stimulation of the sympathetic vasoconstrictor response
2. Dental procedures
 - a. Irritation of the trigeminal nerve
3. Increased cerebral blood flow
 - a. Carotid endarterectomy (hyperperfusion syndrome)
 - b. Following surgical repair of congenital heart defects
 - c. Cardiac transplantation
 - d. Post-migraine

Differential Diagnosis of Hemorrhagic Vascular Disease

The major categories of hemorrhagic vascular disease are:

1. Hypertension

2. Aneurysm, arteriovenous malformation, venous malformation, cavernous hemangioma
3. Medical causes of platelet or clotting factor dysfunction
4. Hemorrhagic transformation of ischemic stroke
5. Anticoagulation
6. Drug abuse (methamphetamine, cocaine, PPA)
7. Thrombolytic agents
8. Congophilic angiopathy (CCA)
9. Cold exposure
10. Post-carotid endarterectomy syndrome
11. Severe migraine
12. Tumor
13. Surgery
14. Moyamoya disease
15. Trauma
16. Alcohol
17. Hemorrhagic transformation of ischemic stroke
18. Hemorrhagic transformation following tPa
19. Ischemia/reperfusion syndrome

Hypertensive Hemorrhage

Hypertensive hemorrhage occurs in very specific places the most common of which are:

1. Basal ganglia – 60% (caudate 10%; putamen 50%; GP1 40%)
2. Thalamus – 20%
3. Cerebellum – 15%
4. Pons – 5%
5. Lobar – 10%
6. Pontine – 5%
7. Medulla – rare <1%
8. Midbrain – rare <1%

If hemorrhages are not found in these locations, they are most likely caused by systemic illness, congenital vascular anomalies, anticoagulation or drugs.

Clinical Manifestations

Clinical Manifestations of Intraparenchymal Hemorrhage

The onset of hypertensive intraparenchymal hemorrhage is most often during wakefulness as a patient pursues the usual activities of daily living. Maneuvers that cause a sudden rise in blood pressure such as heavy lifting, coitus, prolonged vomiting, coughing or straining at stool have been noted to cause hemorrhage with increased frequency. Unusual causes of hemorrhage are related to specific circumstances. Approximately 30% of ICH are due to aneurysm, AVM, and cavernous angioma occur during sleep.

Most patients when first examined are alert (50%) with the remaining being lethargic (25%), stuporous or comatose (25%). The onset may be acute or is gradual over minutes to hours with the neurologic deficit steadily progressive. CT and MRI serial evaluations have demonstrated that expansion occurs in the first 6 hours in approximately 20% of patients while 15% expand during the next 6–12 hours and 6% between 6–24 hours. Expansion may be dramatic. In patients

who suffer hemorrhage from a bleeding diathesis expansion may occur insidiously over days.

Focal deficits and consciousness are preserved at the ictus. Headache and vomiting may be absent. In subarachnoid hemorrhage, headache is severe, reaches maximum intensity almost instantly and focal neurologic signs are minimal. Loss of consciousness in SAH is much more frequent at the ictus than that which occurs with intraparenchymal hemorrhage. Embolism produces the greatest neurologic deficit at onset, is accompanied by a higher percentage of seizures than ICH and a lesser degree of headache. Patients who suffer emboli, particularly to the stem of the left MCA appear stunned. Ischemic vascular disease is more frequent during sleep or the early morning and is accompanied frequently with deficits of a cortical nature such as aphasia or denial of contralateral space. Headache is common in ischemic disease with posterior circulation ischemia causing it more frequently than that from the anterior circulation. Rarely is it a predominant feature.

Headache from intraparenchymal lesions occurs frequently as the hematoma develops and stretches the overlying dura, displaces the venous sinuses and major blood vessels at the base of the brain or spills into the subarachnoid space. Early in the course of the hemorrhage, the stretched dura may project pain to the overlying skull and scalp but most often the headache is projected frontally. The anterior and middle fossa dura and the forehead are innervated by V1 (somatic visceral convergence) and thus lesions in these fossae project to somatic representations of V1. Displacement of the posterior 1/3 of the sagittal sinus may also cause frontal headache. The dura of the posterior fossa is innervated by the posterior roots of C1–C2 and cranial nerves IX and X. Hematomas in the posterior fossa usually project pain to the basiocciput, posterior cervical areas or the trapezius ridge. They may project to the brow, the somatic representation of C2. Displacement of the tentorium and irritation of its under surface (innervated by C1–C2, IX and X) may cause pain in the inner ear. The upper leaflet of the tentorium is innervated by V1. Many patients who have suffered an intraparenchymal bleed are too lethargic to describe their headache accurately. Headache is most common with lobar and cerebellar hematomas due to their close approximation to the dura and may be accompanied by signs of meningeal irritation. Headache increases with hematoma enlargement and is associated with vomiting and deterioration of the level of consciousness. Head tilt to the side of the hematoma, unilateral forced eye closure (ipsilateral to the side of the hematoma) and C2 headache are most suggestive of a cerebellar hemorrhage.

Severe neck stiffness, photophobia, sore eyes, Brudzinski and Kerning's signs suggest caudate hemorrhage with direct rupture into the ventricular system. Hyperthermia, rarely greater than 103° may be present. Thalamic and cerebellar hemorrhage may also be associated with early ventricular extension. Larger putaminal hemorrhages rarely rupture into the ventricular system at onset.

The focal deficits and topography of each type of hemorrhage will be described in detail. Specific neurological deficits suggest a characteristic hemorrhage:

1. A deeply comatose patient with head and eyes deviated to the side of the lesion, a flaccid hemiparesis and hemisensory defect with periodic breathing is characteristic of a deep pallidal hemorrhage
2. Inability to walk, dysarthria, nystagmus with quadriplegia suggests a cerebellar hemorrhage
3. A patient whose eyes are down and in with a greater sensory than motor deficit is sentinel for a thalamic bleed
4. An elderly patient with arm, face weakness who has suffered a seizure suggests a lobar congophilic hemorrhage

Vomiting and nausea may occur at the ictus of an intraparenchymal hemorrhage due to the sudden increase of ICP that is transmitted to the mechanosensitive emetic center of the floor of the IVth ventricle or distortion of the IVth ventricle itself. Vomiting stops as pressure is relieved by displacement of CSF into the spinal subarachnoid space, overbreathing that effects a decrease of pCO₂ and consequent reduction of cerebral blood flow as well as intracranial shifts of brain parenchyma. As the hematoma expands further, vomiting and nausea return due to exhaustion of compensatory mechanisms.

Persistent vomiting out of proportion to dizziness is suggestive of an ischemic lesion of the brainstem. Vomiting with change of head position is characteristic of a mass in the IVth ventricle. Inability to vomit in the face of a strong urge to do so is characteristic of an intrinsic medullary lesion. A smooth gradual deterioration of neurological function over minutes to hours with concomitant headache and vomiting is most consistent with supratentorial intraparenchymal hemorrhage. Headaches are most often seen with larger hemorrhages whereas deep parenchymal lesions may be asymptomatic. Approximately 30% of patients suffer headaches at the ictus, another 20% develop it during evolution of their neurologic deficits and up to 40% may have no headache. Many of the latter patients are lethargic or obtunded at the time of evaluation. Lobar and cerebellar hemorrhages have the highest incidence of headaches due to their proximity to the meninges. Patients with cerebellar hemorrhage vomit shortly after the ictus. Approximately 50% of patients with posterior circulation headaches vomit. Ischemia in this distribution causes vomiting in 1/3 of patients which tends to be more persistent and is not associated with obtundation and stupor. Patients with migraine have severe persistent vomiting accompanied by dizziness and vertigo but minimal focal deficits and no depression of consciousness. Bickerstaff's migraine (vasospasm of the vertebrobasilar arteries) may be associated with transient loss of consciousness and there have been reports of migraine patients who become comatose.

Seizures occur in approximately 15% of patients who suffer an intraparenchymal bleed. They are most common in

lobar hemorrhages which occur at the gray-white junction and excite the overlying cerebral cortex. Seizures are rare in putaminal hemorrhages. They suggest an underlying cavernous angioma, arteriovenous malformation or transformed embolic stroke. A 10 ml hemorrhage is minimal, 45 ml is severe and greater than 100 ml is usually fatal.

Topographical Syndromes

Caudate Hemorrhage

General Characteristics

1. Approximately 7% of ICH
2. Medial hemorrhages:
 - a. Blood dissects into the ipsilateral frontal horn
 - b. Dense hemorrhage is noted at the caudate head
 - c. Ventricular dilatation occurs ipsilaterally > contralaterally

Clinical Manifestations

1. Small hemorrhage: no prominent motor, sensory or visual loss
2. Symptoms: mimic intraventricular bleed or SAH: neck stiffness, severe headache, nausea and vomiting, decreased level of consciousness

Lateral Caudate Hemorrhage

General Characteristics

1. Larger than medial hemorrhage
2. Spreads laterally or posterolaterally into the putamen or anterior or posterior limb of the internal capsule

Clinical Manifestations

1. Headache, vomiting, decreased level of consciousness
2. Hemiparesis, hemisensory loss, ipsilateral conjugate deviation of the eyes with inability to look to the contralateral side (may be dolled across the midline in 12 to 24 hours); in general, minimal sensory loss
3. Less severe and transient signs if the hemorrhage is limited to the internal capsule
4. If blood spreads inferiorly; Horner's syndrome
 - a. Horner's syndrome (ipsilaterally)
5. Right caudate hemorrhage: neglect or mania
6. Left caudate hemorrhage: aphasia, confusional state, disorientation
7. Memory loss (if hemorrhage involves internal capsule and AV nucleus of the thalamus)

Differential Diagnosis

1. HCVD
2. Infarct with hemorrhagic transformation (lenticulostriate, recurrent artery of Heubner)
3. Arteriovenous malformation
4. Carotid aneurysm rupture
5. Moyamoya disease (with hemorrhage)
6. Ependymal vascular malformation

Striatocapsular Hemorrhage

Clinical Manifestations

1. Mild dysarthria and dysphagia
2. Contralateral hemiparesis
3. Contralateral hemisensory deficit
4. Lacunar type syndrome

Anterior Type

General Characteristics

1. 11%; Heubner's artery territory
2. Small caudate hematoma
3. Ruptures into lateral ventricle

Clinical Manifestations

1. Severe headache (similar to subarachnoid hemorrhage)
2. Contralateral hemiparesis – less than 50%
3. Acute confusion; abulia; (lasts approximately one week)
4. Dominant hemisphere: transcortical motor aphasia (transient)

Middle Type

General Characteristics

1. Medial lenticulostriate artery territory
2. <10%; moderate in size (<30 cc; spreads anterolaterally)
3. Primary involvement globus pallidus and medial putamen

Clinical Manifestations

1. Conjugate deviation of the eyes to the side of the lesion
2. Contralateral hemiparesis (mild to moderate)
3. Anomia; global aphasia (transient)

Posteromedial Type

General Characteristics

1. Anterior choroidal artery territory
2. 4% of striatocapsular hemorrhages
3. Small hematoma in posterior limb of internal capsule

Clinical Manifestations

1. Spreads rostrally; pressure on medial putamen or lateral thalamus

Posterolateral Type

General Characteristics

1. Posterior medial branches of the lateral lenticulostriate arteries territory
2. Approximately 33% of striatocapsular hemorrhage
3. Areas affected:
 - a. Posterior 50% of the putamen; moderate in size (35 cc); extend often to the anterior putamen
 - b. Posterior limb of the internal capsule (retrolenticular portion); rupture into anterior horn of the lateral ventricle

Clinical Manifestations

1. Impaired consciousness

2. Cheyne–Stokes or periorotic respiration
3. 2–3 mm reactive pupils
4. Severe flaccid contralateral hemiparesis
 - a. Arm, leg, face, equally involved
5. Dominant hemisphere
 - a. Anterior > posterior aphasia
6. Non-dominant hemisphere
 - a. Severe visuospatial neglect
7. Pure Sensory loss if the thalamus is involved

Lateral Type

General Characteristics

1. Lateral branches of the lateral lenticulostriate arteries
2. Approximately 20% of striatocapsular hemorrhage
3. Areas involved:
 - a. Elliptical hematoma between the putamen and insular cortex
 - b. Often ruptures into the lateral ventricle

Clinical Manifestations

1. Contralateral hemiparesis
2. Neglect for contralateral space (NDH)
3. Language dysfunction (DH)

Massive Hemorrhage

General Characteristics

1. Approximately 25% of lenticulo striato hemorrhage
2. Entire striatocapsular territory involved

Clinical Manifestations

1. Severe flaccid contralateral hemiparesis
 - a. Arm, face, leg equally involved
2. Lethargy to coma
3. Ipsilateral conjugate eye deviation
 - a. Wrong way eyes observed in a percentage of patients
4. Poor prognosis

Putaminal Hemorrhage

General Characteristics

1. Most common location for basal ganglia hemorrhage in hypertensive patients (40%)
2. Largest hemorrhages involve:
 - a. Medial and most anterior portion of the posterior putamen
 - b. Anterior 2/3 of the posterior limb of the internal capsule
 - c. Putative mechanism: rupture of Charcot–Bouchard aneurysms of the large lateral lenticulostriate arteries
 - d. Symptoms depend on the amount of blood extravastion

Clinical Manifestations

1. Abrupt onset of neurologic deficit while awake
2. Approximately 30% have headache at onset and 20% more develop it as the process evolves
3. Vital signs:

- a. Level of consciousness:
 - i. 50% alert at presentation; others obtunded to comatose
 - ii. Blood pressure elevated: 220–240 to 110–140 mmHg
 - iii. Pulse rate tends to be slow and full at 60–70/minute, a rapid thready pulse appears with herniation

4. Respiratory pattern

- a. Most often periodic respiration, inspiratory and expiratory build up and decline with irregular apneic periods. The longer the apneic periods the graver the prognosis
 - i. Rarely Cheyne–Stokes pattern

5. Pupils:

- a. At presentation are usually diencephalic at 2–3 mm and reactive to light, change with evolution of the hematoma and consequent herniation

6. Posture:

- a. Early at presentation:
 - i. Pronated arm with early cortical thumb (adducted) contralateral to the lesion; externally rotated leg contralaterally
 - ii. Right-sided lesion
 1. Patient angled in bed neglecting contralateral space (non-dominant hemisphere)

7. Mental status:

- a. Left-sided lesion (dominant hemisphere)
 - i. Fluent aphasia with intact repetition unless the arcuate fasciculus is disrupted by the lesion
- b. Non-dominant hemisphere
 - i. Visual neglect for left hemispheric space
 - ii. Motor impersistence
 - iii. Constructional dyspraxia

8. Cranial nerve examination:

- a. Contralateral VII paralysis
- b. Head deviated to the side of the lesion
- c. Eyes slightly below the midline if the midbrain oculomotor center for upgaze (riMLF) is compressed
 - i. Conjugate deviation of the eyes to the side of the lesion
 - ii. If the patient is alert pupils may be normal; as obtundation supervenes pupils are diencephalic at 2–3 mm

9. Motor examination:

- a. Flaccid contralateral hemiparesis
 - i. Internal capsule involvement with brain shock
 - ii. More anteriorly in the posterior limb faciobrachial paresis; leg less involved (topographically and bilaterally innervated)
 - iii. Rarely patients may have contralateral increased tone if the putamen is primarily involved
 - iv. Rarely; ipsilateral adventitious movement occur (descending pyramidal or extrapyramidal pathways are stimulated)

- v. Motor impersistence with right-sided lesions
- 10. Sensory examination:
 - a. Contralateral hemisensory deficit to all modalities
 - b. Neglect of left-sided space with right-sided lesions
- 11. Reflexes:
 - a. Depressed on the paretic side
 - b. Positive Babinski or intermediate toe on the paretic side; bilateral Babinski signs if there is severe pressure

Transtentorial Herniation (Massive Hemorrhage (100 cm³) of blood)

General Characteristics

1. Anatomy:
 - a. Compression and torque of the midbrain at the level of the tentorium
 - i. Obliterated ambient cisterns
 - ii. Trapped contralateral temporal horn
 - iii. Rupture of midline penetrating arteries of the pons, midbrain and thalamus (Duret's hemorrhage)
 - iv. Compression and infarction of the PCA under the ipsilateral tentorium
 - v. Lateral pineal shift of 10 mm
 - vi. Downward pineal shift of 7 mm
 - vii. Intraventricular extension of blood with herniation

Clinical Manifestations

1. Vital signs:
 - a. Stupor to coma
 - b. Blood pressure of 90–60 mm/Hg as herniation occurs
 - c. Central neurogenic hyperventilation (20–40 breaths/minute)
 - d. Thready pulse at 100–120 beats/minute
 - e. Temperature 103–105° Fahrenheit dependent on presence of intraventricular blood or posterior hypothalamic damage
2. Cranial nerve impairment:
 - a. Paralyzed horizontal gaze; eyes below the midline (5–10°)
 - b. Ipsilateral pupil smaller then dilates; may become oval ("tad pole") as IIIrd nerve is compressed under P-COM artery
3. Posture and reflexes:
 - a. Bilateral decerebrate posture
 - b. Bilateral Babinski response

Anterior Putaminal Hemorrhage

General Characteristics

Anatomy

1. Anterior putamen
2. Anterior limb of internal capsule

Clinical Manifestations

1. Mild hemiparesis
2. No sensory loss
3. Broca's aphasia; anterior extension

Posterior Putaminal Hemorrhage

General Characteristics

1. Anatomy
 - a. Involves posterior 1/3 of the internal capsule
 - b. Extreme posterior extension of the putamen

Clinical Manifestations

1. Hemisensory loss greater than hemiparesis
2. Inferior quadrantanopia or hemianopia with left dominant posterior putaminal hemorrhage
3. Wernicke's type aphasia:
 - a. If the hemorrhage extends into the isthmus of the temporal lobe
 - b. Undercuts or involves posterior speech areas. Inferior temporal gyrus thought to be involved in semantic aphasia. Dissection of blood into periventricular white matter
4. Non-dominant hemisphere demonstrates neglect, spatial and apractic deficits

Rare Presentations of Putaminal Hemorrhage

1. Pure motor hemiplegia
2. Hemichorea
3. Clumsy hand syndrome
4. Hemiballism
5. Sensorimotor stroke
6. Ataxic hemiparesis
7. Trauma

Asymptomatic Putaminal Hemorrhage

General Characteristics

1. 1.5% of stroke patients (hemorrhagic transformation)
2. 9.5% of putaminal hemorrhage
3. Minor hemorrhage (less than 20 ml)

Hemorrhagic Disease

Neuroimaging

1. Spot sign:
 - a. A bright spot on computed tomography and angiography source images
 - b. Predictive of hematoma growth
 - c. 50% of putaminal hemorrhages have a spot and tail sign (a linear density extending from the MCA toward the spot sign)
 - d. Hematoma volume, spot signs, and intra-hematoma striatic arteries predict acute deterioration

Globus Pallidus Hemorrhage

General Characteristics

1. Often spared from ischemic injury
2. Hemorrhagic and necrotic lesions occur:
 - a. Carbon monoxide
 - b. 3,4-methylene dioxymethamphetamine

- c. Cocaine
 - d. Opiates (5–10% of addicts)
 - e. Cyanide poisoning
 - 3. Medial lenticulostriate artery territory
 - 4. Hypertensive patient with Cushing reflex
 - 5. BP 220/120 – 240/120–130 mmHg
 - 6. Approximately 50% obtunded within minutes to hours after ictus. Progressive deterioration of level of consciousness
 - 7. Periodic or Cheyne's-Stokes respiration
 - 8. Pupils 2–3 mm poorly reactive to light
 - 9. Pulse rate of 50–60 beats/minute full at onset
 - 10. Eyes conjugately deviated below the horizontal 5–10°
 - 11. Head and eyes deviated to the side of the lesions
 - 12. Dense contralateral hemiparesis: arm, face, and leg relatively equally involved; flaccid tone (destruction of medial components of posterior limb of the internal capsule)
 - 13. Dense hemisensory deficit to all modalities (disruption of medial portion of the posterior limb of the internal capsule); thalamic projections
 - 14. Depressed reflexes contralaterally; may be increased ipsilaterally
 - 15. Contra or bilateral Babinski's signs
 - 16. Progression to decerebrate rigidity and central herniation
- 3. Vertical skew deviation:
 - a. Eyes are down on the side of the lesion
 - b. Abnormal displacement is constant in all fields of gaze
 - 4. Disconjugate gaze:
 - a. Limited abduction (pseudo VI nerve palsy)
 - b. Visual fixation from the adducted eye
 - c. Increased convergence vectors neutralize abduction (visual fibers descend into the anterior medial thalamus) and cause eyes to look down and in
 - 5. Pupils:
 - a. 2–3 mm poorly responsive to light
 - b. Afferent arc disrupted
 - 6. Hemorrhage may extend into:
 - a. Diencephalic mesencephalic junction
 - b. Quadrigeminal plate
 - 7. Wrong way eyes

Thalamic Sensory Loss

- 1. All primary modalities affected including vibration:
 - a. Rarely also occurs with a lesion of the dorsal column nuclei
 - b. May split the frontal bone of the forehead
- 2. Patient aware of a line that bisects the body:
 - a. Bilateral sensory loss around the umbilicus
 - b. 20% of patients describe the quality as numb or heavy; 80% describe active paresthesias, formication or burning (VPL)
 - c. May have bilateral intraoral numbness or sensory loss (VPM)
 - d. Tips of all fingers may be numb (VPI as fibers destined for VPL are separated here)
 - e. After 6 weeks to 3 months Déjérine-Roussy syndrome may appear:
 - i. Decreased primary modality sensation in the involved area
 - ii. Static and dynamic mechano-allodynia of the involved area
 - iii. Thermal hyperalgesia particularly to cold in some component of the area of sensory loss
 - iv. Hyperpathia in some component of the area of sensory loss:
 - 1. Pain threshold increased
 - 2. Once threshold is exceeded pain reaches maximum intensity too rapidly
 - 3. Pain is overwhelmingly severe
 - 4. Poorly localized with a deep visceral quality
 - 5. Not stimulus bound (continues after the stimulus is withdrawn)
 - 6. Occurs spontaneously

Territorial Thalamic Hemorrhage

General Characteristics

- 1. 4 major categories dependent on involved vascular territories
 - a. Thalamogeniculate artery (P1) territory
 - b. Thalamoperforate or thalamic subthalamic perforate artery (P1) territory
 - c. Tuberothalamic (polar arteries)
 - i. Originate from the P-COM
 - d. Lateral posterior choroidal artery (P3)
- 2. Most hemorrhages are posterior to descending pyramidal tracts
 - a. Sensory loss greater than motor

Clinical Manifestations

- 1. Ocular manifestations
- 2. Thalamic sensory loss
- 3. Thalamic aphasia
- 4. Behavioral or cognitive deficits
- 5. Thalamic motor abnormalities

Ocular Clinical Manifestations

- 1. Paralysis of upgaze pressure at the level of the superior colliculus, oculomotor center for upgaze the riMLF (rostral interstitial nucleus of the medial longitudinal fasciculus)
- 2. Eyes “down” and “in” in primary gaze (as if looking at the tip of the nose)

Thalamic Aphasia

- 1. Nuclear involvement
 - a. Anterior ventral nucleus
 - b. Pulvinar nucleus
 - c. Dorsomedial nucleus

Clinical Characteristics

1. Normal conversation early
2. Fluent aphasia
3. Jargon intrusions
4. Relatively good comprehension
5. Repeat or duplicate words or syllables at the ends of words in spoken and written language
6. Paraphasic errors
7. Anomia
8. Perseveration

Behavioral and Cognitive Dysfunction

1. Anterior ventral nuclear lesion
 - a. Abulia
 - b. Waxing and waning levels of consciousness throughout the day
2. Dorsomedial nuclear lesion
 - a. Amnesic syndrome
 - b. Anosognosia
 - c. Visual spatial dysfunction

Thalamic Motor Dysfunction

1. Thalamic drift: prominent metacarpal pharyngeal flexion with the thumb adducted into the palm; downward
2. Ataxia of stance (area X involved)
3. Mild limb ataxia (disruption of frontal cortical – thalamic distributed network); Bruns' ataxia variant
4. Contralateral choreatic or dystonic movements
5. Contralateral severely abnormal posture (patient lying on an arm behind his back)

*Topographic Hemorrhages of the Thalamus**Posterolateral (Thalamogeniculate Artery Territory)**Clinical Manifestations*

1. Largest and most common thalamic hemorrhage
2. Thalamic sensory and motor involvement
3. Internal capsule may be compressed with consequent sensorimotor deficits
4. Leg sensation and eye movements transiently and minimally involved

*Anterior or Anterior Lateral Hemorrhage**Clinical Manifestations*

1. Tuberothalamic (polar artery) territory
2. Apathy
3. Abulia
4. Hypersomnolence
5. Waxing and waning level of consciousness
6. Thalamic aphasia

*Posteromedial (Thalamoperforate or Thalamic Subthalamic-Thalamoperforate Arteries)**Clinical Manifestations*

1. Thalamic eye signs:

- a. Pupillary involvement
 - b. Vertical gaze dysfunction
2. Impaired consciousness
 3. Ruptures into the IIIrd ventricle
 4. Compresses the diencephalic mesencephalic junction
 5. Early hydrocephalus

*Posterior Dorsal Lesions**Clinical Manifestations*

1. Posterior choroidal artery territory
2. Pulvinar involved
3. Aphasia
4. Minimal transient sensorimotor involvement (overlapping blood supply to posterior limb of the internal capsule)
5. Rare: neglect, apraxia, amnesia

Sub-Cortical Lobar Hemorrhage*General Characteristics*

1. 10% of ICH; higher frequency in patients <45 years
2. Develop beneath the gray white junction
3. After absorption of blood products there is a "slit like scar"
4. Expand linearly along white matter pathways
5. Undercuts the overlying cerebral cortex
 - a. Epileptogenic
 - b. 15–30% seizures occur at onset
6. Parietal and occipital lobes more frequently affected than frontal lobes

Clinical Manifestations

1. Sudden onset during activity
2. Headache
3. Vomiting in 30–40% during the first hour
4. Seizures 15–30% at onset, focal and status epilepticus (frontal lobe most common)
5. 5–20% present in coma

Differential Diagnosis of Lobar Hemorrhage

1. HCVD (patients <45 years)
2. Cerebral amyloid angiopathy (>65 years)
3. Arteriovenous malformation (<30 years)
4. Cavernous angioma
5. Coagulopathy
6. Illicit drug use
7. Trauma
8. Aneurysm

Frontal Hematoma*Clinical Manifestations*

1. Headache – 80%
2. Vomiting – 80%
3. Seizure – 25–30%
4. Impaired consciousness (lethargy to obtundation) – 50%
5. Gaze preference 30–40%

*Topographic Diagnosis of Frontal Hematoma***Dorsal Anterior***Clinical Manifestations*

1. Cognitive behavioral features:
 - a. Abulia
 - b. Initiate nothing
 - c. If stimulated:
 - i. Short terse answers
 - ii. Slow processing of information
2. Frontal eye field involvement (area 8, 10)
 - a. Eyes conjugately deviated to the side of the lesion; may be dolled across the midline after 12–24 hours from the ictus
3. Dorsolateral prefrontal cortex involvement (DLPC)
 - a. Left-sided executive frontal lobe dysfunction
 - i. Poor memory retrieval
 - b. Right side (non-dominant)
 - i. Disinhibition
 - ii. Poor judgment
 - iii. Witzelsucht (inappropriate jocularity)
 - iv. Bilateral lesions, bowel and bladder incontinence (second frontal gyrus)
4. Area 4 involvement
 - a. Brachiocephalic hemiparesis
 - b. Head and eye deviation to the side of the lesion (if extends to area 8 and 10)
 - c. Lesions above the frontal horn of the lateral ventricle
 - i. Frontal headache
 - ii. Contralateral predominant leg weakness

Inferior Frontal Hematoma*Clinical Manifestations*

1. Below frontal horns of lateral ventricle
2. Impaired consciousness
3. Contralateral brachiocephalic hemiparesis and hemisensory loss
4. Rare presentation:
 - a. No motor or sensory loss
 - b. Abulia

Orbital Frontal Hematoma*Clinical Manifestations*

1. Impaired consciousness
2. Agitated delirium
3. Most often etiology is head trauma:
 - a. Windshield injury in MVA
 - b. Falls (associated basilar skull fracture)
4. Semantic language dysfunction
5. Autonomic dysregulation:
 - a. Cardiac arrhythmia (area 11,12)
 - b. Hypertension

Paracentral Hematoma*Clinical Manifestations*

1. Primary involvement of Brodmann's area 4, 3, 1 and 2

2. Contralateral brachiocephalic motor and sensory deficits
3. Anterior (area 44) aphasia:
 - a. Transcortical motor
 - b. Decreased ability to write out of proportion to weakness (Exner's area 45)
4. Focal and generalized seizures
5. Lesion above the frontal horn:
 - a. Headache (frontal and primarily ipsilateral)
 - b. Contralateral leg weakness

Differential Diagnosis of Frontal Hematoma

1. HCVD – 20%
2. AVM – 25–30%
3. Cavernous angioma – 25–30%
4. Aneurysm – 25–30%
5. Anticoagulation – 10%
6. Congophilic angiopathy – 5–10%
7. Trauma – 10%
8. Illicit drug use – 10%

Parietal Hematoma*General Characteristics*

1. Unilateral headache
 - a. Temporoparietal early; then frontal extension
2. Seizures (20–30% at onset)
3. Contralateral cortical sensory loss
4. Contralateral parietal motor dysfunction (loathness to move extremity)
5. Neglect of the contralateral visual field

*Topographic Parietal Hemorrhage***Anterolateral Parietal Hemorrhage***Clinical Manifestations*

1. Parietal movement disorder
 - a. Updrift of the affected hand with “piano playing” fingers
 - b. Loathness to move
 - c. Sensory ataxia during all components of movement
 - d. Abnormal arm position at rest
 - e. Imprecise fine movement
2. Non-congruent inferior quadrantanopsia in 50% of patients (lesion must extend greater than a depth of 1 cm)
3. Posterior aphasia (dominant hemisphere)
4. Neglect of contralateral space (non-dominant hemisphere)

Anterior Medial Parietal Hemorrhage*Clinical Manifestations*

1. Similar clinical syndrome to lateral hemorrhage
2. Depressed consciousness
3. May extend into the thalamus

Large Posterior Parietal Hematoma*Clinical Manifestations*

1. Seizure at onset

- a. Aura of contralateral spatial tilt
- 2. General deficits:
 - a. Posture copy
 - b. Two point discrimination
 - c. Graphesthesia
 - d. Stereognosis
 - e. Localization of a body part or limb in space
 - f. Extinction of double simultaneous stimulus (contralateral to the lesion)
 - g. Alloesthesia
 - h. Point localization

Non-Dominant Parietal Hemisphere Hematoma

Clinical Manifestations

- 1. Constructional apraxia
- 2. Dressing apraxia
- 3. Posterior type of alien hand (NDH > DH)
- 4. Contralateral spatial neglect
- 5. Anosognosia
- 6. Asomatognosia
- 7. Geographical confusion (NDH > DH)
- 8. Depression of optokinetic nystagmus (eyes deviate to side of the lesion)
- 9. Geometric and colored patterns that moves in contralateral visual field (NDH = DH)

Dominant Left Parietal Lobe Hemorrhage

Clinical Manifestations

- 1. Transcortical sensory aphasia
- 2. von Gerstmann's syndrome components
 - a. Right left confusion
 - b. Finger agnosia
 - c. Acalculia
 - d. Dysgraphia
 - e. Failure to cross the midline
- 3. Dysgraphia and dyslexia (Brodmann's area 37,40,41)
- 4. Alexia without agraphia (Brodmann's area 39,40)
- 5. Bilateral failure to localize body parts
- 6. Poor visual manual dexterity (Brodmann's 5,7 projects to area 4)
- 7. Parietal motor dysfunction
- 8. Bilateral parietal hemorrhage
 - a. Parietal avoidance behavior

Left Inferior Parietal Hematoma

Clinical Manifestations

- 1. Deficits of reading, writing and calculation
- 2. Nominal aphasia (supramarginal gyrus)

Right Inferior Parietal Hematoma

Clinical Manifestations

- 1. Constructional dyspraxia
- 2. Poor visual spatial relationships
- 3. Inability to draw or copy

Temporal Hematoma

Clinical Manifestations

- 1. Agitation and/or delirium (R > L)
- 2. Wernicke's type aphasia (DH)
- 3. Herniation with slight or without hemiparesis
- 4. Insidious decline of consciousness followed by IIIrd nerve paralysis
- 5. Headache:
 - a. Pre-auricular
 - b. Periorbital
- 6. 20% of temporal lobe hematomas have seizures
- 7. Visual field superior quadrantanopsia

Left Temporal Lobe Hematoma

Clinical Manifestations

- 1. Fluent aphasia
- 2. Anomia, paraphasic errors, poor comprehension

Right (Non-Dominant) Temporal Hematoma

Clinical Manifestations

- 1. Confusion without focal signs

Posterior Left Hematoma

Clinical Manifestations

- 1. Wernicke's aphasia
- 2. Right homonymous quadrantanopsia
- 3. Minimal hemiparesis or hemisensory deficit

Inferior Basal Temporal Hematoma

Clinical Manifestations

- 1. Blood in the basal cisterns or cortical sulci suggests AVM or aneurysm

Medial Extension of Temporal Lobe Hematoma

Clinical Manifestations

- 1. Basal ganglia internal capsule compression or destruction
- 2. Contralateral hemiplegia and hemisensory deficit
- 3. Wernicke's or transcortical sensory aphasia
- 4. Horizontal gaze palsy contralaterally
- 5. Right temporal lobe hematoma with extension to the parietal lobe
 - a. Left-sided spatial hemi inattention and neglect
- 6. Partial IIIrd nerve paralysis
 - a. Poor pupillary light response
 - b. Partial IIIrd nerve paralysis (uncal entrapment of the nerve; compression under the posterior communicating artery)

Occipital Lobe Hematoma

Clinical Manifestations

- 1. Headache in or around the ipsilateral eye
- 2. If visual fields' deficit is present:
 - i. Patient is aware of visual loss but may ascribe it only to the contralateral temporal field (may miss ipsilateral nasal cut)

3. Visual neglect of contralateral field if the hematoma extends into the parietal lobe
4. Rare weakness

Medial Occipital Hemorrhage

Clinical Manifestations

1. Headache (C2 distribution or radiates to the ipsilateral eye)
2. Congruent homonymous hemianopia if above and below the calcarine fissure
 - a. Dense quadrantanopia
 - b. Respects the midline
3. Visual field variants depend on topography
 - a. Checkerboard deficit (lesions above and below calcarine sulcus) or opposite sides
 - b. Superior or inferior quadrantanopsia
 - c. Posterior lesions (sparing the temporal crescent)
 - d. Occipital pole lesions (loss of macular vision)
4. No depression of consciousness
5. No memory loss
6. No weakness

Lateral Occipital Hemorrhage

Clinical Manifestations

1. Headache at onset (similar to medial occipital lobe radiation)
2. No visual field deficit
3. No sensorimotor or behavioral deficit
4. If extension is into the parietal lobe or medially:
 - a. Depressed level of consciousness
 - b. Contralateral neglect
 - c. Agitation
 - d. Congruent contralateral homonymous hemianopia

Neuroimaging

1. Susceptibility weighted imaging:
 - a. A 3D gradient echo MRI sequence
 - b. Measures phase and magnetic data for post-processing
 - c. Detects blood, iron, calcium and deoxygenated hemoglobin content in the brain parenchyma
 - d. Scan time is 5–10 minutes, 2 gradient-echo 2 minutes
 - e. Extremely valuable technique for microbleeds in CAA and hypertensive hemorrhages; the former are cortical and the latter are in the basal ganglia
2. Intraoperative computed tomography is now utilized in lobar hemorrhage surgery:
 - a. Able to access real time in 3D information on residual hematoma
 - b. Evaluate unexpected bleeding
3. The sign score correlates with ICH expansion
4. Good functional outcome:
 - a. Hematoma volume of less than 30 ml
 - b. Significant independent neurological predictions in-hospital survival:
 - i. BG/IC bleed
 - ii. Less than 30 ml of blood
 - iii. No midline shift
 - iv. No intraventricular extension

Primary Intraventricular Hemorrhage

Differential Diagnosis

1. Subependymal vascular malformation
2. Cavernous angioma
3. Dissection of caudate hematoma
4. Angioma of the choroid plexus (children)
5. Vertebral artery aneurysm (IVth ventricle)
6. Moyamoya
7. Lenticulostriate aneurysm (blood in IVth ventricle)
8. Cocaine
9. IVth ventricular ependymoma
10. Leukemia/lymphoma
11. Intraventricular cavernoma

Clinical Manifestations

1. Similar to subarachnoid hemorrhage
 - a. Severe headache
 - b. Meningeal signs
 - c. Stiff neck
 - d. Early vomiting
 - e. Lethargy
 - f. Bilateral hyperreflexia
 - g. Positive Babinski sign
 - h. Hyperthermia
 - i. Brainstem compression
 - j. Seizure

Deleterious Effects of Intraventricular Hemorrhage

1. Direct mass effect
2. Impairment of Pacchionian granulations
3. Dysfunction of CSF circulation
4. Acute obstructive hydrocephalus
5. Delayed intraventricular hemorrhage
 - a. Associated with worse outcomes
 - b. Associated with atrial fibrillation
 - c. Higher rate of warfarin use
 - d. More likely to develop hematoma expansion
 - e. Hemorrhage in the lentiform nuclei more likely to evolve into IVH rather than thalamic or caudate lesions
 - f. Usually occur within the first 72 hours in the hospital
6. Site of bleeding:
 - a. Vasculature of subependymal region
 - b. Choroid plexus

Infratentorial Intraparenchymal Hemorrhage

Cerebellar Hemorrhage

General Characteristics

1. 10% of intracranial hemorrhages
2. Anatomy involves:
 - a. The area of the dentate nucleus
 - b. At the level of the anastomosis of distal PICA and SCA
 - c. Long perforating branches of the SCA may be involved
 - d. Rarely:
 - i. Vermis hemorrhage (5%):

1. Medial branches of PICA and the SCA
- ii. Hemorrhage extension
 1. Ipsilateral hemisphere
 2. Opposite hemisphere or vermis
 3. Rarely to the brainstem
 4. Cerebellar peduncles with rupture into IVth ventricle

Clinical Manifestations

Early Signs and Symptoms

1. Inability to walk, rarely to sit or stand (pressure on descending pontine and middle cerebellar peduncle fibers)
2. Falling to the side of the lesion
3. Vomiting
4. Headache (occipital, neck, C2 radiation)
5. Dysarthria
6. Rotary nystagmus (greater to the side of the lesion, occasionally gaze paretic to the opposite side); floccular nodular lobe and PPRF involvement (pressure)
7. Rare loss of consciousness at the ictus

Evolving Neurologic Signs

1. Vth nerve palsy (side of the lesion)
 - a. Ipsilateral forced eye closure (to prevent diplopia)
 - b. Head tilt (C2 root irritation) to the ipsilateral side
2. Smaller ipsilateral pupil
3. Failure to check greater than dysmetria or terminal 1/3 ataxic arm movement
4. Severe gait ataxia
5. Quadripareisis without quadriplegia
6. Increased lower extremity reflexes without Babinski's signs

Large Hemorrhage (Greater than 3 cm)

Clinical Manifestations

Early Brainstem Compression

1. All signs and symptoms noted that are with smaller lesions but telescoped in time
2. Stupor to coma
3. Lateral gaze palsy (eyes deviated to side of the lesion) pressure on the para pontine reticular formation paralyzes contralateral conjugate gaze
4. Quadripareisis (basilar strokes there is severe quadriplegia)
5. Bilateral Babinski's signs
6. Bilateral pontine pupils (<0.5 mm; reactive to light)
7. Central neurogenic hyperventilation (CNH)

Terminal Signs and Symptoms

1. Caudal cerebellum involved
 - a. Medullary cardiovascular and respiratory centers involved
 - i. Respiratory arrest
 - ii. Vasomotor collapse
 - iii. Decerebration
 - iv. Coma

Neuroimaging

MRI

1. Obliteration of the cerebellopontine angle cisterns
2. Displacement of the IVth ventricle
3. Hydrocephalus
4. Rarely upward herniation with vermian compression of the collicular plate
 - a. Gaze palsy > pupillary defects
5. Hydrocephalus of lateral and third ventricles

Small Hemorrhages with Survival

Clinical Manifestations

1. Mild gait ataxia
2. Rotary nystagmus (to the side of the lesions)
3. Signs and symptoms of hydrocephalus
 - a. Dementia
 - b. Abulia
 - c. Gait ignition failure in addition to ataxia (parapontine nucleus compressed)
 - d. Hyperreflexia legs > arms

Lateral Cerebellar Hematoma

Clinical Manifestations

1. Cranial nerve involvement:
 - a. V, VI, VII and VIII
 - b. Concomitant ataxia (ipsilaterally)

Cerebellar Vermian Hemorrhage

Clinical Manifestations

1. Medial PICA and SCA vessels rupture
2. Rare
3. Severe headache
4. Vomiting
5. Quadripareisis
6. Coma

Differential Diagnosis

Differential Diagnosis of Cerebellar Hemorrhage vs Basilar Artery Occlusion

Basilar Artery Occlusion

1. Sudden onset (both)
2. Sentinal hemiparesis
3. Herald hemiplegia
4. Quadriplegia
5. "Ocular bobbing"
6. Horizontal gaze paralysis
7. No cerebellar signs
8. Collapse
9. Central Neurologic Hyperventilation – Early
10. Pupil changes (less than 0.5 mm) – Early
11. Pin-point pupils
12. Vth nerve palsy – Late
13. Coma – Early
14. CNH – Early

Cerebellar Hemorrhage

1. Sudden onset (both)
2. Quadriparesis (Cerebellar)
3. Rotary or horizontal nystagmus (Cerebellar)
4. Conjugate deviation to the ipsilateral side
5. Failure to check (greater than dysmetria) – Early
6. Severe gait ataxia
7. CNH – Late
8. 1 mm pupils ipsilateral greater than contralateral side
9. Coma – Late
10. Forced ipsilateral eye closure
11. VIth nerve palsy – Late

Differential Diagnosis of Cerebellar Hemorrhage

1. HCVD (PICA/SCA vessels; dentate nucleus)
2. AV malformation
3. Hemangioblastoma (lateral lobes)
4. Cavernous angioma (may be multiple)
5. Associated with Von Hippel-Lindau (retinal and spinal angiomas)
6. Metastasis
7. Anticoagulation (INR > 5 on coumadin)
8. Ischemic transformation of infarct (PICA;AICA;SCA)
9. Trauma
10. Venous malformation (usually don't bleed)
11. Coagulopathy
12. Spinal surgery

*Primary Pontine Hemorrhage**General Characteristics*

1. Location:
 - a. Midventral pons (at the level of Vth nerve or junction of basis pontis and tegmentum)
 - b. Oval shape: destroys the center of the ventral tegmentum and basis pontis
 - c. Dissects:
 - i. Rostrally to the midbrain
 - ii. Rarely to the medulla
 - iii. Commonly into the IVth ventricle
 - iv. Rarely ruptures through the pial surface with spread to the clivus
2. Caused by rupture of paramedian basilar penetrating artery

Clinical Manifestations

1. Decreased level of consciousness or coma early in the course
2. Hypertension early evolves to vascular collapse during evolution (pressure on vasomotor center of lateral medulla, lateral pontine and pons)
3. Central neurogenic tegmentum hyperventilation early (20–40 breaths/min to apneustic gasps prior to death)
4. Early hemiparesis
5. Quadriplegia with increased tone of all extremities during evolution

6. Headache (basiocciput) and vomiting (occasional); sudden onset
7. Gradual asymmetric onset (occasional)
8. Asymmetric weakness of face and extremities
9. Abnormal movements:
 - a. Shaking tremors (partial decerebration)
 - b. Shivering and fasciculation (chest wall)
 - c. Dystonic posture versus decerebration
10. Weakness or paralysis of the face, pharynx, palate and tongue
11. Ocular manifestations:
 - a. Pinpoint pupils < 0.5 mm that are reactive to light (destruction of descending sympathetics vs activation of parasympathetics)
 - b. Anisocoria
 - c. Skew deviation (greater part of hemorrhage to the side of down eye)
 - d. Bilateral paralysis of horizontal gaze
 - i. Destruction of the parapontine reticular forma (center for horizontal gaze)
 - e. Ocular bobbing (eyes driven down and float up; vestibular tonic drive of upgaze mechanism)
 - i. May be unilateral
 - f. Up-bobbing (may be unilateral)
 - g. Ocular dipping (rapid down and upward movements), may be unilateral
 - h. 1 and one half syndrome (ipsilateral destruction of the parapontine reticular forma with concomitant destruction of the posterior crossing fibers of the MLF; patient can only abduct the ipsilateral eye)
 - i. Pontine exotropia (lateral and down deviation of the contralateral eye), the only voluntary eye movement is contralateral abduction
 - j. Posterior MLF syndrome (convergence is preserved)
 - k. Paralysis of upgaze if there is midbrain extension and destruction of the riMLF

Rarer Symptoms and Signs

1. Prior to coma:
 - a. Bilateral deafness (trapezoid body)
 - b. Severe dizziness and vertigo
 - c. Gustatory abnormalities (dysgeusia)
 - d. Preservation of reflex horizontal gaze
 - e. Locked in syndrome (destruction of ventral pons)
 - f. Hallucinations (between 3–50 days following the ictus)
 - g. Hyperhidrosis (contralateral)
 - h. Neurogenic bladder (destruction of the pontine micturition center)
 - i. Hypo- or hyperthermia (> 105° Fahrenheit); 104° Fahrenheit often is sepsis

Prognosis

1. Most often death in 24–48 hours, rarely a patient survives 7–10 days

Unilateral Basilar or Tegmental Basilar Hemorrhage*General Characteristics of Paramedian Hemorrhage*

1. Exclusively or predominantly on one side of the pons
2. Basotegmental hemorrhage is usually larger than those confined to one side of the pons

Clinical Manifestations

1. Small lateral basal hematomas
 - a. Present as:
 - i. Pure motor hemiparesis
 - ii. Ataxic hemiparesis
 - iii. Clumsy hand dysarthria syndrome
 - b. Dissection of lateral basal lesions into the tegmentum
 - i. Cranial nerve V, VI, VII deficits
 - ii. Contralateral hemiparesis

Differential Diagnostic Points Separating Hemorrhage Versus Lacunar Strokes

1. Occipital headache (hemorrhage)
2. Nausea or vomiting (hemorrhage)
3. No alteration of consciousness with lacunar stroke

Paramedian Tegmental Hemorrhage

1. Position sense and higher sensory modality loss in the contralateral arm, face and leg
2. Ipsilateral one-and-a-half syndrome ($1\frac{1}{2}$ syndrome)
3. Motor dysfunction of the contralateral extremities:
 - a. Ataxia
 - b. Decerebration
 - c. Dystonia

Lateral Pontine Tegmental Hemorrhage

1. Rupture of small penetrating vessels from long circumferential arteries
2. Pupillary defects:
 - a. Anisocoria (smaller ipsilateral pupil, normal reactivity)
3. Ocular motility defects:
 - a. Paralysis of ipsilateral conjugate gaze
 - b. One-and-a-half syndrome (if posterior MLF affected)
 - c. Intranuclear ophthalmoplegia (posterior type)
 - d. Ipsilateral VIth nerve deficit
 - e. Pontine exotropia
 - f. Ocular bobbing, dipping
4. Cranial nerve deficits:
 - a. V, VI, VII
5. Moderate hemiparesis
 - a. Bilateral weakness may occur at ictus; ipsilateral deficit clears
 - b. Limb and truncal ataxia, ipsilateral > contralateral, may be bilateral

Clinical Differential Points of Lateral vs Paramedian Lesion

1. Quadriparesis or quadriplegia (paramedian)
2. Contralateral hemisensory deficit: (lateral)

- a. Lemniscal modalities and spinothalamic deficits contralaterally
3. Rare findings:
 - a. Decreased hearing (trapezoid body); paramedian lesion
 - b. Dysarthria (posterior 1/3 of ventral tegmentum)
 - c. Dysphagia (corticobulbar fibers X, XII)
 - d. Decreased ipsilateral V (corresponding decrease of corneal reflex)
 - e. Bilateral ptosis (rare)
 - f. Convergent and divergent eye movements associated with:
 - i. Ipsilateral facial numbness
 - ii. Contralateral sensory deficits
 - iii. No motor abnormality

Differential Diagnosis of Primary Pontine Hemorrhage

1. Hypertensive cardiovascular disease
 - a. Middle aged patients
2. Vascular malformations (younger patients)
 - a. Von Hippel-Lindau disease
 - b. Zona-Bannayan syndrome
 - c. Cobb's syndrome
 - d. Cavernous angioma
 - e. Capillary telangiectasia (rarely bleed)
3. Anticoagulation
4. Coagulopathy
5. Trauma (associated with basilar skull fracture)

Midbrain Hemorrhage*General Characteristics*

1. Isolated spontaneous midbrain hemorrhages are rare
2. Location is usually in the tegmentum

*Clinical Manifestations***Neurologic Features**

1. IIIrd, IVth nerve palsies
2. Dorsal midbrain syndrome
3. Convergence, retraction, nystagmus (PAG)
4. Vertical one-and-a-half syndrome
5. Unilateral and bilateral INO (anterior type)
6. Bilateral total ophthalmoplegia
7. Vertical gaze palsies
8. Weber's, Claude's, Nothnagel, Benedict's syndrome

Unusual Signs and Symptoms

1. Pure sensory stroke
2. Unilateral asterixis
3. Upper extremity dystonia
4. Peduncular hallucinosis
5. Retrograde amnesia
6. Spindle coma

Differential Diagnosis

1. Vascular malformations (40%)

2. Bleeding diatheses (5%)
3. Arterial hypertension (25%)
4. Undetermined in 1/3 of patients

Medullary Hemorrhage

General Characteristics

1. Approximately 0.5–1% of ICH
2. Bleeding can occur from:
 - a. Direct penetrating arteries of the distal vertebral artery
 - b. Branch arterial rupture from PICA, AICA or anomalies of the vertebral artery (basilarization of the vertebral artery)
 - i. Hemorrhage may be involved with concomitant cerebellar infarct
 - c. Dorsal branches of PICA:
 - i. Supply the dorsal medulla
 - ii. Concomitant cerebellar infarction if these arteries rupture
 - d. Anticoagulation

Clinical Manifestations

1. Headache is common initially
2. Neurologic deficit correlates with medial or lateral symptoms as seen with infarction
3. Partial or complete lateral medullary syndrome depending on specific arterial rupture
4. Vascular malformations
5. Hypertension

Unusual Neurologic Features

1. Ipsilateral facial pain
 - a. May be “salt and pepper like” particularly around the eye
 - b. Involvement of the trigeminal tract and nucleus
2. Ipsilateral VIIth nerve palsy
 - a. Aberrant cortico-bulbar pathway that traverses the upper medulla
3. Hiccough (singultus)
 - a. N tractus solitarius, nucleus ambiguus
4. Oculomotor disturbances:
 - a. Vertical or oblique diplopia
 - b. Upside down vision
 - c. Ocular tilt reaction
 - d. Involvement of the nucleus prepositus and medial longitudinal fasciculus
 - e. Vestibular nuclei
 - i. Usually at the level of the inferior olive
 - ii. Lateral pulsion to the side of the lesion
5. Opalski syndrome
 - a. Ipsilateral hemiparesis
 - b. The lesion is below C2 (the decussation of the pyramidal tracts)
6. Central respiratory dysfunction
 - a. N. and tractus solitarius

- b. Dorsal and ventral respiratory nuclear groups
7. Central vasomotor interruption
 - a. N. and tractus solitaries (NTS)
 - b. Central sympathetic vasomotor fibers
 - i. Nucleus raphe magnus
 - ii. Nucleus ambiguus
8. Ipsilateral tongue involvement (cranial nerve XII or hypoglossal fascicles)
9. Babinski–Nageotte syndrome
 - a. Wallenberg (no hemiparesis) with contralateral hemiparesis
10. Ceston–Chenais syndrome
 - a. Babinski–Nageotte
 - i. No ipsilateral ataxia (spared ICP)

Secondary Pontine Hemorrhage

General Characteristics

1. Diencephalic herniation:
 - a. Stretch and rupture of paramedian pontine penetrators from the basilar artery (Duret’s hemorrhage)
 - b. Associated midline thalamic and midbrain hemorrhages
2. Blood dyscrasia
3. Coagulopathy
4. Sudden severe increase of intracranial pressure

Prognostic Factors for Intraparenchymal Hemorrhage

1. Size of hematoma and level of consciousness
 - a. $<10 \text{ cm}^3$ – excellent prognosis
 - b. $<45 \text{ cm}^3$ – fair to good prognosis
 - c. $>60 \text{ cm}^3$ – poor prognosis
 - d. $>85 \text{ cm}^3$ – death
2. Other predictors of prognosis
 - a. Intraventricular hemorrhage
 - b. Hydrocephalus
 - c. Edema
3. 30 day mortality – approximately 45%
 - a. 50% of deaths occur in the first 48 hours
4. Pineal displacement laterally $<10 \text{ mm}$
 - a. $<5 \text{ mm}$ ventrally good prognostic sign
5. Lower mortality in lobar ICH than deep hemispheric hemorrhage

Neurologic Deterioration in Non-Comatose Patients with Supratentorial Intraparenchymal Hemorrhage

General Characteristics

1. Occurs in approximately 1/3 of patients
2. Greatest first hospital day
3. Neurologic deterioration:
 - a. $>45 \text{ ml}$ (60%)
 - b. 10 ml (19%)
4. 30 day mortality of patients with neurologic deterioration approximately 50%; 3% in those that are stable

5. Infarct expansion related to large established hemorrhages is the predominant cause of deterioration
6. Prognosis by size of hematoma volume
 - a. 50 ml or > – 78% deteriorated
 - b. 20–50 ml – 33% deteriorated
 - c. <20 ml – 16% deteriorated
7. Hemorrhage growth 0.8–13%
 - a. Progressive deterioration
 - i. Mass effect
 - ii. Cerebral edema

Clinical Manifestations

Major Diagnostic Features of Intraparenchymal Hemorrhage

1. Gradually progressive neurologic deficit
 - a. Minutes to hours
 - b. Headache and vomiting
2. Exceptions: severe early headache
 - a. Caudate hemorrhage with intravascular extension
 - b. Primary intraventricular hemorrhage
 - c. Early severe motor deficits:
 - i. GPe/GP₁ hemorrhage
 - ii. Large putaminal hemorrhage (usually mid portion)
3. Imaging Analysis (CT/MRI)
4. Early < 24 hours
 - a. Regular and smooth hemorrhage
5. First 48 hours
 - a. Blood fluid levels
6. First 72 hours
 - a. Mild edema and mass effect
7. 3–20 days
 - a. Resolution of the mass which starts at the periphery
 - b. Irregular contents that enhance to be differential from metastatic lesion, lymphoma (particularly in an HIV patient), abscess and inflammatory lesion; often hemorrhage is ring enhancing
8. Specific locations:
 - a. Multiple subcortical white matter hemorrhage
 - i. Leukemia
 - ii. Coagulopathy
 - iii. Disseminated intravascular coagulation
 - b. Cerebellum:
 - i. Anticoagulation (Coumadin; INR greater than 5)
 - c. Lobar in the elderly (65–90 years)
 - i. Congophilic angiopathy
9. Nine weeks:
 - a. Enhancement and mass effect have dissipated

Non-Hypertensive Causes of Parenchymal Hemorrhage and Subarachnoid Hemorrhage

Overview

There are multiple causes of parenchymal and subarachnoid hemorrhage that are not caused by idiopathic hypertension. Many are caused by induced hypertension in patients with underlying cystic aneurysms and vascular malformations. They

frequently have very specific clinical profiles that are diagnostic.

Idiopathic perimesencephalic hemorrhage may account for approximately 10% of all SAH. It rarely occurs with congenital aneurysms and seems more likely to be caused by leakage of blood from the prepontine venous plexus. Most patients have no focal neurologic deficits on admission. The headache associated with this bleed reaches maximum intensity within minutes rather than seconds. There is no loss of consciousness with the ictus and no rebleeding or delayed ischemia. There is some evidence for small aneurysmal bleed from the plexus.

Mycotic aneurysms most often occur in the distal branches of the MCA and cause both intraparenchymal and SAH. They may be the initial presentation of SBE.

Drug abuse with sympathomimetic agents and cocaine induce hypertension and cause hemorrhage as well as ischemic stroke. Cocaine in particular is associated with approximately 20% of ICH from an underlying aneurysm or vascular malformation. Drug abuse and SBE are coextensive.

Elderly non-hypertensive patients with superficial lobar hemorrhages should be suspected of having congophilic angiopathy. These hemorrhages are often recurrent which can be demonstrated by gradient Echo MRI (demonstrates hemosiderin from prior bleeds).

Traumatic intracranial hemorrhages frequently are delayed for 4–7 days after ictus. They occur in the originally damaged brain tissue.

Venous thrombosis with hemorrhage should be suspected in pregnant patients and those in a hypercoagulable state. Preceding headache, lethargy and seizures are common.

Vasculopathy or vasculitis may also cause non-hypertensive hemorrhage.

Differential Diagnosis

Differential Diagnosis of Perimesencephalic Hemorrhage

1. Venous or plexus extravasation
2. Caudate hemorrhage that extends into the subarachnoid space
3. Subependymal AVM
4. Trauma
5. Blood dyscrasias
6. Leakage from small nonaneurysmal arteries on the brain surface
7. Ruptured aneurysms; site of rupture is thrombosed and not identified
8. Dural AVM
9. Cocaine
10. Sympathomimetic drugs
11. Pituitary apoplexy
12. Spinal AVM
13. Traumatic LP

Parenchymal Trauma

1. SAH often located in the superficial areas of the cortical sulci

2. Adjacent to a fracture site or area of intracerebral contusion
3. Basal frontal contusion
 - a. Hemorrhage may mimic rupture of an AcoA (anterior communicating) aneurysm
4. Direct neck trauma
 - a. Tear of vertebral arteries or their feeders in the transcranial canals
 - b. Basilar hemorrhage
5. May be delayed
 - a. Occur 4–7 days in the contused area

Mycotic Aneurysm

1. A common cause of nonaneurysmal SAH and intraparenchymal hemorrhage
 - a. Infective endocarditis
 - b. Aspergillosis infection
2. Most common location
 - a. Distal branches of the MCA
 - b. 10% have a proximal location
3. Most patients suffer ICH at the site of rupture; some present with typical SAH
4. May rebleed
5. May be the initial presentation of bacterial endocarditis
6. Mycotic aneurysms secondary to aspergillosis:
 - a. Proximal carotid location
 - b. Proximal vertebrobasilar system
 - c. Rupture is frequently fatal

General Characteristics

Traumatic Intraparenchymal Hemorrhage

1. Associated SAH which is located in the superficial areas of the cortical sulci
 - a. Adjacent to a fracture site or area of intracerebral contusion
2. Mild head injury complicated by ICH:
 - a. Greater than 80% deteriorate within 24 hours
 - b. About 70% – progression of the hemorrhage is the cause of the deterioration
 - c. Approximately 4% have delayed neurologic deterioration
3. Clopidogrel has a higher risk of hemorrhage than warfarin

Traumatic Basal Ganglia Hematoma

1. Motor vehicle accidents and falls are the primary cause
2. Approximately 25% have a skull fracture
3. Location: putamen > thalamus > caudate
4. High frequency of associated intracranial lesions

Posterior Fossa Traumatic Hematomas

1. Four major categories:
 - a. Contusion and associated ICH
 - b. Diffuse axonal injury
 - c. Associated subdural hematoma
 - d. Diffuse brain swelling

Clinical Manifestations

1. Neurologic signs and symptoms dependent on location of the lesion
2. Cranial nerve VI, VII, VIII and I are frequently damaged; rarely CN II
3. Severe headache, nausea and failure of concentration that may last for months
4. Behavioral changes particularly with frontal lobe and temporal parietal junction deficits
5. Executive function deficits with DLPC lesions; general slowness of cognitive processing
6. Chronic dizziness may be prominent for months
 - a. Rarely direct hemorrhage into the labyrinth

Neuropathology

1. Extravasated blood
 - a. Forms a characteristic circle or ovoid mass within the brain parenchyma
 - b. Distortion and compression of adjacent brain substance
 - c. Perihemorrhage edema occurs
2. Evaluation of the clot:
 - a. A clot forms within hours:
 - i. Prior to its formation there is separation of plasma from RBCs that forms a meniscus. This is more prominent in hemorrhages from anticoagulation
3. The hematoma is often surrounded by petechial hemorrhages from burst arterioles and venules
4. Within days hematoxylin and hemosiderin are present. The hemosiderin is contained within histiocytes that have phagocytized RBCs. Phagocytosis begins approximately 24 hours after the hemorrhage
5. The edema may take days or weeks to clear
6. A smooth walled cavity or yellow-brown scar remains

Traumatic Brain Injury Models

1. Utilizing magnetic resonance (MR) spectroscopy
 - a. Evidence for neuronal-glial metabolic uncoupling
 - b. Activated astrocytic glycolysis with production of lactate and failure of neuronal uptake

Neuroimaging

1. The most commonly used method for bedside calculation of hematoma volume is the ABC/2 method
2. Shape classification of hematoma as a predictor of hematoma growth (regular, irregular and separated)
 - a. Irregular may predict growth
3. Oral anticoagulation-related ICH
 - a. ABC/3 may be more accurate measurement for growth of the hemorrhage
4. Associated neuroaxonal injury
5. Associated vertebral artery stroke with brainstem rotational injuries
6. Herniation with deep basal ganglia and hemispheric hematomas
7. SAH into cisterns

8. Secondary bleeding into the ventriculated system
9. SAH often located in the superficial areas of the cortical sulci
10. Basal frontal hematoma or contusion
 - a. Hemorrhage may mimic rupture of an anterior communication artery aneurysm
11. Associated neck trauma:
 - a. Tear of the vertebral arteries of their feeders in the transcervical canals
 - b. Basilar subarachnoid blood

CT

1. CT angiography “spot sign” predicts expansion on acute intracerebral hemorrhage
 - a. “Spot sign” on CTA source images
 - b. Contrast extravasation (CE)
 - i. Pooling of contrast within the hematoma is another marker of hematoma expansion; a better predictor of growth than the spot sign (for spontaneous ICH)

Hemorrhagic Transformation of Stroke (HT)

General Characteristics

1. Fisher and Adams
 - a. Drew attention to hemorrhagic transformation of ischemic stroke following an embolus
 - b. Proposed the concept of “migratory embolism” based on:
 - i. The observation that the hemorrhagic portion of the infarction was proximal to the embolus whereas distal areas were ischemic
 1. The hemorrhage occurred from the proximal to the embolus whereas distal areas were ischemic
2. The current classification of hemorrhagic transformation of ischemic stroke is wide:
 - a. Small areas of petechial hemorrhage
 - b. Space occupying hematoma

Clinical Manifestations

1. May be classified as symptomatic or asymptomatic
2. A large majority have symptoms prior to 12 hours and almost all by 24 hours (derived from NINDS clinical tPA trial)
 - a. Deterioration of level of consciousness
 - b. Increased weakness
 - c. Headache
 - d. Increased blood pressure and pulse rate
3. A significant proportion of patients have asymptomatic hemorrhages between 36 hours and 3 months (tPA evidence)

Neuropathology

1. Patchy petechial bleeding
 - a. Confined within the vascular territory of the infarction
 - i. Diapedesis of RBCs through ischemic capillaries without vessel rupture

2. Parenchymal hematoma
 - a. Rupture of an ischemic vessel that is caused by reperfusion pressure
 - b. Some patients have overlapping characteristics of hemorrhagic infarction and parenchymatous hematoma

Neuroimaging

CT

1. Patchy petechial or more confluent areas of alteration
2. Indistinct margins
3. Gyriiform pattern of cortical involvement
4. Parenchymal hematoma
 - a. Dense homogenous blood (High attenuation) often with mass effect)

MRI

1. Depends on the stage of the hemorrhage
 - a. Development of hemosiderin produces signal loss in T2-weighted sequences
 - b. Methemoglobin increased signal in T1-weighted sequences

New MRI Classification

1. Based on size, shape, distribution and signal intensity of the hemorrhage
2. ECASS CT classification of HT has been successfully modified for MRI
3. Measurement of BBB permeability utilizing MRI may predict HT
4. BBB disruption during the acute and subacute stages following ischemic stroke is pivotal for the development of cerebral edema and hemorrhage:
 - a. MRI can predict HT based on endothelial cell damage and disruption of the BBB that is reflected by the presence of contrast enhancement in structural brain images
5. Hyperdense middle cerebral artery sign is independently predictive of HT
6. Time to peak perfusion (TTP) as assessed by computed tomography perfusion:
 - a. TTP map-defect was correlated with HT
 - b. HT is correlated with delayed recanalization
 - c. TTP may be a method to predict HT
 - d. Cerebral microbleeds as evaluated by gradient-echo T2-weighted MRI is not correlated with HT
 - e. The mean Alberta stroke program early CT-DWI (a measure of the volume of ischemic tissue) is a marker for HT
 - f. Thrombolytic therapy is associated with 1.8 to 8.8% of ICH

Laboratory Evaluation

1. Biomarkers are increased:
 - a. Occludin (BBB protein)
 - b. Claudin-5 (BBB protein)
 - c. Metalloproteinase

- d. Zonula occludins
- e. S100B protein
- f. Lower VEGF growth factor

Perimesencephalic Subarachnoid Hemorrhage

General Characteristics

1. Definition
 - a. Is a benign variant of SAH with a characteristic pattern of extravasated blood on non-contrast CT and negative findings on cerebral angiography
 - b. Low risk of rebleeding
 - c. 20 to 70% of patients with angiographic negative SAH demonstrate perimesencephalic blood
 - d. Good prognosis

Clinical Manifestations

1. Most patients have no clinical deficits on admission
2. The headache associated with this bleed reaches maximum intensity within minutes rather than seconds
3. No loss of consciousness with the ictus
4. Rare rebleeding
5. Small percentage (<10%) develop hydrocephalus and/or delayed vasospasm

Neuropathology

1. Hemorrhages are located anteriorly to the brainstem, in the interpeduncular cistern, with or without extension to the ambient, chiasmatic and horizontal part of the Sylvian cisterns
 - a. Non-perimesencephalic hemorrhage blood is not located primarily in the interpeduncular cisterns but in the Sylvian cistern, interhemispheric cistern or over the convexity

Differential Diagnosis of Perimesencephalic Hemorrhage

1. Venous or plexus extravasation
2. Caudate hemorrhage that extends into the subarachnoid space
3. Subependymal AVM or malformation
4. Trauma
5. Blood dyscrasias
6. Ruptured aneurysms
 - a. The site of rupture is thrombosed and not identified
7. Dural AVM
8. Leakage from small nonaneurysmal arteries on the brain surface
9. Cocaine and sympathomimetic drugs
10. Pituitary apoplexy
11. Spinal AVM
12. Traumatic LP

Mycotic Aneurysm

General Characteristics

1. An infectious process in the wall of a vessel
2. Primarily seen in the setting I.V. drug abuse and SBE
3. Peripheral arteries are involved more than intracranial one

Clinical Manifestations

1. The number of mycotic aneurysms caused by staphylococcal infections and other acute bacterial organisms has increased (I.V. drug use)
2. An ischemic stroke with neutrophils in the CSF
 - a. MCA territory most common
 - b. Peripheral hemorrhage often with severe subarachnoid blood

Neuropathology

1. Wall destroyed by the infective process
2. An embolic occlusion of a small peripheral arterial branch
3. The aneurysm may occur within days of seeding
4. The aneurysm may rebleed
5. Mycotic aneurysms occur in approximately 10% of patients with infective endocarditis
6. Patients with symptomatic peripheral mycotic aneurysms have a higher incidence of the following complications than asymptomatic peripheral aneurysms:
 - a. Intravenous drug use
 - b. Native valve endocarditis
 - c. Intracranial bleeding
 - d. Septic emboli
 - e. Multiple embolism
 - f. Infectious endocarditis diagnostic delay >30 days
7. A small percentage of patients develop symptomatic peripheral aneurysms after complication of antibiotic therapy
8. The microbiologic profile in diverse but organisms with low to medium virulence appear predominant
9. Lemierre's disease with vertebral artery involvement is reported

Neuroimaging

1. The aneurysms are in peripheral branches of conducting pial vessels
2. Approximately 90% present with hemorrhage
3. Mycotic aneurysms secondary to aspergillosis:
 - a. Proximal carotid location
 - b. Proximal vertebrobasilar system
 - c. Rupture is frequently fatal
4. Lemierre's disease
 - a. Primarily an oropharyngeal disease
 - b. Septicemia; thrombophlebitis of the internal jugular vein (IJV)
 - c. Mycotic aneurysms of the extracranial carotid artery and vertebral artery

Hypertensive ICH

Clinical Manifestations

1. Most common cause of ICH
2. Blood pressure is 220–240 mmHg systolic and 110–120 mmHg diastolic (in general)
 - a. In several studies the peak systolic pressure is 160–190 mmHg

3. Pressure may be confounded by the Kocher–Cushing reflex; secondary hypertension due to the effects of pressure on the vasomotor centers
4. Many patients present without a prior history of hypertension
 - a. General examination may reveal:
 - i. Enlarged aortic knob (uncoiled)
 - ii. Thickened and tortuous peripheral blood vessel (radial and axillary arteries)
 - iii. Hypertensive changes in the retinal arteries
 - iv. Loud A2 and S4 gallop
 - v. Sustained cardiac impulse
 - b. Hypertension induced degenerative changes in vessel walls

Neuropathology

1. Fibrinoid degeneration
2. Microhemorrhages:
 - a. Penetrating arterioles to the basal ganglia, pons, thalamus and cerebellum
 - b. Also noted in arterioles that supply the gray-white junction
 - c. Associated concomitantly with lipohyalinosis and fibrinoid degeneration
 - d. Possible relationship exists between iris microaneurysms and those found in cerebral blood vessels

Non-Hypertensive Causes of Intracranial Hemorrhage (ICH)

Clinical Manifestations

1. Acute changes in blood pressure and blood flow:
 - a. Precipitate rupture of penetrating arteries without prior hypertension
 - b. Microaneurysm on penetrating vessels rupture: Predilection for lenticulostriate arteries (Charcot-Bouchard aneurysm)
 - c. Microbleeds:
 - i. May bleed repeatedly (hemosiderin laden macrophages)
 - ii. Located in penetrating vessels of:
 1. Lenticulostriate (MCA)
 2. Pons
 3. Cerebellum
 4. Gray white cortical junction
 - d. Penetrating arteries may rupture:
 - i. Not at the site of microaneurysms
 - ii. Generalized lipohyalinosis of entire artery
2. Exposure to cold weather
 - a. Stimulation of the sympathetic vasoconstrictor response
3. Dental procedures
 - a. Traction on the trigeminal nerve
 - i. Changes in heart rate and blood pressure
4. Increased cerebral blood flow:

- a. Carotid endarterectomy (hyperperfusion syndrome)
- b. Following surgical repair of congenital heart defects
- c. Cardiac transplantation
- d. Post-migraine
5. Older patients:
 - a. ICH at lower pressure than younger patients:
 - i. Possible relationship to amyloid angiopathy
6. Biphasic presentation of ICH
 - a. Onset of new hypertensive state
 - b. Prolonged hypertension

Underlying Medical Conditions That Are Associated with ICH

1. Coagulopathy
2. Vasculitis
3. Subacute bacterial endocarditis
4. Tumor
5. Trauma
6. Thrombolytic treatment
7. Transformed ischemic stroke:
 - a. Frequently multiple
 - b. Not in classic hypertensive ICH locations

Vascular Malformations

Overview

The major vascular malformations that are clinically relevant are:

1. Arteriovenous malformations
2. Dural arteriovenous malformation
3. Cavernous hemangiomas
4. Developmental Venous malformations
5. Capillary telangiectasia
6. Perimesencephalic aneurysm
7. Cobb's syndrome
8. Sturge-Weber syndrome
9. Von Hippel-Lindau disease
10. Wyburn-Mason disease
11. Osler-Weber-Rendu disease

Parenchymal arteriovenous malformations are abnormal connections of arteries and veins with no capillary bed. The arteries themselves have poorly developed internal elastic lamina and often become stenotic and occluded. In a sizable percentage, these vessels harbor aneurysms. The natural history of an AVM is to enlarge, recruit blood vessels from neighboring circulations and to bleed. They most often present with seizures due to the abnormal neurons and glial tissue within the malformation. They may present with seizures, hydrocephalus or chronic migrainous headaches. These headaches are stereotyped and do not switch sides during different attacks. Some patients note fluctuating bruits concomitant with their pulse. Approximately 2% have a progressive neurologic deficit.

Dural arteriovenous malformations are abnormal arteriovenous shunts within leaflets of the dura mater usually within or near walls of the dural venous sinuses. Headache

may be migrainous or localized to the side of the lesion. Patients suffer increased intracranial pressure, hemorrhage, pulsatile, tinnitus and seizures. Headache may be worse in the supine position. They may become symptomatic during pregnancy.

Cavernous angiomas have no entrapped brain tissue, appear anywhere in the brain, but are often periventricular. They are frequently multiple and especially common in Mexican Americans. They usually are not associated with vascular headache. They most often clinically present with recurrent bleeding with focal neurologic deficit (parenchymal type) seizures and subarachnoid hemorrhage. They have a characteristic “popcorn” appearance on MRI from the mixed signal of old and new hemorrhage. They often hemorrhage at night.

Developmental venous anomalies are the most common type of vascular malformation. They are composed of anomalous veins and have no direct arterial input. They most often are linear tubular structures in the cerebellum with connection to the IVth ventricle and may demonstrate a “caput medusa”. They most often are asymptomatic except when occluded during surgical procedures. In these instances, they may cause cortical infarction in the area of their venous drainage.

Telangiectasias are comprised of capillaries separated by normal brain parenchyma. They are most often seen in the cortex and the pons. They are rarely symptomatic.

Perimesencephalic hemorrhage has recently been recognized as a form of hemorrhage that presents frequently as a subarachnoid bleed without focal findings. Blood on CT is most prominent in prepontine and perimesencephalic cisterns. The process only seems to occur once and has an excellent prognosis. It may represent venous hemorrhage, although recently aneurysms of small arterioles have been demonstrated.

Parenchymal Arteriovenous Malformations

General Characteristics

1. No normal brain within AVM
2. No intervening capillary network between arteries and veins
3. Flow related abnormalities:
 - a. Sump-like effect that causes relative ischemia of the surrounding brain
 - b. Venous congestion and ischemia:
 - i. Arterializations of normal venous drainage
4. 10% as common as subarachnoid hemorrhage
5. Peak presentation in 2nd and 3rd decade
6. The prevalence from autopsy studies is .5–.8%
7. Incidental hemorrhage is 1/100,000 persons
8. Natural history:
 - a. Age at presentation is approximately 33 years
 - b. 2% hemorrhage at 1 year, 14% at 5 years, 31% at 10 years
 - c. Result of rebleeding 6–7% during the first 6 months and then to 3–4% per year
9. Occurrence: parieto-occipital lobe > frontal lobe > temporal lobe

Clinical Manifestations

1. Intracerebral hemorrhage:
 - a. Most common presentation; most often intraparenchymal
 - b. Present as ICH in 71–77% of patients
- c. Supratentorial AVM:
 - i. Hemiplegia/hemiparesis
 - ii. Aphasia, visual field or parietal deficits that are location specific
- d. Deep AVM:
 - i. Focal deficits without impaired consciousness (if small)
 - ii. Acute hydrocephalus if there is rupture into the ventricular system
- e. Cerebellar AVM:
 - i. Small and confined to the cerebellum
 1. Focal ataxia
 2. Minimally symptomatic
 - ii. Large hemorrhages:
 1. Depressed consciousness, nystagmus, ataxia
 2. Head tilt to side of the lesion; VIth, VIIth nerve palsy
 3. Central neurogenic hyperventilation
 4. Quadriplegia
 5. Brainstem compression
2. Subarachnoid hemorrhage:
 - a. Most often associated with larger intraparenchymal hemorrhage
 - i. 10–20% association with aneurysms in afferent arteries that may rupture with typical SAH presentation
 - ii. Rare vasospasm from AVM bleeds as opposed to that from an aneurysm
3. Seizures:
 - a. Second most frequent presentation (18–33%)
 - b. Younger age; larger AVM increases seizure risk
 - c. Symptoms and signs are location dependent
4. Ischemia in association with AVM:
 - a. Mechanisms of neurologic progressive deficits:
 - i. Mass effect
 - ii. Recurrent microhemorrhages
 - iii. Ischemia of surrounding parenchyma
 - iv. Steal phenomenon
 - b. Ischemic neurologic deficits develop in a slow progressive manner
 - i. Acute ischemic syndrome can occur with thrombosis of a major feeding vessel or acute thrombosis of entire AVM
 - ii. Acute stroke symptomatology may occur following venous thrombosis
 - i. Usually following AVM resection in the territory of the formerly arterialized venous system
5. Migraine headache:
 - a. Migraines are most often stereotypical
 - b. Occur ipsilateral to the AVM

- c. Most often the AVM is in the occipital lobe
- d. The headache does not switch sides
- 6. Chronic headache:
 - a. May be severe and progressive both in severity and frequency
 - b. In general occurs with large AVMs:
 - i. Cause increased intracranial pressure and high flow
 - 1. Retrograde arterialization of the normal venous drainage system
 - ii. Cognitive dysfunction
- 7. Hydrocephalus caused by:
 - a. Multiple small hemorrhages that occlude the ventricle or subarachnoid space
 - i. Large hemorrhage with acute internal ventricular obstruction
 - ii. Obstruction of CSF pathways by venous variants
 - 1. Deep high flow AVM
- 8. Fluctuating bruit:
 - a. Concomitant with heart beat
 - b. Rarely heard over the malformation
 - c. Jugular venous hum (heard in the neck or over the supraclavicular fossa)
- 9. Hemi-asymmetry:
 - a. Side contralateral to AVM is affected
 - b. Most severe when the parietal lobe is affected

Neuropathology

- 1. Arteries within the arteriovenous malformation are thin walled with poorly developed internal elastic laminae; there is hypertrophy of the media and endothelial thickening of the affected vessels
- 2. Some afferent vessels become stenotic and occluded
- 3. Increased incidence of aneurysms usually occurring on feeding vessels
- 4. Progressive recruitment of vessels from neighboring circulations
- 5. Composition of the AVM:
 - a. Abnormal gliotic parenchyma is intermixed between component blood vessels
 - b. No capillary bed
 - c. Abnormal dystrophic neurons
- 6. Cerebellar, brainstem and basal ganglia/thalamic AVMs have a greater risk of bleeding
- 7. Smaller AVMs have a greater rate of bleeding:
 - a. Increased intra-arterial pressure may be causative
- 8. Venous drainage patterns that are associated with bleeding:
 - a. A single draining vein
 - b. Deep venous drainage
 - c. Stenosis of a draining vein

Neuroimaging

MRI

- 1. Honeycombed areas; may demonstrate prior bleeds with susceptibility weighted or gradient echo sequences

- 2. Evidence of superficial siderosis; linear lesions suggest subarachnoid blood
- 3. Surrounding cerebral atrophy
- 4. Serpiginous flow voids
- 5. Ventricular dilatation (side of the AVM)
- 6. Intralesional calcification

Arteriography

- 1. Enlarged feeding vessels from several circulations
- 2. Tortuous enlarged draining veins
- 3. Central arterial venous complex of vessels
- 4. Rapid arterial to venous shunts
- 5. Percentage of feeding vessels with saccular aneurysms

Negative Arteriogram with AVM Malformations

- 1. Spontaneous thrombosis
- 2. Obliteration with hemorrhage
- 3. Cavernous angioma or dural anterior venous malformation
 - a. No feeding arteries
- 4. Spinal AVM:
 - a. May mimic intracranial signs and symptoms
 - b. Usually at low cervical and high thoracic levels
 - c. Headache and stiff neck

Features Increasing the Risk of Hemorrhage

- 1. Small malformation
- 2. Exclusively deep venous drainage
- 3. High intranidal pressure

AVM of the Lateral Ventricle

Clinical Manifestations

- 1. Less than 40 years of age
- 2. Small
- 3. Interventricular hemorrhage
- 4. Lateral ventricle usually normal sized
- 5. Caudate nucleus and choroid are other sources of ventricular hemorrhage

Dural Arteriovenous Malformation (DAVM)

General Characteristics

- 1. Abnormal arteriovenous shunts within leaflets of the dura mater
 - a. Usually within or near the walls of dural venous sinuses
- 2. Comprise 10–15% of AVM's
- 3. Pattern of drainage:
 - a. Intradural sinuses
 - b. Cortical or deep venous system
- 4. DAVM's with prominent cortical venous systems have a higher incidence of bleeding than those without
- 5. Symptoms of these malformations are primarily those of venous hypertension that is due or related to:
 - a. Increased arterial input and therefore increased flow through the draining veins
 - b. Venous outflow obstruction

6. Congenital DAVM's

- a. Vein of Galen type:
 - i. Due to retention of an embryonic median pre-cephalic vein; if it persists it becomes the sac for the aneurysmally enlarged vein of Galen

Clinical Manifestations

1. Headache (global and frontal); may be migrainous or localized to the side of the lesion
2. Increased intracranial pressure
3. Hydrocephalus
4. Hemorrhage:
 - a. Signs and symptoms depend on the drainage pattern:
 - i. Solely dural
 - ii. Drainage pattern into the cortical or deep venous system
 - b. Intraparenchymal > subdural > subarachnoid in location
 - c. 30% mortality
 - d. Pulsatile tinnitus
 - e. Seizures
 - f. Cerebral edema with venous hypertension and sinus occlusion
 - g. Postural headache (worse in supine position)

Neuropathology

Etiology of Dural Arteriovenous Malformation

1. Trauma; associated with skull fractures
2. Female hormones: influence placental and uterine vascular growth
3. Dural sinus thrombosis; female > males 2:1 with thrombosis of the lateral sinus and increased venous drainage enlarging dural veins
4. May become symptomatic with pregnancy
5. Thrombosis or stenosis within the draining dural sinus:
 - a. Enlarges the DAVM
 - b. Increases venous hypertension

Location of Dural Arteriovenous Malformations

1. Most common are related to the lateral sinus and involve the transverse or sigmoid portions; approximately 60% of DAVM's
 - a. Feeding vessels of lateral sinus fistulae:
 - i. Occipital, middle meningeal, accessory meningeal from the external carotid artery
 - ii. Ascending pharyngeal (arch of the aorta)
 - iii. Meningohypophyseal trunk of the cavernous carotid artery
 - iv. Dural branches of the vertebral arteries

Cavernous Sinus Dural Fistula

General Characteristics

1. Occur in approximately 16% of DAVM; 2% of patients with head trauma

Clinical Manifestations

1. Orbital venous hypertension causes:
 - a. Proptosis
 - b. Scleral arterialized venous blood; the arteries reach the iris whereas in infection they don't
 - c. Chemosis
 - d. Papilledema
 - e. Glaucoma
2. Cavernous sinus drainage into:
 - a. Petrosal veins and sinuses
 - b. Basal vein of Rosenthal
 - c. Results in brainstem venous hypertension
3. Cranial nerve III, IV, VI and first division of V (V1) may be compromised

Neuropathology

1. Abnormal shunting of blood from the internal and external carotid into the cavernous sinus
 - a. Type A:
 - i. Direct carotid cavernous fistula
 - ii. Large shunted blood volume
 - iii. Dramatic symptoms
 - b. Type B:
 - i. Indirect CCF
 1. No direct communication between ICA-cavernous sinuses
 2. Branches of ICA or ECA and the cavernous sinus
 - c. Type C:
 - i. Fed by dural branches of external carotid artery (ECA)
 - d. Type D:
 - i. Fed by branches of ICA/ECA
 - e. Etiology
 - i. Trauma:
 1. MVA with head injury
 2. Gunshot wounds
 - ii. Rupture of ICA infraclinoid aneurysm

Differential Diagnosis

1. Ehlers-Danlos type IV
2. Fibromuscular Dysplasia (FMD)
3. Arteriosclerosis
4. HCVD
5. Indirect Fistulas:
 - a. Post-menopausal
 - b. Spontaneous
6. Direct Fistulas:
 - a. Trauma
7. Tumors
 - a. Pituitary adenoma
 - b. Metastatic
 - c. Craniopharyngioma
 - d. Hemangioma
 - e. Bone Tumor

- f. Mucocoele
- g. Nasopharyngeal cancer
- h. Hyperthyroidism
- i. Retrobulbar masses

Rare Dural Arteriovenous Fistula's

General Characteristics

1. Incisura of the tentorium 8%
2. Cerebral convexity – sagittal sinus
3. Orbital-anterior falx
4. Drainage into the vein of Galen, straight sinus or posterior falx
5. Acquired adult vein of Galen – DAVF
 - a. Related to dural sinus occlusion
 - b. Supplied by middle meningeal and vertebral artery, PCA and meningohypophyseal branches of the ICA
 - c. Shunt is into the wall of the vein of Galen
 - d. Occasional association of a vein of Galen aneurysm with DAVF has been noted

Prognosis and Natural History

1. An aggressive course is correlated with
 - a. Drainage into subarachnoid and parenchymal veins
 - b. Retrograde flow away from the lesion
2. Spontaneous closure may occur
3. Minimal symptoms for prolonged periods
 - a. Headache
 - b. Pulsatile tinnitus

Spinal Arteriovenous Malformation

General Characteristics

1. Present major classification:
 - a. Type I
 - i. Dural arteriovenous fistula (AVF)
 - b. Type II
 - i. Intramedullary glomus AVM
 - c. Type III
 - i. Juvenile or combined AVM
 - d. Type IV
 - i. Intradural perimedullary AVF
2. Spetzler and Kim Classification
 - a. Extradural
 - b. Extra-intradural
 - c. Intradural
 - i. Ventral or dorsal fistulae
 - ii. Intramedullary
 1. Compact
 2. Diffuse
 3. Conus medullaris arteriovenous malformations

Clinical Manifestations

1. Local back pain
2. May present with Brown-Séquard distribution
3. Sudden onset of paralysis with spinal shock at the level of bleed
4. Headache may occur (intracranial meningeal irritation)

Neuropathology

1. Tangled masses of tortuous arteries, veins and abnormal connection channels
2. Lack of development of a capillary bed
3. Veins have thickened collagenous walls; proliferation of fibroblast
4. Reduplicated, interrupted and distorted internal elastic lamina
5. Arterial supply derived from medullary arteries

Dural Arteriovenous Fistulas

General Characteristics

1. Approximately 90% of patients have neurologic deficits
2. Predilection for men

Clinical Manifestations

1. Back pain occurs in approximately 40% of patients
2. Symptoms may worsen after exercise
3. Hemorrhage may be initiated by coagulopathy or anticoagulants
4. Unusual cause of progressive weakness with bladder involvement
5. Compression of the cords and roots (radiculomyelopathy); formerly referred to as Foix-Alajouanine syndrome

Neuropathology

1. The arteriovenous shunt is located within the dural layer of the spinal canal
 - a. Connects branches of a radiculomeningeal artery with the veins of the spinal cord in the intervertebral foramen
 - b. Arterialization of the venous drainage of the spinal cord circulation causes a chronic congestive myelopathy
 - c. Rare

Neuroimaging

1. Associated vascular anomalies occur with intradural AVM not AVF
2. Greater than 90% of patients that have dural lesions had AV nidus in the low thoracic or lumbar segments of the cord
3. In approximately 15% of patients intercostal or lumbar arteries supplying the AVM also provide a medullary artery which supplies the spinal cord
4. The great majority of intradural AVMs are at the cervical and thoracic segments and have fast flow
5. AVMs may have associated saccular arterial or venous spinal aneurysms
6. No aneurysms occur with dural AV fistulas

Adult Ventriculus Terminalis

General Characteristics

1. A cavity within the conus medullaris
2. Rare in adults (less than 30 reported patients)
3. May be associated with AVM

Clinical Manifestations

1. Non-specific symptoms
2. Focal neurologic motor sensory deficits of the lower extremity
3. Bowel or bladder symptomatology

Neuropathology*Adults*

1. Ependymal lined cavity within the conus medullaris
 - a. Putative canalization and retrogressive differentiation during embryonic development
 - b. Putative acquired mechanisms in adults include:
 - i. Trauma
 - ii. Vascular alterations
 - iii. Inflammation
 - iv. Cord compress

Children

1. Associated with:
 - a. Tethered cord syndrome
 - b. Chiari Type I malformation
 - c. Lipomyelomeningocele
 - d. Lumbosacral lipoma

Neuroimaging*MRI*

1. Characteristic feature of VT
 - a. Cystic lesion of the distal central spinal cord canal
 - i. No cord signal alternation
 - b. Some patients demonstrate:
 - i. Septation with cord edema

*Venous Developmental Anomaly***General Characteristics**

1. Developmental venous anomalies (DVA) are congenital anomalies of venous drainage
2. DVA comprises 42 to 63% of all cerebrovascular malformations
3. Incidence is .05 to 3%

Clinical Manifestations

1. Usually asymptomatic
2. Surgical removal may be associated with:
 - a. Infarction of the territory they drain
 - b. DVA should be preserved if possible
3. Rare associations with:
 - a. Hydrocephalus (midbrain)
 - b. Spontaneous hemorrhages
 - i. Thrombosis of central draining vein
 - c. Other developmental anomalies
 - i. Cavernous malformations
 - d. Cerebral hemiatrophy
 - e. Aqueductal compression

Neuropathology

1. DVA is concomitant with cavernous malformations

a. Putative mechanisms include:

- i. Increased local venous pressure in the DVA that leads to recurrent petechial hemorrhage
 - ii. Ischemia that promotes new vessel growth which bleed
- b. Dilated venous channels
- i. Flattened endothelial cells
 - ii. Sparse smooth muscle cells
 - iii. Often connection to cavernous malformations (particularly in the cerebellum)

Neuroimaging*MRI*

1. Radically arranged venous complexes converging into a centrally located venous trunk that drains normal brain parenchyma
2. Linear tubular structure in the cerebellum with a connection to the IVth ventricle
3. Normal brain parenchyma around the malformation

Hereditary Hemorrhagic Lesions*Cerebral Cavernous and Venous Malformations***General Characteristics**

1. Cavernous malformations (CM)
 - a. Angiographically occult vascular malformation (vascular malformation that are not visible by angiography but are recognized by an MRI)
2. Venous malformations:
 - a. Present terminology is now developmental venous anomalies (DVAs)
 - b. Transitional forms between cavernous malformations and capillary telangiectasia have been described
 - c. Cavernous malformations and capillary telangiectasia may be a spectrum within a single entity
 - d. Both may occur in the same individual
3. CMs of the brain
 - a. Now defined as hamartomatous vascular lesions
 - b. Incidence in the general population is .47%
 - c. Constitute 8–15% of vascular malformations
 - d. Median age at presentation is 34; highest incidence is between 3rd and 5th decade; approximately 25% are children
 - e. Males and females are represented equally
 - f. Supratentorial lesions occur in 63–81% of patients
 - i. Frontal and temporal lobes; cortical or subcortical location in 50%
 - ii. Less frequent locations are:
 1. Paraventricular
 2. Basal ganglia
 3. Thalamus
 4. Lateral ventricle
4. Posterior fossa site:
 - a. 7.8–15.8% in the posterior fossa
 - i. Brainstem most frequent location

- ii. Pontine lesions are close to the IVth ventricle (50%); extend into cerebellar peduncles (30%); deep in the pons (20%)
- b. Mesencephalic lesions:
 - i. Greater than 60% are in the tectum
- 5. Spinal cord
 - a. 6%
- 6. Unusual locations of CM
 - a. IIIrd ventricle
 - b. Pineal area
 - c. Extraventricularly
 - i. Rare
 - ii. Middle cranial fossa adjacent to the cavernous sinus
 - iii. Tentorium of the cerebellum; dural vertex; Meckel's Cave; anterior cranial fossa; sella turcica optic chiasm; cranial nerves
 - d. Extension into the skull base
 - e. Interosseous
 - f. Multiple lesions 84.6% of familial and 25% of sporadic cases

Telangiectasia

General Characteristics

1. Approximately 16–20% of intracerebral vascular malformations
2. Most are asymptomatic
3. Grow very slowly by or not at all
4. Associated with:
 - a. DVA
 - b. Cavernous hemangioma
 - c. AVM (rarely)
5. Most often located in the brainstem (pons); rarely in the cerebral and cerebellar cortex

Clinical Manifestations

1. Most often asymptomatic
2. In many, if symptomatic, the associated malformation is responsible
3. Rare complications
 - a. VIth, VIIth and VIIIth cranial nerve palsy
 - b. Possible association with seizures (cortical)

Neuropathology

1. Numerous thin-walled capillary type ectatic vessels
2. Interspersed in a background of normal tissue
3. Devoid of calcification, gliosis, extra-luminal hemorrhage or hemosiderin-laden macrophages
4. May vary from a few millimeters to 2 cm

Neuroimaging

CT

1. Normal

MRI

1. No mass effect

2. Hypo- or isointense on T1-weighted images; slightly hyperintense in T2
3. Enhance with gadolinium
4. Gradient-echo demonstrates low signal intensity
5. Approximately 2/3 demonstrate an enlarged vessel, possibly a draining vein that suggests a transitional malformation

Familial Cavernous Malformations

General Characteristics

1. Autosomal dominant transmission
2. Chromosome 7q21-22 (Hispanic American kindred), CCM1 locus
 - a. Family mutation
 - b. Delayed and incomplete penetrance
3. CCM2 locus:
 - a. Chromosome 7p15-13
4. CCM3 locus:
 - a. Chromosome 3p25. 2-27
 - b. Non-Hispanic kindred
5. Genetic heterogeneity in non-Hispanic Caucasian patients
6. CCM1
 - a. Krev interaction trapped 1 (KRIT-1) gene
 - i. Encodes a 736 aa protein
 - ii. Interaction with RAP1A (GTPase) and ICAP α a modulator of β 1 integrin
 - b. KRIT-1 protein found in vascular endothelium and pyramidal cells
 - i. Important for arterial angiogenesis
 - ii. Endothelial cell morphology
 - c. Approximately 40% of kindreds with familial CM are limited to CCM3 locus on:
 - i. Chromosome 3q25. 2-27
 - ii. Programmed cell death
 1. Encodes 212 aa protein
 - d. CCM3:
 - i. Younger age at onset: less than 15 years old; higher in CCM3 than in CCM2 or CCM1
 - ii. Most common presentation is hemorrhage
 1. Possible role in vascular morphogenesis
 - e. Genotype – phenotype Correlations:
 - i. Penetrance of gene mutations
 1. CCM1 – 88%
 2. CCM2 – 100%
 3. CCM3 – 63%
 - f. Fewer lesions in CCM2 patients
 - g. Number of lesions increased more rapidly in CCM1 than CCM2 patients

Sporadic Cavernous Malformations

General Characteristics

1. Phenotype is similar to hereditary forms
2. Possible CCM1 mutations occur in patients with multiple CCMs

3. 75% of patients thought to have sporadic CCMs have multiple CCMs
 - a. Have an asymptomatic parent with documented lesion by MRI

Clinical Manifestations

1. Sporadic and hereditary forms demonstrate dynamic changes during the life of the CCMs
 - a. Change in size and signal intensity with MRI
 - i. May increase or decrease in volume
 - ii. Trend is for lesions to increase in size with time
2. De novo genesis of lesions:
 - a. Following X-RT
 - b. Along needle biopsy tracts
 - c. Spontaneous occurrence in approximately 30% of patients (.4%/patient/year)
 - d. Greater number of new lesions in familial forms (possibly 15%)
3. Familial CMs:
 - a. True CMs (Type I and II on MRI)
 - b. Related vascular malformation (Type III, IV) are a possible precursor state
4. Symptoms and signs may be acute or insidious and are related to:
 - a. Intrinsic growth
 - b. Bleeding and thrombosis
 - c. Perilesional iron deposition and atrophy
 - d. Siderosis
5. Clinical manifestations due to repeated episodes of exacerbation and remission
6. Seizure:
 - a. Most frequent presentation
 - b. Occurs in 40–50% of patients; incidence of epilepsy is 35–70%
7. Hemorrhage:
 - a. .8–3.1% per patient year in sporadic and mixed series
 - b. 4.3–16% per patient year in familial series
 - c. Rebleeding rate of approximately 4% (controversial)
 - d. Bleeding possibly higher in women and in brainstem lesions:
 - i. Infratentorial and deep lesions may have higher bleeding rate
 - ii. Bleeding incidence is increased in patients with prior hemorrhage
8. Focal neurological deficits:
 - a. Present in 10–40% in general series; higher in brainstem CCMs
 - b. Deficits may be transient, progressive, recurrent or permanent
 - c. Headache occurs in 6–52% of patients
 - d. 13–56% of patients present with symptomatic hemorrhage

Brainstem Cavernous Malformations

General Characteristics

1. Approximately 20% of intracranial CMs

2. No difference in age or gender from supratentorial lesions
3. Sudden onset of symptoms and neurologic deficits; >90% symptomatic at diagnosis
4. Bleeding rate of 4–6% per patient-year (controversial)
5. Rebleeding occurs more frequently than with supratentorial lesions (20–60%)

Neuropathology

1. Well circumscribed lesions
 - a. Closely packed enlarged capillary-like vessels
 - b. No intervening parenchyma
 - c. Multi-lobulated (“mulberry-like”)
 - d. Variation in size from a few millimeters to several centimeters
2. Microscopic examination:
 - a. Complex of dilated vascular channels arranged in a back to back pattern
 - b. Resemble dilated capillaries
 - i. Walls are composed of collagen
 - ii. Lined with a single layer of endothelial cells
 - iii. Contain macrophages that are filled with iron-pigment
 - c. Reticulin fibrils and cholesterol crystals are secondary to thrombosis
 - d. Collagenous stroma devoid of elastin and smooth muscle
 - e. Evidence of prior microhemorrhage and thrombosis
 - f. Gliotic scar in the surrounding parenchyma
 - g. May be associated with capillary telangiectasia

Dural Venous Anomalies (DVA)

General Characteristics

1. Definition of DVA
 - a. Congenital anomaly of normal venous drainage
 - b. Dilated radially arranged medullary veins that converge on a central draining vein – “caput medusa”
2. Surrounded by normal neural tissue
3. Approximately 60% of all intracranial vascular malformations; prevalence of 3% of the normal population
4. Associated with CCMs

Clinical Manifestations

1. Most are benign and asymptomatic
2. Bleeding risk of .22–.34%
3. Possibly more aggressive course if they are associated with CCMs (bleed more)
4. Surgical excision of the lesion during a procedure on the CCM may lead to venous infarction

Neuropathology

1. Lesions that are angiographically demonstrated
 - a. Dilated thin-walled vessels in white matter
2. Angiographically occult venous angioma
 - a. Compactly arranged venous channels with no smooth muscle layer

3. DVAs:
 - a. Congenital lesions
 - b. Lead to mixed and different intracranial formations

Radiation-Induced Lesions

General Characteristics

1. De novo formation of CMs occur after brain X-RT:
 - a. Most occur in pediatric patients
 - b. Males more frequently affected than females
 - c. Occur in medulloblastoma, glioma and acute lymphoblastic leukemia
2. Mean latency from time of X-RT approximately 9 years
3. Mean dose of X-RT 60.5GY
4. Most common presenting symptoms is seizure
5. Over time more than 50% of patients hemorrhage
6. New CMs may form following spinal cord X-RT
7. Cervical and thoracic levels more common than lumbar

Neuroimaging

Angiography

1. CCMs minimal or no findings on angiography
2. Abnormal angiograms demonstrate:
 - a. A vascular area (77%)
 - b. Venous pooling, capillary blush, or neo-vascularization in 20%

MRI

1. Gradient echo sequences are especially useful due to their ability to determine the stages of bleeding from the paramagnetic properties of hemoglobin, deoxyhemoglobin and hemosiderin

Classification of CCM Based on Their Pathological Constitution and MRI – Signal Characteristics

Type I Lesions

1. Hyperintense core on T1-weighted image (T1WI)
2. Methemoglobin
3. Visible on CT
4. T2-weighted image (T2WI)
 - a. Hyperintense core (if methemoglobin present)
 - b. Hypointense core if methemoglobin is broken down with a surrounding dark or hypointense rim (paramagnetic effects of iron and hemosiderin, also cancellation effects)
5. Pathologic correlation:
 - a. Subacute hemorrhage (4–8 days old)
 - b. Rim is composed of macrophages that have engulfed hemosiderin and gliosis

Type II Lesions

1. T1-Weighted Image sequence:
 - a. Reticulated mixed signal core with hypointense rim
2. T2-Weighted Image sequence:
 - a. Reticulated mixed signal core with hypointense rim

3. Pathologic correlate:

- a. Loculated areas of hemorrhage and thrombosis of different age surrounded by gliotic tissue and macrophages laden with hemosiderin
- b. Calcification may occur in large lesions

Type III Lesions

1. T1-Weighted Image sequences:
 - a. Iso- or hypointense signal in the core
2. T2-Weighted Image sequences:
 - a. Hypointense core and slightly darker rim; the lesion appears magnified
3. Gradient echo (more sensitive to blood products)
 - a. Hypointense signal
 - b. Greater magnification than T2WI
 - c. Correspond to chronic resolved hemorrhages (hemosiderin within and surrounding the lesion)

Type IV Lesions

1. Minimally visualized on T1 and T2-weighted images
2. Gradient – echo positive
3. Punctuate hypointense signal

Differential Diagnosis of CCMs

Radiologic Differential Diagnosis by MRI

1. Telangiectasia
2. Hemorrhage neoplasms
3. Cysticercosis
4. High grade glioma
5. Metastasis
6. Meningioma
7. Chronic granuloma
8. Lipoma
9. Hamartoma

Imaging Characteristics of Isolated Vergans Angioma

1. Linear on MRI
2. Frequently near a ventricle
3. Large prominent central draining vein
 - a. May be dilated into a varix
 - b. Hyalinized walls

Wyburn-Mason Syndrome

General Characteristics

1. Combination of retinal, orbital and midbrain AVM
 - a. Probably orbital facial and brainstem AVM without retinal lesions represent the same syndrome
2. Dysfunction at the seventh week of gestation in the vascular mesoform
 - a. Concurrent development of the anterior neural tube and the optic cup
 - i. Vascular plexus differentiates into the hyaloid vascular system and the midbrain vascular supply

Clinical Manifestations

1. Retinal AVM
 - a. Stable and cause no visual loss
 - b. Dilated tortuous arteriole and vein contiguous to the optic disc
 - i. Neovascular induced glaucoma from retinal shunting and ischemia
 - ii. Optic atrophy from orbitocranial AVM
2. Intracranial AVMs associated with:
 - a. Visual loss
 - b. Headache
 - c. Hemiparesis
 - d. Rare: seizures and loss of consciousness
3. Location:
 - a. Tends to be deeper in the brain than usual AVM

Cobb's Syndrome*Overview*

Cobb's syndrome (cutaneous meningospinal angiomatosis) is a somatic disorder characterized by vascular abnormalities of the spinal cord with associated skin, muscle and dura involvement at the same metameric level.

General Characteristics

1. Cutaneous nevus
2. Associated vascular lesion at the same dermatologic level
3. Vascular skin, muscle, bone and dural involvement at the same somite

Clinical Manifestations

1. Large AVM may be associated with congestive heart failure
2. Compression of the spinal cord, bleeding and deterioration of spinal cord function
3. May just have extradural and paraspinal components

Neuropathology

1. Progressive myelopathy
 - a. Venous congestion of an extradural nidus or fistula
 - b. May cause similar neurologic dysfunction as is seen with dural-based intradural lesions
 - c. Large epidural venous lakes

Neuroimaging

1. Type A – spinal extradural AVF:
 - a. Diffuse high signal intensity of the spinal cord on T2-weighted MR images
 - b. No mass effect
 - c. Primarily thoracolumbar and lumbar location
2. Type B – lesions:
 - a. Normal signal intensity of the cord
 - b. Severe mass effect due to enlarged extradural venous plexus
 - c. Cervical and upper thoracic locations

Sturge-Weber Syndrome*Overview*

Sturge-Weber syndrome, also called encephalotrigeminal angiomatosis, is a neurocutaneous disorder characterized by vascular lesions in the skin, eye, and brain.

General Characteristics

1. Facial port-wine stain (cutaneous nevus) in VI
2. Ipsilateral parietal-occipital leptomeningeal angioma

Genetics

1. Sporadic
2. Somatic mosaicism
3. Occurs in all ethnic groups; no gender preference

Clinical Manifestations

1. Cutaneous nevus
 - a. Usually involves the forehead and upper eyelid (VI distribution)
 - i. May involve the face bilaterally and extend to the trunk
 - ii. Trunk or V2 or V3 distribution lesions (without V1) rarely have an intracranial lesion
 - iii. Rarely patients have intracranial lesion without skin manifestations
2. Bilateral cerebral lesions occur in 15% of patients with unilateral facial nevus
 - a. The extent of the nevus increases the risk of a bilateral intracranial lesion
 - b. Similar cutaneous lesion with limb hypertrophy comprise the Klippel-Trénaunay-Weber syndrome
3. Ophthalmologic features
 - a. Glaucoma if the nevus is adjacent to the eyes
 - b. Newborns have buphthalmic amblyopia (rare)
 - i. Abnormal anterior chamber angle
4. Seizures and hemiparesis
 - a. Seizures develop acutely during the first or second year; often triggered by a febrile illness
 - b. Early onset and refractoriness of seizures are correlated with cognitive deficits
5. Adult patients with Sturge-Weber syndrome
 - a. Greater than 50% suffer contralateral motor deficits
 - b. Intracranial hemorrhage is rare
6. Intracranial hemorrhage is rare
7. Seizures occur in:
 - a. 72–80% of patient with unilateral lesions and greater than 90% of those with bilateral lesions
 - i. Early seizures are focal (infantile spasm, myoclonic and atonic seizures also occur)
 - ii. Adults have complex partial seizures or focal motor seizures
8. Patients may develop stroke-like episodes without seizures suggestive of TIA
9. Occipital lobe involvement

- a. Visual field deficits
- b. Cognitive deficit occurs in approximately 50% of patients; particularly severe if there is bilateral involvement

Neuropathology

1. Parietal and occipital lobe involvement is greater than in the frontal lobe
2. Leptomeninges:
 - a. Thickened
 - b. Angiomatous vessels may obliterate the subarachnoid space
 - c. Tortuous deep draining veins
 - i. Thin walled
 - ii. May extend into the parenchyma
 - iii. Ipsilateral choroid plexus may be involved
 - iv. Hyalinization and subependymal proliferation occurs in some vessels
 - d. Cerebral atrophy adjacent to the angioma
 - i. Neural loss and gliosis which may extend into normal appearing tissue
 - ii. Gyriform ("tram track") calcification is seen in outer cortical layers adjacent to blood vessels
 - e. Chronic venous stasis

Neuroimaging

1. Gyral calcification; bilateral calcification is common
2. Calcification more apparent with age; may be present at birth
3. Cerebral atrophy
4. Accelerated myelination in young patients
5. Hypoperfusion:
 - a. Impaired venous drainage
 - b. Several impaired regions demonstrate arterial perfusion deficits

PET

1. Decreased brain glucose utilization beyond the leptomeningeal lesion

SPECT

1. Decreased cerebral perfusion that may include areas with normal glucose uptake; often the deficit is larger than that noted by MRI

Angiography

1. Rare arterial occlusion; may see blush of the angioma
2. Decreased number of superficial cortical veins; enlarged and tortuous draining veins
 - a. Failure of opacification of the ipsilateral sagittal sinus due to occluded cortical veins

Von Hippel-Lindau Syndrome

Overview

Von Hippel-Lindau disease is a rare, autosomal dominant multisystem disorder associated with hemorrhagic blastomas

of the CNS, retinal angiomas as well as cysts and tumors of the viscera. The most common tumors are retinal and CNS hemangioblastomas, clear cell renal carcinoma, pheochromocytoma, pancreatic islet cell tumors and endolymphatic sac tumors.

General Characteristics

1. Autosomal dominant; 95% penetrance by age 60 with incomplete expression
 - a. Von Hippel-Lindau (vHL) suppressor gene on chromosome 3p25-26 is mutated
2. Development of benign and malignant tumors and cysts the include:
 - a. Hemangioblastoma (HB) in the CNS
 - b. Retinal hemangioblastoma (RA)
 - c. Pheochromocytoma (Pheo)
 - d. Clear cell renal carcinomas (RCC)
 - e. Renal cysts
 - f. Pancreatic cystadenoma
 - g. Pancreatic neuroendocrine tumors

Genetics

1. vHL protein mutations cause:
 - a. Decreased ubiquitination of hypoxia-inducible factor 1 α (HIF1 α)
 - b. Dysfunction of vascular endothelial growth factor in stromal cells
 - c. Upregulation of VEGFR1 and 2 in tumor endothelial cells
 - d. vHL protein regulates extracellular matrix formation and the ability of cells to exit the cell cycle
 - e. Major effect of vHL mutation:
 - i. Causes altered vHL protein and Elongin BC complex

Clinical Criteria for the Diagnosis of vHL Disease

1. Positive family history
2. Development of hemangioblastoma in the CNS, retinoblastomas, renal cell cancer, pheochromocytoma, pancreatic tumors or cysts
3. Patients who develop hemangioblastomas or retinal hemangioblastomas concomitant with renal cell carcinoma and the usual associated tumors
4. 80% of patients have a family history
 - a. Inter- and intrafamilial phenotypic variability
 - b. 20% are sporadic and require two manifestations: included requirements are CNS or retinal hemangioblastoma

Clinical Classification

1. vHL type I
 - a. No pheochromocytoma
2. vHL type II
 - a. Type 2A
 - i. Has pheochromocytoma

- ii. Associated hemangioblastoma in the CNS
- iii. No renal cell cancer
- iv. Low risk of renal cell cancer and neuroendocrine pancreatic tumor
- b. Type 2B
 - i. Has pheochromocytoma, renal cell cancer and other CNS tumors
 - ii. High risk of renal cell cancer and pancreatic endocrine tumor
- c. Type 2C
 - i. Has only pheochromocytoma

Clinical Manifestations

1. Isolated hemangioblastoma (HB) present in early adulthood (20 to 40 years of age)
 - a. Type 1 (no pheochromocytoma) or type 2A in 70% of vHL patients
 - b. Males 1.5:1 females
 - c. Location:
 - i. Cerebellum (83–95%)
 - ii. Spinal cord (3.2–13%)
 - iii. Medulla (2%)
 - d. Multiple spinal hemangioblastoma occur
 - e. In 40%, hemangioblastoma may be first manifestation of disease
2. Posterior fossa signs and symptoms
3. High hemoglobin occurs from overproduction of erythropoietin from hypoxia inducible factor (HIF)
4. Hemangioblastomas from vHL disease are 5–30% of cerebellar hemangioblastomas and 10% of spinal hemangioblastomas
5. Asymptomatic vHL gene carriers are approximately 4%
6. Intracranial or intramedullary subarachnoid or intraparenchymal hemorrhage is low (less than 5%)
 - a. Tumors size (1.5 to 5 cm); the average size that bled is 2.7 cm (larger than average HB)
 - b. Size of the tumor is associated with hemorrhage both spontaneous and following surgery
 - c. Subarachnoid hemorrhage occurs in a high percentage of patients that bleed
 - i. Superficial location of medullary HBs
 - ii. Cerebellar hemangioblastoma bleeds occur in the parenchyma
 - iii. Large solid hemangioblastoma have a higher risk of peri- and post-operative hemorrhage
7. Patients with complete deletion mutation of the vHL gene (as opposed to missense or protein-truncating mutations)
 - a. Better visual acuity
 - b. Decreased tumorigenesis incidence of hemangioblastomas
8. Higher levels of vascular endothelial growth factor VEGF, hypoxia-inducible factor (HIF) and ubiquitin have ocular hemangioblastomas

Neuropathology

1. Association with:

- a. Visceral cysts of the kidney, pancreas and epididymis
- b. Pheochromocytoma (type III, vHL)
- c. Pancreatic neuroendocrine tumors
- d. Endolymphatic carcinoma
- e. Head and neck paraganglioma
2. Stroma
 - a. Foamy vacuolated cells
 - b. Tumorlet dells (retinoblastoma) are poorly differentiated, small cells, prominent dark nuclei
3. Epithelial clear cell morphology
4. Increased expression (retinoblastoma) of erythropoietin (Epo); CD133; and the chemokine CXCR4

Neuroimaging

MRI

1. Should be of the entire neuraxis to rule out multiple hemangioma
2. Lesions are well circumscribed and are often associated with a cyst
3. Cystic lesions hypointense on T1-weighted images and hyperintense on T2-weighted images
4. Minimal or no edema
5. Enhancement of a mural nodule with gadolinium
6. May have vascular flow voids (MRA)
7. Solid HB enhance homogeneously with gadolinium

Differential Diagnosis

Neuroradiologic Differential Diagnosis

1. Pilocytic astrocytoma (children; spreads through the brainstem)
2. Astrocytoma (solid or cystic)
3. Metastasis (usually surrounding edema)
4. AVM (appear similar to large solid hemangioblastoma)

Angiography of Hemangioblastoma

1. May demonstrate a large vascular peduncle
2. Early draining vein (AV shunting)
3. Absence of a cystic component suggests metastatic renal cell carcinoma

Hereditary Hemorrhagic Telangiectasia (Osler-Weber-Rendu Disease)

Overview

Hereditary Hemorrhagic Telangiectasia (Osler-Weber-Rendu) is autosomal dominant, characteristic by epistaxis, cutaneous telangiectasia, visual and cerebral malformations. Epistaxis occurs in childhood, pulmonary AVMs at puberty, cutaneous and gastrointestinal telangiectasia in adulthood. Arteriovenous fistulas occur in childhood, small AVMs in adolescents and micro-AVMs in young adults.

General Characteristics

1. Autosomal dominant; high penetrance
2. Incidence of 1 in 5,000–8,000 persons

3. Telangiectasias are found:
 - a. Face
 - b. Nasal mucosa (nose bleeds)
 - c. Conjunctiva (30%)
 - d. Hands > legs and trunk
 - e. Anterior tongue
 - f. Retina (10%)
4. Telangiectasia – enlarge and multiply
5. Telangiectasia occur in internal organs
 - a. Lungs
 - b. GI tract
 - c. Genitourinary tract

International Diagnostic Criteria

1. Epitasis
 - a. Spontaneous
 - b. Recurrent
2. Multiple telangiectosis
 - a. Lips, oral cavity, fingers, nose
3. Visceral lesions
 - a. Gastro-intestinal telangiectosis
 - b. Pulmonary arteriovenous malformation; hepatic, cerebral and spinal AVM
4. Family history of a first degree relative with lesions
5. Clinical manifestations develop with age
6. Epitasis in childhood, pulmonary AVM from puberty, microcutaneous and gastrointestinal telangiectosis in adulthood
7. Approximately 2/3 of patients have some sign of HHT by 16 and 90% by 40 years of age
8. Neurologic symptoms occur in approximately 10–20% of patients

Genetics

1. Autosomal dominant; 2 genes described:
 - a. Endoglin – chromosome 9q24(CD105)
 - b. Activin – chromosome 12q HTT2
 - i. Proteins expressed are found in vascular endothelial cells
2. No definite relationship between the type of mutation and the phenotype of the disease
3. Protein levels from the mutated genes suggest haploinsufficiency
4. Endoglin and Activin receptor-like kinase 1(ALK1) involved in:
 - a. Transforming growth factor signaling pathway
 - b. Cell development
 - c. Vascular remodeling by control of the production of the extracellular matrix
 - d. Endoglin and ALK1 influence angiogenesis by binding with transforming growth factor β proteins
5. Some patients have HTT-juvenile polyposis overlap syndrome
6. HTT3 subgroup:
 - a. Chromosome 5 locus; SMAD-4
 - b. Prominent pulmonary involvement

Clinical Manifestations

1. Nasal and mucocutaneous telangiectosis
 - a. Epistaxis from nasal mucosa is the first complaint in about 50% of patients
 - i. Common in childhood
 - ii. Recurrent in 50 to 80% of patients
2. Skin telangiectasia
 - a. Later in life
 - b. Located on the face, lips, tongue, palate and finger tips
 - c. Size and number increase with age
3. Gastrointestinal telangiectasia
 - a. Recurrent hemorrhages occur in about 30% of patients usually starting in the fifth to sixth decade
 - b. Telangiectasia more prominent in stomach and duodenum than colon
 - i. Rarely AVM or aneurysms
 - c. Rare liver AVMs
 - i. Multiple AVMs may cause portal hypertension and biliary disease
 - ii. Cardiac failure from right to left shunt
 - iii. Hepatic encephalopathy (rare)

Pulmonary AVM (PAVM)

1. Occurs in 5–20%, possibly more are present in the 5HTT 3 subgroups
2. About 70% of all PAVMs occur in 5HTT patients
3. Location is primarily in the lower lobes
 - a. Enlarge with age and become symptomatic during the third or fourth decade
4. Associated with:
 - a. Decreased arterial oxygen saturation (right to left shunt)
 - b. Fatigue, dyspnea and cyanosis
 - c. Hemoptysis and hemothorax
 - d. Polycythemia
 - e. Clubbing, cyanosis
 - f. Platypnea-orthodeoxia (improved breathing with supine position; hypoxemia in sitting position)
5. Differential diagnosis of pathologic arteriovenous defects:
 - a. Patent ductus arteriosus
 - b. PFO
 - c. Right to left congenital heart defect
 - d. PAVM

Neurologic Manifestations

1. Occur at all ages; peak incidence is in 3rd–4th decade
2. Primary mechanisms:
 - a. PAVM (60%)
 - b. Brain vascular malformations (28%)
 - c. Spinal cord malformations (8%)
 - d. Hepatic encephalopathy (3%)
3. Neurologic complications from PAVM
 - a. Bland emboli to cerebral circulation
 - b. Septic emboli associated with SBE that cause cerebral abscess, meningitis and mycotic aneurysms

- c. Cerebral abscess is most frequently a septic complication:
 - i. Usually solitary
 - ii. Supratentorial (MCA territory most frequent)
 - iii. Incidence 3–5%; much higher if there is a recurrence
- d. Embolic patterns:
 - i. Paradoxical from peripheral sources such as DVT
 - ii. In a large ectatic PAVM a clot may develop in the wall of the malformation
 - iii. MCA territory most often affected (40 to 50% of CBF)
 - iv. Rarely CNS embolism is the initial symptom
 - v. Overall risk of emboli is related to the number of PAVMs
 - 1. Single PAVM infarction occurs in about 30%
 - 2. 60% of them are multiple PAVMs
 - vi. Other mechanisms of cerebral ischemia:
 - 1. Hyperviscosity from polycythemia
 - 2. An embolism

Differential Diagnosis of PAVM

1. Hepatopulmonary syndrome
2. Mitral stenosis
3. Trauma
4. Actinomycosis
5. Schistosomiasis
6. Metastatic thyroid cancer
7. Fanconi syndrome
8. Surgery in congenital heart case
9. Bronchiectasis
10. Venous atresia

Hemorrhagic CNS Complications

1. About 30% of HTT patients suffer hemorrhages from cerebral or spinal vascular malformation
 - a. Large malformations bleed at a rate of 1.4–2% per year
2. Prevalence of cerebrovascular malformations by MRI is about 20%
 - a. Large malformations bleed at a rate of 1.4–2% per year
3. Symptoms from malformations also occur due to
 - a. Thrombosis of the venous pouch
 - b. Venous ischemia
 - c. Rarely SAH from AVF or arterial aneurysm
4. Spinal malformations (AVFs):
 - a. Often large
 - b. High risk of hemorrhage
 - i. Progressive para- or tetraparesis the usual premonitory sign

Neuropathology

1. Telangiectasias are the most prominent lesions:
 - a. Focal dilatations of post-capillary venules
 - b. Some perivascular lymphocytic infiltration

- c. Enlargement of telangiectasias associated with excessive layers of smooth muscle without elastic fibers
- d. Connecting arterioles dilate and connect to venules by-passing a capillary bed

Neuroimaging

1. Associated arteriovenous malformation and arteriovenous fistula
 - a. Most often responsible for neurologic sequelae
 - b. Largest arteriovenous malformations occurs in the lungs, liver and CNS
 - c. Rare aneurysm
 - d. Multiple types of malformations may occur concomitantly
2. Three different malformations occur:
 - a. Large fistula
 - i. Direct arteriovenous shunt
 - ii. No nidus
 - iii. Ectatic draining vein
 - b. Small AVMs (1–3 cm)
 - i. Nidus
 - c. Micro-AVMs
 - i. Nidus smaller than 1 cm
3. Malformations most often are near the surface of the CNS
4. Venules are the initial component of the pathologic process
5. PAVM may enlarge during pregnancy (increased hemorrhagic risk)
6. Cerebral and spinal AVM's (16%)
7. No evidence of different features of AVMs among different genetic groups
8. Multiple brain AVMs (23%)
9. AVMs are of small size and tend to be cortical

Drug Abuse

General Characteristics

1. 25% of drug related strokes are ICH
2. 6% related to recreational drug abuse
3. Location
 - a. Subcortical
4. Hemorrhage in a first time user
 - a. Occurs in minutes to hours
5. ICH responsible for approximately 50% of cocaine related stroke

Cocaine Abuse

General Characteristics

1. Crack cocaine
 - a. Aqueous cocaine HCL with NH₃ and baking soda
 - b. Smoked or inhaled
 - i. Aseptic necrosis of the nasal septum
 - c. Reaches the brain 10 seconds after it is smoked (1 circulatory pass)
 - d. Most rapid "high"

Clinical Manifestations

1. Systemic effects of cocaine
 - a. Blood pressure increase
 - b. Increases temperature
 - c. Increases metabolism
 - i. Severe weight loss in chronic abusers
2. Signs and symptoms immediately after use:
 - a. Loss of consciousness
 - b. Headache
 - c. Focal neurological signs (vasospasm of specific blood vessels)
 - d. Frequent signs and symptoms due to concurrent alcohol use
 - e. Hemorrhages
 - f. Strokes occur shortly after use
 - g. Predilection for the brainstem
 - h. Bowel and myocardial ischemia may be associated

Neuropathology

1. Approximately 20% of patient with ICH after cocaine use have an underlying vascular lesion: AVM or aneurysm
 - a. SAH occurs in approximately 48–80% of patients with an underlying aneurysm after cocaine use
 - b. Rebleed may occur even with normal angiography
 - c. Vessels do not show signs of vasculitis
 - d. Deep hemorrhage is less likely to be caused by an underlying vascular lesion
 - e. Some patients present with hypertensive encephalopathy
 - i. Usual pressure is 210–240 mmHg systolic and 110–140 mmHg diastolic
 - ii. Multiple hemorrhages
 - iii. Cerebral edema

Heroin Abuse*General Characteristics*

1. Cerebral or spinal cord ischemic stroke
2. ICH from SBE (IV route); mycotic aneurysm rupture

Clinical Manifestations

1. Stroke occurs with use after a period of abstinence
2. Ischemia of cerebral vessels:
3. Stroke may occur immediately after use
4. Stroke may occur after a 6–24 hour delay
5. Pulmonary edema and transverse myelitis (IV heroin)
6. If hemorrhage occurs:
 - a. Heroin may be altered or used concomitantly with:
 - i. Cocaine or methamphetamine

Laboratory Evaluation

1. Eosinophilia
2. Comb's positive hemolytic anemia
3. Increased immune globulins
4. False positive serology
5. Antibodies to hepatitis C

Amphetamine Abuse*General Characteristics*

1. Hemorrhages occur a few minutes after drug use
2. Associated abuse of alcohol and other drugs
3. Focal ICH may be associated with:
 - a. Diffuse vasculopathy
 - b. Cerebral edema
 - c. Ischemic lesions

Clinical Manifestations

1. Thin patients (severe appetite suppression)
2. Characteristics of adult attention disorder (chronic abusers)
3. Alternate presentation:
 - a. Hypertension
 - b. Fever
 - c. Tachycardia
4. Fibrinoid necrosis of the media and intima of small and medium-sized arteries
5. Arteriographic evidence of segmental constriction and "beading" of intracranial arteries (superficial cortical arteries)
6. Amphetamine and methamphetamine more likely to cause hemorrhage than dextroamphetamine
7. Hemorrhage may occur with doses as small as 20 mg
8. Solid form of D-methamphetamine base that can be smoked
 - a. Street name is "ice"
 - b. May reach the brain in <20 seconds in one CBF pass

Clinical Signs and Symptoms

1. Clinical presentation:
 - a. Symptoms occur a few minutes after use
 - b. Headache
 - c. Seizures
 - d. Focal neurological signs from ICH
 - e. Average age of patients 25.4 years
 - f. Intracerebral lobar hemorrhage most common
 - i. <5% have underlying vascular lesion

Laboratory Evaluation

1. Comb's positive hemolytic anemia
2. Increased immune globulins
3. False positive serology
4. Antibodies to Hepatitis C

Phencyclidine (PCP)

1. Angel dust

*Clinical Manifestations**Signs and Symptoms*

1. ICH
2. Hypertensive encephalopathy
3. Self-destructive behavior
4. Dramatic nystagmus to all fields of gaze

LSD*Clinical Manifestations*

1. Hypertension
2. Hallucinations
3. Vasoconstriction but no ICH

Phenylpropanolamine (PPA)*General Characteristics*

1. May be combined with caffeine or antihistamine
2. Partial α -adrenergic agonist
3. Reactions to PPA are often idiosyncratic
4. Risk of hemorrhage with PPA use occurs with:
 - a. Post-partum use
 - b. Caffeine
 - c. Higher than recommended doses
 - d. Alcohol
 - e. Caffeine
 - f. Prior hypertension
 - g. Monoamine oxidase inhibitors
 - i. Multiple simultaneous hemorrhages

*Clinical Manifestations**Clinical Signs and Symptoms*

1. <30 years of age; female > male
2. SAH may occur
3. ICH
4. Blood pressure on admission
 - a. 160/104–210/110 mmHg

Neuroimaging

1. Segmental angiographic beading of intracranial vessels (similar to amphetamines)

Neuropathology

1. Location: lobar > basal ganglia > thalamic

Ethanol*General Characteristics*

1. Mechanisms predisposing to hemorrhage
 - a. Platelet abnormalities
 - b. Impaired production of clotting factors with concomitant liver disease
 - c. Hypertension associated with chronic alcoholism
 - d. Binge drinking
 - i. Acute elevations of blood pressure
 - e. Concomitant use of cocaine in face of liver dysfunction
 - i. May potentiate vasoconstrictor effects

Pentazocine and Pyribenzamine (“T’s” and “Blues”)*General Characteristics*

1. IV use: associated with: starch, methylcellulose crystals; taken I.V. can cause pulmonary emboli

Clinical Manifestations

1. Pulmonary hypertension:
 - a. Destruction of pulmonary arterioles with right-sided hypertension
 - b. Embolic material reaches the cerebral circulation
 - c. Damaged cerebral vessels result in ICH

Neuropathology

1. Crystals and talc may be noted in cerebral vessels

Methylphenidate

1. Associated with ICH

Metastatic Brain Tumors That Bleed*General Characteristics*

1. The most common hemorrhagic metastases are:
 - a. Melanoma
 - b. Hypernephroma
 - c. Papillary cancer of the thyroid
 - d. Choriocarcinoma
 - i. Often metastatic to the dura
 - e. Lung and breast
 - i. No specific proclivity to bleed but are very common tumors

Clinical Manifestations

1. Onset of brain metastasis is usually insidious
 - a. Sudden onset of neurologic deficits may occur from bleeding into the tumor or tumor embolism that causes vessel occlusion
 - b. Marantic emboli may cause sudden stroke with hemorrhage
 - c. New onset seizures
 - d. Headache
 - e. Focal neurologic deficits
 - f. Signs of increased pressure

Neuropathology

1. Multiple hemorrhagic metastases in several vascular territories
2. Histopathological features of the metastatic lesions are slightly less differentiated than the primary tumor
3. Micro-invasion occurs at the areas of demarcation of the tumor
4. Reactive astrogliosis occurs around the metastatic nodule
5. Microglial activation is noted around areas of necrosis
6. Neovascularization
7. Vascular endothelial/pericytic proliferation

Neuroimaging

1. Hemorrhagic lesions in multiple vascular territories
2. Cerebral edema often out of proportion to the size of the metastases
3. Petechial hemorrhages in many metastatic nodules without overt hemorrhage

Laboratory Evaluation

1. Increased growth factor production including:
 - a. Vascular endothelial growth factor (VEGF)
 - b. PDGF
 - c. EGF
 - d. $TGF\alpha$
 - e. $TGF\beta$
 - f. $FGF\alpha$
 - g. $FGF\beta$

Cerebral Congophilic Angiopathy as Cause of Non-Hypertensive Hemorrhage*General Characteristics*

1. Elderly non-hypertensive patients
2. Approximately 2–9% of ICH

Clinical Manifestations

1. Recurrent ICH or SAH
2. TISA presentation (rare)
3. Focal neurologic deficits depending on location
4. Seizure (rare)

Neuropathology

1. Various mutant amyloid peptides deposited into and weakening of arteriolar walls
2. Putatively accelerated atherosclerosis
3. Lobar superficial hemorrhages
4. Cortical microhemorrhages
5. Superficial cortical siderosis
6. Sulcal SAH
7. Location of CAA lobar hematomas:
 - a. Frontal 35%
 - b. Parietal 26%
 - c. Occipital 19%
 - d. Deep central gray 4%
 - e. Cerebellum 2%

*Neuroimaging***ECHO and MRI**

1. Gradient ECHO and susceptibility weighted MRI sequences
 - a. Cortical microbleeds
 - b. Superficial siderosis

MRI

1. Sulcal SAH
2. WMH
3. Leukoariosis
4. Dilated perivascular spaces

Rare Causes of Non-Hypertensive Parenchymal and SAH

1. Vasculopathy or Vasculitis
2. Sinus thrombosis
3. Post-partum coagulopathies

*Neuropathology***The Cerebrovascular Effects of Hypertension**

1. Arteries and arterioles
 - a. Have one or more layers of smooth muscle cells (myocytes) that are contractile and regulate vascular diameter
 - b. Bind with endothelial cells
2. In capillaries
 - a. Myocytes are replaced by pericytes
3. Innervation of cerebral arteries and arterioles
 - a. Nerve fibers that arise from autonomic and sensory ganglia
 - b. Smaller arterioles ($<100\ \mu\text{m}$) and capillaries are covered by the end feet processes of astrocytes
 - c. Extraparenchymal arteries and arterioles control 2/3 of vascular resistance; intracranial arterioles and capillaries control the other third

*The Adaptive Response of the Neurovascular Unit (NVU) to Changes in the Cerebral Circulation***Functional Hyperemia**

1. Local neuronal activity increases local cerebral blood flow:
 - a. Effected by the release of vasoconstrictive agents released by neurons, astrocytes and endothelial cells that include:
 - i. Nitric oxide
 - ii. Carbon monoxide
 - iii. Prostanoids
 - iv. Adenosine
 - v. P450 metabolite
 - vi. Potassium and hydrogen ions
 - b. Cause vasodilation of local arterioles and regional pial arterioles

Cerebral Autoregulation

1. Autoregulation maintains CBF independent of changes in arterial pressure between 60–150 mm Hg
 - a. Arterioles adjust their resistance according to intravascular pressure to maintain CBF during changes in peripheral arterial pressure
 - b. Arteriole myocytes contract when intravascular pressure rises
 - i. Intravascular pressure depolarizes arterial myocytes that induce Ca^{2+} influx and vasoconstriction by:
 1. Sensitization of the smooth muscle contractile process by activation of protein kinase C (PKC) and Rho-associated protein kinase (ROCK)
 2. Hypertension shifts the pressure-flow curve to the right so that higher blood pressure is needed to maintain the same level of CBF

Structural Alteration of Blood Vessels from Hypertension

1. Exacerbates atherosclerosis in pial arteries and arterioles

2. Induces fibrinoid necrosis of penetrating arteries and arterioles that supply the deep white matter that cause lacunar infarction and hemorrhage (basal ganglia microhemorrhages)
3. Remodeling:
 - a. Hypertrophic remodeling
 - i. Smooth muscle cells undergo hyperplasia and hypertrophy that encroaches into the lumen by increasing wall thickness
 - ii. Eutrophic remodeling:
 1. Smooth muscle cells undergo rearrangement that decreases the vessel lumen without an increase in the wall thickness
 - iii. Increased collagen deposition that decreased the compliance of the vessel wall
 - iv. Mechanisms for hypertrophy include:
 1. Sympathetic perivascular innervation
 2. Increased mechanical pressure on the vascular wall that induces:
 - a. Growth factors
 - b. Oxidative stress
 - c. Nitrogen oxide production decreased
 3. Nitrogen oxide has anti-proliferative smooth muscle activity
 4. Angiotensin II (AngII)
 - a. Pivotal in mechanisms of cerebrovascular remodeling through reactive oxygen species (ROS):
 - b. ROS:
 - i. Promote DMC proliferation
 - ii. Activate matrix metalloproteases (MMP)
 - iii. Extracellular matrix proteins are important for hypertrophy, remodeling and arterial compliance
 - c. Endothelial dysfunction
 - i. Hypertension alters endothelium dependent relaxation of cerebral blood vessels
 - d. Oxidative stress:
 - i. Systemic markers of oxidative stress are increased in:
 1. Essential hypertension
 2. Renovascular hypertension
 3. Malignant hypertension
 4. Pre-eclampsia
 - ii. Experimental models demonstrate:
 1. Reactive oxygen species (ROS) production is elevated in central autonomic nuclei
 - a. Putatively play a role in the neurohumoral changes that maintain hypertension
 2. Models of ANG-II-induced hypertension
 - a. There is an increase in ROS production in large and small cerebral blood vessels
 - b. Free radical scavengers decrease the effects of hypertension on functional hyperemia and endothelial function
 - e. Reactive oxygen species (ROS):
 - i. Cerebrovascular cells may produce ROS from:
 1. Mitochondrial enzymes
 - a. Mitochondrial respiratory chain dysfunction
 2. Xanthine/xanthine oxidase
 3. Lipo-oxygenase
 4. Nitric oxide synthases (NOS) uncoupling
 - a. NOS produces superoxide rather than nitric oxide
 5. Nicotinamides adenine dinucleotide phosphate (NADPH) oxidase:
 - a. A major source of ROS that mediate cerebrovascular dysfunction
 - i. Implication in effects of Ang-II activation
 6. ROS alters vascular regulation by:
 - a. The formation of peroxynitrite (sometimes called peroxonitrite) from the reaction between nitric oxide and superoxide
 - b. Peroxynitrite:
 - i. Damages DNA
 - ii. Induces lipid peroxidation
 - iii. Alters protein function by interaction with transition metal centers, tyrosine nitration and oxidation of cysteine
 - iv. May be pivotal for Ang-II effects
 - v. The main source of nitric oxide that is responsible for peroxynitrite formation is the vascular endothelium

Neuroimaging

1. Hypertensive hemorrhages occur in specific locations. The most significant locations are:
 - a. Basal ganglia (60%)
 - i. Caudate (10%)
 - ii. Putamen
 - iii. GPi (40%)
 - b. Thalamus (20%)
 - c. Cerebellum 15%
 - d. Lobar 10%
 - e. Pontine (5%)
 - f. Midbrain (<1%)
 - g. Medulla (<1%)
2. Cortical microbleeds

3. Superficial cortical siderosis
4. Dolichoectasia
5. Lacunar infarction
6. Leukoaraiosis
7. Increased perivascular spaces

Subarachnoid Hemorrhage

Overview

Subarachnoid hemorrhage is a devastating neurologic illness that carries a mortality of 30% with each bleed and very significant mortality in survivors.

The ictus is frequently characteristic as patients suffer a severe headache that reaches maximum intensity instantly. The headache is frequently basioccipital and then shifts to frontal areas. It is associated with vomiting in a significant number of patients with attendant loss of consciousness in approximately 30–50%. The neck is stiff; patients have positive Kernig's and Brudzinski's signs and focal deficits depending on the location of the bleed. The patients' eyes are sore and photophobia is present. Seizures occur in 20% of patients. A sentinel bleed prior to the rupture of an aneurysm occurs in a significant proportion of patients. There is controversy whether enlargement of the aneurysm with stretch of the dura can cause a sentinel headache. Clearly at surgery there are often signs of hemosiderin and a prior bleed.

Familial aneurysm, polycystic kidney disease, Turner's syndrome and associated AVMs are clear clinical settings for aneurysms. Acquired aneurysms have been noted both with trauma, atrial myxoma and SBE (mycotic) on peripheral arteries. Cigarette smoking and vasculitis may predispose at the circle of Willis. The role of hypertension in causation is controversial, but not in regard to rupture. Some autopsy series have demonstrated 0.9% of patients with a congenital aneurysm. An aneurysm of 7–10 mm is the most likely to bleed. Those less than 3 mm in general do not. An infundibulum at the take off of cerebral arteries is usually less than 2 mm and do not bleed.

The use of coiling and interventional neuro-radiographic techniques has made aneurysm care much safer and successful for many patients. Unfortunately, vasospasm is still a major problem. The differential diagnosis for subarachnoid hemorrhage is wide and includes vascular malformations as well as trauma, congophilic angiopathy, hemostasis dysfunction and diseases of the blood vessel wall.

Clinical Manifestations of SAH

1. Headache
 - a. Severe: 10/10 on a visual analogue scale
 - b. Reaches maximal intensity immediately ("worst headache of my life")
 - c. Cervical-occipital location with frontal radiation; primarily C2 distribution
 - d. Lasts 4–6 weeks
 - e. Associations:
 - i. Vomiting
 - ii. Loss of consciousness 30–50%
 - iii. Pain and soreness of the neck, shoulders and upper back
 1. Absence of head pain suggests spinal AVM
 - iv. Light sensitivity
 - v. Sore eyes
 - vi. Focal motor or sensory deficits depending upon the etiology of the bleed
 - vii. Seizures in 20%
2. Decreased level of consciousness
3. Vomiting: 30–50% of patients
4. Restlessness

Differential Diagnosis of SAH

1. Ruptured aneurysm
2. Arteriovenous malformation
3. Cavernous angioma
4. Congophilic angiopathy
5. Capillary, telangiectasia (very rare)
6. Dural arteriovenous malformation
7. Venous infarctions with hemorrhage
8. Sinus thrombosis
9. Head injury
10. Hemorrhagic metastasis
11. ICH with subarachnoid extension
12. Coagulopathies
13. Hemophilia
14. Amphetamines; cocaine; other sympathomimetic drugs
15. Migraine (extremely rare)
16. Intracranial arterial dissection

Specific Vascular Malformations

Congenital Aneurysms

General Characteristics

1. 0.9–6% of the general populations may have a congenital aneurysm autopsy series
2. 3.6% prospective autopsy series
3. 3.7% in retrospective angiography series
4. 6.0% in prospective angiography series in those undergoing arteriography

Incidentally Discovered Aneurysms by Artery

1. Internal carotid – post-communicating artery – 64%
 - a. Internal carotid ophthalmic artery 19.9%
 - b. IC – anterior choroidal – 12.8%
 - c. IC – cavernous portion – 10%
2. Anterior communicating artery – 12.2%
3. Middle cerebral artery – 6.3%
4. Basilar artery (rare)
5. PICA – vertebral (rare)
6. AICA – basilar (rare)

Meta-Analysis of 23 Studies of Prevalence

1. 0.4% in retrospective autopsy series

Incidence of Unruptured Aneurysms by Age

1. 1.1%: 0–29 years of age
2. 3–5%: 40–49 years of age
3. 5.7%: 50–59 years of age
4. 7.4%: 60–69 years of age
5. 6.1%: 70–79 years of age
6. 9.3%: 80–89 years of age
7. 37.5%: >90 years of age

Natural History of Unruptured Aneurysms

1. 1.4% annual rate of rupture; other studies 3% bleed/year (untreated)
2. 10% have ruptured at 10 years; 20% at 20 years and 32% at 30 years
3. Multiple Aneurysms
 - a. Risk of rupture universally proportional to age
4. Aneurysmal growth is not associated with:
 - a. Sex
 - b. Blood pressure
 - c. Patient's age
 - d. Initial size
5. Associations with Hereditary Diseases of Collagen
 - a. Ehlers–Danlos (type IV; COL 1A gene, type III collagen)
 - b. Pseudoxanthoma elasticum (COL2A gene)
 - c. Marfan's syndrome
 - d. Osteogenesis imperfecta
 - e. Polycystic kidney disease (PKD gene chromosome 12)
 - f. Tuberous sclerosis
 - g. Neurofibromatosis I (chromosome 17)
 - h. Fibromuscular dysplasia (FMD)

Associated Other Diseases

1. Coarctation of the aorta
2. Congenital anomalous blood vessels
3. Arteriovenous malformation (arteries feeding the malformation)
4. Moyamoya syndrome
5. Takayasu syndrome

Familial Aggregation of Congenital Aneurysms

1. 7–10% of patients with aneurysmal rupture have first or second degree relatives with an aneurysm
2. Among first degree relatives of those with ruptured aneurysms risk of SAH is four times that of the population at large
3. Risk highest among siblings of the index patient
4. Most families have 2–3 members that are affected if there is familial aggregation
5. Inheritance patterns are unclear; autosomal dominant most probable

Incidence of SAH with Aneurysms

1. 1/10,000 people
2. At risk for development of new aneurysm (after rupture of the first)

3. Each year: new aneurysms develop in 2% of patients with previously ruptured aneurysms, this group ruptures at an incidence of 6/10,000 in the general population
4. Morbidity and mortality
 - a. 12% die prior to medical attention
 - b. 40% die in the hospital within 1 month after the ictus
 - c. 1/3 of survivors suffer major neurologic deficits

*Clinical Manifestations***Associated Clinical Features of Aneurysms with Underlying Collagen Defects**

1. They are in typical locations
2. Bilateral
3. Associated with enlarged tortuous extracranial vessels
4. Occur at supra clinoid level
5. Associated with A-V fistulas
6. Associated with dural ectasia

Familial Aneurysms

1. Rupture at an earlier age than sporadic aneurysms
2. Smaller when they rupture
3. More often followed by the formation of new aneurysms

Multiple Aneurysms

1. Usually 2–3 in patients
2. Occur in 20–30% of patients
3. Rarely > 10
4. Occur with AVMs and other associated congenital anomalies of blood vessels

Factors Influencing Aneurysmal Rupture

1. Risk of rupture 1.9–3%/year
2. Aneurysms of <10 mm 0.7% rupture/year; usual size 7–10 mm at rupture
3. Aneurysms > 10 mm 5.5% risk of rupture
4. Risk of rupture > in women than men
5. Incidentally found aneurysms lower risk of rupture than those found in addition to one that has ruptured
6. Aneurysmal SAH; male > female
 - a. Premenopausal female low risk of rupture
 - b. Postmenopausal female with hormone replacement (intermediate risk)
 - c. Postmenopausal female without hormone replacement (highest risk)
 - d. Alcohol consumption
7. Cigarette smoking; 3–10× greater risk of aneurysm than nonsmoker
 - a. Smoking increases chance of developing a new aneurysm
 - b. Decreases alpha antitrypsin (inhibits proteases)
 - c. Inherited decrease of alpha antitrypsin causes increased risk of aneurysms
8. ADPKC disease (autosomal dominant polycystic kidney disease) 4.4% (2.7–7.2%) chance of aneurysm

- a. 9% risk in first degree relatives if 2 or more members have aneurysms
- b. Life time risk for SAH in persons with an affected first degree relative is 1% at age 50; 2% at age 70
9. Familial predisposition 4.0% (2.7–6%)
10. Atherosclerosis 2.3%
11. 8% of aneurysms detected >8 mm in size
12. Incidence of rupture increases after the third decade; average age of rupture is fifty years of age, increases with age until 80
 - a. Female > male risk of rupture after 40
 - b. Male > female risk of rupture < 40
 - i. Anterior communicating aneurysms female > male
13. 75% of unruptured aneurysms <10 mm; 80% < than 6 mm
 - a. Median time from diagnosis of unruptured aneurysms to rupture <2 years
 - b. Linear association of risk of rupture with increasing size
14. Younger patients at greater risk of rupture in the setting of multiple aneurysms
15. Aneurysms that were followed and found to have ruptured had grown in size
16. Multiple aneurysms female > males
17. Setting of hypertension
 - a. Rupture more common in older patients
 - b. Hemiparesis, hemihypesthesia, and hemianopsia have been described in:
 - i. 6–25% of unruptured aneurysms
- b. Minute tear of the aneurysm
 - i. Sudden onset: “thunderclap” headache
- c. Maximum intensity instantly
- d. Resolves in 48 hours usually, but may last for weeks
- e. Radiation to shoulder, neck and back, “flu-like” symptoms (with SAH)
2. 50% of patients lose consciousness or are stunned
3. Photophobia
4. 30–50% have suffered a sentinel headache days to weeks prior to the rupture
5. Neck stiffness
 - a. Kernig’s sign
 - b. Brudzinski’s sign
6. Subhyaloid hemorrhage (Torsten’s syndrome) of the retina
 - a. Side of the ruptured aneurysm (if there are multiple); sudden increased ICP with rupture of the preretinal veins
 - b. Shoulder, back or sciatic pain (associated)
 - c. Pain across the shoulders with “flu-like” symptoms (associated)
7. <5% pain is limited to the low back or neck without headache
8. Lethargy; inability to follow four part commands or perform visual praxis
9. Sore eyes to movement or palpation
10. Focal neurologic signs dependent on the specific aneurysm
11. Seizures may occur primarily with MCA and ACA aneurysms
12. A proportion have no neurologic signs but suffer meningeal irritation and altered mentation

Precipitating Factors Associated with Rupture

1. Valsalva maneuvers
2. Pregnancy (release of elastases)
3. Sleep (30% rupture during sleep)
4. Extreme sudden hypertension (amphetamines; cocaine, PPA)
5. Weight lifting
6. Coitus
7. Defecation
8. 30% rupture during normal activity

Neuropathology

The Defect Underlying Aneurysm Formation

1. Occur at branch points of arteries of the Circle of Willis
2. Decrease of type III collagen
3. Defect of the arterial media and localized loss of muscular elements
4. Loss or breakage of the internal elastic membrane

Clinical Presentation of SAH from a Ruptured Aneurysm

Clinical Manifestations

Severe Headache

1. Sentinel hemorrhage
 - a. Occurs in at least 30% of aneurysmal SAH

Specific Clinical Presentation of Congenital Aneurysms

P-COM (Posterior Communicating Carotid)

1. Pain in or behind the affected eye
2. Slowly reactive, oval or paralyzed pupil
 - a. Pressure sensitive parasympathetic fibers affected early or
 - b. Parasympathetic fibers localized to outer area 12–3 o’clock of the IIIrd nerve and are compressed early
3. Partial ptosis (lampshade ptosis secondary to infarction of the IIIrd nerve from medical diseases)
4. CT: Blood in the suprachiasmatic cisterns
 - a. Localized to the side of the bleed

A-COM Artery Complex (Anterior Communicating Artery Complex)

1. Mental status changes
 - a. Acutely: agitation (with no or minimal motor or sensory signs)
 - b. Several days following the ictus:
 - i. Abulia
 - ii. Akinetic mutism
 - iii. Amnesia

- iv. Decrease of executive function
- c. Slight contralateral leg weakness and sensory loss
- d. Dominant hemisphere
 - i. Broca's type aphasia (SMA involvement)
- 2. CT/MRI evaluation
 - a. Blood in medial frontal lobe
 - b. Intrahemispheric fissure anteriorly and extending posteriorly
 - c. Widening of A-Com

Middle Cerebral Artery Trifurcation Aneurysm

Clinical Manifestations

- 1. Anterior temporal headache
- 2. Contralateral hemiparesis and hemisensory defect
 - a. Embolus from giant aneurysm
 - b. Vasoconstriction
 - c. Mass effect from hematoma following rupture
- 3. Rare seizure (compression or irritation of the cortex)
- 4. Aphasia (DH)
- 5. Weakness arm and face > leg

Neuroimaging

- 1. Aneurysm may be > 2 cm (giant Aneurysm)
- 2. Large amount of blood in Sylvian fissure, vasoconstriction of MCA

Internal Carotid Artery Aneurysm

Clinical Manifestations

- 1. Pain behind the eye
- 2. Ptosis (partial) and pupillary paresis
- 3. Rare complete IIIrd nerve palsy
- 4. Contralateral hemiparesis and hemisensory deficits
- 5. Nasal visual field deficit
 - a. Homonymous
 - b. Compression of the lateral chiasm

Neuroimaging

- 1. MRI
- 2. May have giant aneurysm > 1 cm
- 3. MRI signals within the aneurysm may allow estimation of blood flow within the lesion

Ophthalmic Artery Aneurysm

Clinical Manifestations

- 1. Pain in or behind the eye
- 2. Painless loss of central vision
- 3. Rare bitemporal VF deficit
- 4. Chiasmatic syndrome (anterior)

Neuroimaging

- 1. May compress the optic nerve and chiasm

Anterior Choroidal Artery Aneurysm

Clinical Manifestations

- 1. Contralateral hemiparesis
- 2. Contralateral hemisensory defect

- 3. Central sector VF deficit
- 4. Transient focal ischemia of the internal capsule
- 5. Limb shaking (ischemia of internal capsule)
- 6. Tonic spasm (ischemia of internal capsule)
- 7. Rupture with:
 - a. Intracranial or intraventricular hemorrhage

Neuroimaging

- 1. Aneurysm may arise from the ICA adjacent to the AchA
- 2. May arise from the origin of the artery

Posterior Circulation Congenital Aneurysm

Clinical Manifestations

- 1. Vertebral Artery Aneurysm
 - a. PICA symptoms
 - b. Anterior spinal artery symptoms (VA-ASA)
 - i. Hemiparesis
 - ii. Proprioception and vibration loss
 - iii. Pain in the side of the neck
 - iv. Rarely pain radiates to lateral eyebrow
 - v. Acute blood in the IVth ventricle

Neuroimaging

- 1. Origin is close to the basilar artery
- 2. Dissecting aneurysms of the intracranial vertebral artery occurs in approximately 20% of VA aneurysms
- 3. Fusiform dilation of proximal and/or distal narrowing of the affected artery

PICA-Vertebral Artery Aneurysm

Clinical Manifestations

- 1. Dysphagia and hoarseness
- 2. Lateral pulsion (ipsilateral side)
- 3. Inability to stand
- 4. Nausea and vomiting
- 5. Pain in the basiocciput; lateral eyebrow or side of the face
- 6. Crossed hemisensory loss to pain and temperature
- 7. Oscillopsia
- 8. Acute rotary nystagmus (greatest ipsilaterally)
- 9. Ipsilateral Horner's syndrome
- 10. Blood in the IVth ventricle and the posterior fossa

Neuroimaging

- 1. Large proportion arise from the PICA branching sites

AICA-Basilar Artery Aneurysm

Clinical Manifestations

- 1. Sudden hearing loss or tinnitus
- 2. Peripheral ipsilateral facial weakness
- 3. Ipsilateral pain in the face
- 4. Contralateral pain and temperature loss (below the clavicle)
- 5. Contralateral hemiparesis
- 6. Blood in the posterior fossa

Neuroimaging

- 1. Blood in the IVth ventricle and posterior fossa

2. Usually at the junction with the basilar artery
3. Most project laterally; a small percentage are against the clivus

Superior Cerebellar-Basilar Artery Aneurysm

Clinical Manifestations

1. IIIrd nerve palsy
2. Ipsilateral dysmetria
3. Dysarthria
4. Blood in the perimesencephalic cistern

Neuroimaging

1. Blood in the perimesencephalic cisterns
2. A significant portion have other aneurysms associated
3. Mean size of 7.3 mm
4. At the basilar junction

Top of the Basilar-PCA Bifurcation

Clinical Manifestations

1. Pain in the back of the neck or basiocciput
2. IIIrd nerve palsy (peduncular)
3. Visual field deficit (embolus to PCA)
4. Hemiparesis or quadriparesis (emboli or pressure on the cerebral peduncles)
5. Movement disorder (emboli or vasoconstriction of the thalamoperforate artery)
6. Thalamic sensory deficit (emboli or vasoconstriction of the thalamogeniculate artery)
7. Blood in the perimesencephalic cisterns; intrapeduncular blood

Neuroimaging

1. Blood in the perimesencephalic and intrapeduncular arteries
2. Top of the basilar is a site of giant aneurysms

PCA-PI (Posterior Communicating Artery)

1. Similar to top of the basilar-PCA aneurysm

Specific Clinical Signs Denoting Specific Aneurysms

1. Giant MCA aneurysm
 - a. Seizure (focal motor)
 - b. Hemiparesis
 - c. Dysphasia
2. IIIrd nerve compression
 - a. AICA
 - b. ICA (hemiparesis often associated)
 - c. P-COM
 - d. Superior cerebellar artery
3. Isolated VIth nerve following aneurysmal SAH
 - a. Blood
 - b. Increased intracranial pressure
4. Cavernous sinus aneurysm
 - a. VIth nerve first sign
 - b. Severe Vth nerve facial pain
 - c. Late: IIIrd, IVth, VIth

5. Basilar tip
 - a. Forward pointing
 - i. Destroys the pituitary (endocrine failure)
 - ii. Visual field deficits
 - b. Vertical pointing
 - i. IIIrd, IVth nerve
 - ii. Compresses the IIIrd ventricle

Rare Clinical Signs of Aneurysms

1. Transient neurologic signs:
 - a. Ischemia of the parent vessel
 - b. Embolization:
 - i. Usually from giant aneurysms
 - ii. Cause strokes in the affected territory
2. Torsten's syndrome
 - a. Subhyaloid hemorrhage (preretinal)
 - b. Hemorrhage is moveable with changing head positions
 - c. Due to sudden increased pressure
 - d. Occurs on the side of the ruptured aneurysm (20% of patients harbor two or more aneurysms)
 - e. Secondary to rupture of a preretinal vein
3. Prognosis of SAH from an aneurysm is better if no aneurysm is demonstrated

Radiological Features of an Aneurysm That Has Ruptured if More than One Is Present by Arteriography

1. The largest aneurysm most often has bled
 - a. Most commonly between 7–10 mm
 - b. Giant aneurysm usually do not bleed
2. Aneurysm with the most excrescences
3. Local vasospasm
4. Local hemorrhage or hematoma

Aneurysmal Rebleeding

Clinical Manifestations

1. Sudden abrupt severe headache
2. Meningismus
3. Focal signs secondary to early hemorrhage
4. Late
 - a. Vasospasm of the parent vessel with focal expected signs and symptoms
5. Associated ICH leads to rapid coma
6. Aneurysms that cause neurologic symptoms rupture at a higher rate
 - a. 15% of rebleeding within 6 months
7. Fewer rebleeds in patients with Hunt grades I and II
8. Time of Aneurysmal rebleeding
 - a. 0.8–4% rebleed the first 24 hours
 - b. 20% rebleed the first 2 weeks
 - c. 30% rebleed by the end of the first month
 - d. 40% by the end of 6 months
 - e. >6 months 3%/year
9. Vasospasm concurrent with rebleeding
 - a. Occurs from day 3–5
 - b. Peaks between days 5–9

- c. Resolves after the second week
- d. Directly related to the amount of blood surrounding the artery
- e. Configuration of the arteries
 - i. Focal vasoconstriction approximate to area of the bleed
 - ii. Diffuse vasoconstriction of the artery
- f. Lumen of the affected artery <0.5 mm
- g. May occur at a distance from the rupture
- 10. Early clinical signs of vasospasm
 - a. Tachycardia
 - b. EKG changes
 - i. Inverted T-waves in leads V3–V6
 - ii. ST depression or elevation without q waves
 - iii. Atrial and ventricular arrhythmia
 - c. Decreased level of consciousness
 - d. Deficits corresponding to the affected artery
- 11. Early clinical signs of hydrocephalus
 - a. Decreased spontaneity
 - b. Constant headache (often frontal)
 - c. Lethargy
 - d. Incontinence
 - e. Increased reflexes legs > arms

Medical Complications of Aneurysmal Subarachnoid Hemorrhage

General Characteristics

1. Seen at 3 months
 - a. Symptomatic vasospasm – 46%
 - b. Rebleeding 7%
 - c. Total mortality 19%
2. Frequency of at least one severe (life threatening) medical complication
 - a. 40%
 - b. Death from medical complications 23% (of those that die)
 - i. Rebleeding 22% of these deaths
 - c. Vasospasm with stroke 23%

Cardiac Arrhythmia

1. 50% have an abnormal admission EKG
2. 25% have ST segment or T wave abnormalities
3. 15% have prolonged QT interval associated with at least one episode of moderate or severe arrhythmia
4. 35% of all aneurysms have one episode of cardiac arrhythmia on day 0–14; 66% of these are mild; 29% moderate and 5% are severe
5. Onset of arrhythmias usually first 7 days (peak day 2–3)
6. 17% of patients suffer moderate or severe arrhythmia on the day of rupture
7. Cardiac arrhythmia on the day after surgery
 - a. Life threatening 5% of patients
 - b. Less serious 30% of patients
8. Moderate arrhythmias
 - a. Sinus bradycardia

- b. Sinus tachycardia
- c. Atrial extrasystole
- d. Atrial fibrillation
- 9. Severe arrhythmia
 - a. Asystole
 - b. Ventricular tachycardia
 - c. Atrial fibrillation with hypotension
 - d. AV block
 - e. Supraventricular tachycardia
 - f. Ventricular extrasystole
- 10. EKG changes with SAH
 - a. ST depression or elevation without q waves
 - b. Deeply inverted T-waves (Pardee T-waves) V3–V6
 - c. U waves
 - d. Hyperpolarized T-waves
 - e. Pathogenesis
 - i. Myocytolysis
 1. Contraction band necrosis
 2. Myofibrillar degeneration
 3. Effects of increased sympathetic discharge

Pulmonary Edema

1. Occurs in 6% of patients (day 3 to 7)
2. Probable sudden increase in ICP
3. Water and electrolyte disturbance
4. Particularly with anterior communicating artery aneurysms
5. Increase of atrial natriuretic factor
6. Discharge of substance P containing afferents in lung capillaries

Hepatic Dysfunction

1. Occurs in 7% of patients
2. Usually 24% of patients have mild enzyme abnormalities
3. 4% severe hepatic impairment

Renal Dysfunction

1. Occurs in 7% of patients
2. 1.2% severe life threatening renal failure

Thrombocytopenia

1. Occurs in 4% of patients
 - a. Usually associated with sepsis

Sensitivity of Computed Tomography in Detecting SAH

1. Sensitivity of new generation CT scans for patients screened <24 hours from the ictus is 93%
2. Sensitivity of new generation CT scans in patients after 24 hours from the ictus is 90%
3. L.P. remains the gold standard to rule out SAH

Giant Aneurysms > 2 Centimeters

General Characteristics

1. Do bleed but rarely
2. Symptoms are caused by:
 - a. Pressure on local structures

- b. Emboli distally
- c. Seizure activity
- d. Endocrine dysfunction (erosion into the pituitary)

Clinical Manifestation

Giant Carotid Aneurysm

- 1. Pain behind or around the eye
- 2. May erode into the pituitary with endocrine failure
- 3. Compression of the optic chiasm with nasal VF deficit or chiasmal syndrome
- 4. IIIrd nerve palsy

Middle Cerebral Artery Giant Aneurysm

- 1. Anterior temporal or retroauricular headache
- 2. Seizure activity
- 3. Contralateral hemiparesis

Top of the Basilar Giant Aneurysm

- 1. Occipital headache
- 2. IIIrd, IVth nerve palsy (if extends dorsally)
- 3. Compression or invasion of the III ventricle
- 4. May cause obstructive hydrocephalus
- 5. Associated with emboli to the posterior cerebral artery territories with VF deficits
- 6. Hemiparesis (compression of the cerebral peduncle)

Acquired Aneurysms

General Characteristics

- 1. Peripheral arterial location (not at the Circle of Willis)
- 2. May be multiple on superficial conducting vessels
- 3. Cause of peripheral lobar hemorrhage

Differential Diagnosis

- 1. Fusiform
 - a. Secondary to hypertension
 - b. Dolichoectasia
 - c. Primarily Vertebrobasilar system
- 2. Subacute bacterial endocarditis
- 3. Trauma
- 4. Atrial myxoma
- 5. Collagen vascular disease
- 6. Cigarette smoking (women > men)

Basilar Fusiform Aneurysm

Clinical Manifestations

- 1. Occurs in elderly hypertensive patients with associated atherosclerosis
- 2. Dysarthria (pontine compression)
- 3. Hydrocephalus (blocks ventral CSF pathways)
- 4. Spastic gait (pressure on ventral pontine motor fibers)
- 5. XIIth nerve palsy (dysarthria)
- 6. Spastic quadriparesis (ventral pontine compression)

Closed Head Injury

- 1. Aneurysms of superficial subarachnoid conducting vessels

- 2. Rarely basilar artery is traumatized after cervical or basilar skull fracture with aneurysmal formation
- 3. May be multiple

Atrial Myxoma

Clinical Manifestations

- 1. Multiple peripheral aneurysms
- 2. MCA territory most common distribution
- 3. Myxomatous emboli may grow through the wall of the blood vessel

Traumatic Peripheral Carotid Artery Aneurysm (Pharyngeal Portion)

Clinical Manifestations

- 1. Knife or gunshot wound to the neck
- 2. Sympathetic ocular paralysis (complete Horner's syndrome)
- 3. Abnormal neck pulsation
- 4. Embolization in carotid territory
- 5. Pain in the side of the face
- 6. Carotodynia (pain in the artery itself)
- 7. Associated connective tissue disease:
 - a. Ehlers-Danlos type IV and VI
 - b. Marfan's disease
 - c. COLIA gene mutations
 - d. Fibromuscular dysplasia
 - e. May be bilateral

Traumatic Vertebral Artery Peripheral Aneurysm

Clinical Manifestations

- 1. Trauma to the neck
 - a. Often minimal and unrecognized when it occurs
- 2. Pain in the posterior or side of the neck
 - a. Mastoid pain
 - b. Occipital headache
- 3. Chiropractic manipulation (horizontal C2 portion most vulnerable)
- 4. Congenital connective tissue disorders (particularly if bilateral)
- 5. Signs and symptoms:
 - a. Distribution of the vertebral or basilar artery
 - b. Due to emboli at the site of the vessel tear
 - c. Rarely flow limiting pathogenesis for signs and symptoms
- 6. Cancer or cancer treatment (surgical trauma)

Subacute Bacterial Endocarditis

Clinical Manifestations

- 1. May be multiple
- 2. MCA territory most frequent locations
- 3. Hemorrhage is common
 - a. Cause of peripheral ICH
 - b. May be delayed after successful antibiotic treatment (destruction of the vessel wall)
- 4. Seizures are common

5. Focal motor deficits: the symptomatology depends on location
6. Streptococcus viridans; gram negative organisms most common
7. Following dental work
8. In association with deformed valves
 - a. Congenital bicuspid calcified valves
 - b. Rheumatic fever deformed valves
 - c. Rarely mitral valve prolapse

Differential Diagnosis of Subarachnoid Hemorrhage Without Detectable Aneurysm

General Characteristics

1. 15–20% of spontaneous SAH no aneurysm is detected by 4 vessel arteriography
2. There is a better prognosis in these patients than in those in which an aneurysm is found

Diseases

1. Idiopathic perimesencephalic hemorrhage
2. Venous trauma
3. Diffuse or anteriorly located hemorrhage in the basal cisterns
4. Incomplete visualization of the posterior circulation
5. Occult aneurysm
6. Carotid artery dissection
7. Vertebral artery dissection
8. Dural arteriovenous malformation
9. Spinal AVM
10. Parenchymal trauma
11. Mycotic aneurysm
12. Cocaine abuse (and other sympathomimetic drugs)
13. Sickle cell disease
14. Coagulopathies
15. Subarachnoid blood in the basal cisterns
 - a. Pituitary apoplexy
 - b. Cervical tumor
 - c. Rupture of circumferential artery (penetrators) in the pontine cisterns
 - d. Trauma
 - e. Mycotic aneurysm
 - f. Coagulopathies (rare)
 - g. Cocaine or sympathomimetic drug abuse

Idiopathic Perimesencephalic Hemorrhage

1. Approximately 10% of all SAH
2. Comprise 2/3 of patients with normal arteriograms
3. Occur in older patients (>6th decade)
4. Few patients with HCVD
5. Rarely concomitant with congenital aneurysm
6. 1/3 have history of strenuous exercise prior to the bleed
7. Headache reaches maximum intensity within minutes rather than seconds
8. No loss of consciousness with the ictus
9. No focal neurological deficits

10. No rebleeding or delayed ischemia
11. Normal on admission other than headache
12. 20% have hydrocephalus with no other clinical deficits
13. Excellent prognosis
14. Some evidence of capillary bleed as cause

Venous Trauma

1. Shearing head injury
2. Blood most often seen in the posterior part of the cisterna ambiens (superior cerebellar-quadrigenal cisterns) at the level of the tentorium
3. Vein is torn against the tentorium

Diffuse or Anteriorly Located Hemorrhage with Rupture into the Basal Cisterns

1. Patients are lethargic to stuporous
2. Focal neurologic deficits are present
3. Symptomatic hydrocephalus
4. Nidus of bleeding medial frontal lobe
 - a. Blood dissects into the interhemispheric fissure
 - b. May rebleed
5. Deterioration from associated ischemia

Incomplete Visualization of the Posterior Circulation

1. Ruptured aneurysm of the posterior circulation is suspected from the early CT scan
2. 85% of patients demonstrate blood in the IVth ventricle and to a lesser extent the IIIrd and lateral ventricles
3. IVH is the only abnormality on CT scan in 25% of posterior circulation aneurysms
4. Subarachnoid blood is noted in the midbrain cisterns with spread to the anterior basal cisterns

Occult Aneurysm

1. Approximately 20% of aneurysms are detected on the second arteriogram (after 2 weeks; vasospasm has cleared)
2. Aneurysmal rupture is likely if there is blood in the Sylvian or interhemispheric fissure

Carotid Artery Dissection

1. Rare cause of SAH
2. Clinical features:
 - a. Severe neck pain; subacute or acute onset
 - b. Facial pain
 - c. Oculosympathetic paralysis
 - d. MCA or carotid embolic stroke
 - e. May be associated with depressed level of consciousness
 - f. Rebleeding may occur within hours of the initial hemorrhage

Vertebral Artery Dissection

1. Autopsy series – comprises 4% of patients who died from SAH
2. Primarily middle aged patients

3. 1/3 have HCVD
4. Occurs after severe rotational neck movement or minor trauma
 - a. Patient may be going to a chiropractor because he has neck pain from the dissection; further manipulation exacerbates the dissection
5. Rarely associated with lower cranial nerve palsies; symptoms from occlusion or embolus of the PICA
6. May be bilateral if the cause is an underlying collagen defect
7. Rebleed occurs in 30% of patients; may occur within hours of the initial hemorrhage

Anticoagulation with Warfarin or Heparin

Risk Factors for ICH or Systemic Bleeding

1. Prolongation of prothrombin time beyond the therapeutic range
 - a. Hemorrhages occur occasionally in the therapeutic range
2. Large size of infarcted area (ischemic stroke)
3. Uncontrolled hypertension
4. Age related (relative risk); primarily for subdural hematoma

Clinical Features

1. Gradual and insidious onset
 - a. Hours to days
2. Predilection for the cerebellum with INR > 5
3. High morbidity and mortality

Patients Requiring Long Term Anticoagulation After Bleed; Reinstitution of Rx

1. 10–14 days possibly safe; 2–3 weeks heparin or warfarin probably safe
2. First year of anticoagulation most dangerous

Neuroimaging

MRI Evaluation

1. Inhomogeneous infarction mixed signal on T2-weighted images suggest acute bleeding and clots

Primary Tumors That Hemorrhage

1. Glioblastoma multiforme
 - a. In general petechial hemorrhage
 - b. Bleeding and edema may be initiated by minimal trauma
2. Pituitary apoplexy
 - a. Most often MRI demonstrates blood confined to the pituitary
3. Bleeding into tumors account for 5–10% of ICH
4. 1% of tumors bleed
5. Hemorrhagic metastatic tumors
 - a. Melanoma
 - b. Choriocarcinoma
 - c. Papillary Ca of the thyroid
 - d. Bronchogenic Ca
6. Tumors that bleed are overwhelmingly malignant

Clinical Characteristics Suggesting ICH Is Secondary to a Tumor

1. Underlying systemic cancer
2. Focal symptoms prior to hemorrhage
3. Unusual site:
 - a. Corpus callosum (glioma)
4. Multiple simultaneous hemorrhages

Bleeding Diathesis

General Characteristics

1. Platelet abnormalities
 - a. Associated with petechial hemorrhage in the lower extremities
 - b. Bleeding from the gums
 - c. Vaginal bleeding prior to cerebral hemorrhage may occur
 - i. Platelets < 30,000/mm³
 - d. Hemorrhage starts at <30–40 thousand/mm³
2. Waldenström's macroglobulinemia
 - a. Associated abnormalities of platelets with lower extremity petechiae
 - b. Bleeding from mucous membranes
3. Disseminated intravascular coagulation
 - a. Associated bleeding from all former venous puncture sites
 - b. Acrocyanosis
4. Hemophilias
 - a. Joint involvement
 - b. Associated subdural hematoma
 - c. Internal bleeding
 - d. Bleeding may develop gradually
 - e. Recurrent ICH less likely after 14 days
5. Liver transplantation

Differential Diagnosis of Coagulopathies

1. Coagulopathies (inherited and acquired)
2. Anticoagulation (INR > 5)
3. Thrombolytic treatment (TPA; urokinase)
4. Connective tissue disease
5. Sickle cell disease

Specific Diseases of Blood Vessels That Hemorrhage

1. Cerebral amyloid angiopathy
 - a. Autosomal dominant (Icelandic; Dutch variants)
 - b. Sporadic; incidence increases with age
 - c. Concomitant Alzheimer's disease and variants
2. Granulomatous angitis of the CNS
3. Lymphomatous granulomatosis
4. Benign appearing immunoproliferative vasculitis
5. Angiocentric lymphoma
6. Periarteritis nodosa
7. SLE (with and without lupus anticoagulant)
8. Connective tissue diseases
9. Sickle cell disease
 - a. 30% of sickle cell disease SAH occur in children

- b. Blood is in the superficial sulci
- c. Mechanisms
 - i. Distal branch occlusions
 - ii. Collateral leptomeningeal vessels
 - iii. Moyamoya disease (bilateral carotid occlusion)
- d. Adult patients may have:
 - i. Underlying aneurysm
 - ii. Blood in the basal cisterns

Thrombolysis Related Intracranial Hemorrhage

General Characteristics

1. Hemorrhages are large (approximate mean of 70 ml)
2. Solitary in 66%
3. Lobar 77%
4. Confluent 80%
5. Intraparenchymal 80%
6. Mortality 44–83%
7. Increased risk of subdural hematoma

Clinical Manifestations

1. 2/3 of hemorrhages are supratentorial and solitary
2. 1/3 subtentorial or multifocal
3. Perihemorrhage edema is minimal
 - a. Less in those hemorrhages with a blood fluid level
 - b. Mottling and a blood fluid level is indicative of continuing fibrinolysis

Thrombolysis Induced Hemorrhage Occur in 6% of Treated Patients

1. 7% may be asymptomatic; noted on follow-up CT scan
2. Main comorbidities associated with ICH:
 - a. History of diabetes mellitus and cardiac disease
 - b. Use of antiplatelet agents other than ASA prior to stroke related hemorrhage
 - c. Elevated pretreatment blood pressure
 - d. Age
3. Criteria that utilized CT findings and laboratory findings that predicts ICH thrombolysis after:
 - a. Ischemic changes on CT exceeding 1/3 of the MCA territory
 - b. Diabetes
 - c. Elevated serum glucose
 - d. Low platelet counts
4. Pretreatment diffusion-weighted MRI parameters and laboratory values predictive of ICH after thrombolysis
 - a. High systolic blood pressure
 - b. Severity of the stroke
 - c. Elevated serum glucose
 - d. Volume of initial DWI lesion
 - e. Voxels with decreased ADC value
5. Predictive CT findings for thrombolytic hemorrhage:
 - a. Large arterial territory involved
 - b. Obscuration of caudate nucleus (head)
 - c. Loss of the insular stripe
 - d. Sulcal effacement

Hemorrhage After an Acute Ischemic Stroke

1. All ischemic infarctions have petechial hemorrhages microscopically
2. Hemorrhagic transformation determinants:
 - a. Hypertension
 - b. Size of the ischemic area
 - c. Age of the patient
 - d. Embolic > thrombotic stroke
 - e. Endothelial cells of blood vessels are sensitive to hypoxia
3. Unfavorable prognostic signs
 - a. Intraparenchymal hemorrhage
 - b. Extraparenchymal bleeding (often occurs after streptokinase)
 - c. Cerebral edema
 - d. Size of the hematoma
 - i. Increased cerebral edema
 - e. Hemorrhagic transformation of an ischemic stroke has a better prognosis than a hematoma in ICH

Recurrent Intracerebral Hemorrhage

1. 1.8–5% of patients in Asia
2. 2–24% of European patients
3. 6% of ICH are recurrent in the USA; 2.4%/year for primary ICH
4. Mean age is 64.7 years
5. Interval between bleeds is 48 months
6. Recurrent hemorrhages occur at different locations
7. Patterns of recurrences
 - a. Basal ganglionic in hypertensive patients
 - b. Lobar in patients with congophilic angiopathy
8. Younger age and lobar hemorrhage increase the risk of recurrence of ICH
9. Recurrent ICH
 - a. Poor prognosis
 - b. Severe cognitive deficits
 - c. Risk is 4× higher in lobar hemorrhage

Post-Partum Cerebral Angiopathy

1. Cause of recurrent intracerebral hemorrhage in young women
2. Usually a vasospastic process
3. Usually benign and non-relapsing
4. Several intracranial vessels involved; often bilaterally
5. Similarities to benign isolated CNS angiitis:
 - a. Young women
 - b. Headache, seizures, neurologic deficits
 - c. Angiogram consistent with vasospasm

Differential Diagnosis of Multiple ICH

1. Underlying malignancy
2. Hypertension
3. Coagulopathies
4. Subacute bacterial endocarditis
5. Vasculitis of collagen disease
6. Congophilic angiopathy

7. Venous sinus occlusion
8. Multiple cardiac emboli
9. Artery to artery emboli
10. Multiple hemorrhages from thrombolysis therapy (after myocardial infarction)

Multiple Hemorrhages from Thrombolysis Therapy (After Myocardial Infarction)

1. Multiple hemorrhages are unusual in spontaneous ICH
2. Multiple hemorrhages occur earlier than solitary hemorrhages after thrombolytic therapy
3. Multiple hemorrhages
 - a. 0.47% for streptokinase (CSK) with sc. heparin
 - b. 0.57% for SK with iv heparin
 - c. 0.7% accelerated TPA with iv heparin
 - d. 0.95% for SK with both accelerated TPA and intravenous heparin
4. Time from thrombolytic treatment to ICH
 - a. Streptokinase – 17.5 hours
 - b. TPA – 10 hours
 - c. TPA + SK – 13 hours
5. Factors associated with increased risk of hemorrhage after thrombolysis for MI
 - a. Age
 - b. Congophilic angiopathy
 - c. Facial and head trauma
 - i. Risk increases if syncope had occurred <2 days prior to treatment

Clinical Manifestations of Aneurysm

Intracerebral Hemorrhage

General Characteristics

1. Significant parenchymal hemorrhage occurs in approximately 40% of patients
 - a. Associated with SAH
 - b. Origin most often is ruptured aneurysm
 - i. Temporal or frontal lobe hemorrhage whose origin appears in the Sylvian fissure
 1. MCA aneurysm
 - ii. Deep frontal hemorrhage that suggests top of the carotid bifurcation
 1. Ruptured carotid bifurcation aneurysm
 - iii. Basal frontal hemorrhage that extends to anterior communicating area
 1. A-Com Aneurysm rupture
 - iv. Bilateral medial frontal hemorrhage
 1. Pericallosal aneurysm rupture
2. Focal apoplectic deficits occur with aneurysmal intracerebral hemorrhage
 - a. Differential points:
 - i. Subarachnoid Hemorrhage (SAH) hemorrhage alone most often causes minimal focality, depressed consciousness, stiff neck
 - b. Hemiparesis most often with MCA aneurysms
 - i. If hemorrhage extends into the temporal lobe the patient may herniate

Intraventricular Hemorrhage from Aneurysmal Rupture

General Characteristics

1. IVH occurs in approximately 13–28% of aneurysmal ruptures
 - a. A-Com: 40%
 - b. Internal Carotid: 25%
 - c. MCA: 21%
 - d. Vertebrobasilar arteries: 14%
2. Patterns of rupture
 - a. A-Com and upper basilar artery aneurysms rupture into the IIIrd ventricle
 - i. Cardiac arrhythmia
 - ii. Hyperthermia
 - b. Distal PICA and vertebral aneurysms may rupture into the IVth ventricle
 - c. Acute subdural hematoma occurs in 2% of patients with SAH

Ischemic Vascular Disease Associated with Aneurysms

General Characteristics

1. Transient ischemia attacks and infarction may be aneurysm presentation in approximately 3 to 11% of patients
 - a. Most common arteries for this presentation are internal carotid and MCA
 - b. Emboli:
 - i. Most commonly occur from giant carotid and giant top of the basilar aneurysms
 1. Can occur with any size aneurysm (average size 12.5 mm)
 2. Source is thrombosis from inside the aneurysm

Mass Effect from Aneurysms

General Characteristics

1. Most common is compression of the IIIrd nerve:
 - a. May be painless and accompanied by partial or complete IIIrd nerve paralysis
2. Giant carotid aneurysm (greater than 25 mm)
 - a. Pituitary erosion and endocrine failure
 - b. Visual field deficit (lateral chiasm pressure)
 - i. Contralateral nasal deficit
3. Giant ophthalmic and anterior communicating artery aneurysms
 - a. Visual field deficits
 - b. Optic nerve compression
4. Giant MCA aneurysms
 - a. Contralateral hemiparesis
 - b. Seizures
5. Top of the basilar aneurysm
 - a. Emboli to occipital cortex
 - i. VF deficit
 - b. Obstruction of IIIrd ventricle
 - i. Hydrocephalus
6. Cavernous sinus aneurysms
 - a. CN-III, IV, VI and VI; (V2 outside of the sinus)

- b. Middle aged women
- c. Vth nerve often the first affected severe facial pain (may be retro-orbital)
- d. May be bilateral
- 7. Unruptured aneurysms presenting with mass affect rupture at 6% per year
- 8. Aneurysms with mass effect
 - a. Usually demonstrate insidious effects
 - b. Rare: stroke-like presentation:
 - i. Acute expansion from intramural hemorrhage or intra-aneurysmal thrombosis

Isolated Sulcal SAH

General Characteristics

1. Transient and recurrent focal neurological episodes; clinically stereotypical
2. High risk of intracranial hemorrhage
3. SAH is at the cerebral convexity
4. Most often in elderly patients and consistent with CAA

Vasospasm and Delayed Cerebral Infarction Following Aneurysmal Rupture

General Characteristics

1. The rupture of an intracranial aneurysm, causes:
 - a. Increased intracranial pressure
 - b. Decreased cerebral blood flow
 - c. An associated systemic stress reaction
 - d. Adverse effects of the systemic stress reaction
 - i. Myocardial dysfunction (noradrenergic contraction band deficits; cardiac ischemia)
 - ii. Increased levels of natriuretic peptides particularly brain natriuretic peptide (BNP)
 1. Causes renal sodium loss and hypovolemia
2. Approximately 70% of patients develop angiographic cerebral vasospasm between days 3 and 14 after SAH
 1. Delayed cerebral ischemia or infarction occur in 20 to 40% of patients
 2. The most important risk factor is the presence of thick clots in the basal cisterns
 3. Other risk factors include:
 - a. Poor clinical grade
 - b. Acute/chronic hypertension
 - c. Fever
 - d. Intravascular volume depletion
 - e. Cigarette smoking
 4. Focal aneurysm rupture may produce generalized vasospasm

Clinical Features of Vasospasm on Delayed Ischemic Stroke

General Characteristics

1. Pathophysiologic factors independent of angiographic vasospasm important for poor outcome after SAH

- a. Early brain injury before onset of delayed vasospasm
 - i. ICP
 - ii. Decreased CBF
 - iii. Global cerebral ischemia
- b. Above initiate BBB disruption, a proinflammatory state and detrimental oxidative cascades
- 2. Ameliorating of cerebral vasospasm is only partially effective in preventing delayed cerebral ischemia
- 3. Delayed cerebral neurologic deficits
 - a. Result from tissue ischemia in vascular territories in which CVS is documented angiographically
- 4. The clinical vasospasm syndrome
 - a. Manifests between the 4th and 12th day after ictus
 - b. Develops insidiously over several hours to 1–2 days (rarely rapidly simulating a stroke)
 - c. Slight febrile response and increase in leukocyte count 1–2 days prior to clinical deterioration
 - d. Hyponatremia may precede clinical symptoms
 - e. May develop increased headache severity
 - f. Decreased level of consciousness
 - g. Focal symptoms (distribution of the ischemic territory) develop insidiously but occasionally rapidly
 - h. Full syndrome in manifest is one to two days

Neuropathology

1. Aneurysms occur at branch points of arteries both at the circle of Willis and distally
2. Disease of type III collagen
3. Defect of arterial media and localized loss of smooth muscle elements
4. Loss or breakage of the internal elastic membrane

Neuroimaging

1. Determination which aneurysm ruptured (in case of multiple aneurysms):
 - a. Location of blood on CT
 - b. Irregular shape (Murphy's excrescences)
 - c. Larger size
 - d. Local vasospasm
 - e. Intra-aneurysmal thrombus
2. Ventricular and sulcal enlargement with:
 - a. Decrease in gray matter volume
 - i. Marker of general atrophy rather than hydrocephalus
 - ii. Correlates with decreased cognitive function
3. Delayed neurovascular imaging may be valuable in patients with diffuse SAH with negative initial CTA/DSA and DSA at 7 days

Differential Diagnosis of (SAH from Reversible Cerebral Vasoconstriction Syndrome) from Aneurysmal SAH and Convolutional SAH

Reversible Cerebral Vasoconstriction – SAH

General Characteristics

1. RVCS

- a. Recurrent thunderclap headache
- b. Reversible segmental multifocal cerebral artery narrowing
- c. Approximately 30% of patients develop SAH
2. Need to be differentiated from cryptogenic “angiogram negative” SAH (cSAH) versus aneurysmal SAH (aSAH)
3. Approximately 1/3 of RCVS develop ischemic stroke, lobar hemorrhage or convexity SAH
4. Thunderclap headache differential diagnosis:
 - a. Migraine headache with or without aura (common)
 - b. Cerebral artery dissection (rare)
 - c. Cerebral venous thrombosis (rare)
 - d. ICH (common)
 - e. Ruptured aneurysm (almost universal)
5. In approximately 15% of SAH the source is undetected following angiography and through imaging (cryptogenic SAH)
 - a. Perimesencephalic SAH (benign- some evidence of rupture of arteriole in the perimesencephalic venous plexus)
 - i. Headache
 - ii. No focality
 - iii. Usually only occurs once
 - b. Only evidence of blood by L.P.

Differential Clinical Features of RCVS-SAH Versus Cryptogenic SAH

RCVS-SAH

1. Independent risk factors
 - a. Younger age
 - b. History of hypertension
 - c. Chronic headache disorder
 - d. Prior antidepressant use
 - e. Lower Hunt-Hess grade
 - f. Lower Fisher group
 - g. Bilateral vasoconstriction (compared to unilateral or no vasoconstriction)

RCVS-SAH Versus “Non-Perimesencephalic” SAH

1. All patients with RCVS-SAH have convexity SAH
2. Bilateral arterial narrowing the only predictor of RCVS-SAH

Major Differential Feature for RCVS

1. Recurrent thunderclap headache (TCH)
 - a. 80% of a SAH have only one TCH
 - i. Less than 20% have sentinel headache
2. Approximately 80–100% of RCVS have 3–4 TCH
3. 30% of RCVS have convexity SAH
4. Association of chronic obstructive pulmonary disease (COPD) and RCVS-SAH (needs validation)
5. Prior antidepressant use:
 - a. Induces vasoconstriction (increased serotonin and noradrenergic monoamines)
 - b. Associated with both RCVS and vasospasm following SAH

Pathology of Aneurysms

The Arterial Wall and Aneurysms

The arterial blood vessel wall is composed of the tunica intima that is lined by endothelium, the media and the adventitia. The tunica media consists of smooth muscle cells and the extracellular matrix proteins collagen, elastin and glycosaminoglycans. The adventitia is made of connective tissue, nerve fibers and the vasa vasorum. The internal elastic membrane separates the tunica intima from the tunica media. There is no external elastic lamina in cerebral blood vessel walls.

Vessel wall inflammation may occur from several different mechanisms. The proinflammatory cytokine, tumor necrosis factor- α (TNF- α) is pivotal in many pathologic conditions. It damages structural components of the vessel wall that include the endothelium, smooth muscle cells and the internal elastic membrane. It induces inflammatory processes in the vessel wall that include migration of monocytes as well as inhibiting cell proliferation that inhibits cell repair. It also activates matrix metalloproteinases that degrade elastin and collagen which are major structural components of the arterial wall.

Vessel wall inflammation may also be induced by carbon monoxide. Carbon monoxide has a higher affinity for hemoglobin than oxygen which decreases the oxygen carrying capacity of blood which causes hypoxemia induced inflammation. The putative pivotal cause of inflammation of the vessel wall is hemodynamic stress (parameters of shear vessel stress that lead to degradation of the extracellular matrix and apoptosis of smooth muscle cells (the primary origin of the proteins of the extracellular matrix). Tissue infiltration of monocytes and macrophages release proinflammatory cytokines and chemokines (MCP-1) that amplify and recruit inflammatory cells as well as release MMPs. Macrophages are found in a high percentage of surgical aneurysms. M1 (proinflammatory macrophages) predominate in ruptured aneurysms.

In early stages of aneurysm formation, smooth muscle cells migrate into the intimal layer and proliferate which forms myointimal hyperplasia. Over time they undergo phenotypic differentiation from contracting cells to proinflammatory cells. In the process they change morphologically from compact bands to spider-like cells. They secrete less collagen and are a cause of a thinned media. There is evidence that the phenotypic switch noted in aneurysmal smooth muscle cells is induced by TNF- α which induces genes for MCP-1, MMPs, vascular cell adhesion molecule 1 and IL-1 β . Mast cells are found in aneurysm walls and contribute to arterial wall inflammation during aneurysm formation by the release of proinflammatory mediators.

Cytokine mediators of inflammation in the arterial wall are:

1. TNF- α effects:
 - a. Smooth muscle cells phenotype modulation
 - b. Activation of MMPs

- c. Decreases expression of tissue inhibitor metalloproteinase-1
 - d. Proapoptotic effect through FAS
2. IL-1 β effects:
- a. Induced in early stages of aneurysm formation
 - b. Smooth muscle cells apoptosis

Both chemokines (MCP-1 and others) as well as complement are involved in the inflammatory wall mechanisms of aneurysm formation. Reactive oxygen species are being studied in regard to their role in direct endothelial cell injury, SMC phenotype switch of SMC and up regulation of genes that control chemotactic cytokines, adhesion molecules and activation of metalloproteinases (MMPs).

Hemodynamic Stress

Hemodynamic stress is a major initiating factor for the arterial wall structural modulation that occurs with aneurysm formation. Hemodynamic stress is greater at arterial junctions, bifurcations or at areas of vascular angulation. Hypertension, loss of autoregulation and increased blood viscosity may also be synergistic with other factors that cause hemodynamic stress. It has been postulated that hypertension may compromise the vasa vasorum which supply the tunica media of the vascular wall. The effects of wall shear stress (WSS) are complicated and while there is evidence that high WSS may be important in the initiation of aneurysm formation, low WSS may be involved in aneurysm rupture by inducing apoptosis of endothelial cells and structural remodeling of the arterial wall. It has also been suggested that low WSS triggers the growth and rupture of large atherosclerotic aneurysms by an inflammatory mechanism while high WSS induces MMP activation, SMC apoptosis and medial thinning in small aneurysms. There is accumulating evidence that endothelial dysfunction and vessel wall remodeling and inflammation are induced by WSS.

The Effects of Wall Shear Stress

1. Occurs at bifurcation, junctions and areas of acute vessel angulation
2. Induction of inducible nitric oxygen synthase (iNOS) that produces peroxonitrate
3. Stimulation of endothelial production of matrix metalloproteinase
4. Smooth muscle cell injury in the tunica media from increased transmural flow gradients
5. WSS injuries are a component of:
 - a. Endothelial cell damage
 - b. Degradation of the internal elastic membrane
 - c. Thinning and phenotypic change of SMC in the tunica media

Chapter 2

Epilepsy

Overview of Epilepsy

Introduction to Epilepsy

Seizures are now classified as localization-related (focal, local, partial) or generalized. Epilepsy syndromes (formerly classified according to type), neurologic features and EEG findings are now being categorized by their underlying genetic mutations.

In generalized epilepsy, the seizure begins simultaneously in both cerebral hemispheres. The neurologic examination is frequently normal. A great number of the partial epilepsies originate in a localized brain area and then may spread to involve the entire brain.

Generalized Epilepsies

Most generalized epilepsies have complex inheritance patterns, but there is now a rapidly expanding list of single gene mutations that cause the syndrome. They primarily code ion channel proteins (SCN1A, SCN2A, and GABRG2) are early examples. The mutations modify the gating and inactivation properties of the channels. In general, this leads to neuronal hyperexcitability of cortical neurons.

Mechanisms of Partial Epilepsies

Partial seizures are the most common seizure disorder in adults. The mesial temporal lobe that includes the hippocampal formation, amygdala, and adjacent parahippocampal cortex is the most common site of origin. Hippocampal sclerosis is a common pathology in which there is a loss of neurons in the dentate hilus, primarily of the hippocampal pyramidal-cell-layer, with relative preservation of dentate granule cells. Recent high resolution MRI studies demonstrate pathology in Sommer's sector of the hippocampal formation (HF). The amygdala and entorhinal cortex are often concomitantly involved. Hippocampal sclerosis may be caused by seizures in approximately 10% of patients with febrile induced status epileptics in children.

Voltage-Gated Ion Channels in Epilepsy

Cortical neurons have different distributions of voltage-gated ion channels in their functional somatodendritic and axonal domains. Dendritic spines of pyramidal neurons are the primary recipient of excitatory synapses while differential projections of GABA-ergic interneurons to specific domains of these neurons are inhibitory. Summation of excitatory and inhibitory synaptic input at the axon initial segment determines the membrane potential and probability of initiating an action potential.

Voltage-gated sodium (Na_v), potassium (K_v), calcium (Ca_v) and hyperpolarization-activated nucleotide-gated (HCN) channels are expressed differentially in specific neuronal domains and determine the physiology of the cortical neuron. These are transmembrane proteins that are a component of micro-molecular complexes with scaffolding proteins that initiate complex intracellular enzymatic cascades and inter-cellular communication. Cortical neurons, when depolarized, release the cytokine (fractalkine) that activates glia in the micro-environment. Cortical neurons are embedded in an astrocytic syncytium that can secrete proinflammatory cytokines as well as the excitatory transmitter glutamate. In total, the micro-environment of the cortical neuron is a dynamic complex and not fully understood. It may have a major bearing on the membrane potential of the dendritic neuron.

The differential distribution of ion channels on dendritic spines, the soma, and axonal components in conjunction with their scaffold proteins (ankyrin, PSD 93, 95, MAGs) determine the specificity of specific neuronal subtypes and their electrophysiological properties. These include: 1. neuronal excitability and action potential (AP) properties; 2. neurotransmitter release; 3. back propagation of the AP from the axon initial segment to the somatodendritic tree and aspects of activity-dependent neuroplasticity.

SCNA genes encode subunits of Na_v1 channels ($\text{Na}_v1.1$, $\text{Na}_v1.2$ and $\text{Na}_v1.6$) while their B-subunits (Na_v , B1–B4) are encoded by SCNB genes. Sodium channels are responsible for three forms of depolarizing currents; 1. fast inactivation or transient (I_{NaT}); 2. persistent (I_{NaP}) and 3. resurgent (I_{NaR}). Resurgent currents occur following APs and are a component of after depolarization and repetitive firing.

There are several superfamilies of potassium channels that include: 1. voltage-gated (K_v); 2. calcium-activated (K_{Ca}), 3. inward rectifying (K_{ir}) and 2-pore (K_{2p}). Functional KV channels are pivotal in the maintenance of the resting membrane potential, repolarization, and the firing frequency of neurons. KV1, KV2, and some KV3 channels contribute to repolarization. KV4 and some KV3 channels transmit a transient rapidly inactivating sub-threshold A current (A) which delays the initiation of the AP and decreases neuronal firing frequency. The molecular complex of KV 7.2 (KCNQ2) and KV 7.3 (KCNQ3) carry the M-current (I_m) that is important in setting sub-threshold neuronal excitation.

Calcium-activated K^+ channels (K_{Ca}) open in response to Ca^{2+} influx from different types of potassium channels. They include large conductance BK channels that function in the late stages of repolarization and after hyperpolarization and small conductance BK channels. These shape after hyperpolarization and are a feedback mechanism that reduces firing frequency (frequency adaptation) that limits Ca^{2+} influx after depolarization.

Inward rectifying K channels (Kir) whose inward current, active at negative resting potentials, as well as 2-pore K^+ channels that are open at rest are important in determining

the resting membrane potential. The adenosine triphosphate-gated K^+ channel (K-ATP) couples energy metabolism with membrane excitability. Guanine nucleotide binding protein-activated Kir channels mediate inhibitory effects of specific neurotransmitters. The $K_v4.1$ channels localized with aquaporin-4 on astrocytic end-feet processes buffer extracellular K^+ and are important for osmotic homeostasis.

HCN channels, active at hyperpolarization and are gated by cyclic adenosine monophosphate are partially open at rest (subthreshold potentials) and are permeable to Na^+ and K^+ . They also contribute to the maintenance of the membrane potential close to the resting membrane potential. HCN channels dampen the amplitude and duration of both EPSPs and IPSPs.

Calcium channels are classified into high-voltage activated (HVA) and low-voltage activated. L, N, P/Q and R channels are HVA while T channels are LVA. CACNA genes re-code pore forming $\alpha 1$ -subunits that are subdivided into Ca_v1 , Ca_v2 , and Ca_v3 families.

The Ca_v1 family comprises different L channels, the Ca_v2 the P/Q, N, and R channels and the Ca_v3 T-type channels. The HVA channel $\alpha 1$ -subunit forms a molecular complex with β , $\alpha 2$, and γ subunits while T channels only have $\alpha 1$ -subunits. Depolarization of calcium channels contribute to: 1. generation of dendritic spikes; 2. the shape and firing patterns of the AP; 3. neurotransmitter release and neural plasticity (primarily NMDA-mediated). Calcium channels are activated by glutamate release and back-propagating action potentials (APs) (that spreads through the dendritic tree). These calcium channels concomitant with Na channels augment EPSPs, which increases the response to glutamate. In a subset of cortical neurons, LVA $Ca_v3(T)$ channels generate low-threshold calcium spikes that trigger Na-dependent bursts of APs.

Voltage-Gated Channel Integration

Glutamatergic synapses on dendritic spines contain AMPA (α -amino-3-hydroxy-5-methyl-4-isoxazole propionic acid) and NMDA receptors. AMPA receptor activation causes fast synaptic depolarization of the dendritic arbor while NMDA receptors contribute to the intracellular calcium concentration. Back propagation of the AP activates Na_v , K_v and Ca_v channels of the somatodendritic spine arbor. Na and Ca influx augment EPSPs and initiate dendritic spikes (regenerative APs). $Ca_v3(T)$ channels may induce burst firing by producing low threshold spikes. Potassium channels decrease the amplitude, propagation, and duration of back-propagated APs and maintain an inhibitory effect on dendritic spines. Potassium channels also control interspike interval, spine depolarization and intercellular calcium influx. Distal dendritic HCN channels also contribute to the inhibition of both EPSPs and IPSPs.

Mutations of specific voltage-gated channels or their subunits alter the balance of excitation and inhibition of cortical networks that lead to hyper-synchronization that is the basic mechanism underlying seizures.

SCN1A Mutations

In general, SCN1A mutations cause loss of function of the Na 1.1 channel which result in 1. generalized epilepsy with febrile seizures plus (GEFS+) and 2. severe myoclonic epilepsy of infancy (Dravet's syndrome). The mechanism may involve failure of fast-spiking inhibitory interneuron GABA projections from loss of their $Na_v1.1$ currents. The mutation may also cause cognitive impairment, ataxia and increased cardiac myocyte excitability.

SCN1B mutations that encode the Na_vB subunit cause GEFS+, Dravet syndrome, temporal lobe epilepsy and absence seizures from failure to modulate Na_v1 gating that promotes neuronal hyperexcitability.

Mutation of the SCN2A gene that encodes the $Na_v1.2$ channel cause benign familial neonatal-infantile seizures as well as intractable childhood partial and generalized epilepsy. The mutation may cause shifts in activation and inactivation thresholds or reduced channels in the plasma membrane.

Potassium Channel Mutations

Mutations in the KCNQ2 or KCNQ3 genes (encode $K_v7.2$ and $K_v7.3$ channel subunits respectively) cause benign familial neonatal convulsions which usually remit by four months. Mutations in these genes are linked to: 1. Rolandic epilepsy without neonatal seizures; 2. and early onset epileptic encephalopathy responsive to adrenocorticotrophic hormone; 3. approximately 10 to 15% develop seizures later in life.

KCNA1 mutations are linked to seizures in association with movement disorders. KCNA1 encodes $K_v1.1$ and is associated with episodic ataxia type1, neuromyotonia, and seizures. KCNA1 gene mutations (encodes the $\alpha 1$ subunit of the BK channels) which also causes generalized epilepsy and paroxysmal dyskinesia. The mechanism of action is a gain of channel function that causes rapid repolarization and a faster neuronal firing rate.

Mutations in other K^+ genes cause a wide spectrum of seizures that are associated with varying medical manifestations:

1. Mutation in the KCNJ11 gene that encodes $K_v6.2$ or in the ABCC8 gene (encodes the sulfonylurea receptor 1 subunit) cause:
 - a. Developmental delay
 - b. Seizures
 - c. Neonatal diabetes
2. Mutations in the KCNJ10 gene:
 - a. Encodes the $K_v4.1$ channel in glia
 - b. Loss of function
 - c. Expressed in astrocytic end-foot processes
 - d. Extracellular K^+ buffering
 - e. Cause seizures, ataxia, sensory-neural deafness, and tubulopathy
3. KCTD7 (potassium channel tetramerization domain-containing protein 7):

- a. Failure of maintenance of the resting membrane potential causes
- b. Progressive myoclonic epilepsy
- c. Opsoclonus/myoclonus/ataxia syndrome
- d. Infantile neuronal ceroid lipofuscinoses

Calcium Channel Mutations

1. Mutations in $Ca_v2.1$ (P/Q) channels:
 - a. Affect the $\alpha 1$ -subunit (pore-forming) and the B4, $\alpha 2 L$ and r2 subunits of the P/Q channel
 - b. Cause absence seizure with ataxia
 - c. Decreased neurotransmitter release in cortical neurons
 - d. Decreased evoked excitatory potentials in thalamic neurons
 - e. Absence epilepsy (spike-and-wave) from T channel triggered burst firing and synchronization of thalamo-cortical neurons
2. Mutation in CACN1A Gene:
 - a. Encoding $Ca_v2.1$
 - b. Associated with idiopathic generalized epilepsy
 - c. Absence seizures alone or with ataxia
3. Mutations in CACNB4 gene:
 - a. Encodes auxiliary B4 subunit of $Ca_v2.1$
 - b. Idiopathic generalized epilepsy and episodic generalized epilepsy and episodic ataxia
4. Mutation in Ca_v3 (T-channels):
 - a. CACNA1H mutations
 - i. Encodes Ca 3.2 channels
 - ii. Associated with childhood absence seizures

Epilepsy Mechanisms

Juvenile absence and myoclonic epilepsy, febrile seizures, and temporal lobe epilepsy.

A loss of function in HCN2 channels linked to generalized epilepsy.

Electrophysiology

Absence Seizures

1. Thalamocortical circuitry governs:
 - a. Rhythms of cortical excitation
 - b. Physiologic patterns of sleep
2. Thalamic relay neurons respond to excitatory afferents by a burst or tonic mode of discharge
3. The response mode depends on voltage-dependent inward calcium currents through T-type channels of the soma and dendritic arbor
4. Burst mode:
 - a. Occurs with deactivation of T-channels in hyperpolarized neurons

- b. Results in a low Ca^{2+} spike current whose upper limit is 12 Hz
- c. Occurs during non-REM sleep and the abnormal thalamocortical oscillations of spike-and-wave discharges of absence epilepsy
- d. Spike-and-wave discharges emerge from 5–9 Hz oscillations in the cortical circuits
- e. Reciprocal discharge between cortical pyramidal cells, thalamic reticular neurons, and thalamic relay neurons generates the oscillations of the thalamocortical circuits
- f. The oscillatory pattern is determined by:
 - i. The balance between T and P/Q channel activity
 - ii. Thalamic GABA-ergic inhibition
- g. Ascending monoaminergic thalamic inputs:
 - i. Modulate the thalamocortical circuitry increasing or decreasing the likelihood of a burst mode of cell firing
- h. The anterior and centromedian/parafascicular nuclei (cm/pf) are activated during spike-and-wave seizures
5. EEG/fMRI evaluation of genetic generalized epilepsies:
 - a. Enables the study of electrophysiology of genetic generalized epilepsies *in vivo*
 - b. Present information supports the concept that:
 - i. Genetic generalized epilepsies (GGE) are a network disorder that includes multiple nodes in the thalamus and cortex
 - ii. Clinical presentation is dependent on which node of a participating network is affected
6. Voxel-based morphometric studies demonstrate thalamic gray matter (GM) reduction in a portion of patients with idiopathic generalized epilepsy:
 - a. The anteromedial thalamic nuclei demonstrated reduced GM
 - b. Functional connectivity (FC) analysis seeding at the anteromedial nucleus revealed:
 - i. Decreased thalamocortical FC in the bilateral medial prefrontal cortex
 - ii. Decreased precuneus and posterior cingulate cortex
 - c. Thalamo prefrontal network abnormality underlies some of the pathophysiologies of IGE

Basic Electrophysiological Mechanisms Underlying Seizures and Epilepsy

Seizure Initiation:

1. High-frequency bursts of action potentials
2. Hyper-synchronization of a neuronal population
3. A paroxysmal depolarizing shift is the cellular manifestation of epilepsy
 - a. Initiated by Ca^{2+} mediated depolarization
 - b. Opens voltage-gated Na^+ channels that initiate action potentials
 - c. Depolarization is followed by:
 - i. Hyperpolarization mediated by Ca^{2+} -dependent K^+ channels

- ii. GABA-activated CL ion influx
- d. Several million neurons are required to discharge simultaneously to produce a focal interictal epileptiform spike

Seizure Propagation

1. Sufficient activation of the seizure onset zone is required to recruit surrounding neurons due to loss of surround inhibition
2. Different lobes are activated via long association pathways:
 - a. Corpus callosum (bi-hemispheric activation)
 - b. Superior longitudinal fasciculus (parietal to frontal lobes)
 - c. Inferior longitudinal fasciculus (occipital to temporal lobe)
 - d. Anterior commissure (connects the temporal lobes)
 - e. Uncinate fasciculus (temporal to frontal lobe)

Control of Burst Firing

1. Intact hyperpolarization
2. Surround inhibition effected by GABA-ergic inhibitory interneurons

Recruitment of Surrounding Neurons During Seizures

1. Repetitive discharge (burst firing):
 - a. An increase in extracellular K^+ which decreases hyperpolarizing outward K^+ currents and depolarizes contiguous neurons
 - b. Increased Ca^{2+} in presynaptic terminals that enhances neurotransmitter release
 - c. Activation of NMDA receptors that further increase intracellular calcium concentration

Network Level Excitation and Inhibition

1. Increased network excitability
 - a. Loss of GABA-ergic interneurons that cause decreased feed forward and backward inhibition of dentate granule cells (in the HF)
 - b. Recurrent excitatory connections from axonal "sprouting":
 - i. May be due to loss of excitatory input to inhibitory interneurons
 - ii. Development of reverberating self-reinforcing circuits from axonal collaterals

Physiological Mechanisms That Underlie Partial Epilepsies

Mesial Temporal Sclerosis

1. Ictal onset in the hippocampus, amygdala, and parahippocampal cortex
2. Selective loss of neurons in the dentate hilus and hippocampal pyramidal cell layers

3. Relative preservation of:
 - a. Dentate granule cells
4. Pyramidal cell loss of cornu ammonis field 2 of the hippocampal formation
5. Neuronal loss in the amygdala and entorhinal cortex
6. Epileptogenesis from hippocampal sclerosis:
 - a. Sprouting of many fibers from dentate granule cells to:
 - i. Inner molecular layer
 - ii. Aberrant mossy fibers may synapse on dendrites of granule cells
 - iii. Initiate a recurrent excitatory circuit
 - b. Excitatory neurons that activate $Na_v 1.1$ receptors on inhibitory interneurons are lost:
 - i. Decreased inhibition of dentate granule cells
 - c. Abnormal integration of newly generated dentate granule cells into hippocampal circuits that causes:
 - i. An imbalance between excitation and inhibition
 - d. Alterations in the composition and expansion of GABA-A receptors in dentate granule cells
 - e. Hippocampal sclerosis demonstrates:
 - i. Structural reorganization
 - ii. Selective neuronal loss
 - iii. Aberrant neurogenesis that causes circuit alterations
 - iv. Change in neurotransmitter receptors
 - v. Development of focal hyperexcitability

Some Aspects of Electrophysiology in Focal Epilepsy

1. Long term intracranial recording in intractable partial epilepsy reveals:
 - a. Slow modulation of high-frequency activity (40–140 Hz) is a measure of pre-ictal activity
 - b. High-frequency oscillations (80–500 Hz)
 - i. More frequent in the seizure-onset zone (SOZ)
 - ii. Linked to seizure genesis
 - iii. More reliable for localization of seizure onset areas than prediction of seizures
2. Immune Mechanisms in Epilepsy
 - a. Inflammatory processes have been associated with seizures:
 - i. Neuro-inflammation has been demonstrated in epileptic brain autopsy material
 - ii. Systemic inflammation may increase discharge in epileptic neurons by loss of potassium or glutamatergic homeostasis
 - b. Effects of systemic inflammation may be mediated by loss of blood-brain barrier (BBB) function:
 - i. Vascular endothelial cell dysfunction
 - ii. Activation of circulating leukocytes
 - iii. Release of mediators that increase vascular permeability

Immune Seizures

1. Rasmussen's Encephalitis
 - a. Pathology demonstrates hemispheric inflammation

- i. CD4⁺ T-cells
 - ii. Microglial activation and nodules
 - iii. Progressive neuronal loss and gliosis secondary to apoptosis
- 2. Seizures from autoimmune disorders:
 - a. SLE
 - b. Celiac disease
 - c. Associated with autoantibodies and increased inflammatory markers
 - d. Response of seizures to immunosuppressive treatment
- 3. Immune-Mediated Seizures:
 - a. Autoantibodies:
 - i. Against neuronal surface proteins on the NMDA receptor
 - ii. The potassium channel complex protein leucine-rich, glioma inactivated 1 (LGI1) protein
 - iii. Glutamic acid decarboxylase (intracellular)
 - iv. Respond to immunosuppressive therapy to some degree

Secondarily Generalized Tonic-Clonic Seizures (SPECT Imaging) Mechanisms

- 1. Single photon emission computed tomography:
 - a. Images cerebral blood flow (CBF)
 - b. CBF is linked to metabolic activity generated by neuronal firing
 - c. SPECT tracer is taken up rapidly after injection (approximately 30 seconds) and does not redistribute

Cortical and Subcortical Network Analysis

- 1. Secondarily generalized tonic-clonic seizures:
 - a. Early increase of tracer in seizure onset zone (SOZ)
 - b. Progressing to bilateral cortical and subcortical network activity
- 2. Pre-generalization phase:
 - a. Focal CBF increase depending on anatomical area involved
 - i. Primarily in the temporal lobe
 - b. Generalization stage:
 - i. CBF increase in the thalamus, basal ganglia, medial cerebellum
 - c. Post-ictal stage:
 - i. Progressive increase of CBF in the cerebellar hemispheres and midbrain
 - d. Cerebellar increased blood flow correlates with:
 - i. Increases of CBF in the midbrain and thalamus
 - ii. Decrease of CBF in the frontoparietal association cortices during and following seizures
- 3. The thalamus and upper brainstem are critical for:
 - a. Synchronization of abnormal cortical and subcortical electrical discharges

- b. Generation of tonic motor firing
 - c. Impaired consciousness
 - d. Seizure generalization
- 4. Cerebellar CBF increases:
 - a. Contribute to seizure termination and suppression
 - b. Purkinje cell output is inhibitory
 - c. Projects via the deep cerebellar nuclei and thalamus to the cortex
 - d. Decreased CBF of the lateral frontoparietal association cortex cingulate gyrus and precuneus comprise:
 - i. Default mode network that is involved with decreased consciousness

Malformations of Cortical Development

Approximately 20% of adult patients that undergo surgical resection for intractable epilepsy have histopathology proven focal cortical dysplasia. This number rises to approximately 50% of children undergoing seizure surgery. Polymicrogyria, heterotopias, and focal cortical dysplasia manifest as discrete areas of abnormal neuronal migration and disruption of anatomical cortical lamination. Intracortical EEG, SPECT, PET, Doppler studies have demonstrated complex cortical and subcortical networks that intake and maintain seizure disorders. Visible MPI, cortical lesions may be just an indicator of the epileptogenic zone rather than its complete substrate.

The recent classification of patients with malformations of cortical developments is based on deficits of normal development and mutations in genes that control the complex patterns of neuronal circuit generation and maintenance. An outline of this classification follows.

Group Ia: Abnormal Neuronal and Glial Proliferation or Apoptosis

- a. Reduced proliferation or accelerated apoptosis
 - i. Congenital microcephaly
 - ii. Increased proliferation or decreased apoptosis (megalencephaly)
 - iii. Abnormal proliferation:
 - 1. Focal and diffuse dysgenesis and dysplasia

Group Ib: Cortical Dysgenesis with Abnormal Cell Proliferation

This component of Group 1 is particularly important for normal cortical development and seizures:

- 1. The mammalian target of rapamycin (mTOR)
 - a. Causes increased cell growth, ribosome biogenesis, and messenger RNA translation. This occurs in tuberous sclerosis complex gene mutations in which mTOR is activated
- 2. Focal cortical dysplasia I (FCD I)
- 3. FCD II
 - a. Similar to protein phenotype of the tuberous sclerosis complex

- b. Progenitor proteins of early development are found in the dysplastic tissue
- c. Similar to multipotent or pluripotent stem cells
- d. Evidence that seen balloon cells may originate from glioneuronal progenitor cells (radial glial cells)

Group II: Malformations due to abnormal neuronal migration

1. Subcategories:

- a. Neuro ependymal (ventricular epithelium)
 - 1. Periventricular nodular heterotopia
 - 2. Defects in the initiation of migration
- b. Abnormalities of transmantle migration:
 - 1. Lissencephaly
 - 2. Subcortical heterotopia
 - 3. Defects in terminal migration/pial limiting membrane (cobblestone malformations)

Group II A: Heterotopias

Major Forms:

- 1. Periventricular nodular heterotopia
 - a. Most common
- 2. Periventricular linear heterotopia
 - a. Gray matter (smooth) lining the ventricular wall
- 3. Columnar heterotopia
 - a. Linear aggregation of neurons (ependymal to pia)
- 4. Subcortical heterotopia
 - a. Curvilinear aggregation of neurons from deep sulci through the cortical mantle

Group II B: Lissencephaly

- 1. Malformations due to abnormal transmantle migration
 - a. Agyria
 - b. Pachygyria
 - c. Subcortical band heterotopia
- 2. Mutations in the TUBA1A gene
 - a. Dysgenesis involves the cortex, corpus callosum, basal ganglia/white matter, and midbrain
 - b. Specific mutations of the gene are identical to LIS mutations
 - 1. Frontal pachygyria and posterior agyria
 - 2. Complete agyria

Group II C: Subcortical Heterotopia and Sub-Lobar Dysplasia

- 1. Malformations in which aggregates of neurons accrue in deep cerebral white matter
- 2. They include:
 - a. Transmantle (columnar heterotopia)
 - b. Curvilinear aggregates of neurons
 - c. Multiple nodules in deep white matter
 - d. Sublobar dysplasia

Group II D: Cobblestone Malformations

- 1. Mutations in genes involved in:
 - a. O-glycosylation of dystroglycan
 - b. Phenotypic variations of eye, muscle, brain disease
- 2. Defective formation of basement membranes of skeletal muscle, retina, cerebrum and the cerebellum
 - a. Impaired linkage of radial glia to the pial basement membrane

- b. Deficiency of cerebral basement membrane (BM) that causes:

- 1. Abnormal lamination
- 2. Over migration of neurons through the BM

Group III A: Polymicrogyria and Schizencephaly

- 1. The cause is heterogeneous
- 2. Four subcategories:
 - a. Schizencephalic clefts or calcification
 - 1. Infection or vascular etiology
 - b. Group III b:
 - 1. Genetic and vasculature disruption
 - c. Group III c:
 - 1. Genetically defined multiple congenital anomaly syndromes
 - d. Group III d:
 - 1. In conjunction with in-born errors of metabolism

Group III C: Focal Cortical Dysplasia

- 1. Malformations of abnormal postmigrational development
- 2. Associated with prenatal and perinatal insults
- 3. Focal cortical dysplasias III (FCD III) are associated with:
 - a. Injuries
 - b. Vascular malformations
 - c. Tumors

There are many other causes of epilepsy not reviewed in this brief outline that include:

- 1. Specific genetic syndromes
- 2. Glia buffering defects that are pivotal for ion and glutamate hemostasis
- 3. Neuroplasticity of neuronal circuits
- 4. Network imbalance of excitation and inhibition
- 5. The role of epigenetics

Introduction to Epileptic Seizures

Definition of Seizure by Gordon Holmes

A seizure as defined by the eminent British neurologist Gordon Holmes is a sudden involuntary time limited attenuation in function, secondary to an abnormal discharge of neurons in the central nervous system. Seizures may be congenital (genetic mutations in ion channels and subunits or migrational defects) or to an acute systemic process or focal neurologic lesions. Idiopathic seizures have no known underlying definitive cause. Genetic sequencing advances and high strength MRI magnets are rapidly revealing mutations and various migrational defects which are rapidly shrinking the percentage of truly idiopathic patients. The study of epigenetics (gene regulation) will certainly further our understanding of many epilepsies.

Epileptic Seizures

- 1. Discrete epileptic events due to transient hypersynchronous abnormal neuronal discharges
- 2. Epilepsy: Recurrent unprovoked seizures

General Epidemiology

1. Overall incidence:
 - a. 40–70 patients per 100,000 people in developed countries
2. Single seizure:
 - a. 0.5%–3% of the population over a lifetime
3. Greatest incidence occurs during the first year of life
4. Western Europe and the USA:
 - a. By the age of 20, 1–3% of children may have had a seizure. Approximately 25% of these patients will develop epilepsy
 - b. 80% of these children are seizure free within five years; often by one year
 - c. Approximately 20–30% of newly diagnosed epilepsy patients will develop medically refractory seizures (most often partial complex seizures from the temporal lobe)
 - d. There is a secondary rise in seizure incidence after 60 years (primarily due to vascular diseases)
5. Risk factors for the development of epilepsy:
 - a. Genetic predisposition
 - b. Specific syndrome
 - c. Cognitive impairment
 - d. Perinatal disorders
 - e. Cerebral palsy (intrauterine stroke, infection, malformation)
 - f. Cerebrovascular disease
 - g. Neoplasm
 - h. Infection of the CNS
 - i. Neurodegenerative disease
 - j. Drug abuse

The major problems in the epilepsies suffered by adult patients are complex partial seizures and major motor seizures. Occasionally, primary childhood seizure types extend into adolescence and adulthood and will be discussed. Congenital and primarily pediatric seizures will not be discussed in detail, but may be mentioned for completeness.

International Classification of Epilepsies, Epileptic Syndromes, and Related Seizures Disorders

1. Localization-related (focal, local, partial)
 - a. Idiopathic (primary)
 - i. Benign childhood epilepsy with centrotemporal spike
 - ii. Childhood epilepsy with occipital paroxysms
 - iii. Primary reading epilepsy
 - b. Cryptogenic defined by:
 - i. Seizure type
 - ii. Clinical features
 - iii. Etiology
 - iv. Anatomical localization
 - c. Symptomatic (Secondary)
 - i. Temporal lobe epilepsies
 - ii. Frontal lobe epilepsies

- iii. Parietal lobe epilepsies
 - iv. Occipital lobe epilepsies
 - v. Chronic progressive epilepsies partials continua of childhood
 - vi. Syndromes characterized by seizures with specific modes of precipitation
- d. Undetermined epilepsies both generalized and focal seizures
 - i. Neonatal seizures
 - ii. Severe myoclonic epilepsy in infancy
 - iii. Epilepsy with continuous spike-waves during slow-wave sleep
 - iv. Acquired epileptic aphasia (Landau Kleffner syndrome)
 - v. Other undetermined epilepsies without unequivocal generalized or focal features

Generalized Epilepsies

1. Benign neonatal familial convulsions
2. Benign neonatal convulsions
3. Benign myoclonic epilepsy in infancy
4. Childhood absence epilepsy
5. Juvenile absence epilepsy
6. Juvenile myoclonic epilepsy
7. Epilepsies with grand mal seizure on awakening
8. Other generalized idiopathic epilepsies
9. Epilepsies with seizures precipitated by specific modes of activation
10. Cryogenic or Symptomatic:
 - a. West syndrome (infantile spasms)
 - b. Lennox-Gestaut syndrome
 - c. Epilepsy with myoclonic-astatic seizures
 - d. Epilepsy with myoclonic absences
11. Non-specific Etiology
 - a. Early myoclonic encephalopathy
 - b. Early infantile epileptic encephalopathy with suppression burst
 - c. Other symptomatic generalized epilepsies
 - d. Specific Syndromes:
 - i. Epileptic seizures many complicate many disease states
12. Special Syndromes-Situation-related Seizures
 - a. Febrile convulsions
 - b. Isolated seizures or isolated status epilepticus
 - c. Seizures occurring only when there is an acute or episodic event due to alcohol, drugs, eclampsia or non-ketotic hypoglycemia

Definitions

1. Partial Seizure
 - a. The first clinical and/or EEG changes indicate initial involvement of one hemisphere
 - b. Classification depends on impairment of consciousness:
 - i. Simple partial: no impairment of consciousness

- ii. Complex partial: impairment of consciousness
- iii. Partial with secondary generalization
- 2. Generalized Seizure
 - a. The first clinical and/or EEG changes indicate initial involvement of both hemispheres
 - b. Conscious is impaired (rare exceptions) with the following seizure categories:
 - i. Tonic-clonic
 - ii. Absence
 - iii. Clonic
 - iv. Myoclonic
 - v. Tonic
 - vi. Ataxic
- 3. Unclassified
 - a. Some neonatal syndromes
- 4. Epileptic Syndromes
 - a. Heterogeneous groups of disorders with specific manifestations. The classification is based on:
 - i. Cluster of signs and symptoms
 - ii. Seizure type
 - iii. Age at onset
 - iv. EEG evaluation
 - v. Prognosis
 - vi. Response to medications

Video EEG Monitoring of Refractory Seizures

Information that correlates EEG evaluations with clinical signs and symptoms has been determined primarily by prolonged video EEG. Utilization of the technique for guidance in seizure surgery, demonstrate that the ictal onset zone, which at time was found to be distinct from the cortical areas that produce clinical signs and symptoms (symptomatogenic zone).

Semiology of Generalized Tonic-Clonic Seizures

- 1. Phase I
 - a. Simple partial seizure with preserved consciousness; the initial cortical activation and produces the aura
 - b. Generalized idiopathic seizures may have auras (correlated with focal cortical hyperexcitability)
- 2. Phase II
 - a. Four alternative semiology's dependent on whether the seizure was localization-related or primary generalized
 - i. Complex partial pattern
 - ii. Tonic
 - iii. Clonic
 - iv. Absence
- 3. Time course of phase I and II varied between 10 seconds to 4 minutes
- 4. Phase III
 - a. Brief period between antecedent 2 phases is the induction of the generalized seizure
 - b. Clinical manifestations include:

- i. Vocalization
- ii. Head version (may also be seen variably with IGE) a marker of contralateral BA10 eye field activation

Phase IV

- a. Brief period of irregular and asymmetric irregular clonic jerking

Phase V

- a. Sustained contraction of all voluntary musculature (tonic posture) with minimal clonic jerking

Phase VI

- a. Tremulousness or the "vibratory" clonic phase

Phase VII

- a. Main clonic phase
 - i. In localization-related epilepsy the clonic jerking may end asymmetrically on the ipsilesional hemispheric side

Duration of phases

- 1. Phase III – 9.5 seconds
- 2. Phase IV – 8.5 seconds
- 3. Phase V – 18.5 seconds
- 4. Combined phase VI and VII – 43.5
- 5. Almost all seizures end before 2 minutes; rarely all 5 phases were noted, but phases VI and VII are most consistent

Additional Characteristics of Generalized Tonic-Clonic Seizures (Localization Related with Secondary Generalization)

- 1. Prodrome (prior to phase I)
 - a. Extreme fatigue several days to one week prior to seizure onset
 - b. Increase of nocturnal myoclonic jerks
 - c. Mood change (usually depression)
 - d. Increased irritability
- 2. Phase II (tonic phase)
 - a. Tonic contraction of axial musculature and limbs
 - b. Upward eye deviation
 - c. Pupillary dilatation
 - d. "Epileptic cry":
 - i. Sudden contraction of intercostal muscles forcing air through the larynx
 - e. Tongue and jaw contracture:
 - i. Lateral tongue biting (side opposite a focal lesion)
- 3. Phase II (clonic phase)
 - a. Gradual onset
 - b. Low amplitude of clonic activity
 - c. Builds to frequency of 8 jerks per second with increasing amplitude that then decreases to four jerks/second
 - d. Atonic inhibition
 - i. Loss of continence
 - ii. Atonia of somatic muscle
- 4. Post-ictal events
 - a. Post-ictal sleep (variable; minutes to one hour)
 - b. Confusion on awakening (minutes to one hour; may last far longer)

- c. Dull pounding headache (occipital predominant)
- d. Todd's paralysis (may be due to an underlying structural lesion)
- e. Lateral tongue biting (side opposite the lesion)
- f. Soreness of the paraspinal and leg extension muscles
- g. Rare bilateral posterior dislocation of the shoulders (younger patients)
- h. Fracture of thoracic vertebrae (older patients)
- i. Increased blood pressure (during the seizure)
- j. Hyperhidrosis for minutes to hours (ANS activation)
- k. Temperature to 101 degrees F (sustained seizure; induced muscular activity)
- l. CSF up to 100 neutrophils/mm³ (dural movement/irritation)
- m. Post-ictal psychosis (fighting constraints)
- n. Myoglobinuria and renal failure (prolonged seizure)
- o. Briefly arouseable and then falls back to sleep
- p. Rare maintenance of trismus and opisthotonus
- q. Increased prolactin levels (temporal lobe seizures)

Rare Sequela:

- 1. Neurogenic pulmonary edema
- 2. Cardiac arrhythmias (EKG abnormalities)
- 3. Bleeding from the first portion of the duodenum (through and through penetrating ulcer)
- 4. Myoglobinuria with renal failure
- 5. Severe acidosis (pH < 7.0)
- 6. Posterior shoulder dislocation
- 7. Sudden unexplained death (SUDEP)

Progression of Signs and Symptoms of GTC Seizures (localization-related with secondary generalization):

- 1. Aura or focal motor signs signal seizure onset at a cerebral locus
- 2. Loss of awareness with automatisms (limbic involvement)
- 3. Contralateral extremity posturing (centripetal spread to basal ganglia)
- 4. Generalization to clonic-tonic activity:
 - a. Initially contralateral face or extremities are involved followed by ipsilateral involvement

Differential Diagnosis of Causes of GTCS

Monogenetic Causes

General Principals

- 1. Ion channelopathies may disrupt the balance between excitatory glutamatergic and inhibitory GABA-ergic transmission:
 - a. Leads to hyper-synchronization of cortical networks
 - b. Mutations primarily affect the principal or auxiliary subunits
 - c. Axonal initial segment may be involved and contain Na, K, and GABA receptors
 - d. Mutations may affect:
 - i. Developmental regulation of expression of the ion channel

- ii. Subunit composition
- iii. Auxiliary subunit interactions
- iv. Membrane compartmentalization

SCN1A Mutations

- 1. Most common epileptogenic ion channel mutation
- 2. Encodes the Na α 1 subunit
- 3. Loss of function, decreased excitability of fast-spiking GABA-ergic neurons
- 4. Febrile seizure plus (GEF+) as well as severe myoclonic epilepsy of infancy (Dravet's syndrome)
- 5. Missense mutation is most common
- 6. Reduced fast-spiking in GABA-A neurons and, therefore, loss of inhibition

SCN1B Mutation

- 1. Encodes the Na β , subunit
- 2. Associated with:
 - a. GEF+
 - b. Dravet's syndrome (DS)
 - c. Temporal lobe epilepsy
 - d. None-febrile absence seizures
- 3. Decreased ability to modulate Na v 1.1 channel gating

SCN2A Mutations

- 1. Encode Na v 1.2 channel
- 2. Expressed in excitatory pyramidal neurons
- 3. Associated with a spectrum of epilepsies
 - a. Benign familial neonatal, infantile seizures
 - b. Intractable childhood partial and generalized epilepsies
 - c. Dravet's syndrome (DS)
 - d. Infantile spasms
 - e. Mechanisms include:
 - i. Shift of activation and inactivation thresholds of involved neurons
 - ii. Reduced levels of channel proteins in the plasma membrane

Potassium Channel Mutations

- 1. Mutations of KCN Q2 (encoding K v 7.2) or KCNQ3 (encoding K v 7.3)
 - a. Linked to AD benign familial neonatal convulsion
 - b. Generalized epileptic syndromes
 - c. Clinical remission within weeks or months
 - d. Sequence variations of KCNQ2 and KCNQ3 genes are associated with:
 - i. Rolandic epilepsy without neonatal seizures
 - ii. Idiopathic generalized epilepsy
 - iii. Early onset epileptic encephalopathy with multifocal drug-resistant seizures responsive to adrenocorticotrophic hormone
- 2. KCNA1 Mutations
 - a. Encodes the K v 1.1 channel
 - b. Associated with:
 - i. Episodic ataxia type 1

- ii. Neuromyotonia and seizures
- iii. KCMNA1 gene mutations:
 - 1. Linked to generalized epilepsy
 - 2. Paroxysmal dyskinesia
 - 3. Rapid repolarization of action potentials that allow faster neuronal firing
- iv. KCNJ1 gene mutations
 - 1. Encodes K_v (involved trafficking)
 - 2. ABCC8 gene mutation:
 - a. Encodes its regulatory sulfonylurea receptor 1 subunit
 - b. Linked to a syndrome that includes:
 - i. Developmental delay
 - ii. Epilepsy
 - iii. Neonatal diabetes
- v. KCNF10 mutations:
 - 1. Encodes the glial K_r 4.1 channel
 - 2. Expressed in astrocytic end-feet
 - 3. Decreased extracellular K^+ buffering
 - 4. Linked to syndrome that includes:
 - a. Epilepsy
 - b. Ataxia
 - c. Sensorineural deafness
 - d. Tubulopathy
- vi. KCTD7 (potassium channel tetramerization domain-containing protein)
 - 1. Maintains the resting membrane potential; reduces cell excitability
 - 2. Syndrome that includes:
 - a. Progressive myoclonic epilepsy
 - b. Opsoclonus/myoclonus/ataxia syndrome
 - c. Infantile-onset neuronal ceroid lipofuscinoses subtype (CLN14)

Calcium Channelopathies

- 1. Associated with epilepsy mediated by:
 - a. Loss of function of $Ca_v2.1$ (P/Q) channels
 - b. Gain of function of $Ca_v3(T)$ channels
 - c. Linked to generalized epilepsy
 - d. Generalized spiked and wave absence epilepsy

CACNA1 Gene Mutation

- 1. Mutation affects the pore-forming $\alpha 1$ subunit or auxiliary B4 subunits
- 2. Absence epilepsy phenotype with spike-and-wave EEG pattern:
 - a. Reflects enhanced T channel triggered burst firing and synchronization of thalamocortical projection neurons
 - b. Or loss of $Ca_v2.1$ channels in fast-spiking GABA-ergic neuron that would increase excitability of cortical neurons

CACNB4 Mutations

- 1. Linked to idiopathic generalized epilepsy and episodic ataxia

$Ca_v3(T)$ Channel Mutations

- 1. Linked to absence (“spike-and-wave”) epilepsy

CACNA1H Variants

- 1. Encodes $Ca_v3.2$ channels
- 2. Linked to:
 - a. Childhood absence epilepsy
 - b. Juvenile absence epilepsy
 - c. Juvenile myoclonus
 - d. Febrile seizures
 - e. Temporal lobe epilepsy

HCN Channel Mutations

- 1. HCN2 mutation
- 2. Linked to generalized epilepsy
- 3. Dendritic HCN channels reduces EPSP and IPSP amplitudes
 - a. Stabilizes the membrane potential

Metabolic Causes of (Generalized Tonic-Clonic Seizures) GTCS

- 1. Hypoglycemia
 - a. Cerebral spinal fluid sugar is approximately 2/3 of blood sugar. In general, patients may have seizures when the CSF sugar is less than 30 mg/dl. This usually occurs when the peripheral blood sugar is 40–60 mg/dl. The rate at which the sugar falls may also be a determinant if a seizure will be provoked. As the blood sugar decreases, a noradrenergic response causes hunger, piloerection, hyperhidrosis, tremulousness and abnormal behavior. If the peripheral sugar falls to below 30 mg/dl, a parasympathetic discharge occurs that may be associated with salivation, bradycardia and coldness (97 degree F)
- 2. Hypocalcaemia:
 - a. The usual setting is renal failure with secondary hypoparathyroidism or renal tubular acidosis
 - b. Muscle fasciculations occur spontaneously or may be evoked by mechanical stimuli
 - c. Peripheral nerves may discharge to mechanical stimuli Chovstek’s sign (VIIth nerve percussion) or to ischemia (Trousseau’s sign).
 - d. Long QT interval; non-specific T wave change on EKG (may also occur from seizures)
- 3. Hypomagnesia
 - a. Often occurs concomitantly with hypocalcaemia
 - b. Secondary to prolonged enteral feeding
 - c. Burn patients
 - d. Clinically similar to hypocalcaemia
 - e. EKG changes; long AT interval and non-specific T wave changes
- 4. Uremia
 - a. Blood urea nitrogen (BUN) between 90–120 mg/dl but very variable

- b. Following rapid osmotic shifts (post dialysis)
 - c. Need to r/o cerebral vascular disease:
 - i. Ischemic stroke of large and small blood vessels; calcification of large blood vessels occurs with renal failure
 - ii. Embolic stroke; higher incidence of infective endocarditis (lines and shunts)
 - iii. Intracranial hemorrhage:
 1. Uremic thrombocytopenia
 2. Hypertensive hemorrhage
 3. Incomplete reversal of anticoagulation (following hemodialysis; with protamine sulfate)
 4. Subarachnoid hemorrhage (platelet dysfunction; combination of pathologies)
 5. tPA for thrombolysis of blocked shunt
 6. Infection (Staph aureus, gram-negative bacilli, HIV)
 7. Seizures are often short
 8. Pupillary abnormalities (dilated) and often associated with ischemic optic neuritis, (pallor with loss of the optic cup)
5. Hepatic Failure
- a. Usual clinical features are confusion, asterixis, hyperactive reflexes
 - b. Rarely focal neurologic signs
 - c. Seizures often from underlying illness or hypoglycemia
 - d. Hepatic encephalopathy and seizures:
 - i. From many anticonvulsants
 - ii. Dilantin (Steven Johnson's syndrome, arteritis with lobar hepatic infarction)
 - iii. Carbamazepine
 1. Seizures may occur from inappropriate antidiuretic hormone secretion; exacerbation of sodium channelopathies
 - iv. Valproic Acid (VPA)
 1. May induce hyperammonemia without hepatic failure
 2. Combination antiepileptic drugs (AEDs) exacerbate and induce hepatic encephalopathy
 3. Clinical features of VPA-induced encephalopathy:
 - a. Acute onset of impaired consciousness
 - b. Focal neurologic signs
 - c. Increased seizure frequency (in an epileptic patient)
 - d. EEG; pronounced slowing and increased epileptiform discharges
6. Hypernatremia
- a. Seizures are dependent on the rate at which serum sodium decreases
 - b. Seizures occur at levels less than 110 meq/ml
 - c. Hyperreflexia and generalized weakness
 - d. "Finger print sign" (intracellular edema); pressure elicits finger print when tissue compressed against bone
7. Acute intermittent porphyria
- a. Major motor seizure occurs from:
 - i. Porphyrins
 - ii. Concomitant inappropriate ADH (low serum sodium)
 - iii. Abdominal pain, motor neuropathy with wasting, hyperactive ankle jerks in the face of general hyperreflexia and PRES
8. Inappropriate ADH
- a. Usual serum sodium is between 120–130 meq/dl
 - b. Initiated by:
 - i. Head trauma
 - ii. Metabolic abnormalities (AIP, hypothyroidism)
 - iii. Drugs (carbamazepine)
 - iv. Paraneoplastic (squamous cell of the lung)
 - v. Intracranial surgery
 - c. Confusion, generalized seizures, hyperreflexia
9. Hyperosmotic states:
- a. Non-ketotic diabetic coma:
 - i. Blood sugar often between 2000–3000 mg/dl
 - ii. Occurs in type II diabetes following infection (frequently)
 - iii. Associated with confusion, segmental myoclonus, generalized seizures, asterixis
 - b. Renal failure
 - c. Hyperlipidemia
 - d. Insufficient free water with PEG or other internal feeding methods
10. Pulmonary failure:
- a. $p\text{CO}_2 > 70$ torr; $p\text{O}_2 < 80$ torr
 - b. Clinical manifestations:
 - i. Dilated optic veins, suffused optic disc with papilledema
 - c. Asterixis (failure to maintain extensor posture)
 - d. Fasciculation and muscle hyperexcitability
 - e. Generalized seizures

Drugs/Toxin-Associated Features with GTCS

1. Specific features of different drugs and toxins:
 - a. Methanol: hemorrhagic optic neuritis
 - b. INH: hyperthermia, hyperglycemia
 - c. Phenothiazine; hyper or hypothermia, small pupils
 - d. Insulin: severe hypoglycemia
 - i. Used by medical personnel for malingering
 - e. Anesthetics
 - i. Propofol
 - ii. Halothane
 - iii. Enflurane
 - iv. Sevoflurane
 - f. Theophylline (jitteriness)
 - g. Amphetamines: psychosis, wasting
 - h. Tricyclic antidepressants: parasynpathomimetic effects, hyperthermia, cardiac arrhythmia
 - i. Lithium: tremor, myoclonus

- j. Cocaine:
 - i. Hypertension with cerebral hemorrhage
 - ii. Cerebral and coronary vasospasm (may be delayed)
 - iii. 20% of hemorrhages due to underlying vascular malformation
- k. Heroin:
 - i. Pulmonary edema
 - ii. Transverse myelitis
 - iii. SBE with mycotic aneurysm (IV administration)
- l. PCP:
 - i. Hallucinations
 - ii. Dilated pupils
 - iii. Severe rotary and up beating nystagmus
 - iv. Self-destructive behavior
- m. Anticonvulsants:
 - i. Liver failure
 - ii. Ophthalmoplegia (phenytoin)
 - iii. Focal neurological signs (Phenobarbital)
- n. Penicillin
 - i. Large IV doses in a setting of renal failure
- o. Alcohol withdrawal:
 - i. Hypothalamic disinhibition with primarily adrenergic manifestations
 - ii. Delirium tremens

Infections Associated with GTCS

1. Cortex must be involved to initiate GTCS
2. Diffuse inflammation of the meninges and spread of infection to the arachnoid, pia mater and through Virchow-Robin spaces
3. Cortical strokes with GTCS occur with:
 - a. Tuberculosis (endarteritis, meningeal involvement)
 - b. Cryptococcosis (meningeal; spreads through Virchow-Robin spaces; cysts in the basal ganglia)
 - c. Mucormycosis (sinus spread), ophthalmoplegia, black palate; immunosuppressed patients
 - d. Aspergillus: (venous spread); lung abscess; head and neck surgery
 - e. Listeria: pregnant women; lesions in the dorsal pons
 - f. HIV: direct endothelial involvement; opportunistic organisms (when CD4 count < 200 cells/mm³)
 - g. Syphilis (proliferative endarteritis; often with brainstem involvement; associated with HIV (has telescoped pattern-all three stages overlap)
 - h. Subacute bacterial endocarditis (SBE): mycotic aneurysms, arteritis and late focal cortical hemorrhage
 - i. Cysticercosis: multiple cortical calcified cysts; partial and secondarily generalized seizures
 - j. Toxicaria (toxocara canis): primarily seizures in children
 - k. Malaria (microvascular cortical vascular damage)
 - l. Chagas disease (myocardial failure with emboli; esophageal echolalia)

Common Causes of GTCS

1. Often are acute symptomatic without reoccurrence:
 - a. Vascular (infarction, hemorrhage, malformation)
 - b. Head injury (acute or remote)
 - c. Venous infarction (post-partum)
 - d. Tumor (primary and metastatic)
 - e. Prior cortical scar (in the setting of sleep deprivation or metabolic dysfunction)
 - f. Prior stroke (occur in at least 10% of stroke patients)
 - g. Anticonvulsant withdrawal
 - h. Alcohol withdrawal

Precipitating Factors for GTCS

1. Failure of drug compliance
2. Sleep deprivation
3. Metabolic dysfunction
4. Cortical scars
5. Specific drugs that cause seizures
 - a. Cocaine
 - b. Amphetamines
 - c. High doses of penicillin (setting of renal failure)
 - d. Phenothiazine (particularly if there is a structured lesion)
 - e. Antidepressants
 - f. Phosphodiesterase inhibitors (asthma)
 - g. Antihistamines
6. Hypoglycemia (missing breakfast then administering insulin in a diabetic)

Differential Diagnosis of GTCS by Age

1. Adolescent:
 - a. Genetic (channelopathy; Na, K, Calcium, HCN-rare)
 - b. GTCS upon awakening
 - c. Syndrome (tuberous sclerosis complex)
 - d. Noncompliance with drug therapy for localization-related seizures
 - e. Metabolic (hypoglycemia)
 - f. Drugs (cocaine, amphetamine, PCP, barbiturates, alcohol)
 - g. Vascular (infarction, embolus, hemorrhage, malformations)
 - h. Component of autoimmune diseases (vasculitis)
 - i. Encephalitis (herpes simplex)
 - j. Head injury
 - k. Hippocampal sclerosis with secondary generalization
 - l. Mitochondrial disease (MERRF); Kearns-Sayre syndrome
 - m. Migration disorders (nodular and band heterotopias; cortical micro-dysgenesis)

Adult Under 40 Years Old

1. Epilepsy with grand mal on awakening:
 - a. Occurs shortly after awakening regardless of the time of day

- b. Triggered by sleep deprivation
- c. Manifests in the second decade
- d. At 40 years after onset >50% are seizure free for >5 years
- e. Age at presentation determines prognosis; younger the patient at onset worse prognosis
- f. Risk-taking behavior and frontal lobe dysfunction undetermined as different or similar to juvenile myoclonic epilepsy
- 2. Lack of AED compliance
- 3. Illicit drugs (cocaine and amphetamines)
- 4. Vascular (ischemic, embolic hemorrhagic stroke)
- 5. Tumor (primary > than metastatic)
- 6. Metabolic
- 7. Medications
- 8. Alcohol withdrawal
- 9. HIV (associated opportunistic infection)
- 10. Encephalitis (herpes simplex)
- 11. Complication of autoimmune disease (SLE)
- 12. Head injury
- 13. Cardiac arrhythmia (global cerebral ischemia)
- 14. Migrational disorders
- 15. Syndrome

Adults over 40 Years of Age

- 1. Lack of drug compliance
- 2. Localization-related with secondary generalization (partial complex seizure)
- 3. Vascular: embolus > infarction > hemorrhage
- 4. Metabolic causes
- 5. Tumor (metastatic > primary)
- 6. Drugs (illicit; hypnotic sedatives, withdrawal)
- 7. HIV (associated opportunistic infection)
- 8. Herpes simplex infection (temporal and frontal lobe involvement with secondary generalization)
- 9. Migrational disorders

Adult over 60 Years of Age

- 1. Vascular: ischemic > embolic > hemorrhagic
- 2. Cardiac arrhythmia
- 3. Metabolic dysfunction
- 4. Prior CNS structural lesion
- 5. Tumor (meningioma > metastatic > glioma or lymphoma)
- 6. Herpes simplex encephalitis
- 7. Migrational disorder (rarely)

Absence Seizure

- 1. Reciprocal connections between neocortical pyramidal neurons, thalamus reticular neurons, and the thalamocortical projection neurons are the anatomical basis
- 2. Patterns of oscillatory activity of this circuitry determine absence seizures or normal wakefulness
- 3. The pattern of thalamocortical activity is determined by the balance between T and P/Q activation and GABA-ergic discharge within the thalamus

- 4. General Clinical Features:
 - a. Onset between 3–6 years of age
 - b. Most prevalent in first ten years of life
 - c. Rarely persist into adulthood
 - d. Seizures are less than 30 seconds
 - e. Not associated with aura or post-ictal confusion
- 5. Clinical Types:
 - a. Simple typical absence:
 - i. Sudden onset of impaired consciousness associated with absence of facial expressions and without motor or behavioral manifestation
 - ii. Approximately 10% of absence seizure patients
 - b. Complex absence seizure:
 - i. Associated motor or behavioral change
- 6. Clinical Manifestations:
 - a. Sudden onset of a blank stare
 - b. Onset of motor activity
 - c. Clonic components: eye blinking, nystagmus, rapid arm jerking
 - d. Tonic postural contraction causing flexion or hyper-tonic extension postures
 - e. Loss of tone causes head nodding or dropping of objects
 - f. Patients rarely fall
 - g. Automatism:
 - i. These are semi-purposeful moments and behaviors which the patient cannot recall. They are perservative or de novo:
 - 1. De novo: Simple acts such as hand rubbing, licking the lips, chewing, scratching, picking at clothes
 - 2. Perservative: dealing cards, handling an object or playing a hand game
 - 3. Speech is usually dysarthric, but may be normal or preservative
 - h. Autonomic manifestations:
 - i. Pupillary dilatation
 - ii. Hyperhidrosis
 - iii. Salivation
 - iv. Piloerection
 - v. Urinary incontinence

EEG

- 1. Generalized 3 Hz spike-and-wave pattern

Atypical Absence Seizures

- 1. Onset prior to age 5
- 2. Associated with other seizure types, GTCS, myoclonic, tonic and typical absence and cognitive impairment
- 3. Average seizure is longer than typical absence; onset is less abrupt
- 4. Diminished postural tone
- 5. Automatisms are more often perseverative
- 6. Postural tone changes frequently
- 7. Blank stare or change of facial expression greater than typical absence seizure
- 8. Smiling automatism is frequent

EEG Evaluation

1. 1.4–2.5 Hz spike-and-wave discharges
2. Multiple spike-and-wave discharge that are irregular or asymmetrical
3. Interictal EEG is often slow and demonstrates multifocal epileptiform features

Absence Syndromes

1. Epileptic encephalopathy:
 - a. Severe brain disorders of early age
 - b. Manifest electrographic EEG paroxysmal activity
 - c. Multiform and intractable seizures
 - d. Progressive cognitive, behavioral and neurological dysfunction
 - e. Assumption that epileptic activity during maturation may be causative of neurological deficits
 - f. Tendency to abate in adolescence but with severe residual neurologic deficits
2. Classification of the International League Against Epilepsy of the following syndromes have been designated:
 - a. Early myoclonic epilepsy (neonatal)
 - b. Ohtahara syndrome (neonatal)
 - c. West syndrome (infancy)
 - d. Dravet syndrome (infancy)
 - e. Myoclonic status in non-progressive encephalopathy (childhood)
 - f. Lennox-Gastaut syndrome (childhood)
 - g. Landau-Kleffner syndrome (childhood)
 - h. Epilepsy with continuous spike-and-wave during slow-wave sleep in childhood and adolescence

Other Syndromes That Are Similar Include

1. Migrating partial seizures in infancy
 2. Severe epilepsy with multiple independent spike foci
- The infantile and childhood forms of primarily absence and myoclonic seizures will not be discussed further.

Juvenile Myoclonic Epilepsy

1. Seizure onset is in adolescence
2. All have myoclonus; 90% have GTCS and approximately 1/3 absence status
3. Myoclonic jerks frequently the earliest sign
4. GTCS and myoclonic seizures occur upon awakening
5. Fewer retropulsive movements
6. May be features of focal epilepsy in the seizure semiology
7. EEG features:
 - a. Predominance of 4–6 Hz polyspike waves
 - b. In approximately 30% of patients, there are focal abnormalities
8. Mutations in CACN1A; CACNB4; CACNA1H genes

Juvenile Myoclonic Epilepsy of Teens

1. Starts between 12–18 years of age (few patients start in the late 20's)

2. Genetics: associated genes are: CACNB4, CASR, GABRA1, GABRD and Myoclonin 1/EFHC1
3. Early morning: mild to moderate myoclonic jerks of the neck, shoulders and arms
4. Myoclonic jerks may culminate in GTCS; 1/3 of patients suffer absence attacks
5. Seizures are precipitated or increased by awakening, fatigue, alcohol or recreational drugs, reading, writing or cognitive activities
6. EEG evaluation:
 - a. Interictal 3.5–6 Hz irregular spike-and-wave complexes
 - b. Rapid 10–16 Hz spikes followed by irregular slow waves are noted during the myoclonic seizures
 - c. JME persists for life
 - d. Drinking on the weekend in adults may initiate myoclonic seizures with GTCS on Monday morning

Pathology of Juvenile Myoclonic Epilepsy

1. Alterations of mesial frontal connectivity by fMRI and diffusion tensor imaging (DTI)
2. Morphometric abnormalities of medial frontal gray matter; micro-dysgenesis or regional neuronal loss
3. Increased measure of microstructural connectivity between the prefrontal cognitive network (pre-SMA) and the motor system appear pivotal
4. Three mutation-harboring genes for myoclonic epilepsy (JME)
 - a. GABA receptor alpha1 (GABARA1) on chromosome 5q 34–q35 (French Canadian family)
 - b. Chloride channel gene
 - i. Chromosome 3q26
 - ii. German family
 - iii. EFHC1
 1. Hispanic family of native American and European ancestry from California and Mexico
5. Patients with HLA-B 1502 who have taken Tegretol have suffered:
 - a. Stevens-Johnson syndrome
 - b. Primarily Indian and Asian patients

Neuroimaging

1. Routine MRI and CT are negative
2. PET reveals metabolic and neurotransmitter changes in the dorsolateral prefrontal cortex (DLPFC)
3. H-magnetic resonance spectroscopy reveals:
 - a. Thalamic dysfunction
4. Quantitative MRI:
 - a. Cortical gray matter abnormalities in medial frontal areas near SMA

Epilepsy with Generalized Tonic-Clonic Seizure on Awakening

1. Onset in the second decade
2. 90% of seizures occur on awakening at any time of the day
3. May occur with relaxation at night
4. Associated with absence and myoclonic seizures
5. Mutations found in CLCN2 gene

Absence Status Epilepticus*Clinical Manifestations*

1. Sustained impairment of consciousness
2. Patients are confused
3. Partially responsive and able to perform activities of daily living
4. Facial twitching
5. Eye blinking
6. Staring
7. Automatisms
8. Arm, neck, and facial muscles are involved
9. Rare in adults

Electrical Status During Slow Wave Sleep

1. General Features:
 - a. Present between 1–12 years of age
 - b. Cognitive regression
 - c. Patient may not have clinical seizures
2. EEG Manifestations
 - a. Continuous spike-and-wave during non-REM sleep
 - b. Seizures and EEG abnormalities may disappear during the second decade

Progressive Myoclonic Epilepsy

1. General Features:
 - a. Consist of a group of diseases with myoclonic seizures and progressive neurologic degeneration
 - b. Onset in childhood or adolescence
 - c. Major clinical manifestations:
 - i. Myoclonus
 - ii. Seizures
 - iii. Cognitive decline
 - iv. Progressive neurologic deficit

Epileptic Encephalopathy with a Component of Myoclonic Epilepsy

1. Dravet syndrome
2. Channelopathies
 - a. SCN1A and SCN1B
 - b. CACNA1A, CACNB4, CACNA1H
 - c. GABA, GABRD, GABRG2
3. Severe myoclonic epilepsy in infancy (SMEI)
4. GEFS

Specific Myoclonic Epilepsies*Lafora Body Disease*

1. Genetics:
 - a. AR
 - b. Mutations in the EPM2A or EPM2B genes
 - i. Encode Laforin phosphatase
 - ii. Malin ubiquitin ligase
 - iii. Cytoplasmically active enzymes that regulate glycogen construction

1. The normal is symmetric expansion into a spherical shape (soluble)
- c. Early onset Lafora body disease
 - i. Maps to chromosome 4q 21.21
 - ii. Gene is PRDM8
 1. Encoded protein interacts with Laforin and malin and causes translocation of these two proteins to the nucleus
2. Clinical Manifestations:
 - a. Onset in teenage years; death between 17–24 years in 90% of patients
 - b. Myoclonus:
 - i. Affects any area of the body
 - ii. Startle sensitive
 - iii. Absent during sleep
 - c. Visual hallucinations
 - d. Dysarthria
 - e. Rigidity
 - f. Spasticity
 - g. Generalized tonic-clonic seizures often the presenting features; status epilepticus in terminal stage
 - h. Visual seizures occur in 50% of patients
 - i. Scotoma
 - ii. Simple hallucinations
 - iii. Occipital complex seizures
 - i. Dementia follows seizures in 2–3 years
 - j. Fluctuating course associated with episodes of cortical pseudo-blindness
 - k. Myoclonus becomes increasingly frequent:
 - i. Associated with alteration of consciousness
 - ii. Disinhibited dementia
 - l. Terminally a vegetative state in status myoclonus

Pathology

1. Increased glycogen content in tissue
2. Malformed glycogen molecules (Lafora bodies) accumulate in skeletal muscles, heart, liver, skin and brain
3. Accumulation of polygons is primarily in dendrites in the cerebral cortex, substantia nigra, thalamus, and globus pallidus

EEG

1. Bilaterally synchronous spike-and-wave complexes in association with myoclonic jerks

Clinical Features of Early Onset Lafora Body Disease

1. AD; PRDM8 gene; chromosome 21q 21.21
2. Encoded protein interacts with Laforin and malin; translocates these proteins to the nucleus
3. Present at 5 years with dysarthria, myoclonus, and ataxia
4. Course is typical progressive myoclonic epilepsy; more protracted than infantile neuronal ceroid lipofuscinoses
5. Intermediate in severity between Unverricht-Lundborg disease and Lafora body disease

Unverricht-Lundborg Disease (Progressive Myoclonic Epilepsy Type 1; EPM1)

1. Genetics:
 - a. Mutation in a cysteine protease inhibitor cystatin B (CSTB) gene
 - b. Inhibits cathepsins
2. Clinical manifestations:
 - a. Onset at 6–16 years of age
 - b. Begins insidiously
 - c. Stimulus-sensitive myoclonus
 - d. Tonic-clonic seizures
 - e. Overtime ataxia, incoordination, intention tremor, dysarthria, dysphagia develop
 - f. Neuropsychologic evaluation reveals:
 - i. Emotional lability
 - ii. Depression
 - iii. Cognitive decline
 - g. Skeletal abnormalities include:
 - i. Thickening of cranial bones
 - ii. Thoracic and lumbar spine scoliosis
 - iii. Large paranasal sinuses
 - iv. Arachnodactyly
 - v. Accessory ossicles of the foot

Neuroimaging

1. Alterations in:
 - a. Subcortical white matter
 - b. Thalamocortical projections
 - c. Cerebellum

Pathology

1. Atrophy of medulla, pons and cerebellum
2. Loss of Purkinje cells, dentate and olivary neurons

Neuronal Ceroid Lipofuscinoses

1. Genetics
 - a. A family of AR lysosomal storage disorders
 - b. Disease mutations in 13 gene cause approximately eleven variants
2. Mutation in CLN6; chromosome 15q23
 - a. Results in a variant late infantile form
 - b. Adult-onset form
 - c. Encoded protein (CLN6) is a non-glycosylated membrane protein localized to the endoplasmic reticulum
 - d. Animal models suggest CLN6 protein is involved in extracellular matrix modulation, signal transduction, apoptosis and immune/inflammatory response pathways
3. Autosomal recessive adult NCL is linked to childhood CLN1, CLN5, and CLN6
4. Autosomal dominant
 - a. DNAJC5 gene
5. Accumulation of subunit C of mitochondrial ATP synthase or SAPs A and D in lysosome-derived organelles
6. Interference in intracellular vesicle trafficking and lysosomal function

Clinical Features of Juvenile Variant

1. Onset 5–10 years of age
2. Begins with progressive visual loss
3. Pigmentary degeneration of the retina
4. Death by the end of the second decade

Adult Variant (Kuf's Disease)

1. Onset in third or fourth decades
2. Progressive dementia
3. Seizures
4. Myoclonus
5. Ataxia
6. No blindness or retinal degeneration

Pathology

1. Loss of neurons in the cerebral and cerebellar cortices with associated atrophy
2. Accumulation of lipopigments in nerve cells
3. CLN1 and CLN10 demonstrate granular lipopigments
4. CLN2 have curvilinear profiles
5. CLN3 have fingerprint profiles
6. Other forms have a combination of these features
7. Specific profile may be seen in lymphocytes, skin, rectum, conjunctiva and skeletal muscles

Mitochondrial Disease and Epilepsy

1. Mitochondrial DNA mutations are major causes of epilepsy
2. Mitochondrial DNA maintenance disorders
3. Complex I deficiency
4. Disorders of coenzyme Q(10) biosynthesis
5. Disorder of mitochondrial translation (RARS2 mutations)

General Features of Mitochondrial Disease

1. Short stature
2. Sensorineuronal hearing loss
3. Proximal muscle weakness
4. Cardiomyopathy
5. Migraine headache
6. Diabetes mellitus

Specific Mitochondrial Diseases with Myoclonic Epilepsy

1. MELAS
2. MERRF
3. POLG (Alpers syndrome)
4. Spinocerebellar ataxia with epilepsy
5. Myoclonus, epilepsy, myopathy and sensory ataxia (MEM-SA)
6. Sialidosis with Myoclonic Epilepsy
 - a. Mutations in the sialidase gene located on chromosome 6p21.3; AR
 - b. Encodes lysosomal sialidase
 - c. Two clinical forms:
 - i. Type II (severe)

1. Early onset at 6 months
2. Dysostosis multiplex
3. Hepatosplenomegaly
4. Cognitive impairment
5. Myoclonic epilepsy
- ii. Type I (milder)
 1. Late onset
 2. Visual loss
 3. Myoclonus syndrome
 4. Cherry red macular spot
 5. Ataxia
 6. Hyperreflexia
 7. Seizures

Neuroimaging

1. MRI
 - a. Diffuse progressive brain atrophy

Action Myoclonus-Renal Failure Syndrome

General Features

1. AR; French Canadian
2. Mutation in SCARB2
 - a. Loss of function
 - b. Encodes a lysosomal membrane type 2 protein

Clinical Manifestations

1. Progressive action myoclonus
2. Dysarthria
3. Ataxia
4. Generalized seizures
5. End stage renal failure
6. Phenotype is variable
7. Some patients have progressive myoclonus epilepsy without renal failure

Rare Causes of Autosomal Recessive Myoclonic Epilepsy

1. Neuropathic Gaucher's disease
2. Ataxia-PME
3. Type III Gaucher's disease
4. All lysosomal diseases

Rare Causes of Myoclonus with Seizures

1. Gaucher's disease (type III) (also categorized as neurodegenerative myoclonus)
2. GM gangliosidosis
3. Biotin-responsive encephalopathy
4. Dentatorubral-pallidoluysian atrophy (DRPLA)
5. SCA6
6. Atypical inclusion body disease
7. Action myoclonus renal failure syndrome
8. Neuroaxonal dystrophy
9. Pantothenic kinase deficiency

10. Celiac disease
11. Dutch mt-DNA deficiency
12. HARP syndrome (hypoprebetalipoproteinemia, acanthocytosis, retinitis pigmentosa, and pallidal degeneration)
13. Perioral myoclonia with absences
14. Familial cortical myoclonic tremor with epilepsy (FCMTE)
15. Adult onset polyglucosan disease

Myoclonic Seizures with Perioral Myoclonia

1. Generalized electrographic seizures presenting as perioral myoclonus
 - a. Chin twitching while awake
 - b. Video-EEG
 - i. Paroxysms of polyspike and slow wave activity maximal over frontocentral regions
 - ii. Correlates with chin myoclonus
 - c. Rarely juvenile myoclonic epilepsy and other idiopathic epilepsies are associated with perioral myoclonus

Familial Cortical Myoclonic Tremor with Epilepsy and Cerebellar Changes

General Features

1. Approximately 60 families have been described worldwide
2. AD inheritance; 8q23.3-q24.4; 2p11.1-q12.2 and 5p15.31-p15 are chromosomal localizations

Clinical Manifestations

1. Distal tremulous movements
2. Generalized seizures that manifest after the onset of movements
3. Dutch pedigrees have cerebellar signs and pathology
4. Age at onset ranged from 3 to 70 years
5. Symptoms may differ between pedigrees:
 - a. 8q (Japanese)
 - b. 2p (Italian)
 - c. 5p (French)
6. Japanese pedigrees:
 - a. Age of onset 3rd decade
 - b. Tremor followed by seizure
 - c. Photosensitivity
 - d. No cognitive impairment
7. European pedigrees:
 - a. Onset is earlier
 - b. Widespread cortical/subcortical involvement
 - c. Cerebellar involvement
 - d. Greater progression with cognitive decline
 - e. Complex partial seizures
 - f. Night blindness, migraine, visuospatial deficits, glucose deprivation and exercise as triggers
 - g. Gait disorder

Neurophysiology

1. Tremulous movements:
 - a. Cortical origin
 - b. Stimulus-sensitive
 - c. Cortical hyperexcitability
 - d. fMRI tremulous movements correlate with activity of sensorimotor cortex
 - e. Deficits in GABA-ergic inhibition

Neuropathology

1. Dutch pedigrees demonstrate cerebellar degeneration
 - a. Purkinje cell changes similar to SCA6

Differential Points Between Progressive Myoclonic Epilepsies and Genetic Generalized Epilepsy, Progressive Encephalopathies with Seizures and Progressive Myoclonic Ataxias

PME core features:

1. Increasing action myoclonus; also, present at rest
2. Activates with noise, light and touch
3. Coexistence of other seizures, progressive ataxia, and dementia
4. Presentation in late childhood or adolescence

Juvenile myoclonic epilepsy does not demonstrate:

1. Progressive neurologic disability
2. Failure to respond to AED
3. Background EEG slowing

Progressive Encephalopathy with Seizures

1. GM2 gangliosidosis
2. Non-kenotic hyperglycemia
3. Niemann-Pick type C
4. Juvenile Huntington's disease
5. Alzheimer disease

Progressive myoclonic ataxias:

1. Affects adults
2. Progressive ataxia and myoclonus
3. Few tonic-clonic seizures
4. No dementia
5. Mutation in the MRE11 gene
 - a. Cause an ataxia-telangiectasia-like (ATLD) disorder (causes myoclonic ataxia)
6. Mutations in NBS1
 - a. Cause Nijmegen breakage syndrome (NBS) with myoclonic ataxia

Unusual Features Associated with the Myoclonic Epilepsies

1. Hyperostosis frontalis interna with Unverricht-Lundborg disease
2. Myoclonic jerks – misdiagnosed as focal seizures
3. Focal or lateralized EEG findings as local epilepsy
4. Myoclonus may be triggered by muscular contraction or interruption of muscular activity
5. Bilateral massive proximal myoclonic seizures and GTCS occur concomitantly

6. Severe myoclonic epilepsy of infancy (Dravet syndrome) in adults
 - a. Convulsive seizures persisted from infancy to adulthood
 - b. Often nocturnal
 - c. Less frequent than in childhood
 - d. Loss of cognitive function
 - e. Ataxia and extrapyramidal features in approximately 30% of patients
 - f. Majority have SCNA1 mutations
7. Hepatic signs as the first manifestation of Lafora body disease
8. PME with demyelinating peripheral neuropathy
9. Three mutation-harboring genes for myoclonic epilepsy (JME)
 - a. GABA receptor alpha1 (GABARA1) on chromosome 5q 34-q35 (French Canadian family)
 - b. Chloride channel gene
 - i. Chromosome 3q26
 - ii. German family
 - iii. EFHC1
 1. Hispanic family of Native American and European ancestry from California and Mexico
10. Patients with HLA-B 1502 who have taken Tegretol have suffered:
 - a. Stevens-Johnson syndrome
 - b. Primarily Indian and Asian patients

Tonic Seizures**General Features**

1. Sustained muscle contraction that leads to posturing
2. Last several seconds
3. Tonic seizure with focal epilepsy
 - a. Preferentially affects proximal muscles
 - b. Uni- or bilateral (asymmetric)
 - c. Consciousness not clouded at the onset of asymmetric movements
 - d. Consciousness with bilateral activity (localized to SMA)
 - e. Most common in frontal lobe epilepsy (very rare in TLE)
 - f. Unilateral tonic seizure localize to contralateral side
 - g. 1/3 of frontal lobe origin have bilateral tonic activity

Tonic Seizures from the Supplementary Motor Area

1. Bilateral from onset (usual)
2. May be asymmetric with rapid bilateral spread
3. Posturing may be unilateral or restricted to a single limb
4. Proximal limb and axial involvement is prominent
5. Most often all 4 limbs are involved:
 - a. Abduction of the upper limbs
 - b. Asymmetric flexion of the elbows (fencer posture)
 - c. Abduction of the hips; extended or semiflexed knees

Pattern of Tonic Seizures as a Component of a Generalized Seizure (GTCS)

1. Initiated with tonic flexion of the body with shoulder and arm elevation
2. Semiflexion of the elbows
3. Opisthotonus posture:
 - a. Elbows semiflexed in front of the chest (may be extended)
 - b. Forearm pronation and wrist flexion and finger extension or wrist extension and fist clenching
4. Epileptiform scream from contraction of thoracic and abdominal muscles forcing air through the larynx

Pattern of Secondarily Generalized Seizure

1. Demonstrate a motor sequence
 - a. Version and pulling of the face contralateral to seizure focus
 - b. Progresses to M2e position
 - c. Asymmetric tonic limb posturing “sign of four”
2. Lateralizing significance:
 - a. Tonic force and version-contralateral focus
 - b. Fencing posture (M2e) – lateralizes to the hemisphere contralateral to the extended arm

Epileptic Spasms

1. Usually seen with generalized epilepsies
2. May be seen with focal epilepsies
 - a. Parieto-occipital lobes most common foci
3. Symmetric muscle contractions:
 - a. Tonic or myoclonic features
 - b. Predominantly affect proximal axial musculature
 - c. Flexion of the trunk with extension and abduction of the arms
 - d. Variable length from seizure to seizure
 - e. Generalized EEG pattern
 - f. Possible involvement of the brainstem raphe

Seminal Clinical Seizure Patterns

Clonic Seizures

1. Myoclonic contractions at 2–5 Hz
2. Originate in the primary motor strip
3. Progression:
 - a. Face, frontal eye fields, and hands are affected prior to the legs
4. Clonus without alteration of consciousness as first sign of seizure:
 - a. Contralateral primary motor area
5. Secondary generalized tonic-clonic seizure
 - a. Clonic activity may last longer on ipsilesional side at the end of seizure (paradoxical clonus)
6. Asymmetric seizure end is unusual in generalized epilepsies

Versive Seizures

1. Forced and involuntary turning of the head and eyes

- a. Frontal eye field locus is in the contralateral hemisphere
- b. Version occurs earlier in FEF focus than from temporal lobe focus
- c. Lateralization reinforced if the version occurs within 10 seconds of secondary generalization

Complex Motor Seizures

1. Movements that involve several joints and resemble normal activity:
 - a. Running
 - b. Pedaling
 - c. Automatisms with sexual overtones (writhing, pelvic thrusting, touching the genitalia)
2. Proximal muscle involvement with large movements
3. Occur during sleep
4. Origin is primarily orbital or medial frontal lobe; may occur with insular or temporal lobe epilepsy

Automotor Seizures

1. Manifest as automatisms that involve the mouth, hands, feet and tongue
2. Primarily seen with TLE but can occur from the frontal lobe
3. Clinical features:
 - a. Bilateral or unilateral automatisms
 - b. Frontal lobe in origin is shorter than those from the temporal lobe
 - c. Unilateral automatism suggests an ipsilateral origin
 - d. Greater than 90% are associated with altered consciousness; if consciousness preserved the focus tend to be non-dominant mesial temporal lobe

Gelastic Seizures

1. Primarily from hypothalamic hamartomas
2. Also have been described from lesions in the anterior cingulate gyrus, frontal, parietal and temporal lobes
3. Non-modulated laughter

Atonic Seizures

1. Loss of postural tone with falls or head drop
2. Occur in generalized epilepsies (Lennox-Gastaut syndrome)
3. Preceded by generalized proximal myoclonic seizures
4. May be seen in frontal and temporal lobe focal epilepsies
 - a. Not associated with myoclonic seizures

Astatic Seizures

1. Seizure that consist of epileptic falls
2. A myoclonic seizure followed by an atonic seizure

Motor Seizures

Hypomotor Seizure

1. A decrease or total absence of motor activity
2. Occur concomitantly most frequently with temporal and parietal lobe seizures

Akinetic Seizures

1. Inability to perform voluntary movements
2. Activation of inhibitory motor areas of the mesial frontal and inferior frontal gyri

Negative Myoclonic Seizures

1. A brief movement of less than 400 msec duration (similar to asterixis)
2. Due to loss of muscle tone
3. Reported from the postcentral cerebral cortex

Dystonic Posturing

1. Sustained (>10 sec) unnatural position of an upper extremity with a rotational component
 - a. TLE-lateralizes to the contralateral side
2. Due to activation of the basal ganglia
3. May occur from extratemporal lobe foci

Localization Related Epilepsy**Overview**

In the past, focal seizures were thought to be caused by a paroxysmal depolarization shift of neurons in a focal epileptogenic zone with spread of abnormal electrical activity to other brain regions. Structural lesions were correlated with ictal signs and symptoms. Recent advances in both multimodal neuroimaging and electrophysiological techniques exemplified by functional MRI and magnetoencephalography have demonstrated that focal seizures are caused by abnormalities in functional networks of cortical and subcortical neurons rather than a single epileptogenic focus. The new terminology proposes that “focal” indicates a seizure that arises “within networks limited to one hemisphere that may be discrete or more widely distributed.”

It is clear that seizures interact with functional MRI determined (fMRI) “resting state networks”. Resting spontaneous brain activity continuously interacts with brain networks that underlie salience, sensorimotor, visual, auditory and executive functions.

Focal Motor

1. General characteristics
 - a. The most common type originates in the supplementary motor area (SMA)
2. Clinical manifestations
 - a. Version of the head and eye contralaterally to the seizure focus
 - b. Tonic extension of the limbs opposite the focus (“fencer posture”) which may constitute the entire seizure or it may evolve into clonic movement
 - c. Extension of the limbs may occur prior to simultaneously with loss of consciousness

- d. A unilateral frontal lobe lesion may cause a GTCS without the initial version of the head and eyes
- e. Loss of consciousness is postulated to arise from the spread of the ictal discharge to the thalamic and high midbrain reticular formation
- f. Other clinical presentations include:
 - i. Hyperkinetic complex movements (SMA)
 - ii. Dystonic postures (SMA)
 - iii. Speech arrest (Broca’s area; BA44)
 - iv. Frontal absence
- g. Jacksonian seizures
 - i. Initiated with forceful sustained deviation of the head and eyes, most often contralateral to the epileptic zone but rarely to the ipsilesional zone
 - ii. The seizure focus is usually in Brodmann area BA8
- h. Jacksonian “march”
 - i. Patterns of spread within the primary motor cortex (BA4) are:
 1. Partially dependent on the innervation density, size of the cortical representation of the body part and the activation threshold of neurons that control that body part
 2. The seizure may be initiated with tonic contracting of the fingers, face or foot. If it is initiated in the hand, the thumb may demonstrate clonic movements followed by twitching of the corner of the mouth (cortical representations are contiguous). The tonic contraction of the affected body part transforms into the clonic contractions
 3. The typical spread is from the hand up the arm to the face. The shoulder often is minimally affected; it then spreads down the leg.
 4. If the onset is in the foot, it spreads up the leg, down the arm and to the face
 5. The length of time of the “march” is usually 20–30 seconds
 6. Rarely the first muscles affected can be in the abdomen, thorax or neck
 7. Todd’s paralysis may follow contractions of the affected part:
 - a. The paralysis usually lasts for minutes to hours
 - b. May signify an underlying structural lesion
 - c. The length of the paralysis often bears a relationship to the duration of the seizure
 - d. The cause of the paralysis putatively is:
 - i. Overinhibition of the affected area by mechanisms that terminate the seizure
 - ii. A continuing ictal discharge
 - iii. Possibly metabolic failure of the affected area
 8. If there is a sensory component to the focal motor seizure:

- a. The lesion may be post Rolandic
- 9. Brodmann's area 4 lesions:
 - a. Clonic contractions
- 10. Area 6 lesions cause:
 - a. Tonic contractions contralateral to the focus
- 11. Supplementary motor lesions are associated with:
 - a. "Fencing posture"
- 12. High medial frontal lesions (area 8) are associated with:
 - a. Choreoathetosis
 - b. Dystonic postures
 - c. Complex motor movements
- 13. Involved body parts may demonstrate piloerection and hyperhidrosis
- 14. Ictal aphasia may occur in isolation. Post-ictal aphasia causes complete speech arrest; verbalization at the onset of a seizure is often initiated from the non-dominant hemisphere
- 15. A simple partial motor seizure (no spread), particularly of the upper extremity may last for days to weeks:
 - a. Known as Menschikoff's syndrome
 - b. Usually is due to an old vascular lesion or cortical scar
 - c. Difficult to treat

Simple Sensory Partial Seizure

- 1. The abnormal sensations described are usually as numbness, tingling, "pins and needles", formication (crawling), electricity or movement of a part
- 2. Pain and thermal sensations are rare. Pain sensation can be evoked from insular cortex stimulation and in a few instances from SI
- 3. Bilateral and widespread somatic sensations can occur from lesions of the secondary sensory area SII (at the foot of SI) or the supplementary sensorimotor area (SSMA) and the posterior insular cortex
- 4. SII activation may cause pain or a rising heat sensation
- 5. A Jacksonian sensory march is very similar in sequence to that noted for its motor equivalent
- 6. The face and hand are particularly involved (low neuronal activation threshold; high innervation density)
- 7. The trunk may be involved
- 8. The areas of origin of a sensory march is usually the primary sensory homunculus of SI or the posterior parietal sensory BA5 or BA7
- 9. Occasionally sensory seizures may begin in the proprioceptive component of the sensory cortex (SIa) with consequent posturing of the affected extremity; abnormal kinesthetic sensations may be initiated by a specific passive posture
- 10. Posterior parietal sensory seizures may induce a feeling of tingling in a parietal sensory distribution. Patients may feel unduly tired

- 11. SII activation or its spread to the temporal, parietal occipital junction may induce a sensation of heat that spreads from the feet and envelops the body bilaterally

Frontal Lobe Epilepsy

- 1. General characteristic
 - a. The frontal lobe comprises 1/3 of the human brain
 - b. It is the second most common seizure type
 - c. It can be subdivided into three major regions:
 - i. Dorsolateral
 - ii. Medial
 - iii. Inferior orbital
- 2. Lateralizing signs may not be present; EEG, functional imaging may not be localizing
- 3. The clinical features of frontal lobe seizures depend on the area of the frontal lobe affected and the seizure propagation pathways
- 4. Its semiology is diverse due to its major functions that include:
 - a. The planning and execution of movement
 - b. Primary expressive speech
 - c. Higher cortical executive function
 - d. Memory
- 5. Semiology of frontal lobe seizures by stereoelectroencephalography
 - a. Group 1
 - i. Elementary motor signs (precentral and premotor cortex)
 - b. Group 2
 - i. Elementary motor signs and non-integrated gestural movements (premotor and prefrontal cortex)
 - c. Group 3
 - i. Integrated gestural motor behavior with distal stereotypies (anterior lateral and medial prefrontal areas)
 - d. Group 4
 - i. Seizures with fearful behavior (ventromedial prefrontal cortex with spread to the anterior (oral areas)
- 6. The anatomical organization of frontal lobe semiology
 - a. Organized along a rostrocaudal axis
 - b. Bands within a spectrum (anatomical areas with concordant signs and symptoms) rather than a rigid anatomical area
 - c. The more anterior the seizure focus in the frontal lobe the greater integrated behavior during seizures
 - d. Distal stereotypies (repetitive, impulsive, rhythmic, purposeless movements that follow an individual repertoire) are seen with the most anterior prefrontal seizure foci
 - e. Proximal stereotypies are more common with posterior prefrontal areas
 - f. Somatosensory and Jacksonian clonic signs are highly correlated with a periorolandic localization
 - g. General motor agitation are most commonly localized to frontopolar and orbitofrontal localizations

Dorsolateral Frontal Lobe Epilepsy

1. General Characteristics
 - a. Anatomy
 - i. The dorsolateral frontal lobe is classically divided into:
 1. Brodmann's area 4 (BA4) of the precentral gyrus
 2. Premotor cortex
 3. Prefrontal cortex
2. Clinical Manifestations
 - a. Seizures arising from the primary motor cortex (BA4)
 - i. Partial motor seizures: Jacksonian March
 - ii. Rapid secondary generalization particularly if the focus is M1 or S1
 - iii. Often arise out of sleep
3. Propagate into the second inferior frontal convolution (Broca's area; BA44) which causes speech arrest, stammering or stuttering during the seizure
4. May occur in clusters
5. Seizures are often brief, less than 15 seconds
6. Short ictal state
7. Unilateral or bilateral automatisms
8. Motor arrest
 - a. Activation of the suppressor strip of Marion Hines
9. May maintain consciousness

Premotor Cortex (PMC)

1. Versive seizures with involuntary forced head deviation
2. Sustained and unnatural position of the head; more extreme than that which may be seen from a temporal or occipital lobe focus
3. Forced head deviation occurs contralaterally to the seizure focus occurs in 90% of patients
4. Broca's Area Seizure (BA44)
 - a. Aphasia (speech ignition failure; stuttering)
 - b. Patients may suffer prolonged ictal phenomena if the seizure spreads into the dominant temporal lobe by means of the uncinate fasciculus

Prefrontal Cortex

1. Hypermotor seizures:
 - a. Involve both premotor and prefrontal regions
 - b. They may be preceded by a somatosensory aura that is followed by gestures, coughing, bicycling, pedaling movements, running and thrashing
 - c. Arise out of sleep
 - d. Brief duration
 - e. Short post-ictal state
 - f. May be associated with "stereotypies":
 - i. Motor and Verbal
 - ii. Distal motor stereotypies are associated with an anterior prefrontal localization
 - iii. Proximal stereotypies are localized more posteriorly
 - iv. These movements suggest activation of a frontostriatal loop

Supplementary Motor Area Seizures (SMA)

1. Anatomic localization to SMA (BA8)
2. Brief
3. Preservation of consciousness
4. Sudden paratonic rigidity contralateral to the seizure focus
5. Speech arrest
 - a. Involvement of projections to Broca's area (BA44)
6. Vocalization
7. Cluster at night
8. Fencing posture; extended contralateral arm; flexed ipsilateral arm; contraversive head and eye movements

Orbitofrontal Cortex Seizures

1. Present with either frontal lobe type seizures or temporal lobe semiology
2. There may be no aura until the discharge spreads into the cingulate or insular cortex
3. After propagation:
 - a. Autonomic signs
 - b. Olfactory hallucinations and illusions
 - c. Oroalimentary auras
 - d. Persistent vocalization
 - e. Violent dramatic automatisms
 - f. Motor and gestural automatisms

Cingulate Cortex Seizures*General Characteristics*

1. Anatomical subdivisions
 - a. Affective component
 - i. Connected to the periaqueductal gray, amygdala, anterior insula and the nucleus accumbens
 - ii. A functional component of endocrine and autonomic control
2. Cognitive Component
 - a. Connected to the parietal cortex, lateral prefrontal cortex, premotor and supplementary motor cortices
3. Propagation from ictal posterior cortex
 - a. Motor manifestations from spread to:
 - i. Lateral premotor, orbitofrontal, SMA, precuneus and inferior parietal lobule
 - b. Dialectic seizures (alteration of consciousness (unresponsiveness during the seizure)) and amnesia post-ictally:
 - i. Spread to the medial temporal, intraparietal lobe, mesial occipital and mesial frontal areas

Clinical Manifestations

1. Anterior cingulate focus
 - a. Hyperkinetic seizures
 - b. Associated with fear, laughter or interictal personality change
 - c. Early onset but may start in adulthood
 - d. May occur during sleep

- e. Associated with emotional outbursts (aggressive behavior and psychotic symptoms)
- f. Autonomic symptoms (increased sympathetic tone)
- 2. Posterior cingulate focus:
 - a. Semiology suggestive of a temporal lobe origin
 - b. Surgical resection of the supra cingulate gyrus has caused SMA deficits

Frontal Opercular Seizures

- 1. Ipsilesional clonic facial movements
- 2. Mastication, salivation and swallowing movements
- 3. Choking at night:
 - a. Occurs frequently
 - b. Has extrapyramidal features
 - c. Stereotypy of attacks
- 4. Gustatory hallucinations
- 5. Rare epigastric auras, fear and autonomic signs (tachycardia)

Frontopolar Cortex Seizures

- 1. Vocalization
- 2. Truncal flexion
- 3. Complex gestural automatisms
- 4. Hyperventilation
- 5. Sudden awakening after a seizure
- 6. Bimanual and bipedal automatisms
- 7. Forced thinking
- 8. Axial clonic jerks (may cause falling)

Differential Diagnosis of Hyperkinetic Frontal Lobe Seizures

- 1. Location of the seizure focus:
 - a. Orbitofrontal cortex (OFC)
 - b. Dorsolateral prefrontal cortex (DLPFC)
 - c. Frontomesial cortex
 - d. Frontopolar cortex
- 2. Clinical manifestations
 - a. Complex bimanual and bipedal movements
 - b. Kicking, thrashing, clapping and hand rubbing
 - c. Sexual automatisms

Nocturnal Frontal Lobe Epilepsy

- 1. General Characteristics
 - a. Mutations in CHRNA4, CHRNA2, CHRNB2 and KCNT1 genes that encode:
 - i. alpha4, alpha2, and Beta2 subunits of the neuronal nicotinic acetylcholine receptor
 - ii. A potassium channel subunit
 - b. DEPDCD (DEP domain-containing proteins) has been linked to ADNFLE as well as familial temporal lobe epilepsy (FTLE) and familial focal epilepsy with variable foci (FFEVF)
 - c. Wide spectrum of stereotyped motor manifestations

- d. There is a family history of possible nocturnal frontal lobe epilepsy in approximately 25% of patients with nocturnal frontal lobe seizures
- 2. Clinical Manifestations
 - a. Several attacks per night; multiple episodes occur within hours; often within 30 minutes of sleep onset
 - b. Occur during non-rapid eye movement sleep (stages 1 and 2 of non-REM sleep)
 - c. Stereotyped motor pattern
 - d. Drug resistant forms exist
 - e. Brief duration of attacks (<2 minutes)
 - f. Onset is from infancy to adolescence; the seizures tend to persist into adulthood
 - g. Patients with nocturnal frontal lobe epilepsy (NFLE) have a strong family history of parasomnias
 - h. Often patients are aware of their surroundings and can recall much of the event
 - i. There are no cognitive or behavioral alterations
 - j. Excessive daytime sleepiness
 - k. There are rare spontaneous remissions

Clinical Variants of Nocturnal Frontal Lobe Epilepsy

- 1. Paroxysmal arousals of abrupt and brief episodes of stereotypical motor activity
- 2. Nocturnal paroxysmal dystonic seizures:
 - a. Complex movement and dystonic motor attacks lasting <2 minutes
 - b. Episodic nocturnal stereotyped agitated somnambulism

Differential Diagnosis of NFLE (Nocturnal Frontal Lobe Epilepsy)

Non-REM Arousal Parasomnias

- 1. General Characteristics:
 - a. Arise from stage 3 or 4 NREM sleep
 - b. There is no conscious awareness
 - c. There are three major categories:
 - i. Confusional arousals:
 - 1. Little motor or autonomic involvement
 - ii. Somnambulism:
 - 1. Motor activity but little autonomic symptomatology
 - iii. Sleep terrors:
 - 1. Prominent autonomic involvement and variable motor activity

Differential Clinical Signs Distinguishing NREM Parasomnias from NFLE

- 1. Clinical features supporting the diagnosis of parasomnias
 - a. Crying
 - b. Waxing and waning of the episode
 - c. Physical or verbal interaction with bystanders
 - d. Modification of the event by bystanders
 - e. Coherent speech in sentences
 - f. Normal arousal behaviors
 - i. Scratching and face rubbing

2. Clinical features supporting NFLE

- a. Bicycling movements
- b. Thrashing
- c. Grimacing and grunting
- d. Dystonia

Onset

1. Parasomnias begin with arousal behavior (approximately 80% of events)
 - a. Eye opening, staring and head elevation
 - b. Lasts from seconds to several minutes
 - c. In approximately 20% of patients:
 - i. Explosive motor onset (sitting forwards, frightened and agitated behavior)
 - d. The episode may be triggered by an external event such as a noise or an internal stimulus (cough)
 - e. Tachycardia is invariably associated with the episode
 - f. This pattern at onset is seen in approximately 40% of parasomnias
2. NFTLE Onset:
 - a. Brief arousal behavior similar to parasomnias are seen in approximately 50% of patients (median time of the episode is 7 seconds)
 - b. In approximately 50% of patients, there is abrupt onset with no preceding arousal, associated tachycardia is seen in all events
 - c. Triggers for seizures occur in less than 10% of patients

Differential Diagnosis in Offset Between Parasomnias and NFLE

1. Parasomnias terminate with complete wakefulness in 25% of patients or light NREM sleep in 75%
2. Tapering of effects in those that did not awaken completely
3. Clear distinct offset was seen in <20% of patients

Differential Diagnosis in Offset Between Offset Is in NFLE Patients

1. Approximately 90% end with full consciousness
2. 75% demonstrate distinct offset
3. A small percentage of patients demonstrate dystonic posturing

Behavior Patterns in Parasomnias vs NFLE

1. Behaviors are short
2. Less elaborated than NFLE
3. Parasomnia arousal behavior:
 - a. Is seen at some point during all events; usually at onset or offset
 - i. Hypnotic jerks can precipitate events
 - ii. Trembling and shivering can occur throughout the episode
 - b. Non agitated motor behavior
 - i. Sitting forward, manipulating objects, searching

- ii. Perplexed expression
- iii. Speech is coherent
- iv. Interactive speech and behaviors
- v. This behavioral pattern occurs in 70% of patients
- c. Distressed emotional behavior:
 - i. Occurs in approximately 50% of patients
 - ii. Fearful expression, behavior and speech
 - iii. Sitting, standing, screaming and frantic searching, sobbing and anguish
 - iv. Behavior patterns occur in various combinations

EEG Evaluation

1. Parasomnias and seizures arise out of NREM sleep
2. Most seizures occur during light NREM sleep
3. In parasomnia, there is a light sleep pattern with vertex waves; sleep spindles can occur during episodes
4. Some patients demonstrate a posterior dominant alpha rhythm

AD Frontal Lobe Epilepsy

1. Genetics:
 - a. Mutation in DEPDC5 (Dishevelled, Egl-10 and Pleckstrin)
2. Domain containing protein 5
 - a. Reported in families with familial focal epilepsy with variable foci (FFEVF) linked to chromosome 22q12
 - b. DEPBC5 mutations also found in:
 - i. Familial TLE
 - ii. ADNFLE
 - c. Emode a GTPase-activating protein that is part of a complex that negatively regulates mTORC1
3. Seminal clinical features
 - a. Onset in childhood
 - b. Clusters of brief motor seizures with hyperkinetic, tonic or dystonic features
 - c. Rare GTCS
 - d. Breathless feeling (some patients)
 - e. Cognitive/psychiatric features in some patients
 - f. Association with somnambulism
4. EEG: minimal ictal or interictal abnormalities
5. High rate of drug resistances
6. Overlap between ADNFLE and FFEVF

Temporal Lobe Epilepsy

Overview

The major seizure problem in adults and the source of a major component of intractable epilepsy are complex partial seizures of temporal lobes origin. The spectrum of symptomatology is wide and the semiology varies from patient to patient. The symptoms reported may be the only ones remembered and may be due to propagation patterns.

MRI techniques magnetoencephalography, PET, SPECT, video-EEG with concomitant functional MRI and intracranial recordings have allowed a great deal of insight into the localization of temporal lobe auras and consequent semiology. Often the clinical evaluation allows localization of the symptomatogenic zone which may overlap or is in close proximity to the epileptogenic zone. This is particularly important in MRI-negative focal epilepsy which is shrinking as Tesla strength increases. An increasing share of intractable TLE is due to migrational disorders and focal cortical dysplasia (abnormal lamination) which will be detected by 7 Tesla magnets. Careful evaluation of seizure semiology is a major component of determining the epileptogenic zone. The focal epilepsies that often mimic TLE arise from the insula cortex, temporal-plus (extratemporal areas) and parieto-occipital lobes.

General Characteristics

Definition of Semiology

Semiology is the clinical manifestation of epilepsy:

1. Dependent upon electrical activity from seizures that are initiated and organized within existing neural networks
2. The epileptic discharges spread both temporally and spatially which generate the clinical symptomatology
3. Signs emerge after seizure onset
 - a. Temporal lobe seizures propagate more slowly than those from the frontal lobe
4. The “early spread network” is closely related to the epileptogenic zone
5. Clinical features vary according to the degree of involvement of either the primary or associative cortex (more complex symptoms)

Definition of Primary Cortex Semiology

1. Visual or auditory hallucinations
2. Elementary sensorimotor signs
 - a. May occur as a march (Jacksonian)

Definition of Associative Cortex Semiology

1. Involves more widely distributed networks
2. Altered cognitive function
3. Behavioral abnormalities

Definition of Frequency of the Seizure Discharge

1. Fast gamma discharge deactivates normal function
2. Theta discharge may mimic physiologic function

Definition of Synchronization

1. Interaction between nodes of specific networks (determined by functional MRI)
2. Ictal fear:
 - a. Associated with decorrelation between network nodes that induces “release phenomena”
 - b. Increased synchronization as exemplified by increased synchronization between behavioral nodes

- c. A specific semiology during a seizure is dependent on:
 - i. Anatomical origin of the ictal discharge
 - ii. Propagation
 - iii. Activation and dynamic interplay of nodes within specific distributed networks

Definition of Electrocorcography

1. The measurement of electrical brain signals from electrodes implanted subdurally on the surface of the brain and have:
 - a. High signal to noise ratio
 - b. Are less susceptible to artifacts than scalp EEG
 - c. Have high spatial and temporal resolution
 - i. Less than 1 cm of brain surface
 - ii. Less than 1 millisecond in duration
 - d. Electrocochleography (ECOG) amplitudes in specific frequency bands give insight into:
 - i. Motor execution and planning
 - ii. Auditory processing
 - iii. Visual-spatial attention
 - iv. Information is thought to be relayed in the gamma band (70–110 Hz)
 - v. ECOG identifies functional connectivity and task related spatial-temporal dynamics
 - vi. Most often used in pre-surgical evaluation of refractory TLE patients
 - vii. Aura: an ictal event that occurs at the onset of a seizure
 - viii. Prodrome:
 1. An awareness of an impending seizure days in advance; prodromes may cause:
 - a. Headache
 - b. Irritability
 - c. Fatigue
 - d. Insomnia
 - e. Personality change
 - f. Depression
 - g. Increase in nocturnal myoclonic jerks

Automatisms

General Features of Automatisms

1. Involuntary motor activity often during impaired consciousness
2. Patient is partially or totally amnesic for the behavior
3. May continue or begin in the post-ictal period
4. May be a continuation of movements that occurred prior to the seizure (perserverative) or may be a new (de novo) movement
5. Motor activity is usually fragmentary rarely are there sequential coordinated movements
6. Automatisms vary from patient to patient but are stereotypical for an individual patient; increasingly complex with age
7. May occur with absence, frontal lobe and temporal lobe seizure as well as in the post-ictal phase of a GTCS

8. Temporal lobe automatisms:
 - a. Most often are initiated from the hippocampal formation-amygdala complex; meso orbital frontal lobe and cingulate gyrus. They may be the site of origin of motor automatisms. Oral buccal automatisms most often originate from the amygdala and frontal operculum
 - iii. Failure to perceive one's body
 - iv. Seeing a double of the whole body or body part
 - d. Time distortion (usually too slow)
 - e. Feeling of unreality
 - f. Forced thinking (continued thinking of a specific thought or phrase)

Clinical Manifestations

Patterns of Clinical Automatisms (TLE)

1. Oro-buccal lingual automatisms:
 - a. Smacking of the lips, chewing and swallowing, choking, eating, spitting, abnormal tongue movements and water drinking (amygdala; frontal operculum)
2. Gestural: repetitive movements of the hands and fingers may be semi-purposeful (drawing, playing cards) rubbing the nose or face (most often are post-ictal with an ipsilateral focus)
3. Sexual; masturbation, pelvic thrusting (may also be from a frontal focus)
4. Expressional: facial expression of fear, anxiety, confusion or anger (central amygdala nucleus)
5. Motor automatisms:
 - a. May be unilateral or bilateral
 - b. Unilateral (Ipsilateral epileptogenic zone)
 - c. Ictal frontal lobe motor automatisms, in general, are shorter than those from the temporal lobe
6. Upper limb automatisms differ quantitatively in temporal and frontal lobe seizures
 4. Affective symptoms:
 - a. Ictal fear; poorly localized, may be associated with abdominal sensation impending doom, an overwhelming quality (amygdala or medial hippocampal formation (HF))
 - b. Sadness (common)
 - c. Depression (common)
 - d. Embarrassment (usually medial frontal lobe)
 - e. Joy (rare)
 - f. Crying (dacrystic)
 - g. Sexual feelings
 - h. Gelastic (laughing) is more common with hypothalamic hamartoma; laughing without mirth; not modified correctly; patient may be fearful while laughing
 5. Distortion of memory:
 - a. Déjà vu: as if the experience had occurred before
 - b. Entendu: auditory experience
 - c. Jamais-vu: prior experience or place is experienced as new or unfamiliar
 - d. Vivid "flashbacks" of past events
 6. Special Sensory Symptoms:
 - a. Alterations of perception:
 - i. Unusual clearness
 - ii. Heightened sensitivity
 - iii. Poorly formed hallucinations (primary visual and auditory reception areas)
 - iv. Auditory auras – a "buzz" or "a noise" or distortion of a sound (too far away or too near); Herschel's gyrus; Brodmann's Area 22
 - v. Visual auras and visual hallucinations:
 1. Flashing lights of different colors; the patient blinks and they move in the visual field (usually BA17, BA18, BA19)
 2. Hallucination in front of both eyes (not lateralizing); if in one visual field (VF)-lateralized contralaterally
 3. Blindness during the seizure or post-ictally; flashing lights may be perceived above the blind VF
 4. Complex visual hallucinations and visual illusions (parietotemporal function; limbic cortex)

A Common Sequence Preceding Motor Automatisms

1. Arrest phenomena
 - a. The patient stops activity and maintains a posture for a few seconds
2. Autonomic phenomena
 - a. Loss of facial expression associated with pallor
3. Onset of motor phenomena

Psychic Auras

1. Often preceded by alterations in consciousness
2. General anatomical locations:
 - a. Severe anxiety (anterior temporal lobe)
 - b. Complex phenomena (neocortical) lateral temporal lobe
 - c. Fear, impending doom (medial temporal lobe (central and basolateral amygdala complex))
3. Complex cognitive emotional states (neocortical lateral temporal lobe; right side greater than left)
 - a. Dream state
 - b. Detachment and strangeness
 - c. Autoscopic phenomena:
 - i. Feeling of presence without an optical image
 - ii. Observing oneself from above (out of body experience; autoscopia)

Differential Diagnostic Points Between Fear as an Ictal Event vs a Panic Attack

Clinical Features of a Panic Attack (Psychiatry)

1. Sudden spontaneous onset
2. Intense fear and discomfort
3. Impending doom; thoughts of dread

4. Feeling of being trapped; loss of control
5. Event lasts for a few minutes
6. Full recognition and remembrance of the attack

Fear as a Seizure Aura

1. Anticipating anxiety
2. Expression of impending doom
3. Buccal automatism
4. Autonomic disturbance
5. Complex behavioral automatisms
6. Incomplete recall for the event

Abdominal Auras

General Characteristics

1. Occur in 20–60% of patients with TLE
2. Originate primarily in the temporal lobe but have been described from the insula and frontal lobe (about 20% of patients)
 - a. Approximately 65% from the medial temporal lobe; 35% with neocortical origin
3. Extratemporal locations:
 - a. 5% perirolandic
 - b. 17–20% parieto-occipital
 - c. 3% frontal
 - d. Posterior insular cortex
4. Specific simple sensations:
 - a. Nausea
 - b. Squeezing
 - c. Rolling
 - d. Turning in the abdomen
 - e. Electric shock
 - f. Pain
 - g. Butterflies
 - h. Hunger
 - i. Warmth
 - j. Sudden descent in an elevator; flip-flop; feeling of defecation
5. Auras begin in the epigastrium or stomach in the midline:
 - a. May remain localized
 - b. Rise to the chest, throat or face
 - c. Neck or face involvement is associated with loss of consciousness
6. Associated symptoms with abdominal auras:
 - a. Ictal vomiting
 - b. Subjective fear
 - c. Oro-alimentary symptoms
7. May evolve into clonic seizures
 - a. Occurs in 2/3 of patients with frontal seizures
8. Abdominal pain with abdominal auras
 - a. Pain occurs in 5% of abdominal auras
 - b. Pain occurs in 5% of auras initiated from the frontal lobe
 - c. Painful areas may originate from the parietal lobe
 - d. Direct stimulation of the insula cortex may elicit pain
 - i. There is rare pain from stimulation from SI (somatosensory I)

Olfactory Auras

1. Amygdala is the most common location; also described from the uncus of the hippocampal gyrus (“uncinate fits”)
 - a. Unpleasant smells, burning rubber, garbage, feces; rarely pleasant (usually an exaggeration of the pleasant quality)
 - b. May be produced by cortical stimulation of:
 - i. Amygdala
 - ii. Olfactory bulb
 - iii. Uncus of the hippocampal gyrus
 - iv. Posterior orbital cortex
 - v. Medial temporal lobe
 - c. Olfactory auras may be associated with:
 - i. Gustatory, visual and auditory auras
 - ii. Neoplasms of the amygdala

Gustatory Auras

1. Unpleasant tastes: blood, bitter, chemical, rotting, metallic
2. Insula is the symptomatogenic zone (not lateralizing)

Autonomic Auras

1. Palpitations, sweating, piloerection
2. Symptomatogenic zone (anterior insular cortex)
3. Piloerection map spread similar to a Jacksonian march

Rare Visceral Auras

1. Burning, tingling, growing, choking throat sensations
2. Ictal hunger
3. Ictal thirst (common)
4. Severe pain or unusual genital sensations
5. Severe vomiting
6. Goose bumps (piloerection)
7. Coldness-shivering
8. Spitting (expectoration)

Cardiac and Chest Aura (Insular Cortex)

1. Heart racing or pounding
2. Pain in the central chest (no true cardiac radiations)
3. Cardiac arrhythmias (atrial or ventricular) may be associated

Common Visual Auras

1. Blurred vision
2. Micropsia (objects too small)
3. Macropsia (object too large)
4. Perceptual illusions: objects too far or too close
5. Distorted objects
6. Rare: clear visual hallucination (evergreen true in a temporal visual field)
7. Kinesigenic: aura illusion of movement

Common Auditory Auras

1. Sound or voices not clearly perceived

2. A1 (primary auditory receiving area: clicking, roaring, wind blowing, rumbling sounds)
3. Receptive (Wernicke's) aphasia; BA22, BA23
4. Distorted or muffled sounds
5. Sounds too loud or too soft
6. Auditory hallucination (most often a psychiatric or drug withdrawal phenomenon)

Vestibular Aura

1. Non-specific dizziness or light-headedness. One of the most frequent TLE auras (superior temporal gyrus or intraparietal sulcus)

Cephalic Auras

1. Head is perceived as too big or too small
2. Head is off of the body
3. Ice pick (stabbing) headache (also occurs with migraine)
4. Squeezing compression of the head

Medial Temporal Lobe Seizure Localizing Auras

1. Uncinate auras
2. Impending doom
3. Automatism
4. Arrest response
5. Searching head movements
6. Contralateral dystonia
7. Cough or sigh
8. Amnesia
9. Gustatory auras

Lateral Temporal Lobe Localizing Auras

1. Wernicke's aphasia: speech arrest left side
2. Psychical auras (temporal cortex associated areas R > L)
3. Autosomal dominant lateral temporal epilepsy (ADLTE)

Anterior Temporal Lobe Cortex Aura Localization

1. Panic attacks; anxiety
2. No precipitating cause
3. Stereotypical and associated with autonomic features
 - a. Hyperhidrosis
 - b. Piloerection
 - c. Mydriosis

Medial Temporal Lobe Syndrome

Clinical Manifestations of Hippocampal Sclerosis

1. Early age at onset of seizures
2. Prolonged febrile convulsions important in etiology; seizure free interval after initial febrile convulsion
3. Material specific memory deficit
4. Executive and attention attributes are intact
5. Deficits in:
 - a. Verbal comprehension

- b. Perceptual organization
- c. Verbal memory
- d. Some visual spatial abilities
- e. No generalized cognitive impairment
- f. Impairments in access to an array of cognitive functions rather than restricted pattern of memory loss
- g. Post-ictal psychosis
- h. Autonomic auras
- i. Automatism (oro-buccal-pharyngeal)
- j. Ictal fear
- k. Limbic seizure occurs in the late afternoon and early evening

Neuropathology

Hippocampal Sclerosis (6 Patterns)

1. Classic HS with neuronal loss in CA1, hilus and CA3; sparing of CA2 and the sulculum; some patients demonstrate granule cell dispersion (coincident with new fiber sprouting from dentate granule cells)
2. Total HS with neuronal loss in all hippocampal subfields that includes CA2/subiculum
3. <5% demonstrate endfolium sclerosis (EFS); neuronal loss in the hilus and portions of CA3; sparing of CA1 and CA2
4. A small percentage of patients have primary CA1 atrophy (CA1p)
5. Approximately 20% have indeterminate hippocampal sclerosis (HS) with neuronal loss in CA3 and CA2 with preserved CA4
6. Approximately 10% have clinic and EEG findings consistent with MTLE but no HS

Other Hippocampal Sclerosis Pathology

1. Sclerosis that extends more caudally in the hippocampus
2. Neocortical lesions in the amygdala and parahippocampal gyrus
3. Neuronal loss within the hippocampal formation (HF)
4. Extra hippocampal lesions include:
 - a. Migrational defects
 - b. Scars
 - c. Tumor
 - d. Vascular malformations
 - e. Porencephaly
 - f. Hamartoma
 - g. Occur in approximately 30% of patients with hippocampal sclerosis
 - h. 16% of hippocampal sclerosis patients have bilateral abnormalities on MRI in the HF
 - i. Hippocampal sclerosis occurs without hippocampal formation atrophy in 5–10% of patients; they have normal volume of the HF
 - j. Younger children less than 12 years with HF atrophy have:
 - i. Dysplastic lesions and hamartomas more commonly than astrocytic tumors

Neuroimaging Evaluation

1. Unilateral hippocampal atrophy
2. Decreased signal intensity on T1 in the HF
3. Increased signal intensity on T2 in the HF
4. Abnormal anatomic surface modeling of the hippocampal formation
5. Abnormal T2 signal occurs in the contralateral hippocampus in 30–40% of patients
6. Magnetic resonance spectroscopic imaging (MRSI) demonstrates a decrease of N-acetylaspartate to choline plus creatine ratio in 75% of medial TLE patients
 - a. Bilateral changes occur in 45% of patients
7. Functional imaging with PET and SPECT often demonstrate extra HF abnormal areas

Amygdala Sclerosis*Clinical Manifestations*

1. Seizure onset is later than that which occurs with hippocampal sclerosis
2. Amygdala and HF formation involvement account for 50% of ictal events in MTLE
3. In general, there are the same ictal manifestations and auras as those with hippocampal sclerosis

Neuropathology

1. Bilateral histopathologic changes in greater than 50% of patients; in association with hippocampal sclerosis
2. 10% of TLE patients have isolated amygdala involvement
3. Neuronal loss and gliosis occurs in the lateral and basal nuclear groups
4. May have concomitant involvement of the entorhinal cortex and parahippocampal gyrus (in approximately 20% of HS patients)
5. Pathology of amygdala sclerosis includes:
 - a. Microdysgenesis
 - b. Vascular lesions
 - c. Cortical dysplasia
 - d. Abnormal glial cells (large, hyperchromatic)
 - e. Hamartomas (abnormal clusters of neurons and neuroblast cells)
 - f. Low grade tumors

Neuroimaging Evaluation

1. Voxel based morphometry (VBM)
 - a. Significant increase of gray matter volumes of the temporal pole with amygdala enlargement (due to cortical dysplasia)
 - b. Increased gray matter involvement in the affected amygdala
 - c. FDG-PET demonstrates significant glucose hypometabolism the affected amygdala
 - d. MRI studies show greater involvement of the R amygdala with depression and anxiety
2. Endfolium sclerosis:
 - a. Neuronal loss and gliosis confined to the endfolium (hilus and portions of CA3)
 - b. Hypertrophy of endfolium neurons in some patients with MTLE

Neuroimaging of Hippocampal Sclerosis

1. Ultra-High Field Strength Magnetic Resonance – 7 Tesla
 - a. All patients (8 with TLE) had:
 - i. Abnormalities on the epileptogenic side
 - ii. Selective lateral Ammons' horn atrophy in 6/8 patients
 - b. Diffuse Ammon horn and dentate gyrus atrophy in 1/8 patients
 - c. All patients had fewer hippocampal digitations on the epileptogenic side; 3 had similar findings contralaterally
 - d. Hippocampal malrotation in 3/8 patients (also seen in 4 controls)

Ictal Spread of Medial Temporal Lobe Seizures

1. Change from hyperkinetic movements to mild oral and manual automatisms
 - a. Frontal to temporal lobe spread
 - b. Rarely hyperkinetic movements may be initiated from the temporal lobe
2. No difference in seizure onset patterns in those that remain focal vs those patients that had generalized to GTCS
 - a. More prominent activation of posterior-lateral regions in those patients that had generalized convulsions
3. Patterns of medial temporal lobe propagation are primarily to the prefrontal cortex

Clinical Features of Medial Temporal Sclerosis Base on Voxel-Based Morphometry (VBM)

1. Mesial auras:
 - a. Ipsilateral gray matter volume reductions in the hippocampus and amygdala (R > L); right-sided involved patients demonstrated > reduction in the entorhinal cortex
 - b. Anterior mesio-lateral aura:
 - i. Auras particularly of epigastric rising sensation were associated with reduction in hippocampus, amygdala and insula
 - c. Left temporal lobe patients demonstrate:
 - i. More dispersed gray matter volume (GMV) loss than the right-sided temporal lobe patients
 - ii. Ipsilateral hippocampus, temporal neocortex, uncus, insula, precentral gyrus, thalamus, parietal lobe, cuneus and bilateral cingulum demonstrated atrophy
 - d. GMV reduction corresponds to auras elicited by direct cortical stimulation
 - e. Thalamic abnormalities were restricted to areas of the thalamus that were preferentially connected to the epileptogenic zone

Neocortical Temporal Lobe Epilepsy (NCTLE)*General Characteristics*

1. Older at onset than MTLE
2. In general, seizures are shorter than MTLE
3. There is no seizure free interval once seizures are initiated

Clinical Manifestations

1. Psychical:
 - a. Déjà vu, Jamais vu
 - b. Depersonalization
 - c. Forced thinking
 - d. Autoscapy
 - e. Heightened sensitivity
2. Auditory hallucinations
3. Vertigo/dizziness
4. Visual hallucinations
5. Somatosensory auras

Seizure Onset in Neocortical TLE

1. Motionless stare
2. Upper extremity automatism (Ipsilateral to seizure focus)
3. Dystonic posture of the contralateral arm
4. Bilateral upper extremity automatisms
5. Contralateral tonic or clonic activity of the face or extremities; rarely and early manifestation of the seizure

General Differential Feature Between MTLE and MCTLE

1. Mesial temporal lobe epilepsy (MTLE)
 - a. Fear
 - b. Visceral sensations (epigastric rising; antero-mesial)
 - c. High frequency of bitemporal interictal epileptiform abnormalities
 - d. Oral-buccal automatisms
 - e. Olfactory aura
2. Neocortical temporal lobe epilepsy (NCTLE)
 - a. Psychical auras
 - b. Experiential auras
 - c. Somatic, visual, auditory vertiginous aura
 - d. Dystonic upper extremity (contralateral to the focus)
 - e. Less prominent MRI features
 - f. More lateralized EEG
 - g. Interictal EEG demonstrates epileptiform temporal discharges in approximately 60% of patients
 - h. Associated with mutations in LGI1 in a third of patients

Unusual Neocortical TLE Presentations

1. General characteristics autosomal dominant lateral TLE
 - a. Mutations in the leucine rich, glioma inactivated 1 (LGI1) gene is responsible for approximately 50% of affected families
 - i. Micro deletion with a probable loss of function affected
2. Clinical Manifestations

- a. Variable age of onset (childhood to the fifth decade)
- b. Approximately 3/4 have elementary, complex or secondary generalized seizure
- c. Auditory auras in more than 60% of patients
- d. Other auras include:
 - i. Visual hallucinations
 - ii. Vertigo
 - iii. Déjà vu
- e. Sudden noises precipitate seizures in approximately 20%

Neuroimaging

1. MRI – normal

Epileptic Forced Thinking*Definition*

1. Recurrent intrusive thoughts; crowding of thoughts
2. Obsessive thoughts, auditory hallucinations, auditory perseverations, limbic illusions (new thoughts not previously experienced)

Clinical Features of Temporal Lobe Forced Thinking

1. Out of context to the environment prior to the seizure (e.g. a need to think of letters that begin with “L”, need to think of numbers)
2. Obscene thoughts:
 - a. Patient feels a need to resist or negate the irrational thought

Clinical Features of Frontal Lobe Forced Thinking

1. Speech Arrest:
 - a. Seizure of motor language areas (primarily Broca’s area (BA44))
 - b. Speech arrest or disturbances with intrusive thoughts (urge to shout)
 - c. Forced thoughts less stereotypic than from a temporal lobe focus (whatever words or thoughts used by the patient at the time of the seizure)
 - d. Variability of thought
 - e. Context dependency
 - f. Experiential imagery

Special Clinical Aspects of TLE

1. Reproductive dysfunction:
 - a. 50% of women with TLE have:
 - i. Sexual dysfunction
 - ii. Hormonal abnormalities
 - iii. 14–20% have amenorrhea
 - iv. Fertility reduced by 30%
 - b. Men with TLE:
 - i. Approximately 50–70% have sexual dysfunction (lack of libido)
 - ii. Rarely satyriasis occurs
 - c. Associated reproductive dysfunction in women:

- i. Hypogonadotropic and hypergonadotropic hypogonadism
 - ii. Functional hyperprolactinemia
 - iii. Polycystic ovary disease
 - iv. Anovulatory cycles
2. Prolactin surge after medial temporal lobe seizure:
- a. Levels peak approximately 20 minutes after the seizure
 - b. Prolactin is often elevated, but frequently there are no baseline measurements which makes determination of non-epileptic seizure less reliable
 - c. Direct amygdala connections to the VM hypothalamus

Interictal Personality Traits in TLE

1. Diagnostic specificity and validity of specific personality traits in TLE are controversial:
 - a. Existence of these traits in patients with other seizure disorders
 - b. Prevalence is variable
 - c. Common in the general population
2. Noted interictal traits are:
 - a. Catastrophic overemphasis (left temporal lobe)
 - b. Ideational musings (left temporal lobe)
 - c. Overly emotional (right temporal lobe)
 - d. Denial (right temporal lobe)
 - e. Inclusiveness
 - f. Hypersexuality (rare: usually hyposexuality is seen)
 - g. Dependence
 - h. Obsessive/compulsive behavior
 - i. Hypergraphic
 - j. Hyper-religious
 - k. Hypermoral
3. TLE personality traits and psychopathology:
 - a. Most adult TLE patients are well adjusted and functional
 - b. Personality traits that are noted are primarily with bilateral temporal lobe involvement
 - c. Patients with TLE have a higher incidence of psychiatric disorders than a control population. It is primarily:
 - i. Depression
 - ii. Anxiety
 - d. Psychosis ictally or post-ictally resembles paranoid schizophrenia in some patients:
 - i. Better preservation of affect in TLE vs schizophrenic patients
 - ii. Less personal isolation than schizophrenic patients
 - iii. More prevalent in patients with frequent seizures of long duration
4. There may be evidence of semicontinuous epileptic discharge in limbic areas during psychotic and hallucinatory behavior
5. Characteristics of aggressive violent behavior in TLE:
 - a. It is almost always non-directed
 - b. Short lived

- c. Fragmentary
 - d. May be a stereotyped manifestation
6. Temporal lobectomy may cause:
- a. New onset of psychosis
 - b. Improvement of instability and aggressiveness
7. Predictive variables for the development of interictal psychosis in seizure disorders:
- a. Earlier age of onset of the epilepsy
 - b. Complex partial seizure of the temporal lobe and GTCS are the usual seizure types
 - c. A family history of psychosis
 - d. Borderline cognitive function

Clinical Manifestations of Bilateral Temporal Lobe Lesions

1. Klüver-Bucy syndrome:
 - a. General characteristics:
 - i. The syndrome may occur from temporal lobe epilepsy, temporal lobectomy and partial status epilepticus
 - ii. May occur at any age
 - iii. Children are similarly affected as adults
 - b. Clinical manifestations:
 - i. Oral exploration of objects
 - ii. Hypermetamorphopsia (all objects are examined with the same degree of interest and intensity)
 - iii. Short term memory deficit
 - iv. Marked and indiscriminate hypersexuality
 - v. Shame rage
 1. Trivial provoking events cause anger that reaches maximum intensity instantly and returns to the baseline affective state quickly
 - c. Neuropathology
 - i. Medial temporal sclerosis with migrational disorders
 - ii. Trauma (bilateral temporal lobe involvement)
 - iii. Surgery on one temporal lobe (usually lobectomy)
 1. The remaining temporal lobe being dysfunctional
 - iv. X-RT through the temporal lobes
 1. Pituitary tumors
 - v. Viral encephalitis
 1. Herpes simplex
 - vi. Autoimmune
 1. Limbic encephalitis
 - vii. Mucopolysaccharidoses type IIIA
 - viii. Pick's disease
 - ix. Alzheimer disease
 - x. Heat stroke
 - d. Neuroimaging
 - i. MRI:
 1. Bitemporal involvement with extratemporal involvement (frontal lobe, generalized atrophy, extratemporal deficits) depending on specific pathology

Differential Diagnosis of TLE

1. Facial blankness and staring may resemble absence seizures
2. Complex partial seizures (CPS) from the temporal lobe versus affective psychosis

TLE Associated with

1. Geshwind's syndrome (TLE personality traits):
 - a. Schizoid behavior (often bitemporal involvement)
 - b. Hyper-religiousness (3 religious conversions)
 - c. Hypergraphia (lists of every seizure event)
 - d. Viscous (unable to terminate appropriate questions or a personal interaction)
2. Signs and symptoms supporting seizure rather than psychosis:
 - a. Simple visual or auditory hallucination and illusions
 - b. Usually these are of short duration, stereotyped and intermittent
 - c. Associated speech arrest (primarily receptive)
 - d. Autonomic phenomena
 - e. Patients have insight
3. TLE versus episodic dyscontrol syndrome:
 - a. Episodic dyscontrol syndrome:
 - i. Uncontrolled rage
 - ii. May be alcohol triggered
 - iii. Occurs with provocation
 - iv. Out of patients usual character
 - v. May have CNS deficits
 - vi. May have documented seizures
 - vii. Followed by fatigue and confusion
 - viii. May be amnesic
 - ix. Violence against individuals is common
 - b. TLE:
 - i. Personally directed violence is rare
 - ii. Stereotyped
 - iii. Associated signs and symptoms of seizure activity
4. Migraine with abdominal pain or nausea vs. TLE (or insular cortex seizure focus):
 - a. In children with migraine; the abdominal symptoms may be associated with headaches
 - b. TLE the abdominal auras are followed or associated with rising heat sensations, impairment of consciousness or other epileptic phenomena
 - c. Total duration of episodes is longer in migraine episodes than seizures
 - d. Migraine auras last approximately 5 minutes prior to headache onset, epileptic auras are usually only a few seconds to less than 5 minutes
 - e. Consciousness usually intact with migraine (may be lost with Bickerstaff's migraine or some confusional states)
 - f. Automations support the diagnosis of seizure
 - g. Following migraine, there is less alteration of consciousness than after seizures

5. TLE vs. cardiac arrhythmia:

- a. Major cardiac mechanisms that cause altered consciousness are:
 - i. Cardiac arrhythmia
 - ii. Pump failure (ejection fraction <30)
 - iii. Outflow tract dysfunction
 - iv. Long QT syndrome
 - v. Conduction blocks
- b. Insular seizures may be associated both with chest discomfort and autonomic control of blood pressure
- c. TLE and Cardiac Phenomena:
 - i. Attacks are not associated with the usual cardiac risk factors
 - ii. Associated with other epileptic phenomena
- d. Altered consciousness:
 - i. Tachyarrhythmias are usually noted by the patient prior to decreased cerebral perfusion; bradyarrhythmias may cause loss of consciousness without warning (long QT and heart block)
 - ii. Chest pain in TLE not in the usual cardiac distributions (may involve the throat)
 - iii. Post-ictal phenomena (fatigue, dull headache and thirst) greater with TLE. Cardiac syncope rarely causes post-event confusion

6. TLE vs. Vasovagal syncope:

- a. Clinical characteristics of vasovagal syncope:
 - i. Characteristic pallor prior to the episode
 - ii. A precipitating event (specific site or stress)
 - iii. Slow pulse (adults < 40 beats per minute (bpm))
 - iv. Less than 30 seconds in duration; usually less than 10 seconds
 - v. No confusion or other post event phenomena
 - vi. Patients may have a few myoclonic jerks

7. TLE vs. Vasodepressor syncope:

- a. Vasodepressor syncope clinical characteristics:
 - i. Precipitating event (prolonged bed rest; hypertensive medications; sudden upright posture)
 - ii. Rapid pulse (> 120 beats per minute (bpm))
 - iii. Loss of awareness is brief
 - iv. Recovery of consciousness is often very brief (less than 5 seconds, but may take up to 30 seconds)
 - v. Some transient disorientation but no behavioral confusion
 - vi. Patients insight of the event is maintained

8. Syncope by definition is a brief loss of consciousness and postural tone due to insufficient cerebral perfusion. Its prodromes (more often with vasodepressor than vasovagal) are light headedness, dimming of vision (tend to close in from the side) nausea, muffled hearing (sounds distant), diaphoresis and generalized weakness**9. TLE vs. movement disorders**

- a. Repetitive or sustained movements are against TLE and include:
 - i. Tremors
 - ii. Chorea

- iii. Athetosis
- iv. Dystonia
- b. Episodic:
 - i. Tics
 - ii. Myoclonus
 - iii. Hyperekplexia
 - iv. Paroxysmal dyskinesia

Paroxysmal Dyskinesia vs. Frontal or Temporal Lobe Seizures

1. A frontal lobe focus is much more common than a temporal lobe focus with paroxysmal dyskinesia
2. Kinesigenic or non-kinesigenic paroxysmal dyskinesia may mimic hyperkinetic frontal or temporal lobe seizure:
 - a. Features favoring frontal lobe seizures include:
 - i. Explosive onset
 - ii. Duration of <30 seconds
 - iii. Automatisms, extreme restlessness, pedaling of legs, loud vocalizations
 - iv. Progression into tonic or clonic activity
 - v. Post-ictal weakness
 - vi. Impairment of consciousness
 - vii. EEG discharges and post-ictal slowing clinch the seizure diagnosis, but may be absent in up to 40% of patients
 - b. Features favoring paroxysmal dyskinesia
 - i. Onset of abnormal movements is slower
 - ii. Attacks can last for minutes to hours (only a few seconds, with kinesigenic paroxysmal dyskinesia)
 - iii. No impairment of consciousness
 - iv. Paroxysmal choreoathetosis is associated with provoking factors (sudden movement (kinesigenic), physical exertion, alcohol, caffeine, and hyperventilation)

Stereotypies vs. Complex Partial Temporal Lobe Seizure

General Features of Stereotypies

1. Involuntary, patterned, repetitive, purposeless movements or behavior
2. Occur most often in patients with cognitive impairment, autistic spectrum disorders and Reth syndrome
3. Repertoire of stereotypic behavior may be present
4. Duration and frequency of stereotypic movements are of longer duration and occur several times/day; TLE shorter and less frequent
5. No alteration of consciousness with stereotypies
6. Associated with precipitating events
7. Stereotypies occur during wakefulness

Factors Favoring Seizures

1. Duration and frequency are shorter
2. Associated automatisms
3. Alteration of consciousness
4. No repertoire of movements

5. Often arise out of sleep
6. Impairment of consciousness
7. Cardiac arrhythmias that may occur during TLE complex partial seizures that may be associated with altered consciousness:
 - a. Supraventricular tachycardia
 - b. Sinus tachycardia
 - c. Sinus bradycardia
 - d. Sinus arrest
 - e. AV block
 - f. Asystole
 - g. Reduced heart rate variability
8. General features of cardiac arrhythmias during seizures:
 - a. Sudden induced arrhythmias is a cause of death in seizure patients (SUDEP)
 - b. Ictal tachycardias are more common than bradyarrhythmias
 - c. Bradyarrhythmias occur with both right and left temporal lobe seizures
 - d. Intraoperative stimulation of the insular cortex produces
 - i. Tachyarrhythmias and a pressor response (right anterior insular cortex)
 - ii. Bradycardia and depressor response with L anterior insular cortex stimulation
 - e. Sinus arrest with asystole with left temporal cortex stimulation
 - f. Ictal bradycardia; increased parasympathetic outflow through the vagus nerve
 - g. Stimulation of the amygdala causes bradycardia
 - h. Stimulation of the orbital frontal cortex and cingulate gyrus cause brady- and tachyarrhythmias

Insular Cortex Seizure

1. General Characteristics
 - a. The only cortex that is not visible on the brain surface
 - b. Triangular in shape
 - c. Separated from the frontoparietal and temporal opercular cortex by the anterior, superior and peri-insular sulci
 - d. It is morphologically divided by the central insular sulcus:
 - i. The anterior insula is composed of three short gyri
 - ii. The posterior insula contains two long gyri
 - e. The insula is functionally involved in:
 - i. Cardiac rhythm and arterial blood pressure control
 - ii. Visceromotor function
 - iii. Viscero sensation
 - iv. Processing of nociceptive input
 - v. Interoception
 - f. Insular discharges (recorded by stereoelectroencephalography (SEEG)
 - i. Similar to symptomatology to that of the medial temporal lobe
 - ii. Respiratory viscerosensitive (chest or abdominal constriction)

- iii. Oroalimentary (chewing and swallowing) manifestations
- iv. Unpleasant contralateral somatosensory paresthesias opposite the ictal focus (may be painful)
- v. Ictal signs occur with full consciousness (simple partial seizures)
- vi. Temporal lobe seizures frequently propagate to the insula; possibly 10% of TLE originate in the insula
- vii. Hemisensory sensations and dysgusia an insular pattern
- g. Progression in some patients:
 - i. Sensation of laryngeal constriction
 - ii. Unpleasant contralateral somatosensory paresthesias
 - iii. Dysarthric speech and/or elementary auditory hallucinations
 - iv. Seizures terminated with focal dystonic postures
- 2. Clinical Manifestations
 - a. Respiratory
 - i. Modulation of the amplitude and frequency of respiratory movement
 - ii. Patients feel chest fullness and constriction
 - b. Viscerosomatic:
 - i. Chest constriction ascending to the anterior cervical region associated with nausea
 - ii. Abdominal constriction and heaviness
 - iii. Intense distressing abdominal pain
 - iv. A feeling of throat and laryngeal constriction
 - c. Contralateral somatosensory paresthesias
 - i. Ascending retrosternal feeling of heat
 - ii. Unpleasant and at times painful hemisensory paresthesias
 - d. Painful somatosensory seizures
 - i. Analysis of ictal recordings and stimulation with intracerebral electrodes (5 patients)
 - 1. Pain intensity is greater than from stimulation of SI
 - 2. Elicited pain was not somatotopically organized
 - 3. Large receptive fields
 - 4. The insula and SII (at the foot of SI) were involved at the onset of seizures
 - e. Oroalimentary manifestations:
 - i. Sensation of laryngeal constriction
 - ii. Chewing and swallowing
 - f. In six out of 50 patients with insula seizures a specific ictal sequence occurred:
 - i. The patients were fully conscious; the ictal event was initiated by a feeling of laryngeal constriction and paresthesia followed by unpleasant hemibody sensations and terminally by dysarthria and focal motor signs that included focal dystonic postures
 - g. Dysarthric speech and elementary hallucinations are seen as a pattern
 - h. Temporal lobe seizures frequently propagate to the insula; possibly 10% of TLE originates in the insula

- i. Sleep-related hypermotor seizures may originate in the insula
 - i. Complex motor manifestations occur when the ictal discharges spread to frontomesial areas (the cingulum, superior frontal gyrus and the supplementary motor area) or to neocortical temporal lobe

Parietal Lobe Seizures

- 1. General Characteristics
 - a. Greater than 90% of patients exhibit auras
 - b. The electrophysiological organization and clinical manifestations are complex due to propagation pathways and the wide connectivity of the parietal lobe
 - c. Ictal spread to frontal, supplementary motor or temporolimbic areas
 - d. Recognized parietal and occipital epilepsy syndromes include:
 - i. Benign epilepsy of childhood with centrotemporal spikes
 - ii. Benign epilepsy of childhood with parietal evoked spikes
 - iii. Migraine/epilepsy associations
 - e. Frequent poor correlation between clinical and EEG characteristics
- 2. Clinical Manifestations
 - a. Somatosensory auras:
 - i. Paresthesias
 - ii. Rarely painful (SI involved)
 - iii. Thermal (heat; SII)
 - iv. Sexual sensations
 - v. Disturbances of body image
 - b. Visual auras:
 - i. The environment may be tilted
 - 1. Alteration in the subjective visual vertical
 - ii. Complex hallucinations and illusions of body parts
 - 1. Most often in severe pain states the affected body part may be distorted
 - iii. Oculogyric and eyelid flutter
 - c. Vertiginous sensations (originate from the intraparietal sulcus)
 - d. Tonic posturing (epileptic zones that include the superior parietal lobule)
 - e. Automatisms (epileptic zone that extends to the inferior parietal lobe)
 - f. Disturbance of body image (inferior parietal lobule)
 - g. Anosognosia, apraxia (ideational), alexia and aphasia
 - i. Involvement of BA39, BA40, BA41, BA42
 - h. Aphemia
 - i. Severe dysarthria
 - ii. Difficulty with initiation of speech with retained receptive speech
 - i. Confusional states

- j. Gustatory symptoms
 - k. Ipsilateral version
 - l. Oral gestural automatisms; a small proportion with complex automatisms
 - m. Adversive movements
 - n. Unilateral clonic activity
 - o. Hyperkinetic motor behavior (inferior parietal lobule)
3. EEG Evaluation
- a. Frequently there is poor correlation between scalp EEG and Clinical Semiology
 - b. Interictal discharges demonstrate scatter outside of the parietal lobe
 - c. The majority of patients have more than one spike population

Occipital Lobe Seizures

Overview

Seizures emanating from the occipital lobe present a variety of signs and symptoms both from initial areas of activation and from spread. Visual symptoms are the most common feature of occipital lobe seizures. Elementary visual hallucinations that occur with visual seizures usually from seconds to 1–5 minutes. They consist of colored and small circular patterns that may flash and appear in a temporal hemifield. Blurred vision may occur prior to visual hallucinations. Ictal blindness may occur. Eye movement sensations, eyelid fluttering or forced blinking in association with eye or head deviation is common (contralateral to the seizure focus). Ipsilateral head and eye deviation can be seen. Spread to the temporal lobe with concomitant automatism and loss of awareness is common. Percentage of patients demonstrate myoclonic tonic or focal clonic motor activity characteristic of frontal lobe involvement. Visual reflex seizures may be triggered by patterned flashing lights (video games, strobe lights). Seizure triggering properties of video ensembles include brightness, pattern flicker frequency and color.

Simple Partial Seizure of the Occipital Lobe

1. General Characteristics
 - a. Approximately 2/3 manifest temporal lobe auras
 - b. 1/3 have both temporal and frontal auras
 - c. Spread from an occipital lobe focus is by:
 - i. The inferior longitudinal fasciculus
 - ii. Inferior occipital-frontal fasciculus
 - iii. Occipital-parietal junction to the frontal lobe through the superior longitudinal fasciculus
2. Clinical Manifestations
 - a. Initial signs and symptoms
 - i. Forced eye blinking with head version
 - ii. Blurred vision
 - iii. Flashing lights
 - iv. Ictal blindness
 - v. Elementary visual hallucinations

- b. Occipital pole ictal focus (BA17)
 - i. Simple non-colored flashes of light (dots and circles)
 - ii. Do not move across the visual field
- c. Area 18 and 19 ictal focus (visual association cortex):
 - i. Colored (red, green, yellow, blue) dots, circles and geometric figures are experienced
 - ii. Figures and patterns move across the contralateral visual field (migraine and vascular etiologies > seizure)
 - iii. Putatively secondary to cortical spreading depression from stroke or migraine
- d. Posterior temporal/parieto/occipital cortex junction ictal focus:
 - i. Distortion of objects
 - ii. Images are colored
 - iii. Often associated with other temporal lobe semiologic phenomena
 - iv. Unilateral eye blinking (rare)
 - v. Cortical blindness (rare)
 - vi. Epileptic akinetopsia:
 1. Illusory motion perception
 2. The contralateral visual field is affected
 - vii. Epileptic monocular nystagmus
- e. Signs of occipital seizure spread to the temporal lobe
 - i. Specific visual field deficits (superior quadrantanopsia)
 - ii. Psychical aura
 - iii. Olfactory aura
 - iv. Dizziness
 - v. Somatosensory aura

Idiopathic Childhood Occipital Epilepsy of Gastaut (ICOE-G)

1. General Characteristics
 - a. Relatively rare; approximately 2.7% of benign childhood focal seizures
2. Clinical Manifestations
 - a. Elementary visual hallucinations with multi-colored circular patterns and ictal blindness
 - b. Eye deviation with concomitant head version
 - c. Non-visual ictal symptoms follow the visual ones
 - d. Eyelid fluttering may portend secondary generalization
 - e. Headache and post-ictal transient blindness may occur after prolonged seizures
 - f. Consciousness is preserved at onset but becomes clouded with seizure progression
 - g. There is 50–80% remission within 2–4 years at onset
 - h. Often misdiagnosed as migraine with visual aura
3. Neuropathology
 - a. Functional derangement of systemic brain maturation
4. Neuroimaging
 - a. MRI:
 - i. No structural lesions
5. Laboratory Evaluation

- a. EEG:
 - i. Occipital spike-and-wave pattern
 - ii. "Fixation off" sensitive epileptic activity is induced with eye closure and terminated when the eyes are open (fixation)
 - iii. Elementary visual hallucinations occur with fast spike activity
 - iv. Complex visual hallucinations occur with slower ictal discharges
 - v. Ictal fast spike rhythm may occur prior to eye deviation
- 1. Absence
- 2. Myoclonic
- 3. GTCS
- vii. Epilepsy provoked by television and video games
 - 1. The EEG is activated by:
 - a. Video screens
 - b. Flickering screen light
 - c. Patterns that produce parallel lines that form the image
 - d. Frequency of 25 Hz activate approximately 75% of susceptible patients
 - 2. Seizure types provoked are similar to other photosensitive epilepsies; also provoke partial occipital lobe seizures

Photosensitive Epilepsy

1. General Characteristics

- a. Definition:
 - i. Photosensitivity is defined by the elicitation of occipital or diffuse electroencephalographic spikes and waves by intermittent light stimulation
- b. Photosensitive epilepsies are most common in childhood and adolescence or a feature of idiopathic generalized epilepsies
- c. NEDD4-2 (Neuronally Expressed Developmentally Downregulated 4) gene
 - i. Encodes a ubiquitin protein ligase
 - ii. Regulates cell surface levels of ion channels, receptors and transporters that influence neuronal excitability
 - iii. Possible susceptibility gene for epileptic photosensitivity

2. Clinical Manifestations

- a. Affects 1:4000 seizure patients
- b. High incidence of a family history
- c. General features:
 - i. Stimuli are flashing lights or high contrast patterned stimuli
 - ii. Chromatic sensitivity
 - iii. Stimulus frequency: 10–30 Hz
 - iv. Pattern sensitivity: 5–6 cycles/degree
 - 1. There are chromatic sensitive seizure variants
 - 2. Photo paroxysmal response to rapid color frame changes (blue to red: monochromatic light changes)
 - v. Sensitivity to seizures is increased by:
 - 1. Screen brightness
 - 2. Highly contrasted patterns
 - 3. Fatigue
 - 4. Fever
 - 5. Closeness to the stimulus
 - 6. Sleep deprivation
 - 7. "Fixation off" sensitivity
 - a. Elimination of central vision and fixation induces spikes on the EEG (unilateral or bilateral; of high amplitude)
 - vi. Seizure types that are provoked:

3. Neuropathology

- a. In some patients with occipital lobe epilepsy:
 - i. Periventricular subcortical nodular heterotopias
 - ii. Focal cortical dysplasia which includes polymicrogyria, heterotopias and abnormal cortical lamination
 - iii. Migrational disorders tend to occur posteriorly
 - iv. Vascular disease, tumor, head trauma and inflammatory conditions (Balo's concentric demyelination and tumefactive MS) all occur in the occipital cortex

4. Neuroimaging

- a. MRI:
 - i. Pathology specific disorders (stroke, tumor, inflammation)
 - ii. Migrational defects

5. Laboratory Evaluation

- a. Occipital and diffuse electroencephalographic spikes and waves induced by intermittent light stimulation
- b. Only the diffuse spikes and waves induced by intermittent light stimulation are correlated with epilepsy. Spikes are accentuated by sleep in the childhood form
- c. Magnetoencephalography:
 - i. Cortical responses to a static grating stimulus with altered power but not frequency and increased visual gamma responses are characteristic of photosensitive epilepsy

6. Differential Diagnosis Between Occipital Seizures and Migraine Visual Auras

- a. Visual hallucinations of colored and small circular patterns that flash and are noted in any hemifield are most common in occipital lobe seizures
- b. Elementary and visual hallucinations and visual loss may also occur with anteromedial temporal and occipitotemporal foci
- c. Lesions of the lateral occipital lobe (BA18 and BA19) may elicit twinkling or pulsating lights contralaterally
- d. Linear zig zag lines (fortification scotoma) and achromatic black and white patterns are much more common in migraine
- e. Visual seizures are often frequent and occur in clusters:

- i. A segway into temporal lobe or frontal lobe symptomatology
- ii. Ictal blindness may occur from a seizure due to a focus in one occipital lobe
- f. Vomiting may be ictal (focus in the insular cortex) or a component of seizure provoked migraine
- g. A hemicranial headache that occurs during a seizure:
 - i. Seizure focus may be the ipsilateral amygdala or the hippocampal formation
- h. Rapid onset and resolution of symptoms are most often an epileptic discharge
- i. Ictal epileptic headaches occur and are characterized by:
 - i. An onset and termination coincident with scalp or deep EEG pattern of an epileptic discharge
 - ii. May be followed by motor, sensory or autonomic manifestations
 - iii. Migraine may be the sole epileptic manifestation of the seizure
- j. Points favoring migraine:
 - i. Triggering events
 - ii. Prolonged attack
 - iii. Cortical spreading depression (visual signs/symptoms followed by parietal and frontal neurologic deficits)
 - iv. Slight impairment of cognitive processing rather than complete unresponsiveness

Convulsive Status Epilepticus

1. General Characteristics
 - a. Definition:
 - i. Failure to regain consciousness between seizures (convulsive status)
 - ii. Mortality has dramatically fallen with intensive care and newer medications
2. Clinical Characteristics
 - a. Prolonged status of greater than 30 minutes may be associated with neurologic deficits
 - b. Medical associations include:
 - i. Acidosis
 - ii. Hypotension in general but occasionally severe hypertension
 - c. Hyperthermia
 - d. Renal failure secondary to myoglobinuria
 - e. Injury:
 - i. Posterior shoulder dislocation
 - ii. Subdural hematoma (falls)
 - iii. Fractured vertebrae
 - f. Rare neurogenic pulmonary edema
 - g. Deficits in memory (amnesic state)
3. Neuropathology
 - a. Drug withdrawal
 - b. Alcohol withdrawal
 - i. Approximately 2% develop status epilepticus

- c. Vascular disease, head trauma, encephalitis, autoimmune diseases and brain tumors are major causes. All primary causes may cause status epilepticus
- d. Hypoxic changes and borderzone ischemia; putatively hippocampal formation sclerosis
- 4. Neuroimaging
 - a. MRI:
 - i. FLAIR and DWIC (diffusion weighted images) define areas of the focal seizure or in the hippocampal formation
 - ii. The signal changes may last for days

Clinical Variants of Status Epilepticus

Absence Status

1. General Characteristics
 - a. The most common childhood epilepsy
 - b. Absence status is diagnosed when there is no interval of normal mental activity between attacks which may be bunched per day
2. Clinical Manifestations
 - a. Seizures are short
 - b. Rapid onset and termination
 - c. Sudden loss of consciousness
 - d. A brief stare and cessation of activity
 - i. 10% of patients are motionless
 - ii. Most have bursts of myoclonic movements of the eyelids or facial muscles, fingers or synchronous movements of the arms at 3 per second
 - iii. May have minor automatisms
 - iv. Vasomotor alterations occur
 - e. Absence status occurs in adults
 - i. Associated with generalized tonic-clonic seizures
 - f. Carbamazepine or phenytoin may induce absence status in idiopathic generalized epilepsy, atypical absence epilepsy and both typical and atypical myoclonic epilepsy

Myoclonic Status Epilepticus in Juvenile Myoclonic Epilepsy (MSE)

1. General Characteristics
 - a. Rarely occurs in juvenile myoclonic epilepsy
2. Clinical Manifestations (7 patients/247)
 - a. Age range from 17–73 years
 - b. Incidence of 3.2/1000 patient years
3. Three subtypes:
 - a. MSE with only myoclonus (2/7)
 - b. MSE with GTCS (3/7)
 - c. GTCS with myoclonus absence status (2/7)
4. One patient had repeated episodes of MSE
5. Precipitating events:
 - a. Drug withdrawal (4/7)
 - b. Sleep deprivation and alcohol (1/7)

Refractory Status Epilepticus

1. General Characteristics

- a. Definition:
 - i. Status epilepticus that fails to respond to the acute administration of two antiepileptic medications
 - ii. Occurs in approximately 1/3 patients with status epilepticus
 - iii. Is associated with increased mortality and functional disability
- b. If status epilepticus is continuous or recurs 24 hours or more after administration of anesthetics it is termed super refractory status epilepticus (RSE)
2. Clinical Manifestations
 - a. Generalized convulsive status epilepticus or complex partial status epilepticus that fails initial therapies
 - b. Stupor or coma following a GCTS or complex partial seizure
 - c. Stupor or coma following brain surgery or acute brain injury
 - d. Patients with cardiopulmonary complications and prolonged drug-induced have worse functional outcomes
 - i. 75% of RSEs have a poor outcome
 - e. A condition of ongoing or intermittent clinical epileptic activity without convulsions for at least 30 minutes
 - f. It is seen in a heterogeneous group of illnesses and accounts for approximately 20–30% of status epilepticus patients
 - g. The most frequent form is complex-partial status epilepticus
2. Clinical Manifestations
 - a. Partial status epilepticus
 - b. Absence status
 - c. Aura status
 - d. Subtle status
 - e. A possible diagnosis in all patients with unexplained change or altered level of consciousness or behavior
 - f. In the pediatric population
 - i. Can occur in acute neurological injuries
 - ii. Specific childhood epilepsy syndromes
 - iii. Patients with learning difficulties
3. Laboratory Evaluation
 - a. EEG
 - i. Low cut-off frequency limit of 2.5–3 Hz for non-evolving patterns
 - ii. Discharge evolution of frequency, location or morphology
 - iii. A secondary criterion:
 1. A significant clinical or EEG improvement after the administration of a rapidly acting anti-epileptic drug

Electrical Status Epilepticus in Sleep

1. General characteristics
 - a. Electrical status epilepticus in sleep (ESES)
 - i. An EEG pattern of activation of epileptiform discharges in sleep
 - ii. The two clinical epileptic syndromes seen with ESEs are
 1. Continuous spike-and-wave in slow-wave sleep (CSWS)
 2. Landau-Kleffner syndrome (LKS)
2. Clinical Manifestations
 - a. There is an overlap between the two syndromes
 - b. CSWS:
 - i. A global regression of function
 - ii. Difficult to treat seizures
 - iii. EEG foci are primarily in the frontotemporal or frontocentral regions
 - c. Landau-Kleffner syndrome
 - i. Have an acquired auditory agnosia
 - ii. Fewer seizures
 - iii. EEG ictal focus in posterotemporal areas
 - d. Electrical status epilepticus in slow wave sleep
 - i. Is self-limited
 - ii. EEG abnormalities of continuous epileptic activity persists through 85% of non-rapid eye movement sleep
 1. EEG activity is spike-and-wave epileptic discharges
 - iii. The developmental and neuropsychological prognosis is correlated with the length of the ESEs

Non-Convulsive Status Epilepticus

1. General Characteristics
 - a. Definition:
 - i. A wide variety of etiologies have been described as causative and include:
 - i. Rasmussen's syndrome
 - ii. Russian spring-summer tick-borne encephalitis

Epilepsia Partialis Continua

1. General Characteristics
 - a. The eponym for the disease is Kozhevnikov epilepsy
 - b. Typically associated with lesions of the cerebral cortex
2. Clinical Manifestations
 - a. Persistent rhythmic clonic movements of one muscle group most often of the face, arm or leg
 - b. Occur at regular intervals and may last for months without spread to other muscle groups
 - c. It is a focal motor status epilepticus
 - d. The distal muscles of the hand and fingers are more often affected than proximal muscles
 - e. The corner of the mouth and eyelids are most often affected in the face
 - f. Rarely isolated muscles of the neck and trunk may be affected unilaterally
 - g. Different proprioceptive input from the involved muscles may decrease the movements
 - h. The movements may be diminished not abolished in sleep
3. Neuropathology
 - a. A wide variety of etiologies have been described as causative and include:
 - i. Rasmussen's syndrome
 - ii. Russian spring-summer tick-borne encephalitis

- iii. Vascular disease
 - iv. Multiple sclerosis
 - v. Steroid responsive encephalopathy with autoimmune thyroiditis
 - vi. Mitochondrial diseases
 - vii. Alcohol-responsive (one patient reported)
 - viii. Developmental anomalies
 - ix. Hyperosmotic syndromes
 - x. Degenerative disease
 - xi. Unknown cause
 - xii. Autopsy has revealed involvement of the contralateral motor cortex
4. Neuroimaging
- a. MRI
 - i. Characteristics of the underlying neuropathologic cause
5. Laboratory Evaluation
- a. EEG:
 - i. Focal EEG abnormalities that include
 - 1. Repetitive slow wave discharges
 - 2. Sharp waves or spikes either over the central areas of the contralateral hemisphere or the area of discharge
 - b. Some patients have demonstrated concomitant cortical myoclonus with epilepsia partialis continua

Focal Seizures Characterized by Altered Awareness

- 1. General Characteristics
 - a. Focal status epilepticus most commonly occurs from an ictal focus in the temporal lobe. The second most common focus is the frontal lobe
- 2. Clinical Manifestations
 - a. Patients with temporal lobe focal status epilepticus demonstrate:
 - i. Altered awareness and behavior
 - ii. Often manifest by automatism that are perseverative or de-novo
 - iii. Lip-smacking and chewing
 - iv. The patient is amnesic for the event
 - v. The episode may last for hours and rarely for days
 - b. Frontal lobe focal status
 - i. May be associated with complex motor functions
 - 1. Bicycling or pedaling movements, running and complex automatisms
 - 2. Dystonias of the extremities contralateral to the focus
 - 3. Version (forced) of the head and eyes
 - 4. Gyrotory movements
- 3. Neuropathology
 - a. Temporal Lobe status
 - i. Medial hippocampal sclerosis
 - ii. Developmental anomalies of the temporal lobe
 - iii. Low grade astrocytomas
 - iv. Arteriovenous malformations
 - v. Migrational defects

- vi. Head trauma
 - vii. Vascular disease
 - viii. Rare autoimmune or inflammatory disease
 - ix. Paraneoplastic syndromes
- b. Frontal Lobe status
- i. Head trauma
 - ii. Primary or metastatic tumor
 - iii. Migrational defects
 - iv. Vascular disease (stroke or hemorrhage)
 - v. Arteriovenous malformation
 - vi. Autoimmune or inflammatory conditions
 - vii. Rasmussen's encephalitis
 - viii. Paraneoplastic syndromes (Anti-Hu antibody and those associated antibodies to potassium channel complexes)
4. Neuroimaging
- a. MRI:
 - i. Lesions of the underlying pathology
5. Laboratory Evaluation
- a. EEG
 - i. Ictal discharges are demonstrated during the seizure activity

Psychogenic Non-Epileptiform Seizures (PNES)

- 1. General Characteristics
 - a. Definition:
 - i. Episodes which simulate convulsive or non-convulsive seizures that are not the result of an epileptic discharge
 - ii. Comprise a proportion of treatment resistant epilepsies; possibly >50% of patients with PNES have been treated with anti-epileptic medication (AEDs)
 - iii. Approximately 4% of patients with transient loss of consciousness and many with apparent status epilepticus
 - iv. A significant portion of patients with PNES have true epileptic seizures
- 2. Clinical Manifestations
 - a. Synchronous thrashing
 - b. Side-to-side head movements
 - c. Tip of the tongue biting
 - d. Pelvic thrusting; rapid tremor
 - e. Opisthotonic posturing
 - f. Screaming or speaking during the episode
 - g. Forced eye closure against resistance
 - i. Lids are open or demonstrate clonic movements during seizures
 - h. Prolonged episodes
 - i. Rapid breathing
 - i. Apnea occurs during or after an ictal event
 - j. Occur in the presence of observers
 - k. Are precipitated by emotional events
 - l. Continence is maintained
 - m. Avoidance of dangerous falls
 - n. Prolonged vague states may be PNES

- o. Sexual abuse and previous psychiatric difficulties prior to PNES onset
- 3. Neuropathology
 - a. Abnormal functional connectivity density
 - i. Functional connectivity density mapping (voxel-wise data driven technique) has demonstrated:
 - 1. Abnormal functional connectivity density in the frontal cortex, sensorimotor cortex, cingulate gyrus and insula
 - 2. PNES patients demonstrated abnormalities in several resting state networks
- 4. Neuroimaging
 - a. MRI:
 - i. May be abnormal in approximately 1/3 of patients due to varying pathologies
- 5. Laboratory Evaluation
 - a. Video-EEG
 - i. Is able to distinguish symptoms compatible for PNES from Epileptic seizures
 - ii. Interictal EEG may be abnormal in a significant mesiofrontal region and anterior nuclei of the thalamus
 - b. GCTC patients showed no differences from controls

IGE Evaluated by Diffusion-Tensor Imaging

- 1. Analysis of fractional anisotropy (FA), mean diffusivity (MD), axial and radial diffusivity
- 2. There are widespread FA reductions and increases of mean and radial diffusivity as compared to controls in the JME in the:
 - a. Corpus callosum
 - b. Corticospinal tracts
 - c. Superior and inferior longitudinal fasciculi
 - d. The anterior limb of the internal capsule
- 3. There were no fractional anisotropy differences in idiopathic generalized epilepsy with tonic-clonic seizures (IGE-GTC) number of patients
- 4. Epileptiform activity is seen in <10% of patients
- 5. The serum creatinine kinase is normal after PNES episodes

Reflex Epilepsies

- 1. General Characteristics
 - a. Seizures can be evoked in predisposed patients by specific external or internal stimuli
 - b. The classification of these types of seizures is based on the stimulus characteristics
- 2. Clinical Manifestations
 - a. Visual stimuli
 - i. Patterns, colors, frequency of flicker
 - b. Auditory stimuli
 - i. Startle
 - ii. Specific sounds
 - iii. Music (particular tones)
 - iv. Voice
 - c. Somatosensory

- i. Rubbing or touching a specific
- ii. Thermal stimuli (hot bath)
- d. Reading, writing, mental arithmetic, chess playing and various praxis

Characterization by Generalized Versus Focal Reflex Seizures

- 1. Generalized reflex seizures
 - a. Precipitated by specific aspects of light stimuli
 - b. Various aspects of thinking and decision making
 - c. Respond to valproic acid
- 2. Focal reflex seizures
 - a. Reading, writing, other language functions
 - b. Startle
 - c. Somatosensory stimulation (brief or sustained)
 - d. Proprioception
 - e. Auditory stimuli
 - f. Thermal (hot water immersion)
 - g. Vestibular stimuli
 - h. Eating
 - i. Orgasm
- 3. Types of seizures elicited by specific stimuli
 - a. Partial complex seizures
 - i. Reading
 - ii. Voices
 - iii. Eating
 - b. Visual stimuli:
 - i. Myoclonic
 - ii. Generalized tonic-clonic
 - c. Music induced:
 - i. Myoclonic
 - ii. Simple or complex partial seizures
 - d. Visual and higher cortical functions
 - i. Generalized tonic-clonic seizures
 - e. Focal seizures (beginning in a specific body part) may evolve from myoclonic jerks to an absence or GTCS
- 4. Neuropathology
 - a. Focal lesions of the occipital lobe in some instances
 - b. Regions of cortical hyperexcitability or distributed neural circuits that are physiologically activated by sensory, motor or cognitive input
 - c. Migrational defects
- 5. Neuroimaging
 - a. MRI:
 - i. Often normal
 - ii. Rarely a migrational defect or structural lesion most often in the occipital lobe

Sudden Unexplained Death in Epilepsy (SUDEP)

- 1. General Characteristics
 - a. SUDEP is the leading cause of death in patients with refractory epilepsy
 - b. Risk may be as high as 35% in this population
 - c. Occurs most often in adulthood
- 2. Clinical Manifestations
 - a. Most patients have history of GTCS and die in bed

- b. In children a higher risk is seen with:
 - i. Refractory epilepsy
 - ii. Developmental delay
 - iii. Tuberous sclerosis
 - iv. Some epileptic syndromes
- c. Risk factors in adults
 - i. Refractory seizures
 - ii. Non-therapeutic anti-epileptic drugs
 - iii. Post-ictal period following a tonic-clonic seizure
 - iv. Early adulthood
 - v. Cognitive impairment
 - vi. v3 GCTS in the prior year
- 3. Neuropathology
 - a. Putative seizure-induced cardiac and respiratory arrest
 - b. Defects in the serotonergic system
 - c. Ictal adenosine release
 - d. Autonomic dysregulation
- 4. Neuroimaging
 - a. MRI:
 - i. Normal other than the pathologies that may be associated with the underlying seizure disorder
- 5. Laboratory Evaluation
 - a. EEG
 - i. Post-ictal generalized EEG suppression

Laboratory Abnormalities Associated with Seizures

- 1. Disruption of the blood-brain barrier (BBB)
 - a. Following a focal seizure there may be focal cerebral edema at the ictal zone demonstrated by:
 - b. Increased T2-weighted, FLAIR (fluid-attenuated inversion recovery) and DWI (diffusion-weighted) sequence signal in the ictal zone. There may be slight gadolinium enhancement in the same area
 - c. There is a correlation between the length of the seizure and these neuroimaging signal abnormalities
 - d. Angiography and perfusion imaging techniques may also demonstrate increased blood flow and volume in the ictal zone
 - e. Neuroimaging deficits rarely last for more than 24 hours
 - f. Increased T2 signal intensity and DWI signal may be seen in other structures following a prolonged seizure. These include:
 - i. Hippocampus
 - ii. Thalamus
 - iii. Cerebellum
 - iv. Splenium of the corpus callosum
- 2. Systemic abnormalities following prolonged convulsive seizures
 - a. Increased lactic acid with a drop of serum pH to 6.8–7.0
 - b. Rise in serum creatine kinase that lasts for hours (following a convulsive seizure)
 - c. Increased serum prolactin are elevated for 10–20 minutes following all types of seizures with the exception of absence or myoclonic seizures. There may be a slight rise after a syncopal episode

- d. There is a slight rise of ACTH and serum cortisol that have longer latency and brief duration
- 3. The cerebrospinal fluid (CSF)
 - a. In approximately 15 percent of patients there may be 10–50 cells/mm³ in the CSF
 - b. A slight elevation of protein may occur
 - c. The glucose is normal

Neuroimaging Features of Specific Epilepsies

- 1. Dravet's syndrome (SME1; severe myoclonic epilepsy of infancy)
 - a. 2 Tesla MRI (13/58 patients)
 - i. Cortical brain atrophy (8/13)
 - ii. White matter hyperintensities (1/13)
 - iii. Cerebellar atrophy (1/13)
 - iv. Hippocampal sclerosis (1/13)
 - v. Forced cortical dysplasia (1/13)
 - vi. Ventricular enlargement (3/13)
 - b. Visible MRI demonstrated more gross abnormalities in those patients without SCN1A mutations (39% to 11%)
 - c. Approximately 20% of Dravet's patients had gross MRI alterations.
 - d. Brain morphometry (voxel brain morphometry) as well as cortical thickness and gyrification measurements
 - i. There were global reductions of gray and white matter
 - ii. Volume reductions in white matter were noted in:
 - 1. Brainstem, cerebellum, corpus callosum, corticospinal tracts and the left inferior fronto-occipital fasciculus and left uncinate fasciculus
 - iii. Reduced cortical folding in the right precentral gyrus
 - iv. These abnormalities are putatively linked to the SCN1A mutation

Idiopathic Generalized Epilepsies

- 1. Comprise:
 - a. Generalized tonic-clonic seizures
 - b. Childhood and juvenile absence epilepsy
 - c. Juvenile myoclonic epilepsy (JME)
 - d. GTCS on awakening
- 2. Visual assessment of routine MRI in patients with IGE is usually normal
- 3. Voxel based morphometry
 - a. JMC demonstrated increased gray matter concentration in frontobasal regions
 - b. Absence seizures showed increased gray matter in the superior mesiofrontal region

Analysis of Generalized Clonic-Tonic Seizures by Resting State fMRI

- 1. General Characteristics
 - a. fMRI networks are:
 - i. Reproducible across subjects
 - ii. Have appropriate test-retest reliability

- iii. Correspond to brain circuits that are engaged in specific activities
 - iv. Have a close correspondence between intrinsic functional connections and anatomical pathways (demonstrated experimentally)
 - v. Resting-state connectivity is altered in pathologic conditions
2. Generalized tonic-clonic seizures
 - a. As compared to controls GCTS demonstrate:
 - i. Increased interhemispheric functional connectivity between the bilateral cuneus and anterior cingulate cortex
 - b. Decreased functional connectivity between the bilateral olfactory cortex, inferior frontal gyrus, supramarginal gyrus and temporal pole

Functional Neuroimaging Abnormalities in Idiopathic Generalized Epilepsy

1. General Characteristics
 - a. Abnormalities of the amplitude of low frequency fluctuations (ALFF) is neuronally based and is decreased in pathologies of localized areas
 - b. Abnormalities of amplitude of low frequency oscillations have been in widespread disorders such as attention deficit hyperactivity disorder (ADHD)
2. fMRI (amplitude of low frequency fluctuations)
 - a. The studied patients had a normal MRI on visual inspection as well as no deficits in cortical thickness, gray-white contrast measures or thalamic volumes
 - b. There was no structural difference in the anterior medial PFC; abnormal signaling with the thalamus from this area is thought to be pivotal in IGE
 - c. Decreases in fALFF (amplitude of low frequency fluctuations $< .1$ Hz) in the PFC thalamus subregion
 - d. Resting state functional connectivity (RSFC)
 - i. Anterior medial prefrontal cortex (mPFC) is abnormally integrated into the default mode network in IGE patients

Neuroimaging of Focal Epilepsy for the Temporal Lobe

1. General Characteristics
 - a. Temporal lobe epilepsy patients are divided into lesional TLE or non-lesional that is based on MRI visualized structural abnormalities
 - b. High resolution 3T MRI with automated segmentation was used for evaluation
2. MRI segmentation analysis:
 - a. Both groups of patients (lesional and non-lesional) demonstrated:
 - i. Lower normal brain volume (NBV) compared to controls
 - ii. Lower normal white matter volume compared to controls
 - b. Lesional TLE patients had:
 - i. Lower hippocampal volume than healthy control or IGE patients
 - ii. Atrophy in both ipsilateral and contralateral structures

- c. Both lesional and non-lesional TLE patients had:
 - i. Lower amygdala volume than healthy controls
- d. A trend for lower caudate volumes in patients with lesional TLE

Resting State fMRI Network Analysis in Temporal Lobe Epilepsy

1. Impaired connectivity has been demonstrated between:
 - a. The rostral and caudal hippocampus and the entorhinal cortex ipsilaterally to the seizure focus
 - b. Reduced functional connectivity between the ipsilateral and contralateral hippocampi
 - c. Reduced functional connectivity between the epileptogenic mesial temporal structures and bilateral temporal neocortices
2. Abnormal connectivity has been demonstrated between the epileptogenic mesio-temporal regions and the default mode network (prefrontal cortex, posterior cingulate cortex, precuneus, inferior parietal lobules)

Diffusion Tensor Imaging in Temporal Lobe Epilepsy

1. Decreased fractional anisotropy has been demonstrated in the:
 - a. Inferior and superior longitudinal fasciculi
 - b. The internal and external capsule
 - c. The corpus callosum
2. Less extensive disruption in mean diffusivity

Hippocampal Sclerosis

1. MRI features of hippocampal sclerosis include:
 - a. Reduced hippocampal volume
 - b. Increased signal intensity on T2-weighted imaging
 - c. Disturbed internal architecture
 - d. Major pathologic correlates of these MRI features include:
 - i. Neuronal loss
 - ii. Chronic fibrillary gliosis of the pyramidal cell layer
 - iii. Granule cell dispersion
 - iv. Mossy fiber sprouting
 - v. Alterations in interneurons
 - e. Hippocampal sclerosis may occur with a second lesion most often ipsilateral to the HS. It may be in the temporal lobe or extratemporally
 - f. There may be more extensive sclerosis that extends to the amygdala and para hippocampus
 - g. Focal cortical dysplasias type IIIa are increasingly demonstrated in addition to the HS by higher field strength magnets

Pathology of Epilepsy

1. Primary generalized epilepsy

- a. Genetic varieties:
 - i. CNS is grossly and microscopically normal in mutations of ion channels
- b. No lesions are noted in transient episodes of:
 - i. Drug intoxication and withdrawal

Abnormal Neuronal and Alial Proliferation or Differentiation *Tuberus Sclerosis*

A. General characteristics

- a. Autosomal dominant monogenetic disease that causes benign tumors in skin, heart, kidney, lungs as well as brain malformations and neuronal defects
- b. Genetics: The illness is caused by inactivating mutations in one of two genes, TSC1 and TSC2. The inactivation causes increased activity of the mammalian target of rapamycin (mTOR)
- c. TSC1 on chromosome 9q34 and TSC2 on chromosome 16p13 encodes the protein hamartin and tuberlin respectively
- d. The majority of patients is born with at least one identifiable mutation and is heterozygous for either TSC1 or TSC2. There may be subsequent inactivating mutations of the functioning allele which causes loss of heterozygosity. This process occurs somatically in a subset of cells and may be detectable in the brain or other affected tissues
- e. The inactivating mutations cause hyperactivation of mTORC1, hyperphosphorylation of HE-BP1 and activation of ribosomal protein S6 through S6K1 phosphorylation. This pathway activation causes sustained translation of growth promoting transcripts
- f. 1/3 of patients have inherited mutations that are identified in parents; 2–3% of patients have de novo mutations that occurs as a result of germline mosaicism
- g. A small proportion of patients may have sporadic mutations that arise in very early somatic cells and may be unequally expressed in organ systems
- h. Patients are considered to have a mutant allele although some organs exhibit somatic mosaicism
- i. The acquired allelic mutations from the parents as well as the timing of the somatic mutations cause the phenotypic spectrum seen in TSC patients
- j. TSC2 gene mutations have a worse prognosis than those in TSC1 patients
- k. Typically, patients are born with a functional allele of TSC1 or TSC2. A second hit occurs in which the functional allele is mutated in a founder somatic cell that results in loss of heterozygosity or haploinsufficiency with consequent hamartoma formation
- l. The incidence of TSC is approximately 1:6,000 to 1:10,000 individuals

B. Clinical manifestations

- a. The major neurological signs and symptoms of tuberous sclerosis are:
 - i. Seizures

- ii. Cognitive impairment
- iii. Autistic features
- iv. Hydrocephalus
- b. A few patients may have minimal or no neurological deficits in the face of alevor malitis in other organ symptoms
- c. Rarely a patient may have cerebral lesions and be asymptomatic
- d. Seizures
 - i. Epileptic seizures occur in approximately 75% of patients with 30–40% being unresponsive to drug therapies
 - ii. The majority of patients present with infantile spasms
 - iii. The seizures are usually partial with the severity correlated with the number of tubers

C. Neuropathology

- a. Cortical tuber form in utero during corticogenesis
- b. Histologic evaluation of tuber demonstrates:
 - i. Gliosis (subpial fibrillary)
 - ii. Loss of lamination
 - iii. Cytomegalic neurons that are ectopic and dysmorphic
 - iv. At the base of the tubers there may be clusters of cytomegalic neurons that form nodules in white matter (heterotopias) that are associated with hypomyelination
 - v. Tubers may become cystic and may calcify
 - vi. The enlarged neurons of cortical tubers are high in mTOR activity and have increased ribosomal protein S6 phosphorylation
 - vii. Subependymal nodules:
 - 1. Are the most common brain lesions associated with TSC (affect approximately 95% of patients)
 - 2. Histologically subependymal nodules are composed of:
 - a. Enlarged neurons and glia
 - b. Giant or multinucleated cells similar to tubers
 - c. Lesions < 10 mm in diameter are nodules; lesions > than 10 mm in diameter with greater than 5 mm of growth are classified as SEGA (subependymal giant astrocytomas)
 - 3. SEGA are:
 - a. Benign
 - b. Slow-growing grade 1 astrocytomas
 - c. Express both neuronal and astrocytic markers
 - d. Have a low proliferative index
 - 4. TSC is associated with circuit alterations from its effects on dendrites, spine and axons
- c. Neuroimaging
 - i. MRI:

1. Cortical tubers subependymal nodules and giant cells astrocytomas and linear white matter abnormalities
2. In addition MRI may demonstrate:
 - a. Cerebellar tubers
 - b. Cortical dysplasia
 - c. Transmantle dysplasia
 - d. Hemimegalencephaly
 - e. Focal megalencephaly
 - f. Cortical infolding

Focal Cortical Dysplasia (FCDs)

- A. General characteristics
 - a. Method of classification divide FCD both to architectural or cytoarchitectural degree and the presence or absence of balloon cells or large dysmorphic neurons
 - b. Genetics
 - i. There are pathogenic germline and mosaic mutations in P13K/AKT genes
 - ii. DEPDC5 (DEP domain containing protein 5) gene mutations
 1. Encodes a repressor of the mTORC1 signaling pathway
 2. Has been identified in FCDII and FCDI patients
- B. Clinical manifestations
 - a. Seizures
 - i. May be initiated from in utero to adulthood; most present in childhood.
 - ii. Extratemporal FCD has an earlier age of onset than temporal FCD
 - iii. The age and location of the lesions determine if the seizures will be:
 1. Simple partial
 2. Complex partial
 3. Secondarily generalized
 4. The seizure disorder is often medicine refractory
 5. Developmental delay
 6. Cognitive impairment
- C. Neuropathology
 - a. FCD has a spectrum in regard to morphology, topography and histologic features
 - i. Microdysgenesis is the least severe form of the process and is characterized by:
 1. Neuronal heterotopias
 2. Cortical laminations disruption
 3. Neuronal clusters in minimally cellular areas
 4. Abnormal cells within the cortex
 - ii. Focal cortical dysplasia may involve:
 1. A focal area in a gyrus or involvement of several gyri
 2. Transmantle dysplasia (that comprise an area from the lateral ventricle to the cortex)
 3. Lobar dysplasia

4. Hemispheric dysplasia
5. Multifocal bilateral dysplasia
- iii. TSC and SCNA1 mutations may be seen concomitantly with FCDs
- iv. FCD type IA and IIA have been identified in surgical material
- b. Neuroimaging
 - i. MRI
 1. FCD may not be visible by 3T MRI
 2. Subtle abnormalities of:
 - a. Gyration pattern
 - b. Cortical thickness
 - c. Blurring of the gray-white function
 - d. Increased signal intensity on FLAIR and T2-weighted sequences (possibly due to balloon cells)
 - e. White matter alterations (increased signal) may occur in surrounding areas of an FCD that produces intractable seizures (may be due to myelin changes from the seizures or dysplastic white matter)
 3. Focal transmantle dysplasia (FTD)
 - a. Is seen in a wedge of dysplastic and disorganized tissue from the lateral ventricle to the cortical surface with increased T2 signal
 - i. Composed of balloon cells and astrogliosis
 4. Sublobar dysplasia demonstrates:
 - a. Deep infolding of the cortex which is thickened
 - b. Poor gray-white differentiation in the affected area
 - c. Associated brain abnormalities include:
 - i. Ventricular dysmorphism
 - ii. Calloral and cerebellar dysgenesis
 5. Posterior quadrant dysplasia is a form of FCD
 - a. Affects one of both posterior quadrants

Hemimegalencephaly (HME)

- A. General characteristics
 - a. A brain malformation that causes an enlarged and dysplastic hemisphere
 - b. Localized megalencephaly is approximately 25% of HME; it appears to be more prevalent in the left sides
 - c. There are three forms of disease
 - i. Isolated form (66%)
 - ii. Syndromic form (associated with neurocutaneous illnesses)
 - iii. Total HME (least common form)
 - iv. Genetics
 1. De novo somatic mutations in components of the P13K-AKT3-mTOR pathway
 - a. Somatic activation of AKT3 may be causative

B. Clinical manifestations

- a. Intractable partial seizures that start in infancy or the neonatal period
- b. Children may present with tonic seizures, infantile spasms similar to Ohtahara or West syndromes
- c. Contralateral hemiparesis
- d. Severe cognitive impairment
- e. Rarely can present in an adult

C. Neuropathology

- a. HMEG is associated with neurocutaneous syndrome that include:
 - i. Linear nerves sebaceous syndrome
 - 1. Approximately 50% have HME
 - 2. Hypomelanosis of Ito
 - 3. Tuberous sclerosis
 - 4. Neurofibromatosis
 - 5. Macroscopically there is enlargement of one hemisphere; there is no predilection for one side
 - 6. The contralateral hemisphere may be compressed but may also be small
 - ii. Cortical dysgenesis
 - iii. White matter hypertrophy
 - iv. Affiliated and dysmorphic lateral ventricle
 - v. The majority of the hemisphere is affected
 - vi. Histological features:
 - 1. Polymicrogyria (in some patients)
 - 2. Heterotopic gray matter
 - 3. Cortical dyslamination
 - 4. Bizarre enlarged neurons
 - 5. Balloon cells
 - 6. Blurring of the gray-white functions
 - 7. Increased number of neurons and astrocytes

D. Neuroimaging

- a. MRI:
 - i. The cortical gray matter shows areas of thickened and gyral simplification similar to pachygyria or overfolding that is similar to what occurs with polymicrogyria (PMG)
 - ii. An indistinct gray-white junction
 - iii. Markedly increased volume of white matter that contains gray matter heterotopias
 - iv. White matter signal change consistent with demyelination
 - v. The ipsilateral ventricle is enlarged and the posterior horn may extend across the midline
 - vi. Some patients have enlargement of the ipsilateral cerebellar hemisphere and brain stem

Abnormal Neuronal Migration

Classical Lissencephaly

A. General characteristics

- a. The lissencephalies are usually monogenetic disorders that affect neuronal migration during development of the cortex

b. The mature brain is not gyrated

c. Genetics:

- i. Mutations in neuron-specific L- and B-tubulin genes have been found in both lissencephaly and polymicrogyria
- ii. These mutations are often associated with:
 - 1. Callosal hypoplasia or agenesis
 - 2. Cerebellar hypoplasia
 - 3. Abnormal basal ganglia
- iii. Tubulin proteins that are transcribed:
 - 1. Form heterodimers that incorporate into microtubules that are pivotal for cell motility and function
- iv. Mutations in TUBA1A and TUBB2B have been identified in patients with lissencephaly
- v. There appears to be a tubulinopathy-associated spectrum that causes lissencephaly to polymicrogyric cortical dysplasias
- vi. Lissencephaly associated with cerebellar hypoplasia has been associated with mutations in the RELN gene
- vii. Lissencephaly associated with agenesis of the corpus callosum has been described with mutations of the ARX gene
- viii. The major genes associated with lissencephaly are:
 - 1. LIS1 (normal migrations)
 - 2. DCX (normal migration)
 - 3. ARX
 - a. Required for tangential migration
 - 4. RELN (normal migrations)
 - 5. YWHAD (normal migration)
 - 6. TUBA1A (normal migration)
- ix. The LIS gene mutations are the most common cause of lissencephaly
 - 1. LIS protein is required for normal migration, cellular proliferation and intracellular transport

B. Neuropathology

- a. Reduced or absent gyration that is combined with cerebral cortex thickening (seen in classical LIS)
- b. Most patients have a combination of agyria and pachygyria (broad simplified gyration)
- c. Poorly developed Sylvian and Rolandic fissures
- d. Failure of opercularization of the insular areas
- e. Associated with malformations include:
 - i. Enlarged lateral ventricles
 - ii. Absence of the claustrum and external capsules
 - iii. Dysgenesis of the corpus callosum
 - iv. Persistence of the cavum septum pellucidum
 - v. Hypoplasia of the CSTs
 - vi. Heterotopia of the inferior olives
 - vii. Cerebellar abnormalities
- f. Histological features:
 - i. Poorly defined marginal zone

C. Clinical manifestations

- a. Are dependent upon associated congenital malformations, the topography of the malformation and abnormal function of other organ systems
- b. Intractable seizures (often presenting as infantile spasms)
- c. Developmental delay
- d. Cognitive impairment
- e. Early hypotonia that may persist or evolve to mixed axial hypotonia and limb spasticity
- f. The Miller-Dieker syndrome (MDS) has a severe form of lissencephaly with increased cellularity
- g. A cortical gray zone with diffusely scattered neurons
- h. A neuron sparse zone
- i. A deep cortical gray zone with a columnar organization that is thicker than the superficial gray zone and more cellular. Putatively neurons that failed complete migration to the cortex

D. Neuroimaging

- a. MRI:
 - i. Agyria and pachygyria
 - ii. Cerebral surface is smooth with absent opercularization and “figure eight” appearance
 - iii. Grading system for MRI evaluation
 1. Based on the severity of the gyral pattern simplification and a gradient along the anterior to posterior axis
 2. The posterior > anterior gradient is most common with LIS gene mutation but also occurs with TUBA1 mutations

Subcortical Band Heterotopia (SBA)

A. General characteristics

- a. X-linked isolated lissencephaly and subcortical band heterotopias are allelic disorders
- b. The majority of both sporadic and familial cases of the most common form of SBH, that are bilateral symmetric and with frontal predominance are due to mutations in the gene DCX
- c. Males with DCX mutations usually have the lissencephaly phenotype while females have SBH
- d. Females that have SBH from DCX mutations have two populations of neurons:
 - i. Mutant gene inactive group that migrated and formed normal cortex
 - ii. A population in which the normal gene is inactivated which migrate abnormally and form the heterotopic band
 - iii. Carriers of mild DCX mutations may be MRI negative but still may suffer seizures and be cognitively impaired
 - iv. Patients with posterior SBH may have somatic mutations in the LIS1 gene.
 - v. SBH has been reported in patients with trisomy 9P
 - vi. DSX encodes:

1. A microtubules associated protein that is involved in neuronal migration

B. Clinical manifestations

- a. Mild-to-moderate cognitive impairment
- b. Seizures disorder:
 - i. Onset at any age but may be delayed until the second or third decade
 - ii. Mixed seizures type
 - iii. Clinical features are roughly correlated with the thickness of the heterotopic band
 - iv. Females are affected markedly more than males
 - v. Mild partial forms of SBH may be asymptomatic
 - vi. There are usually no dysmorphic features or other congenital malformations

C. Neuropathology

- a. Bilateral bands of heterotopic gray matter imbedded in the white matter between the lateral ventricles and the cortex
- b. There are shallow sulci in the overlying cortex
- c. The bands are symmetric bilaterally with a slight anterior predominance; rarely the bands are restricted to the frontal lobes in the occipital parietal area (partial posterior)
- d. Rarely SBH merges anteriorly with pachygyria cortex
- e. The bands are composed of;
 - i. Superficial zone of disorganized neurons; an intermediate zone of small neurons with a partial columnar organization
 - ii. Deeper zone where heterotopias become nodules
 - iii. The heterotopic band is formed by abnormal neuroblast migrations

D. Neuroimaging

- a. MRI:
 - i. Demonstrates a four layered cerebral parenchyma that comprises:
 1. Normal periventricular white matter
 2. Layer of heterotopic gray matter
 3. A thin layer of subcortical white matter
 4. Normal cortical gray matter

Periventricular Nodular Heterotopia (PNH)

A. General characteristics

- a. Definition:
 - i. Heterotopias are groups of cells that are found in an inappropriate location of the correct tissue of origin
 - ii. Heterotopias occur:
 1. In isolation
 2. In association with other developmental anomalies
 3. As a component of congenital anomaly syndrome
- b. Genetics:
 - i. Classic bilateral PNH is the longest subgyria (approximately 56%) which is an X-linked disorder; there > than 15 PNH subgroups

- ii. Approximately 20% of sporadic patients demonstrate mutations of the filamin A gene (FLNA gene)
 - iii. PNH has also been described in:
 1. 6q terminal deletion syndrome
 2. ARFGEF2 (ADP-ribosylation factor guanine nucleotide exchange factor)
 3. Frontonasal encephalocele, corpus callosal dysgenesis and arachnoid cyst
 4. Peritrigonal and temporo-occipital heterotopias with corpus callosum and cerebellar dysgenesis
 - B. Clinical manifestations
 - a. Epilepsy
 - i. Is present in 80–90% of patients
 - ii. Primarily partial seizures that are intractable
 - iii. The nodules are intrinsically epileptogenic
 - iv. Females > males with bilateral PNH
 - v. Most patients have normal intelligence
 - vi. Autism has been described in association with PNH with peritrigonal and temporo-occipital heterotopias with corpus callosum and cerebellar dysgenesis
 - vii. Described in association with Ehlers-Danlos syndrome
 - C. Neuropathology
 - a. Most nodules are located in the walls of the lateral ventricles; they may be contiguous
 - b. They may be unilateral, bilateral or in the trigone of the occipital horn
 - c. They vary in size and are usually longer than the subependymal nodules of TSC
 - d. PNH is associated with the brain's malformations
 - e. Microscopically:
 - i. Heterotopic gray matter:
 1. Forms clusters of rounded, irregular nodules separated by layers of myelinated fibers
 2. Neurons and glia in the nodules may be disorganized or have rudimentary lamination
 - D. Neuroimaging
 - a. MRI:
 - i. T1-weighted sequences demonstrate the nodules to have identical signal intensity to cortical gray matter
 - ii. Associated malformations include:
 1. Hippocampal sclerosis
 2. Polymicrogyria
 3. Hypoplasia of the cerebellar vermis
 - iii. Classic bilateral PNH is associated with:
 1. Hypoplasia of the corpus callosum and cerebellar vermis
 2. Rarely the heterotopias may be large enough to deform the lateral ventricles
 3. Heterotopic nodules:
 - a. Usually located along the ventricles; may be peritrigonal and in temporo-occipital areas
 - b. They can be single, multiple symmetric or asymmetric as well as unilateral or bilateral
- Abnormal Cortical Organization Polymicrogyria*
- A. General characteristics
 - a. A complex cortical malformation whose most consistent feature is disruption of the brain surface with pial defects, over migration of cells, thickening and duplication of pial collagen layers, increased leptomeningeal vascularity due to processes in the early stage of corticogenesis
 - b. May be an isolated cortical malformation or in conjunction with other cerebral malformations or multiple congenital anomaly syndromes
 - c. Associated with both genetic and non-genetic mechanisms
 - d. Major genes involved include:
 - i. Those involved in peroxisomal disorders
 - ii. 22q11.2 and 1p36 contiguous gene deletion syndromes
 - iii. Mutations in the DISK-AKT pathway (PMG and megalencephaly)
 - iv. Tubulin gene family mutations
 - v. SPPX2; PAX6; TBR2; KIAA1279; COL18A; RAB
 - B. Clinical manifestations
 - a. The clinical manifestations of PMG have a wide spectrum which is due to the extent and location of the malformations and concomitant brain abnormalities that include:
 - i. Metabolic disorders
 - ii. Chromosome deletion syndromes
 - iii. Other congenital malformations
 - b. Oromotor dysfunction with seizures (congenital bilateral perisylvian syndrome)
 - i. Decreased tongue protrusion and lateral movement
 - ii. Problem with facial and pharyngeal movement
 - iii. Facial diplegia
 - iv. Decreased swallowing
 - v. Dysarthria and expressive dysphasia
 - vi. Increased jaw jerk and an absent gag reflex
 - c. Cognitive impairment is seen in approximately 75% of patients
 - d. Approximately 60–85% of patients with PMG have epilepsy
 - i. Seizure onset may be delayed until the second decade but usually starts between 4–12 years of age
 - ii. Seizure types include:
 1. A typical absence (62%)
 2. Atonic and tonic drop attacks (73%)
 3. GTCs (35%)
 4. Partial (26%) that rarely generalize
 5. Rare bilateral facial motor seizures with awareness

6. A few patients present with infantile spasms in contrast with patients with LIS, TSC or FCID
 7. Intractable seizures occur in approximately 50% of patients
- C. Neuropathology
- a. PMG has an irregular cortical surface and may be located:
 - i. Bilateral frontally
 - ii. Unilateral perisylvian
 - iii. Bilateral frontoparietal
 - iv. Parasagittal parieto-occipital (bilateral)
 - v. Bilateral parieto-occipital
 - vi. Multi-lobar
 - vii. Bilateral generalized
 - viii. Bilateral perisylvian (the most common location)
 - b. The perisylvian cortex involvement:
 - i. Sylvian fissures are extended and superiorly oriented posteriorly
 - c. PMG occurs in the periphery of porencephalic or hydrocephalic malformations
 - d. Associated anomalies occur in:
 - i. The corpus callosum
 - ii. Brain stem and cerebellum
 - iii. And may be associated with enlarged ventricles
 - e. Histologic evaluation reveals:
 - i. Abnormal cortical lamination
 - ii. Excessive folding and fusion of adjacent gyri
 - iii. Unlayered and layered forms of PMG are described
 - f. Other mechanisms that have been suggested to cause PMG are:
 - i. Premature folding of the neuronal band
 - ii. Abnormal fusion of adjacent gyri
 - iii. Laminar necrosis of the developing cortex
 - iv. Cytomegalic virus infection
 - v. Metabolic and peroxisomal disorders
 - vi. In utero ischemia
- D. Neuroimaging
- a. MRI:
 - i. Apparent mildly thickened cortex due to probable overfolding
 - ii. Microgyri and microsulci
 - iii. Cortical T2 signal is usually normal; diffuse white matter hyperintensity signals suggest:
 1. Peroxisomal disease (Zellweger's syndrome)
 2. Congenital CMV infection
 - iv. Enlarged subarachnoid space over PMG with anomalous venous drainage (most common in the Sylvian fissure)
 - v. Overfolding of the cortex
 - vi. Structural connectivity between contiguous primary gyri (short U-fibers)
 - vii. Reduced connectivity between distant gyri (long association fibers)
 - viii. Altered cortical network topology

Schizencephaly (SCZ)

1. General Characteristics
 - a. Definition:
 - i. A malformation of the brain characterized by a gray matter-lined defect that extends from the pial surface to the lateral ventricles
 - b. Clefts are frontal or parietal in approximately 65% or temporal or occipital in approximately 35%
 - c. Clefts may be associated with other brain malformations
 - d. Genetics: Familial cases have been identified:
 - i. with mutations in the EMX2 homeobox gene
 - ii. and in patients with chromosomal aneuploidy
2. Clinical Manifestations
 - a. The clinical features depend on
 - i. If the defect is unilateral or bilateral
 - ii. Open-lipped or closed-lipped types
 - b. Patients with a closed-lipped pattern have:
 - i. Hemiparesis or motor delay
 - c. Open-lipped form present with:
 - i. Seizures
 - ii. Hydrocephalus
 - d. Epilepsy occurs in approximately 50% of patients
 - e. Developmental delay in approximately 83%
 - f. Seizures:
 - i. Median age for seizure onset is 13 months
 - ii. Open-lipped form has an earlier seizure onset
 - iii. Seizure types include:
 1. Complex partial (most common)
 2. Infantile spasms
 3. Tonic and atonic
 4. GTCS
 5. The severity and type of seizure does not correlate with the topography of the SCZ
 6. Bilateral open-lipped SCZ has the worst seizure prognosis
 - g. Associated malformations include:
 - i. Agenesis of the septum pellucidum
 - ii. Focal cortical dysplasia
 - iii. Dysgenesis of the corpus callosum
 - iv. The associated malformations may influence the severity of the seizures
3. Neuropathology
 - a. The clefts may be unilateral or bilateral as well as "open-lipped" or "closed-lipped"
 - b. Open-lipped SCZ:
 - i. The walls of the clefts do not oppose each other
 - c. Closed-lipped SCZ:
 - i. The walls of the cleft are opposed and often fused; a line of continuity between the lateral ventricle and subarachnoid space may be visible in fused SCZ
 - d. The gray matter lining the clefts is similar to that of PMG
4. Neuroimaging
 - a. MRI:

- i. The clefts are usually visible on routine MRI sequences and demonstrate if they are “open or closed-lipped”
- ii. SCZ may also demonstrate:
 - 1. “Puckering” or a “dimple” at the margin of the lateral ventricle
 - 2. The cleft is lined by gray matter with imaging characteristics of polymicrogyria that include:
 - a. Apparent cortical thickening
 - b. Irregularity of the surface
 - c. Stippling of the gray-white interface
 - d. SCZ may be asymmetric; the contralateral hemisphere may demonstrate subtle SCZ or PMG
 - e. Agenesis of the septum pellucidum occurs in approximately 30% of patients
- iii. Subtle SCZ may demonstrate:
 - 1. “Puckering” or a “dimple” at the margin of the lateral ventricle
 - 2. Clefts are lined by gray matter
 - 3. White matter or T2 increase

Differential Diagnosis in Epilepsy

- 1. The Generalized Epilepsies
 - a. Arising in and rapidly spreading to bilaterally distributed networks
 - b. Generalized seizures
 - i. Tonic-clonic
 - ii. Absence (typical and atypical)
 - 1. Myoclonic absence
 - 2. Eyelid myoclonia
 - iii. Clonic
 - iv. Atonic
 - v. Myoclonic:
 - 1. Myoclonic-atonic
 - 2. Myoclonic-tonic
- 2. Focal Epilepsies
 - a. Originating within networks limited to one hemisphere
 - b. Simple (without alteration of consciousness)
 - i. Aura
 - 1. Psychic
 - 2. Somatosensory
 - 3. Visual
 - 4. Auditory
 - 5. Olfactory
 - 6. Visceral
 - 7. Vertiginous
 - ii. Motor
 - iii. Autonomic
 - iv. Awareness is unaltered
- 3. Unclassifiable
 - a. Cannot be classified as focal or generalized
 - b. Epileptic spasms

Differential Diagnosis by Age of Onset

- A. Neonatal Syndromes
 - 1. Benign familial neonatal epilepsy (BFNE)
 - 2. Ohtahara syndrome
 - 3. Epileptic encephalopathies
 - 4. Early myoclonic encephalopathy (EME)
- B. Seizure Syndromes in Infancy
 - 1. Febrile seizures
 - 2. Febrile seizures plus (FS)
 - 3. Benign familial infantile epilepsy (BFIE)
 - 4. West syndrome (hypsarrhythmia)
 - 5. Dravet syndrome (severe myoclonic seizures of epilepsy)
 - 6. Myoclonic epilepsy in infancy (MEI)
 - 7. Myoclonic epilepsy in non-progressive disorder (components of other epileptic syndromes)
 - 8. Epilepsy with migrating focal seizures
- C. Childhood Epilepsy
 - 1. Febrile convulsions
 - a. Usual temperature above 38°C
 - b. Precipitants:
 - i. Viral or bacterial illness
 - ii. Immunization (MMR)
 - iii. Herpesvirus
 - c. Genetic mutations
 - i. SCN1A; SCN2A
 - ii. PRRT2
 - iii. ANO3
 - 2. Febrile seizures plus (GEFS plus)
 - a. Genes that encode several Na⁺ channel subunits
 - b. Gamma 2 subunit of GABA A
 - 3. Early onset childhood occipital epilepsy (Panayiotopoulos syndrome); autonomic seizures
 - 4. Epilepsy with myoclonic atonic seizures
 - 5. Childhood absence epilepsy (CAE)
 - 6. Benign epilepsy with centro-temporal spikes (BECTS)
 - 7. Autosomal dominant nocturnal frontal lobe epilepsy (ADNFLE)
 - 8. Late onset childhood occipital epilepsy (Gastaut)
 - 9. Epilepsy with myoclonic absences
 - 10. Lennox-Gastaut syndrome (LGS)
 - 11. Epileptic encephalopathy with continuous spike-and-wave during sleep
 - 12. Landau-Kleffner syndrome
- D. Seizures in Adolescence to Adulthood
 - 1. Juvenile absence epilepsy (JAE)
 - 2. Juvenile myoclonic epilepsy
 - 3. Epilepsy with GTCS
 - 4. Autosomal dominant temporal lobe epilepsy (ADTLE)
 - 5. Familial temporal lobe epilepsy:
 - a. ADFLE (autosomal dominant frontal lobe epilepsy)
 - i. CHRNA4, CHRNA2, CHRN2 and KCNT1
 - ii. Autosomal dominant epilepsy with auditory features

1. LGI1 (encodes epitempin)
 - iii. DEPDC5 (DEP domain-containing protein 5) gene mutations occur in:
 1. ADNFLE
 2. FTLE
 3. FFEVF
 - E. Seizures with Variable Age at Onset
 1. Familial focal epilepsy with variable foci (FFEVF)
 - a. Childhood to adulthood
 2. Progressive myoclonic epilepsy
 - a. Lafora body disease
 - b. Unverricht-Lundborg
 - c. Sialidosis type I
 - d. Ceroid lipofuscinosis type 6
 - e. MERRF (myoclonic epilepsy with ragged red fibers)
 - f. Gaucher's disease
 - g. Dentatorubro-pallidoluysian atrophy
 3. Reflex epilepsies
 - a. Generalized reflex seizure
 - i. Precipitated by specific characteristics of light
 - ii. Various aspects of cognition and decision making
 - b. Focal reflex seizures
 - i. Reading, writing, other language functions
 - ii. Startle response
 - iii. Somatosensory stimulation (brief or sustained; rubbing a specific area of the body surface)
 - iv. Proprioceptive changes of an extremity
 - v. Auditory stimuli
 - vi. Thermal stimuli (hot water immersion)
 - vii. Vestibular stimuli
 - viii. Eating
 - ix. Orgasm
 - iv. HCN channel mutations
 1. HCN2
 2. Metabolic causes
 - a. Hypoglycemia
 - b. Hypocalcemia
 - c. Hypomagnesemia
 - d. Uremia
 - e. Hepatic failure
 - f. Hypo/hyponatremia
 - g. Inappropriate ADH
 - h. Hyperosmotic states
 - i. Pulmonary failure
 3. Drugs/Toxins (partial list)
 - a. Methanol
 - b. INH
 - c. Phenothiazine
 - d. Insulin
 - e. Theophylline
 - f. Amphetamines
 - g. Lithium
 - h. Cocaine
 - i. Inhalational anesthetics
 - j. PCP
 - k. Penicillin
 - l. Anticonvulsants
 - m. Alcohol withdrawal
 4. Infections Associated with GTCS
 - a. Associated with cortical strokes
 - i. Tuberculosis
 - ii. Cryptococcus
 - iii. Mucormycoses
 - iv. Aspergillus
 - v. Listeria monocytogenes
 - vi. HIV
 - vii. SBE
 - viii. Cysticercosis
 - ix. Malaria
 - x. Chagas
 - xi. Herpes simplex
 - xii. Herpes zoster
 - xiii. Enteroviruses
 - xiv. Bacterial associated with meningitis
 - xv. Syphilis
- Differential Diagnosis of Generalized Tonic-Clonic Seizures (GTCS)**
1. Channelopathies
 - a. Mutations in Na^+ channels or their subunits
 - i. SCN1A, SCN2A, SCN8, SCN1B
 - ii. Potassium channel mutations
 1. KCNQ ($K_v7.2$)
 2. KCNQ3 ($K_v7.3$)
 3. KCNA1 ($K_v1.1$)
 4. KCNJ1 ($K_{nn4.1}$)
 5. KCNF10 (glial $K_v4.1$ channel)
 6. KCTD7 – (unknown function)
 7. KCNJ11 – ($K_v6.2$)
 - iii. Calcium channelopathies
 1. $Ca_v2.1$ (P/Q); loss of function
 2. $Ca_v3(T)$ channels; gain of function
 3. CACNA1A gene
 4. CACNB4 gene
 5. CACNA1H
- GTCS by Age (Adults < 40 Years)**
1. Lack of compliance or inadequate medication levels
 2. Localization related with secondary generalization
 3. Vascular: embolus > infarction > hemorrhage; venous (cancer)
 4. Metabolic causes
 5. Tumor (metastatic > primary)
 6. Drugs (illicit, hypnotic sedatives, withdrawal)
 7. HIV (associated opportunistic infections)

8. Herpes simplex
9. Herpes zoster (v1 distribution with delayed carotid artery stroke)
10. Migrational disorders
11. Post-partum/cancer (venous strokes)
12. Head injury

GTCS by Age (Adults > 60 Years of Age)

1. Vascular: ischemic > embolic > hemorrhage
2. Cardiac arrhythmia (AF > tachy – brady)
3. Metabolic dysfunction
4. Prior CNS structural lesion with consequent glial scar
5. Tumor (metastatic > meningioma > glioma or lymphoma)
6. Herpes simplex encephalitis
7. Head injury
8. Prior stroke
9. Anticonvulsant withdrawal or inadequate dosage

Differential Diagnosis of Absence Seizures

1. Childhood absence epilepsy
 - a. Typical/atypical
2. Juvenile absence
3. Absence epilepsy with specific features
 - a. Myoclonic absence
 - b. Eyelid myoclonia
4. Absence epilepsy in adults
5. Genetic mutations
 - a. GABRB3
 - b. SLC2A1 (glucose transporter 1)
 - c. CACNA1A

Differential Diagnosis of Absence Syndromes

1. Epileptic encephalopathy
2. Early myoclonic epilepsy (neonatal)
3. Ohtahara syndrome (neonatal)
4. West syndrome (infancy)
5. Dravet syndrome (infancy)
6. Myoclonic status in non-progressive encephalopathy of childhood
7. Lennox-Gastaut syndrome (childhood)
8. Landau-Kleffner syndrome (childhood)
9. Epilepsy with continuous spike-and-wave during slow wave sleep in childhood and adolescence
10. Migrating partial seizures in infancy
11. Severe epilepsy with multiple independent spike foci

Differential Diagnosis of Progressive Myoclonic Epilepsy

1. Epileptic encephalopathies with a component of myoclonic epilepsy
 - a. Dravet syndrome
 - b. Channelopathies
 - i. SCN1A and SCN1B

- ii. CACNA1, CACNB4, CACN1H
- iii. GABA, GABRD, GABRG2
- c. Severe myoclonic epilepsy in infancy (SMEI)
- d. GEFS
2. Lafora body disease
3. Unverricht-Lundborg disease
4. Neuronal ceroid lipofuscinosis (CLN6)
5. Gaucher's disease
6. Sialidosis (cherry red spot myoclonus)
7. MERRF/MELAS/POLG
8. Action myoclonus renal failure syndrome
9. Dentatorubral-pallidoluysian atrophy

Differential Diagnosis of Myoclonic Epilepsy

1. Progressive myoclonic epilepsies
2. Rare causes of autosomal recessive myoclonic epilepsy
3. Epilepsy with myoclonic absences
4. Generalized electrographic seizures presenting as perioral myoclonus
5. Familial cortical myoclonic tremor with epilepsy

Differential Diagnosis of Motor Seizures

1. Infantile spasms
2. Localization related generalized tonic-clonic seizures
3. Major motor seizure
4. Tonic seizures
5. Motor patterns of secondarily generalized seizures
6. Epileptic spasms
7. Clonic seizures
8. Versive seizures
9. Complex motor seizures
10. Automotor seizures
11. Gelastic seizures
12. Atonic seizures
13. Dystonic posturing

Differential Diagnosis of Localization Related Epilepsy

1. Frontal lobe
 - a. Dorsolateral frontal lobe
 - b. Prefrontal cortex
 - c. Premotor cortex
 - d. Supplementary motor area (SMA)
 - e. Cingulate cortex
 - f. Frontal opercular cortex
 - g. Frontopolar cortex
 - h. Orbitofrontal cortex

Differential Diagnosis of Hyperkinetic Frontal Lobe Seizures

1. Orbitofrontal cortex
2. Dorsolateral prefrontal cortex
3. Frontomesial cortex
4. Frontopolar cortex

Differential Diagnosis of Temporal Lobe Epilepsy

1. Hippocampal sclerosis
2. Amygdala sclerosis
3. Dual pathology with hippocampal sclerosis (extratemporal heterotopias)
4. Head trauma
5. Vascular malformations (cavernous hemangiomas, telangiectasia, arteriovenous malformations)
6. Low grade astrocytomas
7. Metastatic tumors
8. Migration disorders (dyslamination, heterotopias)
9. Congenital malformations (hippocampal malrotation)
10. Ischemic vascular disease
11. Autoimmune disorders (antibody paraneoplastic limbic encephalitis)
12. Infections (Herpes simplex and zoster)
13. Urbach-Wiethe disease

Differential Diagnosis of Medial Temporal Lobe Syndrome

1. Hippocampal sclerosis
2. Amygdala sclerosis
3. Dual pathology (hippocampal sclerosis plus extratemporal migration defects)
4. Trauma
5. Status epilepticus (hippocampal damage)
6. Prolonged febrile convulsion
7. Low grade astrocytoma
8. Vascular malformations

Differential Diagnosis of Neocortical Temporal Lobe Epilepsy

1. Autosomal dominant temporal lobe epilepsy with auditory features
2. Low grade astrocytoma
3. Vascular disease (ischemic)
4. Malformations
5. Head trauma
6. Migrational defects
7. Viral infections (HS, HZ)
8. Psychiatric disease (usually depression; schizophrenia)
9. Episodic dyscontrol
10. Migraine (abdominal aura)
11. Cardiac arrhythmia (R temporal lobe sympathetic; L parasympathetic)
12. Transient global amnesia
13. Vasovagal and vasodepressor syncope
14. Movement disorders (paroxysmal dyskinesia; stereotypies)
15. Cardiac arrhythmia (often from propagation into the insular cortex)

Differential Diagnosis of Insular Cortex Seizures

1. Foix-Chavany-Marie stroke

2. Low grade glial tumors
3. Temporal lobe epilepsy
4. Regional neuropathic pain
5. Cardiac arrhythmia
6. Sleep related hypermotor seizures

Differential Diagnosis of Parietal Lobe Seizures

1. Post-stroke
2. Metastatic and primary glial tumor
3. Benign epilepsy of childhood with centrotemporal spikes
4. Benign epilepsy of childhood with parietal evoked spikes
5. Migraine headaches
6. Frontal lobe (movement) or temporal lobe (aura) epilepsy

Differential Diagnosis of Occipital Lobe Epilepsy

1. Idiopathic childhood occipital epilepsy of Gastaut (IOEE-G)
2. Photosensitive epilepsy
3. Seizures provoked by television and video games
4. Migraine headaches

Differential Diagnosis of Status Epilepticus

1. Convulsive status
2. Absence status
3. Myoclonic status in JME
4. Myoclonic status
5. Electrical status epilepticus in sleep
 - a. Continuous spike-and-wave in slow-wave sleep (CSWS)
 - b. Landau-Kleffner syndrome
6. Non-convulsive status

Differential Diagnosis of Epilepsia Partialis Continua

1. Rasmussen's syndrome
2. Russian spring-summer tick-borne encephalitis
3. Vascular disease (stroke)
4. Multiple sclerosis
5. Steroid responsive encephalopathy with autoimmune thyroiditis
6. Mitochondrial disease
7. Alcohol-responsive
8. Developmental anomalies
9. Hyperosmotic syndromes
10. Degenerative disease
11. Idiopathic

Differential Diagnosis of the Reflex Epilepsies

1. Generalized reflex seizures
 - a. Precipitated by specific aspects of light
 - b. Cognitive precipitant (decision making)
2. Focal reflex seizures (precipitants)
 - a. Language functions
 - b. Startle

- c. Somatosensory
- d. Proprioceptive positions (limbs)
- e. Auditory
- f. Thermal (hot water immersion)
- g. Vestibular
- h. Eating
- i. Orgasm

Differential Diagnosis of Lesional Epilepsy

1. Neuronal loss and gliosis from head trauma (cortical scar)
2. All forms of vascular disease
3. Heterotopias
4. Focal cortical dysgenesis (dyslamination)
5. Cortical migrational alterations
6. Hamartoma
7. Vascular malformations (syndromic)
8. Tumors:
 - a. Primary glial and metastatic
 - b. Benign (meningioma, ganglioneuroma)
 - c. Dysembryoplastic neuroectodermal tumors (DNET)
 - d. Low-grade astrocytomas
9. Autoimmune
 - a. Multiple sclerosis
 - b. Acute disseminated encephalomyelitis
 - c. Acute hemorrhagic leukoencephalitis
 - d. Rasmussen's encephalitis
 - e. Paraneoplastic syndromes (limbic encephalitis)
 - f. Systemic autoimmune disease (with vasculitis); SLE
10. Infections (viral and bacterial)
 - a. Meningitis (bacterial/viral)
 - b. Varicella zoster
 - c. Herpes simplex
 - d. Coxsackie, adeno, enteroviral infections; HIV
 - e. Fungal infection (cryptococcosis)
 - f. Malaria
 - g. Chagas (emboli from the heart)
 - h. Cysticercosis
 - i. HIV (<200 cells mm³) with opportunistic infections (cryptococcosis, tuberculosis, toxoplasmosis and syphilis)

Differential Diagnosis of Major Malformations of Cortical Development

1. Tuberous sclerosis
2. Focal cortical dysplasia
3. Hemimegalencephaly
4. Lissencephaly
5. Subcortical band heterotopia
6. Periventricular nodular heterotopia
7. Polymicrogyria
8. Holoprosencephaly
9. Double cortex syndrome

Differential Diagnosis of Monogenetic Causes of Malformations with Seizures

1. Angelman syndrome
2. Walker-Warburg syndrome
3. Muscle-eye-brain disease
4. Holoprosencephaly
5. Schizencephaly
6. Tuberous sclerosis
7. Lissencephaly
8. Double cortex syndrome
9. Heterotopia
10. Fukuyama muscular dystrophy

Differential Diagnosis of Monogenetic Epilepsy with Mixed Seizure Phenotypes

1. Urbach-Wiethe disease
2. Autosomal dominant lateral temporal lobe epilepsy
3. Neuronal ceroid lipofuscinosis type 8
4. Pyridoxine deficiency
